content knowledge. Ball (2000) stressed that it is crucial for teachers to experience mathematics from varied perspectives and in different contexts. Even though MKT provides a general framework for designing learning tasks for preservice teachers, it has limitations for secondary school mathematics teaching because it was developed as a result of research studies with elementary school teachers. In this paper, the authors provide discussion on using MKT framework and adapting it for secondary school teacher learning to design practices of a content course for secondary school teachers. Many examples given for the MKT model is from elementary school classroom. There are also examples of teacher education tasks for SCK (e.g. Suzuka et al, 2010) which may guide for task design but the examples are focused on elementary teaching. In our effort to adapt SCK concept of MKT model for secondary school teacher education, we used Usiskin's (2001) approach for type of mathematics that secondary school teachers need to experience. Usiskin (2001) provides the approach *teachers' mathematics* to develop mathematical practices to enhance secondary school teachers SMK. It should be noted that, Usiskin is not proposing a model for teacher knowledge research studies but provides an approach to guide practices to study mathematics with teachers. In this study of SCK tasks for secondary school preservice teachers, we use a blend of MKT model for teacher knowledge and approach of teachers' mathematics for teacher education practices.

Moreover, Usiskin and his colleagues (2003) explained three features of teachers' mathematics: concept analysis, problem analysis and mathematical connections. They discussed that even though these three kinds of mathematics experiences are essential for teachers, they are not addressed in a typical college mathematics course. Furthermore, he states that "Often the more mathematics courses a teacher takes, the wider the gap between the mathematics the teacher studies and the mathematics the teacher teaches" (p. 86). Among these three features of studying mathematics for secondary school teaching, concept analysis could be used for the SCK type of knowledge that a teacher needs to experience. In concept analysis, a secondary school teacher is expected to be able to discuss *alternate definitions, instances and applications, generalizations, and the history* of the concept. Furthermore, Suzuka and her colleagues (2009) stated that main features of a SCK task would be unpacking already existing knowledge and developing a flexible understanding of important concepts for mathematics that they would teach while those tasks allow teachers to build connections among representations or ideas. In other words, Usiskin's suggestion of concept analysis (in a sense relearning and deepening already existed knowledge for high school teachers) is very similar to features of SCK tasks as described by Suzuka and colleagues. Therefore, the concept analysis feature of the teachers' mathematics approach may be used to adapt SCK for secondary school mathematics teachers and design tasks for SCK. In this study MKT model and teachers' mathematics perspective for teachers' mathematics knowledge was integrated to answer the following research question: What kind of mathematical tasks enhance preservice secondary teachers' specialized content knowledge during a content course?

METHODS

This study took place at a public university in western Turkey. The target population of this research is secondary school preservice teachers in Turkey. There were 28 students enrolled in an elective content course for secondary school mathematics teachers. All of the students were asked to participate in the study voluntarily. Among them 16 of those students were chosen to investigate research question. It was not practical to choose all of the students for the study, so the participants were chosen to be representatives of the whole group. They were chosen according to their pre-test scores (three students from high, median, and low scores) and their grade level in the program (senior or junior). There were only four junior students and we chose them all, but there was missing data from one of them, so in total the data from 15 participants were used for this study.

Furthermore, it is important to portray students' mathematical background before discussing findings. They had been prepared in advanced mathematics topics such as group and ring theory, complex analysis, linear algebra in addition to calculus topics and differential equations. The curriculum for teacher education departments is provided by the Higher Education Institute (government) with some slight changes in it according to the university. There are some universities where students take mathematics courses from faculty members of college of education. There are also universities where students take advanced mathematics courses from faculty members of mathematics department. The study was conducted at a university of the latter case. When preservice teachers take many advanced level mathematics courses, it is believed that they will be ready to teach high school topics. Even though SMK is a prerequisite for PCK, it is important to address SMK as specialized content knowledge rather than just common content knowledge. In other words, preservice teachers will benefit greatly from a content course in which they will examine, relearn and reflect on mathematics topics that they will teach (Ball et al., 2008; Suzuka, et al., 2009; Usiskin, 2001). For this study we used *teachers' mathematics practices* (Usiskin et al., 2003) in the content course for secondary school preservice teachers. In this course, real numbers, complex numbers, equations, and functions (definition, exponential and logarithmic function) were studied.

The classroom environment for this course was community of learners such that future mathematics teachers explore mathematical ideas that they would be teaching. We would like to note that since participants studied mathematics as teachers, it was inevitable for them to learn SCK type of mathematics without thinking of teaching practice. Indeed, SCK was defined by Ball et al. (2008) as knowing mathematics for teaching. From this point of view, there were two main components of the content course: mathematical explorations and the context of teaching for mathematics. The mathematical explorations were addressed by mathematical tasks prepared by the researchers by adapting resources (e.g. Usiskin, et al., 2003). It should also be stressed that the authors worked with a mathematician for the development of mathematical tasks. Furthermore, the second component of the course, the context of

teaching component, was addressed as participants collect and analyze student work for three topics (rational numbers, complex numbers, and logarithmic function) during the semester. The protocol for analyzing the student work was developed by the researcher for a previous study (Aslan-Tutak, 2009). For this paper, the focus will be the nature of mathematical tasks used in the course.

DATA SOURCE AND ANALYSIS

There were various data sources; mathematics knowledge pre-test, video records of the classroom instruction, two individual interviews during the semester, and mathematics knowledge post-test. All of the video records of the classroom instructions and individual interviews were transcribed.

The participants written mathematical work (pre-test and post-tests) were analyzed according to content; their correctness and their ability to provide valid mathematical proofs. The test was developed by the researchers. There were definition and proof questions in the pre- and post-tests such as definition of commensurability, proof of $.99999\dots = 1$ equality.

Individual interviews were used for two purposes; participants' perception of effective practices for their learning and their answers to given mathematics questions (e.g. the rule for converting infinite repeating decimals to rational numbers). We report both use of the interviews in this paper. There were two interviews conducted with 15 participants. The first interview was about in the middle of the semester while the second interview was at the end of the semester. Furthermore, the video-records of the classroom instructions were used to support other data sources as they were also used to study the practices of the course.

FINDINGS

The findings section will be organized according to the four types of SCK tasks did with for secondary school preservice teachers; *unpacking concept definitions, applications and modeling, procedures and generalizations, and historical perspective of concepts*. It should be noted that all of these types were used together during the course. In this paper, we tried to choose examples which describe best a particular task.

(a) Unpacking Concept Definitions

Concept analysis includes alternative definitions of mathematical concepts (Usiskin et al., 2003), how and why concepts arose mathematically would provide experiences to unpack definitions for concepts. In the MKT model, Ball et al. (2008) defined SCK as a skill unique to teaching and as it required a special work of unpacking of mathematics concepts. It is not necessary for others but it is a requirement for effective teaching. In the Turkish setting, preservice teachers' earlier experiences with secondary school mathematics concepts were limited to short textbook definitions to memorize, as participants stated in interviews. During their education they built further mathematics procedures or concepts without unpacking. However,

these preservice teachers are asked to teach mathematics conceptually. So they had to look at these well-known concepts and definitions with the eyes of a teacher which requires to ask how and why questions. A primary purpose of the content course was to provide mathematical explorations to encourage preservice teachers to unpack the concepts that they thought they may know or understand superficially (Suzuka et al 2009).

All of the participants stated that they would not think of questioning already known mathematics concepts. In the individual interviews, most of the participants mentioned about the discussions of complex numbers and the geometric definition of number i as one of the most eye-opening experience for them.

From the video-records of the class discussions on complex numbers, we saw that all of the participants were aware of the rationale of the complex number i . They knew that when mathematicians were solving quadratic equations there were negative numbers inside square root. So they said that mathematicians came up with a method to represent -1 inside the square root. However pretest results showed that none of the participants were aware of geometric definition of number i before the content course. They defined the number i either as $i^2 = -1$ or as $i = \sqrt{-1}$ (Aslan-Tutak, 2012).

In order to explore number i , instruction started with discussion on the roots of an equation as its constant terms changes (Usiskin, et al., 2003). Then graphs of the equations were plotted on Cartesian plane (geometric representation of the equations) and their roots showed on a number line (geometric representation of real numbers). The number line was sufficient for the roots of first two equations but participants realized that they could not show the roots of third equation on number line. Then, the definition of the imaginary number i was discussed by rotation of 90° perspective (Lakoff & Núñez, 2000; Trudgian, 2009; and Usiskin et al., 2003) which provides a geometrical understanding of the imaginary number. At that point, the participants realized the need of extending real numbers by discussing what it really means to have $i^2 = -1$. During the classroom discussions and individual interviews they stated that none of them had known geometrical definition of the imaginary number i before this course. After the discussion on the geometric definition of complex number, i as a rotation of 90° from real number line, they pointed out that understanding operations with complex numbers, and the connection between rectangular and polar form became easier. Furthermore, according to posttest results, six of the participants defined the imaginary number i as a rotation by 90° (Aslan-Tutak, 2012).

Participant 1: I consider the origin of the imaginary number i from a different perspective and I have learned from where it emerges [...] in the course everyone was able to aware and learn something that are substantially unknown and unnoticed before.

It is important to note that almost all of the participants were able to carry on simple to advanced calculations with complex numbers. However, being able to do some

mathematical calculations is not enough for teaching mathematics meaningfully. Teachers' SMK is not just merely doing calculations (CCK) but also knowing the concept definitions in-depth.

(b) Applications and Modeling

During the content course, the students had the chance to investigate some mathematics concepts from application or modeling examples. For instance, participants discussed the alternative definitions of function and modeling activities or real life application word problems (e.g. water lily problem for exponential growth). When we analyzed the interview data, it was surprising to see participants' emphasis on modeling activities. Participants especially expressed that they did not use idea of function from modeling perspective; rather they solved computational problems by using functions.

Participants 2: I didn't think of modeling for functions before. When I first looked at problems in the book I was very surprised. We never learned such modeling for functions.

First of all, it was interesting for authors to realize that preservice secondary school teachers' perception of the concept of function was limited with the definition of ordered pairs between two sets. They could not think of function as an operation to explain how variables changes according to each other.

Instructor: What is function?

Participant 3: a set which contains ordered pairs

Participant 4: according to a certain rule, it is an operation which brings an element of a set to an element of another set.

By the end of the class hour, examining examples and classroom discussion yielded to the definition of a function as "If a v and a y can be related through an equation or graph, they are called 'variables': that is, one changes in value as the other changes in value. The two have what is known as a functional relationship; the variable whose change of value comes about as a result of the other variable's change of value is called a 'function' of that other variable" (Rao & Latha, 1995, p. 32). Later, two examples from Bremigan et al. (2011) were discussed whether if they were an example of a function. The purpose of the modeling discussion in this course was to make preservice teachers to relearn concept of function (a very crucial mathematical idea for high school mathematics) by studying alternative definitions.

As the concept of function was introduced from covariation perspective, during the following parts of instruction preservice teachers experienced modeling examples for exponential and logarithm functions. In addition to growth problems, participants were given a problem about oil spill and the cleaning procedure of such an environmental issue. The problem starts with some information about latest oil spill incidents in Gulf of Mexico and France. We discussed briefly about the enormous destruction of oil spill in even one day. So we decided that it is important to clean the

oil in the fastest way and to know when all oil would be cleaned up. Then preservice teachers were given the problem: *If there was 8000 gallon oil due to a spill, and the crew can clean only 80% of oil for a week. So how much oil would remain after a week? And how long will it take to clean until there is 10 gallon of oil is left?* In this problem, one can start solving by using simple arithmetic calculations for percent. However especially for the second question, one should think of exponential function and its inverse logarithm function in order to find required time to clean the oil.

During the individual interviews, participants stated that they were surprised not being able to think of covariation definition of function, and not being introduced to modeling practices for functions until the content course.

(c) Procedures and Generalizations

Besides mathematical concepts, the procedures, rules and formulas are important elements in mathematics. The theorems including mathematical rules and formulas are deduced from both definitions and procedures. Deductions can be made from mathematical definitions (Usiskin et al., 2003), and the rules and formulas may be seen as generalizations of procedures. Beyond knowing procedures and rules teachers need to know why a certain procedure works (SCK). Ball and her colleagues gave an example from elementary school years. Division of fraction procedure (invert and multiply) is commonly used but one may not necessarily need to know why the algorithm works. However, a teacher should know why it works, and this knowledge is defined as SCK. Therefore, in this content course, we also had mathematical tasks to explore underlying mathematical reasons of mathematical procedures and rules.

According to participants' responses for the first interviews, the most impressive experience in terms of unpacking procedures for them was the rule from the topic of rational numbers and their decimal representations. Furthermore, the pre-test included the question which asked the proof of the equality $0.999\dots=1$. Seven participants tried to prove the equality and other eight did not answer the question. Among the seven answers, three of them just used the method of converting a repeating decimal into a rational number and four of them used different arguments. Also, at one point of the instruction on decimal representations there were discussions on the rationality of infinite repeating decimals. Students had homework from previous lesson and they were asked to give justifications of each step of arguments which are given in the textbook for the equality of $0.999\dots=1$ (Usiskin, et al., 2003). During the classroom discussion, infinity concept was also discussed with this question; however, the focus of the classroom discussions was to study $0.999\dots$ as an infinitely repeating decimal. The purpose was to study the procedure of converting infinitely repeating decimals to rational numbers.

Individual interviews show that most of the participants (14 of all 15 participants) did not know why the procedure worked. The connection between the procedure (the method of converting a repeating decimal into a fraction) and the argumentation was provided in class by extending one of the arguments for the $0.999\dots=1$ equality. The

discussion was broken into proofs of three theorems for terminating, simple-periodic and delayed-periodic decimal representations respectively.

Moreover, participants' answers to mathematics questions asked in the individual interviews showed that for many of them, this was the first experience of elaborating the rule of converting an infinitely repeating decimal into a fraction. Until the content course they have known the rule but they didn't know why the methods work. After the course, according to post-test results, all of the participants could explain the rationale of the rule. This kind of knowledge which belongs to SCK is a special knowledge for teachers, knowing why a rule works but when teachers decide how to use this kind of knowledge in their practice that would be knowledge of content and teaching (KCT).

(d) Historical Perspective of Concepts

Another type of SCK tasks used in the content course is the historical perspective of concepts. It is important to note here that it is not the story part of mathematics history but the historical aspect of mathematics problems and concepts. Historical aspects of mathematics concepts were used to provide explorations to relearn mathematical ideas. Throughout the semester for each topic, there were discussions about historical perspectives in order to study why some rules work and how some mathematics concepts developed. Furthermore, almost all of the participants stated that addressing historical mathematics problems and how mathematicians handled them was a helpful approach for them to be able to see concept formation. Even though we cannot support their perceptions with pre- and post-test results, we take their feedback in consideration for developing tasks to enhance their learning in the content course. We will report about using history of logarithm because in individual interviews all of the participants stated that this was an approach that helped them to relearn logarithm.

First, logarithm was studied as the inverse of exponential function in the course. Then when we told preservice teachers that logarithm was developed before exponential function, they did not believe. Then the instructor introduced Napier and his problem which led to invention of logarithm function. Preservice teachers were given the problem and asked to work on Napier's problem (Panagiotou, 2011). Their work and Napier's solution yielded into the Napier's definition of logarithm. Later, there were discussions on Euler's definition of logarithm.

According to their feedback in the classroom and their responses during the second interview, we were able to conclude that even though this kind of knowledge of logarithm was available in resources, it was never introduced to preservice teachers, neither in high school nor in college level courses. They have been using logarithm since high school but none of them ever heard of Napier's problem or his definition of the logarithm function. Pre-service teachers were able to relearn logarithm by studying the historical perspective of the topic. They also reported that they thought this was a kind of knowledge that a teacher should have. Therefore, we may again

conclude that this kind of practice, studying origins of mathematics concepts, allows preservice teachers to unpack and relearn some mathematics concepts.

DISCUSSION

In this paper, the purpose was to report findings regarding the type of tasks which can be used for content course to enhance preservice secondary teachers' SMK, specifically SCK. While studying the research question, we used the MKT model (Ball et al., 2008) as the theoretical framework, and teachers' mathematics (Usiskin et al., 2003) approach to construct the tasks for the content course. Learning tasks for secondary school preservice teachers should not be merely advance mathematical tasks. Rather the emphasis should be looking deeper in mathematics concepts, as unpacking and relearning them. Therefore, concept analysis practice as suggested by Usiskin and his colleagues (2003) was our primary approach to design learning tasks to enhance preservice secondary teachers' SCK. The SCK tasks developed for preservice secondary school teachers consisted of four types; unpacking concept definitions, applications and modeling, procedures and generalizations, and historical perspective of concepts. It should be noted that during the content course all four of these approaches were blended in a way to allow preservice teachers to study mathematics concepts. Since research questions were about the tasks, we reported findings according to these four types of SCK tasks. As, participants' knowledge from pre- and post-tests, and their perceptions from individual interviews and classroom discourse showed that all four of these elements of concept analysis helped participants to examine and study mathematical concepts.

Furthermore, all participants stated their purpose of relearning mathematics was to be more knowledgeable teachers. They were not engaging in those tasks not just as a student but as a future teacher. Even though there were no discussion on how to teach topics in this course, some findings suggested that preservice teachers were thinking of using what they learned for their teaching practice. So, we cannot propose that these practices affected only their SCK but not their KCT, because SMK is necessary but not sufficient condition for PCK. Here, the authors might conclude that as participants experienced learning mathematics for conceptual understanding, they valued teaching in such a way. One of the participants stated that the course was like a laboratory class for them to experience teaching for understanding. Further research may focus on including more topics to this study with a larger sample. The authors also plan to study effect of the content course on preservice teachers' belief about mathematics and teaching mathematics.

VISUALIZING AND COMPARING TEACHERS' MATHEMATICAL PRACTICES

Badillo, E.*; Figueiras, L.*; Font, V. **& Martínez, M.*

*Universitat Autònoma de Barcelona, **Universitat de Barcelona

We report the use of a tool to display and analyze essential elements of mathematical activity (definitions, properties, processes, etc.) arising during the development of a class. It has been applied to the study of the commonalities and differences among three classes conducted by three different teachers in the same institution, year and school level when they teach the bisector. The results allow us to infer some aspects about the mathematical knowledge of the teachers involved.

INTRODUCTION

Research on mathematical knowledge and the professional development of teachers has become increasingly important in recent years, and has revealed not only its complexity but also the limitations of the results (Sullivan and Wood, 2008). In particular, we need a research agenda that links theoretical outcomes with practice, conceptualizes teaching practice, and describes and discusses how mathematical knowledge for teaching is developed during a class.

Several authors assume the complexity of mathematical objects and that teachers' mathematical knowledge is large, intricate and evolves constantly. According to Davis and Renert (2013), instead of thinking of teachers' mathematical knowledge of concepts as a discrete set of basic knowledge in the heads of individuals, it is more productive to think of it as systems of changing instantiations (formal definitions, algorithms, metaphors, images, applications, gestures, etc..) emerging in practice and distributed among the whole community of professional teachers. Also, it is important to note that each of these instantiations has different conceptual value, and that it is desirable for teachers to know as many of these instantiations as possible in order to build a rich net of connections between them and acquire a more robust knowledge of the concept. We also assume that the complex nature of mathematical objects may be perceived in different institutions and different historical moments, different textbooks, or different methodological approaches. From this it follows that comparing the practice of different teachers working in the same institution, presenting the same mathematical concept at the same level and at the same time, will enrich our understanding of teachers' mathematical knowledge in practice. From this standpoint, the objectives of this research are as follows:

- To design a visualization tool that displays mathematical knowledge arising during a math class in terms of formal definitions, properties, examples and mathematical processes, among others.

- To use this tool to highlight the essential elements of the mathematical knowledge of the bisector used by the teachers during their practice.
- To account for the commonalities and differences of the mathematical activity of different teachers presenting the same mathematical content (bisector) in the same school year and the same institution.

TOOLS FOR VISUALIZING AND ANALYZING PRACTICE

In order to investigate mathematical practice we need tools specifically designed to address its complexity. To this end research in mathematics education has produced specific methodological tools and analytical frameworks. For example, the work of Rowland and colleagues (Rowland, Huckstep and Thwaites, 2005) and the knowledge quartet provides very specific conceptualization of practice. The works of Tomás Ferreira and Da Ponte (Tomás Ferreira, 2005; Martinho and Ponte, 2009) emphasizing the role of the teacher in the communication process, and the contributions from the Lesson Study methodology (Fernandez and Yoshida, 2004) include a collaborative model to enhance teachers to plan, implement, monitor, and reflect on math classes. All of these are important contributions that allow us to contextualize the interest of our research problem, namely to visualize the essential elements of the mathematical activity arising during classroom practice (definitions, properties, mathematical processes, etc.).

We observed the practice of three different teachers (hereinafter Laura, Antonia and Encarna) when they taught the perpendicular bisector in the final year of primary school (ages 11-12). The three classes were videotaped and transcribed for later analysis, looking for commonalities and differences in the mathematical activity. For the methodological design of the instrument we have decided to use the ontosemiotic approach for three reasons: First, it allows us to describe how mathematical objects emerge in the classroom and pay attention to the complexity associated with the object (*concept study* in the terminology of Davis (2013)). Secondly, because the ontosemiotic approach characterizes mathematical activity in terms of practices, objects and processes when primary and secondary curricula are also structured in terms of processes (reasoning, communication, modeling, etc.). Finally, because the ontosemiotic approach has already yielded visualization tools. Godino, Contreras and Font (2006) made an attempt to display primary mathematical objects during a class, and in this paper we enrich these attempts by incorporating also emergent processes.

For the analysis of transcripts we used one of the levels of the ontosemiotic approach (Godino, Batanero and Font (2007); Pochulu and Font (2011)). It focuses on the primary objects and the mathematical processes involved in conducting practices, as well as those emerging from them. For the ontosemiotic approach (hereinafter OSA), mathematical activity is modeled in practices where primary objects (we will refer here to definitions, properties, construction procedures and problems) emerge. On the

other hand, instead of giving a general definition of process, the ontosemiotic approach selects a list of processes that are considered important in mathematical activity, without claiming that such a list includes all the processes implicit in all mathematical activities (we will refer here to automation, institucionalization, argumentation, communication, modeling, and connection). Tasks or problems are considered primary objects because they are triggers of the mathematical activity.

An example to distinguish primary objects and processes is the construction of the bisector. For this construction, the student performs a sequence of actions, such as those underlying the use of the ruler and compass. In particular, students can use a construction procedure (algorithm) using only a ruler and a triangle with a 45 degrees angle (it is a procedure, which is considered a primary object type in EOS). With the repetition with other similar exercises the student engages in a process of automation.

TEACHING THE BISECTOR: MATHEMATICAL KNOWLEDGE INVOLVED

Detailed analysis of primary objects and mathematical processes illustrates relevant aspects of the structure and development of each of the three classes and permits us to distinguish many instantiations (using the terminology of Davis and Renert, 2013) of the bisector, as well as to establish relationships between them. Table 1 summarizes objects and processes that emerged from the practice of the three teachers, as well as the codes used to label them in Figures 1,2,and 3.

Table 1: Mathematical objects and processes emerging from the practice.

Mathematical objects	
Definition of perpendicular bisector: Teachers refer explicitly or implicitly to one definition of perpendicular bisector. It includes also definitions of related as segment or line.	
D ₁ :	Perpendicular line passing through the midpoint of the segment.
D ₂ :	Locus of all points equidistant from two given points.
D _{2A} :	Locus of all points equidistant from the ends of the given segment.
D _{2B} :	Line (boundary) which separates the plane into two regions, so that in a region all the points are nearer one of the two points than the other.
Properties: Any statement regarding the definition and the construction method of the perpendicular bisector, which can be true or false, but there is an attempt to justify it in class.	
P ₁ :	The point where the line intersects the segment is the midpoint.
P ₂ :	The obtained line is perpendicular to the given segment.
P ₃ :	Points on the boundary (D _{2B}) are aligned.

Construction procedure: Construction algorithm of the perpendicular bisector.	
Pr ₁ :	Euclid's procedure (Book I prop. X): given a <i>finite straight line</i> , describe an equilateral triangle on it (Prop. I) and bisect its angle (prop. IX).
Pr ₂ :	Perpendicular bisector as a locus: Given two points, find any other two points equidistant from them and connect these last two points with a line.
Pr ₃ :	Carpenter's procedure: Given a segment, measure its length, take its half and draw the perpendicular at the midpoint with the triangles 45 or 60 degrees, or the protractor.
Problem: tasks that incite mathematical activity, examples and counterexamples.	
EP:	Task based on paradigmatic examples
ENP:	Task based on non paradigmatic examples
CE:	Counterexamples

Mathematical processes		
Institutionalization: A definition, property or procedure is explicitly considered as valid, so from that moment on it is assumed to be known.		
Automation: Students are asked to repeat a certain procedure mechanical and individually.		
Communication: Oral or written statements on mathematical contents are expressed or understood. We explicitly exclude from this category mathematical arguments. Three subcategories have been included:		
EP: Teacher's lecture	DPA: Dialog among teacher and students	DA: Dialog among students
Argumentation: Existence of chains of mathematical arguments		
Modelling: At least one of the following phases of modelling (Blom, 2002) occurs: (a) starting point is a certain situation in the real world; (b) simplify, structuring and making the content precise; (c) objects, data, relations and conditions involved in it are translated into mathematics, and mathematical results derive, (d) retranslation into the real world.		

COMMONALITIES AND DIFFERENCES AMONG THE THREE CLASSES

In each of the three classes there emerge different definitions and construction procedures. In Laura's class she defines the bisector as the perpendicular line passing through the midpoint of the given segment (D_1), and uses Euclid's procedure (PR_1) for the construction. The carpenter's procedure (PR_3), which is suggested by a student, is not institutionalized. In Antonia's class, she institutionalizes the same definition (D_1), but a different procedure (PR_2 : given two points, find two equidistant from them and connect them with a line). In Encarna's class, she refers to the bisector as the boundary between two regions in the plane so that in a region all the points are

nearer to one of the two points than the other (D_2B), and does not give any construction procedure.

In each of the three cases there appears one process that predominates, occupying approximately three quarters of the total time. In Antonia and Laura's classes it is the automation process, which takes about the last 75% of the class. In contrast, in the case of Encarna's the communication process predominates, taking up approximately three quarters of the total. We emphasize that in this third class modeling and argumentation processes appear, which have little or no presence in the other two.

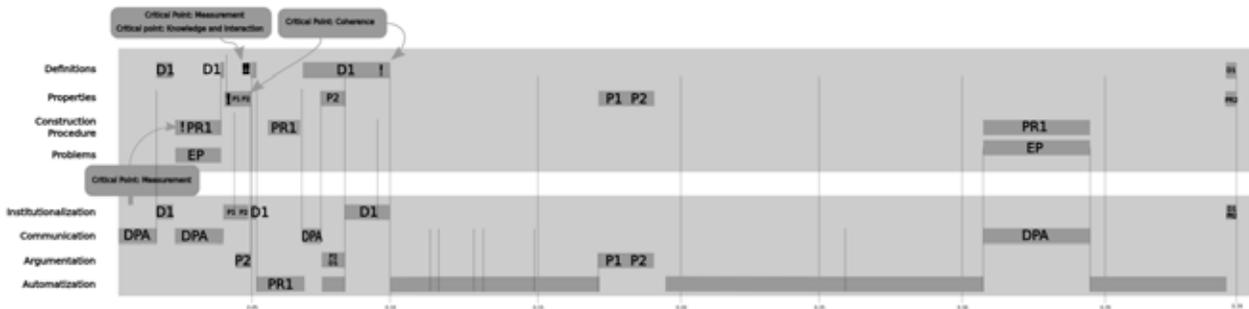

Figure 1. Graphic visualization of Laura's class. See Table 1 for label descriptions.

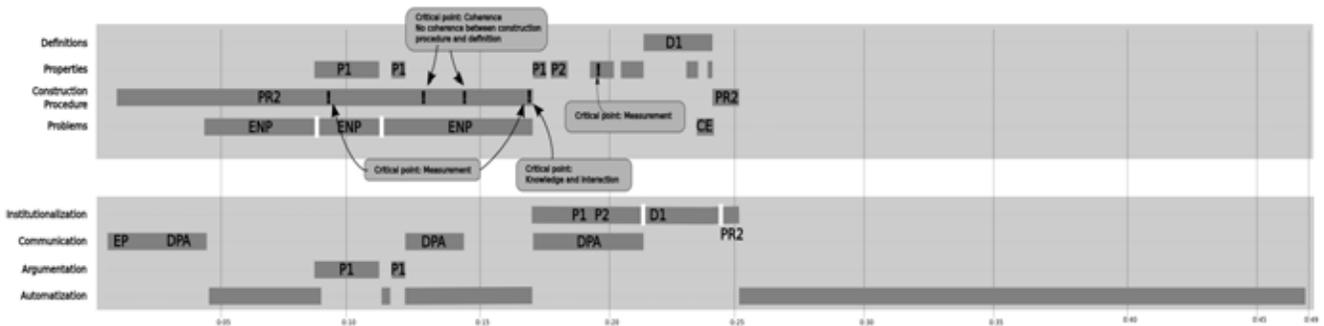

Figure 2. Graphic visualization of Antonia's class. See Table 1 for label descriptions.

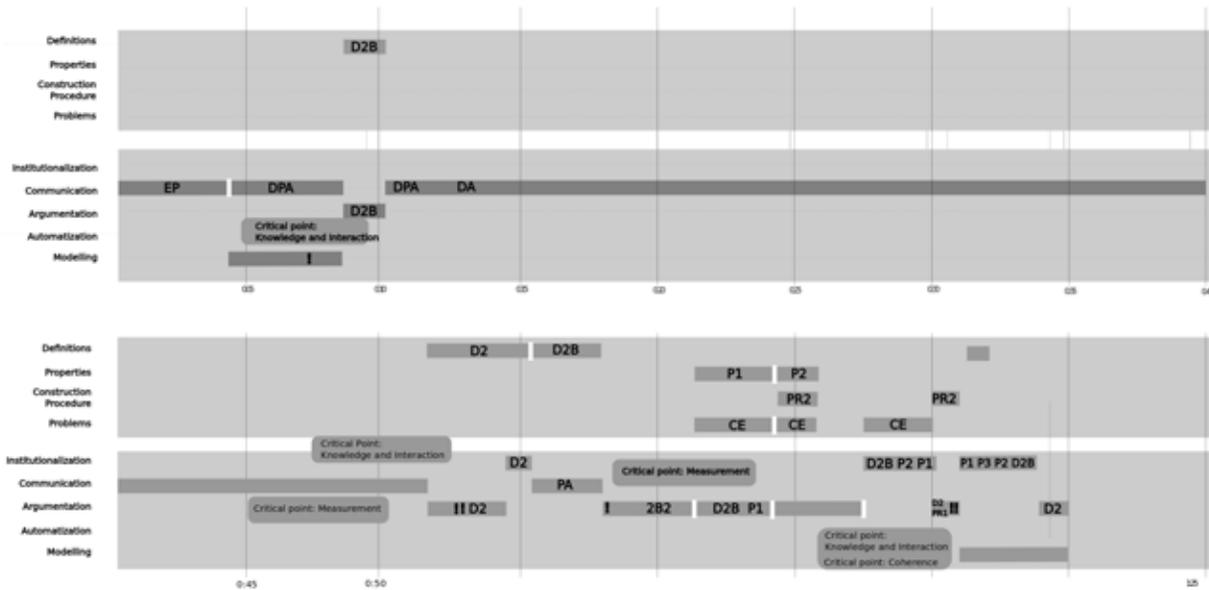

Figure 3. Graphic visualization of Encarna's class (significantly longer). See Table 1 for label descriptions.

A first analytical approach to the graphics shows also that mathematical activity is not uniformly developed during each class, but in all three we find slots of time in which the density of processes, definitions, procedures, etc. is higher. These periods of time occupy approximately from one quarter to one third of the total time of the class. However, in the case of Laura (Figure 1) there is an important accumulation phase during the first ten minutes, when most primary objects are presented. In the case of Antonia (Figure 2) this phase begins approximately in minute ten, while in Encarna's class (which is significantly longer) it appears at the end (Figure 3). We have analyzed in detail the way in which the three teachers connected primary objects and processes (considered instantiations of the bisector) as they emerged in these time slots.

CRITICAL POINTS IN TEACHING THE BISECTOR

The two following extracts from Laura's class illustrate some lack of consistency regarding the use of measure for constructing the bisector or proving its properties. In the first one, a student intends to find the midpoint of the segment using a graduated ruler, but the teacher makes explicit that direct measurement is not permitted for the construction.

Excerpt 1:

Teacher: So the bisector of the segment is nothing else than the straight line perpendicular to this segment that divides exactly it into two equal parts, right? What do you do to get the midpoint of that segment and split it into two equal halves? Say.

Student: I could put this on it -raising a ruler- and measure it.

Teacher: I could measure it with the rule but, would I obtain the same? Exactly? Exactly?

Student: With the compass.

Teacher: [nodding] With the compass (takes the chalkboard compass). The compass is the right tool with which the midpoint of the segment is going to be perfect.

However, in the second extract below, the same teacher uses direct measurement with the angle protractor to verify that the properties of the definition hold.

Excerpt 2:

Teacher: Therefore, one condition is that the line dividing the segment into two equal parts, the bisector of the segment, must be perpendicular. How can I know if these two lines are perpendicular? What do I have to do? Perpendicular (she points the four quadrants in the chalkboard)

Student: Measuring with the protractor.

Teacher: [nodding] Measuring with the protractor. (takes the chalkboard protractor)

Student: A right angle.

Teacher: and I have to obtain...

Students: A right angle, ninety.

Teacher: and I have to obtain four right angles. One, two, three, and four. If I put the protractor here (on the first quadrant)... Let's see. Note that I obtain exactly 90 degrees. OK? And If I put it this way I also obtain 90 degrees exactly. So I can say that the bisector of the segment is the line which is perpendicular to that segment and divides it into two perfectly equal parts. Exactly.

The selected dialogues above reveal as a fundamental aspect of professional knowledge related to the teaching of the perpendicular some reflection on the foundations of the mathematical activity. For the students, finding the midpoint of a segment leads naturally to a problem of direct measurement with the rule, while if the decision of the teacher is to follow the norms of Euclidean geometry, measuring with the ruler has no place in the constructing or proving properties of the bisector. This difference creates a professional problem that teachers can only manage with previous reflection on the validity of using approximated measurement in geometric constructions.

Such situations emerging from teaching practice on a specific concept are very important to connect the different instantiations of it. The existence of this, and other similar situations lead us to define critical points, which require some interpretive analysis. A critical point is a manifestation of the difficulties that the teacher has to deal with the mathematical object (In This case the perpendicular bisector) due to its complexity. They are explicit in the form of errors, omissions, inaccuracies or lack of logical consistency in the teacher's speech. It is important to note that critical points relate to teachers' decisions and probably to their knowledge of the content, but are

not necessarily a consequence of its lack. Seeking for those indicators in the transcription of the lessons, we have identified two critical points related to teachers' knowledge about the bisector. The first one has to do with measurement, as was illustrated above. The second one is related to the lack of consistency between the process of constructing the bisector and the definition in use. Both of them are reflected in Figures 2,3, and 4 with an exclamation mark.

The construction procedure (PR_2) used in Antonia's class considers the bisector as the locus of points equidistant from the two ends of a segment. However, she defines the bisector as the perpendicular through the midpoint of a given segment (D_1). This lack of coherence has important consequences for making sense of the bisector.

FINAL REMARKS

Having tools to visualize practice on a particular mathematical concept is important to decompose the intricate system of definitions, properties, processes, etc. (instantiations) that teachers use to approach this concept. Knowing not only which those instantiations are, but also how and when they arise in the course of a class, how they relate to each other, and the difficulties they involve is critical to understanding teachers' mathematical knowledge. Furthermore, it is assumed that mathematical knowledge for teaching is a complex system of instantiations distributed among all professionals.

We have applied a method based on the model proposed by the ontosemiotic approach to visualize three different mathematics classes on the bisector. The results highlight the use of different definitions, construction procedures and processes, as well as two critical points that inform about the difficulties for connecting the definitions, properties or procedures used. From our research derives the close relationship between the teaching of the perpendicular and the fundamental problem of using direct measurement for geometrical constructions, conjecturing or proving. To define the bisector as the perpendicular line through the midpoint of a given segment has been associated with an automation of its geometrical construction. On the other hand, defining the bisector as a locus has been associated with a broader communication process, and the emergence of modeling.

TEACHERS AS INVESTIGATORS OF STUDENTS' WRITTEN WORK: DOES THIS APPROACH PROVIDE AN OPPORTUNITY FOR PROFESSIONAL DEVELOPMENT?

Sinem Bas¹, M. Gozde Didis¹, A. Kurşat Erbas¹, Bulent Cetinkaya¹, Erdinc Cakiroglu¹, Cengiz Alacaci²

Middle East Technical University¹, Istanbul Medeniyet University², Turkey

The aim of the study was to examine how teachers' investigation of students' written works contributed to their professional development. The research was conducted at a public high school with the participation of six mathematics teachers and their students. The teachers have examined their students' written works as products of their solutions for some modeling problems for 5-week period. The preliminary analyses showed that teachers' collective examinations and interpretations of their students' written works have contributed to their professional development in terms of their subject matter knowledge and pedagogical content knowledge. Moreover, the collaborative learning environment in the study had positive effects on the affective domain regarding teachers' ways of knowing of students' thinking.

Keywords: Teacher education, professional development, student thinking

INTRODUCTION

This study reports on preliminary findings from a study carried out as a part of a larger research project about mathematical modeling where the primary purpose is to develop pre-service and in-service mathematics teachers' knowledge and skills about using modeling problems in teaching mathematics. The main three components of in-service teacher education dimension of this program were (a) planning a lesson in which a modeling problem was integrated, (b) implementing the problem in the classroom, and (c) investigating/assessing students' works in modeling problems. The focus of this study is on the third component.

More precisely, the purpose of this study was to examine how teachers' investigation of students' written work contribute to their professional development in terms of their subject matter knowledge and pedagogical content knowledge. The following research question guided this study: How does teachers' collective investigation of students' written works contribute to their professional development in terms of subject matter knowledge and knowledge of students' thinking as a sub-component of pedagogical content knowledge?

Teachers' Knowledge of Students' Thinking

It is widely accepted that teacher knowledge comprises three major dimensions: subject matter knowledge (SMK), pedagogical knowledge (PK), and pedagogical content knowledge (PCK) (e.g., see Shulman, 1986). In particular, teacher knowledge of students' mathematical thinking has attracted much interest. In this regard,

teachers' knowledge of students' conceptions, difficulties and potential misunderstanding have been the subject of various studies as an important aspect of teachers' pedagogical content knowledge (e.g., Carpenter et al., 1996; Chamberlin, 2002; Gearhart & Saxe, 2004) as it could offer crucial contributions to teachers' professional growth. According to Gearhart and Saxe (2004), knowing what students know is crucial for effective classroom practice. When teachers attend to students' mathematical thinking, they can prepare the instruction with respect to their needs and level of understanding, emphasize important mathematical ideas, understand students' misconceptions and create learning environment to foster students' mathematical ideas (Kulm, Capraro, Capraro, Burghardt, & Ford, 2001 as cited in An, Kulm & Wu, 2004). All these studies highlighted that when teachers attend to and understand their students' thinking, both their instructional practice and students' achievement can benefit (Chamberlin, 2002)

However, although teachers' understanding of students' mathematical thinking is important for teachers to teach mathematics effectively, teachers usually had poor subject matter knowledge and their knowledge was not connected to students' thinking (e.g., Nathan & Koedinger, 2000; Bergqvist, 2005). Ball (1997) indicated that during classroom teaching, attending students' thinking was not easy because teachers often could not find an opportunity to interact with all of their students in their own classrooms. Additionally, teachers have difficulties in identifying students' ways of thinking as students' thinking can change under different circumstances or they cannot always express their thinking although they construct the idea in their mind (Ball, 1997; Chamberlin, 2002). Because of these reasons, it may be difficult for teachers to understand students' mathematical thinking.

All of these are particularly true when teachers attend to students' reasoning in modeling problems. One of the main features of these problems is that they allow students to think about the problem differently and solve it in different ways. Thus, teachers are confronted with different ways of student thinking when they attempt to understand students' reasoning while implementing the problem and assessing students' written works after the implementation. This is quite challenging for teachers (Doerr, 2007).

Professional Development Approaches That Focus on Student Thinking

In reviewing the works on the professional development of mathematics teachers, Sowder (2007) contented that one of the main goals of professional development is "developing an understanding of how students thinking about and learn mathematics" (p. 163). The studies that use students' ways of thinking on mathematical concepts as a tool for improving teachers' content knowledge and pedagogical content knowledge are designed based on the fact that attending students' mathematical thinking provides benefits for effective instruction and thus help support increasing students' achievement.

Ball (1997) suggests three approaches to improve teachers' attending to students' thinking. The first approach is "discussing cases of students' thinking" (p. 808). In this approach, teachers work together with written cases of episodes of students' thinking, and they investigate and find different interpretations of students' thinking. The second approach is "using of redesigned curriculum materials" (p. 808), and the third approach is "investigating artifacts of teaching and learning" (p. 811). The third approach is related to teachers' examination of "unnarrated" students' works and thoughts. Unlike the other two approaches, in the third approach, teachers engage in the artifacts obtained from real classroom settings, such as videotaped classroom lessons, students' written works and drawings on a paper or a chalkboard. Therefore, this approach is more realistic and provides teachers the opportunity to examine actual student products which are not interpreted by somebody else (Ball, 1997). The main idea of this approach can be seen in different professional development programs. For instance, *Cognitively Guided Instruction* (CGI) (Carpenter, Fennema, & Franke, 1996), *Multi-tier Program Development* (Koellner-Clark & Lesh, 2003), and *Integrating Mathematical Assessment* (IMA) (Gearhart & Saxe, 2004) can be considered as well-known examples of such programs. All of these programs acknowledged the importance of teachers' attending to and understanding students' mathematical thinking, although they used different approaches to develop it. For example, CGI was based on using the research-based knowledge of students' ways of thinking about a certain mathematics topic (e.g., addition and subtraction) to enhance teachers' instruction. As an alternative to CGI model, the professional development program of Koellner-Clark and Lesh (2003) situated in Models and Modeling Perspectives was grounded on providing opportunities for teachers to work on their students' works rather than providing research-based knowledge to teachers. According to this professional development approach, changes in teachers' knowledge and ultimately in their views about their teaching is possible only if they engage in situations where their existing knowledge is challenged and thus they experience some kinds of cognitive conflicts. The way of doing this includes activities of giving teachers tasks where they are required to interpret students' mathematical thinking (in modeling problems), and having teachers create conceptual tools (e.g., student thinking sheets, concept maps, etc.) to use in teaching practice (Koellner-Clark & Lesh, 2003). In this study, we adopted the *Multi-tier Program Development* (Koellner-Clark & Lesh, 2003) by having teachers engage in activities in which they investigate and think about students' modeling processes. Our main intention in this design was to foster teachers to think about their knowledge for teaching mathematics.

METHOD

Participants

This research was conducted at a public high school during spring semester of 2010-2011 school years. The school was selected because it was one of the distinguished

schools with a well-organized workgroup of teachers in order to meet regularly across the semester. In addition, this school was willing to open their doors to carry out the study.

Six of the mathematics teachers in the school and their students participated in the study. The teachers had more than 8 years of experience and four of them had master degree in mathematics. On average, the teachers had strong mathematical knowledge and their students had quite high achievement level relative to other schools in the district.

Procedures

The teacher investigations lasted four weeks. Before the first week of the investigations, the introductory meeting was conducted with all teachers. In this meeting, the outline of the 5-weeks program was explained, the Student Thinking Sheet (STS) was introduced, and modeling problems that would be implemented in the classrooms were determined with the teachers.

During the 5-weeks period, each week a modeling problem was implemented in two classrooms at the same grade level by two teachers. Students worked on the problems in groups of 3 or 4 students during the two class periods (i.e., 90 minutes).

Before implementing a modeling problem in the classrooms, teachers were asked to solve the problem like a student and to create pre-implementation STS individually according to their predictions. After the modeling problem was implemented by two teachers in their classrooms, student works were collected and copies of them were provided to the teachers. Then, teachers were asked to examine the students' works in depth and to create individually post-implementation STS.

Next, teachers met for the follow-up meetings that lasted about 90 minutes. In these meetings, the teachers evaluated the classroom implementations. However, teachers who implemented the modeling problems shared their opinions about the tasks with other teachers and their experiences during implementation. These deliberations lasted approximately 15-20 minutes. Then, teachers interpreted their students' thinking strategies by the help of the STS. At this stage, teachers sequentially were asked to express verbally their individual written notes on the STS and to share with other teachers. Initially, the teachers, who conducted the classroom implementations, shared their thoughts. During this process, teachers showed examples of students' works while presenting their observations. In this way, teachers discussed their students thinking and collaboratively produced a shared STS which included students' fundamental thinking strategies.

Data Sources

Student Thinking Sheet (STS)

Student Thinking Sheet (STS) is a form designed to help teachers to think about and document students' mathematical thinking. It consists of a two-page document formatted as a table. The first page is divided into rows in which teachers are required

to report different solution strategies used by their students in working on modeling problems. The table in the second page includes sections in which teachers are asked to report mathematical concepts, skills and process as well as students' errors and misconceptions for each different solution strategy.

Modeling Problems

For this study, five modeling problems were used to examine the interpretation of teachers' to understand their students' ways of thinking in certain mathematical situations. Modeling problems are non-routine tasks and they differ from the traditional textbook word problems. In each of these modeling problems, students interpret a complex real-world situation and formulate a mathematical description; therefore, what students produce has to go beyond short answers (Lesh & Doerr, 2003).

Weekly Meetings

The aim of the weekly meetings was to help teachers to examine and interpret students' different solution strategies, their misconceptions and errors. Each meeting lasted approximately 90 minutes and was audiotaped and videotaped. In these meetings, the researcher (the first author of the study) had a facilitator role and managed the group discussions. While teachers were sharing their thoughts about students' thinking strategies, the researcher posed some questions like "What do you think about the students' mathematical thinking underlying this strategy?", "What do you think about the effectiveness of this strategy to solve the problem?" in order to encourage teachers to think about students' ways of thinking more deeply.

Interviews

For this study, two different types of interviews were carried out. The first type of interviews was conducted with the teachers who implemented modeling problems in their classrooms. These interviews occurred before and after teachers implemented modeling problems in their classrooms and they lasted approximately 20 minutes. In pre-implementation interviews, teachers were asked about their predictions and expectations about students' ways of thinking; e.g., "What are your predictions about solutions students would have?" and "What are your predictions about students' difficulties and errors?" On the other hand, in post-implementation interviews, teachers were asked questions such as "Were there any ways of solutions which you found surprising? If any, what were they? Please explain them briefly" or "Which important mathematical ideas did students reach at the end of the process?"

The second type of interviews was conducted individually by all six teachers at the end of the semester and lasted approximately 40 minutes. The aim of the interviews was to inquire into how to examine students' thinking and work on STS and to see how attending weekly teaching meetings affect teachers' professional development. During the interviews, teachers were asked questions such as "Could you compare your interpretation of students' ways of solutions in the first week to the last week?"

or “How was this experience for you? Each interview was audio-taped and transcribed verbatim.

Data Analysis

The analysis of data was completed in two stages as pre-data analysis and in-depth data analysis. The pre-data analysis of the study has already been done and the in-depth analysis of data is in progress. For pre-data analysis, all written, audiotaped and videotaped data were examined carefully and organized by the researchers to prepare for analysis. Although students’ written works produced during implementations were not the main source of data, they were used to provide background for the data analysis. Therefore, students’ works were first examined by the researchers to determine the required data. The video recordings of the weekly teachers’ meetings were carefully watched and notes were taken. Next, field notes were looked over; the transcripts of interviews and “Student Thinking Sheets” were reviewed. In this way, the initial codes were determined. In order to construct actual codes and present certain findings of the study, in-depth analysis of data will be conducted.

RESULTS

Pre-analysis of the data indicated that teachers’ collective examinations and interpretations of their students’ written works provided contributions to their professional development both in terms of subject matter knowledge and pedagogical content knowledge. Besides, there were some affective contributions of this type of collaborative learning environment to teachers’ professional development. Despite the fact that finding out probable contributions of a professional development environment to teachers’ knowledge requires a long-term study, the four-week study provided some clues about these contributions as follows.

Contributions to Subject Matter Knowledge

When teachers were trying to interpret students’ different solution strategies from their written works, they were also trying to understand the mathematical aspects of these strategies. While they discussed the mathematical thinking underlying the strategy, they reveal their own mathematical knowledge and shared it with their colleagues. Especially when teachers detected some errors in students’ solutions, they discussed what the mathematical sources of the error were. These discussions provided them with meaningful opportunities to reveal and improve their own subject matter knowledge. For example, the following excerpt shows that teachers discuss deeply on the mathematical concepts such as linear function, geometric series or slope etc. while they are investigating whether students’ solution strategy is correct

Fevzi: Then, we accept the elements of the geometric series as linear. Is there such a thing?

Huseyin: No no. But actually, this ratio is the slope, isn’t it? Can we think of this ratio as the slope?

Fevzi: It is just like the terms of a geometric series.

Huseyin: The ratios that I took their ratios in the geometric series.

Fevzi: The r 's

Huseyin: Are the r 's slope? Can we think of them as slope?

Fikret: Is there any linearity at there?

Fevzi: So, if x -axis [*represents*] is the number of bounces and y -axis is the height, linearity does not hold.

Huseyin: No, then it is not. Is it quadratic, then?

Handan: Yes, it becomes quadratic. When it is linear, it has to decrease at a constant rate, doesn't it? Isn't it a property of a linear function?

Contributions to Pedagogical Content Knowledge

This study focused on teachers' knowledge of their students' thinking as one main dimension of their PCK. Data indicated that this type of collaborative investigation of students' works had potential to improve teachers' understanding of their students' thinking. Teachers' interpretations of students' written responses to the modeling problems improved noticeably from the first meeting to the last one. For instance, in the first meeting, although there were many different solution approaches in students' work, almost all teachers were not able to see and detect the different solution strategies except for two or three strategies. In the interviews, they explained this situation that they didn't know exactly what the focus of the activity was. Especially, when a student used a strategy different from their expected solution, they tended to ignore this strategy. Some teachers explained the reason of this situation as they were accustomed to assessing students this way in their daily teaching practice. That is, student work often did not get credit if it did not follow teachers' "expected" way of solution. But as meetings proceeded, they tried more to examine and understand different solution approaches even if they were incorrect. Also, teachers could better see and interpret different solution strategies, mathematical ideas underlying these solutions and errors when they came across with them.

Additionally, the ways in which teachers interpreted and described students' solution approaches changed considerably from the first meeting to the last. For instance, at the beginning, they often looked only at what students did superficially. They did not tend to investigate what the mathematical thinking underlying the solution was, whether this solution was correct or not. As the following excerpt exemplifies, during the first investigation of students' written works teacher Handan just describe students' solution strategy superficially rather than making inference or providing detailed analysis.

Handan: Students obtained a value with trial and error and then they transformed it into a formula to support it. So, at least the students began with the trial and error method but then they formulated it.

As meetings proceeded, teachers focused more often on the underlying thinking processes rather than just looking at what students did. They considerably tried to understand their students' thoughts.

Contributions to Attitudes Towards Students and Collaboratively Working with a Colleague

Almost all teachers expressed the changes in their attitudes towards their students, especially towards those students who were not successful in standard tests and examinations. The following excerpt illustrated changes in a teacher's point of view towards their students.

Huseyin: Now, I thought of that. These students shut down themselves after an hour. But, they solve whatever they want if they are provided with an appropriate question and the environment. They [*the project activities*] changed my thoughts about these students. Namely, yes, when you provide these children with an appropriate environment and offer them appropriate things, there is nothing they would not do. Now, it has increased my respect to these children.

Accordingly, teachers explained that through these close examination of students' work, they knew their students better and they appreciated their different ways of thinking. They also expressed their thoughts and feelings about the collaborative working with their colleagues. Similarly, the data from the whole group discussion in meetings showed the benefits of discussions and exchanging ideas for better interpreting their students' thinking and filling the gaps in their subject matter knowledge.

DISCUSSION

Our findings showed that interpreting students' different and sometimes unusual strategies on thought-revealing non-routine tasks were initially not so easy for teachers. This result is compatible with the findings reported by others (e.g., see Koellner-Clark & Lesh, 2003). However, as teachers analyzed students' work over time, they started to appreciate and understand students' solution strategies and also better interpret the mathematical ideas underlying these strategies. Like other professional development programs (e.g., Carpenter, Fennema, & Franke, 1996; Koellner-Clark & Lesh, 2003), these findings indicated that a learning environment in which teachers work collaboratively to analyze and interpret students' works on thought revealing non-routine tasks, provides crucial contributions to not only teachers' subject matter knowledge and pedagogical content knowledge but also to their attitude and beliefs towards teaching mathematics. On the other hand, collaborative work with colleagues on STSs and the nature of the modeling problems are two major factors that positively affect teachers' professional development. Nevertheless, when teachers did not solve the tasks themselves and/or come to the

meetings without analyzing students' works carefully, they had difficulties in interpreting students' thinking. Therefore, as consistent with findings of Nathan and Koedinger (2000) and Bergqvist (2005), this study shows that such conditions can create barriers to provide adequate contributions to their professional developments while teachers investigate students' works. In addition, it is also observed that teachers need to spend adequate time to work on students' works for their professional development. In summary, this study contributes to our understanding of the literature on teacher knowledge and changes thereof in that investigations of students' works resulting from non-routine, thought-revealing activities could be a starting point for in-service teachers regarding what they know and think about their students' thinking and change their instructional practices.

NOTES

1. Work reported here is based upon a research project supported by the Scientific and Technological Research Council of Turkey (TUBITAK) under grant number 110K250. Opinions expressed are those of the authors and do not necessarily represent TUBITAK's views.
2. The modeling problems used in this study were developed by the researchers working on this research project.

ENHANCING MATHEMATICS STUDENT TEACHERS' CONTENT KNOWLEDGE: CONVERSION BETWEEN SEMIOTIC REPRESENTATIONS

Claire Vaugelade Berg

University of Agder, Kristiansand, Norway

A developmental research project in mathematics teacher education is currently running at University of Agder. One of its aims is to enhance student teachers' content knowledge and to develop awareness of the specificity of mathematics as a subject-matter. Results from the research presented in this paper show the nature of the difficulties student teachers meet as they engage with mathematical tasks addressing the transition between semiotic representation registers. Implications for teacher education programs are discussed.

INTRODUCTION

How do we, as mathematics teacher educators, face the challenge of enhancing student teachers' content knowledge? And how do student teachers evaluate their own engagement with mathematical tasks addressing the idea of conversion between semiotic representations? In order to address these questions, I present results from a research project called "Inquiry-based mathematics teacher education: preparing for life-long learning", (the IBMTE project from now) and it is elaborated in collaboration with my colleague Barbro Grevholm. The ideas developed in our research project are rooted in our earlier research in teacher education (Grevholm, Berg, and Johnsen, 2006) where the idea of inquiry plays a central role. It was during spring 2011 that we initiated the IBMTE project and it is currently running at UiA. Based on this research project we elaborated the main aspects of an innovative course in teacher education currently running at the University of Agder (UiA), Norway. The aims of the research project are to strengthen mathematics teacher education at UiA by making explicit the link between theory (results from research in mathematics education) and teaching practice, and to facilitate the transition from being a student teacher to becoming an in-service teacher (Grevholm, 2003, 2010). In addition it aims at bringing the specificity of mathematics as a subject-matter to the fore by adapting and designing tasks as a means to enhance student teachers' awareness of the importance and the relevance of the use of semiotic representations (Duval, 1995, 2006).

In this article my focus is on student teachers' reflections on mathematical tasks which were designed as a means to develop both their awareness of the specificity of mathematics as a subject-matter, and to engage in reflecting on the transition between semiotic representations. Based on this approach the research questions addressed in this paper are: What is the nature of student teachers' reflections as they engaged with a task designed to encourage exploring the transition between different semiotic representations? And do student teachers recognise the importance of using different

representations? The structure of the paper is as follows: First I present the rationale of the IBMTE project emphasising the role played by the ideas of “inquiry” and “transition between semiotic representations” in mathematics teacher education, considering a perspective both from student teachers’ content knowledge and didactical knowledge (Durand-Guerrier & Winsløw, 2005). Then I turn to analysing student teachers’ reflections after engaging with a mathematical task and discussing the relevance and meaning of the transition between semiotic representations. The data presented in this article are selected from student teachers’ answers to a questionnaire and to an interview conducted with two students. I conclude by discussing possible development of and implications of this research for mathematics teacher education. Especially I argue for recognising the importance of developing student teachers’ awareness of both the relevance of and transition between different semiotic representation registers.

THE MAIN ASPECTS OF THE IBMTE PROJECT

Rationale for the IBMTE project

Our research project emerges from the recognition that teachers and teaching play a central role in creating rich learning opportunities for pupils (Jaworski, 2006), and therefore we consider that it is important for student teachers to experience a rich and stimulating learning environment. From studies in teacher education it is well documented that the gap between theory and practice often creates a reality-check for new educated teachers (Grevholm, 2003, 2010). Therefore our research project aims at designing a course that could enable new educated teachers to see how they could engage in a continuous learning process, as in-service teachers, and use tools like “inquiry cycle at three levels” as a means to engage in life-long learning while recognising the importance of results emerging from research in mathematics education. In Norway there is a demand for developing teacher education programs which are research based. However the consequences and implications of this claim are not clear. The IBMTE research project and the innovative course in mathematics teacher education emerging from this project are to be considered as an attempt to address this challenge. Finally by bringing the idea of *inquiry* to the fore, we introduce the dimension of reflection at three levels, as explained below, an aspect which we consider as central to the education of future mathematics teachers.

Inquiry cycle at three levels

The idea of inquiry is crucial in the IBMTE research project and it refers to a cyclical process consisting of asking questions, recognising problems, exploring, investigating, seeking answers and solutions and thereby engaging in an inquiry cycle (Berg, 2011b, 2011c, 2013; Jaworski, 2006, 2008). This process is understood at three levels: at the first level *inquiry in mathematics* as the student teachers engage in mathematical tasks; at the second level *inquiry in teaching mathematics* as student teachers engage in reflecting on and looking critically at how to organise and prepare teaching in order to enhance pupils’ conceptual understanding of mathematics; and at

the third level *inquiry in student teachers' own reflections* as they engage in looking critically at their own development as future mathematics teachers. Our aim is that student teachers recognise inquiry as being a useful tool and gradually move into considering “inquiry as stance” (Cochran-Smith & Lytle, 1999) or “inquiry as a way of being” in practice (Jaworski, 2006, 2008). We consider it important to offer student teachers’ opportunities to engage in an inquiry cycle as a means to raise their awareness, as future teachers, of the specificity of mathematics as subject matter.

The specificity of mathematics as subject-matter

What is the specificity of mathematics as a subject-matter and what are the consequences of this specificity for learners of mathematics? On the contrary to physics, chemistry or biology where the objects of study are accessible either by perception or by instruments, mathematical objects like numbers, functions, geometrical shapes or vectors are not directly accessible. The only possibility to have access to these objects and to perform some operations on them is to introduce signs and semiotic representations (Duval, 1995, 2006). As a consequence learners need to use signs, diagrams, figures, and notations which stand for and represent the mathematical object at study. More generally Duval’s approach emphasises the role played by visual representations in the learning of mathematics (Arcavi, 2003). For example, according to Duval (2006), the algebraic expression of a function, a table of the different values of the function, a text describing a situation, and a graph are four different semiotic representations of the mathematical idea of function (see Figure 1). Other representations are possible, as a correspondence between sets.

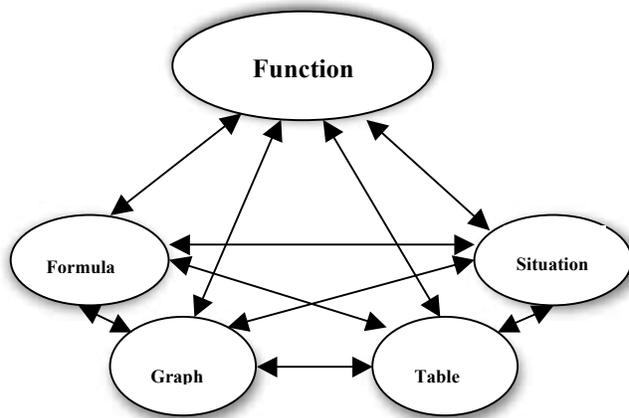

Figure 1: Distinguishing the mathematical object “function” from its semiotic representations (Berg, 2013)

Furthermore, Duval (2006) introduces the distinction between the ideas of *treatment* and *conversion* where the former is defined as “transformations of representations that happen within the same register” while the latter refers to “transformations of representation that consist of changing a register without changing the objects being denoted” (p.111-112). The nature of treatments which can be carried out within a register is depending of the possibilities of semiotic transformations and these are specific to the used register. Conversion refers to “a representation transformation

which is more complex than treatment because any change of register first requires recognition of the same represented object between two representations whose contents have very often nothing common” (p.112). For example the process of solving an equation belongs to treatment while the transition from the algebraic notation of a function to its graph brings the necessity of using two different semiotic representation registers and illustrates the notion of conversion. According to Duval (2006) the teaching and learning of mathematics witnesses a lack of recognition of the specificity of mathematics as a subject-matter and he argues that

Changing representation register is the threshold of mathematical comprehension for learners at each stage of the curriculum. It depends on coordination of several representation registers and it is only in mathematics that such a register coordination is strongly needed. Is this basic requirement really taken into account? Too often, investigations focus on what the right representations are or what the most accessible register would be in order to make students truly understand and use some particular mathematical knowledge. With such concern of this type teaching goes no further than a surface level. ... The true challenge of mathematics education is first to develop the ability to change representation register (p.128).

As teacher educators we need to take Duval’s claim into account seriously and to avoid that student teachers engage in teaching mathematics at a surface level and without recognising its specificity. This acknowledgement brings with it clear demands to teacher education as to create opportunities for students to engage in activities where they are challenged by different semiotic representation registers and need to move between these. Furthermore I see Duval’s distinction between treatment and conversion as related to the syntactic and semantic aspects of algebra. *Syntactic aspect* refers to the organisation and transformation of symbols following specific rules of manipulation, while the *semantic aspect* addresses the meaning endorsed by symbols and by expressions (Berg, 2009; Drouhard & Teppo, 2004; Puig & Rojano, 2004). Thereby the process of treatment is deeply related to the syntactic aspect of the expression at study (symbols manipulation), while the process of conversion is rooted in the ability of addressing the semantic aspect (developing awareness of the meaning of symbols, expressions and figures). I argue that bringing to the fore the specificity of mathematics as a subject-matter, as explained above, has deep implications for mathematics teachers’ education. More specifically I consider that the design of activities aiming at developing student teachers’ awareness of the importance of semiotic representation registers in the learning and teaching of mathematics is central and might be used as a means of enhancing their content knowledge and didactical knowledge (Durand-Guerrier & Winsløw, 2005).

Methodological considerations and research setting

The methodology adopted within the IBMTE project follows a developmental research approach. This implies that Barbro Grevholm and I, we engage in studying, documenting and researching student teachers’ development and, at the same time, we recognise that our research activity contributes to that development (Goodchild,

2008). Concerning methods used in this research, the data was collected as part of the first teaching period during fall semester. The semester is organised as follows: students have first one week with teaching at the university and then three weeks with teaching practice in different schools, both primary and secondary, around Kristiansand. It was during the first teaching period that I decided to introduce a task related to the process of conversion between different semiotic representations as a means to address the specificity of mathematics as a subject-matter and to address Duval's claim concerning developing the ability to change representation register. Inspired by a task called "multiplied representations" (Swan, 2006), I designed an activity consisting of putting together cards representing the same mathematical idea, but using different representation registers (algebraic notation, sentence with words, geometric shape). I consider that this task offers a rich opportunity to discuss and compare, for example, the meaning of $3n^2$ compared to $(3n)^2$. Thereby student teachers need to consider not only the syntactic aspect of algebraic notation (calculation and manipulation of expressions) but also the semantic aspect, which corresponds to the meaning of these expressions (Berg, 2009; Drouhard & Teppo, 2004; Puig & Rojano, 2004). I present the following three corresponding cards as a complete and coherent set in Figure 2:

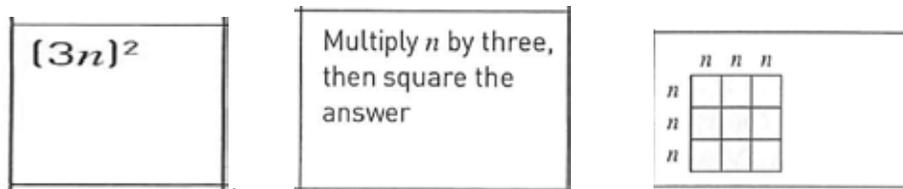

Figure 2: Example of the multiple representations task (Swan, 2006)

In addition I decided to give students some cards which were empty and where they had to draw the corresponding geometrical shape, to find the corresponding algebraic expression, or to formulate an adequate sentence with words in order to have a complete and coherent set of cards. This activity formed a basis from which I could introduce Duval's theory and emphasise results emerging from his research (importance of distinguishing a mathematical concept from its representation and developing the ability to move between several representations). The task was proposed to 52 student teachers and they were sitting in groups of three or four during the activity. I could follow how the task stimulated a lot of discussions as they tried to find corresponding cards and to make sets addressing the same mathematical idea. Right after the activity I distributed a questionnaire where I encouraged the student teachers to reflect on how they experienced this task and if they could see it as useful to introduce in their own teaching. In addition to students' answers to the questionnaire, I present excerpts from an interview conducted at the end of the semester with two student teachers who volunteered to reflect on their engagement with the task. The analysis of this data is presented in the following section.

Conversion between semiotic representations: Student teachers' reflections

Results of the analysis of data show that students' answers to the questionnaire can be grouped in three categories: those who are very positive to the task (38), those who think it was a nice task (12) and some few who find it not interesting (2). In the following I present results from the analysis according to these three categories, and results from the interview with two student teachers.

Analysis of student teachers' answers from the first group

Answers from that group are very positive and the students offer the following explanations

Student 1: I think this task was very funny because we get different perspectives within the same task. Get to look at the algebraic expressions in another way, what we actually did. It is easy to see the difference between $3n^2$ and $(3n)^2$ here. The cards with text help us about how to read these expressions. To draw was a nice exercise. It was not so difficult to find the cards which belong to each other, it was more challenging to draw [the corresponding geometrical shapes]. We could test if we understood what is happening

Student 19: Very exciting. Here we need basic understanding of what a sentence, a formula or a drawing means and represents. We get a larger overview over the connection [between these representations] and also the fact that these are the same even if they look different.

Student 15: I think it was a very interesting task because we really had to think hard to be able to draw the missing cards or to write the corresponding text. It was in fact challenging.

Results of the analysis indicate that the following aspects are in common in many student teachers' answers from the first group. Several of them refer to the task as "very funny", "very exciting" or "very interesting" and it seems that these students recognise the importance of engaging with different representation registers. In addition many students characterise the task as offering a very nice opportunity to explore the meaning of an algebraic expression. They use the expression "developing understanding" and my interpretation is that the task encourages them to inquire into the semantic aspect of algebra (Berg, 2009; Drouhard & Teppo, 2004; Puig & Rojano, 2004) as represented on the cards. Thereby, the focus is now on *the meaning* of the algebraic expression and not only on the computational aspect (syntactic aspect of algebra) of the expression and it seems that this element is new for these students. Furthermore, it seems that most of the student teachers have less difficulty in establishing a link between an algebraic expression and a text than linking these to a geometrical shape. However some students report on experiencing a challenge as they engaged in finding or drawing the corresponding geometrical shape. Analysis of students' answers from the second group brings further evidence concerning the nature of this challenge and its relation to the other representation registers.

Analysis of student teachers' answers from the second group

In this group the students were also positive to the task but it is possible to see in their answers the nature of the challenges they met

- Student 2: I think it was ok to put together the corresponding cards, but when we had to write [the algebraic expression] or to draw [the geometrical shape] it became difficult. A lot of confusion.
- Student 8: Interesting because we had to justify why we think it was correct, and sometimes we saw that it [the drawings] was not correct. It was unusual and difficult to see how the answer should be, especially when we had to draw [a geometrical shape].
- Student 13: I think it was nice to see the connection between a figure, a text and an expression. It helps with understanding and one cannot make mistakes because one can see that the expression/text/figure do not fit together.
- Student 42: I think the task was ok. It was challenging, especially because it is a while since I have been working with this.
- Student 49: It was ok, but the problem is that my knowledge in mathematics is not quite good yet.

In this group it seems that the student teachers still agree about the usefulness of the task in offering an opportunity to see connections between different semiotic representations. At the same time they recognise the challenges they meet while engaging with it and report on “a lot of confusion”, “challenging”. One of them acknowledge the lack of having a robust knowledge in mathematics and my interpretation is that since the task does not address usual questions involving calculations and manipulations of expressions (treatment related to the syntactic aspect of algebra) students get confused and fail in developing understanding of the meaning of the different expressions (semantic aspect of algebra). Thereby they are not able to see that the same mathematical idea is illustrated through the different representations (conversion) and to group the cards in coherent sets. In the following I present a short excerpt of the interview with two students as it offers deeper insights into the reason why students found this task both interesting and difficult.

Analysis of excerpts from the interview

Student B: It was a nice task, but it was difficult.

Student A: Yes, and I realised very clearly what was difficult for me. Because I had difficulties with the geometrical shape, where you could see how big it [the expression] was. That part was a real challenge for me. I think it was difficult. For me algebra is so easy, I can see it at once, but this geometrical shape, it's all Greek to me. Then I could see clearly where my limits are....

Student B: Maybe we are at that level [draw a horizontal line with her hand], the level of formula and we do not manage to get down to the practical level.

Student A: yes, but it was also because I think, well I mean, for me this was unnecessary to have that kind of representation.

According to these two students the difficulties appear when they tried to establish a link between the proposed geometrical shape and the two other representations. It seems that, for these two students, a geometrical shape belongs to another level, “the practical level”, and stands in contrast to a more abstract level “the level of formula”. Furthermore they could not see the necessity of introducing this kind of representation and it provoked difficulties rather than bringing deeper understanding of the meaning of the algebraic expressions (semantic aspect). These insights are important for us, as teacher educators, as we aim at developing student teachers’ awareness of the importance of engaging with different representation registers.

Analysis of student teachers’ answers from the third group

Results of the analysis shows that there are only two students in this group

Student 21: Difficult, don’t remember basic knowledge in mathematics.

Student 44: Quite boring and too difficult.

It seems that these two students agree about the level of difficulty of the task, but unfortunately they do not offer deeper considerations about the nature of these difficulties. My interpretation is that the way the task is formulated is unusual for them and, due to a lack of mathematical content knowledge, they are not able to engage with it. It is also interesting that student 21 explains his answer by referring to the lack of “remembering basic knowledge in mathematics”. Here it seems that mathematical knowledge is understood as a process of memorising.

Discussion and conclusion

My aim with this article is to present how student teachers evaluate their engagement with a mathematical task which aim is to develop awareness of the process of conversion between semiotic representation registers (Duval, 1995, 2006). The analysis of student teachers’ answers both to a questionnaire and during an interview shows that most of the students recognise the task as interesting as well as challenging. More particularly they express difficulties at two levels: firstly in recognising geometrical shapes as useful representations, and secondly in deciding which geometrical shape corresponds to the two other representations. In addition, results seem to indicate that a conversion between an expression with words (a sentence) and an algebraic expression is understood as a process between entities at the same level of abstraction, while a conversion involving a geometrical shape introduces a level of different nature, “the practical level”. I consider these results as important since these bring to the fore a demand for us, as teacher educators, to illustrate and justify the use of several semiotic representation registers and to make explicit the important relation between geometrical shapes and other registers. I argue that in order to develop conceptual understanding of mathematics, it is necessary to offer student teachers rich learning opportunities where the specificity of

mathematics as a subject-matter is brought to the fore and discussed. According to Duval (2006) recognising the importance of using and moving between representation registers constitutes the true challenge of teacher education and I consider that his claim needs to be seriously addressed by teacher educators. The research presented in this article is an attempt to face this challenge.

EXPLORING TEACHER PERCEPTIONS OF THE DEVELOPMENT OF RESILIENCE IN A PROBLEM-SOLVING MATHEMATICS CLASSROOM

Pavneet Braich & Joyce Mgombelo

Faculty of Education, Brock University, Canada

This paper draws from an exploratory study of how mathematics teachers perceive the development of characteristics of resilience in mathematics students, as it is facilitated through a problem-solving teaching approach. Qualitative research approach was used to gain understanding of teachers' perceptions of the development of resilience in a problem solving mathematics classroom. A key objective was to understand strategies which teachers used in their problem solving classroom, as well as their understanding of their role in developing resilience characteristics in students.

Keywords: Problem solving, resilience in mathematics, mathematics teaching

INTRODUCTION

In 2004, The Report of the Expert Panel on Student Success in Ontario, titled Leading Math Success (Ontario Ministry of Education, 2004), stated the following:

Too often, society has accepted the stereotype that mathematics is for the few, not the many. The reality is that mathematics is deeply embedded in the modern workplace and in everyday life. It is time to dispel the myth that mathematics is for some and to demand mathematics success for all. (p. 9)

This statement alludes to a perpetuating dualistic belief about mathematics education which exists in society: you either can or cannot be a successful mathematics student, depending upon an innate ability which allows for less or more mathematical understanding. This false belief reinforces negative self-perceptions for students, hindering or completely ceasing their motivation to understand mathematics. This underlines the need for a shift in the understanding of teaching and learning mathematics, particularly with respect to strategies that encourage students to remain resilient in learning mathematics, regardless of the false belief. Educators are continuously attempting to understand teaching approaches for helping students who are “at risk.” The At Risk Working Group (2004) in part defined ‘students at risk’ as “students who are disengaged, with very poor attendance” (p. 16). These are the students who find no purpose in attending a mathematics classroom, and have probably internalized the notion that mathematics is not a subject which correlates with their skills and abilities. Ross, Hogaboam-Gray, and McDougall (2002) state that “one of the chief elements of mathematics education reform is teachers who make the development of student self-confidence in mathematics as important as achievement” (as cited in Ontario Ministry of Education, 2004, p. 26). Findings from Vatter (1992)

suggest that at-risk students can be more successful if: “(1) school work is hands-on; (2) students’ feelings of worth and accomplishment are nurtured by the work itself; and (3) the work is tied to real work in the real world” (as cited in Ontario Ministry of Education, 2004, p. 38).

According to the National Council of Teachers of Mathematics (2000), “solving problems is not only a goal of learning mathematics but also a major means of doing so” (p. 52). The problem-solving approach could possibly help develop characteristics of resilience, since it is emphasized and promoted. Teachers need to understand and identify strategies which can help in building students’ mathematical understanding, as well as their resilience, so that they improve as mathematicians. This paper draws from a study that was aimed at exploring how mathematics teachers perceive the development of characteristics of resilience in students, as it is facilitated through a problem-solving teaching approach. The study was guided by the following questions: 1) To what extent are teachers aware of the development of characteristics of resilience within students in a problem-solving classroom? 2) How do teachers create conditions for students to succeed, through strategies and approaches, in a mathematics classroom, when solving problems? 3) What are the challenges for teachers, if any, in creating a problem-solving environment? and, 4) What successful factors/qualities have they seen develop in students, through implementing problem solving in classrooms?

THEORETICAL FRAMEWORK

The research was framed by the following ideas: Resilience, Problem Solving, Outcomes of Problem-Solving Approach and Development of Resilience.

Resilience

Although the question of resiliency in students within the mathematics classroom has not been widely researched, it is a topic of current interest in mathematics education. ‘Resilience’ describes “a set of qualities that foster a process of successful adaptation and transformation despite risk and adversity” (Benard, 1995, p. 2). The American Psychological Association (2013) states that resilience means being able to ‘bounce back’ from difficult experiences, and adapt well in the face of significant sources of stress. According to Borman and Overman (2004), characteristics underlying resilient children typically include high self-esteem, high self-efficacy, and autonomy. The development of resilience is seen as a process. Research focusing on adolescent resilience as a process “aims to understand the mechanisms or processes that act to modify the impact of a risk setting, and the developmental process by which young people successfully adapt” (Bond, Burns, Olsson, Sawyer, & Vella-Brodrick, 2003, p. 2).

Henderson and Milstein (1996) found that the capacity for resilience varies from one individual to another, and can grow or decline based upon “protective factors within the person that might prevent or mitigate the negative effects of stressful situations or

conditions” (as cited in Borman & Overman, 2004, p. 178). Findings have been consistent in showing types of protective mechanisms that are important in the process of successful adaptation at three main levels: individual level, family level, and community level (Bond et. al, 2003). Borman and Overman (2004) conducted a study, in which they found that the most powerful model for promoting characteristics of resiliency was the *supportive school environment model*, which stressed fostering healthy social and personal adjustment of students. Three variables were the focus of this model: (a) safe and orderly environment, (b) positive teacher-student relations, and (c) support for parent involvement. It was comprehensively found that the most powerful school models for promoting resilience included “elements that actively shield children from adversity” (p.192). This illustrates the importance of identifying and regulating protective mechanisms, since these have shown associations with academic resilience.

Problem Solving

A focus on problem solving seems to be a key component of sound mathematics teaching and learning. There are various definitions of problem solving; these have been limited for the purpose of the paper. Lovin and Van de Walle (2006) define a *problem* by citing the definition of Hiebert et al. (1997): “any task or activity for which students have no prescribed or memorized rules or methods, nor is there a perception by students that there is a specific correct solution” (p. 11). Another definition used for the purpose of the study is given by Kantowski (1980):

A task is said to be a problem if its solution requires that an individual combines previously known data in a way that is new. If he can immediately recognize measures that are needed to complete the task, it is a routine task (or a standard task or an exercise) for him. (as cited in Pehkonen, 2007, p. 1)

Within the problem-solving process, the lesson begins with the teachers posing a problem question or story, which contextualizes the learning, and then afterwards concepts and procedures are derived and understood by students (Small, 2008). Students should be engaging in tasks posed by the teacher, which allow them to engage in the mathematics that they are expected to learn through interactions, and struggle with the mathematics, by “using their ideas and their strategies” (Lovin & Van de Walle, 2006, p. ix).

Outcomes of Problem-Solving Approach and Development of Resilience

The idea of resilience being important to the study of mathematics is understood and better realized when educators value a holistic view of education, along with the constructivist understanding of problem based learning. Vatter (1992) suggests that at-risk students’ success is attributed to a more hands-on, project-based approach to curriculum involving increased student choice, flexibility, and connections with students’ everyday lives (as cited in Ministry of Education, 2004). By viewing mathematics education from constructivist problem based learning, the study of

resilience can help in supplementing educators, to emphasize the need for students to be successful despite feeling that they are not a ‘good’ mathematics learner.

The Ontario Ministry of Education (2004) also encourages the idea that students need a certain amount of stress-producing conditions in order for learning to occur. Students must regularly be given the opportunity to struggle with mathematics problems. By denying them these experiences, or by providing excessive assistance to shelter them from what is perceived as mental pain, teachers and parents can end up ‘crippling kids with kindness’ (Chatterley & Peck, 1995, p. 39).

Glendis and Strassfeld (n.d.) understand that “students’ mathematical development occurs within the social context of the classroom (Cobb, 1996), in an environment where the emotional experiences of students ‘have the potential to influence teaching and learning processes’ (Schultz & DeCuir, 2002)” (as cited in Glendis & Strassfeld, n.d., p. 4). Thus, it is important to learn strategies to help students regulate their emotions of low self-confidence and low self-esteem. Implementing problem solving in classrooms allows students to experience some stress and exit their comfort zone, thus, they push their existent learning into new situations. Therefore, educators need to explore and learn about strategies used in a problem solving classroom that help students in overcoming their emotions of inferiority towards learning mathematics.

METHODOLOGY

The study used a case study design where qualitative methods for data collection and analysis were used. Participants were selected using purposeful sampling (Creswell, 2008). Two teachers, who are well experienced in implementing the problem-solving approach in their classrooms, were selected. An interview guide with questions was the primary data collection instrument. Interviews were approximately one hour long; they were audio-recorded and transcribed. Teachers were asked open-ended questions. This allowed the teachers to discuss their experiences and share their teaching pedagogy and practice.

To analyze the interviews, an intrinsic case study analysis (Creswell, 2008) was used to separately understand each teacher’s case. This put focus on the uniqueness of a single case, since a key objective of the study was to gain knowledge of specific strategies used by teachers; strategies could be similar or vary in ways, yet, have similar objectives and outcomes for teachers. Afterwards, a cross-cases analysis (Stake, 1995) was conducted to compare results from the two teachers by understanding commonalities and differences in teaching practice, as well as the understanding of developing resilience characteristics in students. These were examined by understanding common themes amongst the cases.

Description of the Cases

Mrs. A is currently teaching third grade. She described her personal journey, which lead her to implement “true, meaningful problem solving” in her classroom, over the

last 5 years. Mrs. A had felt that the way she had been previously teaching was not the best approach, and there “had to be a better way to teach and develop true mathematical understanding in my students.” As a result of feeling the need to learn a more suitable and successful approach for teaching mathematics, she turned to the Math Curriculum document, and was struck by the process skills discussed; specifically the statement that asserted “mathematical problem solving should be the mainstay of all math programs.” She was beginning to understand that problem solving deserved more eminence; while teaching skills and concepts directly is also important, “problem solving should be folded into a teacher’s approach in order to compliment the learning that is taking place.” Mrs. B currently teaches grades 7 and 8. She has taught math as a core subject for 19 years. About 8 years ago she began to explore and teach math through the problem-solving approach. Mrs. B believes that mathematics needs to be taught in the real world context, and not “individually or singularly out of the blue,” so students understand that it applies to the real world. She further states that “the more that you can bring it into their life or something they understand, is better, so that they can more grasp the concepts that you’re doing.”

FINDINGS

For the purpose of this paper, findings from the cross-case analysis of the two cases, named Mrs. A and Mrs. B, will be discussed in the following themes which emerged from analysis: Assessment providing relevance of mathematics curriculum in problem solving; Questioning; Successful instructional strategies in a problem solving environment; and Development of characteristics of resilience in problem solving.

Assessment Providing Relevance of Mathematics Curriculum in Problem Solving

The teachers described a crucial reason for implementing problem solving to be that they felt there was disconnect in the way that the mathematics curriculum was being taught to students, thus, creating a lack of relevance for them. A decisive link to be recognized is that in order to make mathematics learning more relevant for students, and to pose appropriate problem questions, assessment for learning is essential. Teachers must have an understanding of their students’ level of mathematical knowledge in order to begin from a context which students can relate to, and sequence the lesson in a way that all students can make connections. Mrs. B discussed the use of diagnostic assessments as a form of assessment for learning. In order to choose an appropriate question which allows for multiple entry points to solve it, teachers must know their students’ zone of proximal development. Using diagnostic assessments also allows teachers to anticipate the range of solutions which students might present. Mrs. A discussed how formative assessment, as a form of assessment for learning, is also advantageous for teachers. Since problem solving allows for more dialogue and communication, as students are solving the problem, teachers are able to help students in recognizing the relevance of their mathematics learning by questioning them, and

further activating their prior knowledge and ability to make connections. Teachers are able to make more balanced, written and oral assessments of their own students as well.

Questioning

Questioning is a key strategy in facilitating the development of resilient characteristics in students, as teachers motivate students to remain persistent in solving problems. Asking students to explain their thinking, or why they chose the strategy were examples of the types of questions which could be asked. Mrs. B sometimes answers students' questions with a question, knowing that the students will be frustrated for some time, but she also assures them to keep struggling. This can be reassuring for students since they feel that the teacher understands that the students have the ability to meet the challenges presented to them. Findings by Gaye Williams (2007), an Australian researcher, also suggested that in some cases, giving students time to struggle and stress, and refraining from telling them how to solve problems will build more resilient children. Educators need to foster the characteristic of adolescents to meet challenges. Mrs. A asks open-ended questions such as: Why did you choose that strategy?; How does drawing the groups help you with your thinking?

These types of questions further the thinking of the students, and sometimes they realize that their strategy may not be on the right track, or the most efficient. While doing so, it is important for Mrs. A to ensure that students understand that there is no "right" way to solve a problem, since everyone has a different level of understanding, and some may prefer a methodical approach, whereas another may have a more creative approach to solving a problem. She reiterates that "no child is told they are not doing it right." Mrs. A gives the example of a student who came in her classroom almost afraid of math, because she had weak memory skills. She slowly began to understand that the teacher was not looking for the "right" way to solve problems. Math began to make sense to her, and something as simple as decomposing numbers into parts that were easier to manage, and then putting them back together made working with larger numbers so much easier for her (e.g. $63 + 15 + 21$ became $60 + 10 + 20 = 90$ and then $3 + 5 + 1 = 9$ and then $90 + 9 = 99$). This opened up her mathematical thinking and allowed her to think differently about math. She began to volunteer lots of answers and show guests her most recent strategies, and how she solved certain problems.

Successful Instructional Strategies in a Problem-Solving Environment

During the time when students are struggling, strategies that teachers use to facilitate a problem solving classroom can be useful. These include group work and *gallery walks*, where students go around and observe solutions of peers with sticky notes; they put any questions on one colour of sticky notes, and comments on another colour. Mrs. A has also discussed how she challenges her stronger students to try different problems or work with more difficult numbers. The *congress*, or extended discussion that occurs

once all students have had time to work on the problem, is also a successful strategy in the problem-solving approach used by Mrs. A and Mrs. B. Students gain comfort and confidence in their learning as they explain their solutions to the class, and are able to justify and defend their understanding to their peers by being questioned or asked to reaffirm their thinking. As this occurs, simultaneously the rest of the class is able to learn from their peers and value the diversity in thinking within their class. In relation, Mrs. A also discussed how students who are weaker in their mathematical understanding may not participate in the mathematical conversations, but they will still be exposed to ideas and skills. Gradually, all students can gain confidence in themselves as they realize that others are thinking along the same terrain; those who have approached the problem in either a very distinct or less efficient, sophisticated way are valued members of the class.

There are various ways to differentiate learning for students, so that they feel safe to struggle and take risks. Mrs. A states that children often deal with their math frustrations by shutting down, asking for help at every step, or simply putting anything down. Her method is to ensure that a safe math environment has been set up, as mentioned previously, and there is lots of teacher modelling, especially when it is time to share each others' mathematical thinking during a math congress. Encouraging the use of manipulatives is also useful, in order to create models of the problems in order to make sense of the problems. Using parallel tasks is also helpful. This is where the same question is posed but different sets of numbers are used, so that students can still maintain similar discussions later. Mrs. A and Mrs. B have both witnessed positive development of qualities in students, and become aware of how the problem-solving approach creates a sense of community in the classroom. This, in turn, helps students become more confident in their learning, as they feel a sense of belonging. Mrs. A gave the example of a comment she had heard: "I want to try the strategy that _____ used next time I do a problem." This type of comment can be powerful for students, since they feel as if they are a contributing member of their class. Mrs. B also spoke to this point by discussing one of the positive outcomes of the learning community: students are able to learn from peers that they might not normally interact with. Within the relationship dynamics of a classroom, this is influential for students who may feel that they are not noticed or may have low self-esteem as a learner. Tools, such as the *bansho*, have also shown to be a source of pride for the entire class as well. The Japanese term *bansho* means board writing (Kubota-Zarivnij & Kestell, 2010), and is used in a very systematic manner, in order to keep record of all parts of the problem solving lesson and show various approaches used by students to solve a problem.

Students learn to use their peers as a source of help, if they feel that they are failing individually; this is acceptable and advocated in a safe classroom. Students are able to use the strategy of *tailgating* or doing a *spywalk*, where they are allowed to move around the room, looking at or questioning how others are solving the problem. It is not about children taking their paper around to classmates and copying their work, but

rather a way to stimulate the thinking of those who are not sure where to begin or are more resistant to get started. This can help students become more resilient since they learn to ask peers for help in their learning, and not feel isolated. Also, they are able to clear misconceptions that they may have, through extended mathematical talk with others, and being able to fuse the ideas or suggestions of others with their own. This relates to Margaret Glendis and Strassfelds' (n.d.) findings from their action based research, in which it was observed that students had begun to rely on one another when they worked through their 'crucial points,' and felt a sense of pride in their work as a group. Another finding, stated by Mrs. A, was that the problem-solving approach strengthened friendships between students, as the feeling of inclusiveness developed in the classroom. These relationships extend beyond the subject, and into other curriculum areas.

Development of Characteristics of Resilience in Problem Solving

Mrs. A and Mrs. B discussed the importance of allowing students to solve problems in their own ways, and build self-confidence in them. This also concurs with Small (2008), who believes that allowing students to approach problems in their own way builds confidence and maximizes the potential for further understanding. When students are able to succeed in solving problems through their chosen approach, then they feel ownership of their learning. If they struggle during the process of finding a solution, teachers are able to help accordingly. Strategies, such as spy walks, tail gaiting, gallery walks, group work, extended discussion or congress, and guided questioning all help in acting as protective mechanisms against failure. Allowing students to struggle, and helping them understand that it is a natural part of the problem-solving process is important.

Another significant type of protective mechanism which Mrs. A and Mrs. B advocated, was the development of a safe community in the classroom. This is done through the various strategies mentioned above. Using peers as resources around the classroom, and discussing with them to clear misconceptions; these are qualities of resilient mathematics learners. Mrs. A and Mrs. B have identified that these are achieved through extended discussion, and time given to discuss with peers. Creating a supportive atmosphere is the key to creating a safe classroom in which students can progress and become resilient in overcoming the struggles which they face.

Being a resilient mathematician describes a learner who has "a set of qualities that foster a process of successful adaptation and transformation despite risk and adversity" (Benard, 1995, p. 2) that they may face in the process of working on problem solving in a mathematics classroom. The perceptions of Mrs. A and Mrs. B, in discussing their awareness of the development of resilience, shows students want to be successful mathematics learners. Although some students may come into the classroom believing that they are not good at math, or they dislike math, Mrs. A and Mrs. B have observed positive outcomes in teaching through the problem-solving approach. It can be

assumed that all humans want to feel successful and good about themselves, therefore, naturally, they would be open to developing characteristics of resilience. This coincides with the understanding of Benard (1995), as it is explained that “we are all born with an innate capacity for resilience, by which we are able to develop social competence, problem-solving skills, a critical consciousness, autonomy, and a sense of purpose” (p. 2).

The cases of Mrs. A and Mrs. B have shown that students are able to succeed and become resilient mathematics learners. This is enabled through structured strategies for problem solving which are used to create an environment in which students can develop characteristics of resilience. This is very important in the teaching of mathematics, since the subject has been stereotypically known to only be understood by some students, not all.

CONCLUSION

Findings of this study highlight the importance of the problem-solving approach in teaching mathematics, and the development of resilient characteristics in students. This study extends the conceptualization of resilience within mathematics education, claiming that the definition is based upon the context and types of risks which are under study. For the purpose of this study, the risk was students failing in understanding mathematics, and believing that they are not good at mathematics. The conceptualization of resilience remains open to interpretation, since there is no unified theory or definition. Findings are useful for educators who are interested in supporting students to gain specific characteristics of a resilient mathematics learner, which include: (a) developing self-confidence, (b) regulating emotions of mathematical anxiety and struggling to succeed, (c) remaining persistent by struggling in solving problems, (d) using resources around the classroom, (e) and clearing misconceptions and incorrect solutions. The findings from the case studies show that the strategies that teachers use when teaching problem solving promote the above characteristics for students.

SPECIALIZED AND HORIZON CONTENT KNOWLEDGE – DISCUSSING PROSPECTIVE TEACHERS KNOWLEDGE ON POLYGONS

Emma Carreño; C. Miguel Ribeiro; Nuria Climent

University of Piura, Peru; Research Centre for Spatial and Organizational Dynamics,
University of Algarve, Portugal; University of Huelva, Spain

The specialized and horizon content knowledge (SCK and HCK), two of the MKT (Mathematical Knowledge for Teaching) sub-domains, are the focus of this paper. We focus our attention on these two sub-domains of teachers' knowledge due to the delimitations problems concerning the content of SCK and the need to discuss the nature of HCK with greater precision. We approach this problem from a case study focusing on the knowledge of the concept of polygon that has a prospective high school math teacher. Such knowledge is discussed from descriptors referred to SCK.

Keywords: Mathematical knowledge for teaching (MKT), specialized content knowledge, horizon content knowledge, polygons, prospective secondary teachers.

INTRODUCTION

The teaching-learning process is influenced by a large set of factors (e.g., beliefs, goals, class/school size). One of the most influential factors concerns teachers' knowledge (e.g., Nye, Konstantopoulos & Hedges, 2004). Such knowledge influences, inter alia, focus, the pursued goals, and, consequently, what and how students are intended to learn, as well as the view of mathematics they are intended to experience and acquire. Thus, it is of fundamental importance to call attention to teachers' knowledge at all moments, being one of the more crucial initial teachers training (Llinares & Krainer, 2006).

Although there is almost unanimous acceptance of the influence of teachers' knowledge on students' learning, what is comprised in such knowledge, its type, content and specificities (or not) can be understood differently under different perspectives (e.g. Ball, Thames & Phelps, 2008; Rowland, Huckstep & Thwaites, 2005).

From amongst the most recent and influential conceptualizations on teachers' knowledge in the course of our recent work, we opted for the Mathematical Knowledge for Teaching (MKT) model (Ball et al., 2008). This option was made taking in consideration the very specific orientation to the teacher's mathematical knowledge of MKT, placing emphasis on the mathematical reasoning involved in the work of teaching. Such a choice was also connected to our perception of the sub-domains of the MKT as a relevant starting point for designing tasks for the

mathematical preparation of teachers, and for doing research on what inputs to teachers training show effects on students and practices. Intending to contribute to an advance on the understanding of the MKT and on the content of its sub-domains, we began research focusing on discussion of the content of some of the sub-domains. That broader research includes work focusing on teachers practices from kindergarten till Higher Education and is leading us to question some particular aspects of the MKT conceptualization concerning the similarities and differences in the content of some of the sub-domains (Carrillo, Climent, Contreras & Muñoz-Catalán, 2012). In this paper we discuss the limits of SCK and HCK nature from mathematical knowledge, concerning polygons, revealed by Marta, a prospective high school math teacher. Such a discussion also aims to call attention to the need of a deeper specification of the content of these sub-domains.

SPECIALIZED CONTENT KNOWLEDGE (SCK) AND HORIZON CONTENT KNOWLEDGE (HCK)

One of the core aspects that the MKT brings to light concerns the specificities of teacher's knowledge for teaching, when compared with the knowledge involved in other professions in which the same topic (mathematics) is, also, used.

Having the genesis on Shulman's (1986) work, the MKT conceptualization considers the two domains of teachers' subject matter knowledge (SMK) and pedagogical content knowledge both divided in three sub-domains (see Ball et al., 2008). Our focus here concerns only the sub-domains included in SMK. The MKT conceptualization considers that Common Content Knowledge (CCK), the knowledge that allows one to know how to do mathematics for oneself, although necessary, is neither sufficient nor specific for the teaching of math. Thus, included in the content domain is a specialized Mathematical Knowledge for Teaching (SCK), which differs from the knowledge needed in settings other than teaching and also another kind of knowledge, related with how things can be perceived interconnected along schooling (HCK) – but not related with the content being approached at the moment.

The SCK is perceived as *the mathematical knowledge and skills unique to teaching* and thus, it only makes sense to be part of teachers' knowledge and not necessarily part of the knowledge needed outside teaching. Such knowledge implies *the use of decompressed mathematical knowledge* (Ball et al., 2008), in such a way that teachers are in a position that allows them to understand and explain (with and for understanding), amongst others things, the mathematical reasons embedded in students' errors or alternative reasoning; generate or reformulate examples that reveals key mathematical ideas; or identify the critical characteristics of a given definition or when proposing one. SCK is, in this sense, seen as the knowledge required by the teacher who genuinely wishes their students to understand what they do, and not merely mechanically run through a set of given procedures – this is not limited to procedures but has a broader meaning that includes the necessary concepts and how they interrelate and influence each other (Ribeiro & Carrillo, 2011).

On the other hand, HCK can be understood as an awareness of how the current mathematical topic fits into the overall scheme of the students' mathematical education, how the various topics relate to the others, and the way in which the learning of a particular topic may relate with others as one moves up the school. (We have to remark that HCK does not concern the knowledge immediately related with the content being approached at the moment -Jakobsen, Thames and Ribeiro, 2012). It is thus a kind of knowledge that is neither common nor specialized and that is not about curriculum progression. It is knowledge about having a sense of the larger mathematical environment of the discipline (Ball & Bass, 2009), allowing one to perceive different types of connections between and amongst different topics or even in the space of one topic at different school levels or in one level (e.g., Fernández, Figueiras, Deulofeu & Martínez, 2011). Such knowledge (even in these complementary perspectives) can enable teachers to make judgments on what is mathematically important and worthwhile to pursue – not being part of the curriculum they are supposed to teach – at a particular moment/school level. Such knowledge can also be perceived as an advanced mathematical knowledge from an elementary mathematical stand point (Montes, Aguilar, Carrillo & Muñoz-Catalán, 2012), meaning that advanced mathematics for teachers need to be demonstratively related to the teaching that takes place in school.

In our research group, and what concerns specifically the work focusing specifically on teachers' knowledge, we went across several stages: firstly, we aimed to identify, from observed classroom practice, the knowledge teachers show evidence of deploying at every specific moment (e.g., Ribeiro & Carrillo, 2011); the knowledge prospective teachers evidenced when answering a questionnaire/solving a task on fractions or polygons (e.g., Ribeiro & Jakobsen, 2012; Carreño & Climent, 2010) or even when interpreting and giving sense to students nonstandard productions (e.g., Jakobsen & Ribeiro, 2013). Such an approach leads us to a complementary focus of attention, in which we discuss and reflect upon the content of the MKT sub-domains and the conceptualization itself (e.g., Carrillo et al., 2012; Montes et al., 2012).

Although there is a certain consensus that there are no well-defined borders around MKT domains, such undefined borders make it difficult to differentiate what is included in each one of the domains (e.g., when analyzing a classroom practice, a questionnaire or an interview).

Specifically, if we are looking at what could be considered for inclusion in the SCK, we face some problems in achieving such a unique identification because it might be impossible to say, for certain, if some aspect of knowledge is specifically related with SCK or could be included in the CCK or even, according to with some perspectives (as connections), included in the HCK. These difficulties may be related to the fact that all these sub-domains have a straight relationship with the SCK (it influences how teachers perceive all the teaching-learning process and, thus, all the others domains) and thus with the specificities of teachers' knowledge when compared with other professionals who use mathematics as a tool. Such difficulties are perceived as

one of the limitations of MKT and, if the aim is to call attention to the specificities of teachers' knowledge, it should be possible (at all times) to distinguish the nature (and content) of all its sub-domains.

These limitations of the MKT lead to a possible (re)conceptualization of teachers' knowledge (e.g., Carrillo et al., 2012), having as a starting point the problematic of the specificities of teachers' knowledge and if such specificities are better perceived as integrated in the previously mentioned sub-domains and not only in one (or some) of them. In such a process of deepening and clarifying the nature and content of the mathematical knowledge of the mathematics teachers, we felt the need to characterize each one of the involved MKT sub-domains, which lead to an enlargement and more refined delimitation of each of the components of teachers' knowledge. A discussion of its similarities and differences is central in this process.

METHOD AND FINDINGS

In this paper we use Marta's case as a means to address the problems of delimitation of SCK and the link with HCK, and at the same time, question the nature of these two sub domains. Thus, the specialized knowledge revealed by Marta when solving a questionnaire on the concept of polygon as an object of teaching and learning, is what allows us to discuss the focus of this paper.

Marta is one of the 7 prospective high school math teachers (PMT) who are part of a larger study aimed at characterizing the specialized knowledge that PMT reveal on the subject of "polygons". She is 22 and answered the questionnaire when she was a student in the course named Practical Teaching 1 when she started the last year of Initial Training. This group of students is the class group of the matter referred to an academic year at a private university in Peru. The academic mathematics courses results were generally low, but Marta's attitude towards reflection and debate on their own knowledge, was one of the reasons to consider her part of the study. In addition, Marta was the one with more closeness to the teaching-learning situations (from peers) because she had some teaching experience, which claimed she had some contact with students and their reasoning and arguments and thus, one could think that her mathematical content knowledge was linked to SCK and HCK and not simply to CCK.

We decided to address the concept of polygon because it is a subject that is studied from elementary through high school and it becomes conflicted when it comes to using it in differentiation of figures that are or are not polygons, or in the study of polyhedra. The analysis of the questionnaire was made from desirable descriptors of mathematical knowledge for teaching of the subject of polygons. Some of these descriptors were elaborated from the literature review (research on the knowledge of students and teachers and difficulties with the subject – e.g., Tall and Vinner, 1981; Fischbein, 1993, Fujita and Jones, 2007; Battista, 2007) and others emerged during the analysis process.

Here we propose a discussion and reflection on the nature and content of the SCK

and HCK, in conceptualizing MKT, from three SCK descriptors used in the case of Marta. That reveals some difficulties in determining the boundaries of SCK, regarding HCK. We have chosen, in turn, a questionnaire item for illustrating such descriptors.

In the analysis of each answer, we need to identify the subdomain that addressed each question, respectively. One of the possible ways to overcome difficulties in determining the borders of the SCK, in concrete related with HCK, was to equate and question ourselves (and, explicitly, other experts) as to whether a certain specific aspect of knowledge on polygons would, or would not, be shared with other professions – such as mathematicians. Although we are not absolutely certain of the limit of the mathematical knowledge of a mathematician on this topic, it was assumed that a mathematician could know a definition of a polygon without linking it to the basic necessary concepts (sub-concepts) that are fundamental in order to be able to elaborate the notion of such a geometric being with and for understanding. We considered that such knowledge related to linking the sub-concepts to elaborate a geometric notion is necessary and somehow exclusive for developing the tasks of teaching (e.g., choosing and developing useable definitions; selecting representations for particular purposes). One other option had to do with the fact of considering (after some discussions with persons with some mathematical training) that in any other profession would be necessary (involved) to note the critical characteristics of a polygon, being that such knowledge is essential for teaching mathematics while elaborating/exploring a definition of polygon. Such centrality has to do with, amongst other things, the fact that these critical features correspond to the ones students' are supposed to note while differentiating polygons from non-polygons.

From the previous ideas, assuming the sub-concepts and critical characteristics as core elements in a definition of a geometrical concept, we have elaborated some indicators aimed at describing prospective secondary teachers' SCK. We have selected three of them to discuss here (our choice is due to the fact that these are the ones more present in the prospective teachers' answers and, on the other side, because they allow for illustration of the difficulties in defining SCK borders, the focus of our paper).

SCK1: Know to identify the concepts and sub-concepts involved in a geometrical concept.

Understanding a sub-concept as a specific concept that allows the elaboration of a more general concept, it is assumed that a teacher must have knowledge that allows for its identification. Such identification allows for the elaboration of a deeper sense and understanding of the concept itself, with an ampler sense and not associated to prototypes, and thus also allowing for detection of students' conceptual errors and misconceptions, being useful while elaborating a verbal definition of a geometrical object. While discussing some aspects related with the sub-concepts, Blanco & Contreras (2002, p. 112) mentioned that, in order to represent (draw) the orthocenter

of an obtuse triangle it is necessary to know the concept of orthocenter and high of a triangle; but in order to be able to represent this last concept of high of the triangle, it is essential to have an understanding of the sub-concepts of perpendicularity from a point, of a line perpendicular to each other and of vertex opposite to a side of a triangle. Such knowledge is essentially mathematical knowledge but specific to the task of teaching, which justifies its inclusion in SCK. On the other hand, identifying the sub-concepts involved in a certain geometrical concept implies the knowledge of a net of relationships between concepts (which is also perceived as HCK in Fernández et al., 2011) and differentiating them between more or less fundamental (basic) concepts (in the sense of Ma, 1999) and others in which such sub-concepts form a part. This idea of mathematical structure is one of the reasons that makes us doubt if such knowledge, which was initially, in an obvious way, included in SCK, should be included in the HCK – as defined also by Ball and colleagues.

In one of the questions, several different (pseudo)definitions of polygon were given and the prospective teacher had to comment on them and discuss the sub-concepts involved. (There was a clarification in the question of what meant a sub-concept – necessary concepts know in order to be able to understand the concept of polygon.)

Three such (pseudo)definitions were: (i) *it is a geometrical shape with sides and different angles. They can be concave, convex, regular and irregular;* (ii) *a polygon is a geometrical figure with equal sides and angles;* (iii) *it is the interior of a geometrical closed figure made by the lines that join three or more dots and the dots should not cross.*

When analyzing the given definitions, Marta points as sub-concepts only those that are involved explicitly in a given definition. When commenting on the first two (pseudo)definitions she considers as sub-concepts: geometrical figure; geometrical shape; angle; classification of angles; measurement of a line (as an element of a polygon). But in the third she introduces a nuance considering “interior region” as a sub-concept associated to a critical characteristic to differentiate between what is and is not a polygon (such an idea is reinforced when she proposes a four-sided polygon, with the sides crossed, as a way of identifying the error in pseudo definition, as it would define two regions (iii)).

SCK2: *Know to identify the critical features (characteristics) of a definition or given notion of a geometrical object.*

Perceiving as critical features (characteristics) the ones that are necessary and sufficient to define a concept, we assume this corresponds to the knowledge the teachers must possess to distinguish the general characteristics from the specific or accessory ones. As an example, from Marta’s answers in the first given (pseudo)definition (mentioned previously in (i)), when discussing the misunderstood features (they can be concave, convex regular and irregular) she mentions that, “*here the student is confusing classification by its angles and by its sides with the definition*”. In such, she reveals that in the definition of polygon there is no need

explicitly to classify and she thus describes such a characteristic as accessory rather than critical. Putting together this evidenced knowledge and the previously mentioned in SCK1 concerning Marta's knowledge (a polygon is closed and has only one interior region), it lead us to wonder if knowing these defining characteristics of the concept of polygon can be considered as common content knowledge, not being exclusive from the teachers' knowledge space.

SCK3: Know to identify the critical characteristics when proposing a definition of a geometrical object.

The elaboration of a geometric definition is influenced by the choice of the fundamental concepts to focus on and the critical characteristics that allow differentiating two different objects. In Marta's case, when asked to give her own definition, she includes as sub-concepts and critical characteristics some of the ones she discussed previously in the students' (pseudo)definition. For Marta, a polygon is:

“a geometrical flat closed figure with a polygonal region and its border is the union of three or more non-collinear dots”.

Although Marta considers a set of critical characteristics that may give us an idea that she has a specific knowledge that can be associated with the SCK on what a polygon is (flat and closed figure; interior of a polygonal line; with the minimum of three points), she mainly reveals herself to have knowledge related with the structure of a mathematical definition. Such a nuance is essential when analyzing teachers' SCK and it can be better discussed by analyzing Marta's examples, and non-examples of polygons in light of her given definition¹. When asked to represent polygons and non-polygons, in light of the definitions she presents, we could expect her to draw convex and concave or even complex polygons (with sides crossed) or simply closed flat forms as a circumference, but she draws the following representations:

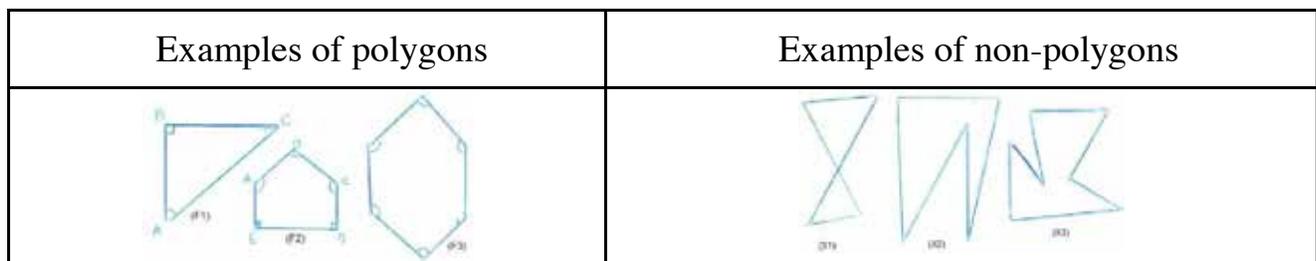

Figure 1: Examples and non-examples of polygons drawn by Marta

Putting the puzzle together (both the critical characteristics she presents and the representations she draws), it can be seen that the concept image she has contributes more information to her definition of polygons. Such an image leaves aside the critical characteristics of a polygon (in her own notion/knowledge of it), which lead

¹ These examples, and non-examples also, are obviously related to the example space she possesses and we, as teacher trainers, are supposed to allow teachers and prospective teachers to develop.

to a deficient/imprecise and incoherent definition with the mental image she has of the geometrical object.² Such discussion lead us, again, to equate if, when elaborating a definition, the critical characteristics are not more closely related with knowing what a mathematical definition is than with an SCK.

CONCLUSIONS AND FUTURE WORK

We have used a prospective secondary teacher's answers to one questionnaire for giving examples about some questions on the nature and content of teachers' SCK and HCK. Some of these questions concern the prospective teachers' knowledge on the role of the sub-concepts in the definition (and thus, what a definition is and the different possible approaches in defining a certain geometrical object). Examples of such questions: Is the identification of the sub-concepts and the acknowledgement of the critical characteristics associated to polygons part of SCK or is it part of CCK (in the sense that any person with some mathematical training is supposed to have a knowledge on these sub-concepts and its role in the definition)? Is the identification of the sub-concepts an SCK or a specific knowledge related with connections and thus in the space of HCK (in the sense of the HCK conceptualization presented by Fernández et al., 2011)? Is the fact of considering the critical characteristics when proposing a definition (of a polygon) related to the nature of mathematics itself?

The previous questions are part of the examples that lead us to discuss and reflect on the limitations (and difficulties) in differentiating some aspects of the MKT sub-domains in terms of its content and nature and in particular on which aspects of the mathematical knowledge are specific for teachers to teach mathematics with and for understanding. Aligned with this problem, our research group has started working specifically on the space of the knowledge a teacher has/must have in order to perform their work of teaching, leaving aside a discussion on whether such knowledge is shared with other professions or not. Carrillo et al. (2012) present a theoretical discussion of such an approach and its impact on the conceptualization of teachers' knowledge. Further research is needed in order to clarify the content of each of the domains. Such identification and discussion would allow for the creation of a body of knowledge allowing a deeper and more fruitful focus of attention on the more problematic and promising aspects of teachers' training. It would allow us to focus our attention where it is most needed, as well as reinforce the need for a specialized knowledge for the teaching of mathematics.

MATHEMATICS TEACHER'S SPECIALIZED KNOWLEDGE. REFLECTIONS BASED ON SPECIFIC DESCRIPTORS OF KNOWLEDGE

Emma Carreño; Nielka Rojas; Miguel Montes; Pablo Flores¹

We present some reflections on mathematical knowledge for teaching arising from the descriptors proposed by Sosa (2010) and linked to the model of mathematics teachers' knowledge constructed by Ball, Thames and Phelps (2008). The former leads us to reflect on the model and to adopt the proposal of Mathematics Teacher's Specialized Knowledge so as to make progress in describing the mathematical knowledge brought into play when teaching. This suggests the need to scrutinise the model carefully and to refine its characterisation. To do so, we embark on a search for evidence which allows the incorporation, integration and interconnection of aspects of knowledge apparently unrelated in the model of Mathematical Knowledge for Teaching (MKT).

Key words: Mathematical knowledge for teaching, mathematics teachers' specialised knowledge.

INTRODUCTION

In this paper we discuss the theory underlying the different domains which comprise the construct of mathematical knowledge for teaching developed by Ball, Hill, and Bass (2005) and Ball, Thames, and Phelps (2008), a model widely used in Mathematics Teaching research for the purposes of teacher training. The model devised by these authors allows teachers' knowledge to be studied from observations of classroom practice in primary education. Building on the work of Shulman (1986), it focuses on mathematical content through the categories of content knowledge and pedagogical content knowledge.

¹ This article represents part of the studies into teachers' knowledge by the SIDM group (from the Spanish 'Research Seminar into Mathematics Education') based at the University of Huelva, Spain. It comprises the following researchers: José Carrillo (coordinator), Nuria Climent, M. Cinta Muñoz-Catalán, Luis C. Contreras, Miguel A. Montes, Álvaro Aguilar, Dinazar I. Escudero, Eric Flores and Enrique Carmona (University of Huelva), Pablo Flores, Nielka Rojas and Elisabeth Ramos (University of Granada, Spain), C. Miguel Ribeiro, Rute Monteiro and C. Susana dos Santos (University of the Algarve, Portugal), Leticia Sosa and José L. Huitrado (University of Zacatecas, Mexico), and Emma Carreño (University of Piura, Peru).

We discuss the model of MKT in terms of the general descriptors of mathematical knowledge defined by the research group headed by José Carrillo at the University of Huelva, Spain. Amongst the results of this line of research are the studies by Sosa and Carrillo (2010) and Sosa (2010), which report on an interpretative study into the MKT displayed by two teachers working on the topic of matrices at Spanish baccalaureate level. For more specificity of mathematical knowledge for teaching, Sosa identifies and builds indicators or descriptors of knowledge or specific skills of the teacher while teaching (p.54). In order to specify more precisely mathematical knowledge for teaching, Sosa identifies and draws up a set of descriptors and indicators of the specific knowledge and skills deployed by teachers in their work (p.54). These studies suggest that further work on the features demarking the subdomains of mathematical knowledge would be beneficial. Sosa's study, dealing with general aspects of mathematical knowledge, is a good starting point.

This paper aims to discuss the knowledge domains described by Sosa (2010) and to scrutinise the model in order to develop its characterisation. The need to illustrate a new system of organising teachers' mathematical knowledge, drawing on MKT and being made operative by means of practice-based descriptors, leads to a new organisation which lays emphasis on the specific features of this knowledge in relation to teaching.

Below we discuss aspects of MKT in terms of Sosa's indicators, and consider how the new perspective might deal with certain problems arising, with the aim of refining the model so as to better understand the knowledge teachers display as they go about the work of teaching.

THE RELATION BETWEEN MKT AND KNOWLEDGE DESCRIPTORS

Mathematical knowledge for teaching is understood by Ball and her collaborators as the specific knowledge required for teaching mathematics. This model builds on the work of Shulman and collaborators several decades previously. Furthermore, as an emergent contribution of the qualitative analysis of the classroom practice of various practising and trainee teachers in the United States, it confirms the specialisation of the knowledge required for teaching mathematics, distinguishes components of this knowledge (in terms of domains, subdomains and descriptors), and includes the subdomain of specialised content knowledge, which is fundamental to the work of teaching.

With this in mind, the group based at the University of Huelva aims to explore the MKT model so as to better understand and identify its components. Hence, in 2010, the group compiled a list of 100 general descriptors (Sosa, 2010) for mathematical knowledge which enable elements to be differentiated and features of the observed knowledge to be established in the practice of teaching. These descriptors correlate with the components defined by Ball et al. (2008), and are carefully phrased to capture each particular characteristic pertaining to the various knowledge domains, such that items representing evidence of aspects of knowledge in the MKT model can be built up, integrated and inter-related. Below, we describe how the MKT knowledge subdomains relate to some of the descriptors proposed by Sosa (2011) and discuss several issues arising.

The subdomain *Common Content Knowledge* (CCK) is based on the notion of encapsulating the mathematics that anybody making use of the subject might know, such as might be the case in using definitions, rules, properties and theorems associated with a specific topic (*CCK1*), using mathematical notation, and understanding the importance of an item (*CCK2* and *CCK3*), and knowing how to apply mathematics and do demonstrations (*CCK4* and *CCK5*). Complementing the foregoing, we would add that is a kind of knowledge that teachers need, and although other professions might draw on it, too, it forms an integral part of what makes mathematics teachers specialists.

The subdomain *Specialised Content Knowledge* (SCK) refers to a deeper and more thoroughgoing knowledge of mathematical content, and includes understanding the significance of concepts (*SCK1*), knowing the unseen steps behind procedures (*SCK2*), intuiting the root of pupils' mathematical errors (*SCK4*).

The descriptors corresponding to *Horizon Content Knowledge* (HCK) refer to associations between concepts, relationships between general and specific content (*HM1* and *HM2*), and awareness of interdisciplinary applications (*HM3*). In the case of descriptors referring to understanding how one item relates to another that comes before or after it in the curriculum, the knowledge that is brought into play concerns curricular issues and the sequencing of the subject, as the teacher has to know the contents both previous and subsequent to any particular item being taught.

Pedagogical Content Knowledge (PCK) combines knowledge of teaching with knowledge of mathematics (Ball et al., 2008, p. 401). This subdomain concerns aspects such as those embodied in descriptors *PCK30* and *PCK31*,

respectively: “*Knowing how to introduce a new concept by relating it to concepts studied previously,*” and “*Knowing different ways of introducing a mathematical topic through some information or brief historical background about it; or knowing how to contextualise a topic through a brief anecdote or historical background.*” These descriptors illustrate that PCK is a subdomain which implies learning mathematics with meaning. Indeed, sometimes descriptors tend to be associated with features of learning mathematics such as “Knowing which exercises to leave the pupils for homework.”

With respect to *Knowledge of Content and Students* (KCS), there are two sets of descriptors, those referring to general pedagogical knowledge, and those referring to knowledge about the students’ interaction with mathematics. The first of these sets represents knowledge that mathematics teachers probably need, and hence the descriptor (KCS2), “*Understanding the needs and difficulties of students with mathematics.*” The second group is based on understanding how pupils assimilate and apply material, as can be seen in the descriptor (KCS3), “*Anticipate the misunderstandings that might arise with specific items being studied in class.*” The descriptors in this subdomain enable us to distinguish when knowledge involving aspects of learning mathematics is being deployed, which is an appropriate starting point for describing this subdomain.

Finally, regarding *Knowledge of the Curriculum* (KC), Sosa (2010) sets out three descriptors describing the organisation of content in textbooks (KC1), the prior and subsequent treatment of an item (KC2), and content deriving from teachers’ institutional environment (KC1). These descriptors also teachers’ critical responses to the established objectives and standards to be noted.

TOWARDS THE SPECIFICATION OF MATHEMATICS TEACHERS’ KNOWLEDGE

Taking into consideration the conditions for distinguishing the subdomains of MKT and attempting to find those defining features which specify mathematics teachers’ mathematical knowledge, we find it necessary to place mathematics at the hub and focus attention on the knowledge that is significant only to mathematics teachers. This position has given rise to the MTSK model advocated by Carrillo, Climent, Contreras, and Muñoz-Catalán (2013), in which specialisation receives an alternative focus centred on mathematics teachers’ specialised knowledge (MTSK), which abandons the

notion of mathematical knowledge for teaching to centre on knowledge of significance only to mathematics teachers.

In the following section we summarise several key aspects of devising descriptors for the six subdomains of the MTSK model. We begin with the three subdomains concerned with mathematical knowledge (MK), which all concern the way teachers' understand mathematics.

Knowledge of Topics (KoT). The fundamental concern of this subdomain is the idea of “knowing” a topic, and this would need to be reflected in the corresponding descriptors. However, it is important to consider everything this knowledge implies, from rules, procedures and calculation methods associated with the concept to the different meanings of a topic in itself (e.g., the derivative as the gradient of a curve or as the limit of finite increments). Equally important is to consider the different phenomena associated with mathematical concepts (Rico, 1997). These are some of the considerations that the group which developed the MTSK model took into account when drawing up the description of KoT. Nevertheless, a thoroughgoing review of the various considerations involved in this subdomain is still necessary. For this subdomain, for the topic of matrices considered in Sosa (2010), we could write a descriptor such as the following, *Knowing why the elements of a specific matrix in a problem are laid out in a particular way.*

Knowledge of the Structure of Mathematics (KSM). In the MKT model, the characterisation of mathematical horizon knowledge tends to make us think of connections as the defining element of this subdomain (drawing on Fernández (2011) and Martínez, Giné, Fernández, Figueiras, and Deulofeu (2011)). However, knowledge of structure represents understanding the connections with elements that are prior and subsequent to the item being studied (Montes, Aguilar, Carrillo, & Muñoz-Catalán, 2013). It is worth noting that such shifts forward and backwards in time are not so much curricular as mathematical. An example is knowing the connection between the integration and measurement, even though they are not concepts which occur in the same year. Hence, we regard the descriptors in this subdomain as being related to the topic being studied. Thus, one such descriptor might be, *knowing the relationship between matrix algebra and geometry*, which gives us information about the knowledge of a topic which could be covered in one year, with matrix geometry, which could be from another topic in the same, or other, year.

Knowledge of Practices of Mathematics (KPM). This subdomain, which corresponds to the idea developed by Ball (1990), refers to ways of dealing

with mathematics (Carrillo et al., 2013; Montes et al., 2013). In order to provide a description of knowledge about mathematics it is necessary to give preeminence to aspects of mathematical reasoning. For example, the descriptors should incorporate concepts such as definition, demonstration and argumentation, which reflect understanding of what constitutes a definition, or when a demonstration has been completed, or when a particular line of reasoning is valid. Depending on the topic in hand, this subdomain will reflect certain aspects of mathematical procedure, but these will not be concepts inherent in the concept itself. Hence, for multiplying matrices again, a KPM descriptor such as *Knowing that definitions and properties have limits* could be phrased as *Knowing why any two matrices cannot be multiplied*, which would already form part of KoT.

In the following section we will consider the subdomains corresponding to pedagogical content knowledge.

Knowledge of Features of Learning Mathematics (KFLM). It is worth reminding ourselves that understanding the manner in which pupils learn mathematics is not in itself purely mathematical, although it clearly involves mathematics, but it is very closely linked to the work of teaching. In our opinion, teachers' understanding of their pupils' learning is influenced by the way they understand learning, and hence there will be differences between those teachers who endeavour that mathematics be learnt mechanically or meaningfully (Skemp, 1978), and those who do not, or who consider only one of the modes. Thus, the descriptors for this subdomain will totally depend on the topic under consideration, as the learning related to fractions, for example, need not necessarily share the same features as the limit, although theories such as those advanced by Sfard (1991), APOS (Asiala, Brown, DeVries, Dubinsky, Mathews, & Thomas, 1996), or any other theory of learning could prove useful in devising descriptors for every learning state. Such a descriptor from this subdomain, referring once again to the multiplication of matrices, could be phrased as *Knowing that students tend to use the commutative property for multiplying matrices*.

Knowledge of Mathematics Teaching (KMT). The knowledge described in this subdomain is that which allows teachers to take the complex series of decisions that constitutes the task of teaching, such as making the choice of an appropriate textbook, selecting a representation for a particular concept, or finding specific resource material for dealing with a topic. Hence, this subdomain requires descriptors which reflect teachers' decision making processes for carrying out a lesson. A typical descriptor would be, *Initiates the teaching of matrix algebra using non-square matrices of limited size (as with*

the scalar product of vectors), which draws on knowledge that is considered in other subdomains, but which also has its own existence.

Knowledge of Mathematics Learning Standards (KMLS). In this case, we consider the descriptors proposed by Sosa (2010) for curricular knowledge a good starting point, although we think it necessary to add descriptors relating to teachers' institutional context, such as aspects of knowledge deriving from professional associations (such as the NCTM), journals or research groups, beyond the confines of the prescriptions of educational authorities. As such, it would be necessary to explore which of these teachers considered conventional sources of information. For example, *being aware of professional papers dealing with student problems with matrix algebra* would be accepted as a descriptor as here research literature constitutes a standard source for developing one's educational knowledge.

A FINAL REFLECTION

As suggested above, the MTSK model represents a change of perspective in the MKT model, given that it considers all specialised aspects making up mathematics teachers' knowledge, including both the teaching profession and the object of teaching, in this case, mathematics. The specialisation of mathematics teachers' knowledge means going deeply into the idea of pedagogical knowledge and distancing on self from it, in order to achieve a 'mathematisation' of the model, which goes from considering the specificity of pedagogical knowledge referring to teaching and learning mathematical content, to focusing on the mathematical pedagogical knowledge which defines the profession of mathematics teacher.

Given that the MTSK model is under construction, we think that one of the most important tasks to see through in future studies is a more precise description of the model, creating descriptors for the subdomains which enable us achieve a better understanding of the nature of teachers' knowledge in line with the above. In like fashion, access protocols to the distinct components of teachers' knowledge are needed to thus resolve the controversies surrounding them, as in our opinion certain subdomains, such as mathematical horizon knowledge in the MKT model, despite being generally accepted as a dimension of teachers' knowledge, has limited accessibility for describing what is observed.

NOTES

[1] Each descriptor with its respective acronym and definition can be found in Sosa (2010, pp. 63-70).

DETERMINING SPECIALISED KNOWLEDGE FOR MATHEMATICS TEACHING

J. Carrillo, N. Climent, L.C. Contreras, & M.C. Muñoz-Catalán¹

University of Huelva, Spain

Drawing on the work of Deborah Ball and collaborators in the field of Mathematical Knowledge for Teaching (MKT), we draw attention to several areas of difficulty in applying this framework to actual samples of mathematics lessons, due to a tendency for the subdomains that make up the model to overlap. Tackling these shortcomings by viewing all mathematics teachers' knowledge as specialized has led us to reinterpret and rename these subdomains in what can be considered a reformulation of MKT.

Keywords: *mathematical knowledge for teaching, teachers' specialized knowledge, mathematics teachers' knowledge.*

INTRODUCTION

One of the benefits of research into teachers' knowledge – in our case relating to mathematics teaching – is ascertaining desirable elements and characteristics that can be taken as reference points when working with teachers. From the many such characterisations of knowledge developed in the last two decades (Bromme, 1994; Rowland, Turner, Thwaites, & Huckstep, 2009), the theory of *Mathematical Knowledge for Teaching* (Ball, Thames, & Phelps, 2008) has proved to be especially powerful in describing the knowledge required by teachers in their practice, underlining its ties with mathematics while at the same time considering other elements involved in the teaching process (e.g. the pupils and their learning, and the curriculum) and the connections between them. What is more, *Mathematical Knowledge for Teaching* (MKT) has pioneered consideration of mathematical knowledge from the point of view of teaching, including knowledge of the structure of the subject, the rules governing how it works, and careful thought about the contents and their relations. In this respect, it seems to us that the purpose of MKT is that it should be an analytical tool for studying teachers' knowledge, as opposed to a model of such knowledge itself. On the other hand, we are aware that the authors' description of teachers' knowledge is partial, omitting other equally important

¹ This article represents part of the studies into teachers' knowledge by the SIDM group (from the Spanish 'Research Seminar into Mathematics Education') based at the University of Huelva, Spain. It comprises the following researchers: José Carrillo (coordinator), Nuria Climent, M. Cinta Muñoz-Catalán, Luis C. Contreras, Miguel A. Montes, Álvaro Aguilar, Dinazar I. Escudero, Eric Flores and Enrique Carmona (University of Huelva), Pablo Flores, Nielka Rojas and Elisabeth Ramos (University of Granada, Spain), C. Miguel Ribeiro, Rute Monteiro and C. Susana dos Santos (University of the Algarve, Portugal), Leticia Sosa and José L. Huitrado (University of Zacatecas, Mexico), Diana Vasco (State Technological University of Quevedo, Ecuador) and Emma Carreño (University of Piura, Peru).

dimensions, such as teachers' beliefs and knowledge not specifically related to mathematical issues such as class management.

MKT has meant a significant advance in attempts to characterise mathematics teachers' knowledge domains. The most significant contributions are probably the differentiation of the subdomains *specialized content knowledge* (SCK), *common content knowledge* (CCK), and *horizon content knowledge* (HCK), within Shulman's (1986, 1987) classic *content knowledge*, in addition to the subdomains *knowledge of content and students* (KCS) and *knowledge of content and teaching* (KCT), within *pedagogical content knowledge*. However, as the authors themselves recognise, the new subdomains do not in practice mean an exhaustive classification of a teacher's knowledge, and often it is difficult to know whether an excerpt of classroom practice is unambiguously illustrative of one of these subdomains or rather the intersection of two or more of them. What is more, the very differentiation between SCK and CCK leaves the system open to the possibility that all teachers' knowledge is to some extent specialised.

It is precisely such difficulties in applying MKT to our studies that we wish to highlight in this paper, at the same time suggesting a reformulation of the framework from a perspective that does indeed regard all teachers' knowledge as specialised.

OUR EXPERIENCE WITH MKT

In our work on mathematics teachers' knowledge using the MKT framework (Sosa, & Carrillo, 2010; Figueiras, Ribeiro, Carrillo, Fernández, & Deulofeu, 2011; Ribeiro, & Carrillo, 2011a, b; Climent, Romero, Carrillo, Muñoz-Catalán, & Contreras, in press), we have identified various difficulties which have led us to raise questions about the model. The chief shortcomings were recognised by Ball and associates in their 2008 work, and concern *specialized content knowledge* (SCK) and *common content knowledge* (CCK [1]). Essentially, there are two related problems [2]:

- 1) The difficulty in deciding where CCK ends and SCK begins, as a result of the very definition of CCK. In brief, CCK is defined as that knowledge held by anybody educated to the corresponding level under analysis (Ball *et al.*, 2008). In this way, although the model of MKT is based on observation, in order to decide whether the knowledge underpinning a teacher's action during a teaching episode corresponds to CCK or not, we need to compare it with the hypothetical knowledge of someone at a hypothetical level of education, without knowing anything about the educated person's practice or their typical knowledge, but instead, a compendium of desirable knowledge drawn from various curricula. Hence, for example, it is not clear whether CCK or SCK is invoked when explaining why the same denominator is needed for adding or subtracting fractions (but not in the case of multiplication or finding the quotient, although this might lead us to an alternative algorithm). Deciding whether such knowledge is typical of a well-educated individual involves a large degree of speculation. It therefore occurs to us more reasonable to define

CCK intrinsically, that is, referring exclusively to mathematical knowledge itself, without reference to other professions or qualifications.

- 2) The difficulty in demarking SCK from HCK, and SCK from KCS, again as a result of the definition of SCK. SCK is understood as a way of thinking about mathematics which occurs only when considered as something to be taught. However, it is sometimes difficult to determine whether this reflection refers to the relations between the item to be taught and others (HCK) or to the learning of the item (KCS). In this case, we can consider the example of the commutative property in relation to different objects. First, we will consider this property in relation to the addition and multiplication of natural numbers. Although both operations fulfill this property for this particular numerical set, from the point of view of their meaning, we can say that addition is semantically commutative, but not multiplication in general (adding or uniting 2 elements and then 3 is the same whichever the order; considering 3 groups of 2 elements is not the same, however, as considering 2 groups of 3 elements). This subtle difference affects how each case is perceived, and relates to how each is learnt. Now we will consider the property in relation to multiplying matrices. In this case, commutability does not generally occur, except in the case of square matrices in which the operation can be done either way (although these matrices do not fulfill the commutative property either). This fact differentiates the multiplication of matrices from that of numbers, and knowledge of this difference implies associating both contexts, which we would argue forms part of HCK. Additionally, it provides a mathematical explanation for a common student error in multiplying matrices, which associates it with KCS.

We have found, then, problems in the demarcation of the subdomains, in which respect we concur with the impression of other authors (Silverman, & Thompson, 2008). There is a need, we feel, to define the subdomains in a slightly different way, more appropriate, we would say, to teachers' knowledge regarding teaching mathematics. At the same time, we have tried to see to what point SCK permeates, or is included within, other subdomains, thus emphasising the valuable contribution it has made to the MKT model.

It is important at this point to give due recognition to the development of the MKT model by Ball and her collaborators, although at the same time the difficulties noted above lead us to think that it would be more appropriate to alter the focus of teachers' knowledge so that, on the one hand, it can be better understood, and on the other, its contents can be better discerned.

The difficulties in demarcation suggest the need to look more closely at MK (ie, 'mathematical knowledge' [3], that is the left hand side of the MKT model) and to progress towards defining and delimiting CCK, SCK and HCK. This is the work which we have undertaken and which we would like to present in this paper, along with the reformulation of the subdomains pertaining to *pedagogical content*

knowledge (PCK, the right hand side of the MKT model). Throughout, we have been guided by two premises. First, we have not limited ourselves to merely observing episodes of classroom practice, but have proposed a sound theoretical model, which can be subsequently tested in practice (observations), especially longitudinal studies combining classroom observation and shared reflection. Secondly, we have remained open to the possible restructuring of the MK domain, and the potential for new or different subdomains, and even the possibility of the subdomains of PCK being affected. Moreover, this model is designed to reflect teachers' beliefs about mathematics and its teaching and learning. Although the role of these beliefs in the model is not the focus of this paper, the fact of its inclusion marks a divergence from the MKT model.

SPECIALISATION AS A GENERAL FEATURE OF MATHEMATICS TEACHER'S KNOWLEDGE: MATHEMATICS TEACHER'S SPECIALIZED KNOWLEDGE (MTSK)

What interests us as researchers and trainers within the area of Mathematics Education is the extension of teachers' professional knowledge linked to mathematics as the focus of the teaching-learning process, the recognition of which was one of the chief contributions of the work of Shulman (1987). For their part, the research team headed by Ball (Ball *et al*, 2008; Ball, & Bass, 2009) outline the mathematical knowledge within the specialised area, and it is precisely this mathematical character which causes problems when it is applied to *pedagogical content knowledge*.

We attempt to focus the specialisation of mathematics teacher's knowledge from another perspective. Instead of talking about 'specialised content knowledge' (as a part of teacher's knowledge), we talk about 'mathematics teacher's specialised knowledge' (*MTSK*). We try to distance ourselves from the idea of mathematical knowledge for teaching and think of mathematics teacher's knowledge that makes sense only to them (in which, therefore, the specialised nature defines all knowledge under consideration).

The specialisation of *MTSK* should allow it to be differentiated from general pedagogical knowledge (knowledge of pedagogy and general psychology, which also forms part of mathematics teacher's professional knowledge), from the specialised knowledge of teachers of other disciplines, and the specialised knowledge of other mathematics professionals. In other words, it is specialised in respect of mathematics teaching.

We have reconsidered the content of this knowledge from this perspective, basing ourselves on the domains of MKT and on our beliefs concerning what we consider desirable as the content of mathematics teacher's specialised knowledge in each subdomain. The outcome is that we propose to eliminate the reference to 'common content knowledge' from the domain of mathematical knowledge (given that our interest lies only with knowledge in relation to mathematics teachers; for example, we believe that teachers should possess not only the knowledge of *how* but the knowledge of *why*, and the students too, see Flores, Escudero, & Carrillo, 2013). As a

result, ‘specialised content knowledge’ ceases to be necessary and ‘horizon content knowledge’ broadens its scope (resulting in two related subdomains). With regard to ‘pedagogical content knowledge’, we have renamed and reinterpreted KCS, KCT and KCC, recalibrating them to what we believe is their content.

We present this new proposal in more detail below and in a visual display (Fig. 1).

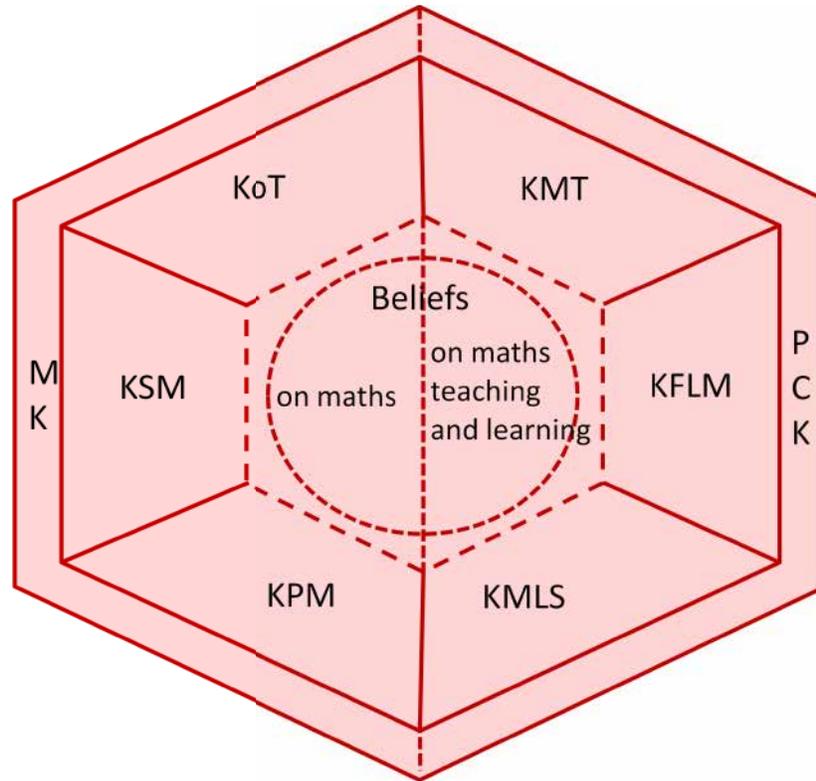

Fig. 1: Chart of *MTSK*

Elements of *MTSK* referring to Mathematical Knowledge (MK)

a) *Knowledge of topics (KoT)*

This includes the knowledge of mathematical concepts and procedures along with the corresponding theoretical foundations. We can say that all knowledge considered desirable for a pupil to be in possession of at any particular level [4] would form part of the teacher’s CCK at this level, including a certain degree of formalisation or vision of the content from a somewhat higher viewpoint (for example, knowing that the property of commutability represents a more technical explanation of the fact that the order of addends in an addition sum does not affect the result).

b) *Knowledge of the structure of mathematics (KSM)*

Building on Ball and Bass’ (2009) description of horizon knowledge, we consider two elements of MK relating to the structure of the discipline (this subdomain) and the ways of proceeding in mathematics [5] (the next subdomain).

The first of these elements, knowledge of the structure of the discipline, includes knowledge of the main ideas and structures, such as knowledge of properties and notions relating to specific items being tackled at any moment, or the knowledge of connections between current topics and previous and forthcoming items. It implies

seeing the content in perspective, basic mathematics from an advanced point of view, and advanced mathematics from a basic point of view. Also included is the idea of increasing complexity, as explained in Montes, Aguilar, Carrillo, & Muñoz-Catalán (2013, in this volume).

c) Knowledge of the practice of mathematics (KPM)

The second of these elements refers to ways of proceeding in mathematics. It includes knowledge of ways of knowing and creating or producing in Mathematics (syntactic knowledge), aspects of mathematical communication, reasoning and testing, knowing how to define and use definitions, establishing relations (between concepts, properties etc), correspondences and equivalences, selecting representations, arguing, generalising and exploring. Knowledge about relations or connections between concepts, pertaining to *knowledge of the structure of mathematics*, should be distinguished here from knowledge about how such relations are established.

Defined in this way, MK extends over the full range of mathematical knowledge, covering the whole universe of mathematics, comprising concepts and procedures, structuring ideas, connections between concepts, the reason for, or origin of, procedures, means of testing and any form of proceeding in mathematics, along with mathematical language and its precision. The denomination *KoT* emphasises that the subdomain is defined in purely mathematical terms, and this we think makes it clearer that *knowledge of topics* and *knowledge of the structure of mathematics* form a complex system. At the same time, this way of defining *KoT* avoids the somewhat mechanical slant which the definition of CCK was prone to, as sometimes was the knowledge of mathematics (in the sense of knowledge of and about mathematics, Ball, 1990).

Returning briefly to one of the examples above, knowing that the product of matrices is not commutable pertains to *KoT*; knowing that in this sense it is different from the multiplying natural numbers would pertain to *knowledge of the structure* (as it means taking a basic viewpoint to the multiplication of matrices, like multiplying numbers) and knowing that the pupils believe that the product of matrices is commutative because they extrapolate this property from multiplying numbers (which they learn at school) would form a part of *pedagogical content knowledge* (as we will now explain). If we take the point of view of *specialized content knowledge* within the MKT model, reflection about specialisation in both contexts is a reflection about the specific content of the act of teaching, for which reason we consider it as SCK, which, as we have noted above, results in overlap with *horizon knowledge* and *knowledge of content and students*.

Elements of MTSK referring to Pedagogical Content Knowledge (PCK)

d) Knowledge of Features of Learning Mathematics (KFLM)

KFLM derives from the teacher's need to understand how pupils think when faced with mathematical activities and tasks, the same as KCS in Ball's model. It is important that the teacher is aware that the pupils may have problems with a

particular topic. This awareness is fed by the teacher's general knowledge of the topic and by their familiarity with the pupils. This subdomain encompasses a range of knowledge, including (and not, we believe, explicitly included in KCS) theories or models of how students learn mathematics (for example, the process which takes pupils from action to schema according to the APOS perspective –Asiala, Brown, DeVries, Dubinsky, Mathews, & Thomas, 1996). It is not a question of knowing these theories or perspectives, but rather their significance, that is to say, what these theories contribute to describing the process of learning mathematics. *KFLM* is not mathematical knowledge, although the teacher needs to have a background in mathematics in order to understand it and put it to use. KCS refers to content and students, while *KFLM* is concerned with how mathematics is learned, that is, with identifying the features of mathematics learning.

e) Knowledge of Mathematics Teaching (KMT)

KMT is not mathematical knowledge either, though it does require it. It is the kind of knowledge which allows the teacher to choose a particular representation or certain material for learning a concept or mathematical procedure, and which allows them to select examples or choose a textbook, in much the same kind of way as Ball's KCT. We would underline here (encapsulated in the name of the subdomain) the integration of mathematics and teaching, in that it is not a question of mathematical knowledge on the one hand and teaching knowledge on the other; pedagogic knowledge is not included here in the context of mathematical activities, but rather only that in which the mathematical content constrains the teaching. In *KMT* we locate knowledge of resources from the point of view of their mathematical content or the knowledge of approaching a structured series of examples to help pupils understand the meaning of a mathematical item.

f) Knowledge of Mathematics Learning Standards (KMLS)

KMLS concerns knowledge of curricular specifications, the progression from one year to the next, conventionalised materials for support, minimum standards and forms of evaluation, in the same way as KCC does in Ball's model. However, *KMLS* seeks to extend knowledge of learning objectives and standards beyond those deriving from the institutional context of the teacher. We include objectives and measures of performance developed by external bodies such as examining boards, professional associations and researchers, thus adding an element of assessment and evaluation drawn from the appropriate educational agencies.

FINAL COMMENTS

With *MTSK* we have intended to focus solely on mathematics teacher's specific knowledge with respect to teaching the subject, eliminating any reference to a common core of knowledge shared with others who make use of mathematics. *Knowledge of topics* and *Knowledge about mathematics* are shared by all mathematicians, as is to a certain extent *Knowledge of the structure of mathematics*, though not to the degree of familiarity required by teachers. Conversely, *KMT*, *KFLM* and *KMLS* are exclusive to teachers.

With MKT the focus was on the class as a whole, including pedagogical concerns (KCT, KCS) to an extent that the framework might be applicable to other disciplines, but in so doing it shifted away from mathematics and its core essence. In contrast, rather than consider the class as a whole, we aim to consider mathematics as the hub of *MTSK*, around which this new framework offers different ways of viewing the mathematics which the teacher knows and uses. We refer not only to mathematics in itself, but to reflections about mathematics that a teacher establishes by interacting with it in their daily practice, out of which aspects of mathematics pedagogy inevitably arise (*KMLS*, *KMT*). MKT concerns the educational circumstances constraining the teacher: recognising the causes of error, using powerful examples, identifying incorrect definitions in textbooks, etc. In contrast, *MTSK*, by virtue of being designed to encapsulate teacher's specialised knowledge, focuses its attention on mathematical content and, with greater precision, on the different ways of fully engaging with mathematical content when teaching.

In this paper we have endeavoured to discuss the defining features of the subdomains comprising MKT and suggest an alternative model based around it. We propose that this model (and others) be conceived of, and brought into play, as a kind of researcher's kit which helps them to avoid a prescriptivism which might impede understanding the phenomenon under scrutiny. Studying *MTSK* using this kit will enable our knowledge of its categories and subdomains to be reinforced.

At the same time, it would be interesting to pursue another line of research attempting to situate the model within a theoretical framework, in which, amongst other things, we would have to explicitly present our grounded position regarding how we understand teaching and learning mathematics, teacher training (both initial and in-service), our mathematics beliefs, the utility of models and other analytical tools, the purpose of our research, and the role of the subjects being studied/participating in that research, especially in relation to the researchers and the carrying out of the research itself.

In our work group we are drawing up research projects into mathematics teachers' knowledge in terms of different topics and different kinds (some structuring, such as the notion of infinity, and others more local, such as the concept of a polygon), and focusing on different dimensions of *MTSK*. Some of these projects involve experienced teachers (occasionally in the context of professional development), others with novice teachers, and others with students' teachers. Different educational phases are also involved, and likewise different stages of the teaching-learning process (exemplification, the introduction of concepts or procedures, designing tasks, and making decisions in class). Our aim across the board is to explore the limits and potential shortcomings of our proposal for *MTSK*, and to refine it further.

It strikes us that a better specification of desirable professional knowledge for a mathematics teacher from research is especially important in contexts of professional development, particularly in collaborative situations, where the group itself is at liberty to decide what to study and reflect on (in terms of professional practice, for

example), *MTSK* being one such possibility. It is not a question of having available a model which can be gradually assimilated, so much as having this model available as a point of departure for shared reflections forming the platform on which to design the group's collaborative work (Carrillo & Climent, 2011).

NOTES

1. We use the acronyms coined by Ball and collaborators themselves; in addition to those above, KCT for Knowledge of Content and Teaching, KCS for Knowledge of Content and Students, and likewise HCK for Horizon Content Knowledge and KCC for Knowledge of Content and Curriculum.
2. For further explanation, as well as examples of the difficulty in applying MKT, see Flores, Escudero, & Carrillo (2013, this volume).
3. Mathematical knowledge is understood as Shulman's subject matter knowledge. We use MK instead of SMK to avoid confusion with SCK or SMK in reference to specialised content or mathematical knowledge, respectively.
4. From a conception of school mathematics in which the pupils also learn the 'whys' of procedures and the reasons for certain concepts (for example, why fractions with the same denominator are needed to add fractions, but not to multiply them).
5. Ball, & Bass (2009, p.6) mention four elements constituting HCK: "a sense of the mathematical environment surrounding the current "location" in instruction; major disciplinary ideas and structures; key mathematical practices; and core mathematical values and sensibilities". In our case, we have considered the first three elements, given that values and sensibilities means introducing a different kind of element from the rest of the components of the model.

TEACHING MULTIDIGIT MULTIPLICATION: COMBINING MULTIPLE FRAMEWORKS TO ANALYSE A CLASS EPISODE

Stéphane Clivaz

University of Teacher Education, Lausanne, Switzerland

This paper provides an analysis of a teaching episode of the multidigit multiplication algorithm, with a focus on the influence of teacher's mathematical knowledge on his teaching. The theoretical framework uses Mathematical Knowledge for Teaching, mathematical pertinence of the teacher and structuration of the milieu in a downward and upward a priori analysis and an a posteriori analysis. This analysis shows a development of different didactical situations and some links between mathematical knowledge and pertinence. In the conclusion, the contribution of the two traditions originated frameworks is briefly addressed.

Keywords: *Mathematical knowledge, teacher, elementary teaching, multiplication algorithm, pertinence, structuration of the milieu*

This paper originated in a doctoral research project (Clivaz, 2011) that aimed to describe the influence of the mathematical knowledge of primary school teachers on their management of school mathematical tasks. The origin of that question partly came from U.S. mathematics education research and partly from the French *didactique des mathématiques*. Ball's categories of Mathematical Knowledge for Teaching (Ball, Thames, & Phelps, 2008) were used to describe the teacher's knowledge, while I described the effect on teaching through mathematical pertinence of the teacher (Bloch, 2009). I analysed the teacher's knowledge and the effect of this knowledge in ordinary classroom situations with the model of structuration of the milieu (Margolinas, Coulange, & Bessot, 2005) to take into account the complexity of the teacher's activity.

After a brief explanation of these three frameworks, their interaction will be shown through an episode about the teaching of the algorithm of multidigit multiplication. Finally, I will discuss the interaction of these frameworks for analysing the teacher's knowledge and teaching.

FRAMEWORK

CATEGORIES OF MATHEMATICAL KNOWLEDGE FOR TEACHING

Refining Shulman's (1986, 1987) categories of teacher knowledge for mathematics, Ball, Thames, and Phelps (2008) provide a practice-based division of Mathematical Knowledge for Teaching (MKT).

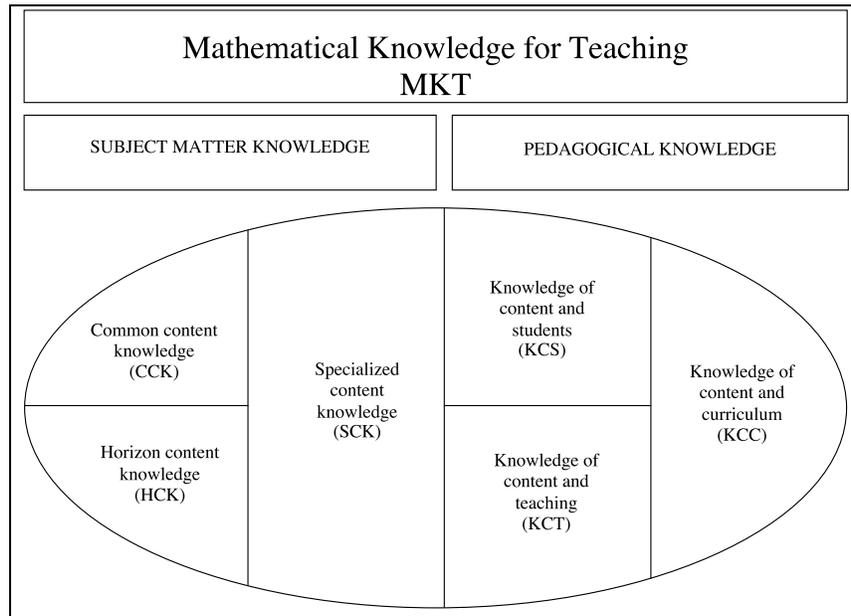

Figure 1: Domains of mathematical knowledge for teaching (Ball et al., 2008, p. 403)

One of the special features of this categorization is the existence of a *Specialized Content Knowledge* (SCK), defined as

the mathematical knowledge and skill unique to teaching. In looking for patterns in student errors or in sizing up whether a nonstandard approach would work in general, [...] teachers have to do a kind of mathematical work that others do not. [...] This work involves an uncanny kind of unpacking of mathematics that is not needed—or even desirable—in settings other than teaching” (Ball et al., 2008, p. 400).

One of the examples of the use of MKT Ball and her colleagues often provide is the teaching of the multiplication of whole numbers algorithm (Ball, Hill, & Bass, 2005, pp. 17-21). I studied examples of this teaching with four teachers in the Lausanne region of Switzerland (Clivaz, 2011), and the case I will analyse is about this teaching.

MATHEMATICAL PERTINENCE OF TEACHER’S ACTIONS

In order to detect the effects of a teacher’s mathematical knowledge, Bloch (2009) suggests considering the *mathematical pertinence of teacher’s actions*. An action is pertinent if it allows the student to grasp the functionality of mathematical object, with enunciation of mathematical properties, mathematical arguments for the validity of procedures, or for the nature of mathematical objects¹. Bloch gives three criteria for this pertinence, the first being the “ability to interact with the students on mathematical aspects of the situation and to encourage their activity by the means of interventions and feedback on their mathematical production²” (p. 32).

STRUCTURE OF THE MILIEU

To describe the teacher's activity, Margolinas (Margolinas, 2002; Margolinas et al., 2005) has developed a model of the teacher's *milieu*³, based on Brousseau (1997), which she also uses as a model of the teacher's activity.

+3	<i>Values and conceptions about learning and teaching</i>
	Educational project: educational values, conceptions of learning, conceptions of teaching
+2	<i>The global didactic project</i>
	The global didactic project, of which the planned sequence of lessons is a part: notions to study and knowledge to acquire
+1	<i>The local didactic project</i>
	The specific didactic project in the planned sequence of lessons: objectives, organization of work

	Interactions with pupils, decisions during action
-1	<i>Observation of pupils' activity</i>
	Perception of pupils activity, regulation of pupils' work

Figure 2: Levels of a teacher's activity (Margolinas et al., 2005, p. 207)

At every level, the teacher has to deal not only with the current level, but at least also with the levels directly before and after the current level. This tension makes a linear interpretation of teacher's work inaccurate (Margolinas et al., 2005, p. 208). In fact, a more complete model can be considered, including the student (E, for *élève*), the teacher (P, for *professeur*), and the milieu (M). Each milieu M_i is constituted at each level i by the lower E_{i-1} , P_{i-1} , and M_{i-1} component and the situation S_i is made at each level i by E_i , P_i , and M_i . This can be written as $S_i = (M_i ; E_i ; P_i)$ and $M_i = S_{i-1}$, or more visually represented in an onion diagram (Figure 3) or in a table where the teacher's levels range from +3 to -1 and the student's levels range from -3 to +1.

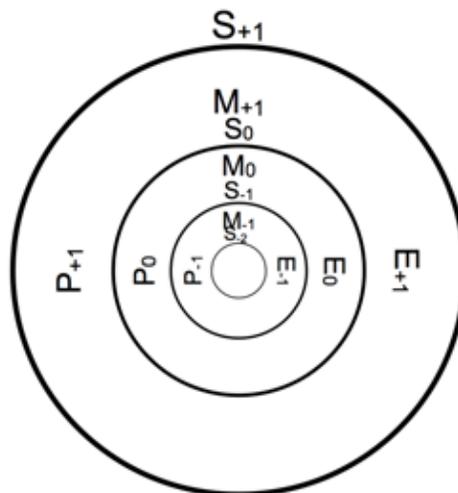

Figure 3: Structure of the milieu, level -1 to +1

Therefore, S_0 , the didactical situation, can be determined either from the teacher's point of view, by a *downward analysis*, or from the student's perspective, by an *upward analysis*. This latter may conduct to one or more didactical situations S_0 which may not be the same as the situation determined by the downward analysis. Margolinas (2004) calls this a *didactic bifurcation*.

The downward analysis uses mainly the audio-recorded interview we had with each teacher before the lessons about multidigit multiplication. The upward analysis is *a priori* "in the sense that it doesn't depend on experimental or observational facts"⁴ (Margolinas, 1994, p. 30). Both are then tools to analyse the classroom observations in an *a posteriori* analysis.

THE CASE OF DOMINIQUE

The episode, 27 minutes in duration, that was analysed is taken from the series of seven lessons Dominique, a Grade 4⁵ teacher, devoted to this algorithm in his class. The analysed episode features the moment where Dominique plans to show the multidigit multiplication algorithm. The video recording was transcribed and coded with Transana software (Fassnacht & Woods, 2002-2011) according to the categories of mathematical knowledge for teaching, mathematical pertinence, and the levels of the teacher's activity. This extract can be situated in the series by means of a *synopsis* (Schneuwly, Dolz, & Ronveaux, 2006) and a *macrostructure* (Dolz & Toulou, 2008).

The *a priori* downward analysis will be presented in the following sections of this paper. Due to space constraints, the *a priori* upward and *a posteriori* analyses cannot be developed here. We will very briefly describe the situations S_0 these *a priori* analyses reveal and, in the *a posteriori* analysis, we will suggest reasons for some highlighted troubles, in terms of types of Mathematical Knowledge for Teaching (MKT) and mathematical pertinence.

A PRIORI ANALYSIS

Downward analysis

Based on the interview with the teacher, the downward analysis goes from level +3 to level -1 and determines *a priori* the didactical situation S_0 from the teacher's point of view. The topics Dominique addresses are various, so I focus only on the question about the type of algorithm, the MKT linked to that question, and the consequence about the determination of S_0 didactical situation.

Dominique thinks that pupils should understand what they do in math (level +3). He also feels this way about the algorithms, but he views algorithms as tools for problem solving (+3). So, for the series of lessons about multidigit multiplication, the main goal is that the students are able to carry out the algorithm and use it efficiently (+2). The type of algorithm is not important if it is efficient for the students (+2). Dominique knows that there are several kinds of algorithms for multidigit

multiplication, and he plans to show two of them: the “table algorithm” (Figure 4, left) and the algorithm *en colonnes*⁶ (EC) (Figure 4, right). This way of showing more than one algorithm is consistent with the official regional instructions (DFJ, 2006) and textbooks (+3) (Danalet, Dumas, Studer, & Villars-Kneubühler, 1999). At the end of the chapter of the textbook about this topic, Dominique will ask students to only retain and use the EC algorithm, with the justification that this is the algorithm everybody learned at school, and it is more efficient than the table algorithm (+2).

For the lesson, Dominique plans to show first the table algorithm on a two-digit by two-digit multiplication question and then to show the EC algorithm on the same example. He knows that the two algorithms give the same results and that the partial results can be compared line by line (SCK, +2), and he plans to show that (+1). However, he doesn’t mention any other link between the table algorithm and EC – in general (+2), when planning the lesson (+1), or when envisioning teaching the lesson (+1). In addition, he does not observe the students using the two algorithms on the same multiplication question (-1). To make the line-by-line comparison possible, he plans on asking the students to “put the tens below”: “It’s not very logical, but it allows the student to have the two (lines) in front of each other”⁷. He never mentions any other reason or justification for this step and never mentions the possibility (and the effects) on the inversion of the two factors (SCK, +2).

Dominique thinks that the only problems pupils will face in the EC algorithm are multiplication facts and the second line zero (KCS, +2). He foresees that he will observe many errors about this zero (KCS, -1). So he plans to repeat the *zero rule*: “when one works with tens, a zero must be added”⁸.

For Dominique, multiplication is shortcut for addition (SCK, +2). He never plans to mention any link with area when explaining the table or EC algorithm (+1) even if he asked one area problem to introduce the necessity for building an algorithm (+2). Challenged about his representation of multiplication, he never gives any other representation, and when asked about the link between multiplication and area, he answers that the area has to be computed with multiplication (CCK, +2).

These elements contribute to determine the didactical situation S_0 from the teacher’s perspective. It can be summarized in four points:

- 1 Show the table algorithm for the example 12×17 , requiring writing the units first for 17.
- 2 Show the EC algorithm on the example 12×17 . Write the EC algorithm next to the table. After the first line, highlight the fact that the results of both algorithms’ first lines are the same.
- 3 Write the zero at the right place in the second line, because “when one works with tens, a zero must be added”. Carry out the second line and highlight the fact that the results of both algorithms’ second lines are the same.
- 4 Finish by adding the two lines.

x	10	2

Figure 4: Two algorithms for the multiplication 12×17 , written by Dominique on a poster.

Upward analysis

The elaborate upward analysis (Clivaz, 2012) starting from M_3 material milieu, shows that the student can deal with M_3 in different ways about the parallelism between the table and the EC: one row with one row (same correspondence as the teacher), partial product to partial product, just copy the results or do the two algorithms independently. He/she can also apply the *zero rule* in three ways: he/she can write a zero before beginning the second row with no further interrogation, he/she can link this zero to each zero in the table's second row, and he/she can literally apply the teacher's explanation, adding a zero each time he/she works with a ten. The combination of these two dimensions conducts to twelve situations S_{-2} , from which six seem consistent and lead to six S_0 didactical situations.

A POSTERIORI ANALYSIS

The detailed *a posteriori* analysis of the 27-minute episode (Clivaz, 2011, pp. 194-204; 2012) compares the *a priori* analysis with the video and the transcript of the actual lesson. It shows that most of the students considered the two algorithms independently or in a line-by-line correspondence, and wrote the zero without interrogating. These students were in two of the S_0 situations that the upward analysis determined. However, one student, Armand, repeatedly asked questions about why the teacher didn't add a zero *each time* he used tens. He was in another S_0 situation. He also asked several times, "Is it 1×1 or 10×10 ?". However Dominique kept *his* S_0 situation and was not able to even understand Armand's interrogations.

MKT and pertinence

The proliferation of didactical bifurcations and the inability of the teacher to notice that the Armand's S_0 radically differed from his have their origin in the teacher's choices made at the +3 to 0 levels. Additionally, these choices may be understood as a consequence of the teacher's MKT.

The first choice was to use the table algorithm and particularly the correspondence between the lines' sum in the table and in the EC's lines, but with no explicit correspondence between each partial product. Dominique's MKT about the table

were accurate, as revealed in the interview, but they were not pertinent, since they didn't allow him to interact with the students on the mathematical parts of the situation (pertinence's first criteria according to Bloch, 2009). The reason for this discrepancy between knowledge and pertinence was the knowledge of multiplication itself. For Dominique, multiplication was only a shortcut for repeated addition. He never considered it as a Cartesian product or as the area of a rectangle. Therefore, to Dominique, EC and table algorithm were two ways to perform multiplication; they were not linked to multiplication itself and they were just linked to each other because they gave the same result.

The second choice was the “recipe” for *zero rule*. This rule is problematic in many ways: use of additive words (add a zero), lack of link with place value, and above all, fallacy if literally applied. Regarding these two choices, Dominique had a working *Common Content Knowledge*, but he couldn't unpack it and couldn't use the corresponding *Specialized Content Knowledge* to explain why a zero appears when one multiply by tens.

CONCLUSION

This episode analysis used the structure of the milieu to highlight and to analyse links between mathematical knowledge for teaching (MKT), pertinence, and teaching choices of the teacher. It showed that not only Common Content Knowledge is necessary to apply pedagogical MKT, but also “that each of these common tasks of teaching involves *mathematical* reasoning as much as it does pedagogical thinking” (Ball et al., 2005, p. 21). It is one illustration of the way one U.S. mathematics education framework and elements of the *Theory of didactical situations* (Brousseau, 1997) can interact to analyse a math teaching issue. The original question was about mathematical knowledge of the teacher, but the finesse of the structuration of the milieu was necessary to show the multiplicity of the various didactical situations. The distinction of specialized content knowledge among MKT was needed to analyse the causes of the phenomena when the structuration of the milieu and the pertinence were crucial to capture the movement of didactical situations beyond the static character (Ball et al., 2008, p. 403) of Ball's categories, to see not only mathematical knowledge for teaching but mathematical knowledge *in* teaching (Rowland & Ruthven, 2011).

The combination, in the sense of Prediger, Bikner-Ahsbabs, and Arzarello (2008), of the frameworks from two cultural backgrounds allowed to “get a multi-faceted insight into the empirical phenomenon in view” (p. 173). It was more vastly used in other parts of the doctoral research (Clivaz, 2011) and gave some interesting results, for example about the correlation between MKT and pertinence. For that purpose, we invite the interested reader to read the full dissertation.

These two frameworks also raise one more general issue. The question of mathematical knowledge of the teacher is widely studied in the English-speaking

mathematics education community, but, according to the National Mathematics Advisory Panel (2008), it was often studied with the quantitative point of view of the influence on students' test outcomes. It is far less disputed¹⁰ in the French speaking *didactique des mathématiques*, even though the developed model could offer tools to discuss the influence of MKT on teaching. I hope that studies using frameworks originated in the two contexts will be developed to connect different theoretical approaches as promoted in the ERME spirit.

NOTES

¹ « Une intervention mathématique est pertinente si elle rend compte dans une certaine mesure de la fonctionnalité de l'objet mathématique visé ; ou, s'agissant d'enseignement, si elle permet au moins de progresser dans l'appréhension de cette fonctionnalité, avec des énoncés de propriétés mathématiques contextualisées ou non, des arguments appropriés sur la validité de procédures ou sur la nature des objets mathématiques. » (Bloch, 2009, p. 32)

² « [...] capacité à interagir avec les élèves sur des éléments mathématiques de la situation et à encourager l'activité des élèves par des interventions et des retours sur leur production mathématique. » (Bloch, 2009, p. 33)

³ Milieu is the usual translation for Brousseau's French term "milieu", but, in French, it refers not only to the sociological milieu but it is also used in biology or in Piaget's work. A more accurate translation would be "environment".

⁴ « dans le sens qu'elle ne dépend pas des faits d'expérience ou d'observation », my translation.

⁵ 9-10 year-old students.

⁶ Literally "in columns" but the accurate English name would be "long multiplication".

⁷ « Mettre les dizaines en dessous. C'est pas très logique, mais ça permet d'avoir les deux en face. »

⁸ « Quand on travaille avec les dizaines, on ajoute un zéro. »

⁹ « c'est 1×1 ou 10×10 ? »

¹⁰ With the notable exception of Quebec and the presence of a Working Group on the topic in EMF congress (Clivaz, Proulx, Sangaré, & Kuzniak, 2012).

TEACHERS' BELIEFS ABOUT KNOWLEDGE FOR TEACHING – AN INDIRECT APPROACH

Jason Cooper, Israel Touitou

Weizmann Institute of Science, Israel

In this paper we analyze teachers' beliefs about the knowledge needed for teaching elementary school mathematics. Eliciting such beliefs is important for designing and evaluating teacher education. We find indications of these beliefs in anonymous feedback questionnaires the teachers submitted in an in-service professional development course. This indirect approach avoids discrepancies between teachers' declared (conscious) beliefs and tacit beliefs that actually influence their learning. We found that beliefs changed during the course, at first favouring pedagogical content knowledge (PCK) as a learning goal, and shifting toward subject matter content knowledge (SMCK). The significance of this research is not only its findings but also its method, which avoids some issues inherent in traditional methods.

Keywords: Teacher beliefs, knowledge for teaching, mathematics education, professional development, mixed methods

INTRODUCTION

Teachers' beliefs are an important theoretical construct which has been receiving much attention in recent years. Teachers' beliefs about mathematics and about teaching and learning mathematics have an impact on their in-the-moment teaching decisions (Schoenfeld, 2010); however in this paper we are interested in teachers as *learners*. Teachers' beliefs about the knowledge they need for teaching influence what they learn and how they learn it. "... *teachers may be guided by their beliefs about teaching knowledge ... Such beliefs may lead them to question the value of information presented...*" (Fives & Buehl, 2008, p. 135). This idea is also supported by the theory of Adult Learning (Knowles, 1990), which states that adults tend to have a task-centred orientation to learning, i.e. are motivated to learn to the extent that they believe the learning will be instrumental in their professional practice.

There are at least two ways in which teachers' beliefs about knowledge for teaching might be considered when designing in-service professional development (PD¹): taking their beliefs as given and aligning the PD teaching goals with them, or conversely, considering their beliefs as something that may change as a result of the PD and making beliefs an explicit teaching goal, thus aligning them with the intended PD content. In either approach, a reliable tool for revealing teachers' beliefs about knowledge for teaching is required.

The most direct method for revealing teachers' beliefs is asking the teachers about them, either through questionnaires or through interviews. A problem with such an approach is related to what Toerner (2002) calls *membership degree* attributes of beliefs, and more specifically, levels of *consciousness* and levels of *activation* of beliefs. Belief systems are complex; people may hold a variety of beliefs, more or

less conscious, possibly conflicting, which are activated in specific situations. It is questionable whether beliefs that are activated when answering a questionnaire (necessarily conscious beliefs), or even during an interview, will be consistent with "situated" beliefs activated while teaching in a classroom or while learning (or refraining from learning) in a PD course. Beliefs activated in a "lab" environment may reflect an idealized version of teachers' beliefs, disregarding the complexity of natural situations, where unconscious or tacit beliefs may influence behaviour. Group interviews have been used to address this issue (Fauskange, 2012). A group discussion is more likely to elicit beliefs in all their complexity (Bryman, 2004). However, group dynamics are quite complex in their own right. It may be difficult to discern individuals' beliefs from a group interview, and furthermore, a group interview may actually influence the individual's beliefs - a fact which may serve the PD goals, but impairs the method's validity as a research tool.

In this paper we use an indirect approach to eliciting teachers' beliefs about the knowledge they need for teaching. We examine anonymous feedback forms, where the teachers reflect on more and less successful PD activities, and explain *why they were more or less successful in their opinion*. We will argue, after presenting our methodology, that this indirect approach to beliefs addresses the theoretical and methodological difficulties listed above; however, we justify this claim only from a theoretical perspective. Justifying this claim empirically is a goal for future research.

We aim to answer the following research questions:

- What beliefs about the nature of mathematical knowledge needed for teaching are tacitly implied in the teachers' feedback questionnaires?
- How did these beliefs change during the one-year PD course?

RESEARCH SETTING

In our research project we observed a mathematics professional development course for in-service elementary school teachers. A unique aspect of this PD was the fact that it was conceived by a professor from the mathematics department of a leading university in Israel, and was taught by graduate research students, primarily mathematics Ph.D. students. In this setting, the teacher-students and the mathematician-instructors had quite different initial beliefs about the knowledge that should be taught in the PD. Roughly speaking, interviews with the instructors revealed a belief that the teachers' knowledge of mathematics should be deepened and broadened, whereas teacher expectation questionnaires revealed beliefs to the effect that what they need most is knowledge related directly to the teaching of mathematics, primarily teaching strategies and ready-made classroom activities. The course consisted of 10 3-hour sessions. *Learning episodes* typically began with a mathematical problem related to the teachers' grade-level content (i.e. multiplication properties, representations of fractions, etc.). Sometimes the problems were designed to challenge the teachers' understanding of these topics. The problems often led to

open discussions where the teachers could raise pedagogical concerns. More details can be found in (Cooper & Arcavi, 2012).

In this paper we focus on one group of 19 elementary school teachers (grade 3), taught by two graduate research students in tandem². The teachers were all general teachers, who teach a variety of elementary school subjects in addition to mathematics. In addition to expectation questionnaires, which revealed the teachers' *prospective* views, the teachers were invited to submit anonymous feedback questionnaires after each of the PD sessions. These questionnaires comprise the data for our research. We present here the questions, along with authentic sample answers:

1. Select an activity from today's PD which you consider particularly successful. Explain in what ways it was successful. "...[because the activity] provided a look at what goes on in the children's heads."³
2. Select an activity from today's PD which you consider less successful. Explain in what ways it was less successful. "...[because the activity is] not suitable for my classroom."
3. If you have any additional comments, write them here. "...[the PD] is becoming more accurately aligned with needs from the field."

Throughout the 10 PD sessions, a total of 69 feedback forms were submitted, comprising approximately 40% response rate. In the general research design, the main purpose of these questionnaires was as a means to identify more and less productive learning episodes as perceived by the teachers. However, in this paper we are not interested in the selected episodes themselves, only in the *reasons* the teachers brought to justify their selections. Our assumption is that this will elicit teachers' beliefs (possibly tacit) about the knowledge they need, and that eliciting these beliefs indirectly may alleviate many of the problems inherent in traditional methods. In referring to teaching episodes (and not to themselves), the teachers are more likely to reveal genuine beliefs. Furthermore, these beliefs are activated in the context of learning mathematics, which is exactly the situation in which these beliefs are relevant to mathematics education and research. Another theoretical issue that our approach addresses is related to the differences between teachers' prospective and retrospective views (Roesken, 2011). By gathering information throughout the PD, we are filling the gap between prospective views, as indicated at the outset, and retrospective views formed as a result of the PD.

METHODOLOGY

In this research we mixed qualitative and quantitative methods. We analyzed the teachers' feedback in a qualitative manner – coding and categorizing the data – and proceed to analyze the coded data quantitatively to find patterns and trends.

Once the feedback forms were transcribed and fed into a technological tool (Atlas.ti), we segmented the data into phrases (*quotations* in the tool's terminology), and coded each data segment according to the knowledge for teaching that it implied. This is a crucial point: Teachers did not *tell* us what they believe, but rather they *made use* of

their beliefs, perhaps tacitly, by selecting outstanding episodes, and revealed these beliefs indirectly by explaining their selections.

This initial coding was fine grained, resulting in 81 different codes. For example, the phrase "... [the activity] provided a look at what goes on in the children's heads" was coded as "*understanding students' thinking*", since this utterance, as a reason for selecting a particularly successful activity, indicates that for this teacher, understanding students' thinking is important. At this early stage, codes were **not** mapped to any particular categories. The fine-grained coding was intended to permit a variety of different categorizations. Although we had a theory-based coding scheme in mind (MKT, described below), we could later adopt a completely different categorization scheme very efficiently, without re-coding.

In explaining why a PD activity was particularly (un)successful, the teachers are implicitly answering the question "what kind of mathematical knowledge should be taught in the PD"? The theoretical framework of mathematical knowledge for teaching (MKT), as put forth by Hill, Ball, & Schilling (2008), was a natural framework for categorizing responses, since we expected the data to reflect the teachers' beliefs about the types of mathematical knowledge that they need in order to teach, and therefore hoped would be taught in the PD. This framework, inspired by Shulman (1986), differentiates between subject matter content knowledge (SMCK) and pedagogical content knowledge (PCK), and further refines each of these categories. SMCK is sub-categorized into common content knowledge (CCK - mathematical knowledge that is used in teaching in ways similar to the ways in which it is used in other occupations that use mathematics), specialized content knowledge (SCK - mathematical knowledge that specifically serves teachers when engaging in teaching tasks), and horizon knowledge (HK - an awareness of how mathematical topics are related over the span of mathematics included in the curriculum). PCK is sub-categorized into knowledge of content and teaching (KCT - knowledge that combines knowing about teaching and knowing about mathematics), knowledge of content and students (KCS - content knowledge intertwined with knowledge of how students think about, know, or learn this particular content) and knowledge of curriculum (KC - a familiarity with text books and other teaching resources).

Codes were categorized into one of the six categories of MKT. For example, the code *understanding students' thinking* was categorized as KCS. Some teachers were more verbose than others, and indicated a variety of reasons for selecting activities. In such cases more than one code was assigned to a single quotation, but each code was mapped to one MKT category at most. Some codes (for example *I enjoyed the activity*) were not mapped to any MKT category.

All the coding was carried out by the two researchers, working together. Some quotations were difficult to code and to categorize, due to ambiguity in the teachers' words. These and all other points of disagreement were debated until unanimous agreement was achieved. As a rule, when teachers indicated satisfaction or dissatisfaction with the subject matter, we tended to assume they were referring to

SCK, since the **common** content (CCK) for lower elementary school (the mathematical content that the children should acquire) is quite straightforward.

In our analysis we checked the prominence of the various categories, and looked for trends over time.

ANALYSIS

We begin with some descriptive statistics. In 67 out of the 69 forms the teachers indicated a particularly **successful activity**. A total of 32 different activities were selected as particularly successful, and were indicated a total of 80 times (clearly, some teachers listed more than one successful activity in a single form). Nearly all of the teachers explained their selection. These explanations generated 27 codes in 82 quotations, for example: the quotation "*... use this method to uncover student errors*" was coded as *discovering student errors*. In 24 out of the 69 forms a particularly **unsuccessful activity** was indicated. A total of 12 different activities were selected as particularly unsuccessful and were indicated a total of 24 times. The teachers' explanations for their choice generated 16 codes in 23 quotations, for example: the quotation "*the movie clip was tiresome*" was coded as *tiresome*.

28 out of the 69 forms included **general comments**, which generated 38 codes in 62 quotations. Teachers' general comments, e.g. "*please teach us fractions*", "*I like the PD because it provides tools I can use*", were analyzed separately from teachers' reasons for choosing particular activities. Although general comments do elicit beliefs about knowledge for teaching, we felt that this data suffers from many of the methodological problems we described in the introduction, since they are not situated in learning activities. We analyzed these data, and found that the picture they reveal is similar to the one drawn by the other data, but this analysis is not included here.

The number of quotations associated with each category is summarized in table 1:

SMCK			PCK		
Common Content Knowledge	Specialized Content Knowledge	Horizon Knowledge	Knowledge of Content and Teaching	Knowledge of Content and Students	Knowledge of Curriculum
2	18	0	32	10	0

Table 1: Number of quotations assigned to each knowledge category

We see that reasons related to PCK (42 quotations) were provided twice as many times as reasons related to SMCK (20 quotations). Within SMCK, specialized knowledge is more prominent than common knowledge, and within PCK, KCT is more prominent than KCS. We note that HK and KC were not indicated at all.

We now take a temporal view, presented in figure 1. In order to compare PD sessions, where varying numbers of teachers submitted feedback questionnaires, we normalized the quotation count by dividing by the number of submitted forms. At the

beginning of the PD aspects of PCK were prominent, and this prominence tended to decrease as the PD progressed. Specifically - the average number of PCK-related comments per feedback in the first three sessions was 3 times greater than the average in the other session. On the other hand, the prominence of SMCK started out low and tended to increase over time.

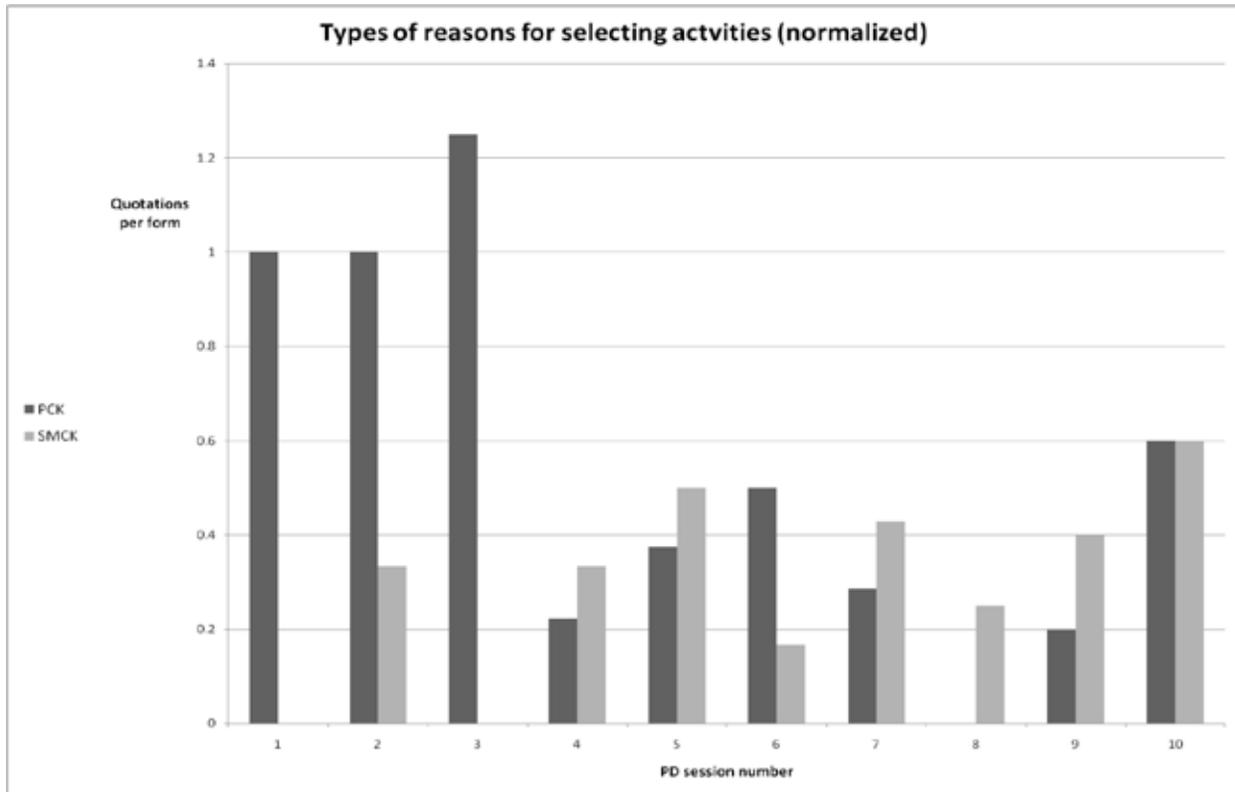

Figure1: SMCK/PCK reasons for selecting activities (normalized)

We see in these findings an indication of a shift in the teachers' beliefs. In this shift, the teachers are moving closer to beliefs that are consistent with the instructors' goals for the PD, focusing on SMCK. We cannot say with certainty what caused this shift, but we speculate that it is connected to the nature of the content that the instructors brought to the course. Initially, the teachers did not believe there was anything new for them to learn about grade 3 mathematics, but the mathematicians managed to bring a new depth to this content, as described in (Cooper & Arcavi, 2012) and in (Cooper & Pinto, 2012). In a broad sense of the term, this can be considered an indication of the teachers' *learning* in the PD.

METHODOLOGY AND ANALYSIS – A DIFFERENT CATEGORIZATION

Our initial analysis provided some interesting results, but we were not totally satisfied with the coding scheme. Ten of our codes, representing 33 quotations (30% of the total), did not map to any MKT category, suggesting that there may have been an important message in the data which we were missing. We decided to look for an alternate categorization scheme, based on the data. Upon re-reading the feedback forms, we realized that the teachers' reasons for selecting particular activities said something not only about *what* they would like to learn, but also about the role of PD

in their eyes, and how it should relate to their teaching. At one end we found quotations implying that the PD should contribute to the teachers' practice in a direct way, mainly by providing classroom activities and teaching tips, for example: "...[the activity] teaches how to teach in the classroom". We call this category *classroom focus*. At the other end we found indication of a loose connection, where the teachers' comments were aimed directly at what occurred in the PD, with little or no reference to teaching practices, for example: "I really enjoyed that activity". We call this category *PD focus*. In between were quotations that indicated a connection between the PD and teaching practice, but not by contributing directly to classroom teaching, for example: "...[the activity] got me thinking about ... how to teach for understanding". This intermediate attitude seems to see the teacher as having a role in incorporating knowledge learned in the PD, and adapting it for her classroom practice. We call this category *teaching focus*. In this new categorization, all codes were assigned a category, suggesting that this categorization has better grounding in the data. This new category scheme is very different from the first. Its categories cut through the various MKT categories, for example, a focus on *classroom* teaching is related to SMCK in some quotations (e.g. "content was not appropriate for my classroom") and to PCK in others (e.g. "...ways for dealing with students' difficulties"). Furthermore, in this new scheme some codes which appeared indistinguishable in terms of MKT were seen to be quite different. For example, *ways for dealing with students' difficulties* is a case of *classroom focus*, whereas the apparently similar *understanding students' thinking* is a case of *teaching focus*. Using the MKT categories, they both mapped to KCS.

We see (table 2) that the quotations are distributed among all three categories, with more prominence for *PD focus*, but again the temporal picture is more interesting (figure 2). The focus on *classroom* practices started high and tended to gradually decline over the course of the PD, whereas the focus on the *PD* itself started out low and increased quite steadily. The prominence of the *teaching* category changed very little over the course of the PD. It appears that teachers started out with beliefs indicating that the PD should contribute to teaching practices in a direct manner, and gradually accepted the possibility of less direct contributions, even to the extent where they consider the PD on its own terms, setting aside the question of how it will contribute to their teaching. This shift in beliefs, like the shift described in the previous section, can be attributed to the nature of the content that the instructors brought to the course. If the teachers accept goals of deepening their understanding of the elementary content as worthwhile, it is natural that they should not see this as contributing *directly* to their teaching practices, since this is not content they will bring to their own classrooms.

Classroom focus	Teaching focus	PD focus
33	20	43

Table 2: What teachers focus on in their reasons for selecting activities

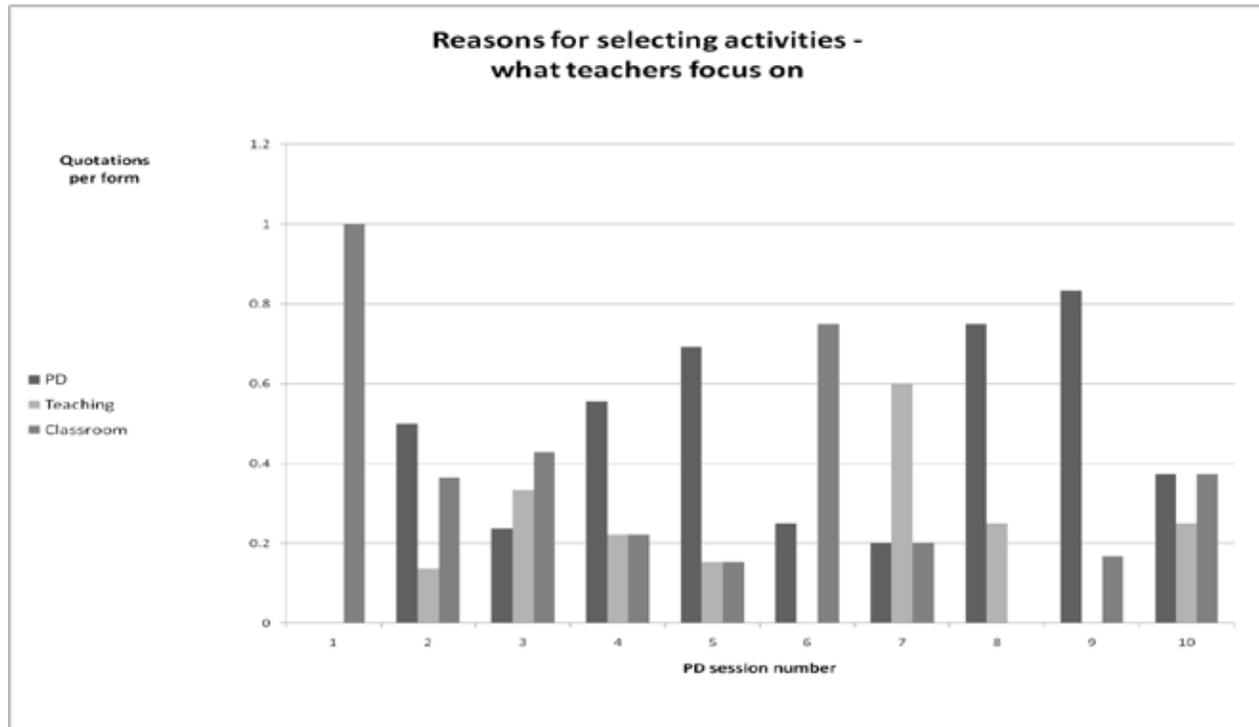

Figure 2: Reasons for selecting activities - normalized

DISCUSSION

We have shown trends in the teachers' attitude towards the PD, both in the knowledge it should focus on, and in the nature of its role as a means for improving teaching practice. The teachers moved from beliefs whereby the PD should enhance mainly PCK in a manner that can be utilized in classrooms, to beliefs whereby the PD may also enhance SMCK, and that the PD need not focus on classroom teaching directly. Although the change is modest, this is encouraging news for teacher educators, since it is usually difficult to show evidence of changes in teacher beliefs as a result of PD. But beyond these results, we would like to reflect on the research *method*.

Validity and reliability of the methodology

Although we believe that teachers *have* beliefs that transcend particular situations, our methodology is grounded in a particular situation - the PD. It is not only the teachers' beliefs that changed; the teacher educators' goals and the nature of the activities evolved in parallel. The change that we have shown is in the beliefs of the teachers *as they interact with the activities and the instructors*⁴. In this context issues of sustainability are not pertinent⁵. The scope of the teachers' beliefs about knowledge for teaching is the duration of the PD. This is acceptable, since our interest in these beliefs is mainly how they affect the teachers' attitudes toward learning in the PD.

The reliability of our method would appear to be dependent on the particular activities in the PD. Were the activities varied enough to elicit a broad spectrum of beliefs about knowledge for teaching? We believe the answer is yes, though space

constraints do not permit us to describe these activities. However, we wish to claim that such a description would have been of limited relevance. When a teacher says that an activity was successful because it *suggested ways for dealing with students' difficulties*, we are concerned mainly with the implication that knowing how to deal with student difficulties is important knowledge for this teacher. The question of reliability is thus whether each PD session provided activities that were rich and varied enough to elicit the teachers' beliefs reliably. Consider, for example, what would happen if all the activities in a particular session were to focus exclusively on SMCK. There would be no opportunities for the teachers to select a successful activity based on its PCK nature. This is a serious concern, which is addressed as follows: If there is a lack of activities which focus on PCK, teachers will still be able to indicate their beliefs about the importance of PCK through *unsuccessful* activities ("*this activity was unsuccessful because it did **not** address PCK*"). If the feedback questionnaires had asked only about successful activities, reliability would have relied strongly on the variety of the PD activities. The coupling of the two questions greatly reduces the dependence on the choice of activities.

CONCLUSION AND IMPLICATIONS

This paper has both practical and methodological implications. On the practical side, it highlights an unusual PD course, conceived by a mathematics professor and taught by mathematics Ph.D. students, where there is an explicit focus on SMCK and on teachers' attitudes to mathematics. We have shown a change in teachers' beliefs during the course, and there is reason to believe that this change is a result of the PD. This suggests that the PD is worthy of the careful scrutiny it is receiving in the first author's Ph.D. dissertation. One of the issues under investigation is how these teacher educators, with their university approach to mathematics, managed to influence the teachers' beliefs. On the methodological side, we presented an indirect approach to eliciting teachers' beliefs about knowledge for teaching. This method was shown to be sensitive enough to reveal a change in teachers' beliefs. Although the change was modest, we have more faith in these results than we would have had in results obtained directly, for all the reasons listed in the introduction to this paper. We believe our method is less susceptible to teachers' tendency to gratify researchers, and can reveal tacit beliefs which may even contradict their declared beliefs. Whether or not this method really is an improvement over traditional methods is an important question left for future research.

NOTES

¹ PD is used throughout the paper for "professional development".

² One of the instructors was a mathematics Ph.D. student, the other was a computer science M.Sc. student.

³ The scope of this paper does not permit us to describe the activities to which the teachers referred. Data of this nature will be presented at the conference.

⁴ The nature of this interaction is a central research question in the first author's Ph.D. dissertation.

⁵ The PD's impact on teaching practices is being investigated in the first author's Ph.D. dissertation.

A THEORETICAL CONSTRUCT TO ANALYZE THE TEACHER'S ROLE DURING INTRODUCTORY ACTIVITIES TO ALGEBRAIC MODELLING

Annalisa Cusi and Nicolina A. Malara

Università di Modena & Reggio Emilia

Abstract

In this work we will introduce a theoretical construct that we have elaborated as a tool for the analysis and the interpretation of the teachers' actions during class activities which are aimed at fostering an aware learning of the use of algebraic language as a thinking tool. Through the analysis of an excerpt of a class discussion concerning introductory activities to algebraic modelling, we will show how this construct could provide "transparent" indicators to highlight the effectiveness of the teachers' actions during class interaction.

1. INTRODUCTION

The idea of an early approach to algebra, with a strong focus on generational activities (Kieran 1996) to help students overcome the well-known difficulties they usually face in the study of the formal aspects of algebra, is widespread and consolidated (Kaput&Al. 2007, Cai&Knut 2011).

Starting from the 90s, these ideas are developed by research together with a new vision of the teaching of arithmetic, characterised by a focus on relational aspects and meta-level activities, aimed at making students control the properties subtended to arithmetical equalities in order to create a connection between arithmetic and algebra (Kieran 1996, Lincevski 1995). Although in the first decade of 2000 many research studies are devoted to the implementation of these activities at school (also at the primary level), only few of them consider the role played by the teacher together with the problem of teacher education (Carpenter&Franke 2001, Blanton&Kaput 2001).

Our research studies, that can be conceived within this frame, are devoted to the planning of innovative didactical paths in arithmetic and algebra (grades 4-8) to be implemented through a socio-constructive approach in a strict cooperation with the teachers (Malara&Navarra 2003). The possibility to cooperate with different teachers (while in the first period we only collaborated with teacher-researcher, in these last ten years many other motivated and experienced teachers were involved) enabled us to highlight two main gaps: (1) a gap between the teachers' declared conceptions and the hidden ones displayed by their behaviours in the classes; and (2) a gap between the theoretical assumptions they shared with researchers and their actual practice (Malara 2003). These results suggested us to focus not only on class experimentations but also on teacher education activities. In tune with Mason (1998) and Jaworski (2003) ideas, we designed and implemented specific tools and methods aimed at fostering teachers' development of different levels of awareness through the activation of joint critical-reflection practices (Cusi, Malara&Navarra 2011).

Our actual research objective is to design a specific methodological tool aimed at guiding teachers in the fundamental process of a-posteriori reflection on their own

practice. Our idea is to refer to a theoretical construct, that has been defined as a result of one of our studies (Cusi&Malara 2009, Cusi 2012), as both a diagnostic tool in the analysis of class processes and a tool for teachers' self-reflection on their own teaching: the construct of “*model of aware and effective attitudes and behaviours*” (in the following M-_{AE}AB). Although it was aimed at identifying the specific features of a teacher who is able to make his/her students develop fundamental competences in the use of algebraic language as a tool for thinking, we believe that this construct could represent an effective “theoretical lens” for the analysis of the role played by the teacher, even during different algebraic activities, such as those aimed at the introduction of algebraic modelling.

In the following, we will introduce the M-_{AE}AB construct in the theoretical frame within which it has been developed and, through the analysis of a class excerpt, we will show how it could be referred to as a tool for analyzing the role of the teacher during introductory activities to algebraic modelling, highlighting its effectiveness in providing “transparent” indicators to describe the teachers' actions.

2. THE M-_{AE}AB CONSTRUCT FOR THE ANALYSIS OF THE TEACHER'S ROLE

The theoretical frame within which the M-_{AE}AB construct has been developed is constituted by two threesomes of components. The *first threesome* refers to the theoretical components we identified for the analysis of the development of thinking processes through algebraic language: (a) the model of didactic of algebra as a thinking tool proposed by Arzarello&Al. (2001), who, in particular, highlight the essential role played by the activation of conceptual frames and appropriate changes from a frame to another for a correct interpretation of the algebraic expressions which are progressively constructed; (b) the idea of anticipating thought developed by Boero (2001), who introduces it as a key-element in the “game” transformation-interpretation, which is typical of the processes of construction of reasoning through algebraic language; (c) the theoretical analysis proposed by Duval (2006), who identifies in the coordination between different representation registers a critical aspect in the development of learning in mathematics. Thanks to previous studies (Cusi 2009) we were able to highlight that an effective use of algebraic language as a thinking tool requires the management of three main key-components: (a) the appropriate application of conceptual frames and coordination between different frames; (b) the application of appropriate anticipating thoughts; and (c) the coordination between algebraic and verbal registers (on both translational and interpretative levels).

The *second threesome* of components is related to our theoretical framework of approach to the study of the teaching-learning processes and of the role played by the teacher. The first component is Vygotskian: we, in particular, refer to Vygotsky's stress (1978) on the importance of a teaching aimed at expanding students' zone of proximal development in order to stimulate, thanks to their interaction with the teacher or with more expert classmates, the activation of internal learning processes associated to a higher level of mental development. The second component draws its

inspiration from the work carried out by Leont'ev (1978), who stresses the importance of making students increase their awareness about the meaning of the processes they activate during class activities in order to foster their learning. Our third component is the cognitive apprenticeship model introduced by Collins & Al. (1989), which draws its inspiration from an idea of learning as an “aware” apprenticeship and pursues the objective of “making thinking visible”, through the activation of teaching methods which give students the opportunity of observing, discovering or even inventing the experts’ strategies in the same context in which they are worked out. We, in particular, refer to two sets of typical methods of cognitive apprenticeship: (a) modeling, coaching and scaffolding, aimed at helping students acquire skills through processes of observation and guided practice; (b) articulation and reflection, related to metacognitive objectives and aimed at helping students achieve a conscious control of their own problem-solving strategies.

We believe that the ‘games’ of coordination between different linguistic registers and of interaction between the syntactical level, the interpretative level and the level of activation of anticipating thoughts, which can be automatically set up by an expert, *should be “made visible” to novices* in order to make them acquire and understand their meaning. Therefore our hypothesis is that, in order to help students progressively develop the competences and awareness necessary to carry out advanced tasks through an effective use of algebraic language, it is necessary that the teacher, during class interaction, adopts and makes visible specific attitudes and behaviours. *In this way, his/her students could be guided to the acquisition of the same attitudes and behaviours, which corresponds to an effective management of the three key-components we have previously introduced.*

This is the reason why we decided to refer to the expression “*teacher as a model of aware and effective attitudes and behaviours*” to highlight the approach of a teacher who consciously behave with the constant objective of “making thinking visible”, in order to make his/her students focus not only on syntactical aspects but also on the effective strategies and on the meta-reflections on the actions which are performed.

In order to identify the peculiar characters of a teacher able to adopt this kind of approach in the class, during previous studies (Cusi&Malara 2009; Cusi 2012) we analyzed the audio-recordings of whole class activities and the subsequent students’ small-groups activities, with the aim of highlighting: (1) *the role* played by the teacher during class activities as a “stimulus” to foster an approach to algebra as a tool for thinking, and, (2) *the links between the types of approach proposed by the teacher and the types of approach chosen by students* during small-groups activities, with particular reference to the meta-reflections they propose. It is important to stress that the teachers who carried out the activities we analysed (activities focused, as we stated before, on the construction of proofs by means of algebraic language) have been involved in a shared process of both didactical innovation and professional development conceived within the theoretical framework we presented before and were therefore aware of the importance of acting with the constant aim of “making thinking visible”.

Thanks to our analysis of class discussions and students' small groups activities, we were able: (1) on the one hand, to highlight how unsuitable teacher's choices can lead to a missed acquisition of competences and awareness by students; (2) on the other hand, to identify the specific characteristics of a teacher who is able to act in order to foster students' acquisition of the key-competences in the use of algebra as a thinking tool and their development of an awareness of the meaning of the activated processes. The distinguishing features of an effective approach were, therefore, identified highlighting not only the teacher's capability of making his/her fundamental thought processes "visible" to students, but also the development of new competences the students display when they autonomously face the same kind of problems. These features, which can be placed in some fundamental behavioural categories of the cognitive apprenticeship, characterize the M_{AEAB} construct.

The following table summarizes the characters of a teacher who poses him/herself as a M_{AEAB} , relating them to our theoretical framework of reference: in the first column the main roles of a M_{AEAB} are recapped; in the other columns the associated teacher's actions (second column) and the reference to our theoretical framework (third column) are highlighted.

Roles played by a teacher who acts as a M_{AEAB}	Corresponding actions of the teacher	Reference our theoretical framework
(a) <i>Investigating subject and constituent part of the class in the research work being activated</i>	He/she tries to stimulate in his/her students and attitude of research towards the problem being studied	It is in tune with <i>Vygotsky's</i> ideas of learning as a social process, according to which the interaction with adults or with more expert peers enables students activate internal learning processes which help them achieve a higher level of mental development.
(b) <i>Practical/Strategic guide</i>	He/she shares (rather than transmit) with his/her students the adopted strategies and the knowledge to be locally activated.	It refers to the <i>modeling category of cognitive apprenticeship</i> : it requires that an expert performs a task externalizing the internal processes in order to make students observe and build a conceptual model of the processes that are required to accomplish it.
(c) <i>"Activator" of processes of generalization, modelling, interpretation and anticipation</i>	He/she provokes and stimulates the construction of the key-competences for the development of thought processes by means of algebraic language	The teacher has to play the role of both: <ul style="list-style-type: none"> - activator of <i>interpretative processes</i> (fostering a correct identification of the <i>conceptual frames</i> that have to be chosen to correctly interpret and transform algebraic expressions and a good <i>coordination between different frames</i>) and - activator of correct <i>anticipating thoughts</i>. At the same time it refers to the <i>categories of modeling, coaching</i> (which consists of offering to students hints and feedback while they carry out a task) and <i>scaffolding</i> (it refers to the supports the teacher provides to help students carry out a task).

<p>(d) <i>Guide in fostering a harmonized balance between the syntactical and the semantic level</i></p>	<p>He/She helps his/her students control the meaning and the syntactical correctness of the algebraic expressions they construct and, at the same time, the reasons underlying the correctness of the transformations they perform.</p>	<p>It requires to foster a good coordination between the verbal and the algebraic <i>register</i>, through the activation of <i>correct conversions</i> and <i>treatments</i> (Duval 2006). This role also refers to the <i>articulation category</i> of cognitive apprenticeship, which involves the methods applied to make students articulate their knowledge, way of reasoning and problem-solving processes.</p>
<p>(e) <i>Reflective guide</i></p>	<p>He/She stimulates reflections on the effective approaches carried out during class activities in order to make students identify effective practical/strategic models from which they can draw their inspiration.</p>	<p>Through this role, the teacher highlights those processes which can be associated to an effective activation of the <i>three key-competences</i> in the use of algebraic language as a thinking tool. It refers, in particular, to the <i>reflection category</i> of cognitive apprenticeship, which involves enabling students to compare their own problem-solving processes with those of an expert or of another student, so that they ultimately could be able to compare them with an <i>internal cognitive model of expertise</i>.</p>
<p>(f) <i>“Activator” of both reflective attitudes and meta-cognitive acts</i></p>	<p>He/She stimulates and provokes meta-level attitudes, with a particular focus on the control of the global sense of processes.</p>	<p>The focus is on the <i>control of the processes associated to a real acquisition of the key-competences</i> in the use of algebraic language as a thinking tool. Again the reflective practices that the teacher aims at provoking are focused on the <i>articulation</i> of the activated processes in order to evaluate their appropriateness. Playing this role, which also refers to the <i>reflection category</i>, fosters, in tune with the ideas developed by <i>Leont’ev</i>, students’ development of a real awareness of the meaning of both the class activities and the learning processes themselves.</p>

The first three roles (a, b, c) that a teacher should perform in the class require him/her to carry out the activities posing him/herself not as a “mere expert” who proposes effective approaches, but as a *learner* who faces problems with the main aim of making the hidden thinking visible, highlighting the objectives, the meaning of the strategies and the interpretation of results. The other three distinctive characteristics of the profile of a teacher as a $M_{AE}AB$ (d, e, f) refer to a different role played by the teacher: he/she must also be a point of reference for students to help them clarify salient aspects at different levels, with an explicit connection to the knowledge they have already developed.

The previous table highlights that the algebraic and the social/methodological dimensions of our theoretical framework result to be complementary in combining to each other to foster an analysis of the teaching practices that goes beyond the discourse of the teacher in such a manner as to highlight the underlying intentions that link directly to the mathematics at stake. For this reason, it is important to stress that our aim is not to give an exhaustive definition of “effective teaching” as an absolute. Nevertheless, through the distinctive features of the $M_{AE}AB$ we aim at identifying those teaching practices that can directly influence the quality of student

learning in the specific context of the teaching of algebra. At the same time, the construct enables the identification of those attitudes and behaviour that can negatively influence students' learning. As we stated before, in fact, our studies allowed us to contrast the positive effects of this kind of approach with the effects of an approach which is not in tune with the M_{AEAB} construct, which can provoke students' development of a sort of pseudo-structural approach to the use of algebraic language as a thinking tool (Cusi 2012).

3. THE ANALYSIS OF A CASE

In this paragraph we analyze an excerpt of a class discussion focused on an introductory activity to algebraic modeling, referring to the M_{AEAB} construct as an a-priori tool for analyzing teaching.

The excerpt refers to the initial part of a discussion conducted in a first class of lower secondary school (grade 6). The teacher, who is really motivated and interested in engaging with projects aimed at fostering curricular innovation, has collaborated with us in different experimentations, sharing with us the aims, the methodology and the meaning of the approach subtended to the activities we promote. Since the following discussion constitutes a good example of conduction of class activities aimed at the introduction of algebraic modelling, we chose to focus on this excerpt in order to test the effectiveness of the M_{AEAB} construct in providing "transparent" indicators to describe effective teachers' interventions.

The specific activity was proposed at the end of an introductory path to the algebraic modelling of figural sequences. The problem situation was adapted from the Pisa task usually named as "the apple trees". The characterizing feature of this task is the combination of the figural and verbal registers with the aim of fostering generalization and the algebraic formalization of the relationship between the number of apple trees and the number of conifers in the different possible configurations. In order to simplify the problem situation and to help students in its exploration and in making the identified relationships explicit, tables were introduced together with the requirement of specific argumentations. Due to space limitations we do not present the original worksheet, but only the proposed patterns and the first questions.

<p>n = 1</p> <pre> X X X X ● X X X X </pre> <p>n = 2</p> <pre> X X X X X X ● ● X X ● X X ● ● X X X X X X </pre> <p>n = 3</p> <pre> X X X X X X X X ● ● ● X X ● ● X X ● ● ● X X ● ● ● X X X X X X X X </pre> <p>n = 4</p> <pre> X X X X X X X X X ● ● ● ● X X ● ● ● X X ● ● ● ● X X ● ● ● ● X X ● ● ● ● X X ● ● ● ● X X X X X X X X X </pre>	<p>Below you can find the patterns which represent the disposition of apple trees and conifers in relation to the number (n) of the rows of apple trees.</p> <ol style="list-style-type: none"> 1) After having carefully observed the patterns, what can you say about the disposition of apple trees and conifers in the different cases? 2) Try to reproduce, through a drawing, the disposition of apple trees and conifers when $n=5$. Motivate your answer. 3) Explain how you can find the number of apple trees if you know the number of rows.
---	--

In the class discussion that we propose, the teacher tries to guide her students to the exploration of the number of conifers and apple trees in the different patterns. The left column of the following table contains the excerpt of the first part of the discussion (T stands for the teacher, while the other alphabetical letters stand for the different students who take part in the discussion; due to space limitations we will skip some interventions which are not fundamental in the development of the discussion). In the right column we propose an analysis of the teacher's interventions with reference to the M_{AEAB} construct.

Class discussion excerpt	Analysis of T' interventions through the M_{AEAB} construct
<i>The class exploration starts with T's request of reproducing the patterns on the workbook while she is doing the same at the blackboard.</i>	
1. T: What did you check, while I was drawing on the blackboard, to exactly reproduce the disposition of apple trees and conifers?	T poses herself as an <i>investigating subject</i> , stimulating an attitude of research towards the problem. Moreover she simulates an <i>attitude of sharing</i> .
2. M: (I checked) how many conifers there are on each side. ... <i>Other pupils intervene.</i> 6. K: In the first drawing there are 9 conifers.	
7. T : In the first drawing there are 9 conifers. How did you determine the correct number of conifers, K?	T poses herself as a <i>reflective guide</i> . When K looks at the total number of the conifers and makes a mistake, T does not express any judgment. On the contrary, she intervenes to turn K's attention to the counting strategies he adopted in order to prompt a correct attitude of inquiry and to foster a self-correction.
8. K: I did 3... 3... I got wrong.	
9. T: Try to explain that.	T poses herself as an <i>activator of metacognitive acts</i> : she fosters an attitude of enquiry, encouraging K so that he can be able to make his thoughts explicit.
10. K: They are 8. I considered 3 at the beginning, on the first side, then I added 2, then 2 on the other side, and then 1.	
11. T: Eight. Good, K! And how many apple trees are there instead, G?	T encourages again the students and poses herself as a <i>practical-strategic guide</i> , making them focus on the first configuration and re-directing the inquiry towards the identification of the interrelation between the number of conifers and the number of apple trees.
12. G: One!	
13. T: Let's explore the other representations as well. How many conifers are there in the second representation?	T poses herself as a <i>participant</i> , constituent part of the class group, and as a <i>strategic guide</i> , drawing students attention toward the second configuration.
14. GF: 8 multiplied by 2. Two is the number of the rows. Therefore 16.	
15. T: A said that he would have wanted to know how many apple trees are exactly in the drawing.	T poses herself as an <i>activator of reflective attitudes</i> , trying to focus students' attention to a comparison between the different cases. Focusing on the objective of the discussion, she is also trying to activate correct

	<i>anticipations</i> , with the aim of making them highlight a correlation between the number of conifers and the number of apple trees.
16. GP: In this one there are 4 (apple trees)	
17. M: I noticed that the number of rows is equal to the number of apple trees in the rows.	
18. T: What would you say about M's observation?	T does not judge M's observation and ask the other students to examine it, posing herself as a <i>reflective guide</i> , with the aim of both stimulating reflections on the different approaches proposed and making them explicit.
19. A: It's right. When $n=2$ there are two apple trees in every row.	
20. G: So, in order to calculate the number of apple trees in the enclosure we should multiply the number of the rows by the number of trees in every row.	
21. K: I didn't understand anything.	
22. T: The observations actually overlapped.	When K declares his doubts, T poses herself again as a <i>participant</i> , stimulating the class in order that the different proposed observations could be better made explicit. In this way she fosters the sharing of knowledge and poses herself as an <i>activator</i> of both <i>reflective attitudes</i> and <i>metacognitive acts</i> .
23. G: I meant to say that in this case, K, in order to calculate the number of apple trees you must take the number of apple trees in every row and multiply it by the number of rows. Therefore two multiplied by two.	
24. M: That is you must multiply the number of rows by itself because the number of apple trees is equal to the number of rows.	
25. T: So let's see if I am able to understand. What do "the number of rows" and "the number of apple trees in every row" mean?	Instead of evaluating G and M's observations, T poses herself as a <i>reflective guide</i> , asking students' to clarify the meaning of some terms, with the aim of "making their thinking visible". At the same time she poses herself as an <i>activator of interpretative processes</i> , trying to stimulate correct conversions from the verbal to the symbolic register.
26. A: The rows are those (he points at the drawing) ... that is the number of rows, how many rows there are. The number of apple trees is how many apple trees there are in every row.	
27. K: I have understood!	
28. T: I have understood now. Thanks, M. So how can we write this number 4 which stands for the number of apple trees?	T <i>stimulates</i> and <i>provokes</i> the <i>construction</i> of key-competences for the development of thought processes by means of algebraic language, posing herself as an <i>activator of interpretative processes</i> , gradually stimulating the <i>activation of correct conversions from the verbal to the symbolic register</i> .
29. Group of students: 2 multiplied by 2!	
<i>The discussion continues with the analysis of the number of the conifers in every pattern and the following identification of the symbolic expressions which represent the relation between the number of apple trees and the number of conifers in every configuration and the number of rows. Lastly it ends with a naive study of an inequality in order to determine in what cases the number of the apple trees exceeds the number of the conifers.</i>	

4. FINAL REMARKS

The analysis we conducted testifies that the M_{AEAB} could represent an effective diagnostical tool in the analysis of the quality of the teacher's management of introductory activities to algebraic modeling. Through the theoretical lenses we adopted, in fact, it was possible to highlight an effective action of the teacher, characterised by a specific focus on the strategies aimed at making students control their thinking processes and develop an awareness about the meaning of the performed activities. In this discussion the teacher's interventions associated to the roles strictly connected to the algebraic dimension of our construct are less frequent than the roles associated to the meta-cognitive dimension. For this reason, the construct could also enable to highlight that, while during global-meta-level activities (Kieran 1996) there is a need of a good balance between the algebraic dimension and the meta-cognitive dimension, introductory activities to algebra requires a major focus on those roles which can better help students develop a deep awareness of the meaning of the processes they are involved in.

We believe that the M_{AEAB} construct could be also a useful tool to promote teachers' reflection on their own practice. In tune with Mason's idea of teaching as "educating awareness" (1998), we think that making the teachers analyse their class processes through specific theoretical lenses could provoke what Mason defines "shifts of attention", which play an essential role in fostering the development of new awareness and hence in determining an effective teaching. We believe indeed that these activities could allow teachers to perform their first "guided" reflective practices, receiving and afterwards interiorizing the necessary stimulus for the construction of their own models for reflection, to which they can refer everytime they have to analyse their practice. In the future we intend to test this hypothesis referring to the M_{AEAB} construct in the work with both pre-service and in-service teachers, proposing it to them as a tool for self-analysis.

USING REDIRECTING, PROGRESSING AND FOCUSING ACTIONS TO CHARACTERIZE TEACHERS' PRACTICE

Ove Gunnar Drageset

University of Tromsø, Norway

'Redirecting, progressing and focusing actions' is a framework for describing how teachers use students' comments to work with mathematics. In this article, the framework is presented using examples from two teachers' practices. Then the article demonstrates how this framework can be used to characterize the two practices and differences between them.

Keywords: Communication – Teachers role – Orchestrating discourse

INTRODUCTION

There is a need for more detailed understanding of communication in practice generally, and how teachers' use or not use students' comments to work with mathematics. This article presents an example of how the framework of 'redirecting, progressing and focusing actions' (Drageset, 2012) can be used to characterize teachers' practice. This is done by looking into the amount of different types of teacher comments in two teachers' practices and exemplifies how this might be interpreted.

COMMUNICATION

Researchers often finds that classroom discourses are dominated by teacher talk, in a discourse pattern where the teacher initiates the questions, the students respond to them, and the teacher evaluates the responses (Franke, Kazemi, & Battey, 2007). This pattern is often labeled as IRE (initiation-response-evaluation). Cazden (2001) describes IRE as 'the default option – doing what the system is set to do 'naturally' unless someone makes a deliberate change' (Cazden, 2001, p. 31). In this pattern, the students are normally engaged in a procedure-bound discourse, such as calculating answers and memorizing procedures, and with little emphasis on 'students explaining their thinking, working publicly through an incorrect idea, making a conjecture, or coming to consensus about a mathematical idea' (Franke et al., 2007, p. 231).

During what Stein, Engle, Smith and Hughes (2008) call the first generation with respect to mathematical discussions in the classroom, focus was on the use of cognitively demanding tasks, encouragement of productive interactions, and letting the students feel that their contributions were listened to and valued. Little attention was directed towards how teachers can guide the class towards worthwhile mathematics, and many teachers had the impression that guidance should be avoided (Stein et al., 2008). The result could be that the students took turns sharing their solution strategies without any filtering or highlighting.

However, even though an increased level of discourse is positively related to student learning we know that just getting students to talk is not enough (Franke et al., 2007). Merely making your thinking available to others is insufficient because too much is normally unsaid. The manner in which we make our thoughts available seems to be crucial (Kieran, 2002). Consequently, details matter, or in the words of (Franke et al., 2007, p. 232): ‘One of the most powerful pedagogical moves a teacher can make is one that supports making detail explicit in mathematical talk, in both explanations given and questions asked’

The second generation practice ‘re-asserts the critical role of the teacher in guiding mathematical discussions’ (Stein et al., 2008, p. 320). The hallmark is that the teacher actively uses students’ ideas and work to lead them toward more powerful, efficient and accurate mathematical thinking. Ball uses the term ‘show and tell’ as an example of the same:

‘For the lesson to be more than a drawn out “show and tell” of the different methods requires the composition of a mathematical discussion that takes up and uses the individual contributions ... making available one child’s thinking for the rest of the class to work on.’ (Ball, 2001, p. 20)

Ball here emphasizes an active use of students’ contributions. However, even though there is increasing agreement that students’ contributions must play an important role in classroom communication there is a need to understand how this can be achieved. Carpenter, Fennema, Franke, Levi and Empson (1999) suggest using a careful selection and sequencing of student strategies. Stein et al (2008) suggest a similar strategy as part of a model that specifies five key practices in order for a teacher to use student responses more effectively in discussions; anticipating likely student responses, monitoring, selecting responses to be presented, sequencing the presentation, and making connections.

This model may move attention away from learning mathematical content independently of student thinking. Instead, attention is directed towards how students’ thinking about mathematical content can be used to create reflection and learning. Such a strategy will also give the teacher regular access to students’ ideas and the details that support them. This is essential knowledge for teaching and learning in mathematics (Franke et al., 2007).

Fraivillig, Murphy and Fuson (1999) and Cengiz, Kline and Grant (2011) report studies of how teachers actively use the students’ ideas to lead them towards more powerful, efficient and accurate mathematical thinking and in which situations this occurs. Fraivillig et al (1999) present a framework called ‘Advancing children’s thinking’ (ACT) based on an in-depth analysis of one skilful first grade teacher. The framework has three components: eliciting children’s solution methods, supporting children’s conceptual understanding, and extending children’s mathematical thinking. While the eliciting and supporting components focus on the assessment and facilitation of mathematics with which the students are familiar, the extending

component is focused on the further development of the students' thinking. Each of these components is defined by several categories of instructional techniques, for example 'encourage elaboration', 'remind student of conceptually similar situations' and 'demonstrate teacher-selected solution methods'.

Alrø and Skovsmose (2002) introduce the notion of inquiry co-operation as a particular form of student-teacher interaction when exploring a landscape of investigation. As part of the inquiry-cooperation model they identify eight communicative features: Getting in contact, locating, identifying, advocating, thinking aloud, reformulating, challenging and evaluating. These features were present both in the student-student interaction and in the teacher-student interaction.

Several scholars have described a phenomenon where the teacher dominates the solution process and in different ways reduces the complexity for the students. Brousseau (1997) describes that teachers sometimes provides more and more information to help students when they fail repeatedly. The result is that the teacher gradually takes responsibility for the essential part of the work. When the target knowledge disappears completely, Brousseau (1997) describes it as the Topaze effect. A similar way for teachers to reduce complexity for students is described by Lithner (2008) using the term guided algorithmic reasoning. In guided algorithmic reasoning 'all strategy choices that are problematic for the reasoner are made by a guide, who provides no predictive argumentation' (Lithner, 2008, p. 264) and the remaining routine transformations are executed without verificative argumentation. Predictive arguments are related to why the chosen strategy will solve the task, while verificative arguments are related to why the strategy solved the task. A third concept for this phenomenon is funneling (Wood, 1998). A teacher's questions funnel the conversation when the teacher does most of the intellectual work and 'the student's thinking is focused on trying to figure out the response the teacher wants instead of thinking mathematically himself' (Wood, 1998, p. 172).

Several studies have developed tools for characterizing teaching practices, such as Wood's (1998) funneling and focusing and Brendefur and Frykholm's (2000) four levels of communication. While these concepts have explanatory power in the study of entire practices, the limitation lies in the lack of detail. Other studies, such as 'Advancing children's thinking' (Fraivillig et al., 1999), its further development by Cengiz et al (2011), the inquiry co-operation model described by Alrø and Skovsmose (2002) are different, as these studies characterize elements found in teaching without describing an entire practice. These are concepts that enable us to describe single teacher comments at a level of detail which is not possible using more general concepts such as funneling and focusing. Detailed descriptions are critical for researchers to be able to describe and analyze teachers' communication in more detail. It is also crucial for professional development as teachers have little use for general advice. Further development of detailed frameworks is needed in order to create concepts to describe and understand how single comments might contribute to the mathematical discourse.

PURPOSE OF THE ARTICLE

The purpose of this article is to illustrate how the framework of redirecting, progressing and focusing actions can be used to characterize and interpret teachers' communication in practice.

REDIRECTING, PROGRESSING AND FOCUSING ACTIONS

The redirecting, progressing and focusing actions framework was developed through several stages. The data comes from five teachers practices at upper primary (grade 5-7, students aged 10-13). All their mathematics teaching for one week was filmed from the start of the topic of fractions, typically four or five lessons. The five teachers participated in a larger survey (Drageset, 2009, 2010) and were selected for further study based on a selection of diverse profiles from the survey. Altogether this meant that the data was approximately 2000 teacher comments. In this case a teacher comment is defined to be a response to a student comment.

In the first step of the development, each teacher comment of several excerpts from five teachers was characterized with respect to how teachers use or not use student comments to work with mathematics. Similar comments were collected in groups that formed initial categories with a preliminary definition. The definitions were inspected with each comment added and adjusted whenever necessary, and categories were sometimes divided or merged as a result of this. When the categories seemed to have stabilized, all the rest of the data were coded. During this coding the definitions were adjusted whenever necessary, and also at this stage some new were created, some were merged and others divided. During the end of this work the categories were organized in three superordinate groups, the redirecting, progressing and focusing actions. This method has similarities with grounded theory (Charmaz, 2006; Glaser, 1978; Glaser & Strauss, 1967). However, this is done without following the original emphasis on discovery, detachment of theory, and the step-by-step procedure. For further information about the development, see Drageset (2012).

TWO CASES COMPARED

This article will use the practices of Anne and Linda, two of the original five teachers, as an example. During the filming of Anne and Linda, their practices were considered to be quite different. Their practices were described in several ways, both intuitively and using existing concepts and coding schemes. For example, concepts from 'The knowledge quartet' (Rowland & Turner, 2009; Rowland, Turner, Thwaites, & Huckstep, 2009) and the 'Content knowledge for teaching' framework (Ball, Thames, & Phelps, 2008) and the coding scheme for measuring the quality of mathematics in instruction (LMT, 2006) were used. But all these failed to have any explanatory power related to the perceived differences. When these initial attempts were unsuccessful, it was decided to instead try the approach of characterizing single comments and creating categories of similar comments. This turned out to be a more productive approach, resulting in the framework of 'Redirecting, progressing and focusing actions' (Drageset, 2012).

ACTION	CATEGORY	ANNE	LINDA
Redirecting		6 %	22 %
	Put aside	2 %	8 %
	Advising a new strategy	2 %	5 %
	Correcting question	2 %	9 %
Progressing		58 %	53 %
	Demonstration	3 %	7 %
	Simplification	4 %	17 %
	Closed progress details	45 %	26 %
	Open progress initiatives	5 %	2 %
Focusing		36 %	25 %
	Enlighten detail	10 %	7 %
	Justification	2 %	1 %
	Apply on similar problems	0 %	0 %
	Requesting assessment from other students	2 %	0 %
	Notice	20 %	13 %
	Recap	3 %	4 %

Figure 1: Amount of each category and summarized for each action. The percentages are based on number of comments. When ‘Put aside’ is 2% for Anne it means that 2% of all of Anne’s comments were of this type.

The three redirecting actions of ‘put aside’, ‘advising a new strategy’ and ‘correcting questions’ are all comments with the common feature of trying to change the students approach. Linda uses redirecting actions far more than Anne (see figure 1). In fact, more than one fifth of all Linda’s comments were about changing the students approach without trying to understand the reasons behind the answers given. Especially the categories of ‘correcting questions’ and ‘put aside’ are used far more by Linda than by Anne. This is consistent with the intuitive observation that this teacher gives fast, direct and sometimes harsh feedback to the students. One example of Linda’s direct feedback is this one (an example of ‘put aside’):

Teacher: No, but we are not talking about pizza now, we are talking about... pure calculation with numbers, what is it that really happens?

This comment works redirecting because the student approach is rejected and a new direction is suggested. It is also fairly direct, not giving any form of support to the student’s suggestion. And even with less direct feedbacks like ‘I think you answer on

something different than I ask for' (Linda) such a large amount of redirecting actions will necessarily characterize the practice.

Anne seemed to avoid such confrontations by rarely using redirecting actions. Instead, Anne used focusing actions considerably more than Linda. By using focusing actions instead of redirecting actions, she appreciates the student's approach and might also understand more of the reasons behind it. However, the dominating type of focusing actions in Anne's practice is 'notice'. This is comments that stops or even interrupts the students and points out what the teacher finds important. It is a teacher-led focusing action, as this example from Anne's practice illustrates (the teacher just asked what the student did to expand the fraction):

Student: Expanded by four

Teacher: You expanded by four, so that you could have a common denominator. Yes.

The core of 'notice' is that the teacher points out and emphasizes some information that occurs during a dialogue. Sometimes 'notice' comments acts supporting for the student, and sometimes it is a way to add information necessary for the rest of the students to understand.

While Anne's practice has a considerably larger amount of focusing actions than Linda's practice, they are similar in that 'notice' is the dominating type of focusing actions and that the other major type is 'enlighten details'. One example of the use of 'enlighten details' from Linda's practice is this one (the task is to find out how many fifths nine of fifteen chips are):

Student: The answer is three

Teacher: The answer is three. Explain to me. Here are three. Here are three fifteenths... no fifths, is it? Three, six, nine, twelve, fifteen, there are fifteen chips. What are three fifths then?

In this example the teacher is not satisfied with only an oral answer but requests the student to find three fifths of the chips also. This is about requesting students to enlighten reasons behind the answer and to make thinking explicit. According to Franke et al. (2007), making detail explicit is one of the most powerful pedagogical moves a teacher can make. It is worth mentioning that in both practices comments requesting students to enlighten details are almost only used as a response to correct answers.

Progressing actions are dominating both practices, but there are differences on which type of actions are used most frequently. The dominating type of progressing actions in Anne's practice is 'closed progress details'. This category is formed by comments where the teacher asks for one detail at a time, moving along one step at a time. Instead of asking about the final answer, the teacher splits it up into several smaller tasks and asks for answers to each of these. One aim of this strategy might be to ensure that every student is able to follow the line of thought by following them through every important step. The result is that the teacher takes control of the

process and probably reduces the complexity of the task for the students, as that they do not need to see the whole picture. These questions typically have only one correct or desired response, which is quite often easy to find. This type of comments is dominating the entire practice as 45 % of all Anne's comments are 'closed progress details'. This illustrates Anne's tendency to split up tasks, control the process and request the students to answer rather simple step-by-step questions. The following example of 'closed progress details' above is from Anne's practice. The task is to add $1/2$, $2/5$ and $1/10$. The teacher writes ' $1/2+2/5+1/10=$ ', and then this follows:

Teacher: What is the common denominator?

Student: Ten

Teacher: Ten. And then you did what here? (points out $1/2$)

Student: Multiplied by five

Teacher: Multiplied by five, above and below. And here? (points out $2/5$)

Student: Two

Teacher: Multiplied by two, above and below. And here? (points at $1/10$)

Student: Nothing.

Teacher: Nothing. Okay, and then you got?

'Closed progress details' are also the most frequent category in Linda's practice, but the use is much less frequent. On the other hand, Linda uses simplification considerably more than Anne. The comments that form the simplification category are typically comments where the teacher simplifies the task by adding information, changing the task, giving hints or telling the student how to solve the task. And it is characteristic for Linda's practice that she adds information or changes tasks in order to make the student give the wanted response. One striking example comes when the teacher asks how much two fifths and three fifths are. There are ten orbs at the blackboard, and the teacher has told that two orbs is one fifth.

Student: Ten.

Teacher: *Two* fifths and *three* fifths, how many fifths is that? (emphasizes *two* and *three*)

Student: Ten.

Teacher: If you have two fifths here (holds up two fingers) and three fifths there (holds up three fingers on the other hand), how many fingers do you see?

Here, the teacher first emphasizes the numerators as a response to the student answering ten. When this does not help the teacher asks the student to count fingers so that the correct and wanted response 'five' will be said. The large amount of 'simplification', 'closed progress details', 'notice' and redirecting actions is characteristic for Linda's practice as the teacher gives clear and direct feedbacks of both incorrect (redirecting actions), correct (notice) approaches and when the student fails to progress (simplification and closed progress details).

The dominating amount of ‘closed progress details’ combined with a large amount of ‘notice’ is characteristic for Anne’s practice as the teacher controls the process by dividing up tasks and pointing out what is important. Also, the students are quite frequently asked to explain how or what (enlighten detail).

By looking at some specific types of student comments more information is available. In Anne’s practice there are very few incorrect answers from students (7 %), which might be explained with the large amount of closed progress details that reduces complexity. In Linda’s practice the amount of incorrect student responses are larger (23%) and these are mainly followed up by redirecting actions. This indicates that the Linda is not interested in the reasons or thinking behind incorrect answers, but instead tries to change the students approach to something more productive. It might also mean that Linda opens more up for student suggestions than Anne does. Looking at student explanations changes this picture slightly. There are a larger amount of student explanations in Anne’s practice (15% of the student comments) than in Linda’s practice (9%). Also, these are more often followed up by focusing actions (mainly notice) by Anne than by Linda.

CONCLUSION

The ‘Redirecting, progressing and focusing actions’ framework adds to concepts that can describe and characterize comments and practices in detail. This article has illustrated how these concepts can be used to characterize practices and understand differences based on a simple counting of the different types of comments. Further details are accessible by inspecting how teachers respond to different types of student comments. This is just briefly exemplified for two rather intuitive types of student comments, incorrect answers and explanations. It is also possible to inspect qualitative differences within each category, for example how teachers ask students to enlighten details, how teachers use closed progress details in different ways, or even how different kinds of student explanations are followed up by the teachers. One might also be able to find patterns of comments frequently used by teachers, for example when repeated use of redirecting actions has no effect on the progress towards a solution this might lead to the use of simplification.

The example from the practices of Linda and Anne illustrates how concepts from the ‘Redirecting, progressing and focusing’ framework can be used to characterize and interpret teachers’ communication in practice. For example, a practice dominated by the use of closed progress details is a practice where the teacher takes control of the process by doing all the important strategic choices and leaving the calculation to the students. This reduces the complexity and probably also has an effect on what opportunities the students are given to learn mathematics. Another practice might be dominated by teacher comments that request the students to enlighten details. This means that the reasons, thinking and arguments behind answers are being made explicit regularly, which according to Franke et al. (2007) is one of the most powerful pedagogical moves a teacher can make. In this way, concepts from the ‘Redirecting, progressing and focusing’ framework can be used to study qualities in these practices.

But there is one main limitation to the approach in this article as only the amount of each category is studied and not how different types of teacher comments work together in sequences. To progress it is important to study how different types of teacher actions, such as for example closed progress details and enlighten details, can interact productively in a mathematics discourse in the classroom. One such example is to study how each type of teacher comment affects the students' comments, approach or behavior. Then it also becomes possible to study qualities of different teacher actions.

The power of research frameworks lies in the concepts created. Further research is needed to find out the explanatory power of the concepts developed in the 'Redirecting, progressing and focusing' framework when describing, interpreting or characterizing entire practices or shorter discussions (sequences of comments) in mathematics classrooms.

PRE-SERVICE AND IN-SERVICE TEACHERS' VIEWS ON THE LEARNING POTENTIAL OF TASKS – DOES SPECIFIC CONTENT KNOWLEDGE MATTER?

Anika Dreher, Sebastian Kuntze

Ludwigsburg University of Education, Germany

This study examines views of pre-service and in-service mathematics teachers on the learning potential of tasks and interrelations of such views with relevant content knowledge. Focusing on the role of representations for learning and the content domain of fractions, the paper hence aims at connecting different sub-aspects of professional teacher knowledge. The results indicate that the learning potential of problems focusing on a conversion of representations is hardly acknowledged in comparison to tasks requiring only a calculation on a numerical-symbolical representational level and giving a rather unhelpful pictorial representation. However, there is a tendency that teachers with higher content knowledge scores rate the learning potential of the first type tasks comparatively higher.

INTRODUCTION

Epistemological views related to tasks are expected to play a key role when mathematics teachers select or create problems for the classroom. Hence, professional knowledge related to overarching aspects of pedagogical content knowledge (PCK) – such as the idea of using multiple representations – should also be examined on the level of task-related views. However, other components of professional knowledge might have an influence on task-related views, such as domain-specific content knowledge (CK), but unfortunately there are still very few studies making such links. Consequently, this paper focuses on views of pre- and in-service teachers regarding the use of representations in tasks in the content domain of fractions, for which the teachers have also been assessed in a CK test.

The results indicate that there is task-specific variation in the views about the learning potential of the tasks presented to the teachers. Nevertheless, the analysis yielded two types of tasks, in line with the theoretical design of the corresponding questionnaire unit: tasks making use of the learning potential of changing between representations (1) and tasks with rather unhelpful pictorial representations (2). In-service academic-track secondary teachers rated the learning potential of type 1 tasks higher than pre-service teachers. Moreover, teachers with higher CK scores tended to acknowledge the learning potential of those tasks comparatively more.

The following second section gives a brief overview of the theoretical background, which leads to the research interest of this study presented in the third section. We will then describe the methods and design in the fourth section, present results in the fifth section, and conclude with a discussion in the sixth section.

THEORETICAL BACKGROUND

National standards in many countries emphasize the importance of dealing with multiple representations for mathematical learning. In the case of the German standards for the mathematics classroom “using mathematical representations” is stated as one out of six core aspects of mathematical competency - in particular, recognizing interrelations between different representations and changing between them is stressed explicitly (KMK, 2004). There are very good reasons for such an emphasis of multiple representations in the mathematics classroom: Representations play a major role in all kinds of mathematical activities, since the perception of mathematical objects is dependent on representations (Duval, 2006). We take the notion *representation* to mean something which stands for something else – in this case for an ‘invisible’ mathematical object (cf. Goldin & Shteingold, 2001). In particular, *pictorial* representations are illustrations, diagrams or sketches. Since usually a single representation makes visible only some aspects of the corresponding object, multiple representations complementing each other are needed to develop an appropriate concept image (cf. Tall, 1988). Hence, the ability to recognize a mathematical object behind its different representations, to use them flexibly, and in particular to change between them is a key for successful mathematical thinking and problem solving (i.e. Lesh, Post, & Behr, 1987; Duval, 2006). Consequently, reflecting and discussing interrelations and conversions between different representations should be part of the mathematics classroom in order to foster the students’ ability to use multiple representations flexibly. In particular, tasks focusing on conversions from one mode of representation to another (and back), which promote insight into their interrelations, can make an important contribution to students’ understanding (Duval, 2006). Therefore, the awareness of the importance of dealing with multiple representations and also of the difficulties which come with them for learners, as well as knowledge about how to foster their abilities in making use of multiple representations are important aspects of PCK.

Against this background the question arises as to what extent teachers are aware of the learning potential of tasks focusing on conversions of representations. The results of a prior study about pre-service teachers’ views on pictorial representations in tasks indicate that many pre-service teachers tended to overemphasize the motivational aspect of pictorial representations and hardly saw the learning potential of such pictorial representations which enable students to take an additional approach to mathematical concepts. (Dreher & Kuntze, 2012; cf. also Dreher, 2012). In this prior study, the teachers were asked about their views regarding the pictorial representations. A follow-up question was how these views may impact on the learning potential of a task as a whole in the eyes of the teachers, i.e. how they see the potential of the learning opportunity which is set by the task. In addition, there has been a need for including data from in-service teachers in order to get insight

into the role of experience e.g. in organizing contents for the classroom. Both of these follow-up research interests have been taken up in the study reported here.

Views about the learning potential of tasks are considered to be individual, conviction-like and in the first place restricted to the particular case of the task considered. However, when looking at types of tasks and investigating the views of teachers related to such types, the data may give insight into whether teachers are able to ‘see the difference’, i.e. to realize opportunities for conceptual learning associated with the types of tasks. In this sense, task-related views also reflect components of PCK on a level beyond the specific case of a particular task.

As a theoretical background for analyses on these two layers, this study uses a multi-layer model of professional knowledge (cf. Figure 1), which combines the spectrum between knowledge and beliefs (e.g. Pajares, 1992), the professional knowledge domains by Shulman (1986; cf. also Ball, Thames & Phelps, 2008) – with levels of globality respectively situatedness (cf. Törner, 2002; Kuntze, 2012). As professional knowledge is often structured episodically and as there might be inconsistencies e.g. between global beliefs and situation-specific views, it appears as necessary to consider these levels of situatedness respectively globality separately and to examine their interrelatedness an approach which is facilitated by the model (Kuntze, 2012).

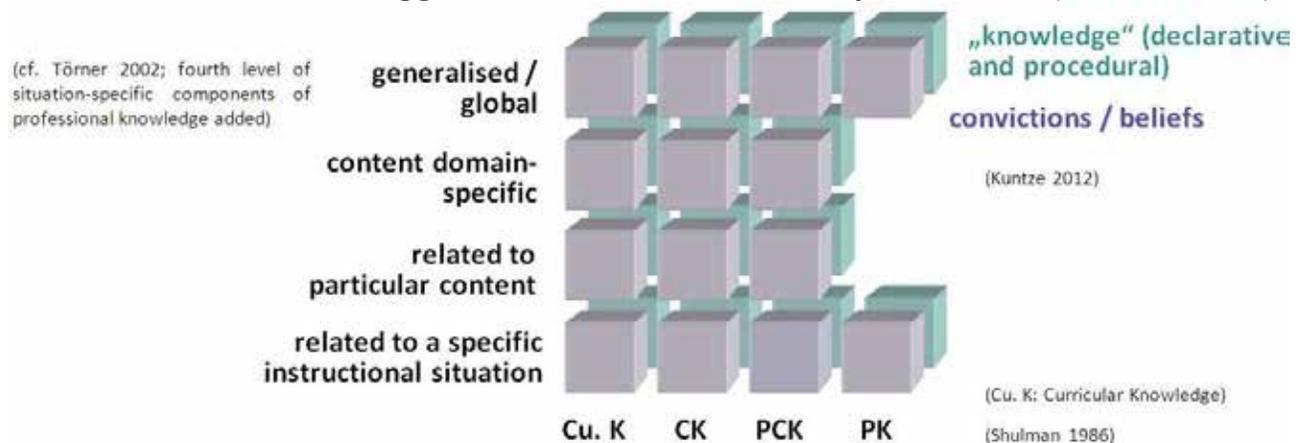

Figure 1: multi-layer model of professional knowledge (Kuntze, 2012)

Task-related views can – according to this model – be described as basically content-specific convictions in the domain of PCK (Kuntze, 2011). As argued above, there is the possibility of going up one level of globality and making a bridge to the knowledge side, if the data affords looking empirically at types of tasks.

In the case of the present study, the tasks are situated in the content domain of fractions with an emphasis on representations of fractions and on operating with fractions. The PCK component mentioned above is hence bound to this content domain. As low CK mastery has repeatedly been reported especially for pre-service teachers (e.g. Toluk-Uçar, 2009) this aspect calls for including content domain-specific CK. This affords answering the question whether CK is sufficient for PCK related to the use of representations in the task types and/or which role CK plays for

PCK in that content domain. Exploring such links between content-specific convictions (related to tasks) and relevant CK could provide useful information for designing effective professional development activities.

RESEARCH INTEREST

Given the significance of professional teacher knowledge related to the idea of using multiple representations (cf. Kuntze et al. 2011) in particular related to the design of learning opportunities provided by problems, the previous section highlights that task-related views and corresponding PCK and CK components are in the center of interest. Moreover, empirical insight into relationships between these components of professional knowledge is needed. In our study, we hence concentrate on the following research questions:

- Which task-specific views relevant for the use of representations do mathematics teachers hold? In particular, how do they evaluate the learning potential of types of problems which make use of multiple representations in different ways?
- Are there differences in the views between groups of teachers with different qualification levels?
- Is CK interrelated with such task-specific views?

DESIGN AND METHODS

For answering these research questions, a questionnaire was administered to 219 pre-service teachers (183 female, 26 male, 10 without data) and 83 in-service teachers, of which 58 were teaching at academic track secondary schools (23 female, 32 male, 3 without data) and 25 at secondary schools for lower attaining students (15 female, 10 male). The pre-service teachers were on average 20.7 years ($SD = 2.5$) old and at the beginning of their first semester of teacher education. The teachers at academic track secondary schools resp. at secondary schools for lower attaining students were on average 41.5 ($SD = 12.3$) resp. 39.9 ($SD = 11.3$) years old and had been teaching mathematics since 13.6 ($SD = 12.3$) respectively since 10.8 ($SD = 9.5$) years.

Corresponding to the first two research questions for this study, the participants were asked to evaluate the learning potential of six fraction problems by means of multiple-choice items. A sample item is: “The way in which representations are used in this problem aids students’ understanding.” The teachers could express their approval or disagreement concerning these items on a four-point Likert scale. They were told that the problems were designed for an exercise about fractions in school year six. Three of these tasks are about carrying out a conversion of representations, whereas solving the other three tasks means just calculating an addition or a multiplication of fractions on a numerical-symbolical representational level. The pictorial representations which are given in the problems of the second type are

<p>Make up a situation or a word problem which is suitable for the calculation $3 \div \frac{1}{4}$ and then use it to solve the calculation.</p>	<p>Do you know what $\frac{1}{2} \cdot \frac{1}{4}$ is? You can use the pictures below to help:</p> 
--	---

Figure 2: Samples for tasks of type 1 (left) and of type 2 (right)

rather not helpful for the solution, since they can't illustrate the operation needed to carry out the calculation. Some of them may even be misleading. Samples for both kinds of tasks are shown in Figure 2. These two types of tasks were chosen, because from the perspective of our previous research (c.f. Dreher & Kuntze, 2012; Dreher, 2012) they represent two rather opposite ways of using multiple representations i.e. focusing mainly on affective aspects respectively focusing rather on content-specific criteria.

In order to find answers to our third research question, a further section of the questionnaire was included in the analyses: A test on specific CK about dealing flexibly with multiple representations for fractions and their operations. As in the sample item shown in Figure 3, given (incorrect) conversions between different forms of representations had to be checked and corrected or a conversion had to be carried out.

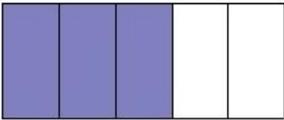

<p>Please change the diagram, if necessary, so that $\frac{3}{5}$ of $\frac{1}{4}$ is shaded. Otherwise just tick the box on the right-hand side.</p>		<input type="checkbox"/>

RESULTS

We start with the results concerning the first two research questions, namely the teachers' evaluation of the learning potential of the six tasks given in the questionnaire. The design of this questionnaire section could be confirmed by a factor analysis: For each task there is a single reliable four-item scale (Cronbach's α range from 0.72 to 0.87) about its learning potential with respect to its use of representations. Figure 4 shows the means and standard errors of these six scales for all three subsamples. The value 1 means strong disagreement, whereas the value 4 stands for strong approval. Looking for differences between the means of the subsamples yields mainly that the in-service teachers at academic track secondary schools have evaluated the learning potential of the first two type 1 problems much higher than the other participants.

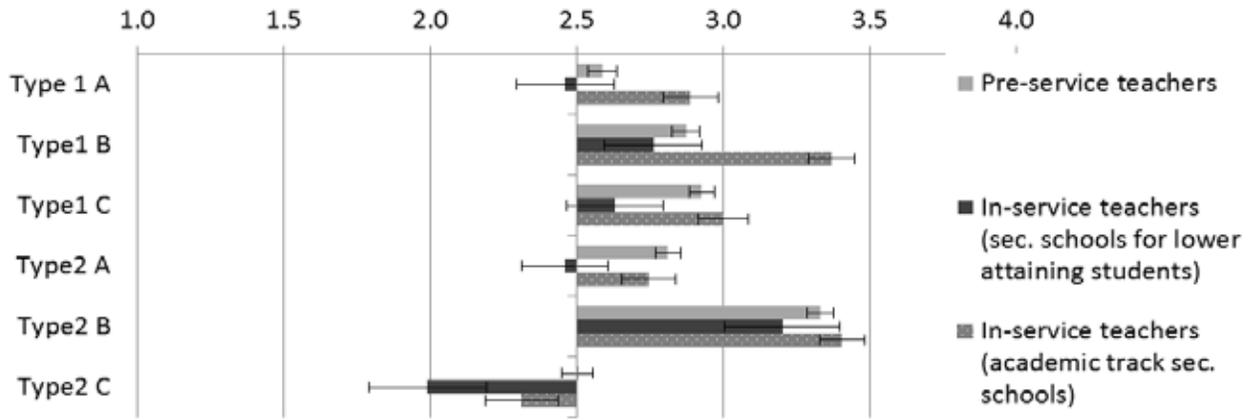

Figure 4: Evaluations of the task-specific learning potential

Comparing the evaluations of the different tasks creates the impression that the views, which were expressed here, are very task-specific. The uniqueness of each problem seems to be predominant over their classification into two types according to their use of representations: The tasks with the most positive and the most negative ratings both belong to the second type (calculation tasks with rather unhelpful pictorial representations). Nevertheless, the theoretical classification of the tasks underlying their creation can be reconstructed empirically from the teachers' evaluations of their learning potential:

Component	Type1_A	Type1_B	Type1_C	Type2_C	Type2_A	Type2_B
1	.719	.696	.659			
2				.786	.628	.610

Extraction Method: Principal Component Analysis. Rotation Method: Varimax with Kaiser Normalization.
 a. Rotation converged in 3 iterations.

Figure 5: Factor analysis (Rotated Component Matrix; 48.9 % of variance explained)

Carrying out a factor analysis with the six scales about the learning potentials of the six problems yields two “meta-scales” linked to the two types of tasks (cf. Figure 5), where both scales are reliable with $\alpha = 0.79$. Having now scales corresponding to the learning potential of two types of tasks which make use of multiple representations in different ways, it is worthwhile comparing the aggregated evaluations of the subsamples once again. The means (and standard errors) in Figure 6 show an

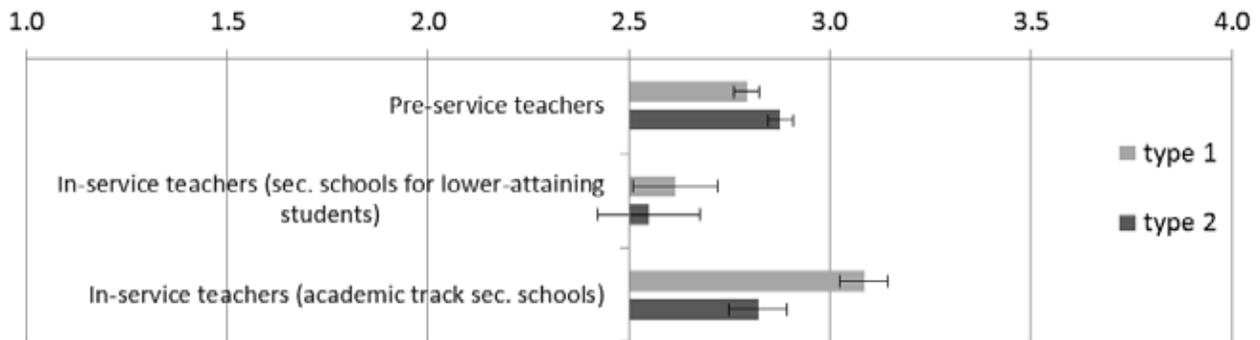

Figure 6: Evaluations of the learning potential regarding the two types of tasks

interesting result concerning the subsamples of this study: While the pre-service teachers' rating of the learning potential is higher for type 2 tasks than for type 1 tasks ($T=2.121$, $df=218$, $p<.05$, $d=0.18$), the pattern might be reversed for the in-service teachers at secondary schools for lower-attaining students (not significant) and is completely reversed for the in-service teachers at academic track secondary schools ($T=3.015$, $df=57$, $p<.01$, $d=0.53$). Focusing on the views about the learning potential regarding tasks of the first type, a comparison between the subsamples yields that the in-service teachers at academic track secondary schools have given higher ratings than the pre-service teachers ($T=4.221$, $df=275$, $p<.001$, $d=0.63$) and than their colleagues at secondary schools for lower attaining students ($T=4.113$, $df=81$, $p<.001$, $d=0.98$). Comparing the sub-samples regarding their view about type 2 tasks on the other hand shows that the pre-service teachers have assigned a higher learning potential than the in-service teachers at secondary school for lower-attaining students ($T=2.487$, $df=26.9$, $p<.05$, $d=0.68$).

These results give rise to the third research question of this study: Is specific CK interrelated with such views concerning the learning potential of types of tasks as a part of domain-specific PCK? Comparing the evaluations of those participants having a score of at least 50% in the test about specific CK to the rest of the sample might give some insight. Figure 7 shows that the participants with at least 50% CK

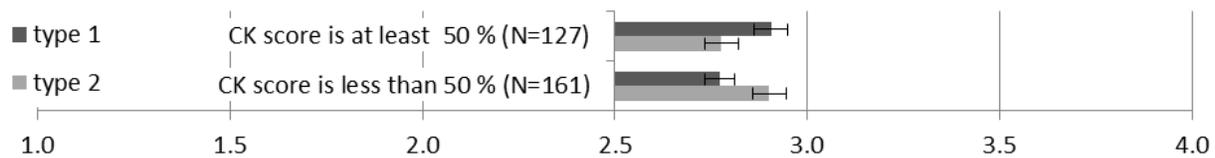

Figure 7: Evaluation of the types of tasks according to CK score

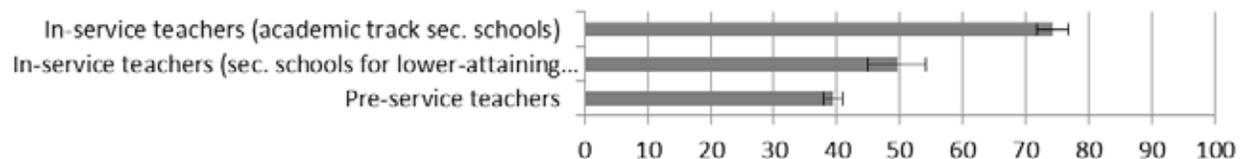

Figure 8: Content-specific CK scores (in percent)

score have assigned a higher learning potential to type 1 tasks than to type 2 tasks ($T=2.413$, $df=126$, $p<.05$, $d=0.27$), whereas the evaluations of the subsample of teachers with a lower CK score shows the reversed pattern ($T=2.564$, $df=160$, $p<.05$, $d=0.29$). The rather low effect sizes are not the only reason why this result should be interpreted with care: Another indication for scepticism can be found in the results concerning the CK scores shown in Figure 8. The mean scores of the three subsamples in the test on specific CK are very distinct: The in-service teachers at secondary schools for lower-attaining students have on average scored higher than the pre-service teachers ($T=2.196$, $df=229$, $p<.05$, $d=0.47$), but lower than their colleagues at academic track secondary schools ($T=5.111$, $df=80$, $p<.001$, $d=1.23$).

Thus, the division into groups according to CK scores as done above leads to a rather uneven distribution of the subsamples. This calls for considering the groups separately: as CK may not be the only aspect in which pre-service teachers differ from in-service teachers, it doesn't necessarily have to be the specific CK that is decisive for the distinct task-specific views of the two groups. Consequently, Figure 9 shows scatter plots according to subsamples.

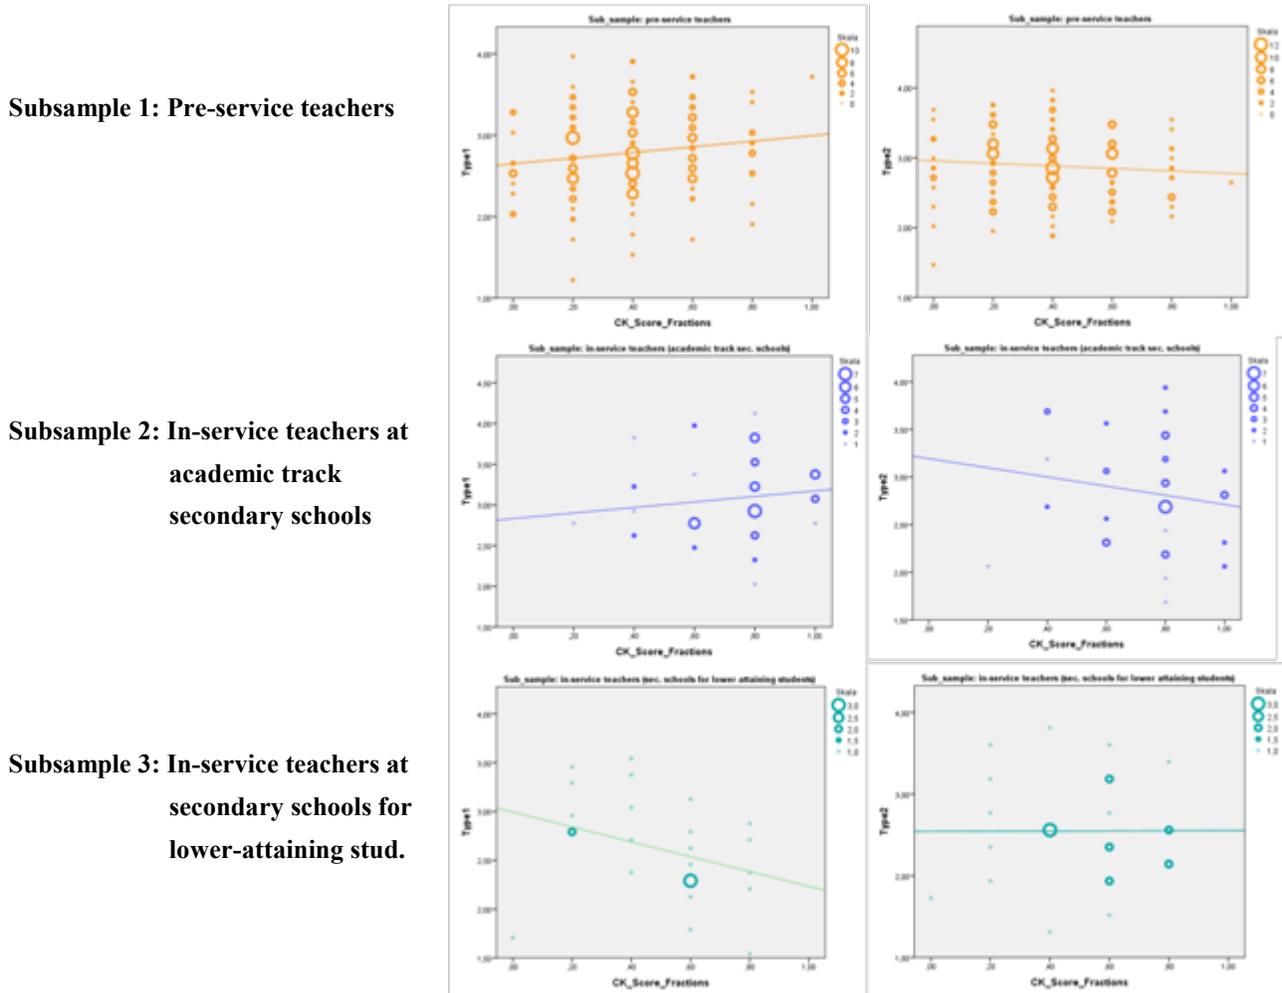

Figure 9: Content-specific CK scores and task-specific views according to subsamples

Regarding the pre-service teachers and the in-service teachers for academic track secondary schools in the sample, a relationship of the task-specific views with CK is visible to some extent, whereas it cannot be found with respect to teachers working at secondary schools for lower-attaining students.

DISCUSSION AND CONCLUSIONS

The interplay between situatedness and globality is a challenge for teachers in their everyday work: e.g. specific and individual classroom situations with learners, snapshots of learning processes seen through the lens of interactions in the classroom on the one hand and the rather non-individual contents, the relatively 'stable' and 'global' mathematical knowledge catalogue on the other hand may be seen in

contrast to each other, and the teacher's role is to bridge this gap in order to support the students' (individual) learning. This contrast is in a way 'mirrored' in the teachers' professional knowledge. Consequently, research about professional knowledge on different levels of globality respectively situatedness can help to describe interdependencies between these two poles.

The present study aims at explaining task-specific views through more general characteristics of the tasks which are linked to the way they make use of representations. Hence, the overarching idea of using multiple representations is reflected in the tasks (to different degrees). Against this background, one of the major results of this study is that the overarching idea can explain task-related views even to the extent that they form scales according to task types.

As knowledge about using multiple representations in teaching and learning situations can be considered as PCK, this empirical structure makes the analysis of task-specific views to an indicator of domain-specific PCK. The results suggest that the subsamples differ with respect to this aspect of PCK.

However, even if these subsamples also differ with respect to their content-specific CK, CK differences are not sufficient for explaining differences in task-related views, as the study shows for the example of using multiple representations in the content domain of fractions. Beyond a base of CK, domain-specific PCK appears as a professional knowledge component of its own right.

A key follow-up question concerns the further exploration of such PCK and its structure. Corresponding evidence may come from an analysis of other questionnaire sections, which is currently being carried out.

ACKNOWLEDGEMENTS

The data gathering phase of this study has been supported in the framework of the project ABCmaths which was funded with support from the European Commission (503215-LLP-1-2009-1-DE-COMENIUS-CMP). This publication reflects the views only of the authors, and the Commission cannot be held responsible for any use which may be made of the information contained therein. We further acknowledge the support by research funds of Ludwigsburg University of Education (project La viDa-M) during the data analysis phase.

DISENTANGLING A STUDENT TEACHER'S PARTICIPATION DURING TEACHER EDUCATION

Andreas Ebbelind

Linnaeus University, Sweden

The effect of teacher education is of international interest, at the same time expectations on newly educated teachers increase. Deep understanding of what it means to become a primary school mathematics teacher is necessary and this constitutes the focus in the research project. The aim of this paper is to illustrate how two conceptual frameworks, System Functional Linguistics and Patterns of Participation, have been used in the study. The first has been used as a methodological tool and the second as an analytical tool. The use of these will be illustrated by the case of Lisa, a student teacher. The results show that System Functional Linguistics successfully disentangles the heritage of Lisa's past and present practices, and facilitates interpretations through Patterns of Participation.

Keywords: identity development, participation, student teacher, teacher education

INTRODUCTION

The role of teacher education in the educational system is highlighted and discussed more and more, both in Sweden and internationally. Expectations on teachers seem to increase, and the increased demands raise questions about the quality of teacher education and how its various parts affect student teachers' knowledge and identity development (Hejzlar, 2008). To develop as a teacher is a long process that evolves gradually. By understanding that process leading to the formation of a teacher can we better understand what it means to become an upper primary school mathematics teacher.

The content of this paper derives from a study focusing on student teachers' identity development. The study aims to disentangle these students' participation in different practises, analyse and understand how different practices influences students' identity development. It is about understanding and contributing to knowledge in the process of becoming an upper primary school mathematics teacher. The point of reference is that student teachers' participate in different situations that reflect aspects of what mathematics is, how to learn and teach mathematics and what it means to know mathematics. The focus in the study is on how student teacher's participation, according to these questions, change during teacher education in relation to external and internal influence. Internal influences may be different parts of teacher education and possible external influences may be family, media, social structures or relationships.

Historically, in Sweden, there has been some changes within the educational system regarding teacher education between 1968 when the program started to 2012. One of these changes concerns 1988, when teachers went from a special upper primary school teacher education to a general primary school teacher education (Hejzlar,

2008). In 2011 a new upper primary school teacher degree was reinstated. The main reason for this was that the former teacher education had neglected the specific content regarded to teach children aged ten to twelve.

Phillip (2007) points out that traditional research on teacher development generally has focused on the individual. However, in recent years the focus has been changing towards more social theories. According to Morgan (2010) taking a social perspective to analyse and understand teacher development and identity can bring greater understanding of processes within teacher development. Above all, a social theory provides us with other information about teachers' identity development and change than, for example, traditional research on beliefs.

The aim of this paper is to illustrate how two conceptual frameworks, System Functional Linguistics and Patterns of Participation, have been used in the study. The case of Lisa, a student teacher at teacher education, will be used as illustration.

METHODOLOGICAL AND THEORETICAL FRAMING

Two conceptual frameworks are used as methodological and analytic tools. First to address and unfold situated communication System Functional Linguistics (henceforth SFL) has been used (Halliday, 2004). It is strictly considered as an methodological part in the analysis when disentangling students participation. Also, it is a well established concept when addressing and unfolding communication that are situated (Björklund Boistrup, 2010). However, SFL does not empirise any content or situation, it mainly focus on, in this case, how the student teacher addresses the content or situation. Therefore there is need for a framework that focuses on the content and situations that has been addressed. Doing this, the conceptual framework Patterns of participation (henceforth PoP) will be used (Skott, in press).

Coordinating theories

As stated above, the purpose of this paper is to present the analysis of a case study using as analytical approach concepts from two different conceptual frameworks. I hold that I am coordinating two different theories. Prediger, Bikner-Ahsbabs, and Arzarello (2008) make a distinction between coordinating and combining theories. They define coordinating as a term for bringing theories together that contains interpretations of notions that are compatible, whereas combining is when theories are only juxtaposed.

In both perspectives the concepts: learning, identity development and evaluations are seen as situated within context. They do also explicitly focus on the construction of context as something that arises within situations. In this sense they are alike, but they complement each other in one imported way. SFL addresses and PoP describes shifted participation in situations, evaluations and communication. The outlined approach uses therefore SFL to unfold situated communication to reveal traces of context (Morgan, 2006). These traces of context are then interpreted through the conceptual framework of PoP (Skott, in press).

System Functional Linguistic

SFL draws upon the notion that a text is not something predefined, rather, it is something that is constructed while participating with others. It regards a text as being handled in three different functions (the ideational function (1), the interpersonal function (2), and textual meta-function (3)), so-called meta-functions, simultaneously. Morgan (2006) says that this unfolding into meta-functions does not create descriptions about mathematical situations but it serves as a crucial window when following processes. It provides means that can be interpreted through a compatible framework.

I will present these meta-functions while addressing the following sample from the transcript of Lisa's first interview. The approach described below is illustrated in Table 1.

I do not really know what I want to be, and I still do not really know. Then I was at a school and had practice, so it was there the idea came. But as I said I do not still really know [...] I thought that teacher education would be a little easier than this. You have of course heard from various people, that everyone goes through and no one will fail. That was why I chose it too. That is, if you have nothing to do, you can always be a teacher.

The first meta-functions concern people's expressed experience, the ideational function (Halliday, 2004). It focuses on the construct of reality by linguistic means. It concerns statements that address the interpretation of one self in different contexts. An example of this is when Lisa expresses her scepticism towards the choice of being a part of teacher education. "I do not really know what I want to be, and I still do not really know."

Ideational Function	Interpersonal Function	Textual function
<p>We address experience in relation to things, events, situations, thoughts and feelings.</p> <p>It is interested in the verbs that are expressed and the entities that it refers to.</p> <p>Firstly you have those processes that involve physical actions. There is an actor (doer) that does something.</p> <p>Secondly you have those processes that are mental like thinking, wanting, to know etcetera. The senser is addressing a phenomenon.</p>	<p>Concerns past and present experiences, focus on the addressed interaction.</p> <p><i>"Then I was at a school and had practice."</i> The subject is "I" and finite verb "was". The addressed interaction is "a school".</p> <p>When using a finite verb the evaluations can signal:</p> <ol style="list-style-type: none"> 1. Whether the proposition is valid for the present, past or future time. 2. Whether the proposition is about positive or negative validity. 	<p>Finally we have to consider the context and the language that surrounds us.</p> <p>We have to construct our message so that it fits into a bigger conversation.</p> <p>"You have of course heard from various people, that everyone goes through and no one will fail."</p> <p>Here the theme is connecting to a meta-discussion that addresses coherence. Coherence is concerned a mental phenomenon that cannot be identified.</p>

Table 1: The methodological framing

While using language and express our experiences we at the same time focus our participation against someone or something. This is the second function and is called the interpersonal meta-function. Lisa continues, "Then I was at a school and had practice, so it was there the idea came." This is more active than the ideational meta-function; it is interpersonal by mean that it is both interactive and personal (Halliday, 2004). This means that a text is about something and is addressing someone. This is done within situations and calls the textual meta-function (the third function). It concerns the process of construing the coherence of a text. Lisa continues. "You have of course heard from various people, that every one goes through and no one will fail. That was why I chose it too. That is, if you have nothing to do, you can always be a teacher."

Patterns of Participation

Lerman (2002) suggests that research on teacher development would go from focusing on acquisition to focus on participation. To learn is to participate and become another. This means to pay more attention to the interpersonal, namely the personal experience in a social setting. This perspective sees student teachers' identity formation and learning as a result of shifted participation in educational situations and acknowledges that all activities are situated (Lave, 2000; Skott, 2010).

Through students' participation, there are several aspects of patterns that are related to different levels: individual, social, institutional, political and cultural. It is the shifting participation in these levels and aspects that PoP want to describe by focusing the pre-reified processes that are said to precede mental construction (Skott, in press).

Teacher education includes several contexts of actions that are separated and connected in different ways and intends to reproduce and alter students' participation in situations (Dreier, 2000; Lave, 2000). According to Dreier (2000), a context of action is an arranged situation in a specific location with specific content and specific participants. This notion, context of actions, is not used within the PoP framework but will be used in this article to emphasis that it is the actions that makes the context occur. This notion is consistent with Skott's (2010) use of context as something that arises in situations.

Participation requires participants, that is, individuals who by participating develop their individual participation. The individual is part of a situation and a part of the context of actions overall repertoire. Since participation is situated in specific location individuals participate in a specific way. A prospective teacher brings multiple ways of participating into the educations different contexts of actions. Some of them derive from mathematics and others do not. The different contexts of actions that prospective teachers during teacher education involves in will somehow transform their way of participating in relation to what mathematics is, how to learn and teach mathematics and what it means to know mathematics.

In PoP student teachers' individual mathematic skills or beliefs are not central, but the process said to precede it. This process is phrasing, in participatory terms, the

shifted movement when relating to these different aspects of teaching and learning mathematics. PoP is described as an alternative approach to research about beliefs, teacher change and identity development (Skott, 2010).

METHODS CONCERNING THE STUDY

The study, from which the content of this paper derives from, is a theory driven multi-sited ethnographic study. Theory driven because theories that emphasize the social are guiding the choices made during the ongoing project (Walford, 2009). Multi-sited because the mode of construction is not a single site, instead the mode of construction is a process that takes place in multiple sites (Pierides, 2010). In the study four student teachers are followed through their teacher education. They are observed and interviewed before, during and after different context of actions like courses, lectures, seminars, internships, study groups and examination work.

The focus in observations and interviews are on learning and teaching mathematics and the interviews have been transcribed word by word. The assumption is that student teachers cannot evaluate their participation in past and present context of actions without simultaneously identify their self and relate to different people in different ways. When this occurs they present specific content while in communication addresses others through an evaluation.

In the analysis one case will be focused on, the case of Lisa. The generated data intended to give examples of Lisa's participation in different past and present context of actions and comes from semi-structured interviews (Kvale, Brinkmann & Torhell, 2009) with voice recording.

When analysing the data first SFL has been used. Every clause in the transcripts has been connected with the specific meta-function. Then the unfolded communication has been coded, analysed and organized in a Static – Dynamic Analysis (Aspers, 2007). Then the aspect found in the transcripts are summarized and compared. The next step in the analysis was to apply the framework of PoP with the intention of phrasing Lisa's participation in participatory terms to describe the shifting movement when she relates to different aspects of teaching and learning mathematics.

THE CASE OF LISA

Lisa, who is in her 20s, started teacher education directly after high school. According to Lisa she comes from a family history of not entering University. Her family is proud that she wants to continue studying after high school. Lisa is included in this study because of her interest in mathematics and because she intends to write at least one master thesis, 15 credits, at advanced level in mathematics education. This means that she will have at least 45 credits in mathematics education after her graduation. The school where she carried out her first internship is located in a small town. The supervisor teaches Mathematics and Natural Science. In this example I choose for space reasons only to present one aspect, among others, that Lisa

emphasised in her initial interview. This aspect is related to competitions as inspiration for motivation in learning.

The first interview was directly conducted in the beginning of her teacher education and focused on past classrooms experiences and current understanding about teaching and learning mathematics. The second interview was made at the end of the first five-week internship period, this after seven months at teacher education and concerned Lisa's experience gained during this period in relation to what mathematics is, how to learn and teach mathematics and what it means to know mathematics.

Lisa highlights in the first interview her own experiences from her own schooling by pointing out that different competitive elements increased her motivation, "this to get it a little more challenging." The example is collected from her experience when learning multiplication, which was the beginning of her interest in mathematics that continues today: "I have studied to level D and it has been great fun to study mathematics.". Mathematics is one of the topics ranked highest, and she looks forward to teaching mathematics after her teacher education is completed. In this interview, Lisa relates to how these experiences occurred. She mentioned one very good teacher that taught in a playful manner in which the element of competition is presented as important: "we had a lot of competitions". Competitions helped Lisa become more interested in the subject and "get better results because you are more engaged". The competitive element made "you get interested".

In the second interview, Lisa's involvement with the supervisors on the internship makes her have a general discussion about what and how a teacher should be. She highlights that: "[...] teachers should be committed; being knowledgeable is very important, the desire to develop students, to be close to students and I think it is important to have a sense of humour and the ability to see the students. It is possible to make the long list even longer.". All these diverse criteria were fulfilled, according to Lisa, in the mathematics teacher whom she had met in recent weeks.

In the second interview, the experience she gained from being part of the classroom is that the mathematics teacher engaged in teaching, according to Lisa, closely to the pupils' thoughts. "The teaching is at their level, it is very playful all the time, experiments and interaction with the students, they contend all the time.". Participation and the competitive element are something she highlights in this interview in relation to the above elements: "where the competitive instinct may be awakened and so.". This is highlighted as something positive, that the mathematics teacher according to her awakes the competitive spirit in the students.

One additional interview was conducted a month before Lisa's first internship with her future supervisor and it concerned school culture, experience about teaching and learning mathematics and prospective teachers' expected participation during internship. While interviewing the supervisor, before the practice period began, the mathematics teacher stressed the students' individual competing against themselves as central to how the students would be able to see their own individual learning.

I teach multiplication every third week. We do it both on Mondays and Fridays on time. It may seem a bit stressful and messy but they like it very much because it is easy to measure against oneself. I always tell them that you have to beat yourself and no one else. Then we do the same thing on Friday and compare. There is no one that I can show that they have not developed and I think that is pretty cool.

This is a deliberate strategy by the teacher, to increase their motivation and confidence. "When I say I have not done anything, it is you who have done this. I think that is fantastic when they realize that I have actually taught myself this.". The key features described above are illustrated in Table 2.

Table 2: Aspects and key features in Lisa's evaluation

Aspect	Evolution		
	Interview 1	Interview 2	Remarks
Competitions as central for learning mathematics.	Ideational – connected to past experience Increasing motivation Challenging Good performance through commitment Beginning of Lisa's interest in mathematics Playful Better results	Interpersonal – connected to present experience Playful Interaction Good performance through commitment Competitive instinct Competitive spirit Recurrent contending in competitive element	The mathematics supervisor at internship emphasise students' individual competing against themselves as central to how the students would be able to see their own individual learning.

Interpreting the case from a participatory stance

Lisa re-engages initially, in the first interview, in a pattern that emphasises the element of competition as central for creating engagement and motivation. The competitive element makes teaching, according to her, more challenging and it was seminal to her interest when participating in past mathematical contexts of actions. This is her own re-enactment in relation to the situations she herself experienced through the schooling she participated in, her earlier experience that is part of her current patterns. Through participation in various contexts of actions the aspect described will either be enacted or re-enacted, moulded, fused, and sometimes changed beyond recognition as they confront, merge with, transform, substitute etcetera (Skott, in press).

Lisa's representation emerged through participation in a specific teacher's context of action. This teacher is, according to Lisa, the person who kinder her interest in mathematics through participation in various competitions. Participation in these competitions enables you to relate your own skills towards yourself and to others. In Lisa's first two interviews this is a key element for learning mathematics. Her prior interest in mathematics is unsupported by the subject itself. It is the engagement that arose through participation, in competitive teaching that is central. Good performance

is achieved by commitment and this occurred, in Lisa's case, through participation in competitive elements.

The difference between the representations in Lisa's first and second interview is that the first one is to a great extent ideational, because she cannot relate to anything else but personal experience from her previous life. This observation is relevant when discussing past and present participation and how Lisa re-enacts to these practices. It is only when following up on the competitive aspect, later in interview one, that she relates it to the teacher's physical actions from her past experience. In the second interview she relates the aspect entirely to the interpersonal, i.e. the experience she gained from participating in the mathematics teacher's classroom during the practise period. Her prior engagement and experience from historical mathematical classrooms has been absorbed, merged and/or changed into another representation. Lisa's identity has changed through shifted participation.

However, she discusses how a teacher should be, without relating to social relations, and then intertwines this argumentation to include the mathematics teacher whose practice she participates in. Lisa describes an active classroom where participation in the mathematical situation is crucial. What she describes as central in this participation is the competitive instinct that the teacher creates in students. The teacher is said to enact and re-enact this competitive instinct recurrently, which gives good working pace and makes the teacher's instruction varied.

Lisa's representation regarding 'competitions as inspiration for motivation in learning' has been both complemented and constructed through her participation in relation to the first interview. Competitions during interview one is motivating, challenging, playful and engaging. After participating in the mathematics classroom, competitions form a natural part of teaching. My interpretation is that the repertoire of words she uses to describe the aspect expanded while she participated in the supervisor's, mathematics teacher's context of action and has deepened her reasoning about the importance of competitive elements.

After the analyses of Lisa's two interviews were conducted, an iteration of the supervisor's interview was done using the categories that had emerged from the initial analysis. Regarding the element of competition, there was a long section, about four minutes, where the mathematics teacher devoted himself to describe his teaching. He emphasised competitions as a developmental force when teaching multiplication, that it is in this phase that students clearly view their progress. What the supervisor describes as a three-week interval, Lisa describes as something frequent, a natural part of teaching. Whether it is every third week or a natural part of teaching, it can be interpreted as Lisa's participation in this mathematical classroom has re-enacted her past experience and that her representation about competitions as inspiration for motivation in learning in the mathematics classroom has been complemented and strengthened.

SUMMARY

The article is based on a participatory perspective on students' identity development and is derived from the overall interest to better understand what it means to become a primary school mathematics teacher. To follow this process of becoming makes it possible to take into account both internal and external influences from past and present practices. Both the internal and external are a natural part of all situations which student teachers participate in. The participation in these past and present practices has in this paper been highlighted or more explicitly one chosen aspect has been presented and how this aspect has evolved during the first part of teacher education.

To follow student teachers in teacher education is therefore based on patterns that occur not only as institutional context of actions, but because of the length of the education and its complexity it evolves from diverse social practices. The analytical tools showed potential in disentangling Lisa's participation in these past and present complex practices and enabled interpretations through PoP. Especially, when describing the difference in Lisa's two interviews concerning the aspect, competition is central for motivation in learning mathematics.

Lisa's evaluation is not seen as an expression or an individual imprint that she believes in, but as an identity expression that arising from the situation. Nor does her statements sees as expressions of a position but as a continuous variable motion through teacher education. SFL has helped to demonstrate this movement by the assumption that texts have different functions, i.e. addressing different objects and situations. In relation to different aspects and levels it is possible to disentangle and compare patterns and discuss if they have been enacted or re-enacted, moulded, fused, changed, merged, transform etcetera.

By using the specific conceptual framework PoP it has been possible to interpret different patterns and present one aspect in participatory terms. I have also presented how this aspect during practice at a school has an effect on Lisa's identity development. The data construction and data analysis made it possible to interpret her shifted participation during the first year of education. The analytical tools have contributed to highlighting how Lisa's representation of competitions as inspiration for motivation in learning has changed.

SFL showed to have unexpected potential in relation to the ethnographic approach. As mentioned earlier the mode of construction is not a single site, but a process that takes place in multiple sites. When addressing and unfolding situated communication it became, in many cases, very clear which sites or phenomenon to further explore. In Lisa's case for example the teacher from past experience and the present supervisors' classroom. SFL made it very explicit where to further conduct research to understand Lisa's participation in past and present practises.

A THEORETICAL REVIEW OF SPECIALISED CONTENT KNOWLEDGE

Eric Flores, Dinazar I. Escudero, & José Carrillo¹

University of Huelva, Spain

This work is a bibliographical review of Specialised Content Knowledge from the model of Mathematical Knowledge for Teaching. It offers a discussion of the most frequent definitions for this subdomain. We work with two examples of specific tasks which, according to the authors, require specialised knowledge on the part of the teacher. We identify the essential characteristics of the mathematical knowledge involved in these tasks and contrast these with the features commonly employed to identify specialised knowledge. We conclude with a discussion of the nature of specialised knowledge, which serves as the starting point for several papers by our research group to be presented to this working group.

Keywords: Specialised Content Knowledge, Mathematical Knowledge for Teaching.

INTRODUCTION

What does a teacher need to know to teach mathematics? What mathematical knowledge does the teacher require to teach a specific topic? How and where can teachers use this knowledge in practice? Questions like these have prompted numerous research projects aimed at studying the *ideal* knowledge and skills which a mathematics teacher should possess. In particular, a research group based at the University of Michigan has spent several years working on a scheme which allows them to categorise the typology of mathematical knowledge observed in, and required by, education: Mathematical Knowledge for Teaching (MKT).

MKT refines the map originally put forward by Shulman (1986) into subdomains, thus: the superordinate ‘Subject Matter Knowledge’ domain is subdivided into ‘Common Content Knowledge’ (CCK), ‘Specialized Content Knowledge’ (SCK), and ‘Horizon Content Knowledge’ (HCK); ‘Pedagogical Content Knowledge’ is in its turn subdivided into ‘Knowledge of Content and Students’, (KCS), ‘Knowledge of Content and Teaching’ (KCT) and ‘Knowledge of Content and Curriculum’ (KCC). This breaking down of domains into more finely defined sub-categories owes as much to lesson

¹ This article represents part of the studies into teachers' knowledge by the SIDM group (from the Spanish ‘Research Seminar into Mathematics Education’) based at the University of Huelva, Spain. It comprises the following researchers: José Carrillo (coordinator), Nuria Climent, M. Cinta Muñoz-Catalán, Luis C. Contreras, Miguel A. Montes, Álvaro Aguilar, Dinazar I. Escudero, Eric Flores and Enrique Carmona (University of Huelva), Pablo Flores, Nielka Rojas and Elisabeth Ramos (University of Granada, Spain), C. Miguel Ribeiro, Rute Monteiro and C. Susana dos Santos (University of the Algarve, Portugal), Leticia Sosa and José L. Huitrado (University of Zacatecas, Mexico), and Emma Carreño (University of Piura, Peru).

observation as to reflection on what sort of knowledge teachers should have, and the demands, in terms of mathematical reasoning, intuition, understanding and skill, the profession places upon them (Ball, Thames, & Phelps, 2008).

The aim of this short research is to take a closer look at SCK, and map out the advances made in the field, its nature and the difficulties that arise when it is applied to systematising teachers' mathematical knowledge.

DEFINITION OF SCK

One of the main contributions of MKT, according to its authors, is the identification of knowledge in terms that are purely mathematical and specific to the profession, SCK. This has been largely well received by the research community in that it specifies the teacher's knowledge. However, there are also some drawbacks which make it difficult to observe and analyse.

In this section we present the results of a wide-ranging literature review on what, from the point of view of the definition, is understood by SCK, drawing on the work of various authors who have used MKT in their research, whether seeking a better understanding of this subdomain or aiming to develop it in some way. Our intention is to give an overview of a collection of studies, looking specifically at how the definition has been adapted and developed over time.

Our starting point is the work of Ball *et al* (2008) in which the definition of SCK is predicated on notions of the profession and Common Content Knowledge, a practice followed by many subsequent authors (Hill *et al*, 2008; Delaney, Ball, Hill, Schilling, & Zopf, 2008; Hill, Ball, & Schilling, 2008; Krauss, Baumert, & Blum, 2008; Knapp, Bomer, & Moore, 2008; Carreño, & Climent, 2009; Suzuka *et al*, 2009; Kazemi *et al*, 2009; Markworth, Goodwin, & Glisson, 2009; Rivas, Godino, & Konic, 2009; Godino, 2009; Van, 2009; Godino, Gonzato, & Fernández, 2010; Sosa, & Carrillo, 2010; Ribeiro, Monteiro, & Carrillo, 2010; Castro, Godino, & Rivas, 2011; Herbst, & Kosko, 2012; Rivas, Godino, & Castro, 2012). However, none of these definitions specifies the nature of the knowledge in itself, but rather they all evoke external agencies.

Definitions alluding to professional demands, tend to make reference to the mathematical knowledge and skills unique to education, and which are generally not used in other contexts. Education requires knowledge beyond the pupils' mode of thinking. This implies a particular way of unpacking mathematical knowledge which is not necessary (or even desirable) in other professions (Ball *et al*, 2008).

Great emphasis is placed on the insistence that this kind of knowledge pertains exclusively to the ambit of mathematics teaching, and is not required in other professions. Nevertheless, one might justly ask how it is that we know that a certain kind

of knowledge is not required in other professions. Is it necessary perhaps to check what kind of mathematical knowledge is used in each profession?

Fortunately, an indication of how this task might be undertaken is offered by such definitions themselves. The use of the term ‘skills’ indicates what, until this point, has been lacking in determining the nature of the knowledge involved in SCK. In other words, the definitions of SCK tend to be phrased in terms of what having this knowledge enables one to do: “responding to students’ ‘why’ questions, [...] choosing and developing useable definitions, modifying tasks to be either easier or harder” (Ball *et al*, 2008, p. 400), to mention just a few.

Drawing on the work of Rivas *et al* (2012), amongst the skills which can be attributed to this kind of knowledge are selecting and designing class activities, and making representations and giving explanations of curricular items. Suzuka *et al* (2009) emphasise that one skill demanded by SCK is that of interpreting mathematical productions, both those generated by students and those to be found in materials.

From the above, then, it follows that SCK is defined as unique to teachers in that the tasks it allocates to them are indeed specific to mathematics teachers. Nevertheless, it seems to us that there remains the question of whether the mathematical knowledge which allows these tasks to be successfully performed is shared by other professions.

The other tendency which is frequently deployed when defining SCK is comparison with CCK. CCK is defined as the knowledge required in order to solve such tasks as are given to pupils. Other definitions describe it as the knowledge held by a well-educated adult at the educational level in question. Markworth *et al* (2009) symbolically define SCK as “content knowledge needed for the teaching of mathematics, *beyond* the common content knowledge needed by others” (pp. 69). Hence it is knowledge that the pupil may not necessarily learn. Are we to understand ‘beyond’ in this context as a deeper or amplified kind of CCK? And what if the educational intention was to extend and amplify the knowledge of a topic, with the result that these defining features now formed part of CCK? Is this form of knowing content separate from the way mathematicians usually know mathematics or is some kind of intention required, and hence knowledge of teaching/learning to be so? What benefits are there to separating out mathematical knowledge in this way?

Defining SCK in this way raises the difficulty of clearly demarking what can be considered common knowledge from specialised knowledge. The point at which one shades into the other depends on various factors ranging from general considerations (educational level, the school system) to more specific ones (the teacher’s particular intentions).

EXAMPLES OF SCK

By way of illustrating what SCK refers to, in what contexts it is used, and how it is applied, we collated various examples from the literature. These include classroom sequences, or episodes, in particular those in which the teacher has to deal with difficult or unexpected circumstances, which show how the teacher interacts with mathematics.

In this section we offer a full analysis of two of the most representative examples that have been employed to illustrate SCK. The examples are reported in the literature as specific educational tasks. So as to identify as explicitly as possible the purely mathematical features required to solve these tasks, we will go through each task step by step, unpacking the information.

In the first example (Figure 1), a subtraction problem is given along with a typical algorithm for solving it and two potential errors that pupils might make. The mathematical knowledge involved in the analysis of procedures leading to the detection of these errors (one of a teacher's specific task) is identified as SCK.

Subtraction by regrouping

The subtraction is presented:

$$\begin{array}{r} 307 \\ - 168 \\ \hline \end{array}$$

Most readers will know an algorithm to produce the answer 139, such as the following:

$$\begin{array}{r} \overset{2}{\cancel{3}}\overset{0}{\cancel{0}}7 \\ - 168 \\ \hline 139 \end{array}$$

Many third graders struggle with the subtraction algorithm, often making errors. One common error is the following:

$$\begin{array}{r} 307 \\ - 168 \\ \hline 261 \end{array}$$

Consider another error that teachers may confront when teaching this subtraction problem:

$$\begin{array}{r} 307 \\ - 168 \\ \hline 169 \end{array}$$

Figure 1: Subtraction by regrouping. (Ball et al., 2008, pp. 396-397)

The authors offer the following commentary:

...in the subtraction example [...], recognizing a wrong answer is common content knowledge (CCK), whereas sizing up the nature of an error, especially an unfamiliar error, typically requires nimbleness in thinking about numbers, attention to patterns, and flexible thinking about meaning in ways that are distinctive of specialized content knowledge (SCK). In contrast, familiarity with common errors

and deciding which of several errors students are most likely to make are examples of knowledge of content and students (KCS). (pp. 401)

This example offers a description of SCK which leads us to wonder about the terms employed: What does ‘sizing up the nature of an error’ refer to? What is meant by an ‘unfamiliar error’? What does it mean to have ‘nimbleness in thinking about numbers’ or ‘flexible thinking about meaning’? What can we say about going beyond the answer to the subtraction? Indeed, we could ask ourselves what can be identified as purely mathematical here?

To answer this last question, let us go through the mathematical arguments leading to the identification and characterisation of the origin of each of the errors set out in the example.

Regarding the first, the algorithm is misapplied such that the smaller number is subtracted from the larger one in each of the three columns, resulting in error as the pupil fails to grasp the importance of the relationship between the top and bottom rows in the subtraction, as Ball *et al* (ibid) make clear. The way of thinking which leads to this error is the understanding of subtraction as the ‘distance’ between two numbers: the fact that ‘1’ appears at the foot of the column with ‘7’ and ‘8’, ‘6’ at the foot of the column with ‘0’ and ‘6’, and ‘2’ at the foot of the column with ‘3’ and ‘1’ strongly suggests that this was the operation applied to these numbers.

In the second example, the source that Ball *et al* (ibid) suggest for the error is a failure to recognise the positional values of the numbers at the moment of regrouping. To this we can add the consideration that according to the algorithm, zero is associated with an absence of value, so that it cannot *lend*, forcing it to borrow from the ‘3’. The knowledge which leads to this interpretation is the *statements* about 0 and the use of the subtraction algorithm.

In both examples, ample understanding is required about the mechanics of subtraction by regrouping works, and particularly the expanded notation of numbers.

According to the reasoning of the authors, we can say that the kind of knowledge identified above (the use and justification of the subtraction algorithm, numerical notation, subtraction as the ‘distance’ between two numbers, the statement about zero) would fall within SCK, given that it refers to knowledge put to use by the teacher in providing or evaluating mathematical explanations of how such errors occur, in addition to recognising and analysing them. However, we consider that the mathematical elements brought to light in the detailed analysis of the task do not provide sufficient evidence to guarantee that such knowledge is exclusive to mathematics teachers. What is more, all the knowledge involved could be categorised as Common Content Knowledge, depending on the researcher’s beliefs regarding how the pupil should understand the topic in question.

This example allows us to see one of the most repeated difficulties in the literature, the lack of a clear distinction between CCK and SCK.

Another example which is a particular challenge for mathematics teachers consists in coming up with a story which represents the division of fractions, such as $1\frac{3}{4} \div \frac{1}{2}$. We will focus on the second part of the activity suggested by Suzuka *et al* (2009), in which the teacher has to analyse a story which apparently contains errors in the set up, but which has the correct answer (Figure 2).

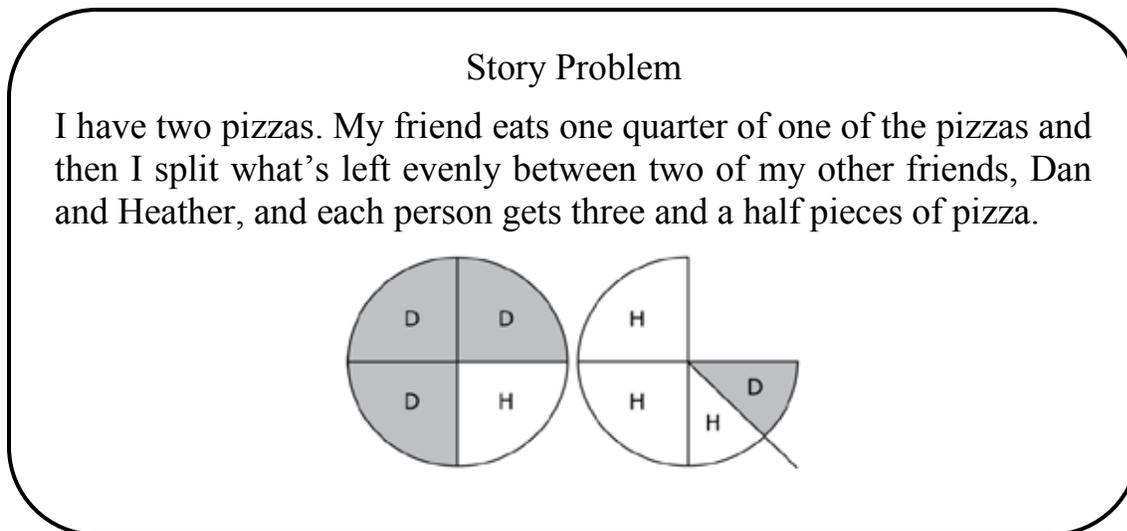

Figure 2: Incorrect story problem to represent $1\frac{3}{4} \div \frac{1}{2}$. (Suzuka et al., 2009, p. 11)

As mentioned above, one of the skills considered representative of SCK is that of interpreting mathematical productions – whether by pupils, other teachers or written material – something that this example embodies.

Let us repeat the exercise of going over the task making use of purely mathematical arguments to identify and describe the specific knowledge required to solve it. For this example we set ourselves the task of identifying the knowledge which enables one to know, on the one hand, that the result is correct, and on the other, that the setup of the story is incorrect.

Understanding why the result is correct requires being able to see the relation between the operation that the task intends to represent ($1\frac{3}{4} \div \frac{1}{2}$) and the operation actually represented by the story problem ($7 \div 2$). In the first of these, given that the divisor is a fraction, it is not possible to devise a natural context based on the partitive sense of division. The metamorphosis into the second operation attempts to express precisely this sense of division, but in this formulation it is not $1\frac{3}{4}$ pizzas that are divided but 7 slices

of pizza (the size of each of which is $\frac{1}{4}$). This number of slices is the numerator of the improper fraction deriving from the mixed number: $1\frac{3}{4} = \frac{7}{4}$. The dividend in the second operation is the numerator of the corresponding fraction, once this has been transformed into an equivalent so that the denominators of both are the same: $\frac{1}{2} = \frac{2}{4}$. That is:

$$1\frac{3}{4} \div \frac{1}{2} = \frac{7}{4} \div \frac{2}{4} = \frac{7 \times 4}{2 \times 4} = \frac{7}{2}$$

It should be noted that we are not suggesting that this was the mental process by which the story problem was devised, rather we are setting out the mathematical arguments which allow one to analyse and account for the equivalence between the operations and for the answer being the same in both cases.

Hence, the knowledge involved in this first part is: knowing that the quotient of two fractions is equal to the quotient of any two equivalent fractions; knowing an algorithm for dividing fractions; knowing the multiplicative inverse property of numbers.

In order to understand why the problem posed in the story is incorrect, the required mathematical knowledge concerns the use of the meanings of division $a \div b$ as quantifier (How many times does b go into a ?) and as sharing out (How many does each b get if we share out a ?). The meaning inherent in the story problem cannot be extrapolated to the operation to be represented.

As with the example of subtraction, there is no purely mathematical knowledge here that can be seen as exclusive to mathematics teachers, or to which the pupil cannot have access.

CONCLUSION

In this paper we have aimed to scrutinise elements of knowledge pertaining to SCK. We began with an analysis of definitions and looked closely at examples which, according to the authors, involved specialised knowledge. We kept in mind throughout the notion of SCK as purely mathematical knowledge, whether viewed as an accumulation of special knowledge or as a special way of regarding content.

The definitions review we carried out leads us to conclude that these always employ elements which are extrinsic to specialised knowledge, such as making reference to other professions or the notion of going beyond CCK. In the analysis of the examples, we found that the specific tasks called for knowledge of meanings, properties and definitions of the mathematical topics involved. Nevertheless, it is natural to ask whether this knowledge can be considered specialised with respect to mathematics teachers. We would maintain that the answer is 'no'. We cannot see any way of viewing the topic concerned that is particularly special, nor can we perceive any specialist mathematical

knowledge which is habitually inaccessible to pupils or other professionals. What is evident is a specific use of this knowledge.

We are not trying to say that mathematics teachers' specialised knowledge does not exist; however, the data suggest that it might not be exclusive to the mathematical domain. We believe that it is impossible to think about this kind of knowledge without bringing to mind knowledge about mathematics teaching, such as ways of constructing the subject, the development of complexity within topics, and the features of learning mathematical content, amongst others. Specialised knowledge takes into account more aspects than meanings, properties and definitions.

The above conclusions form part of a series of considerations and reflections which together have led the research group SIDM in the Department of Mathematics Teaching at the University of Huelva (Spain) to work towards the development of a model which focuses on the study of what is specialised in terms of the results of an interaction between types of knowledge of and about mathematics, the structure, the teaching, the characteristics and standards of mathematics education, as well as connections to beliefs about mathematics (and its teaching/learning), mathematical knowledge always occupying the central focus. This work is the first of a series of papers (Carreño, Rojas, Montes, & Flores, 2012; Carrillo, Climent, Contreras, & Muñoz-Catalán, 2012; Montes, Aguilar, Carrillo, & Muñoz-Catalán, 2012) to be presented in this volume with the aim of offering a full picture of our advances as a research group (Carrillo *et al*, 2012, in this volume).

ACKNOWLEDGEMENTS

THE ROLE OF DIDACTICAL KNOWLEDGE IN SEIZING TEACHABLE MOMENTS¹

Rosa A. Tomás Ferreira*, Maria Helena Martinho**, & Luís Menezes***

University of Porto & CMUP, Portugal*, *University of Minho & CIEd, Portugal*

****CI&DETS & College of Education of Viseu, Portugal*

Drawing on a short analysis of a classroom episode, we reflect on the teacher's actions and their relationship to his/her didactical knowledge, namely in its dimensions of knowledge of mathematics and knowledge of instructional processes. Focusing on these dimensions, we discuss the answers of some future and practicing teachers to a written assignment based on that episode. Anchored in the notion of didactical knowledge, we raise some issues regarding teacher education programs and their adequacy to comply with current demands of mathematics teaching.

TEACHERS' DIDACTICAL KNOWLEDGE AND CLASSROOM EPISODES

Portugal's recent mathematics curriculum for basic education (grades 1 to 9, pupils aged 6 to 14) (Ministério da Educação (ME), 2007) stresses three transversal skills – problem solving, reasoning, and communication – which are seen of crucial importance towards achieving the curriculum overarching learning goals. However, we believe that the recommended changes in the dynamics of the mathematics classroom are the crucial features which put the biggest challenges to teachers. Indeed, teachers and their students are called to play very active roles within mathematically rich environments.

In our work with future and practicing mathematics teachers, we pay special attention to issues of classroom communication, stressing the teacher's role in the process (Bishop & Goffree, 1986; Menezes, 2004; Tomás Ferreira, 2005; Martinho & Ponte, 2009; Ruthven, Hofmann & Mercer, 2011). The analysis and discussion of short classroom episodes – written vignettes of lesson snapshots – is a way that has been found to be useful in helping teachers recognize situations which illustrate challenges that they find when engaging students in meaningful mathematical discourse (Ruthven et al., 2011; Tomás Ferreira, Menezes & Martinho, 2012). Having a sound didactical knowledge seems to be of utmost importance to attain such goal.

Though acknowledging other interpretations for the idea of didactical knowledge (Ponte, 2012), we follow Ponte's (1999) perspective in which it is directly related to aspects of practice and is “essentially oriented towards the action” (p. 61). The notion of didactical knowledge encompasses four inter-related dimensions:

- (1) *knowledge of the content* that is to be taught, including connections amongst mathematical concepts and connections with other areas and their reasoning, argumentation, and validation forms;
- (2) *knowledge of the curriculum*, its goals and objectives, and its horizontal and vertical articulation/alignment;

(3) *knowledge of the students*, their learning processes, interests, and most frequent needs and difficulties, as well as knowledge of social and cultural factors that may influence students' performance at school; and

(4) *knowledge of the instructional process*, namely the planning and teaching of lessons, and the assessment of teachers' own practices. (Ponte, 1999, p. 61 [italics added])

This notion also involves knowledge of the contexts (e.g., school, community) and knowledge of self as a teacher (Ponte, 2012). Didactical knowledge is dynamic in nature since “the experiences and situations of practice the teacher encounters in the classroom contribute to its development and constant reformulation” (Tomás Ferreira et al., 2012, p. 283; see also Ponte & Santos, 1998).

The study reported in this paper emerged from our practice as mathematics educators. We start by analyzing a classroom episode, discussing some aspects of the teacher's didactical knowledge that support her core actions. We then present the analyses of that episode made by prospective and practicing teachers, discussing aspects of their didactical knowledge regarding the domains of *knowledge of mathematics* and *knowledge of instructional processes*. Finally, we share some thoughts about teachers' didactical knowledge and raise issues about teacher education programs and their adequacy to comply with current demands of mathematics teaching.

A Classroom Episode

In the episode *Rita and Prime Numbers* (Figure 1; Boavida, 2001, adapted from Prince, 1998), the teacher starts by proposing a closed task – to list all prime numbers up to 50 – which has a low level of cognitive demand for her students (the students in the episode correspond to Portuguese 7th graders, aged around 12). Yet, by building on a student's (Rita) comment, the teacher raised the task's cognitive demand, engaging the students in complex thinking processes, such as conjecturing, refuting, arguing, and proving. In addition, they have the opportunity to discuss aspects of basic logics (such as implications, reciprocals, examples, and counterexamples).

Rita's teacher asked her class to **find all prime numbers up to 50**. After some time, Rita noticed that the prime numbers larger than 5 she had identified so far ended in 1, 3, 7, or 9. She called her teacher to show her this finding. The teacher asked Rita to work with her partner in order to find the best way to share her finding to the class during the collective discussion of the work. Rita listed on the board all prime numbers smaller than 50 and she read what she had written in her notebook:

Rita: The prime numbers except 2 and 5 end in 1, 3, 7, or 9.

The teacher then asked the class to analyse if the same thing happened with other prime numbers. The students started checking several cases of prime numbers, some of which much larger than 100, and they did not find any prime that would not end in 1, 3, 7, or 9. Shortly, they were strongly convinced that what Rita had found was true for all prime numbers, regardless of having been checked, because all prime numbers that they would check always ended in one of those digits. At this time, the teacher wrote on the board:

Rita's conjecture: All prime numbers, except 2 and 5, end in 1, 3, 7 or 9.

She made sure the students remembered the meaning of conjecture and she challenged them to find a process that would allow them to be sure if the conjecture were, indeed, valid for all prime numbers and why that was so. The students tried to respond to the challenge and, in this process, they reinforced their conviction that the conjecture was true; yet, their work did not progress. Then, working with the whole class, the teacher wrote on the board the numbers from 0 to 9, circling 1, 3, 7, and 9. Almost immediately the students offered several suggestions:

Maria: Teacher, cross out numbers 0 and 5. A prime number larger than 5 cannot end in 0 or 5.

Teacher: Why?

Maria: If it ends in 0 or 5, it is a multiple of 5 and, therefore, it is not prime.
 Daniel: You also have to cross out 2, 4, 6, and 8. If it is larger than 2 and is a prime number, it cannot be even!
 Bernardo: Of course not. 2 divides...
 Teacher: So what?
 Bernardo: A prime number can only have two factors.
 Rosa: Yeah. If it ends in 2, 4, 6, or 8, that is because it is even and even numbers are multiples of 2.
 Rita: We only have 1, 3, 7, and 9 left. Therefore, all prime numbers except 2 and 5 end in the way I found. We're now sure of it.
 Inês: **But the opposite is not true.** For example, 21 ends in 1 and it is not prime.
 Teacher: Why isn't 21 prime?
 Several students: Because 3 divides 21; 3 times 7 is 21.
 Bernardo: It has divisors that are different from 1 and 21.
 Teacher: So, check if this is true, or not, this that I am going to write on the board: all numbers ending in 1, 3, 7, or 9 are prime.
 One could hear several voices saying "it's not true". They mentioned 21, 27, 33... (...)

Figure 1. Episode *Rita and Prime Numbers*

Which instructional actions are central in the unfolding of this episode? The teacher refrained from validating Rita's idea; instead, she gave Rita and her colleague the opportunity to present their finding to the class. By building on Rita's input, the teacher extended the original task, asking the class to check whether Rita's idea would work for other prime numbers. The class naturally accepted its truthfulness as students were unable to find a way to contradict Rita's finding. The writing of "Rita's conjecture: All prime numbers, except 2 and 5, end in 1, 3, 7, or 9" on the board seems to have been deliberate – the teacher knew that the proof of a conjecture and the role of examples in that process were at stake, and that the term "conjecture" could be unfamiliar to some students. In addition, she turned Rita's conjecture more explicit to the whole class by clarifying its scope.

The collective discussion that was initiated engaged students in reflecting on the meaning of conjecture and of proving or refuting a conjecture. This was not an easy task for the students who could only see their ideas reinforced by finding more and more examples which, nevertheless, proved nothing. After letting the students struggle with this, the teacher wrote on the board all ten digits and circled those corresponding to the units of a prime number – her intention seems to have been to list all possibilities for ending a natural number while highlighting those related to Rita's conjecture. Drawing on their knowledge of divisibility criteria, the students eliminated the non-circled digits and the teacher's questions ("Why?"; "So what?") ensured that they justified all their options. By building again on a student's comment (that the opposite of Rita's conjecture was not true), the teacher involved the students in working with counterexamples, which started to emerge after she wrote the new conjecture on the board. In sum, the teacher's actions raised the cognitive level of the initial task and helped engaging the students in significant mathematical activity.

We can identify some aspects of the teacher's didactical knowledge in the episode *Rita and Prime Numbers*. For example, the teacher listened to her students in a

responsive manner (Empson & Jacobs, 2008), valuing all contributions as worthy discussing collectively, regardless of their correctness or rigorousness in language. By giving the students the responsibility for proving or refuting the two conjectures presented in the episode, the teacher orchestrated a collective discussion in a productive way (Stein, Engle, Smith & Hughes, 2008), pushing for a shared understanding of conjecture and for explanation and justification of all assertions.

We believe the teacher's actions were anchored in her *mathematical knowledge*, which allowed her to recognize a teachable moment triggered by Rita's finding, and in her *instructional knowledge*, which allowed her to seize the situation and build instruction upon Rita's idea, encouraging her students to do mathematics (Tomás Ferreira et al., 2012). The teacher transformed a task of procedures without connections (Stein & Smith, 1998) into a task with much higher cognitive demand, involving processes of proof. The new task and the fruitful discussion around it pushed the students to engage in rich mathematical activity.

DATA GATHERING

Our practice as teacher educators reflects our belief that is it important to have (prospective) teachers discussing aspects of the teacher's role regarding the management of mathematical communication in the classroom. For that purpose, we frequently resort to the analysis of classroom episodes such as the one presented before. The data we present and discuss next is based on the analysis of the episode *Rita and Prime Numbers* guided by the following questions: (1) *How do you think the teacher should lead the classroom discourse after the last interventions of the students?* and (2) *Do you believe Rita's conjecture is proved? If so, why? If not, why?* At the end of 2011/12, a group of 12 prospective teachers, enrolled in a 2-year master's teacher certification program, was asked to complete a short written, individual, in-class assignment which included the analysis of the episode *Rita and Prime Numbers* and accounted for 10% of their final grade of a mathematics education course. There was great variation in the answers obtained not only regarding the mathematics underneath the episode but also in terms of the didactical choices that were thought to be adequate to give continuation to the episode.

Feeling the need to see practicing teachers' reactions, we asked a group of eight teachers, enrolled in a professional development course, to analyse the same episode, using the same guiding questions; yet, the assignment did not count explicitly for assessment purposes. The two cohorts of participants worked in different universities located in large urban areas in northern Portugal; in both contexts, participants had been involved in reflecting and discussing several issues of communication, especially the teacher's role in managing meaningful classroom discourse (National Council of Teachers of Mathematics (NCTM), 1991), and the challenges faced when orchestrating productive mathematical discussions (Stein et al., 2008). The participants' written productions were analysed in the light of Ponte's (1999) notion of didactical knowledge, focusing on the dimensions of mathematical and instructional knowledge.

RESULTS

In this section, we present and analyse some of the data collected from both groups of participants, resorting to our translation of the participants' work because it is originally written in Portuguese. We chose the work of three prospective and two practicing teachers as it illustrates the respective cohort productions. We structure our discussion by each of the two questions that guided the analysis of the episode.

How Should The Episode Continue?

Júlio held a bachelor degree in mathematics from the same institution he was seeking teacher certification. In his response to the first question there was evidence that he acknowledged the existence of two implications in the episode, one being the reciprocal of the other. Focusing on sense making and knowledge building, he emphasized the need of recognizing and distinguishing reciprocal implications, and understanding the role of examples and counterexamples in proofs and refutations:

Based on the students' answer[s], the teacher should tell them that they had shown the assertion was false, through a whole-class discussion, making them understand that it is enough to give an example that does not verify the assertion for this to be invalid. Then, she should ask the students to relate Rita's conjecture to the latter one, questioning them about their difference[s] and truthfulness, in order to conclude the task.

Júlio's sensitiveness towards the important issue of developing mathematical reasoning, particularly formulating, testing, and proving (or disproving) conjectures, in the teaching and learning process seemed to be clear.

Carlos was a colleague of Júlio's, with a similar academic background. Unlike Júlio, Carlos did not evidence much understanding about the episode, due to an incorrect interpretation of the episode or to weaknesses in his didactical knowledge. His suggestion to continue the episode began with some considerations about Rita's finding, which evidence fragilities in his mathematical knowledge:

The way Rita phrased the conjecture seems to indicate that all prime numbers are all odd numbers except those that end in 5. During the lesson, it became clear that this is not true since 21, 27, 33 are odd numbers ending in 1, 7, and 3, and they are not prime.

This prospective teacher did not seem to realize that the discussion at the end of the episode was about the reciprocal of Rita's conjecture and that the examples provided by the students (21, 27, and 33) were, indeed, counterexamples for the reverse of Rita's conjecture, not counterexamples for the conjecture itself. Besides a poor understanding of the mathematical situation underlying the episode, Carlos's suggestions to continue the episode missed some important points emphasized in current curricular orientations:

After the students said that it was not true, that all prime numbers end in 1, 3, 7, or 9, the teacher should ask them for explanations. Some mention examples that do not verify the conjecture; yet, the teacher should ask for more examples and have them discussing the

reason why they are not prime [numbers]. Afterwards, [the teacher] could build on the fact that 9 is not prime since the conjecture said that all numbers ending in 9 were prime.

Carlos did not assign an appropriate value to having students understanding the meaning of conjectures, reciprocals, examples, counterexamples, proofs, refutations, etc. (at the level of 7th graders), nor to having a moment in the lesson to summarize the ideas that emerged during class discussion. In addition, it was not clear why, according to Carlos, the teacher should deal with the number 9 in a *special way*. Data suggested that Carlos had a poor mathematical understanding of the episode.

Joana had earned a bachelor degree in applied mathematics and computing several years before enrolling in a teacher certification program. She worked in the field of applied mathematics and had a very short teaching experience. Her knowledge of mathematics exhibited several weaknesses, which seemed to account for inadequate instructional decisions. She misunderstood Rita's conjecture and its reciprocal; hence, not surprisingly, her suggestions to continue the episode seemed to be senseless:

The teacher should have let the students reach the conclusion that 'all numbers ending in 1, 3, 7, 9' are not prime and she should not have written on the board and telling the conclusion. Maybe saying the students should conclude or even writing only the sentence 'all numbers ending in 1, 3, 7, or 9 are prime; do you agree?' because, by saying 'So, see if it is true' she is implicitly telling the students that something is wrong.

Joana did not interpret the teacher's intentions when writing on the board the two implications as a means to help students understanding what was at stake and to help them differentiating the two situations; instead, she saw the teacher's actions as intending to offer the students with clues for what would be correct or incorrect.

Cláudia was a certified teacher with more than ten years of experience teaching 7th to 9th graders (ages 12 to 14). In her response to the first question, she stressed critical features for continuing the episode: she believed that "at the end, the teacher would probably let the students prove that not all numbers ending in those [units] digits are prime [numbers]", giving the students accountability and ownership for drawing an important conclusion based on their own (counter)examples; in addition, she reinforced the need for a moment of synthesis – "in the end, it is important that they make a synthesis" – making explicit the main ideas that had been discussed.

Lina's teaching experience was similar to Cláudia's but she worked with 5th and 6th graders instead. Lina might have not understood what was being discussed at the end of the episode. She believed that "after the last interventions [...] the teacher should ask the students to reformulate the conjecture". Her response to the second question (which we discuss later) sheds more light into her thinking.

Is The Conjecture Proved or Not? Why?

Júlio understood that Rita's conjecture was true and realized the process that was used to prove it collectively: "the conjecture is proved, since the students know that all the numbers end on some digit between 0 and 9, and using divisibility criteria,

they managed to exclude the even digits and the 5, remaining 1, 3, 7, and 9". The data suggest that Júlio valued the whole-class discussion and students' (prior) knowledge as means to help them proving Rita's conjecture: "In this way, and using their own knowledge, the students proved Rita's conjecture, through discussion and exchange of ideas". Thus, Júlio seemed to have pulled adequate aspects of instructional knowledge to the analysis of the episode *Rita and Prime Numbers*.

Carlos believed that Rita's "conjecture may lead to two interpretations, the first being that all prime numbers are all [numbers] that end in 1, 3, 7, and 9, except 2 and 5, and, on the other hand, that all prime numbers except 2 and 5 end in 1, 3, 7, or 9". Although this latter interpretation was, in fact, Rita's conjecture, it was the first interpretation that Carlos believed to be at the core of the episode. He did not think that Rita's conjecture was proved during the lesson: "Rita's conjecture was not proved since prime numbers except 2 and 5 end in 1, 3, 7, [or] 9. What was proved was that the numbers ending in 1, 3, 7, and 9 aren't always prime". Resorting to the two possible interpretations of Rita's conjecture he had identified, Carlos stressed that "in [this] lesson, the only thing that was proved was that the first interpretation is not valid". Data seemed to suggest that Carlos did not recognize a process of proof (of whatever conjecture he would consider) in the teacher's and students' joint work.

Joana did not understand Rita's conjecture *per se* and, in fact, it seemed that she had no understanding of what a conjecture is, nor what might be entailed in proving (or refuting) such an assertion:

Rita's conjecture was proved and it was incorrect, since the students checked for a large array of numbers, even bigger than 100, thus establishing a degree of certainty in their answers and even finding numbers like, for example '21' which though ending in 1 is not prime since 3 divides 21.

Joana confused the two reverse implications involved in the episode; yet, she seemed to value the testing process as important to strengthen one's conviction.

Cláudia believed that Rita's conjecture was proved during the lesson; yet her response may indicate how easily teachers do what they say should not be done! In fact, she referred that "...although the student [Rita] had said 'We're now sure of it', she [the teacher] should show that there were prime numbers ending in 1, 3, 7, and 9". Cláudia showed concern for illustrating the core idea that was being discussed (Rita's conjecture) with concrete examples, which she seemed to believe that would help in reassuring the validity of the conjecture or in better understanding the conjecture. Though understandable, such a concern and subsequent actions may actually induce students into an erroneous conception of proof, namely mistaking proof for exemplification using particular cases.

Lina did not seem to be sure about whether Rita's conjecture had or had not been proved; in fact, after stating that the conjecture had been proved, she changed her opinion supported in a mathematically incorrect argument. Like Carlos, Lina brought

up the number 9 into the scene, suggesting that she also had an unclear understanding of the conjecture that was collectively proved during the lesson:

It seems that Rita's conjecture is proved because valid arguments were used allowing to conclude that the assertion is valid for all prime numbers except 2 and 5. However, the number 9 is not a prime number. There is at least one exception that was not considered; thus, the conjecture is not proved. Proof, in mathematics, entails demonstration.

On one hand, Lina believed that the conjecture had been proved but, on the other hand, the *proof* that was made during the lesson was not enough! Data suggested that Lina held a rigid and formal perspective of proof and made contradicting assertions since a logical chain of valid arguments no longer seemed to be at the core of a proof.

CONCLUDING REMARKS

The participants' difficulties in analyzing the episode *Rita and Prime Numbers* seemed to be anchored in a poor knowledge of the mathematics involved. The differences in academic background of the prospective teachers may have accounted for the differences in the mathematical knowledge they evidenced. However, caution must be exercised. Carlos, whose background and grade point average was similar to Júlio's, also showed gaps in his mathematical knowledge. Joana, unlike her colleagues, did have some teaching experience; yet, her knowledge of instructional processes in the classroom emerged as much weaker than that of Júlio or Carlos.

An inadequate understanding of proof (in Cláudia's case) or a very rigid and formal conception of proof (in Lina's case) may also have been at the origin of the difficulties found whilst analysing the episode. It was possible to find, in both groups of participants, illustrations of misunderstandings regarding the role of examples and counterexamples in proving or refuting assertions; yet, only in the participant practicing teachers did we find clear evidence of closed conceptions about proof, which may have hindered them from recognizing a process of proof in the episode.

The gathered data suggest that a poor knowledge of mathematics on the (future) teachers' part seems to be associated with a weakened instructional knowledge. This supports the claim that adequate instructional decisions can hardly be made when teachers do not have a deep understanding of the underlying mathematics of teaching situations (Kahan, Cooper & Bethea, 2003). In particular, the orchestration of productive mathematical discussions and the systematization of (new) knowledge, two complex communicative actions (Menezes, Canavarro & Oliveira, 2012; Stein et al., 2008) and essential aspects of the teacher's role within the current (Portuguese) curricular orientations, cannot be appropriately approached if the teacher's knowledge of the mathematics underneath the teaching situation is not sound (Martinho & Ponte, 2009; Ponte, 2012; Tomás Ferreira et al., 2012).

Teachers need solid mathematical and instructional knowledge, in Ponte's (1999) sense, to be able to build on teachable moments such as the one triggered by Rita's contribution and, more generally, respond adequately to the many demands of

classroom teaching. Yet, the current typical organization of teacher education may be failing to develop (future) teachers' didactical knowledge, including mathematical knowledge, despite a significant emphasis on content courses, especially in many teacher certification programs. In addition, (prospective) teachers may not be developing adequate conceptions of proof, aligned with current recommendations for school mathematics, which go much beyond processes such as two-column proofs.

Despite a heavy content load in the participants' academic background and despite all the emphasis put in the teacher's role in managing meaningful classroom mathematical communication in the two contexts in which the participants worked, we were surprised to see how much difficulty they had in making sense of the episode and in reflecting upon it in the light of current curriculum orientations. We believe that the discussion of concrete situations, based upon classroom episodes as the one presented in this paper, may contribute to teachers' increasing consciousness about their conceptions and practices, helping them in recognizing teachable moments and in building on them, seizing the opportunities that emerge during classroom interaction and taking the most of them. But this is obviously insufficient.

We had no opportunity to interview the participants in this study in order to have a better grasp of their mathematical and instructional knowledge. Our data provides only a limited and short glimpse of what might be happening. Further research is needed to address more deeply how (future) teachers manifest their didactical knowledge and how teacher education and professional development programs may help them in developing that kind of professional knowledge.

NOTES

1. This work is supported by national funds through FCT – Fundação para a Ciência e Tecnologia, under the projects *Professional Practices of Teachers of Mathematics* (Grant PTDC/CPE-CED/098931/2008) and PEst-C/MAT/UI0144/2011, and by FEDER funds through COMPETE.

MATHEMATICAL COMMUNICATION: TEACHERS' RECOGNITION OF THE SINGULARITY OF STUDENTS' KNOWLEDGE

António Guerreiro¹, João Pedro da Ponte² and Lurdes Serrazina³

¹School of Education and Communication, University of the Algarve (Portugal)

²Institute of Education, University of Lisbon (Portugal)

³School of Education, Institute Polytechnic of Lisbon (Portugal)

This paper discusses the role of collaborative work in the development of social interactions in the classroom and how teachers value such interactions in the development of the modes of communication, as well as in the interaction patterns centered on student' individual knowledge. Data are collected in the context of collaborative work involving a researcher and three teachers participating in this study. The development of the interaction among the students themselves and between them and the teachers, along with the recognition of the students' singular mathematical knowledge determined the adoption of reflexive and instructive modes of communication and also the extraction and discussion patterns in mathematical communication.

Key words: mathematical communication; modes of communication; interaction patterns; teaching practices; collaborative work.

INTRODUCTION

Mathematical communication is as much part of mathematics classes as mathematics itself. Such communication takes different forms according to the conceptions of the nature of mathematics, its teaching and learning and the role of communication in teachers' professional practices. Teachers' positions concerning the nature of mathematics as a way of understanding society are translated into forms of mathematical communication as the foundation of the mathematics teaching and learning process, considering the existence of several strategies and singular forms of mathematical knowledge in the classroom.

Mathematical communication as the foundation of the teaching and learning process is based on the recognition of the social interactions in the classroom between the teacher, the students and mathematical knowledge (Sierpinska, 1998) and considers discourse as a social practice (Godino & Llinares, 2000), where the role played by all actors in the negotiation of mathematical meanings is of the utmost importance. In this perspective, mathematical communication is a social process in which participants interact, exchanging information, influencing each other, taking up the attitude of the other and, simultaneously, expressing and asserting his or her singularity (Belchior, 2003; Mead, 1992). Teaching becomes the organization of an interactive and reflexive process, where the teacher is continuously engaged in updated and differentiated activities with students (Cruz & Martínón, 1998) and

where students become aware of their cognitive and affective processes, mobilizing them for learning (Ponte, Brocardo & Oliveira, 2003).

This paper looks into the role of collaborative work in the teachers' recognition of the interactions among the students themselves and between them and the teacher, as well as the way in which these social interactions are valued in the recognizing the singularity of the students' mathematical knowledge. We focus on the relation between the development of social interactions among students between and them and the teacher, and the recognition of students' mathematical knowledge. We also seek to understand how the valorization of the students' mathematical knowledge is related to the modes of communication and the interaction patterns centered on reflecting and sharing of knowledge among all the actors in the mathematics classroom.

RESEARCH DESIGN, ACTORS AND COLLABORATIVE WORK

Access to empirical data concerning classroom practices, conjugating action and meaning, resulted in the adoption of the case study format (Stake, 1994) for this study, which relied on participant observation and inquiry, with the development of a collaborative work, grounded on the reflection and questioning about communication practices in the classroom. Three teachers of the 1st cycle of basic education – Alexandra, Carolina e Laura (pseudonyms) – took part in this study for a period of over two years (December 2006 – February 2009), in the course of which there were twelve meetings of collaborative work (collaborative meetings), fourteen classroom observations by each teacher (participant observation) and two interviews and two individual meetings by each teacher (inquiry) for over two years (December 2006 – February 2009) (for more details see Guerreiro, 2011).

These teachers had a significant professional experience, with a minimum of twelve years of teaching in this cycle, and were highly motivated to work in collaboration with a view to strengthen their professional knowledge about mathematical communication in the classroom. The definition of common interests and goals resulted from the need to ensure a level of intentionality of the collaborative work with regard to their professional development (Boavida & Ponte, 2002) and to the construction and reconstruction of the classroom practices, giving way reflective constancy and successful changes in the partnership that existed between the first author of this paper (from now on referred to as "the researcher"), and the participating teachers (Ruthven & Goodchild, 2008).

The axes of collaborative work were trust, as referred to by Boavida & Ponte (2002), and the valorization of the critical analysis of the researcher and his colleagues, who acted as external observers, as mentioned by Saraiva & Ponte (2005). However, the teachers' initial response after the first classes were conducted and discussed was of anxiety in relation to the quality of their performance and that of their students', evidencing insecurity about their knowledge and professional performance. This

anxiety waned as the collaborative work went on and was replaced by a significant level of comfort and complicity among actors.

Self-knowledge about teaching practices through the viewing of classes and critical reflection fostered by the researcher led to changes that were acknowledged by teachers and within the scope of the students' group work and were visible in the presentation of mathematical tasks, in the acceptance of error as an educational resource, in the promotion of communicative interactions between the students themselves and between them and the teacher, as well as the recognition of the students' personal and individual mathematical ideas and strategies.

This attitude towards the mathematical ideas of the students and of others justified the teachers' growing disposition to further their training in order to expand their professional and mathematical knowledge. The changes that the teachers made resulted from the recognition of the students' singular knowledge. They also indicate an effective valorization of learning as teachers look upon the students as autonomous learners within the context of communicative sharing marked by the negotiation of mathematical meanings.

MATHEMATICAL COMMUNICATION PRACTICES IN THE CLASSROOM

Mathematical communication practices in the classroom are structured into several modes of communication, in accordance with the teacher and the students' role in the classroom discourse. Brendefur e Frykholm (2000) classified them as unidirectional, contributive, reflexive and instructive communication. The unidirectional and contributive modes of communication are associated with the teacher's absolute, or almost absolute, power over the classroom discourse. Reflexive and instructive modes of communication show the importance of classroom discourse as an object of reflection and sharing of knowledge between the teacher and the students, which takes on a metacognitive and reflexive dimension.

The nature of the interactions between the teacher and the students is expressed by interaction patterns that swing between the control of the students' thought on behalf of the teacher and the sharing of mathematical ideas and strategies through reflexive discussions about the processes of construction of mathematical knowledge. The existence of reciting, funneling and focusing patterns (Godino & Llinares, 2000, Wood, 1994, 1998) results from the centering the students' thought and knowledge on the teacher's knowledge by means of routine processes of reproduction of mathematical knowledge. Extraction and discussion patterns (Godino & Llinares, 2000, Wood, 1994, 1998) reveal the students' individual contribution in the construction of mathematical knowledge, through a collaborative dialogue between the teacher and the students.

Modes of communication

The usual communication practices of the teachers seem to result from the conception of the roles of both teacher and student as doers of a structured and finished mathematics, based on the resolution of mathematical tasks. In this perspective, mathematical communication is characterized by the dominant role of the teacher in the classroom discourse as the holder of knowledge to be passed down and the role of the student as keen listener, which is what defines unidirectional and contributive modes of mathematical communication, through the inclusion of examples, solution strategies and correct solutions of exercises and mathematics problems.

The teachers felt relatively uncomfortable in countering these practices of educational and communicative control, and were unable to conceal a significant effort not to condition the autonomous work of the students and to accept alternative or diverging solutions, giving some scope for the comparison and sharing of different solutions to the mathematical tasks, even if confusing, incomplete or incorrect. The growing participation of students in the classroom discourse, through the valorization of the moments of communicative interaction within the group or the class, led to an important autonomy on the part of the students and to the reflection in the action, by the teachers, incorporating in the discourse those ideas and difficulties expressed by the students or felt by the teachers, thus promoting the reflexive and instructive modes of communication:

[We have to] give them time and tasks where they interact with each other; to give them time to interact, to understand, to discuss strategies, first within the group, without having to keep an eye on them all the time, guiding them, [or] leading them to the right answer; to give them time and some room.

[February_2009 _ interview _ Alexandra]

The way in which the teachers learned to increasingly value the personal knowledge of each student resulted in a significant reinforcement of the sharing of knowledge among all actors and in the recognition of the value of the knowledge held by the students and teachers alike. Such a change increased the students' critical awareness and sense of responsibility in the autonomy with which they validated the solutions of mathematical tasks, as a feature of reflexive communication. This strengthened the sharing of mathematical ideas and strategies, instead of explicating the solution of the tasks.

The instructive dimension of communication derived from the debates about the reasonability of the results, from the reformulation of incorrect solutions, from the process of knowledge construction generated by solution of the mathematical tasks and from the recognition of the students' learning. Carolina's students began to compare their strategies to reach a mathematical solution regularly, thus showing a greater autonomy in the comprehension of alternative processes:

Jessica (reading the question paper): – Antonio needed a fence seventy-six meters long to enclose his backyard... (she does not finish reading the question)

Dennis: – We wrote a division statement where we divided the figure by two (he writes the traditional division algorithm on the blackboard): seventy six divided by two, to see how much is half of it (the student makes the calculation resorting to his notes). And then we divided thirty-eight by two to estimate the half of thirty-eight to get the answer (he makes a new calculation). And then to see if it works out correctly we (he consults his notes) calculated nineteen times four (he writes an addition sentence with equal parcels). And it makes seventy-six. Therefore, our equation is correct.

Beatriz: – Why didn't you just divide it by four?

Teacher: – Your colleague is asking you a question!

Dennis: – I wanted... wanted half of this.

Beatriz: – Half? But if the square has four sides, I think that instead of dividing seventy-six by two, well, you could simply divide it by four, since the square has four sides.

Dennis: – We did it this way...

Beatriz: – You did it step by step?

Dennis: – We divided it by two, and then, after getting those two, we would find out the other two.

Beatriz: – Yes, I know. You did it step by step, didn't you?

Dennis: – Yes.

Beatriz: – It's just that you could have done it all in one. Instead of thirty-eight divided by two, you could have gone straight on to divide it by four. But OK, you did it step by step, which is all right, too.

Dennis: – More questions?

[March _ 2008 _ class _ 3rd year _ Carolina]

These occurrences are characterized by a metacognitive dimension of reflection about the action itself, assigning value and integrating the students' knowledge. The teachers' assumption of the specific and personal knowledge of each student gave birth to the development of a reflexive and instructive communication, as well as the increase in the students' autonomy in the teaching and learning process, besides the students' recognition of the mathematical knowledge of the other students.

Interaction patterns

The permanent validation of the students' solution in the course of such an autonomous work seems to result from the uniformity of strategies and solutions expunged of errors and fitting the teachers' knowledge. This attitude on the part of

the teachers derives from a learning process centered on the solving of mathematical tasks, without imprecision or ambiguities, within a short time span. This drives towards the right answer avoiding errors owes much to the initial interaction practices between teachers and students according to the reciting, funneling and focusing interaction patterns based on the teacher's knowledge:

Sometimes, as I have my own strategy, when they divert from it and are confused, maybe, and have some difficulty in explaining how they managed it, when I explain, I explain it my way. (...) when they are moving away from it, instead of listening through to the end, we cut it short to guide them. (...) Maybe not to waste time and not to let them create wrong concepts.

[January _ 2008 _ meeting _ Alexandra]

Accepting and understanding the error as a learning resource, conjugated with the valorization of the interactions between students and the decentering of the teachers in relation to the blackboard in the classroom, resulted in the valorization of the students' individual and personal knowledge, and triggered the appearance of extraction and discussion patterns based on the recognition of the students' mathematical thinking. The existence of these patterns reveals the valorization of the students' individual thinking on the part of the learning community.

The extraction pattern results from the valorization of solutions that were different and potentially incomprehensible to other students and the teacher herself, giving way to a questioning pattern where one intends to recognize the validity of ideas, solving strategies or solutions presented by students. In the above problem that consisted in determining the length of the side of a square from its perimeter, one group of students chose to go on dividing by two successively in order to establish the fourth part of the initial figure, as illustrated above. Carolina tries to understand the boy's thinking using an extraction pattern:

Dennis: – Does anyone else want to ask a question? Yes, please?

Teacher: – I do. I heard what you explained to Bia. Bia ended up explaining, ended up saying, getting your explanation, but I want to know the reason why it crossed your minds to divide seventy-six by two.

Dennis: – To find out how much the half was.

Teacher: – One question: the half of what?

Dennis: – Half of seventy-six.

Teacher: – Why?

Dennis: – To find out the half...

Teacher: – And that half of seventy-six is what? What is it half of?

Dennis: – Where, Ms.?

Teacher: – Mind you, I'm not saying it is wrong, Dennis. Did I tell it was wrong?

Dennis: – No.

Teacher: – OK. I just want to know... to figure out... to try to understand what you were thinking.

[March 2008 _ class _ 3rd year _ Carolina]

Questioning seems inconclusive, which warns us about the difficulty to know the singularity of the knowledge of the other, even through a questioning based on an extractive patterns. Such difficulty seems to have roused a moment of uncertainty in the student in relation to the correction of his solution, which made the negotiation of mathematical meanings problematic. Likewise, the discussion pattern manifests itself in the way the teacher helps to publicize and explain the different types of reasoning, solving strategies or solutions present by the students in group/class. Laura contributes to the explanation of the students through a set of questions so as to guarantee that the students' solutions are validated and accepted by the whole class. In the next classroom episode, the algorithmic solution of an addition statement containing many parcels was set against a strategy of mental calculation involving notes to support it.

Teresa: – We did the following: we added six and five, which is B plus E, six plus five, which makes eleven. And then we added four and four, which makes eight; this makes nineteen.

Miguel: – We started with the larger numbers.

Teresa: – Then we added four, which makes twenty-three. And then three plus three, this makes six, twenty-three, twenty-nine, and then one. This makes thirty.

Teacher: – Doubts?

Students: – No.

[November _ 2008 _ class _ 3rd year _ Laura]

Faced with different solutions, Laura takes on the role of inquirer aiming to clarify procedures, conjugating extraction of knowledge with the sharing and discussion of solving strategies among the students:

Teacher: – So how did you proceed so as to avoid getting lost?

Miguel: – We ticked the numbers that he had already added.

Teresa: – We added E and B, which makes eleven, and we drew a dotted line, an X to know (she writes on the board as she speaks).

Miguel: – Right.

Teresa: – We then added G, F and C (she writes on the board as she speaks).

Teacher: – Because those are worth what?

Teresa: – Four.

Teacher: – Each.

Miguel: – And we started with the large ones.

Teresa: – We added G and F, that makes eight, plus... (she follows the letters with the piece of chalk) twelve (she writes “twelve”).

Teacher: – And now how much do you have?

Teresa: – We already have twenty-three. Then we went on to add H and A. They are three each, it makes six. Twenty-three plus six makes twenty-nine (she writes the partial results). And then we drew another dotted line and added another one ...

Teacher: – Which was the line that was missing.

Teresa: – And we got thirty in the end...

Miguel: – ... of the news stories.

[November 2008 _ class _ 3rd year]

The revelation of these patterns results from the teachers accepting the existence of singular mathematical strategies on the part of the students, instead of the normalization of mathematical knowledge grounded on the teacher’s knowledge. The teachers’ recognition that it is possible to conduct a positive exploitation of the error and that students have a personal knowledge of their own resulted in a sharing, among all, of the singular knowledge of every student, based on patterns of discussion and extraction.

MATHEMATICAL COMMUNICATION AS VALORIZATION OF STUDENTS’ KNOWLEDGE

Collaborative work took on a significant role in the development of teachers’ self-knowledge of their practices of mathematical communication. These were broadened by viewing classroom episodes and by the critical questioning of the researcher. This collaboration resulted in a change in teaching practices based on the valorization of the interactions between students and these and the teacher, in the recognition of the error as a learning resource and in the recognition of the singularity of the students’ ideas, strategies and mathematical knowledge.

The progressive valorization of the individual student’s mathematical knowledge induced a change in the classroom mathematical communication practices, encouraging the teachers to broaden their mathematical knowledge, as a way to contribute to the understanding of students’ mathematical knowledge.

The path from the initial mathematical communication practices, grounded on teachers’ knowledge, and the later mathematical communication practices was largely based on the valorization by teachers of the interactions among students and between students and teacher as well as of the singularity of students’ knowledge. This led to the strengthening of the students’ capacity to communicate their

mathematical ideas and to interpret and understand the ideas of the others. The deepening of social interactions in the classroom promoted the existence of reflexive and instructive modes of communication, generating a sharing of responsibilities between the teacher and the students in the recognition of the mathematical knowledge constructed in the classroom. The teacher's acceptance of the students' original mathematical ideas and strategies, though confusing, incomplete or incorrect as a valid learning resource triggered processes of knowledge comparison fed by discussion and extraction patterns centered on students' knowledge.

In this way, mathematical communication practices were far beyond the reproduction of the teachers' mathematical knowledge and assumed an intentional action in the valorization of singular mathematical knowledge constructed by each student. The existence of reflexive and instructive modes of communication and of patterns of extraction and discussion evidenced students' mathematical knowledge, generating a significant level of autonomy in the construction and validation of mathematical solutions. The recognition of the existence of diverse mathematical ideas and strategies on the part of students and teachers promoted mutual respect for the opinions, mathematical ideas and strategies of students.

NEW TEACHERS' IDEAS ON PROFESSIONAL DEVELOPMENT

Guðný Helga Gunnarsdóttir and Guðbjörg Pálsdóttir

University of Iceland

It is a challenge for teacher educators to constantly evaluate and reflect on the studies they are organizing for future teachers. The aim of this paper is to find out whether newly graduated teachers find that an emphasis on learning communities in mathematics teacher education has been useful during their studies and now in their work as teachers. We also want to know what further support they would wish for in their professional development. Five teachers, who are working in compulsory schools and graduated in 2010–11 with 80 ECTS specialization in mathematics, were interviewed. Our conclusion is that the collaborative practices in their studies were important for them both during the studies and now when they are all team teaching and collaborating with colleagues. All five teachers work in schools where no other teacher has the same degree of specialization in mathematics and are given leading roles in their schools. They feel they need support from others outside the school and seek varied possibilities to develop professionally outside their school. This is a challenge for those responsible for teacher education.

Keywords: learning communities, professional development, teacher education

INTRODUCTION

Mathematics teacher education in Iceland has been changing and developing during the last decades. From 1971 teacher education for teachers in compulsory school (grades 1–10) has been a three year B. Ed. Degree (180 ECTS). The structure has varied but student teachers have always specialized in one or two subjects. From 2007–2011 the B. Ed. degree consisted of 80 ECTS in pedagogy and didactics, 80 ECTS in specialization and 20 ECTS in studies of their own choice. From July 2011 teachers have to have a master's degree in order to qualify as teachers.

The authors of this paper have taught different mathematics education courses for more than 20 years and have taken part in developing the studies in cooperation with colleagues. We have chosen to introduce our students to various ways of collaborating and building learning communities during their studies. They have been introduced to lesson study (Lewis, 2002), they prepare their teaching practice in groups, they discuss course readings in groups and write reflective diaries together, prepare for oral exams in groups and work on various other group assignments (Gunnarsdóttir & Pálsdóttir, 2010; Gunnarsdóttir & Pálsdóttir, 2011). This is based on the belief that the creation of learning communities in teacher education gives the students good learning opportunities for developing a professional language and a collaboration competency. Our aim is also to introduce professional learning strategies to our students they can use when they enter the teaching profession.

In the spring 2010 and 2011 approximately 24 students graduated with a B. Ed degree and 80 ECTS specialization in mathematics and mathematics education. We found it

interesting to find out whether students from this group found the emphasis on learning communities in their mathematics teacher education useful during their studies and now when they have entered the teaching profession. We also wanted to know how they were thinking about their professional development and what further support they felt they would like to get.

PROFESSIONAL DEVELOPMENT AND LEARNING COMMUNITIES

According to the OECD –Teaching and Learning International Survey (TALIS) 22,4 % of teachers in lower secondary school in ICELAND took no part in professional development activities during the last 18 months and 48,5% took part in activities that lasted for less the 11 days. When asked what prevented them from more participation 47,2% of those who give a special reason said that there was nothing on offer that suited them (Ólafsson & Björnsson, 2009).

A study on the formal professional development possibilities given to lower secondary school teachers in Iceland during the period of 2005-2010 shows that the opportunities given are limited and do not meet features that characterize effective professional development (Desimone, 2009). That applies specially to duration and coherence which are considered very important features along with, focus on content, active learning and collective participation. The organization and funding of professional development in Iceland does not seem to allow for continuation and progression (Gunnarsdóttir, submitted).

Teachers have many opportunities for professional development both within formal professional development settings such as courses and in-service days and informal settings such as common planning and discussion of lessons, self-reflection and reading of professional journals (Borko, 2004; Desimone, 2009; Wei, Darling-Hammond, Andree, Richardson, & Orphanos, 2009). Several researchers have tried to point out some principles for effective professional development by synthesizing results from various research and development projects (Borko, 2004; Desimone, 2009; Loucks-Horsley, Stiles, Mundry, Hewson, & Love, 2010; Wei, et al., 2009)

Wei et al. (2009) define effective professional development as development that leads to improved knowledge and instruction by the teachers and improved student learning. They draw on research from both the US and elsewhere that links student learning to teacher development. Darling- Hammond, Wei and their colleagues put forward four main principles for designing professional development:

- Professional development should be intensive, on-going, and connected to practice.
- Professional development should focus on student learning and address the teaching of specific curriculum content.
- Professional development should align with school improvement priorities and goals.
- Professional development should build strong working relationships among teachers. (Darling-Hammond, Wei, Andree, Richardson, & Orphanos, 2009)

They also indicate that other factors like school-based coaching and mentoring and induction programs for new teachers are important and likely to increase the effectiveness of teachers. They also point out that intensive professional development rooted in practice is most likely to change teaching practices and lead to increased student learning.

Loucks-Horsley and her colleagues have for more than a decade worked on professional development and in the third edition of their book *Designing Professional Development for Teachers of Science and Mathematics* published in 2010 they review new developments in the knowledge base for professional development and use it to enrich the basic principles of effective professional development they presented in their earlier work.

According to Loucks-Horsley et al. (2010) effective professional development is designed to address students' learning goals and needs. It is driven by images of effective classroom learning and teaching and gives teachers opportunities to develop both their content and pedagogical content knowledge and inquire into their practice. It is research based and implies active learning for teachers in learning communities with their colleagues and other experts. It is a lifelong process, linked to other parts of the school system and should be continuously under evaluation.

Professional learning communities seem to play an important role in supporting teachers in continuously improving their teaching and sustaining their professional learning (Fernandez, 2002; Loucks-Horsley, et al., 2010). Lesson study is referred to as an example of a professional development strategy that has many of the aspects that characterize effective professional development. Lesson study enhances teachers' knowledge and quality teaching, it develops leadership capacity and the building of professional learning communities (Loucks-Horsley, et al., 2010).

According to Desimone (2009) there is a consensus among researchers on the main critical features of professional development that can be linked with changes in teachers practice and knowledge and to some degree in student learning. She points out five main features. These are focus on content, active learning, coherence, duration and collective participation. According to Desimone there is strong evidence that focus on content and how students learn that content in professional development can be linked to teacher development and to some extent to student learning. Active learning where teachers engage in various activities like observations, reviewing of student work and discussions is also an important feature. Teachers also need to feel a coherence between their beliefs, knowledge and their experiences in professional development and reforms and policies at all levels. Collective participation and duration are also very important features. Teachers need time to work with, reflect on and try out new ideas and they need to do this in a learning community with others dealing with the same issues. The critical features Desimone points out seem to capture the core in principles for effective professional development both Darling-Hammond et al. (2009) and Loucks-Horsley et al. (2010) present.

They also have much in common with what Borko, Koellner, Jacobs & Seago (2011) claim to be the shared view of many teacher educators on professional development. According to this view professional development for teachers should be a collective endeavour, it should be about the work of teaching and the learning opportunities should be situated within the teachers practice.

METHOD AND DATA

In this study we interview five teachers from the group that graduated as mathematics teachers in 2010 and 2011 from the University of Iceland, School of Education. They were chosen from the group we knew were teaching in compulsory schools which is less than half of the whole group. They were chosen because we knew how to reach them and they were willing to participate with short notice.

The interviews were semi-structured (Bryman, 2004). Both researchers conducted the first three interviews but in the last two only one researcher was present. The themes discussed in the interviews were experiences especially regarding lesson study and learning communities in the interviewees' pre service education and their ideas on how to develop professionally now when they are professionals. All interviews were recorded, transcribed and analysed. We read and coded the interviews and from the codes some themes emerged (Flick, 2006). The themes, linking professional development to practice, opportunities for collaboration with other teachers, and better opportunities for professional development are evident in the data. In writing up the cases we summarize what the teachers said in relation to these themes. We looked at each teacher as a case and tried to capture more in-depth information about their conceptions of learning communities and their actual situation now.

The case of Eva

Eva finished her teacher education in 2010 and has since been teaching in a private primary school. She remembers taking part in planning teaching in cooperation with fellow students which now she considers a useful experience and a good preparation for the team teaching in her school. She thinks that in teacher education it is necessary for students both to learn to work alone and in collaboration with others. She learnt a lot from her teaching practice when a practice teacher gave her critical comments on her teaching and discussed it with her.

In her school Eva has the role of a math leader as she is the only teacher who has mathematics as a specialization. She has been giving courses in her own school and other schools working according to the same ideology..

I have given lectures within our schools about mathematics teaching and the use of teaching materials. We do not use textbooks for the children only as support to us and teachers ask what do we do when you don't have a book ... what do you if a child cannot do subtraction?

She finds it important that teachers can have discussions and get support in their school. They should have easy access to information about new ideas and materials on mathematics. At the same time they should also have opportunity to attend courses. She has participated in some short courses which she found very useful for her professional development.

I don't think it matters if I take courses inside my school or outside, but in-service days where you learn something new, where something new is happening and just give a course, for those who wish to attend.

Eva expresses the view that teachers have to extend their knowledge and be prepared to search for new knowledge otherwise they will not be able to develop their teaching.

The case of Freyja

Freyja finished her studies in 2011. From her teacher education she remembers the lesson study process as a time of cooperation and discussions. She found it rewarding to share ideas and knowledge when preparing and planning a lesson together with others and having to come to an agreement at the end of that process. She also found it most rewarding to observe a fellow teacher student teach the lesson

...and how because we are two different persons doing the same thing, it turns out different even though we have the same plan, then there are always some aspects that change, both the class and the teacher. I also find it just interesting to come and sit down and see how another class reacts to the presentation and how the teacher is...

Collaborative planning and teaching during teaching practice Freyja considers a good preparation for the job as a teacher. She feels that she has learnt that the teacher's personality, the group of students and the situation are all important factors in teaching and that it is impossible to plan teaching exactly the same way everywhere. She also finds teachers' collaboration very important and vital for students' wellbeing.

We need to decide what to do, also cooperation with other teachers in the school is important. For example in the upper grades where we are working together, because I am only teaching two subjects and then there are other teachers teaching and we are teaching the same students.

Freyja has been trying out many of the ideas she got during her studies but she still has many questions and is looking for new experiences.

...and I left the studies here with a lot of questions. Even though I felt I had learnt a lot there were many questions I would like to get answers to, so maybe it is just the interest of the individual, whether there is an interest to continue educating yourself, keep nurturing what you have been doing or I don't know.

Freyja is seeking knowledge and advice when she meets new challenges both from colleagues and her former teacher educators. She finds it difficult to meet the

different needs of students and wants to get new ideas to cope more effectively and to change emphasis in her teaching towards more hands-on projects. She thinks it is important to have professional development activities like short courses/workshops within and outside the school and be able to have access to the instructors later for questions and discussions.

Freyja finds it important that mathematics teachers have a variety of opportunities for support and professional development and to her the possibilities lie in teamwork at her school and in courses for mathematics teachers.

The case of Helga

Helga finished her teacher education in 2010 and has been teaching both in grade 3 and grades 8-10. She remembers clearly the lesson study process:

...I remember that we prepared the teaching all together, decided on the goals and planned a lesson from A-Z with the reactions to, that if this happens, try to find the ifs too. Look, then we went out and taught it and then the others observed and one taught and then we summarized and could go back home and work on that and try to improve the lesson, fix the goals, or as we did it then I remember that we divided the tasks, we had some group work, then there was one that observed the teacher while the other observed the students. So yes this is what I remember most from that.

Helga says that through the lesson study process she learnt to think more about the structure of a lesson and that the discussions were deeper and more open because the group discussing was jointly responsible for the planning of the lesson.

I found that we thought much more about the structure of the lesson than when we were planning other lessons and then this process afterwards and we taught twice, ... I found that made our reflections deeper, because we reflected twice... you get more things to discuss because everyone was more aware of their role in the lesson... because most of the time we were three in the lesson even though we had taken on different roles and so, then we talked about it afterwards, it was still different, you could criticize the lesson without criticizing the one who taught, because we were working on it together.

When asked about the courses in mathematics education she attended during her studies she mentions the experience from lesson study and the work on reflective diaries on readings in groups as valuable tasks.

Helga has taken part in a professional development activity concerning literacy instruction. It was a process of two years where all the teachers at the school formed a learning community and met regularly both within the school, with teachers from other schools and the course-leaders. She is interested in trying out a similar program in mathematics or to participate in a lesson study with teachers from other schools. She is the only mathematics teacher in grades 8-10 and would find it challenging to plan with other mathematics teachers even though she works in a team in her school with teachers of other subjects and feels she can discuss her ideas about mathematics teaching with them. She finds it important for teachers in small schools to have the

opportunity to meet other teachers and finds meetings with mathematics teachers in others schools in her area important. Such meetings are organized by the school authorities a couple of times each school year.

...it gives you another point of view, and ideas and support and of course the people you are with in school, you have talked to them and they have the same kind of thought and then you need someone else to get out of that...

Helga has just started a course in mathematics teaching for teachers in her school community that will run the whole school-year.

But I also find it very good to have the possibility of, like this course in mathematics where you start with a course and then you can continue just to get some support so you do not forget the ideas when you are back out there.

Helga finds it challenging to try something new and feels she needs support to teach more in the way she would like to teach. She remembers an international math conference she attended during her studies and found that very interesting. She is also considering further studies.

The case of Lára

Lára graduated in 2010 and has been teaching in grades 7-10 in a school in rural Iceland. She remembers doing a lot of group-work in her studies. She found it useful to share ideas and have discussions as a teacher student and experiences it also as a teacher.

I found it useful to hear from others what ideas they had and I hope they got some ideas from me

She feels that in her school teachers share ideas, tell each other about good experiences, collaborate and help each other out.

I like it a lot and I feel that here in my school people work together and it is very easy to ask someone and everyone gives you advice and tells you what has worked well before.

Lára means that her students are the driving force in her professional development.

Just how different students are and that things somehow are never the same, no lesson, no group or just students, they change from year to year and even from one month to another

She feels that because of how different students can be and how many unexpected things can happen in teaching she is always challenged to develop her teaching. She believes that with more experience she will become more competent as a teacher

She is the only teacher in her school that has specialized in mathematics. That means that she has a leading role and chooses teaching materials for the school. She feels that it is a big responsibility and finds it hard to have to argue for her decisions for teachers, parents and school authorities. Now she would like to have support from outside, from teachers from other schools and some specialists through meetings and

courses. In her studies Lára wishes that there had been more emphasis on mathematics teaching for young children and teaching materials for all grades.

Lára claims that she needs more opportunities to meet and discuss with other mathematics teachers. She has good support in her school but not in developing her mathematics teaching and she needs support to work on and develop her own views and opinions.

The case of Margrét

Margrét finished her studies in 2010 and has been teaching in two different schools. She mentions books and articles that she read during her studies and how she can use ideas from them to guide her in her teaching. She is now using some of these resources for building up her competence in using questions in teaching.

Margrét thinks that lesson study rests on interesting ideas that could be useful for her and she finds it helpful to share the classroom with another teacher and to be able to discuss at the end of the day the teaching experience.

I think that it can be good to use lesson study. ... I think we get some of the good things from it in team teaching, especially if you are honest and critical in the discussion when evaluating the teaching.

What Margrét misses from her teacher education is more knowledge about students with special needs and feels that she needs more tools and concrete learning materials to meet their needs. She would like to have an opportunity to join a course or get support to increase her knowledge on that matter.

In Margrét's school the teachers are organized in teams. She feels that it gives her flexibility and support in her professional development. She also mentions that the workload can be spread because the teachers trust each other. Margrét tells that she is working in a new school where the teachers are developing new practices and are curious and inspired to develop their teaching.

.. and in this school, I don't know if it is because it is a new school, very different from the old school where I taught the first year, ... everyone is so ready and willing to develop professionally.

Margrét feels that she is in an environment where many things are happening that will help her in her professional development and that she still has many issues and ideas from her teacher education to work on and develop further.

DISCUSSION

In this research study five different teachers tell about what they found useful from their experiences from taking part in learning communities during their initial teacher education and their ideas about professional development after their first years of teaching. Here we draw attention to what they all mention and discuss those issues.

In the interviews all the teachers show interest in their own professional development and have some ideas about their needs and possibilities. What they mention as

important factors for them is in line with what Darling-Hammond and her colleagues (2009) put forward as four main principles for professional development. They see their professional development as closely linked to their practice and are striving to meet the needs of their students. They want to form some working relationships with teachers both in and outside their schools. Because of their specialization they all have leading roles in mathematics in their schools and feel that they need outside support to develop and meet the challenges of being math leaders. As young teachers they feel that collaboration and team teaching gives them the support they need to meet the daily challenges of teaching. Experiences from the collaborative practices in teacher education prepared them for this part of the work but the in-depth discussions about mathematical content and practices are missing. Opportunities for participating in learning communities with teachers from other schools as for example in lesson study could meet these needs as Loucks-Horsley et al., (2010) point out.

The fact that these new teachers are all given leading roles in their schools shows that they meet some expectations from the school environment and some support from their school principals. This also reflects that schools need professional leaders with good specialized knowledge and what these new teachers bring with them to the schools is valued and in line with the schools' goals for development and improvement. That should be a good basis for their professional development and it is an important principle for effective professional development as Darling-Hammond et al. (2009) draw attention to.

All the teachers are aware of the need for further professional development. They mention courses, in-service days, conferences and meetings with other mathematics teachers as a support for their development. Professional development activities within the schools do not meet their needs to develop as mathematics teachers and mathematics leaders in their school. This applies both to teachers in schools in urban and rural areas. From the interviews it is evident that the teachers would like to have had opportunities to attend courses, workshops and other professional development activities. Because of the size of the population it is difficult to fulfil their wishes and it is important to seek new ways to create a forum for teachers to meet in reality or in virtual space. This is a challenge for us as teacher educators.

COMPETENCE IN REFLECTING – AN ANSWER TO UNCERTAINTY IN AREAS OF TENSION IN TEACHING AND LEARNING PROCESSES AND TEACHERS PROFESSION

Dr. Markus A. Helmerich

Universität Siegen, Germany

Teaching and learning processes and the teacher's profession are afflicted with tensions of conflicting goals. After giving an outline on these areas of tension, the competence in reflecting will be suggested as an answer to the question on how to deal with tensions. Reflection support teachers and learners in bearing the often unsolvable tensions. The article then suggests facilitating actions in university education by integrating reflection tasks in teacher's education. Examples of students' reflections and first analysis results in changes of student's beliefs are given.

Keywords: reflection, tension, teaching, learning, process

THE SITUATION OF TEACHERS IN LEARNING PROCESSES

In Mathematics teaching and learning processes (prospective) teachers often experience uncertainty in dealing with conflicting situations. They feel lost in having to deal with contradicting interests. Prospective teacher students tend to search for „simple answers” - not for vagueness in decisions on how to set up and manage the learning process, to get the „one solution” on deciding how to teach, trying to step on one side of the contradicting poles of areas of tensions. This tendency is quite understandable as teaching and learning processes challenge teachers on a wide range of diversity: heterogeneity of primary school students shows in social and cultural background, literacy, language, interests, gender, skills, effort and achievement ability, and many more. In addition to those already demanding aspects (prospective) teachers are challenged to fulfill high expectations of school administration in their teaching and pedagogical actions. Modern teaching methods and a strong orientation towards the learning-outcome and competences leave (prospective) teachers often helpless.

The areas of tension are already coining the university studies and some of them are just lying in the nature of mathematics. Mathematics is presented strongly product-orientated as an elaborated theory which leaves no space for individual ways of thinking. Moreover it is actually just the power of mathematics being a product with clearly outlined rules and structures. But learning processes start at a totally different point. Students activate their pre-knowledge and try to connect to the mathematical concepts, what hardly turns out to happen in a straight way and nor getting to the intended rules. Teachers have to and should support this process, but often struggle in that area of tension. Both sides are important, having an individual conceptualization and the conventions, and it seems difficult to set up a balanced learning environment.

The answers from first year students at University of Siegen who were asked in a survey 2010 about their opinions and experiences with mathematics and their expectations of their studies reveal an image of mathematics and learning processes which can be characterized by putative conflicting interests and traits of mathematics, which tend to become even more diffuse during university studies. From these opinions of students the areas of tension could be drawn: students, enrolled for mathematics educational studies, come with a strongly closed view on mathematics and the teaching and learning processes due to self-experienced classroom action. Their view is affected by conventions and rules, strongly regulated learning activities, which leads to internal tensions if the (prospective) teachers simultaneously reach out for more real life applications and comprehension orientated activities, clearness and more openness in teaching mathematics. The survey was used to extract some main areas of tension from students in mathematics training. The extracted areas of tension correspond well to my observations in university lectures and in mentoring teacher students in their first practical experiences at school.

These areas of internal tension, which afflict educational studies students and teachers, could be grouped in five classes (see Helmerich, 2012), given here by stating the extreme poles of tensions:

- form and content
- openness and closeness
- rigour and intuition
- product and process
- singularity and regularity

These concepts are the result of a survey among first year students in year 2010. The students were asked to describe their view on mathematics and teaching and learning processes with their own words. Basis for the clustering of the students' answers was the work of Krauthausen and Scherer (2007) on the foundations of teaching mathematics as "at first contradicting extremes" (translated by MH). The extreme poles mentioned by Krauthausen and Scherer (2007), like application orientation versus structure orientation, student orientated versus subject orientated teaching, individual ways of solving problems versus conventions, open tasks versus closed-ended problems link quite well to the areas of tension identified of the Siegen research group and mirror the results of the prospective teachers' survey. I focused rather on the mathematics-related aspects of the "contradicting extremes" of Krauthausen and Scherer instead of the more general pedagogical ones.

Although we know that teachers encounter conflicting situations, and their professional knowledge and necessary competences are extensively discussed and investigated, studies like TEDS-M still describe areas of tension as a liability for teachers, but not the great potential of activating these tensions in the learning processes as dialectic concepts. Helsper names it "constitutive professional antinomies of teaching" (Helsper, 1996, 2004) (translated by MH), "which entangle

the uncertainty of representative interpretation and the simultaneous aspects distance and proximity.” (Baumert & Kunter, 2006, p. 471) (translated by MH).

“Taken the antinomious structure of teaching seriously, teachers necessarily will have to make decisions about their actions in teaching, which cannot be in accordance to both conflicting claims of validity at the same time. This situation will only turn out to be bearable and productive, if there is a working agreement of their free will” (Baumert & Kunter, 2006, p. 471) (translated by MH).

Among many areas of tension the five mentioned above are vital in mathematics education of our students – relating to their image of mathematics and their issues in learning mathematics – and seem to be characteristic for the nature of mathematics. Many other areas of tension could be brought into consideration, but most of them are rather on a pedagogical level and apply entirely only to classroom interaction but not to specific learning processes in mathematics.

REFLECTION IN AREAS OF TENSION

The experience in teacher education is that many university concepts do not spring into action in school teaching. One reason might be the strong beliefs built up over years during school which could hardly be affected by university teaching and breaks through under pressure in school teaching situations. So we set up a couple of actions in university teaching to form at least some awareness of the students beliefs, make them reflect on their own beliefs and attitudes towards mathematics, teaching mathematics and the learning process of mathematics.

Teaching mathematics does only work in areas of tension, teachers have to make decisions, have to hold on these conflicts lay out in the nature of mathematics, in the clash of own standards and environmental restrictions. In order to stand these tensions, and to achieve “mathemacy” (Skovsmose, 1998, p. 199), which is “more than an ability to calculate” (Skovsmose, 1998, p. 199), reflection competence is required.

Before showing examples for these reflection tasks and what students made of it, the term of reflection, as it is used here, is explained. The American Heritage Dictionary [TAHD] gives the following definition on reflection:

- “1. The act of reflecting or the state of being reflected. (...)
- 3. a. Mental concentration; careful consideration.
- b. A thought or an opinion resulting from such consideration.” (TAHD, 2009)

This definition points to important aspects of reflection: consideration of your own actions and thoughts and come to an opinion on that. To reflect your own standards on learning processes, the reasons for your decisions and the origin for your belief systems (see Törner & Pehkonen, 1995) is necessary to get over the uncertainty and learn to deal with it, accept it as a necessary state in which learning and teaching will happen.

“Reflection means reconsidering what is taking place. Reflection is a mental, a conscious or a theoretical activity. In my terms: It is a critical activity and a process of grasping basic processes of social development. If reflexive modernization has mathematics as constituent, then reflections with respect to mathematics become of particular importance.” (Skovsmose, 1998, p. 200)

Reflection on opinions of prospective teachers towards mathematics and learning processes can oppose to uncertainty in areas of tension. The own positioning between the poles of areas of tension and knowing the reasons and justifications for the positioning must be learned and trained already at university.

The problem arising at this point is, that reflection in university's education could only be a “reflection on action” (Schön, 1983), or even less it might be only a reflection on *possible* actions, since the reflection project presented below stimulate reflection on very general issues concerning teaching and learning processes. The aim of encouraging teacher students to reflect during the university studies is to make them aware of their attitudes *on* teaching, learning and learning environments, and how this could affect their performance *in* classroom action. The reflected knowledge about one's beliefs and preferences, about potentials and threads in areas of tension, strengthen the teachers in their later reflection processes in action. If teachers accept the tensions in teaching situations as a fact and furthermore that teaching actions are not bind to one of the far ends of the tension's spectrum, teachers will feel less pressure and less uncertainty in such situations. If the prospective teachers learn by reflection during their education about how to take benefit from tensions as dialectical concepts, they will be able to get a broader view on learning processes. Solutions and questions of pupils could be judged and answered more open-minded, considering the areas of tension offer different views on learning processes. Those areas of tension could be even made explicit and integrated as opportunities for reflection in classroom interaction. This leads to more communication about mathematical ideas, pupil's conception of mathematics and a reflected knowledge and image of mathematics.

A REFLECTION PROJECT IN TEACHERS EDUCATION

This section illustrates how reflections and reflection competence could be encouraged and facilitated in university education for prospective teachers. Examples of reflection essays from students are used in a case study on reflection competence. In this paper a first attempt of a theory orientated analysis of these essays is given by using Skovsmose's dimensions of reflection (see Skovsmose, 1996, 1998) as a framework for analyzing the statements of the students. Further research on the development of reflection competence in teachers training by writing reflection essays will follow. So far the aim of this project was to get students to a reflected position of their image of mathematics and how to learn and teach mathematics at school.

In the beginning of the project accompanying a lecture, occasions of reflecting were integrated, to start off with just describing opinions on material presented in my lessons, and to continue with writing tasks throughout the whole semester, provoking processes of reflection and enforce my students to take a firm stand on their beliefs, decisions and opinions in teaching and learning processes. The university course on “Learning Mathematics as Construction Processes” for third year students seemed to be the right place for starting with the reflection project. About 200 of the 350 enrolled students took part in the take-home reflection assignments which came in addition to the tutorial work and homework, included some kind of reflection tasks already as for example to discuss advantages and difficulties of different teaching settings or mathematics problems.

With the reflection assignments, shortly called „E-Reflex“, the teacher students are encouraged to reflect their own learning process and to comment on the presented contents, as reflecting is crucial for reasonable and sustainable learning und understanding. In this way of reflecting the teacher students got the possibility to express their observations and thoughts in order to become aware of their own learning process and issues. By working on the reflection assignments the mathematical and didactical content knowledge is increased and competence in reflecting is trained and elaborated. Moreover those E-Reflex texts gave me a good feedback on the learning progress of my students and enabled me to respond in further lectures. The student texts had to be uploaded to a learning platform “Moodle”, were revised by myself and handed back with attached short comments. With these comments the students got a feedback on depth and width of their thoughts.

As a guideline for setting up the reflection tasks and an analysis and evaluation tool I adapted the theory of Skovsmose (1996, 1998), who differentiates several dimensions of reflection in mathematics:

- mathematics-oriented reflection
- model-oriented reflection
- context-oriented reflection and
- lifeworld-oriented reflection.

Usually these dimensions are used by Skovsmose to describe reflection processes of mathematical actions. For the E-Reflex project the aspects were applied for reflection on learning and teaching processes of mathematics. Mathematics-oriented reflection was transferred to didactics-oriented reflection, covering questions on the coherent usage of specific didactical theories, stringent lines of argumentation and reasonable usage of didactical terms and concepts for describing phenomena in teaching or learning processes. The model-oriented reflection applies to considerations about the ideas of teaching and learning processes and their adequacy. Furthermore it questions whether a didactical theory or concept covers a certain idea or process, or whether an alternative conceptualization could be brought up. Context-oriented reflection gives insight to thoughts on learning environments and surrounding requirements, whereas

the lifeworld-oriented reflections should connect didactical and pedagogical thinking and action with individual beliefs and discussion of the relevance of didactical theories for distinct actions. The reflection tasks try to cover these dimensions and link them to specific mathematical problems or classroom action considerations.

Besides giving a framework for the formulation of the reflection tasks, these dimensions of reflection are later deployed for the analysis of reflections of the students in mathematical educational studies. Since the reflection tasks are not focused on one possible answer, one needs to have an analysis tool for differentiated evaluation and feedback processes.

The first E-Reflex task covered the didactical concept of learning by discovery, which is based on a constructivist position. The students should reflect on the question whether mathematical discoveries of primary or secondary school students are possible at all, and if so, to give a practical example, how discoveries could be made in certain teaching settings or mathematical problems. In addition, it had to be discussed, if there are specific mathematical concepts and contents which could not be learned by discovery. Last but not least the teacher students should state their preferred mathematical content for interrogative-developing teaching method and teacher centered classroom action, and the reason for their decision.

In this first assignment the students had to reflect on possibilities for discoveries in mathematics, taking a closer look on mathematics in primary school in a mathematical-oriented way, but also with respect to pedagogical concepts and beliefs on how teaching might be. Student Kerstin wrote:

“(...) In my opinion, almost everything can be learned by kid’s own discoveries, assumed that one provides specific learning materials. Even concepts could be established by working on tutorial sheets. But I think it is good for kids, if you bring some variety to teaching and don’t withdraw yourself all together. ‘Let the kids just do their own thing’ is not a healthy attitude in discovery learning. (...)” (translated student’s text)

In order to reflect on the given question Kerstin has to make her own concept of teaching explicit, moreover she combines her experience and belief of good teaching with lifeworld attitudes and take up a position ‘pro discovery learning’. Most of the student’s texts argued for discovery learning as an important principle in teaching, but some students expressed their tendency to go for teacher centered, guided learning methods if it comes to secondary school and putative more abstract and conventional mathematics.

The second E-Reflex assignment challenged the students to justify mathematics in school. With Heymann’s claim that mathematical instruction should provide a general education (Heymann, 1996) and Winter’s call for important basic experiences with mathematics (grasp mathematics as a certain way of looking at our world, experience mathematics as a structured, well-formed theory and as a certain way of thinking providing problem solving abilities (see (Winter, 1995)) the students got two positions during lecture to potentially set up their arguments. But the reflection task

aimed on their own opinion and their individual justification for teaching mathematics in school, too. It was motivated to make their point of view explicit by giving practical examples or choosing only distinct contents out of the wide range of mathematical knowledge.

Most students argued with the importance of mathematics for every-day life, applying a dimension of lifeworld-oriented reflection. A typical sequence is found in Eva's text:

“(...) Personally I think, that mathematics is sort of basic competence for social life in our culture (in the jungle of course applies something else). But in our industrialized world mathematics is essential. Regardless whether it is shopping, work or leisure we will be confronted with mathematical topics. Some kids say things like: ‘I wanna be a hair dresser, gardener or baker, what do I have to know maths for?’ But you can easily find concrete examples for mathematical topics even in these jobs. (...)” (translated student's text)

The third E-Reflex problem was a rather mathematical-oriented task. The students were confronted with a supposedly ‘illogical spot’ of mathematics. The students then had to understand, what is going on in this problem and complete a dialogue of two school kids talking about this problem and trying to figure out, how it works. By using the dialogue setting, the students had to think about the answers to the given problem, but also about difficulties in understanding the mathematical concept underlying the problem, so they had to think about both parts in the conversation. This method and its positive learning effects are discussed more deeply in Wille (2011). After writing the dialogue it was mandatory to reflect on this kind of task: How did it feel to work on this assignment? What could be learned by doing this? Is this method a possible starting point for learning processes at school?

Working on this task the students experienced the constraints and opportunities of putting yourself in another's position. Many students found themselves struggling with the problem and so having difficulties to take over the explaining part in the dialogue. But they all acknowledged the high potential for learning and deeper understanding of mathematics throughout this reflecting way. Since the dialogues turned out rather lengthy and would have to be shown in reasonable large sections to grasp the line of argumentation, examples could not be displayed in this article.

In the last E-Reflex task, the students were asked to describe their idea of heterogeneity in classroom action and how they would deal with this diverse situation in teaching and why in this way. To carry it further on, a preference for teaching in a homogeneous (assuming this would be possible to form) or a heterogeneous class should be given. Insisting to take up a stance on the dialectics of learning processes is important to really reach the students in their core beliefs and get a reflection process started on this. A final remark should be made to outline possible actions of differentiation in learning processes and to discuss, if – assuming again that

homogeneous learning groups could be put together – differentiation is actually necessary.

In the last task I have noticed a huge step towards a reflection competence in the student's texts. Almost all reflections turned out longer than the obligatory two pages and showed the effort of lay out the reflection in different dimensions. The student got more confident in positioning themselves in areas of conflict demonstrated in sophisticated and deliberative lines of argumentation. Exemplarily the text of Diana shows the progress in belief changes:

“(…) If I had been asked several weeks ago, whether I prefer a homogeneous over a heterogeneous learning group for teaching, I would have probably said yes. Because one cannot imagine anything better for a teacher than teaching kids who are all on the same knowledge level and learning the same content at the same pace and time. (…) The teacher would be able to plan teaching precisely and would cover all anticipated content. (…) I want to be a teacher actually just because of the variety and individuality of the students. Of course I want to teach a heterogeneous learning group. (…) The individuality of learners has to be exploited for a good learning environment.” (translated student's text)

CONCLUSIONS AND FURTHER RESEARCH WORK

The reflection tasks were used in the course to enable prospective teachers to overcome their uncertainty in areas of tension by reflecting on mathematics teaching and learning issues, their own point of view and last but not least their options in dealing with conflicting situations.

This first review of the student's reflections is encouraging for future reflecting projects in university's teacher education since a development from uncertainty in teaching actions towards a reflected way of taking position in the range of possible actions in areas of tension is noticeable.

The reflection impetus of the assignments could be improved by stressing out even more the importance to have a look at both sides of the tension spectrum. Not only the positioning on one pole of the areas of tension, but the experience of opportunities and threads of the far ends and the ability to find your place in many situations somewhere in the middle, not being able to make an easy decision for one side but instead having to bear with the tension, is a desirable goal in future reflection projects. This will help students to establish a reflected way of knowing in which situation the decision for one pole is appropriate and in which situation you have to stand the tension.

In further research it is profitable to take a closer look on the student's texts and carve out types of reflection characters to achieve a deeper insight of persistence or approaches to changes in belief systems and thereby a better understanding of the effectiveness of university teaching on students.

This reflection projekt is linked to the broader research topic of the Siegen group, searching for objectives and educational goals and a curriculum for mathematics teachers (see Lengnink, 2011; Helmerich, 2011). With those objectives the competences in mathematical repertoire (content knowledge in mathematics), attitude on and to mathematical content and the observable performance are combined to an education framework. In this framework reflection links repertoire, attitude and performance together by defining the relation between the triplet: education manifests in a reflected attitude on a mathematical repertoire which implies performances in teaching and learning processes.

ONE POSSIBLE WAY OF TRAINING TEACHERS FOR INQUIRY BASED EDUCATION

Alena Hošpesová, Marie Tichá

University of South Bohemia České Budějovice,

Institute of Mathematics of the Academy of Sciences of the Czech Republic

The paper describes the results of a research study aimed at preparation of pre-service primary school teachers for inquiry based mathematics education (IBME). The teaching experiment involved pre-service teachers' work using a variety of techniques (with strictly formulated questions and open problems) in various environments suitable for this approach. We concentrated on pre-service teacher content knowledge and ability to apply the gained knowledge in problem solving.

Keywords: inquiry based mathematics education, pre-service teacher training, subject matter knowledge, knowledge base for teaching

INTRODUCTION

We have been focusing on various issues connected to the process of professionalization of teachers for many years. Contemporary we tried to find the ways of improvement of teachers' knowledge base for teaching (Scherer, Steinbring, 2004) through introducing substantial learning environments (Tichá & Hošpesová, 2011). The issue is closely connected to the question of how to introduce these environments into reality of teaching at schools. This lead us to inquiry based mathematics education (IBME), to the role of the teacher as understood in thus conceived education, and to the requirements on pre-service teacher training. This contribution is concerned mainly with the quality of pre-service teachers' content knowledge, and their ability to apply the gained knowledge in solving process of problems leading to IMBE (requiring discovery, exploratory approach).

INQUIRY BASED MATHEMATICS EDUCATION

IBME in contemporary education raises great interest (for example Canavarro, 2011). It transmits procedures known from real scientific research to everyday school work with pupils. It puts emphasis on independent discovery (a self-discovery), on proper justifying, and on links with everyday reality (i.e. on a practical desirability).

“Inquiry based mathematics education refers to an education which does not present mathematics to pupils and students as a ready-built structure to appropriate. Rather it offers them the opportunity to experience how mathematical knowledge is developed through personal and collective attempts at answering questions emerging in a diversity of fields, from observation of nature as well as the mathematics field itself, ...“ (Artique, Baptist, Dillon, Harlen and Léna 2011, p. 10).

The concept of this approach is far from new. Let us recollect here for example the concept of *guided rediscovery*, anchored in the concept of genetic style of teaching

governed mainly by psychological reasons and the concept of guided discovery. It built on characteristics of genetic style of teaching of Brunner (1966), Wittmann (1974), Freudenthal (1973).

“H. Freudenthal expressed his opinion on guided discovery and genetic style of teaching on a number of occasions. He characterizes the genetic principle as “rediscovery”, i.e. such teaching of mathematics, in which discoveries stand for what they really are, i.e. for discoveries. Discovery takes place even in a modest pupils’ rediscovery by non-prescribed procedure... Freudenthal adds the attribute guided to the concept of “rediscovery”. Although this attribute should be self-evident, it is not useless because of left-wing didacticians who refuse to understand and interpret rediscovery as a process in which pupils should discover everything on their own.” (Vyšín, 1976, 584-585).

As we want to focus on creation of future teachers’ knowledge base for teaching in IBME, it is worthwhile to recollect at this point also Brousseau’s concept of a didactical situation (explanation in endnote 1) and *a*-didactical situation (Brousseau, 1997). “In *a*-didactical situation the educators enable the student(s) to acquire new knowledge in the learning processes without any explicit intervention from them” (Brousseau in Novotná, Hošpesová, 2012, p. 282). This does not necessarily imply that the student (solver) must discover the new knowledge on his own, but IBME can become a specific type of *a*-didactical situation. This makes us ask what the educator’s role in situations of discovery is. Brousseau distinguishes several phases in an *a*-didactical situation that can be used in IBME:

“Situation of action – its result is an anticipated (implicit) model, strategy, initial tactic

Situation of formulation – its result is a clear formulation of conditions under which the situation will function

Situation of validation – its result is verification of functionality (or non-functionality) of the model” (Brousseau in Novotná, Hošpesová, 2012, p. 282)

The educator’s intervention in these phases will be of different nature. Let us presume that a discovery is initiated by the educator using a problem that opens opportunities for collaborative orientation. We can expect the educator to intervene in the first phase only if the pupils/students are not active, if they do not look for solutions. In contrast the educator’s role in the second and the third phases is crucial. This role is far from traditional: the educator does not explain, produce illustrative examples and exercises. He poses questions, asks for clearer explanations, for assessment of validity of argumentation (e.g. questions: Why do you think so? Could you explain it more clearly? How do you mean this? Are you sure it is so?). In mathematics, this is of specific meaning, as the nature of mathematical knowledge is also specific.

In our study the students were in dual role. They solved the problem (the role of the student) and at the same time, they are supposed to think as the teachers and analyze

the didactic potential of the solved problem (the role of educator). The aim of this paper is to find out how this dual role influenced the process of problem solving.

TEACHING EXPERIMENT, ITS PARTICIPANTS, METHODOLOGY

Participants

The teaching experiment was carried out with two groups of participants. We used similar framework steps for both groups.

The first group consisted of pre-service primary school teachers in the second half of their studies attending the course of Didactics of Mathematics (in total all 63 registered students). The students completed in their previous study several courses of mathematics, which focused on the theoretical basis for teaching mathematics for primary school level. Partly we solved problems in learning environments suitable for implementation of IBME. Students analyzed their mathematical content, discuss the possibility of putting them into practice. We tried it show how the traditional subject matter could be enriched through IBME.

The other group consisted of students who had already finished their course of Didactics of Mathematics but wanted to amplify their knowledge by attending an optional subject with the aim of connecting the knowledge gained in the seminars of mathematics and didactics of mathematics in isolated topics and to gain a full, comprehensive view of primary mathematics education. They do not focus specifically on IBME.

Teaching experiment and research tool

Our approach will be illustrated on the problem “Who hits 50”. The assignment of this problem was inspired by a paper of Scherer and Steinbring (2004). The problem was posed as follows (the original German wording of the problem is in the endnote 2):

The following rules for calculations hold in the scheme in Fig. 1:

- You can choose arbitrarily the start number (initial - given in an oval) and the number you are adding (addend - given in the circle).
- You gradually get the numbers in the other four squares by adding the “addend”.
- You get the “target number” by adding all the numbers in the five squares in a row.
- Which natural numbers do you have to choose as “initial” and “addend” to get the “target” number 50?

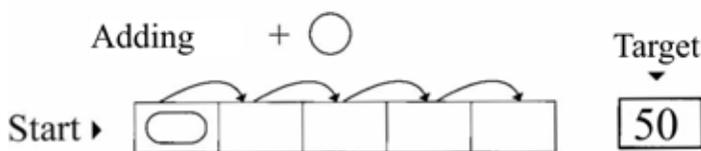

Fig. 1 The scheme for the problem “Who hits 50”

The students were introduced to the environment and assigned the problem. However, they were not told that the problem focused on searching for patterns, coherences and relations and their properties. They were expected to find that out on their own.

The procedure:

1. The participants solved an unknown problem/set of problems in order to get familiar with the environment.
2. a) They were asked questions and assigned problems in the form: “What will happen if the target number is 60, 90? What will happen if there are 6 boxes?” etc.
 b) The students were asked to think over the aim of the assigned problem. They were asked to pose other tasks and questions.
3. This group work was followed by a discussion in which various aspects of the problem were analyzed (mathematical content, number of solutions, possible obstacles for the pupils, different models and representations, possible solving methods, possible extensions of the problem).

In the background of the experiment was our conviction that our students should first get hands-on experience with discovery in these environments, i.e. try to solve problems similar to those they will assign to their prospective pupils (number walls, race to twenty, etc.), which should be followed by a discussion on the didactical aspects.

The students in both groups were first asked to solve the assigned problem, answer the question.

The students in **the first group** then worked in groups of four on modifications of the assigned problem. They were looking for answers to questions aiming at developing their subject matter knowledge and were solving the assigned tasks:

- What relations could you observe in the scheme?
- Propose other target numbers and find several solutions.
- Solve the problem with a different scheme: e.g. a different number of squares; a different target number; 6 squares and target number 60.
- Articulate conclusions on the relationships between the target number and the shape of the scheme.

In **the other group** the students worked in pairs. The work in seminar concentrated mainly on students’ ability to elaborate didactically the subject matter. The students were asked to think over the following questions (and look at the situation in a different perspective):

- What task was given? Why? (Which concept, solving method is being developed?)
- Why did we assign this problem? What is the benefit of this problem? What may become a source of difficulty, problems?

Later, in a whole-class discussion, they came to the conclusion that this was about regularities and dependencies, the students were asked to:

- Think of other questions and tasks leading to discovery of regularities.
- Assess whether this was a suitable and stimulating task.

In the end students in both groups were asked to pose other questions and problems in this environment.

Data collection and analysis

When analyzing the students' work we were inspired by the method of grounded theory. We classified the students' written productions and sorted them with respect to their characteristic features. We gradually identified and formulated emergent phenomena, and interpreted them.

FINDINGS AND DISCUSSION

We realized several phenomena. The students differed considerably in:

- ways how to find the solution,
- ability to describe what they saw and which representations they were using,
- which regularities and dependencies they uncovered,
- what type of problems they posed.

How did the students proceed when looking for the solution?

All students managed to find several solutions to the problem. The students were not satisfied with one solution of the problem; they tried to find all solutions. But the most frequently used strategy was the trial and error strategy. The initial numbers were most often chosen at random and some of the groups of students did not try to proceed in a systemic way. This was the case of looking for the "first" as well as the following solutions (that is pairs of starting and adding numbers). In consequence, some groups of students were not sure in the concluding discussion on the number of solutions whether they managed to find all of them. Moreover, they could not tell how to make sure that all the solutions be found. Trial and error strategy is the natural way of solving this type of problems unless the solver knows the procedure and is undoubtedly appropriate in case of primary school pupils (although Scherer & Steinbring (2004, p 68) showed that some of German four-graders were able to proceed in a systematic way).

Students also did not attempt to apply algebra. The exception was a group in which two students who originally studied mathematics worked (see their solution in endnote 3). The question is whether their approach was not caused by the student tendency to solve the problem in a way understandable to their future pupils. Rather, it seems that they were not able to use the knowledge they have acquired in previous studies, although in the seminar they regularly worked like this.

What representations did the students use?

Previous findings are related to the modes of representation, which students used. Despite the attention paid to different modes of representation, translation among them, and transformation within them (Lesh et al., 1987) the students probably neglected and underestimated the role of iconic and pictorial representations in concept construction and tend to overuse verbal representation. They for example wrote:

The sum of the start and the final numbers is the same number as the sum of numbers in the 2nd and the 4th squares. In case of the target number 50 it is 20. This means that the number in the middle is always the same number. In this case 10. And as there are five squares, the “target number” must be divisible by five. If there are 6 boxes, the “target number” must be divisible by 6.

Visual representation (Fig. 3 for target number 90, Fig. 4 for 6 boxes) accompanying the verbal description of the calculation was used only rarely.

We divide the final number by the number of boxes (squares) (5) and get the middle number. The sum of the first and the fifth numbers and of the second and the fourth numbers is twice as large as the middle number.

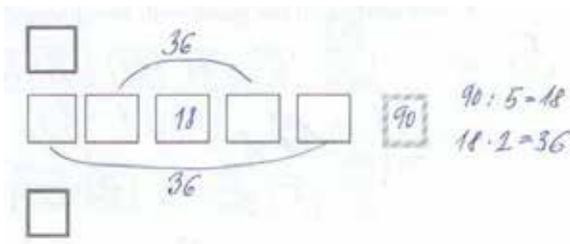

Fig. 3 Visual representation accompanying the verbal description

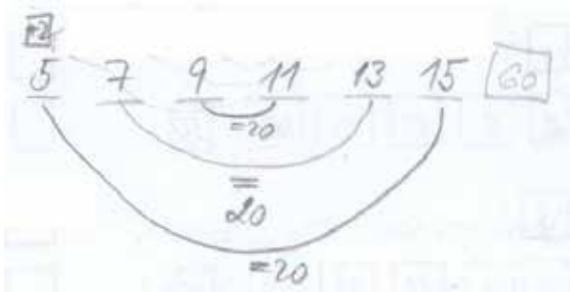

Fig. 4 Visual representation for schema with 6 boxes

In several cases, the visual representation helped us grasp how the students were reasoning (Fig. 5a, b). As important we consider the students' efforts to seek patterns and coherence. For example Griffith claims that mathematics may be characterized as the search for structures and patterns that bring order and simplicity to our universe. Moreover, it is the discovered patterns and coherence that give mathematics its power (Griffith, 2000).

An odd number of numbers means that the middle number is always the same and the sum of the outside numbers is double the middle number. An even number of numbers means that the two numbers in the middle are three times smaller than the final number.

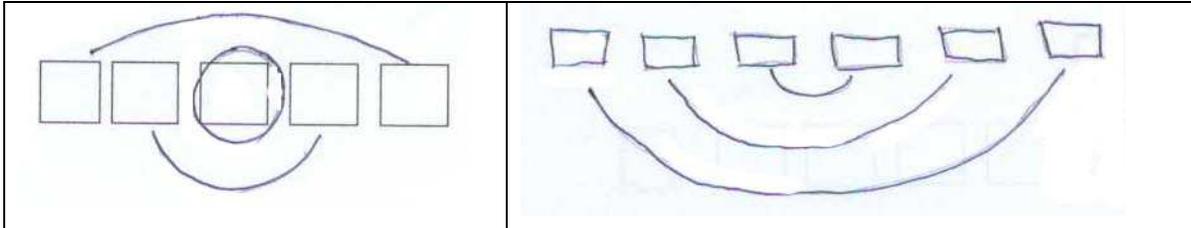

Fig. 5 Visualisations of statements mentioned above

The joint discussion made most students realize the “usefulness of making illustrations”. However, only some of them were able to grasp the table that followed these visualizations (Fig. 6).

$x - 2a$	$x - a$	x	$x + a$	$x + 2a$
----------	---------	-----	---------	----------

Fig. 6 Visualisation through table

What regularities and coherence did the students notice?

The students usually described their calculation; they stated what they had been doing and how they had proceeded. They mostly recognized that the final number must be divisible by the number of squares but rarely did they verify or justify this conclusion. Their explanations are not always easy to understand. For example

$50/5 = 10$, 10 must be in the middle because we divide 50 into five parts (10, 10, 10, 10, 10) and then the 10 in the middle is left while I always subtract something from the tens on the one side and then I have to add something to the tens on the other side.

$50/5 = 10$... to the third. We divide the final number by the number of boxes, the result of which will be in the middle box. We subtract a selected number in the upper box to the left and add it to the right.

Fig. 7 Students' solution

We can see that there is number 10 in the 3rd box. We calculated 10 as $50/5 = 10$.

These observations also included some interesting remarks that were consequently discussed in the joint reflection. For example:

The sum of the pair of outside numbers is 20.

The addend and the number in the second square are together 10.

If the addend is larger by 1, the initial number is smaller by 2. (This was observed in cases that the students' procedure of looking for other solutions was systematic.)

The greater the initial number is, is the smaller the addend is.

Posed questions and problems

The students' interest in problem posing was raised in case of both groups by the following tasks: Why did we assign this problem to the children, what were our intentions? What kind of problem would you recommend as suitable for assignment to children in the given situation? Why? With what intention?

Let us present a few questions posed by the students:

Which least number can there be in the middle?

What would happen if the middle number were 8?

What would change?

What least number can the target number be?

Can the start number be zero? Can the addend be zero?

What will happen if the target number is odd?

In general, the students tried to pose such questions and problems that could be answered or solved unequivocally.

The students in the second group also considered how to broaden the solution in case that the problem was not limited only to natural numbers. In other words how this environment could be used for motivation of negative or even rational numbers.

CONCLUSIONS

In this study, we dealt with the problem how to prepare future teachers for IBME. We assumed that the solution of appropriate problems and connecting it with didactic questions shows the students how important their knowledge of mathematics is and how they can use it in school practice. Our starting point was in accordance with other authors, for example Lamon stated: "... facilitating teacher understanding using the same questions and activities that may be used with children is one way to help teachers build the comfort and confidence they need to begin talking to children about complex ideas." (Lamon, 2006, xiv)

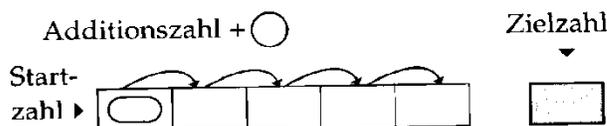

One of the key problems was the students' failure to realize the connection of what they learned before in mathematics courses to the needs of school practice. This fact was in our study manifested by students' preference of arithmetic when solving given problem. Algebra as a tool for solution was used only by those students who were proficient enough, and who are persuaded that they are able to work quickly and without errors. Other students tended to stereotypical procedures: they regarded the use of visual aids, illustrative examples as manifestation of lower level of knowledge. It seems that they perceived as substantial only the questions of WHAT? and HOW? to teach. The question WHY? did not interest them so much. Such belief is in our opinion unsuitable, inadequate, especially in case of primary school teachers.

We formulated several questions for continuation of this research: how to change this opinion, how to develop the ability to visualize, explain using visualization, how to show the students that thorough study of mathematics is important for teachers; how to change students' understanding of the role of reasoning in education (not only mathematical) and the related generalization, looking for similarities and differences, discovery of regularities, patterns and coherences. It is also the question of making the students aware of the dangers of badly-founded statements (hypotheses, proclamations) and of when it is the right time for drawing conclusions.

In our previous research (Tichá, Hošpesová, 2006) we realized that joint discussion and reflection of problems and their solutions can be a fruitful way. IBME offers, in our opinion, good grounds for such activities.

END NOTES

1. A system in which the teacher, student(s), milieu and restrictions necessary for creation of a piece of mathematical knowledge interact "to teach somebody something". The educator "organizes a plan of action which illuminates his/her intention to modify some knowledge or bring about its creation in another actor, a student, for example, and which permits him/her to express himself/herself in actions" (Brousseau & Sarrazy, 2002).
2. The scheme of the problem "Wer trifft die 50" in the original (Scherer, Steinbring, 2004, p. 65).

3. The students formulated and solved an equation:

$$x_1 + x_1 + a + (x_1 + a) + a + (x_1 + a) + a + a + (x_1 + a) + a + a + a = 50$$

$$5x_1 + 10a = 50$$

$$5(x_1 + 2a) = 50$$

$$x_1 + 2a = 10$$

and systematically proceeded in its solution:

$$10, 10 + 0, 10 + 0, 10 + 0, 10 + 0 = 50$$

$$8, 8 + 1, 9 + 1, 10 + 1, 11 + 1 = 50$$

$$6, 6 + 2, 8 + 2, 10 + 2, 12 + 2 = 50, \dots$$

ANALYSIS OF PRE-SERVICE ELEMENTARY TEACHERS' PEDAGOGICAL CONTENT KNOWLEDGE IN THE CONTEXT OF PROBLEM POSING

Cemalettin Isik* Tugba Ocal** Tugrul Kar*

*Ataturk University **Agri Ibrahim Cecen University

In this study, it was aimed to study the level of pre-service elementary teachers' proficiencies in determining 5th grade students' problem posing errors about addition with fractions. This study was realized with 36 senior class pre-service elementary teachers in an eastern university during spring term in 2011-2012 academic year. Error Determination Test, which has six problem statements about addition with fractions, was applied to pre-service elementary teachers. Participants were asked to compare addition operations with the given problem statements and to clarify errors if there were any. Research findings indicate that participants had problems in determining errors and made different errors in their explanations about the students' errors.

Keywords: Pre-service elementary teachers, problem posing, fractions, addition operation with fractions.

INTRODUCTION

Problem posing takes increasing attention in recent years. Main reasons that lie behind this attention are establishing relationship between mathematical concepts, operations and daily life (Abu-Elwan, 2002; Dickerson, 1999; Knott, 2010), transitions between representations (English, 1998; Işık, Işık & Kar, 2011) and it contributes to these issues. This study draws attention to the analysis of pre-service teachers' pedagogical content knowledge which includes being aware of students' misconceptions and also errors. Particularly, the following aim was addressed: studying pre-service elementary teachers' proficiencies in determining errors in problem statements about addition with fractions.

THEORETICAL FRAMEWORK

There are some knowledge categories that professional teachers should have. One of these categories as determined by Shulman (1987) is pedagogical content knowledge. It is specifically about illustrations, explanations, and examples used in making a subject more comprehensible to learners. In detail, it is about knowing functional representations and illustrations of content and concepts, knowing what the issues that makes learning content easier or harder, knowing students' misconceptions and errors, knowing analogies, symbols, examples or explanations that helps overcoming misconceptions and understanding concepts, and lastly knowing different age group and level students' thoughts, perceptions, and previous knowledge about concepts (Shulman, 1987).

Problem posing is about generating new problems and reformulating problems from the given problems or situations (Duncker, 1945). As English (1998) indicated that students could improve defining symbolic mathematical expressions ability and relating them with daily life issues ability through problem posing. Besides, Crespo (2003) stated that problems posed by teachers give students chances to learn mathematics. Işık and Kar (2012) determined elementary school mathematics teachers realized more problem posing activities about fractions sub learning domain than other ones under numbers learning domain. Additionally, all of the teachers, who gave more place to problem posing activities about fraction sub learning domain, expressed that problem posing contributes students in relating conceptual understanding to symbolic expressions in daily life.

Moreover, Hill, Rowan and Ball (2005) stated that teachers' mathematical knowledge should give chance to students to explain and teachers to analyze their students' answers. On the other hand, there are limited studies studying teachers' and pre-service teachers' pedagogical content knowledge in operations with fractions. Toluk-Uçar (2009) found out that pre-service elementary teachers thought fractions represent pieces instead of amount and as well the solutions of the problem they posed necessitates addition in natural numbers instead of addition in fractions. The problem a participant posed for the operation $\frac{1}{3} + \frac{1}{2} =$ was "My mum gave me 1 of her 3 apples and my brother gave me 1 of his 2 apples. How many apples did I have altogether?" and it exemplifies this situation. Ticha and Hošpesová (2009) asked pre-service teachers to pose a problem from $\frac{1}{4} \times \frac{2}{3}$ operation; afterwards, from the problems participants posed, they asked them to evaluate three of them. The researcher determined that pre-service teachers ignored the conceptual dimension of the operation, could not relate the given operation with the daily life issues, and some of them posed problems that necessitate multiplication instead of addition and students indicated that it was easy to formulate same type of problems but it was difficult to formulate problems of a growing difficulty. Işık (2011) concentrated on conceptual analysis of the problems about multiplication and division in fractions posed by pre-service elementary mathematics teachers. The results of study showed that pre-service teachers had difficulties in the conceptual dimension of fractions and operations in fractions. On the other hand, in the literature there is not any study about teachers' and pre-service teachers' pedagogical content knowledge in determining the errors in the problems posed about addition with fractions by students.

Problem posing is effective in both clarifying students' mathematical skills thoroughly and giving chance to assessing what students did (Whiten, 2004). In addition to this, problem posing informs teachers about students' skills, attitudes, and conceptual learning about a situation (Işık & Kar, 2012). As mentioned before, one of the categories of pedagogical content knowledge is being aware of students' misconceptions and errors. From this aspect, when pre-service teachers are

encountered with the students' errors in the problems posed, pre-service teachers' awareness could be enhanced.

The success of problem posing activities was based on the guidance of teachers to students about true problem posing and exploring. When the successes of instructional process and student were affected from teachers' knowledge (Dooren, Verschaffel & Onghena, 2002; Fennema & Franke, 2006; Shulman, 1987) issue is considered, it is significant to analyze teachers' and pre-service teachers' pedagogical content knowledge under different dimensions. Besides, as Crespo (2003) mentioned mathematical problem posing is one of the difficulties in learning mathematics, and as well it isn't clear when and how the pre-service elementary teachers could learn about this issue. In this regard, this study is realized with pre-service teachers and it was aimed to study pre-service elementary teachers' proficiencies in determining errors in problem statements about addition with fractions. Therefore, this study would contribute possible planning processes in teacher education.

METHOD

This study was realized with 36 senior class pre-service elementary teachers in a public university in eastern part of Turkey during spring term in 2011-2012 academic year. These participants took Basic Mathematics I and II (freshman year course) as well as Teaching Mathematics I-II (junior year course) during their instructional process. In addition, they had also chance to observe and practice in class instructional activities at schools. Pre-service teachers were coded with pseudo names like PT1, PT2, ..., PT36.

Error Determination Test (EDT), which contains six problem statements about addition with fractions, was applied to pre-service teachers. Items in the test were given in Table 1 below.

Table 1: Problem Statements in EDT

Problem Statements	
1.	I ate $\frac{1}{3}$ of the oranges my mother bought. My brother ate $\frac{1}{2}$ pieces. How many oranges are left?
2.	We bought a cake for my birthday. My sister and I ate $\frac{1}{2}$ of the cake together. $\frac{1}{3}$ of the rest of the cake was eaten by my mother and father. Accordingly, what is the fraction of the rest of the cake?
3.	First day, Ali's classmates planted $\frac{1}{3}$ trees to the school garden. In the second day, they planted $\frac{1}{2}$. Hereunder, how many trees did Ali's classmates plant totally?
4.	Süleyman at first picked $\frac{1}{2}$ of the roses and then picked $\frac{3}{4}$ of the roses. How many roses did Süleyman have totally?

-
5. Ahmet joined the game with $\frac{1}{2}$ of the marbles and Mehmet joined with $\frac{1}{3}$ of the marbles. So, what is the amount of marbles from the total did Ahmet and Mehmet join the game with?
 6. Ali participated in a penalty game two times. In the first game, he made one goal from two kicks, and in the second game, he made three goals from four kicks. Therefore, what is the fraction of goals did Ali do at the end of two games?
-

First four problem statements in Table 1 were selected from problem statements posed by 5th grade students from $\frac{1}{3} + \frac{1}{2} = \blacksquare$ and $\frac{1}{2} + \frac{3}{4} = \blacksquare$ operations. In the first item, the sum is a proper fraction, and in the second item, the sum is a mixed fraction. Işık and Kar (2012) asked 210 7th grade students to pose problems from the five items given about addition with proper and mixed fractions. Afterwards, the researchers analyzed the problems posed by the participant students and determined error types. In the first four problem statements in EDT, there are six error types determined by Işık and Kar (2012); *expressing the added second fraction over the remainder of whole (E₁)*, *failure in expressing the operation in the question root (E₂)*, *attributing natural number meaning to the result of the operation (E₃)*, *confusion about units (E₄)*, *attributing natural number meaning to the added fractions (E₅)* and *failure in establishing part-whole relation (E₆)*. Fifth and sixth problem statements were added to EDT by the researchers. In the literature, these types of problem statements were utilized by different researchers (Chick & Baker, 2005; Newton, 2008; Ward & Thomas, 2007) for determining students' conceptual knowledge about fractions. Explanations about the errors in problem statements were presented in the findings part.

In the implementation process of EDT, participants were told that *fifth grade students were asked to pose resolvable problems about addition with fractions based on only the given operations. All of the problem statements in the test were posed by students. There is an explanation like compare given addition operation with problem statement, and express error types if there is any;* in this process for participants not to lose their motivation and for them not to analyze with prejudice, fifth and sixth problem statements were also said as problem statements posed by students. EDT was applied to pre-service teachers in one class hour. Answers of pre-service teachers were analyzed with content analysis method.

Two different researchers analyzed pre-service teachers' answers about each item in the EDT concurrently and independent of each other. Based on the analysis of each item in EDT, the consistence was found as; 87,5%, 98,43%, 96,88%, 100%, 98,43% and 90,62%, respectively. In the comparison process, answers that were not appropriate to determined error types were presented under *other* category. This category contains some statements that do not express errors instead problem statements were written with little changes in the sequence of words (ex. *what is the fraction of money collected?* Instead it was written like *what is the fraction of money*

collected from the class did our teacher spend?), and expressions were not open enough to make error analysis.

FINDINGS

Conceptual Analysis of Problem Statements

In the first problem statement, it was mentioned that $\frac{1}{2}$ of the pieces were eaten by brother. With the *piece* word in a fraction form, it was tried to express quantities like in the natural number form. Therefore, there is an E_5 error type in the problem statement. Besides, *how many oranges are there left?* question has a subtraction meaning. From this aspect there is an E_2 error type in the problem statement.

In the second problem statement in EDT, addend $\frac{1}{3}$ fraction is expressed via rest of the cake. However, this necessitates $\frac{1}{2} \times \frac{1}{3}$ operation. On that sense there is an E_1 error type in the problem statement. In addition, in the problem statement rest of the cake is asked instead of the amount of that was eaten; so, it does not meet addition meaning. Consequently, there is also an E_2 error type in the problem statement.

Third problem statement in the EDT involves $\frac{1}{3}$ trees and *how many trees were planted totally?* question, with these expressions it was tried to give addend fraction and the result of the operation which were fraction the natural number meaning. From this aspect, there are E_3 and E_5 error types in the problem statement. Besides, with $\frac{1}{2}$ expression it is not clear if $\frac{1}{2}$ indicates the amount of trees or $\frac{1}{2}$ represents the area of school garden. On that sense, fraction does not represent an appropriate unit and there is an E_4 error type in the problem statement.

In the fourth problem statement of EDT it is mentioned that at first $\frac{1}{2}$ of the roses in the garden were collected. In this situation rest of the roses was the half of the total roses. On the other hand, student gave place to *later on $\frac{3}{4}$ of them were collected* expression. This situation is not logical from the point of part-whole relation. From this aspect there is an E_6 error type in the problem statement. In the question it is asked like *how many roses did Süleyman have totally?*; with this expression the result of the operation which was a fraction was given a natural number meaning. Therefore, there is an E_3 error type in the problem statement.

In the fifth problem statement in EDT, there is not any information that shows if the addend fractions were taken from the same whole or not. On that sense, although it looks like formal of problem statement meets the operation, in a conceptual sense it is not possible to add fractions from different wholes. Besides, although two wholes are similar the total of two fractions is not the result of the problem statement. In the sixth problem statement in EDT it was mentioned that at the end of the game only four kicks of the six kicks were turned into goal. On the other hand, the result of $\frac{1}{2} + \frac{3}{4}$

operation which was tried to be posed a problem based on this doesn't meet this result. Problem statement necessitates $\frac{1}{6} + \frac{3}{6}$ operation which accepts the total amount of kicks as a whole instead of $\frac{1}{2} + \frac{3}{4}$ operation. From this aspect, problem statement and the operation which was tried to be posed a problem based on this are not consistent.

Pre-service Teachers' Proficiencies in Determination of Error Types in Problems Posed

The distribution of what error types pre-service elementary teachers found in the first four items in EDT is presented in the following Table 2.

Table 2: The Distribution of Error Types Found in the First Four Items in EDT

Items	E ₁	E ₂	E ₃	E ₄	E ₅	E ₆	Errorless	Blank	Other
1		27(75)			18(50)		3(8,3)	0(0)	2(5,5)
2	18(50)	23(63,9)					5(13,9)	1(2,8)	1(2,8)
3			13(36,1)	8(22,2)	16(44,4)		8(22,2)	0(0)	2(5,5)
4			11(30,6)			3(8,3)	4(11,1)	3(8,3)	2(5,5)

*Values in table were calculated based on 36 participants and presented with frequency (percentage).

According to Table 2, in the first problem statement one fourth of the participants could not determine E₂ error type and half of them could not determine E₅ error type. From these proportions, it could be said that to determine E₅ error type is harder for participants. 13,9 % of the participants mentioned that there was not any error in the second problem statement. Moreover, half of them did not determine E₁ error type, almost 36 % of them could not determine E₂ error type. From these proportions, it is harder to determine E₁ error type. About the third problem statement 22,2 % of the participants mentioned there was not any error. Besides, 44,4 % of the participants could determine E₅ error type, meanwhile the proportions of determination of E₃ and E₄ error types are less. Specifically to determine E₄ error type is harder for participants. In the fourth problem statement, 11,1 % of the participants stated that there was not any error in the problem statement. Almost 70 % of them could not determine E₃ error type, and 92 % of them could not determine E₆ error type. From these proportions, it could be said it is harder to determine E₆ error type.

Besides, about the fourth problem statement some of the participants made different error types in their explanations about the errors in this statement. Five of the 11 participants who determined E₃ error type stated that the question should be like *what is the fraction of roses collected?*. PT23's explanation about this issue was;

PT 23: It is a wrong way to ask how many roses did Süleyman have. If it is asked like what is the fraction of roses collected, it would be a true problem.

In the PT23's explanation the result must be fraction, so, it was emphasized with *what is the fraction of* expression. On the other hand, part-whole relation was

ignored; due to this, in the question *what is the fraction of* was used. This expression is not appropriate to logical aspect. Six of the 11 participants who determined E_3 error type stated that they did not know the beginning amount, so, they could not answer the issue that was asked in the question. PT4's explanation about this issue was that;

PT4: In here, the total number of roses in the garden is not mentioned, so, it is not possible to calculate how many roses were collected. Whereas if it is known given operation could be calculated.

Students were asked only to pose a resolvable problem with just $\frac{1}{2} + \frac{3}{4}$ operation. In the given application directive it was emphasized that pre-service teachers should analyze problems posed through this aspect. Therefore, explanations about the necessity of knowing the beginning amount are not appropriate approach when the given operation is considered. In addition, when it is thought if the beginning amount is known, in a logical sense this would not be an appropriate problem. Due to the result of the given operation being a mixed fraction, expressing addend fractions as a part of the whole would cause violation of part-whole relation.

The distribution of pre-service teachers' answers to fifth and sixth problem statements in EDT was presented in Table 3 below.

Table 3: The Distribution of Answers Given to Fifth and Sixth Items in EDT

	Errorless	With Error	Blank	Other
Fifth Problem	9(25)	24(66,7)	2(5,5)	1(2,8)
Sixth Problem	21(58,3)	6(16,7)	7(19,5)	2(5,5)

*Values in table were calculated based on 36 participants and presented with frequency (percentage).

According to Table 3, 25% of the participants stated that there was not any error in the fifth problem statement. On the other hand, two thirds of the participants mentioned that problem statement was not appropriate to given operation. 20 of the 24 participants, who mentioned the problem statement had an error, said that if the reference fractions indicating the number of marbles were equal or not was not known, so, these two fractions could not be added. PT27's explanation about this issue was as follows;

PT27: There is an error. Are the numbers of Ahmet's and Mehmet's marbles equal? This is not known, so, it is not possible to find the true answer with just addition.

In addition, four participants found the error in the way of how the question was asked. Participants mentioned that problem should be asked like *what is the fraction of total marbles that they joined to the game?*. PT5's expression about this issue was;

PT5: Problem should continue like: Accordingly, what is the fraction of total marbles that Ahmet and Mehmet joined the game with?

According to Table 3, more than the half of participants (58,3 %) stated that there was not an error in the sixth problem statement. On the other hand, six participants

determined the error in the problem statement, but they could not give a conceptual explanation to the reason of this error. Four of the participants said that there is not appropriate relationship between the result as $\frac{5}{4}$ to the operation and the result of the solution of the problem posed. Four of the participants mentioned that the result of the problem posed based on the given operation was not consistent with problem statement. PT1 mentioned about this issue as;

PT1: The result of given operation found as $\frac{5}{4}$. The number of kicks that were done as goal was higher than the whole, so, the problem had an error.

Moreover, two participants saw the reason of the error as different number of kicks in each penalty kicking game. PT3 made an explanation about this issue as;

PT3: It was played two times. There were two different wholes, so, the sum could not give how many kicks were turned into goal.

RESULT AND DISCUSSION

In this study, pre-service teachers' proficiencies in determining the errors that 5th grade students done in problems posed about addition with fractions were studied. It was found that determining E_1 and E_2 error types in the problem statements was higher than other error types. In the focus of these errors, it could be said that there was problem of transferring fractions and addition to the problem statements. It could be said that these errors were related with formal aspect of the operation, but other error types were related with conceptual aspect of the fractions. Therefore, increased determination E_1 and E_2 error types could be thought that analyses were generally done on the formal aspect. It was found that pre-service teachers had more difficulty in attributing a natural number meaning to the result of the operation in the first four problem statements of EDT, not stating fractions with appropriate units and not associating fraction in the reference amount with whole. Specifically, not associating part-whole relation was the least found error type done by pre-service teachers. It could be mentioned that participants not being able to determine the sum as a mixed fraction caused them living more difficulty. Moreover, some participants made new errors in their explanations about their errors. These findings supported by different studies' results (Işık, 2011; Redmond & Utley, 2007; Rizvi, 2004; Toluk-Uçar, 2009; Zembat, 2007) that pre-service teachers had difficulties in problem posing about operations with factions.

25 % of pre-service teachers indicated that there was not an error in the fifth problem statement and only 55,6 % of them could make a conceptual explanation about the reason of the error. These findings were supported by Newton (2008) as pre-service teachers had difficulties in determining the impossibility of addition with fractions defined in different wholes. Only six pre-service teachers determined the error in the sixth problem statement in EDT. On the other hand, none of them could make a conceptual explanation to error. These findings were similar to the results of other studies realized by different researchers (Chick & Baker, 2005; Ward & Thomas, 2007).

Crespo (2003) mentioned that pre-service teachers posed problems without thinking mathematical and pedagogical aspects and did not study the resolvableness of them. Based on the findings of this study, they supported what Crespo mentioned, and besides they indicated that these skills like addition with fractions should be enhanced. Findings of this study were gathered from six problem statements about addition with fractions topic. This could be seen as a limitation of the study. In the future, this study could be extended with problem statements involving different fractional number and possible other error types and these studies could be done with pre-service teachers or in-service teachers. By qualitative studies, from participants' frames of mind that include the reasons behind different error types from some pre-service teachers' explanations it could be revealed. Experimental studies could be realized for removing the difficulties by considering the results of these like studies in the future.

DELINEATING ISSUES RELATED TO HORIZON CONTENT KNOWLEDGE FOR MATHEMATICS TEACHING

Arne Jakobsen¹, Mark Hoover Thames² & C. Miguel Ribeiro³

¹*University of Stavanger, Norway;* ²*University of Michigan, USA*

³*University of Algarve, Portugal*

The conceptualisation of mathematical knowledge for teaching (MKT) has recently received much attention. Scholars have provided examples, studied effects, and debated importance. However, from among the MKT domains, horizon content knowledge (HCK) has received less attention. In particular, the nature of the knowledge as it is related to teaching is unclear. We argue for efforts to clarify definitions and to test and refine those definitions with the use of realistic and vetted examples of professional work. To advance this agenda, we provide a working definition of HCK and use it to discuss a vignette involving irrational numbers.

INTRODUCTION

Teachers' content knowledge is of current interest, both the nature of such knowledge and ways to improve it. Among proposed conceptualisations, one that emerged from trying to understand and describe the nature and form of teaching and its mathematical demands is mathematical knowledge for teaching (MKT) (e.g., Ball, Thames, & Phelps, 2008). Grounded in Shulman's (1987) notions of subject matter knowledge (SMK) and pedagogical content knowledge (PCK), these researchers define MKT to be mathematical knowledge needed to perform the recurrent tasks of teaching mathematics to students and propose a refinement of SMK and PCK into sub-domains. Of these, horizon content knowledge (HCK) is less-developed.

The problem of defining HCK stems from an overabundance of metaphors and from inadequate clarity and consensus, especially regarding HCK's relation to teaching. Thus, deeper discussion of what HCK comprises (what it is and what it is not) is needed. Ball and Bass (2009) situate their conception of HCK within their practice-based theory of MKT. They describe HCK as "a kind of mathematical 'peripheral vision' needed in teaching, a view of the larger mathematical landscape that teaching requires" (p. 1). They provide a compelling foray into the ideas, but their provocative proposal leaves much to further development.

Starting with Ball and Bass' ideas, Zazkis and Mamolo (2011) use Husserl's work to propose a conception of "knowledge at the mathematical horizon." They use Husserl's notion to analyse ways in which topics from undergraduate mathematics provide inner and outer horizons of school mathematics. Their paper prompted two

commentary papers. Foster (2011) discusses what he calls “peripheral mathematical knowledge” to refer to mathematics that matters for teaching but is out of the view of the learner. Figueiras, Ribeiro, Carrillo, Fernández and Deulofeu (2011) point out that the language for HCK needs to be consistent with basic assumptions of the nature and role of teacher content knowledge. They argue for locating the meaning of HCK in the work of teaching instead of conceptualising HCK as advanced knowledge that is then applied to teaching. They write, “Our critique of Zazkis and Mamolo’s paper is much more in terms of their assumptions about the nature of the mathematical knowledge that elementary and secondary teachers need, rather than in terms of their conceptualization of knowledge at the mathematical horizon” (p. 26). The point they seem to be making is about whether the knowledge from an advanced course would have the bearing on practice that Zazkis and Mamolo claim.

A different view of knowledge in relation to teaching is evident in the work of Vale, McAndrew, and Krishnan (2011). They use the phrase “connecting with the horizon” to characterize the knowledge implicated by teachers comments that learning more advanced mathematics in a professional learning program helped them see more connections and structure both among representations related to a topic and among different topics. They report that, as teachers saw connections between topics they teach and more advanced topics, it helped them see connections and more general structure inside the mathematics they teach.

In these studies, several images, phrases, and issues recur, often in ways that reveal unresolved issues. For example, some scholars identify with the language from Felix Klein’s book title, elementary mathematics from an advanced standpoint, or higher perspective, while others suggest inverting it to be advanced mathematics from an elementary perspective. As another example, references are sometimes to students’ horizons and other times to teachers’ horizons. In describing horizon knowledge issues also arise regarding distinctions between HCK and knowledge of the curriculum and its trajectory. Some scholars are concerned with the importance of requiring undergraduate mathematics courses, while others are concerned with the treatment of that content and the way in which it is framed and named.

We suggest that these scholars are engaged in a difficult process of developing a clear definition of HCK around which consensus could be built and that examples are central to this process. Explicit definitions, good examples, and disciplined analyses are crucial to making progress. In this paper, we offer our current “working definition” of HCK and then use it to examine a candidate example of HCK. We then use this examination to reconsider some of the issues central to HCK. Although situated in empirical work, our primary goal is conceptual — to surface, delineate, and clarify key issues for advancing work on HCK.

THEORETICAL BACKGROUND

Researchers have found that teachers' mathematical knowledge and experience, broadly construed, are not consistently associated with greater student learning. Instead, the mathematical knowledge associated with achievement gains is specifically related to the work of teaching and to the mathematical tasks that constitute that work. It is this evidence that led Ball and her colleagues to develop a conceptualization of mathematical knowledge for teaching, where the "for teaching" expression conveys a practice-based characterization of teacher content knowledge.

In addition to common knowledge of the subject (SMK), Shulman (1987) defines PCK as knowledge that is an amalgam of knowing the subject with knowing how students engage with the subject and knowing effective ways of representing the subject and rendering it for learning. Ball et al. (2008) subdivide both SMK and PCK. PCK contains: i) knowledge of content and students (KCS); ii) knowledge of content and teaching (KCT); and iii) knowledge about content and curriculum (KCC). SMK contains: i) common content knowledge (CCK), mathematical knowledge that is involved in teaching but not unique to the teaching profession; ii) specialized content knowledge (SCK), mathematical knowledge that is unique to teaching and not used in professions outside teaching (namely, knowledge that allows the teacher to engage in tasks specialized to teaching, such as analyzing patterns of errors or readily solving problems in multiple ways); and iii) horizon content knowledge (HCK), knowledge about mathematics outside the curriculum. An important contribution of the work of Ball and her colleagues is that all of these domains are defined in relation to the work of teaching: MKT is knowledge that serves as a resource for addressing the mathematical demands of teaching. It is this knowledge "for teaching," with clear links to the demands of specific tasks of teaching, has been shown to have positive effects on student achievement (Baumert et al. 2010; Hill, Rowan, & Ball, 2005; Kersting, Givvin, Sotelo, & Stigler, 2011; Rockoff, Jacob, Kane, & Staiger, 2008). In this discussion, it is also worth noting that, because MKT is intimately linked to teaching, it is different for different school levels and topics: MKT for kindergarten differs from MKT for upper elementary differs from MKT for secondary, and MKT for geometry differs from MKT for number and operation differs from MKT for algebra.

HCK is one of the sub-domains of such a practice-based mathematical knowledge for teaching. It involves a sense of how mathematics at play in instruction is related to a larger mathematical landscape (Ball & Bass, 2009). HCK is thus perceived as implicated by the proximal demands of teaching but not directly related to the curriculum (mathematical content) that has to be taught at a particular point in instruction. Importantly, even though it is about mathematical knowledge removed from the content being taught and learned at a particular level, HCK needs to be demonstratively related to the teaching that takes place in school.

In collaboration with Ball and Bass' research group at the University of Michigan, we developed the following working definition.

Horizon Content Knowledge (HCK) is an orientation to and familiarity with the discipline (or disciplines) that contribute to the teaching of the school subject at hand, providing teachers with a sense for how the content being taught is situated in and connected to the broader disciplinary territory. HCK includes explicit knowledge of the ways of and tools for knowing in the discipline, the kinds of knowledge and their warrants, and where ideas come from and how "truth" or validity is established. HCK also includes awareness of core disciplinary orientations and values, and of major structures of the discipline. HCK enables teachers to "hear" students, to make judgments about the importance of particular ideas or questions, and to treat the discipline with integrity, all resources for balancing the fundamental task of connecting learners to a vast and highly developed field.

HCK is neither common nor specialized, and it is not about a curriculum progression, but more about having a sense of the larger mathematical environment of the discipline being taught. In that sense, when discussing HCK, it is not sufficient to simply consider knowledge about advanced mathematics or knowledge about different topics that may arise in students' future studies. HCK also includes, but not to the exclusion of other things, knowledge that would allow teachers to make additional sense of what students are saying and to act with an awareness of connections to topics that students' may or may not meet in the future.

HCK is distinct from specialized content knowledge (SCK) because SCK is immediately about the content being taught and HCK is not. SCK is about unpacked, elaborated, explicit versions of the content being taught, in ways that are useful to teachers as they teach. Beyond what students directly need to learn, it includes knowledge about representations, explanations, language, and features of these that increase teachers' capacity to teach them. The distinctive character of SCK is evident in Foster's (2011) discussion of peripheral mathematical knowledge. As he writes when discussing knowledge that he found useful as a teacher (such as knowing that both $x^2 + 17x + 30$ and $2x^2 + 17x + 30$ factorise with integer coefficients and how to generate other such pairs), "that whereas the process of *coming to know* these things may be of great value for learners, *knowing them* may not be" (p. 25).

The notion of SCK as distinctively mathematical knowledge directly related to the content being taught but that is specialized to the work of teaching has a certain parallel to the notion of an inner horizon as described by Zazkis and Mamolo (2011, p. 9) as not at the focus of attention, but also intended. If the last part were amended to "also present" or "also relevant to teaching," the parallel would be quite strong. It is this issue of relevance to teaching that seems to distinguish Zazkis and Mamolo's examples from those of Foster's. When we read Zazkis and Mamolo's example of knowing that the number of triangles in a pentagon with all diagonals drawn is a multiple of five, we can follow the logic that there might be a situation in which this might be relevant as a teacher, but it does not pass a kind of reality test for

professional knowledge. At a practical level, in an extended discussion in the professional community, we are not convinced that this would be seen as having much utility, whereas many of Foster’s examples seem likely to stand up to such a test. At the heart of this is the basic definitional character of MKT — that it be professional knowledge *for teaching*.

The other distinction to make is between HCK and KCC. We argue that it is important to distinguish these and that doing so reveals a central issue, that HCK is distinctively relevant to the conversation about “advanced” mathematics courses and the role of mathematicians in the education of teachers, whereas KCC is much more about an understanding of school mathematics and particular approaches to organizing the school curriculum. Unfortunately, Ball et al.’s description of HCK as “an awareness of how mathematical topics are related over the span of mathematics included in the curriculum” confounds the issue. Their statement was meant to be about one example of HCK and the meaning of “related” was not meant to be about the curricular development of the content, but about the other kinds of relatedness that might exist among topics (personal communication). In this unfortunate wording, we see potential problems with the term “horizon.” The idea of a curricular horizon as being about a curricular trajectory is distinct from what we mean by HCK. The statement also raises the issue of how remote something needs to be in order to be about the horizon. Our current proposal is that HCK is not the content being taught and not about curricular development of that content. Next we discuss the empirical context of our work and then present a vignette from secondary school teaching and use it to discuss the constitution of HCK.

METHODS

To establish a practice-based conception of mathematical knowledge at the horizon, we have grounded our analyses in teaching and practice-based reasoning about teaching, such as that occurring in the context of focus-group interviews, professional development programs, and collaborative investigation of teaching. The data consist of records of such practice from the United States, Norway, and Portugal. From this data, we selected and developed candidate, teaching vignettes — critical situations perceived as effective teaching and supporting professional deliberation, discussion, and discernment. We then analyze these vignettes in relation to our working definition of HCK and vet them with other members of the mathematics and mathematics education community.

Although we focus on practice, it is important to note that the object of study is not a particular teacher or classroom, but tasks entailed in teaching and an analysis of their mathematical demands (Ball & Bass, 2003). With a focus on idealized tasks of teaching and the demand they create for horizon knowledge, we developed vignettes from selected episodes gathered in different contexts. The vignettes are consistent with professional practice, which allows us to use them to examine and test notions

of HCK. The vignettes provide a reference point for discussing, reflecting upon, and further analyzing both the work of teaching and our findings about practice-based HCK. Given limited space, we discuss a single example, and then use it to illustrate and reflect on the proposed definition.

Vignette of HCK in practice

Mr. Lee's class has been discussing different types of numbers. While his students have a firm knowledge of whole and rational numbers, they have now been introduced to irrational numbers and are given examples of such numbers (like $\sqrt{2}$ and π , listed on the board). Based on what is on the board, Mr. Lee asks his student whether they can think of any other rational or irrational numbers they have learned about in the past. A student, Jay, suggests $2\sqrt{2}$. Writing it on the board, Mr. Lee asks, "And is $2\sqrt{2}$ rational or irrational?" To his surprise, Jay says it is rational. Jay continues and another student Ben responds.

Jay: If you have a rational number and an irrational number and you multiply them, the product will be a rational, and you will still have a fraction.

Ben: I don't think so, because when we multiplied a rational with an integer, we still got a rational — I think the same... the product of an irrational and a rational will be irrational.

Jay goes to the board to explain his thinking:

Jay: Look..., say you have a rational a/b and multiply it by the irrational v , you get av/b , which is rational, see?

Ben: No, that can't be.... If it's rational... that is only possible if a/b is zero, and that was not the case.

Jay: What? ... how come?

Ben: Oh, now I understand why you're saying that it's rational... you were missing something... well..., if the product is rational, then v is rational too, and it can't be because we said at the beginning that it was irrational...

There are several issues here that teaching needs to handle. First of all, a teacher would need to decide if the argument provided by Ben is correct. Second, after understanding that Ben's solution is correct, a teacher would need to decide whether it is worth pursuing, in particular when the argument used by Ben is unrelated to the learning goals of the lesson and is outside Mr. Lee's secondary curriculum. Asking students to explain their ideas to their peers may be risky when the mathematics is in an area that is less familiar to the teacher. These situations, corresponding to improvisations (Ribeiro, Monteiro, & Carrillo, 2009), lead to contingency moments (Rowland, Huckstep, & Thwaites, 2005) in which the teacher has to put in practice all of his or her intuitive knowledge. Even when teachers are aware of some of the

possible implications in following, or not, a certain path, they face dilemmas that can profit from a familiarity with mathematics beyond the scope of what is being taught.

A teacher should notice that Jay's first argument is wrong. In the vignette, Mr. Lee does not intervene and lets the two students continue, possibly because Ben is providing an argument and is trying to generalize from previous experience — an integer multiplied by a rational number yielded a rational number — so the teacher lets the students continue without intervening. However, in responding to the (wrong) argument Jay presented at the board, Ben is using a kind of proof-by-contradiction argument, content that is outside of the curriculum Mr. Lee intends to teach. When Ben states that av/b being rational implies $a/b = 0$, he starts by assuming that a/b is not zero. Then $(a/b)(v) = (av)/b = p/q$ is a rational number, and because a/b is not zero, $v = (pb)/(aq)$, meaning v is a rational number too, but that contradicts the assumption. So, a/b cannot be different from zero if av/b is a rational number. Having knowledge about proof by contradiction and the characteristics of irrational numbers would help a teacher to understand Ben's argument and to handle the teaching of this matter with integrity. However, having learned about irrational numbers and proof by contradiction in advanced university courses in mathematics is not a warrant that a teacher can make sense of students' arguments in a classroom. What is needed instead is a treatment that accounts for how these topics may arise in teaching.

As stipulated in the definition, HCK includes an understanding of disciplinary ways of knowing and of establishing validity. Being familiar with proof by contradiction and other important ways of building mathematical arguments would help a teacher hear student reasoning, in the many different and emerging forms it takes, whether at the primary or secondary level. Such knowledge would allow a teacher to appreciate and understand how proof by contradiction can be related and imbedded in students' comments and reasoning in many topics. Proof (and in particular proof by contradiction) is a topic more extensively taught and used in university mathematics courses, yet it is rarely related to what is done in teaching (and not all advanced topics have such a relation — direct or indirect).

The decisions faced by Mr. Lee require subject matter knowledge not part of the curriculum he is teaching. Hence, it is not obviously part of SCK or CCK, which involve representations, explanations, and unpacked knowledge of the content being taught. Knowledge of proof by contradiction and being able to use this knowledge in teaching, can help a teacher hear students, see beyond the topics being taught, and make judgments about what to do in the unfolding dynamics of instruction.

SUMMARY AND REFLECTING COMMENTS

We have used this example to examine a view of advanced mathematical knowledge related to teaching and how it is different from advanced mathematical knowledge

typically taught to prospective teachers. Knowledge of advanced content is in itself not a warrant that a teacher can make sense of student thinking in instruction.

Returning to our working definition of HCK, teachers need to have an “orientation to” and “familiarity with the discipline.” It would be helpful for teachers who are working with specific content to know how the discipline handles this content at different stages in its development. A topic can be related to other content, outside the immediate curriculum, with different aims and not directly related to the content being taught. Proof by contradiction is often taught in the context of number theory, yet familiarity with it can have a bearing on the teaching of a wide range of topics. Thus, teachers need knowledge that supports connecting the notion of a proof technique, and the mathematical steps of such a proof, with what students may say. This lead us back to our working definition, which says that HCK “contributes to the teaching at hand, providing teachers with a sense for how the content being taught is situated in and connected to the broader disciplinary territory.”

Even though the reasoning of the students may be considered to be outside the curriculum, such as in the vignette above, a teacher may value the way students make use of specific proof techniques in their arguments, without necessarily trying to make the logic behind the proof an important part of the discussion. Instead, a teacher may recognize a proof technique, its validity, and the intuitive way it convinces students. Such knowledge is an important resource for teaching.

Our view is that teachers need a treatment of “advanced” mathematics tailored to the orienting and navigating demands of the teaching in which they engage. Experiences with proof in general, and proof by contradiction in particular, in the context of teaching, provide a teacher with resources for hearing the mathematical ideas behind Ben’s argument — ideas related to major structures and developments in the discipline, another part of our working definition of HCK. A teacher needs to make decisions about how to handle discussions that occur in the classroom, and to do so in a way that has integrity as students learn additional mathematics. Knowing mathematics at the horizon gives a teacher awareness of potentialities of situations and suggests possibilities for dealing with the mathematical content being taught at a given level. In order to do so, a teacher does not need to know everything about proof by contradiction, but needs to have a sense of what it is and its potential. That would allow students (at least in theory) to further understand and make sense of other topics, both directly and indirectly related.

Developing tasks related to advanced content, yet situated in artifacts from teaching — such as student work, a task from a textbook, or a dialog among students — might motivate prospective teachers to study mathematics, provide a focus for learning that mathematics, and develop a sense of when and how to use such knowledge in teaching. Similarly, developing instruments to measure HCK might help advance our understanding of HCK by forcing greater clarity about what it is we are trying to measure. Instruments could be similar to many of the recent

multiple-choice instruments developed to measure other domains of mathematical knowledge for teaching (e.g., Hill, Schilling, & Ball, 2004; Tatto et. al, 2008), or they could be developed using interviews or observational techniques. Indeed, measuring and validating the models underlying such concepts would be important steps in developing an understanding that could inform policy and practice.

ACKNOWLEDGEMENTS

We thank Deborah Ball, Hyman Bass, and the Mathematics Teaching and Learning to Teach research group at the University of Michigan, as well as Seán Delaney, Marino Institute of Education, Ireland, for contributing to and responding to our ideas. Errors of fact or thought are, of course, ours. This paper has been partially supported by the Portuguese Foundation for Science and Technology (FCT), and the paper forms part of the research project "*Mathematics knowledge for teaching in respect of problem solving and reasoning*" (EDU2009-09789EDUC), funded by the Ministry of Science and Innovation in Spain.

PRIMARY TEACHERS' ASSESSMENT IN MATHEMATICS: RESOURCES EXPLOITED IN THE PEDAGOGICAL DISCOURSE

A. Klothou and H. Sakonidis

Democritus University of Thrace

Teachers' pedagogical discourse concerning mathematics education and, particularly, the resources they draw upon within it allow the study of how they make sense of and evaluate pupils' work in the mathematics classroom. The article focuses on the resources utilised within five primary school teachers' pedagogical discourse articulated in the context of a semi-structured interview on mathematics education issues. The analysis of the data indicated the exploitation of not necessarily compatible resources which might lead to surface or inequitable evaluations.

Key words: assessment, mathematics, resources, pedagogical discourse, teachers.

THEORETICAL CONSIDERATIONS

Assessment constitutes a critical factor of the educational process, which, in combination with others, shape teaching and learning. The relative research in Mathematics Education had been rather limited until early 1990s, focusing mainly on the development of tools for measuring mathematical knowledge (Gipps, 1999). The recognition of the determining role of assessment in cultural reproduction and social stratification, particularly in mathematics, with its profound consequences for future educational and professional success of both students and teachers, led to the adoption of a sociological perspective for its study. Within this perspective, assessment practices are viewed as social in nature: reflective of often implicit assumptions about knowledge and what counts as valued knowledge; about the relationship between learning, teaching and assessment; about teachers' evaluative practices and their understandings of students' achievements and curriculum demands (Wyatt-Smith & Gunn, 2009).

Contemporary views on assessment attribute special significance to the ways teachers make sense of and engage in the assessment process (e.g. Morgan, 2009). The investigation of these ways has been related to the notion of the pedagogical discourse, which offers a framework for studying the linguistic activity developed by a teacher with respect to teaching and learning mathematics that allows the identification of the meanings attributed by him/ her to the assessment process (Morgan et al, 2002). The pedagogical discourse is constituted through processes of 'recontextualisation' of knowledge and practices. These processes are determined by the agents responsible for them, the processes of selection, simplification, condensation, repositioning and refocusing through which this discourse is enacted and the resources exploited (Bernstein, 2000). Resources are accumulated knowledge structures people hold in their heads and "draw upon when they produce or interpret texts – including their knowledge of language, representations of the natural and

social worlds they inhabit, values, beliefs, assumptions and so on” (Fairclough 1989, p. 24).

Within the above perspective, teachers construct meanings when reading a mathematical text dependent on the features themselves discern in the text. These meanings are determined by the discourses enacted for the reading of the text for assessment purposes, designated by the resources and the positionings exploited (the latter concerns different relationships to students and authorities and different orientations towards texts and assessment tasks).

Morgan (1998) examined how teachers assess students’ texts (verbal and nonverbal behaviour) and found that they tended to draw on resources from different and often contradictory discourses. In a later study, Morgan & Watson (2002), looking at teachers’ assessment activity both in the classroom and with respect to written tasks, confirmed the previous finding, highlighting particularly the interpretive nature of the assessment activity due to the different resources individual teachers bring to the assessment task. These resources may include (a) teachers’ personal knowledge of mathematics and school mathematics, including their personal “mathematical history”, (b) their beliefs (conceived as dynamic rather than as static constructions) about the nature of mathematics and the ways these are related to assessment, (c) their expectations about how mathematical knowledge can be communicated, (d) their experience and expectations of students and classrooms, (e) their experience, impressions and expectations for individual students, and (g) their cultural background and linguistic skills as decisive parameters for the assessment process, related to downgrading students’ mathematical achievements (Watson, 1999; Morgan & Watson, 2002).

Morgan’s and her colleagues’ studies also showed that, when assessing students, teachers are positioned in certain, distinct and occasionally contradictory ways and this can lead to different evaluations of the same text (Morgan et al, 2002). For example, a teacher might be positioned as an examiner using personal criteria or criteria determined by exterior factors or as an advocate, who seeks opportunities to afford a grade to the student. Different positionings are likely to lead to the employment of different resources during the assessment process and, consequently, to the realization of different actions and judgments from different teachers or from a teacher at different times and in different circumstances. However, the issue teachers’ positions as they evaluate students’ work is not addressed here and it is only mentioned in order to provide a complete and comprehensive account of the perspective employed.

The sociological perspective for examining how teachers make sense and evaluate pupils’ mathematics productions briefly outlined above has not yet attracted much research attention. Only sporadically one comes across studies barely related to this perspective. For example, examining mathematics classroom assessment interactions from a semiotic point of view, Björklund Boistrup (2010), in accordance with Morgan’s and her colleagues’ studies, concluded that these interactions are part of

different discourses, which steer the individual towards what is valued and who has the authority to act, but also provide possibilities for active involvement, dependent, however, on the interplay of these discourses.

Also, Wyatt-Smith & Gunn (2009), focusing generally on assessment within a sociocultural perspective, view it as critical inquiry in need to be considered in relation to four main interrelated and interdependent lenses: (i) conceptions of knowledge, including its nature and the related capabilities to be assessed; (ii) conceptions about the alignment of assessment, learning and teaching and how teachers enact them in practice; (iii) teacher judgment practices, especially related to standards, moderation opportunities, requirements and expectations of quality performance and (iv) discipline-specific literacy demands required to participate in and contribute to knowledge. There are certainly similarities between these lenses and the discourse resources exploited by Morgan and her colleagues, both notions enabling particular characteristics of enacted assessment related to the suite of conceptions, values and assumptions at play to come to the fore.

The present study focuses on the resources designated in primary teachers' pedagogical discourse as a means to examine the meanings they attribute to the assessment process in mathematics. These resources constitute what Wenger (1998) calls a "repertoire", the elements of which shape the ways they think and act when assessing pupils' mathematical texts and thus their relevant assessment practice (the term 'practice' is used as suggested by Wenger, that is, to involve the whole person, acting and knowing at once). Gaining insight into the content and structure of this repertoire might be seen as important in understanding how classroom assessment occurs.

THE STUDY

The present study constitutes part of a research project examining primary teachers' pedagogical discourse about basic components of mathematics education developed in various contexts (e.g., in classroom, in informal exchanges, in interview settings and so on). The aim of the project was to study the resources exploited and the positionings adopted by the teachers within this discourse, seeking to understand how they make sense of and put in practice assessment in mathematics.

The focus here is exclusively on the resources emerging in the pedagogical discourse of five primary teachers evolving in the context of a semi-structured interview about mathematics education issues and, in particular, on how these resources frame the ways in which they understand and evaluate students' mathematical texts. The interview consisted of three parts. The first part included questions related to the nature of mathematics as well as to learning, teaching and assessing in mathematics, while the second part focused on teaching and assessment practices in mathematics. Both these parts intended to provide opportunities for the pedagogical discourse to unfold, allowing for the resources exploited by the teachers to emerge. The third part of the interview sought information related to the teachers' mathematics background

and professional profile. The pedagogical discourse developed around the questions of all three parts was completed over three meetings, each of which lasted for more than two hours.

All five teachers (4 females and 1 male) were teaching in public primary schools in the north eastern part of Greece and their professional profile varied in terms of teaching experience (5 to 19 years), their University degrees (one or more) and their professional activity (none to high participation to conferences, research programs and short training courses). The teachers were each the subject of a corresponding case study carried out in the context of the main research project, which included classroom observations as well as informal discussions and interviews, like the one under consideration here.

A combination of Grounded Theory and Content Analysis techniques was used for the analysis of the teachers' transcribed discourse (Thornberg & Charmaz, 2012; Berg, 2004), while the categorization/ scheme suggested by Morgan and Watson (2002) was used to identify the content and the structure of the repertoire of resources of each teacher. More specifically, a three stage analysis was followed: (a) careful reading of the data and detection of extracts relevant to each category of the scheme (b) coding of the extracts within each category and grouping them in sub-groups with relevant meaning and (c) repetition of the previous stage within each of the emerging sub-groups for the formation of the third level resources. For reliability reasons, the whole process was realized simultaneously by the two researchers. Finally, the systemic network was used to present the results of the analysis, as it allows a united depiction of the outcome in repeated levels of complexity, rendering thus transparent the internal relations of the data (Bliss et al, 1987).

RESULTS

The data analysis led to the construction of a systemic network for each teacher with regard to the resources s/he was drawing on within her/his pedagogical discourse and are informative of the ways s/he is making sense of and evaluates pupils' mathematical texts. The five individual networks were then combined to form an overall network of resources that depicts the content and the structure of the individual as well as the collective repertoire of resources identified. Due to space limit, only part of this overall systemic network is presented below. In particular, Figure 1 concerns the resource "Beliefs about the nature of mathematics and their relation to assessment" (see Morgan and Watson, 2002 above) which dominated all five discourses and especially its branch that focuses on the teachers' alleged assessment practices in mathematics, which is closely related to how they conceptualize and assess pupils mathematical productions.

Below an overview of the resources utilized and their interconnections is first provided and then particular features of these resources are discussed in relation to how teachers view and practice assessment, substantiated by data extracts.

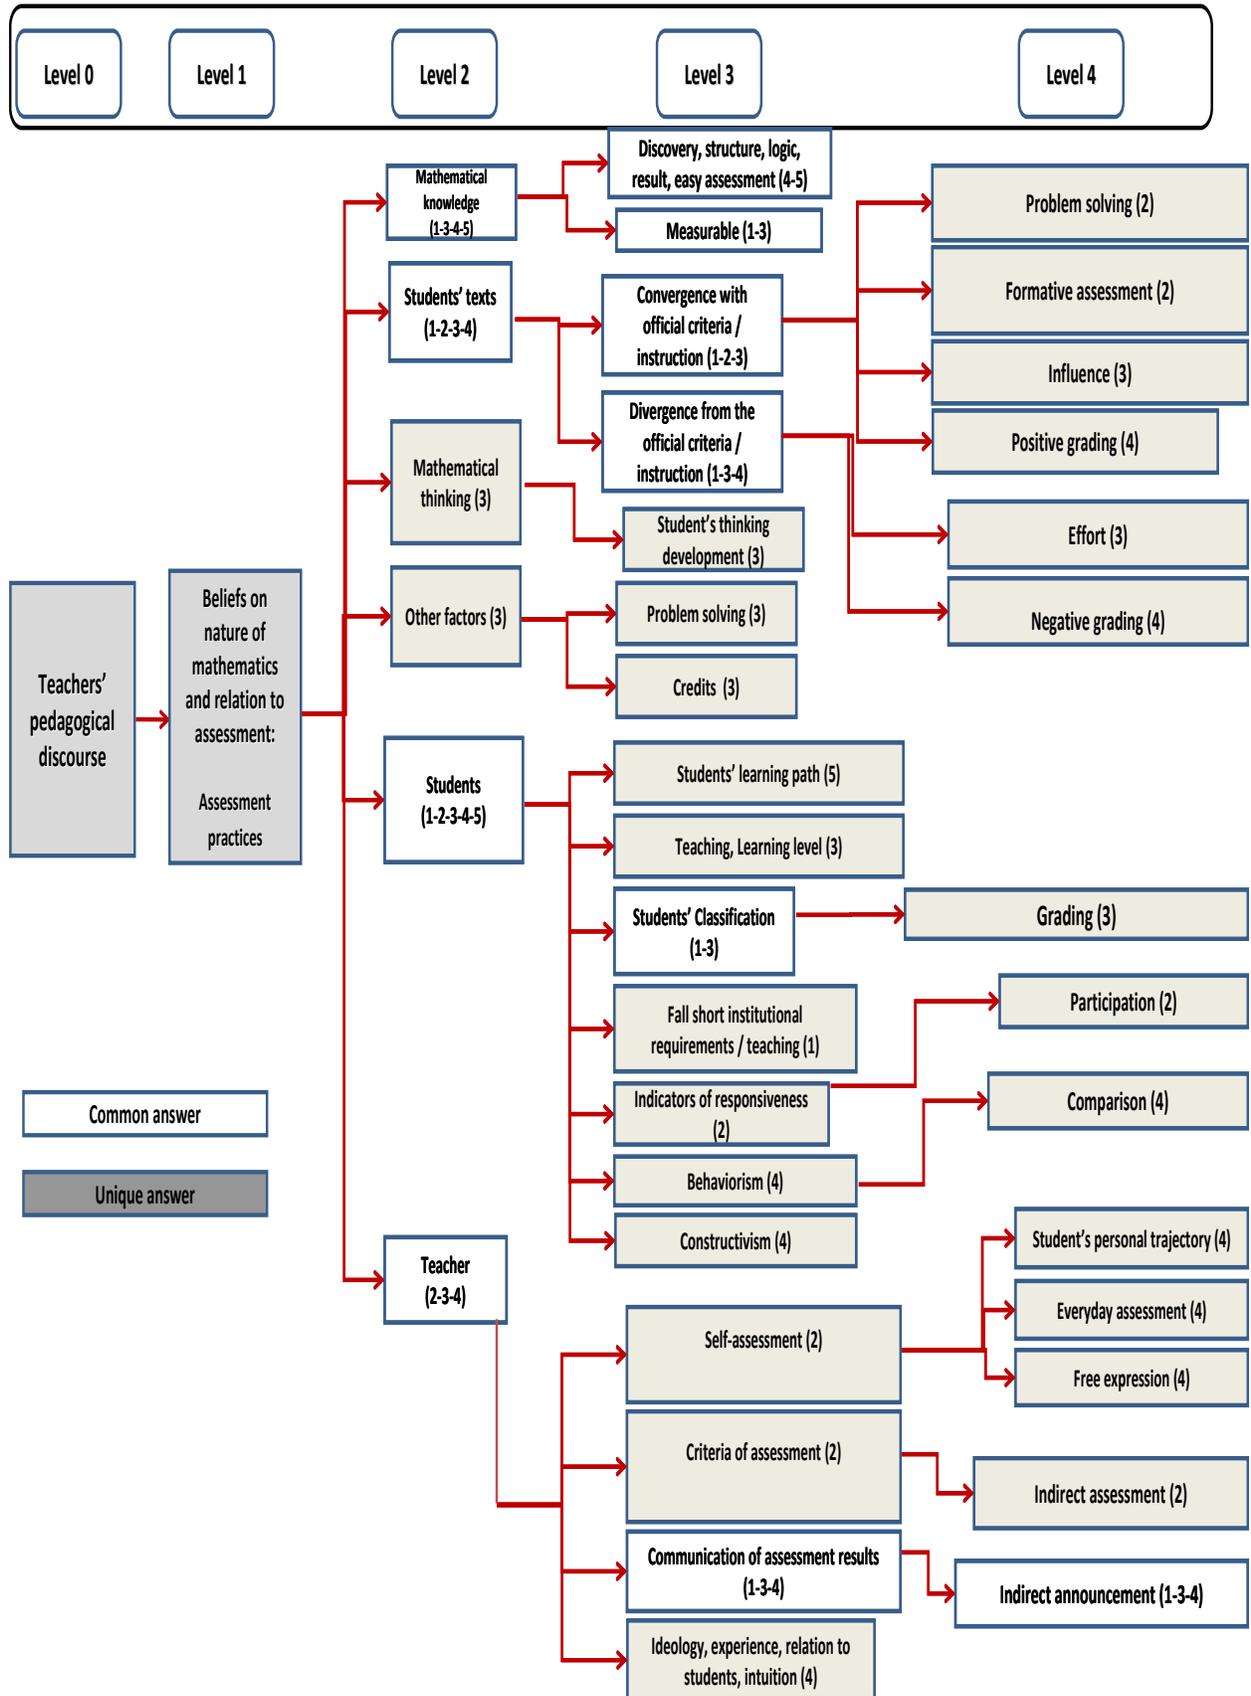

Figure 1. Teachers’ alleged assessment practices as a sub-branch of the resource “Beliefs about the nature of mathematics and their relation to assessment” [1=Nikitas, 2=Chrisa, 3=Anastasia, 4=Antonia, 5=Antiopi]

Overall, the analysis showed that the teachers of the sample appear to approach the task of assessing pupils' mathematical texts with a set of predispositions and experiences. The resources they employed in their pedagogical discourse concerned mainly their beliefs about the nature of mathematics and how these are related to assessment, as well as their expectations about how mathematical knowledge can be communicated. In addition, these resources were more collective than personal, were frequently related to the official discourse of assessment and were often incompatible to one another across time and contexts.

The view that mathematical knowledge can be measured characterized two of the teachers' discourses (Fig. 1, levels 2 & 3 – mathematical knowledge).

I would say, it is more measurable in mathematics (the knowledge)... because, perhaps, we have to deal with more standardised things... What I mean...when we do, for example, simple additions, one succeeds and another does not. While the concept, what you define as love, can be discussed, you just need to convince me. But you can't convince me that $1+1$ makes 9, it is a little difficult to convince me. Perhaps this is the reason why assessing in mathematics is different...the results are more expected.

(Nikitas, 16 years of teaching experience, BA in Education & BSc in Mathematics, limited professional activity).

The teachers tended to judge students' mathematical texts on the basis of the degree these satisfy or not the official criteria of assessment, as substantiated, however, within the classroom (Fig. 1, levels 2 & 3 – students' texts). In this context, the assessment process allows the comparative classification of each student according to his/her mathematical behaviour and its divergence from the officially defined, as well as from the one designated as desirable in each class (Fig.1, levels 2 & 3 – students).

My tests are always in the "spirit" of the textbook, perhaps a little bit different with respect to the way questions are phrased or to the difficulty level. This means you might find much easier but also much harder exercises compared to the ones in the textbook. Not unrealistic (exercises)... neither I do something extreme, nor I look for genius students in the class... This is not my aim!

(Chrisa, 17 years of teaching experience, BA in Education, high professional activity).

For example, I will assess a student... I will give him two problems and if he solves them with no difficulty and somebody else solves half of it...this is for sure an indicator of assessing differently each one of them...interest and effort is what counts

(Anastasia, 19 years of teaching experience, moderate professional activity)

Teachers' pedagogical discourse often drew on resources related to learning behavior rather than to specific achievements, when reporting on individual pupils; they tended to avoid describing specific features of their texts. Although they valued oral language in assessing, the teachers were not consistent with this view. For most, evaluation was predominately based on a combination of students' written performance, memory and effort made. Furthermore, referred to the importance of knowing the students they were

about to assess, as this knowledge provided a framework within which they could interpret students' mathematical texts instead of drawing on informal, loose criteria (Fig. 1, levels 2 & 3 – teacher).

Few teachers articulated a pedagogical discourse that presented some internal coherence. All of them, however, tended to employ discourses which came from different fields, thus allowing conflicts and contradictions to emerge within their pedagogical discourse, which can be summarized as follows: students' mathematics knowledge is not imprinted in the texts they produce, is seen as if it can be measured on the basis of the compatibility of certain features it bears with official ones, which, however are disputed with respect to their effectiveness and the necessity in the classroom, thus questioning the traditional function of the assessment process to classify students according to their mathematics performance (Fig.1, across and within levels).

The safest index for my students' assessment is their willingness to engage with mathematics. That is, if I see a student, even if he is not good, to want to begin the lesson, to come to the board, to be asked, for me is the safest index

(Antiopi, 10 years of teaching experience, BA in Education, high professional activity).

I am not interested in all these! That is, when I am in good terms with my students, the difficult part is to allocate grades to them and many times I offer higher grades, because I am interested in their relationship with mathematics ... It is better for a student to be not always excellent but to be given "10/10", in order to escape home oppression... I also rely on the teacher's guide that describes the objectives ... But in mathematics, during my teaching ... How do I know what do the students know? ... by assigning some assessment tests. I do this often, very often! It might be some short exercises. It might be a problem to solve and is usually something intended for the average student, so they are not blocked. Short tests, small exercises ...

(Antonia, 5 years of experience, BA in Education and BSc in Mathematics, substantial professional activity)

Based on the preceding findings, the pedagogical discourses developed by the five teachers appear to share features but also present tensions as well as contradictions and inconsistencies with respect to how the assessment process of pupils' mathematics is understood and allegedly exercised. These discrepancies are due to the different set of resources utilized across time and contexts and emerge not only between teachers but also in a single teacher.

Generally speaking, the teachers' pedagogical discourse tended to draw on resources that come mainly from two opposing discourses (traditional/performance oriented and alternative/ competence oriented respectively) (Broadfoot & Pollard, 2000 drawing on Bernstein), to adopt official criteria, re-contextualised according to each teacher's personal biography in mathematics education and shows overall moderate internal coherence.

DISCUSSION AND CONCLUDING REMARKS

Teachers' assessments are inevitably influenced by a number of factors, neither necessarily relevant to the students' mathematical achievements nor indispensably compatible to the official evaluation criteria. This influences their official, summative assessments of individual students. The results of the study presented here support this and could be attributed to the fact that in the Greek educational system, teachers are not yet required to proceed to assessing students using reliable and clearly defined criteria (officially or personally) and produce judgments for which they will be accountable.

The results also suggest that different teachers can interpret the same text or similar students' texts in many different ways, either because of judging different characteristics as significant or because of attributing different value to similar features. These different approaches might arise in informal classroom assessment contexts as well as in official circumstances. Due to the highly interpretive nature of every assessment activity in mathematics, it is almost impossible for a teacher to avoid such discrepancies. This raises important questions related to issues of equity in mathematics education. More specifically, it brings to the fore the possibility that some groups of students, who do not share the same social, cultural and linguistic background with their teacher-assessor, might be provided with fewer opportunities to access the resources s/he draws in assessing. As a consequence, it is harder for them to produce texts bearing the features expected by the teacher, in order to be highly valued. This way, there is a strong possibility that these groups of students will be systematically disadvantaged because of their failure to exhibit the mathematical behaviour expected and valued by their teacher (Morgan & Watson, 2002).

It is clear that assessment depends heavily on teachers' interpretations of specific students' textual productions. These interpretations might not be compatible with students' intentions, depending on the personal resources exploited by the teacher when assessing. The pedagogical discourses articulated in the context of this study indicate teaching practice as the basic regulating factor in the assessment process, which re-contextualises the official discourse, in order to become functional in practice. This process finally leads to the formulation of a limited number of assessment criteria, mostly inflexible and not necessarily compatible to one another. Thus, assessment is downgraded to a simple "confirmatory" act of what students do rather than of what they are able to do in mathematics, based on criteria which are not always compatible to the official ones.

The matters discussed above illustrate the interpretive nature of assessment in mathematics and provide some insight into the possible sources of different evaluations, which are likely to disadvantage certain groups of students. Such an insight may enable teachers to engage in critical reflection on their everyday professional practice. The recognition of the incompleteness of their awareness of students' behavior, of the potential for alternative interpretations of this behavior and

its situated and temporary nature may increase the sources of evidence on which teachers base their judgements. Overall, may help them become aware of the social and cultural forces in effect, their own beliefs and practices included, when success and failure in school mathematics is at stake. Providing experiences and opportunities of reflection towards this direction can be of great value for teachers' professional development.

HEURISTIC STRATEGIES PROSPECTIVE TEACHERS USE IN ANALYSING STUDENTS' WORK

Stefanie Kuhlemann

University of Oldenburg, Germany

In this paper I will describe with what specific heuristic strategies two prospective secondary school mathematics teachers, who are students towards the end of their academic education at the university, analyse a student's work and reconstruct possible thinking processes of this student. The research of these two prospective teachers reported in this paper is part of a qualitative study which investigates prospective teachers' behaviour of analysing students' work consisting of students' written answers to mathematical problem-solving tasks. The prospective teachers were questioned in clinical interviews and videotaped while analysing the students' work individually.

Keywords: heuristic strategies, prospective teachers, teacher education, teacher knowledge, analysis of students' work

INTRODUCTION

Examining students' work and their thinking in order to give feedback is an important part of effective teaching. For future teachers it is important to acquire diagnostic competence in order to understand and assess students' answers with the aim to make appropriate pedagogical and didactical decisions (Hußmann et al., 2007). This study draws on the process of analysing students' work. One of the main aspects of the study discussed in this paper is how prospective teachers analyse students' work and what they take into account. Particularly the following question is addressed: Which heuristic strategies do prospective teachers use in analysing students' work consisting of students' written answer to mathematical tasks?

THEORETICAL FRAMEWORK

Over the last couple of years many research projects have addressed teacher knowledge. Ball et al. (2008) discussed what makes Mathematical Knowledge for Teaching (MKT) special. They include among this, finding out what students have done, interpreting students' errors and assessing whether the thinking and approaches are mathematically correct and would work in general.

Examining students' work and thinking should be a part of everyday teaching practice (Borasi et al., 2002). Mathematics teachers "need to know how to [...] analyse students' solutions and explanations." (Hill et al., 2005, p. 372) Hill et al. (2005) include among the work of teaching mathematics, among others, "interpreting students' statements and solutions" (p. 372). The Teaching Principles of the National Council of Teachers of Mathematics (NCTM) Standards include "Effective mathematics teaching requires understanding what students know and need to learn and then challenging and supporting them to learn it well." (NCTM, 2000, p. 2)

According to Hattie (2009) powerful teaching also includes that the teacher knows what the students understand, when they have misconceptions, and where they make errors.

In fundamental ways Schoenfeld (2011) views “teaching as a much more complex problem-solving activity” (p. 3). It is a challenging task for teachers to know how to deal with students’ oral or written mathematical utterances, what to pay attention for (Crespo, 2000), and to understand what they are saying and doing (Wallach, 2005). Especially when students employ unusual strategies of solving a task, for example with nonstandard approaches which are unfamiliar to the teacher (Ball et al., 2008), students’ thinking is not always directly obvious and easily comprehensible. Teachers have to figure out the students’ thinking process and what they have done (ibid.). There is a need for teachers to use heuristic strategies to reconstruct possible thinking processes with the aim to understand the students’ work. In the analysis of students’ work possible thinking processes must be reconstructed in hypothetical, empathetic thinking by interpreting the work.

Crespo (2000) found in a study with elementary preservice teachers that they struggle with interpreting students’ work. The elementary preservice teachers tend to evaluate the students’ work immediately without analysing it carefully. In my study I had chosen prospective secondary school teachers towards the end of their academic education because I am interested in to what extent the academic education of secondary school teachers prepares for mathematical requirements needed in the analysis of students’ solving processes.

Schoenfeld (2011) claims “that what people do is a function of their resources (their knowledge, in the context of available material and other resources), goals (the conscious or unconscious aims they are trying to achieve) and orientations (their beliefs, values, biases, dispositions, etc.).” (p. xiv) The attempt in this study is to regard analysing students’ work as a function of knowledge and resources, of goals and of orientations. What people do in this study is analysing students’ work. In the following I describe which kinds of knowledge could have influence on these analyses.

Analysing students’ written work can be based on Pedagogical Content Knowledge (PCK), Content Knowledge (CK), and problem solving as mathematical competence (Figure 1). Shulman (1986) includes among Pedagogical Content Knowledge “the ways of representing and formulating the subject that make it comprehensible for others [...] [and] the conceptions and preconceptions that students of different ages and backgrounds bring with them” (Shulman, 1986, p. 9). Content Knowledge includes knowledge of the subject and its organising structures (Shulman, 1986). A teacher “need not only understand that something is so; the teacher must further understand why it is so” (Shulman, 1986, p. 9). Problem solving as mathematical competence is another important aspect for analysing students’ written work as semiotic representation of the student’s problem-solving activities. Reconstructing

possible thinking processes of the student can be based on identifying specific problem-solving strategies in the student's work.

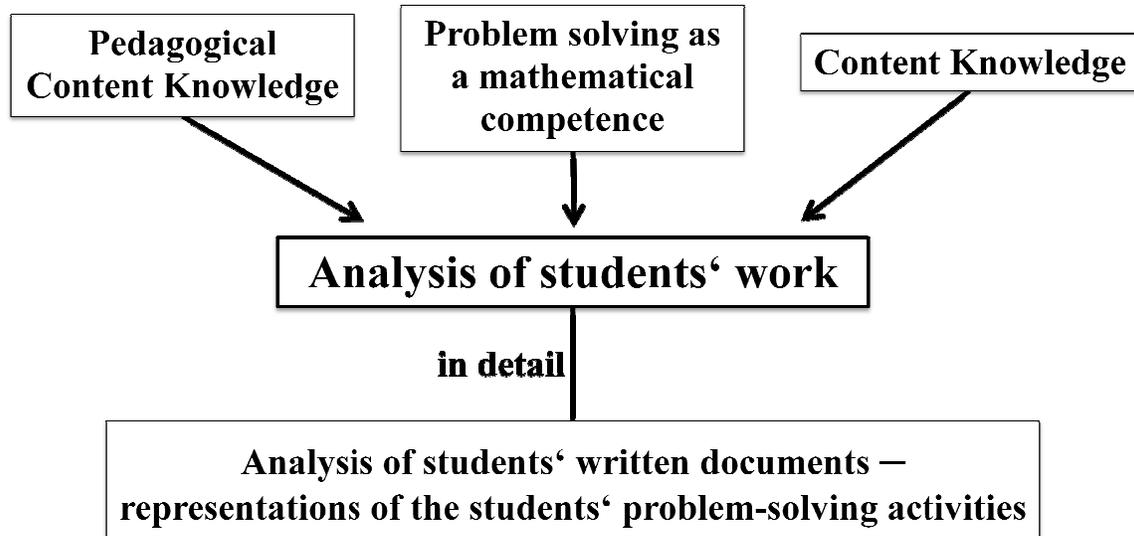

Figure 1. Analysis of students' work

In the process of analysing students' work it is in some cases necessary to change from one representation system to another, for example, if the student has chosen two different representation systems within his or her solution process. Duval (2006) distinguishes two different types of transformations of semiotic representations: treatments (transformation from one semiotic representation to another in the same register) and conversions (transformation from one semiotic representation to another in a different register).

METHOD OF INVESTIGATION AND ITS JUSTIFICATION

Research design and sample

The two cases described in this paper are situated within a qualitative study of 19 prospective secondary school mathematics teachers, towards the end of their academic education at the University of Oldenburg, Germany. In Germany the teacher education is composed of two parts. The first part is an academic education at the university and the second part is a practical training in teacher seminars and in school.

In a two step design prospective teachers were asked to solve three different mathematical tasks, and to analyse one student's written work to each of these tasks. More precisely, the prospective teachers should reconstruct possible thinking processes of the student and propose feedback to or support for the student. This should be done individually with unlimited time. The mathematical tasks have multiple ways of solving and differ in their mathematical content. Some of the students' written answers are fictive and others are real. These written answers of students to the different tasks include different ideas and ways of solving, e.g. graphic or algebraic.

The data includes on the one hand written work of the prospective teachers concerning their answers to the mathematical tasks and their analyses of students' work; on the other hand videotaped, transcribed material of oral comments while solving tasks and analysing students' work and a semi-structured interview afterwards. To understand their ideas in more detail, the prospective teachers were asked to explain their work and their hypotheses on the students' thinking processes in an interview. I had chosen this combination of written and oral form, because to one hand the participants could think more profoundly about different aspects to write down, and they were not in hurry to answer something quickly; on the other hand to get also data about what they perhaps have already thought concerning the student's work but did not write down. Additionally the prospective teachers are working with the students' work twice thereby they can get more ideas.

In this paper I describe the heuristic strategies two prospective teachers (Marc and Tim) show in analysing Lilly's written work to the task "Find the solution set", one of the three different mathematical tasks. I want to describe the analyses of these two participants because they use some identical strategies and some which are completely different from each other. In comparison with the other 17 participants of the whole study, the strategies of these two cases are also used by other participants.

The mathematical task and Lilly's answer, which were given to the participants, are shown in Figure 2.

Mathematical problem "Find the solution set"

Find the solution set of $\begin{cases} x + y = 9 \\ x - 2y \leq 0 \\ 10x + y > 9 \end{cases}$ where x and y are natural numbers.

Describe your approach and document your way of solving as accurately as possible. What alternative approaches do you know? Carry them out.

Lilly's work to this task

Lilly has rearranged the system and created the following illustration in a Cartesian coordinate system.

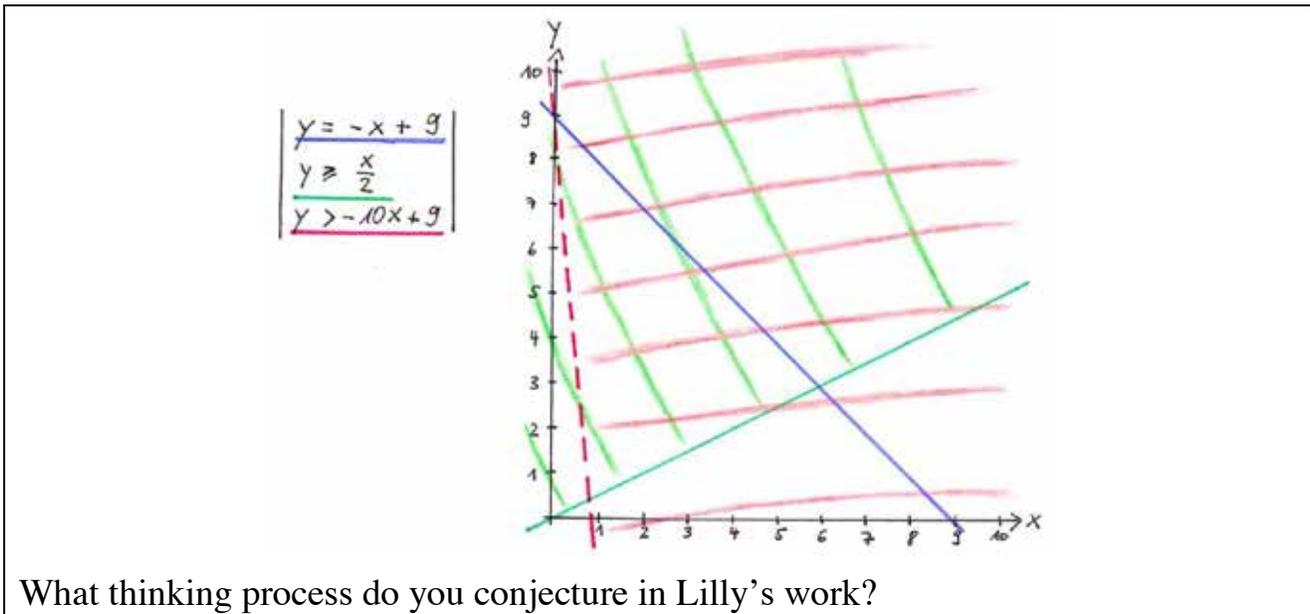

Figure 2. Mathematical problem “Find the solution set” and Lilly's work

For this task content knowledge about the meaning of such a system, the solution set, and the concept of variables is needed. Depending on the chosen solution strategy more content knowledge is required, such as the substitution method or knowledge of geometric illustrations. German students are familiar with systems of linear equations, but not with dealing with linear inequalities. They have to transfer their problem-solving strategy for solving a system of linear equations to a system with inequalities or to think about another solution strategy where mathematical process skills will be needed.

Lilly has rearranged the inequalities and the equation for y by treatment within the algebraic register. She changes into the graphic register (conversion according to Duval, 2006) with her other representation. In the xy -plane the solution set of each inequality and equation is graphed as lines or areas for x and $y \in \mathbb{R}$. A possible reason why the line for $y = -10x + 9$ is drawn as a dashed line could be that the set of the line is not included in the set of $y > 10x + 9$. The missing solution set of the complete system can be found graphically as the intersection of the three individual solution sets of the equation and the two inequalities. Since $x, y \in \mathbb{N}$, the solution set consists of the following ordered pairs: $IL = \{(1/8), (2/7), (3/6), (4/5), (5/4), (6/3)\}$.

Data analysis

To find out heuristic strategies the prospective teachers use in analysing Lilly's work I go through the written and transcribed material in combination both line by line for analysing and interpreting significant statements and strategies with the aim to expose categories for heuristic strategies.

ANALYSES OF LILLY'S WORK

In the following I want to describe the strategies that two prospective teachers (the case of Marc and the case of Tim) use to analyse Lilly's work. The prospective

teachers had unlimited time to analyse Lilly's work, both of them worked on it ten minutes. Before analysing the student's work the prospective teachers were asked to solve the mathematical task on their own.

Marc

Marc chooses in his own solution the substitution method (a target-aimed method for this task). He rearranges the equation for x and replaces it in the inequalities. His way of solving indicates the safe use of algebraic transformations and solving inequalities. In his solution process, he shows strength in formal-operational activities. Marc finds out two correct restrictions for x and for y (namely $0 < x \leq 6$, $3 \leq y < 9$). However, he refers to the restrictions found for the variables separately, but not combined as ordered pairs and without regard to the condition $x+y=9$. Marc claims that he cannot write down a solution set.

Marc explains what thinking process he conjectures in Lilly's work after a few minutes looking at her written work and writing down some aspects. Marc mentions:

Marc: She sees in y this function and tries to write down every equation, which is here [points at the system with equation and inequalities], as a function and tries to solve it with a drawing and yes, she has done it right. [...]

She is now thinking the solution set is everything which is on the line. At this it is all what is over it and for $y \geq 3$ it has to be definitely bigger, therefore she has drawn it as a dashed line, because it doesn't include this value thus this line.

Lilly has rearranged the inequalities and the equation for y . Hence he concludes that she will regard it as a function. A possible reason for this could be that her rearranged conditions remind him of the standard presentation of functions. Before commenting this orally he wrote down

- Lilly sees in y the function $f(x)$, rearranges the equations for y
- equation=function

This indicates that he sets himself a framework namely the context function as a fundamental idea concerning Lilly's work. This fundamental idea of function occurs also at the end of his analysis.

In his written and in his oral analysis he numbers consecutively the three conditions for y in the algebraic representation of Lilly's work ($y \geq 3$ for the third condition). He hereby separates the conditions for y from each other (deliberately or not).

Marc tries to reconstruct the action by splitting up Lilly's work and analysing it separately. He splits up the solution in two ways: 1) At the beginning of his analysis he thinks in the algebraic register and changes into the graphic register (Duval, 2006). 2) Marc interprets the equation and the inequalities separately as straight lines and as designated areas in Lilly's graph.

He interprets elements of the solution locally like the graphed solution set of the equation and each inequality as lines or areas. In his analysis of Lilly's work he is influenced by his attitude towards the correctness of the work. Some of Marc's

statements indicate that he thinks something is wrong but he is unsure. Nevertheless he takes it seriously and tries to understand Lilly's approach.

Marc: What would happen now, if I take a value for x , which is smaller than one? [...] She doesn't need to regard this, it is completely indifferent for her.

In this excerpt his analysis goes on with using a "what if"-strategy as occasion to think from Lilly's perspective. This approach does not advance him in reconstructing the thinking process. He rejects his strategy because he thinks that it is irrelevant. Later he thinks about how Lilly could go on working on this or how he would help her exactly.

Marc: Perhaps one can go on working on this but I don't know it now. [...] What would be, if I interpret it with my solution? So, I don't know, how do it with that, but if I take my solution to interpret it in connection with this solution.

Following this he tries to deduce the thinking process in Lilly's work with the help of his own solution. He shows his conditions ($0 < x \leq 6$, $3 \leq y < 9$) in Lilly's work at the corresponding axes, but he does not respond to a combination of x - and y -values with respect to the solution set. Marc finds his conditions in the graphic representation, but he does not understand Lilly's representation. It can be said, that he does not succeed in understanding how the graphic representation of Lilly is related to the determination of the solution set of an algebraic system. His main problem is the mathematics. In the analysis of Lilly's work, he shows a weakness in the cross-linking by not associating his algebraic solving method with the graphic determination of the solution set of an algebraic system. So, he cannot complete Lilly's solution idea or reconstruct a possible thinking process completely even with the help of his own solution.

Marc can explain details, but he cannot relate the three conditions (equation and inequalities) in Lilly's work because he describes three solution sets. It shows that this is an analogical problem as in his own solution because he does not relate his two found conditions. Altogether he does not grasp the complete strategy of Lilly's approach, but rather the dealing with the separated conditions. He interprets some aspects of the solution locally.

Summary of Marc's strategies:

- sets himself a framework
- reconstructs the action by splitting up the work and analysing it separately
- deals with representations
- "what if"-strategy as occasion to think from Lilly's perspective
- uses his own solution to interpret her work

Tim

In his own solution, Tim makes use of the substitution method by rearranging the equation for x and replacing it in inequalities. Tim exploits two correct conditions for y ($y \geq 3$, $y < 9$). He writes down a solution set for y ($y = \{3, 4, 5, 6, 7, 8\}$) and for x

($x=\{1,2,3,4,5,6\}$) in a way that x and y are separated. He does not write down ordered pairs (x, y) regarding the condition $x+y=9$.

By analysing Lilly's work, Tim mentions:

Tim: First she tried to put the whole thing down to something familiar namely to a linear system of equation and then look at each as intersection of two lines.

When Tim describes Lilly's approach, he identifies Lilly's strategy which I call "drawing on something familiar".

Tim: This matches. This intersection point [points at $P(6/3)$ in Lilly's graph] x equals 6 is ok and also y which is 3. Thus the points [points at his solution sets] are included.

Tim refers to intersection points. He checks if the intersection point $(6/3)$ that he looked at in Lilly's graph is included in his own solution because he intends to verify Lilly's work. Then he states that his solution and Lilly's graphic representation is consistent. This excerpt is an indicator for the strategy "referring to his own solution".

He says that Lilly did not mark the solution set and that he does not quite see it. Following this he mentions:

Tim: She didn't understand the question of the task which is to find the solution set [points at the task] which fulfills this. This she didn't do exactly because [...].

By referring to Lilly's work Tim points out that Lilly's solution is not completed, when he explains that Lilly did not answer the task. He assumes that Lilly did not understand the question and takes the graphic representation into account. He points at the point $(0/9)$ and says that this would be possible in this representation, but this does not fit to the fact $9 > y$ (he points in the direction of the task), namely that it is only included up to the point $(1/8)$ at which he is pointing. It indicates that he examines the correctness of the solution like he has done at the beginning of his analysis. Possibly Tim refers to his own solution again (however implicit) because he knows that the point $(0/9)$ is not included in the solution set.

The same as in the case of Marc Tim applies the strategy of splitting up the solution. Thereby he focuses on single transformations and changes from algebraic register into graphic register. Later he mentions that something special is the dependence in the solution set. Take it together it has to be nine in each case.

Summary of Tim's strategies:

- identifies Lilly's strategy "drawing on something familiar"
- reconstructs the action by splitting up the work and analysing it separately
- deals with representations
- verifies Lilly's solution by referring to his own solution

Comparison of the two cases

Marc and Tim use some identical strategies to analyse Lilly's work (reconstruct the action by splitting up the work and analysing it separately; deal with representations). Both of them refer to their own solutions but in a different way. Marc uses his own solution to interpret Lilly's work whereas Tim refers to his solution to verify special aspects of Lilly's work.

Marc has difficulties in understanding Lilly's work and thinks something is wrong. However, he is unsure, so he takes it seriously and tries to understand Lilly's approach. He interprets details of her work locally, but cannot reconstruct a possible thinking process completely even with the help of his solution. Tim gives greater consideration to Lilly's strategy which he identifies in her work. Altogether he gives the impression that he rather verifies Lilly's work.

CONCLUSIONS

Concerning the answer of the research question the analyses of the two prospective teachers were analysed to find out their heuristic strategies by which they analyse a student's work and reconstruct possible thinking processes. The results of these cases show that analysing a student's work evokes specific heuristic strategies and that different heuristic strategies can be reconstructed. Marc and Tim use similar and different strategies in their analyses. Both of them use the strategy "refer to the own solution" which seems to be a typical strategy. "Reconstruct the action by splitting up the work and analysing it separately" as another heuristic strategy is one which is used frequently with the aim of understanding students' work, especially if the students employ unusual strategies of solving a task.

With the help of the whole study of all participants further strategies and their detailed descriptions can be investigated. All strategies of each prospective teacher will be regarded individually in order to find out different types and to identify different pattern. So far, the analyses of the data show that some prospective teachers have difficulties in analysing students' work and tend to evaluate the students' work immediately without analysing it in a deeper way. Other prospective teachers try to reconstruct the student's thinking processes carefully and do not only describe obvious activities of the student, for example describe not only written calculus, but also possible ideas of the students' solution strategy. These differences which may be caused in different orientations, strategies or differences in available knowledge need to be investigated. This can make contribution to the development of the academic teacher education by making proposals for example of analysing students' work what can be regarded in a didactic course at the university. Some prospective teachers can improve their analyses by knowing further strategies to be more flexible in their analyses of student's work. To pay attention to the mathematical thinking of students, try to make sense of what they are saying and doing is an important part of effective teaching and can help teachers to improve their practice and students' learning.

RICHNESS AND COMPLEXITY OF TEACHING DIVISION: PROSPECTIVE ELEMENTARY TEACHERS' ROLEPLAYING ON A DIVISION WITH REMAINDER

Caroline Lajoie & Jean-François Maheux

Université du Québec à Montréal

Division, one of the most difficult topics to teach in elementary mathematics, is rarely examined from the perspective of student teachers engaging with peers and making use of mathematical or pedagogical knowledge in teacher-pupil interaction. In this paper, we examine prospective elementary teachers preparing, realizing and discussing a role-play on division with remainder. Using the concept of “structure of attention”, we offer a positive understanding of prospective teachers’ performances in terms of navigating the richness and complexity of teaching division.

INTRODUCTION

Division is known as one of the most difficult topics to teach in elementary mathematics (e.g. Salama, 1981; Silver *et al.*, 1993). Thus, many studies examine preservice teachers’ understandings of division (e.g Graeber & Tirosh, 1988; Ball, 1990; Simon, 1993; Campbell, 2002; Crespo & Nicol, 2006). Globally, researchers characterize those understandings in terms of actual or expected mathematical knowledge, stress on student teachers' difficulties, and occasionally offer alternatives to improve or extend their understandings of division and standard algorithms. However, those researches rarely examine student teachers as they engage with peers or make use of mathematical knowledge of division to teach (Simon, 1993).

Role-play involves staging a problematic situation with characters taking roles. It may be used to fulfill various objectives such as therapeutic objectives, personal and professional training objectives, or may be used as a pedagogical method (Mucchielli, 1983). The premise of role-play is to have persons, such as students, become active characters in a given situation. In one of our “mathematics method” courses, for example, students take the part of a teacher while others act as students, and they improvise around a mathematical task, a students’ question or production, the use of teaching material, and so on (Lajoie & Pallascio, 2001; Lajoie, 2010). Since role-play asks student teachers to become active actors in different teaching situations, instead of simply imagining or analysing such situations, it provides an approach to research on mathematics teacher education that matches both of Simon (1993) demands.

In this paper, we report observations we made on a lesson in which student teachers prepared, performed and discussed a role-play on division with remainder. Bringing forth the richness and complexity of teaching division, we discuss how prospective teachers’ *structure of attention* (Mason & Spence, 1993; Mason, 2003) played out in their actual use of resources such as mathematical knowledge, contextualization, or models such as the partitive and quotitive orientation to division.

BACKGROUND

Division with remainder presents a real mathematical challenge for prospective teachers. The division algorithm involves many arithmetical concepts, including positional, decimal numeral system, associativity, multiplication tables; while the remainder in itself opens to deeper questioning in terms of fractions, periodicity and infinite operations, and so on. In a somehow deficit perspective, previous research on the topic in the context of teacher education, giving attention to what might be missing rather than to the richness and potentiality of what is actually taking place, suggests that preservice teachers hardly make use of these concepts when confronted with division and its standard algorithm. More specifically, a gap is seen to exist between the conceptual and procedural levels (Silver, 1986) whereas:

(...) the prospective teachers' conceptual knowledge was weak in a number of areas including the conceptual underpinnings of familiar algorithms, the relationship between partitive and quotitive division, the relationship between symbolic division and real-world problems, and identification of the units of quantities encountered in division computations (Simon, 1993, p. 233).

In this quotation, Simon also refers to two “primitive” models of division, the *partitive* (sharing) and the *quotitive* (grouping or measuring) models. As a way to student teachers' understanding of division, Fischbein *et al.* (1985) use these models to observe that even with a “solid formal-algorithmic training”, students continue to be influenced by these intuitive models. Attachment to the models could explain a number of difficulties arising in unfamiliar problems, such as division by zero (Lajoie & Mura, 1998), because those models do not always constitute a solid conceptual basis (Simon, 1993). In addition, Kaput (1986) suggested an important mismatch between the dominant partitive experience of division and the quotitive approach generally used to teach division algorithms. Boulet (1998) confirmed this tendency in preservice teachers, noting that while the sharing model largely dominates when making sense of a division in real context, the measurement model clearly takes on when verbalising the algorithm. Finally, research pointed to student teachers' struggle to interpret remainders or the fractional part of the quotient (Silver, 1986; Simon, 1993). With a closer attention to teaching situations, some highlighted multiple possible treatments of the remainder, and turned our attention to the importance of being able to deal with children's ideas while making connections between the concrete, the symbolic and the algorithmic dimensions of the operation (Fang, Lee & Yang, 2012). Campbell (2002) observed that a quotitive disposition toward division also seems to impact future teachers' ability to make sense of the remainder, while confusions between the remainder and the quotient of a division may also appear when student teachers are confronted with unfamiliar tasks (e.g. reconstituting the remainder from a calculator). As we can see, literature on the topic is rich in conceptual analysis in relation with division. But less is said about the ability actually to call on, articulate and make use of these underlying concepts and rooting metaphors while teaching.

ELEMENTS OF A CONCEPTUAL FRAMEWORK

Teaching involves various kinds of knowing (e.g. Shulman, 1987), among which “pedagogical” and “content knowledge” attracted much attention in the community. But beside knowledge “about” teaching and mathematical concepts, a growing attention is given to what some call “know-how” or “knowing-to act in the moment” (Mason et Spence, 1999): the ability to draw on various knowledge in response to actual situations. Mason and Spence (1999) suggested that such ability “depends on the structure of attention in the moment, depends of what one is aware of” (p. 135). “Structure of attention” is concerned with what is attended to and how (Mason, 2003), and its development can be conceptualized at two levels: learners need to gain access to increasingly sophisticated structures of awareness and attain greater flexibility to allow their attention to be multiply structured. Experiencing situations in which a rich network of triggers and connections come about and can be rendered explicit is considered fundamental to this development.

Educating this awareness is most effectively done by labelling experiences in which powers have been exhibited, and developing a rich network of connections and triggers so that actions 'come to mind'. No-one can act if they are unaware of a possibility to act; no-one can act unless they have an act to perform (Mason & Spence, 1999, p. 135).

Hence, it is important for the students to be in the presence of someone, like an instructor, who is aware of the awarenesses (Mason & Spence, 1999).

Knowing is not a simple matter of accumulation. It is rather a state of awareness, of preparedness to see in the moment. That is why it is so vital for students to have the opportunity to be in the presence of someone who is aware of the awareness that constitute their mathematical 'seeing' (Mason & Spence, 1999, p. 151).

As an element of a conceptual framework underdevelopment in order to understand the competencies future teachers develop in “maths method courses” (e.g. Lajoie, 2010; Maheux & Lajoie, 2011), the concept of “structure of attention” enables us to look into their ability to make use of various knowledge. In this paper, we exemplify this and the potential outcome of such approach in a case on division with remainder.

METHOD (RESEARCH CONTEXT AND DESIGN)

As part of our research program on teacher education, we decided to investigate division with remainder in a study involving 40 preservice teachers enrolled in a 45 hours undergraduate course (3h weekly) on *Didactique de l'arithmétique au primaire* [primary arithmetic maths method]. No selection of the students was conducted, beside a general appreciation of the group (as whole) as typical of those we worked with for the last decade. Students were in their second of a four-year program, and had completed a first mathematics course. The course used for this study was designed around ten different *role-plays* (Lajoie, 2010) on various topics including numeration, operations and algorithms, fractions and decimal numbers.

Each *role-play* is organized in four moments. First, we introduce the ‘theme’ on which students will need to improvise (introduction time). Students then have about 30 minutes to prepare in small groups (preparation time). Third comes the play itself, where students chosen by the instructor (and coming from different preparation teams), come in front of the classroom and improvise, in an informed way (Maheux & Lajoie, 2011), a teacher-pupil interaction (play time). Finally, we have a whole classroom discussion (discussion time). Importantly, students thus have a preparation time to consider what might happen between a teacher and a pupil, but the role-play is essentially improvisational since there is no script and students learn only minutes before the play if they will be performing that day, and what role they have to take. We designed, taught (first author) and videotaped (second author) the three hours role-plays using two cameras (one capturing the whole classroom setting and interactions, the other following some teams more specifically). In this paper, we will focus on the role-play presented in Figure 1, which was also transcribed.

Role play theme

Fifth grade students (10-11 years old) who worked on a problem involving division with a remainder are sharing their answers. You observe mathematical difficulties in their approaches. You wish to engage with them in such a way that you can build up on their mishaps and help them move toward correct answers. Here is the problem they have been working on:

A student from the other class made a mistake while dividing 18181 by 9. Here is his answer.
Can you help find his error?

$$18181 \div 9 = 22,111 \text{ remain } 1.$$

Your students worked in team, and among them Team A and B arrived at the following explanations:

- Team A: The answer is 2020 remain 1/18181
- Team B: The answer is 2020 remain 0,111

Prepare yourselves to either play the role of a student from Team A or B, or that of the teacher who wants to help them starting from their reasoning.

Figure 1

That particular lesson, involving division with a remainder, took place midway into the term (when the students felt comfortable with role-play). As homework, the week before, they had to read Boulet’s (1998) paper on the verbalisation of the division algorithm in terms of partitive or quotitive models, which were also discussed in class. The role-play (Figure 1) was designed to bring about multiple mathematical concepts potentially involved in (long hand) division with a remainder. This includes the fact that no context was provided for the division itself, so that preservice teachers would not be directed towards a partitive or quotitive model. To collect data, the moving camcorder mostly follows a team of four, part of which Justine will end up playing the role of the teacher. We thus focus on the interactions taking place in that team (during preparation time), on the play itself (play time), and on the whole group discussions (discussion time).

ANALYSIS

During preparation time, Justine's team quickly engaged in figuring out the correct mathematical answer to the division problem under investigation, and then turned to what should be done in regard with Team A's solution:

Cindy. We could ask them what they did, and they may answer that they have 1 remaining unit over the 18181. But that's not really it, because the unit, you have to divide it in 9, but you can't divide it in 9. (...)

Bella. When.. if you only look at this... it is part of the 18181... from the moment you decide to divide by 9... actually, when you see it written here it is still a unit part of your 18181, but when you write the result of the division, you can decide that it will stay as a unit, or you decide to write it as a remainder of 1 that you are going to divide by 9.

Justine. If you write 1, its because you decide not to divide it. You keep the whole unit.

Attending to the operation as presented, the students here stay in the symbolic domain, focusing on what appears as problematic in Team A's answer: their writing of the remainder. Inasmuch, students in this discussion did not *explicitly* make use of the sharing/partitive or grouping/quotitive models despite the classroom discussion that preceded. More so, they discuss the problem indistinctively using the "dividing in" and "dividing by" expressions which might refer to two different views on the division and its remainder. That is, as we can anticipate, exposure to the models through literature or classroom discussion does not spontaneously translate into resources for designing a teaching intervention.

When prompted by the second author (holding the camcorder), who asked them to explain what the remainder could represent, the students moved from the symbolic to the contextual level. They gave flesh to the problem in terms of "sharing candies between 9 children", clearly leaning toward a partitive orientation. If this contextualisation seemed to help them to confirm a relationship between the dividend (18181) and the remainder (1), Justine's team, however, did not anticipate the challenge of drawing on this model to verbalize the actual division. Nor did they consider where it would lead them, were they to continue the division.

As a result, during play time, when the role-play took place and Dominique – the student teacher chosen to play the pupil – tried using a similar context to explain her division, Justine did not react to her problematic verbalisation of the algorithm:

Dominique. So I want to divide 1 candy between 9 friends, but I can't [writes 0 in the quotient]. So I'll take the 8, and now I have 18 candies to split between 9. Each will have 2. Now I subtract and I take the 1. Now if I want to divide it again between 9... well I place a 0 here [in the quotient] and I'll put my 1 there. Now again I take the 8, 18 candies between 9 friends gives them 2 each. 18-18 is 0. I have 1 left to take. If I want to divide it between 9 friends it doesn't work [adds another 0 to the quotient, now 02020]. I have 1 candy left over the 18181, so 1/18181 [writes it next to the quotient and add "remain" between the two].

Justine. Ok, so what you are telling me... If we draw this like... Wait! Actually, what you are telling me is that I'm left with 2020... no, 2020 remaining 1 over the whole 18181. So your reasoning is good, but we'll illustrate that another way. [...] Say you have a chocolate bar left. What did you do all the way through? You were dividing by?

Focusing on the remainder, she did not pick up on Dominique successively treating all “1” and “8” as units (she calls the first 1 in 18181 “one candy” instead of 1 group of 10000 candies, etc.). That is, she did not make use of the model, the context, nor the mathematical concepts at play to notice and act upon the problematic, highly procedural verbalisation of the algorithm. Justine responded to the student in the way she explored the problem in her group, the structure of her attention (to use Mason and Spence (1999)' expression for the condition of knowing-to act in the moment) being directed toward the problem of the remainder.

On the other hand, the context and partitive orientation to the problem are made use of when Justine guides Dominique to give meaning to 1 as a remainder. But when the time comes to consider $1/9$ in relation with the quotient and what was previously the remainder, Justine's attention is all to the possibility of dividing this remainder which was at the center of her team's preparation. Hence, she does not pick up on Dominique (and her own!) confusion, calling $1/9$ the remainder:

Dominique. So I have a chocolate bar and I divide it in 9 equal parts [drawing a 3x3 rectangle].

Justine. Yeah. I have... I have one left, one part ... over nine. (...)

Dominique. Before I had $1/18181$ but now I'm at $1/9$. A remainder of $1/9$.

Justine. So your remainder is 1 on 9, and could I... You agree that we divided the chocolate bar we had left in 9, so its like 1 divided by 9. (...)

This is particularly interesting because Justine actually faced the very same problem during preparation time, some time *before* they contextualized the problem. When the fraction $1/9$ first came about, the second author, observing the team, asked Justine if $1/9$ was the remainder. After a hesitation, she worked it out on paper and concluded that this was not the case: “there's nothing left, no remainder”.

The question of the remainder came back minutes later, after Justine and her teammates move to Team B's solution (“2020 remain 0,111”). But first, we can see how confrontation with the decimal development took them to a procedural approach:

Justine: Here the students say that they have a remainder of 1, and because they cannot divide it anymore, they add a period because they are no more in the integer, they are in the decimal. They say “I add a zero, it give us one tenths. Like 10, I divide it by 9, it fits in only once.”

In contrast, the first part of their preparation, with its concerns about the relations between the “1” and the “18181”, now appears quite conceptual! We also see students moving back to the symbolic domain, trying to make sense of the division in algorithmic terms. And although they had just worked out a context (sharing candies) that could give meaning to their work on the decimals part (turning the remaining

unit into ten tenths to be shared among 9 friends), they did not use it. And when asked to do so, Bella explained “You divide the candy in 9, and there is a little bit left”. This curious formulation (was the candy divided in 9 or in 10?), rephrased for her by the camera-holder as “divide it into 10, what you have left is 0,1”, then led to an actual explanation of the residue: “You are always left with something, but maybe its one tenth, maybe one thousandth...”.

This brings to light not only the difficult task to linking the algorithm with a concrete situation, but also the particular challenge of articulating the remainder, the fractional part of the quotient, its decimal expression, and presence of a “remaining part” yet to be divided. This complexity was at the core of the role-play setup we presented to the students (during introduction time), involving many of the possible confusions, including dividing by 9 and dividing in 10 (so that sharing or grouping in 9 becomes possible). And indeed, when Justine plays with Dominique, she soon comes to a point where she asks her “pupil” to transform the fractional part of the quotient ($1/9$) in its decimal expression. As Dominique struggles, Justine offers to try and divide 100 by 90 instead: “you have bigger numbers but it’s the same”. Dominique then finds her way to mechanically proceed to the division (finding “1.11”), which Justine uses to emphasise the infinite development of the decimal part. Linking it with the answer, Dominique as a pupil was supposed to be answering to (“ $18181 \div 9 = 22,111$ remain 1”, see Figure 1), Justine offers an interpretation of the “remain 1”. As she explains to Dominique, “there is still something to divide”, but “we don’t have a chocolate bar anymore”: the decimal part is thus something already divided, it belongs with the quotient (in contrast with Team B’s answer). After what she concludes to Dominique’s original division: “it’s the same here.”

Along the conversation, Justine thus again, passes up the algorithm to keep focus on the decimal development of $100 \div 90$, so much so that she also cuts through the fact that its quotient is actually ten times bigger than the one they were initially looking for. This could be analysed in terms of a lack of mathematical understanding, or as an effect of insufficient understanding of the division, its algorithm, of the pedagogical importance of making sense of computations, and so on. However, we must appreciate Justine’s consistency in attending to what emerges from the task at hand in the moment. The sensitivity to notice, the instinct to call upon, and the flexibility to make use while keeping track of one’s intention: those are complex, intricate dimension of attending that can only slowly develop. It seems possible, however, to correlate this development with the very design of the situations student teachers are presented with. Here, a task in which they were confronted with “extremes” in terms of possible interpretation of the remainder of a division, took them to an extended sense of the relations at play. During discussion time, when asked how they felt about the role-played interaction, students said “it was very good”, but agreed (Justine included) that there was something missing in the part where she began dealing with the $1/9$ and the decimal part.

Summing up, we could say that Justine made use of mathematical understanding, the contextualisation and the intuitive models she actively experienced in preparation time, and also *as* they appeared in that moment. The problem as presented to the students (Figure 1) also seems to have largely oriented the students' preparation. So much so that it rendered invisible even what might appear as obvious aspects to consider (contextualization of the problem, verbalisation of the algorithm, interpretation of fractional part of the quotient), all elements the students discussed previously in whole class discussions and read about in the article we gave them.

CONCLUSION

The analysis we conducted in this study illustrates that the complexity of teaching a mathematical subject goes way beyond the complexity of the mathematical subject itself. The analysis allowed us to consider student teachers' ability to deal (before, while and after teaching) with the richness and complexity of a difficult subject in a positive way. That is, we came across the *multiple challenges* (prospective) teachers are presented with when preparing or actualizing teacher-pupils-like interactions on division with remainder: making use of models, contextualization and mathematical knowledge, making sense of the remainder and navigating through various forms of expressing the fractional part of the quotient, or attending to and verbalising the algorithm.

We think this is an important nuance when comparing with, for example, Simon's (1993) analysis stating that prospective teachers “do not make use of their concrete conceptual knowledge” to make sense of division computation and rather seem to “search for meaning within a narrow procedural space, reiterating rules for the procedure” (Simon, 1993, p. 248). As we see it, student teachers work with/in situations that strongly contribute to a structuring of their attention, which leads to the observed behaviour. An interesting question would then be: what may it take for the situation to allow students to have even more conceptual issues co-structuring their attention? (How) could mathematical understandings, contextualisation and models be made part of the situation so that student teachers actively use them in preparing or realizing an intervention? Giving the usual conditions of 3 hours x 15 weeks maths method courses, how readily available could those elements be so they play out as actual resources for students? How to ensure, in doing so, that those structuring resources do not become *too* constraining, leading student teachers to a technical view on preparing and performing mathematics instructional interactions?

It may feel easy to answer that student teachers should be *explicitly requested* to use various resources when they engage in preparation and the role-play. Although this might be the case, we find interesting to contrast what we observed in this study with similar claims. In a research design that used images and stories of real classroom teaching to help prospective teachers develop and practice the problem solving and decision-making skills they need, Crespo and Nicol (2006, p. 93) note:

Although we acknowledge that this issue relates to the wording in this task, the preservice teachers' lack of mathematical exploration before designing a pedagogical response is concerning. In the context of teaching practice, mathematical challenges arise in much the same way as in this first version of the task; that is with no invitation or prompt to first explore and clarify one's own mathematical understanding.

In our case, although nothing was said about mathematically exploring the task, we could see how Justine's team is challenged right from the beginning of preparation time to develop an understanding of division with remainder. That is, before agreeing on a pedagogical response, the team took time to explore the situation mathematically. We suspect that the *goal* presented in the task (be ready to improvise on the theme, actually engaging with a “pupil”) made the difference here. In other words, structure of attention may not only be only awareness to the possibilities a situation offers: it is also motivated, purposeful, and probably goal *orienting* as well (*situating* as much as *situated*). If this is the case, greater attention might be needed to the understanding of how prospective teachers are supported in the process. To put it bluntly, on this one aspect illustratively, even if mathematical exploration went on, this was clearly not enough to resolve all the mathematical confusions that came up. More so, these confusions arose even though our students already took a mathematics course focused on elementary mathematics the previous year. And actually, we could feel that, at the end of the lesson, many of our students were left with more *new* questions than new answers. Now, we wonder, might not this be the result of the expansion of those students' awareness of what is at stake? And may not this increasing awareness, fundamental to knowing to act in the moment, be the decisive outcome of teacher education? Another question being then: how can we provide, support, help students gaining means and confidence to navigate their queries?

PATTERNS OF PARTICIPATION – A FRAMEWORK FOR UNDERSTANDING THE ROLE OF THE TEACHER FOR CLASSROOM PRACTICE

Dorte Moeskær Larsen, University College Capital, Denmark

Camilla Hellsten Østergaard, University College Metropol, Denmark

Jeppe Skott, the Linnaeus University, Sweden & Aarhus University, Denmark

Research on teachers' knowledge and beliefs has grown big in recent years. The larger parts of these fields are built on acquisitionist interpretations of human functioning. We explore the potentials of a participationist framework for understanding the role of the teacher for emerging classroom practices. The framework is built on social practice theory and symbolic interactionism and adopts a processual approach to understanding the role of the teacher. We use the framework in a qualitative study of two teachers with different prior experiences.

Key words: mathematics teachers, patterns of participation, classroom research.

Research on and with mathematics teachers has grown over the last decades. Among others, it has addressed the questions of how to reconceptualise the mathematical knowledge teachers need in instruction (Ball et al. 2008; Davis and Simmt 2006; Ma 1999; Rowland and Ruthven 2011; Rowland et al. 2009) and of the relationships between their conceptualisations of mathematics and its teaching and learning on the one hand and the classroom practices on the other (Leder et al. 2002; Maasz and Schlöglmann 2009; Rösken et al. 2011). This research on teachers' knowledge and beliefs generally interpret human functioning in acquisitionist terms. Knowledge and beliefs are considered entities that reside within the individual. They may be challenged socially, but such challenges are considered a result of an experiential encounter between the individual and an external reality.

This conceptualisation of the individual is somewhat at odds with other current attempts to interpret human functioning in more social terms and view learning and learning to teach as shifting modes of participation in socially established practices. For the purposes of the present paper we adopt a perspective more in line with this latter perspective as we use what we have called a patterns-of-participation framework to understand how the teacher contributes to the practices that emerge in mathematics classrooms (Skott forthcoming; Skott et al. 2011).

THE PATTERNS-OF-PARTICIPATION FRAMEWORK

Patterns-of-participation research (PoP) draws on social practice theory (Holland et al. 1998; Holland and Lave 2009; Lave 1996; Lave and Wenger 1991; Wenger 1998) and symbolic interactionism (Blumer 1969, 1980; Mead 1934) to develop processual and dynamic interpretations of the role of the teacher for classroom practice. The argument is that the locally social emerges as individuals view themselves from the

outside and in the parlance of symbolic interactionism take on the attitudes of individual and generalised others. In interaction one interprets others' actions and actual and envisaged reactions to one's own conduct symbolically and adjusts one's actions accordingly. This does not necessarily imply becoming in line with one's immediate interlocutors' expectations. Rather it may involve reintroducing the perspective of for instance other individuals, a group of people who are significant for the context as seen by the person in question (e.g. a team of collaborating teachers), and what Holland and her colleagues (1998) call figured worlds (i.e. imagined as-if worlds such as academia, games of Dungeons and Dragons and Alcoholics Anonymous; - or a reform discourse in mathematics education).

In Wenger's terms a community of practice is characterised by mutual engagement, a joint enterprise, and a shared repertoire; to participate in a practice is to engage in the negotiation of its meaning. When a teacher works with a team of colleagues to develop mathematics education or to find ways of addressing more generic educational problems she may be said to participate in a community of practice in Wenger's sense. However, the notions characterising a community of practice need to be stretched if they are to account for the relationship between a teacher and for instance the figured world of the reform in mathematics education. In spite of that we use 'participation' also to account for the latter situation. It is in this case a matter of negotiating meaning and positioning oneself in an internalised discourse about the teaching and learning of mathematics.

As teachers engage in immediate classroom interaction they draw on a range of other past and present practices and figured worlds, some of which relate to mathematics and its teaching and learning, while others do not. The task for PoP may then be rephrased as an attempt to disentangle the multiple practices and figured worlds in which the teacher participates during classroom interaction as well as their transformations and mutual relationships.

In this paper we use PoP to analyse the practices that evolve in two different classrooms at two different primary and lower secondary schools in Denmark. The two teachers are Susanne, working at Southern Heights, and Astrid, working at Eastgate. The question we address is what the patterns are in Susanne's and Astrid's participation in their mathematics classrooms?

THE STUDY OF SUSANNE AND ASTRID

The study of Susanne and Astrid is part of a larger study involving four other practising and prospective teachers. The study spans almost two years.

Susanne is 36 years old when she graduates as a teacher of mathematics from a city college in Denmark. She began teaching at Southern Heights four years prior to that without a degree in education, but she enjoyed teaching and after two years at the school she decided to enrol in a 2-year college programme for second-career,

prospective teachers, specialising in mathematics. Formally, the course in mathematics deals not only with the subject itself, but is an integrated course in mathematics and mathematics education.

Astrid has taught for 18 years. During her pre-service education she studied most of the subjects in elementary school, but she specialized in music and physical education. After 9 years of teaching at different schools she gets a position at Eastgate, and begins to teach mathematics. At that time, all mathematics teachers at Eastgate, including Astrid, become involved in a teacher development programme involving four days of lectures and workshops and individual supervision by the teacher educator. Astrid enrolls in a similar programme again 8 years later. By then she is also a mentor for prospective teachers in their practicum, she teaches at in-service programmes for other teachers, and she has repeatedly been invited to lecture at college on teaching methods in mathematics.

METHODS

The PoP framework invites analyses of the processual and dynamic character of teachers' participation in classroom interaction. Consequently we need a methodology that views instruction as continuous transformations of teachers' participation in classroom practice in view of broader social practices and figured worlds at the school in question and beyond. Also, we need an interpretive stance that views these practices as well as shifts in the teachers' engagement in them from the perspective of the teachers themselves.

Consequently we use a qualitative approach inspired by grounded theory (Charmaz 2006). We have previously used GT without the objectivist connotations associated with it, and we by no means consider ourselves free from theoretical prerequisites in the present study. However, we still use the coding schemes, constant comparisons, and memo writing of GT as flexible guidelines for theorising classroom processes. They have proved helpful not least as it is not apparent at the outset what and how practices and figured worlds are significant for the teacher in question. The openness of the analytical procedures in GT allows us to address these questions empirically.

The data on Susanne include observations of 12 lessons, six from before her graduation and six from five months after, as well as three semi-structured interviews (Kvale 1996) conducted before and after the observations.

The main data on Astrid are observations of four lessons and two 2-hour semi-structured interviews. Supplementary data include observation notes from her mentoring of three prospective teachers and group interviews with the prospective teachers on their experiences from the practicum. For our present purposes these are used as a supplementary perspective on Astrid's tales of herself as a professional. .

Classroom observations and interviews were video and audio-recorded, respectively, using Transana. The recordings were transcribed in full, and the data were coded

moving back and forth between the transcripts and the recordings. The initial and focused codings resulted in 23 tentative categories (e.g. *curriculum*, *epistemological reflections*, *teaching college*, *teamwork*, and *helping students develop mathematical understanding*). The data were re-coded and memos were written while the categories were conceptualized in two steps, leading to a set of theoretical concepts, including *knowledge of mathematical teaching*, *the reform* and, *life story*, *participation in practices*, and wrote memos.

SUSANNE AT SOUTHERN HEIGHTS

In the interviews and observations Susanne engages in three significant practices and figured worlds beyond the one of the classroom. We describe these as *the tradition*, *the reform*, and *handling students*.

Susanne claims that her instructional approach is traditional. She tries to give explicit and precise directions for the students' subsequent individual work by presenting concepts and procedures for them to copy and follow. This is likely to create a calmer and quieter classroom than any alternative she can think of. She refers to her experiences as a student in secondary school as a source of inspiration for this, and also mentions her pre-service teacher education. At odds with the intentions of the teacher education programme, Susanne describes it as dominated by the teacher educator's exposition of proofs for the students to remember and copy. Susanne is not particularly fond of this approach to teacher education. Her criticism, however, is not directed against this way of working in mathematics. Rather, she suggests that prospective teachers should not spend their time studying the subject itself, but need to be "pumped full of great ideas for how to teach" (int. 1).

Susanne knows about the reform discourse from national curricular documents, from textbooks, and from the theoretical part of her college education, even though she does not think of the practices of the teacher education programme as in line with the reform. She refers to the dominant rhetoric of the programme as "college talk" and says that it focuses on student investigations and the use of manipulatives. Also, the students are to work independently, using informal methods before they are introduced to formal mathematics. However, Susanne is highly critical of the reform and associates "college talk" with what she describes as a pedagogy of "cut and paste", "fiddle and touch", and "cubes and gadgets". She finds it hard to see the mathematical potential in this, except for the emphasis on student understanding, "you know that doctrine that they need to understand and not just follow the rules" (int.1). Also, she thinks that in practice it takes too much time for the teacher to prepare lessons according to the reform and the resulting classroom atmosphere is bound to be too noisy. Susanne is aware the curricular documents are influenced by the reform, but she does not worry that her teaching is incompatible with the formal requirements, because she and her students follow a textbook scheme closely, in which "you can even smell the college talk" (int. 1).

Officially Susanne and her colleagues at Southern Heights work in teams, but the mathematics team meets rarely and irregularly, and when it does, they discuss practicalities and organizational issues. Susanne says that the school consists of “a lot of one-man armies, with each teacher running his own race” (int.1). In spite of that they share a concern for how to handle students, who are in some sort of trouble. Susanne is proud that the school “takes incredibly well care of” the students’ individual problems by using different organizational measures” (int. 1). For instance there is a special needs department for students with learning problems and an “observation class” for students, who are violating school norms. Susanne explains that she sometimes sends students off to the observation class, and that she refers some of the weaker ones to the special needs department. In line with this policy of separation, Susanne also separates the students who are not sent off to other departments into more manageable groups. For instance she asks students who are good in mathematics and who behave well to work alone outside the classroom. The remaining students are then a more homogeneous and manageable group.

Multiplication in grade 5

Susanne introduces the first lesson on multiplication in grade 5 by asking the students to suggest a one-digit and a two-digit number. 5 and 55 are suggested and she writes ‘ 5×55 ’ on the board. When she asks what this means, a girl, Mira, says that you have “Fifty-five five times” or “the reverse”. Susanne continues:

Susanne: Or the reverse, yes, or five fifty-five times. Exactly. Okay, but that means that I can say that now I take those five [points to ‘5’ on the board] five times first, and then afterwards I take them fifty times. That should be the same, right? Then I get fifty-five times altogether. It does not matter if I take fifty-five times at once, or whether I first take one pile and then the other pile and add them up, does it? So, let us do that. We begin by taking five five times [points to ‘5’ and the last ‘5’ in 55]. Five times five.

Dagmar: Twenty-five

Susanne: That is 25. And then this one, this is all the ones, so I write all the ones down here [writes ‘5’ underneath the ‘ 5×55 ’].

Dagmar: And the twos go down there? [Points to the left of ‘5’ in the result].

Susanne: Well, these are the tens, aren’t they? I add those to the next pile, because now I am to multiply the tens. Right. So in reality this is twenty, even though I have written ‘2’ up here, it is really ...?

Dagmar: Twenty.

Susanne: It is really twenty, because it was twenty-five, wasn’t it [says twenty-five slowly, emphasizing both parts of the word]? But we just write ‘2’. Okay? Then I say, well really I say five times fifty, don’t I? I really say five times fifty, but we just do five times five.

Molly: Well, it is 25, but//

Susanne: Yes.

Molly: But isn't it 125? [This may be Molly's suggestion for the result of the whole task].

Susanne: No, because you need to add those two [points to the number carried]. Twenty-five and two?

Molly: Twenty-seven.

Susanne: Then it is twenty-seven. In reality it is two hundred and seventy, because it is five times fifty, this is what I says isn't it? But we did already put the ones down there, so we just write 27 [writes '27' in front of the '5' in the results line]. [...]

Michael: I don't understand this.

Susanne: No, but then I try to explain it once more. [Repeats the explanation].

The introduction and the subsequent whole class examples to multiplication last more than half an hour.

Interpreting the above classroom episode, we consider Susanne's contributions to the classroom practices a result of the meaning she makes of the interactions that unfold. Doing so, Susanne draws on practices described previously.

In the lesson Susanne presents a multiplication algorithm. She emphasizes value of the digits several times, but in the process talks for instance about "the twos" instead of two tens. Several of the students suggest different results, and others complain that they do not understand. Susanne responds by going over the calculations again, but does so without explaining the value of each digit and without explaining the underlying mathematical reasoning.

Apparently Susanne attempts to introduce the procedure of the multiplication algorithm as well promote student understanding of how it works. In relation to *the tradition* and *the reform* as outlined previously, it seems as if the element of 'understanding' in *the reform* is inserted into a *traditional* instructional approach dominated by procedural competence. In the process it is transformed from being an outcome of the students' own mental activity (in *the reform*) to being transmitted by careful exposition.

Apart from sporadic attempts to supplement *the tradition* with an element of understanding there is a sharp discontinuity between Susanne's re-engagement in *the tradition* of school mathematics and *the reform* discourse. The two practices, then, do not merge to any great extent. Susanne at times inserts an element of understanding in isolated pockets of *the tradition*, possibly changing the meaning of understanding in the reform on the way. And she takes the organizational measures at the school further when asking students to go elsewhere to work, so as to have

manageable group to teach according to *the tradition*, apparently changing the intention of supporting students with problems into handling problematic students in the process. But in general *the tradition* appears to be an almost monolithic structure and other practices function primarily by suggesting ways of handling issues at the outskirts of the main practice.

ASTRID AT EASTGATE

Astrid engages in two significant practices and figured worlds beyond the one of the classroom. We describe these as *the reform experiences* and *supporting students*.

Astrid's tales of her professional self at Eastgate has come to include her position as a mathematics teacher. This is primarily due to her participation in the two reform-oriented teacher development programmes. They were influential, not least "because we talked about teaching" and the need to understand the students thinking: "We got into mathematical thinking, and we have done this many times ever since" (int. 1). This includes an increased emphasis on student communication and the requirement that they explain not only their results, but also their solution methods.

Astrid's comment above refers to the spirit of collaboration between the mathematics teachers at Eastgate, "the Eastgate spirit" (int. 1). Astrid is enthusiastic about collegial collaboration, both when they jointly plan lessons and instructional sequences and when they discuss episodes from different teachers' classrooms.

One of the things Astrid has contributed to the collaboration with her colleagues is her collection of good teaching experiences. Following from the teacher development programme she has collected experiences with emphasising students' work with mathematical problem solving and other processes as well as some illustrating the role of task contexts for students' reactions to mathematics. These experiences have been discussed among the colleagues, and Astrid is still keen to use problem solving with the students.

Eastgate prioritises equity issues, not least as they relate to students with special needs. On the homepage it says that the school builds on the children's diverse abilities, in class as well as on the playground. Astrid agrees with the intention of including and supporting all children and says that she makes an effort to make instructional objectives for the children individually. In spite of her support, she suggests that the school's priorities come at the price of sometimes reducing the emphasis and level of the subject matter taught at Eastgate.

Multiplication in grade 5

Reintroducing multiplication in grade 5, Astrid asks the students to solve single-digit multiplications tasks. Subsequently the students are to draw rectangles of different sizes and find ways of determining the number of unit squares in each.

Astrid: If it was me, and I felt like a little (.), whew: I'm not good to keep track of too many numbers, so I might say, well, I just take such a little piece here

[draw a small rectangle – 11 multiply 13]... we must remember two things; it is possible to make it into a multiplication task, and it is smart to multiply by 10.

Peter: Okay.

Astrid: Just think about it. Now, if you think, "ah, this is okay, I would like to do something more difficult", then you could for example say, "Well, I'd like to have" [draw a large square on the board – 24 multiply 32, Astrid whistles].

Olga: Frederik can do that one.

Astrid: Frederik can solve this one. You know, I think there are many of you who can solve this one.

Olga: Mostly Frederik

Jens: 100 times 100

Astrid: Okay. Now I want to go crazy, I want to try this. And so you can try to split it or count it – you can do whatever you want. The only thing is, NB, NB, NB [writes "!!" on the board], keep in mind what we have learned. You can make multiplication tasks and we have learned something like - it is very easy to multiply by 10.

Simon: I have an idea. If you find, what is here – you just count 1, 2, 3, and find it here, and multiplies them [referring to the length and width of the rectangle] – that is what you have to do.

Astrid: [holds out her arms in a gesture of approval of Simon's suggestion]. That is a way to do it. There are many ways to solve it. But before I hear any more pieces of good advice, I would like you all to try.

After the introduction, the students work individually for 20 minutes. They are to set tasks for themselves, and Astrid walks around among the students, asking questions like: "How can you work this out?", "Why do you do it like this?", "If you do like this, how can you show it in the rectangle?" and "You have to write it down, so you can remember what you did". Later the students show and discuss their different methods for finding the size of the rectangles.

The lesson aims to support the students' understanding of the idea of multi-digit multiplication and to work towards proficiency in carrying out a procedure. Some of the students' individual suggestions are shared at the end, but it is not apparent if this is to form the basis for a common approach. At the end of the lesson Astrid tells the students, that she has written a letter to their parents. The letter states a mathematical aim: The students must know the multiplication table up to ten; "the trick" of multiplying by 10; that a multiplication task can be written as an addition; and how to multiply one-digit numbers by two-digit numbers.

Astrid seems to draw on different prior practices in the episode above. She draws rectangles of different sizes on the board, and the students are to find the number of unit squares in each. Working individually the students are later to decide themselves how big a rectangle they want to work with as well as how they want to find the size. It is an open task that may be solved at many different levels. In that sense Astrid draws on the school's approach to inclusion. Discussing the task with the students in a whole class setting afterwards Astrid also focuses on getting all students to talk about their individual approaches. Astrid does not reject or openly approve of the various solutions, in effect avoiding prioritising any of them.

Astrid uses the rectangles, to support student understanding. She draws on her practical experiences with the reform in the teacher development programme and her collaboration with her colleagues. This seems evident from her emphasis on the students setting their own tasks and the lack of emphasis on a standard procedure, leading to an element of investigation. Also, as the students work, Astrid wants them to discuss mathematics and her focus is on the students reasoning.

There is one practice, however, that is conspicuously absent in this, the one of mathematics in a more traditional sense. Although there is a close connection between the drawing and an understanding of multi-digit multiplication and the related algorithms, it is not obvious if the students understand the mathematical point or if they simply are "counting squares". One can speculate if they understand that this is a possible road towards a general procedure for multi-digit multiplication.

CONCLUSION

The above two analyses are attempts to understand how teachers' participation in different present and prior practices relate differently to the ones that develop in the classroom. They are an alternative to interpreting teachers' contributions to classroom practice in terms of their knowledge and beliefs. In the case of Susanne at Southern Heights one practice is dominant while other and more reform-orientated practices are less obvious. In the case of Astrid at Eastgate several practices form a more equal pattern. Susanne's and Astrid's conditions are similar, but the participatory patterns differ. Doing away with the acquisitionist connotations of other lines of research, the patterns of participation framework has some promise for a better understanding of the dynamical nature of classroom interaction. PoP sheds light on the dynamic relationships between the teacher's engagement in the practices of the mathematics classroom and other, personally significant, past and present ones.

INTEGRATING TECHNOLOGY INTO TEACHING: NEW CHALLENGES FOR THE CLASSROOM MATHEMATICAL MEANING CONSTRUCTION

Angeliki Mali*, Irene Biza*, Michalis Kaskadamis**, Despina Potari** and Charalambos Sakonidis***

*Loughborough University (UK), **University of Athens (Greece), *** Democritus University of Thrace (Greece)

The paper examines the ways in which technological tools shape teachers' and students' activity and hence the meaning construction related to linear function in a Year 10 classroom. The Extended Mediation Triangle of Cole and Engeström (1993) is used to analyze the aforementioned activity and to interpret conflicts and contradictions. Results show that students face difficulties to follow their teacher's effort for conceptual understanding via connections of different representations and mathematical context. The teacher's knowledge and flexibility helps him to exploit contradictions between his and students' objectives mostly productively. Technological tools are generally supportive to this direction but also giving rise to complications in teacher-students' communications.

INTRODUCTION

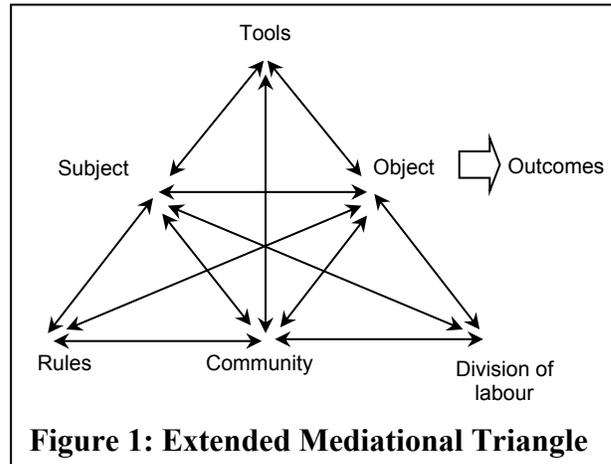

The learning and teaching challenges of using technology in the mathematics classroom have been repeatedly addressed in Mathematics Education. In exploiting computational environments, teachers' main responsibility is to act as orchestra conductors, aiming at students' interaction with the provided artefacts in ways that allow mathematical meaning to collectively emerge. To this direction, they are expected to tailor scaffolding conditions, exploiting technology in ways that promote students' transpositions towards mathematical meanings. However, this is not a straightforward process, as complications may arise in its course, due to conflicting interests and understandings emerging in the context of the resultant classroom activity. This paper presents an attempt to explore such a situation, aiming to contribute to the wider discussion on students' conceptual understanding via the exploration with technological tools.

THEORETICAL BACKGROUND AND LITERATURE REVIEW

Mathematics teaching is characterized by complexity as it is framed by the classroom interactions, the tasks assigned to the students and the overall social context. Skott (2010) talks about teachers' patterns of participation in different practices that frame their teaching. In technology-based mathematics lessons the situation becomes even more complex, as the nature of tools and management issues complicate student – teacher interaction in moving from the technological to the mathematical objects (e.g., Marracci & Marriotti, in press).

Activity Theory embodies the individual and the society in a unity in a way that the individual acts on his/her society at the same time as he/she becomes socialized to it (Mellin Olsen, 1987). This interplay between the individual and the society could capture the systemic nature of mathematics teaching by addressing its complexity. Recently, Jaworski and Potari (2009) used the activity theory and in particular the Extended Mediation Triangle (EMT) (Figure 1) of Cole and Engeström (1993) to consider the role of the broader social frame in which classroom teaching is situated. In this study, the activity of a teacher and of his students is contrasted and certain contradictions are identified.

The topmost of the subtriangles represents the visible actions of the subject, in our case of the teacher and the students, who use a number of tools to reach a goal (the object). Engeström (1998) refers to this as the “tip of the iceberg” and argues that “the ‘hidden curriculum’ is largely located in the bottom parts of the diagram: in the nature of the rules, the community and the division of labour of the activity” (p. 79).

Students’ participation in different communities (classroom, school, friends, parents etc.), each with its own rules and division of labour, has an impact on their classroom activity. Teacher’s activity, on the other hand, based on the tasks and the tools s/he designs to achieve certain goals, is framed by the rules of the communities he belongs to.

In the present paper EMT is used to analyze the activity of the teacher and the activity of the students and to interpret conflicts and contradictions that the teacher faces in his attempts to support students using technological tools as a means to construct mathematical meaning.

Various attempts have been made to study technology integration into mathematics teaching, especially in the upper secondary school, as well as the particularities of this integration. For example, Biza (2011) investigated Year 12 students’ understanding of the concept of tangent in computational contexts. She initially identified students’ misconceptions with the concept itself and their difficulty in moving between representational systems. The teaching intervention employed was based on the usage of examples and of dynamic graphs. The classroom discussions analyzed showed limited taken-for-shared mathematics meanings between the teacher and the students as well as conflicts and fluctuations in students’ arguments. Furthermore, the teacher’s attempt to negotiate the construction of a shared mathematical meaning was not straightforward, fluctuating between orchestrating the classroom discussion, introducing new examples and changing the sequence of the examples.

Kendal and Stacey (2001) studied the teaching of derivatives by two secondary teachers to Year 11 students via a Computer Algebra System. One of the teachers relied predominately on lecturing and demonstrating while the other on exploiting children's ideas emerging during classroom discussions. The analysis of these discussions revealed that teachers' pedagogical choices were compatible with their conceptions about mathematics and its teaching as well as about technology usage for educational purposes. In particular, the first of the teachers exploited technology more and his students used effectively the technological artefacts to solve procedural problems. However, the students in the second class were more capable in dealing with conceptual issues related to derivatives.

Monaghan (2004) looked at how secondary mathematics teachers take advantage of digital technology in teaching. The participating teachers, who made moderate educational use of technology in their regular classes, encountered substantial difficulties in exploiting effectively technology and tended to encourage classroom activity that differed in structure from that employed otherwise. In particular, they showed preference for open-ended tasks, often requiring extensive investigative processes. They also expressed concerns for the nature of the mathematics involved and noticed that the students tended to concentrate on technological details to the expense of mathematics. The author concludes that students' interpretations of the tasks affected the emergent teachers' goals and the design of the teaching sessions.

In Trouche's (2004) study, Year 12 students were invited to deal with a demanding task in computational contexts, involving solving equations, studying function variation, finding limits and studying sequence variation. The students worked in groups and were expected to submit a research report by the end of the session. The researcher claims that the reported success of the activity should be attributed to the expertise of the teacher and to the highly motivated and intelligent students and that it is hard to carry out in "normal" classes due to the demanding instrumental orchestration required. Such an orchestration should allow students to first make sense of the problem, then to explore some special examples and to finally discuss relevant conjectures.

The studies presented above indicate that the usage of technology may facilitate students' classroom participation but it also gives rise to unexpected and unexplored challenges during the mediation process. These challenges might increase instead of decreasing the conflicts and contradictions present in the activity of the teacher and of the pupils, thus weakening and blurring the mathematical meaning construction process. The study presented below is an attempt to investigate how this takes place.

SETTINGS-METHODOLOGY

The study is an action research of a high school teacher with 20 years of teaching experience and his collaboration with four researchers. The teacher had just completed a Masters' program in Mathematics Education and participated initially as a teacher and later as a teacher educator in a number of professional development

seminars related to the introduction of digital technologies in mathematics teaching. By returning to school, after a three-year school leave to complete his postgraduate studies, he wished to “implement” innovative ideas and approaches he came across during his studies. To this end, he introduced digital technologies into his teaching, promoted students’ conceptual understanding through different representations and generally encouraged students to make connections across contexts and representations. These approaches were beyond students’ experiences of mathematics teaching, which were textbook-based, over-emphasizing procedures and sophisticated techniques.

During the first months he faced a number of tensions related to students’, colleagues’ and parents’ expectations and thus decided to inquire his teaching and investigate systematically its effectiveness. To this purpose, he established a cycle of planning-implementing-reflecting lessons, which was regularly discussed with the first author of this paper at the planning and reflection phases. Furthermore, central classroom incidents were placed under scrutiny and emerging issues were explored in weekly meetings of all four researchers (mostly through Skype). In the occasion reported here, the teacher wanted to investigate how he could help students to explore algebraic relations and in particular the linear function and its graphical use to solve algebraic equations and inequalities in the context of dynamic environments, such as Geometer’s Sketchpad and Geogebra.

The first author of the paper observed and audiotaped his teaching in a Year 10 class (15-16 years old) for two months (27 students, 12 boys and 15 girls, for 17 teaching periods). In some of the sessions more than one audio recorder were used in order to capture a broader spectrum of the classroom activity. The main research question addressed here concerns the ways in which the available technological tools related to the teacher and the students’ activity and thus the mathematical meaning construction. The data consisted of the transcribed classroom observations and the discussions both at school and at the meetings. Analysis was based on the identification of critical incidents, where contradictions and conflicts emerged and the teacher had to interpret and manage. The EMT was used to analyze the incidents, allowing the interpretation of these contradictions and the deepening of our understanding of what could be characterized as effective teaching management.

RESULTS

In both incidents reported below the students work in pairs or groups of three in the computers’ room with a Geogebra file and a worksheet with technical instructions and mathematical tasks, both prepared by the teacher. The first comes from the first teaching session on linear functions while the second from the 5th and 6th sessions.

Incident 1: Teacher’s management of students’ unexpected responses

The teacher tries to use the possibilities offered by technology in order to allow students to identify many instances of the graph of a linear function. His goal is the students to explore general function properties by linking different representations.

For the needs of the introductory session on linear functions, the teacher prepared a Geogebra file consisting of a kinaesthetic representation of the function with two sliders, one for each parameter of the formula of the function. As the teacher explained just before the lesson: “They will manipulate the object [intuitively], gain a familiarity with this [make sense] and then make an interpretation of the object [typical meaning]”. The use of technology influences his decision, as “it allows testing dynamic changes”.

At the beginning of the session, he gives the students the worksheet and asks them to directly answer the first question: “Use the slider. What is the shape of the graph?” Students work in pairs:

- 1 S1: Sir, when you say what is the shape, it is a triangle, that means if we use a specific [she means a specific value of the parameter a], it is true.
- 2 Teacher: Which one is the graph?
- 3 S2: A straight line.
- 4 Teacher: The graph is this. Where is the triangle?
- 5 S1: Here it is! Isn't this the triangle? [she points at the triangle defined by the line and the two axis, see a similar inscription at Figure 2]
- 6 S2: I can see it too.
- 7 Teacher: We are not interested in the axes. What if [they are] hidden? Hide the axes.
- 8 S2: Yes, what if ... but.
- 9 Teacher: Just a minute
- 10 S1: Sir, I understood it.
- 11 Teacher: If you cover the axis, this is the shape; this is the function graph, you need to refer to this.
- 12 S3: What do you mean ‘what shape is the graph’?
- 13 S4: Sir, you don't have good expression.

The environment in which students work combines paper-pencil and computer based activities and includes: the symbolic representation; the kinaesthetic representation; two sliders; and the open-ended question regarding the *shape* of the graph. Students face difficulties in the connection of the representations of the linear function, so a group of them concludes that the shape of the graph is a *triangle* (Figure 2). The teacher did not expect this response from the students. For him, a graph is a geometric expression of an algebraic relationship; therefore, the line on the screen is the *shape of the graph*. However, for the students, a *shape*, in both geometric and algebraic contexts, is the same: does not represent a relationship, but something that should have area. Students' prior experiences of “shapes” regard geometrical tasks, whereas for algebraic tasks the word “graph” is usually used. So, the students, failing to see the connection between the algebraic and the geometrical contexts of a linear function (transcript lines [12], [13]), they identify only a *triangle*. A linguistic conflict can be identified here between the teacher and the students: the graph of a linear function is a shape for the teacher, whereas students expect to see a geometric

shape that has a surface. This interpretation gave rise to a new teaching goal for teacher –students’ understanding of what *the shape of the graph* is. To this aim, he tries to make the mathematical objects transparent to the students through questions and features of the educational software (transcript lines [2], [4], [7]):

In the first question, I say: "What shape is the graph?" They say: "It is a triangle." I understood that in this case they also saw the axes as part of the graph. So, I hid the axes and said: "Which is the graph?"

The teacher has chosen to negotiate different contexts (geometrical and algebraic) of the concept of linear function, with the intention to link the two, a process that was not easy for students. Finally, after the teacher used the Geogebra tool to hide the axes of the graph, students’ responses (“Isn’t that the graph?”, “It is always a straight line.”, “A line?”) showed that they began to understand what he referred to.

Incident 2: Teaching goals versus students’ explorations

In the second incident, the initial intention of the teacher was to engage students with the investigation of the properties of the linear function ($f(x)=ax+\beta$), especially regarding the role of a and β . To this aim he created a Geogebra file with a graphics window for the function graph and a spreadsheet window for the values of x and y (Figure 3).

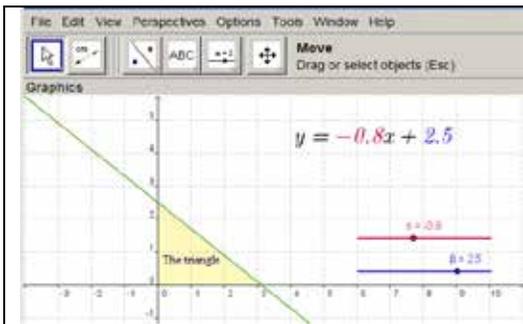

Figure 2: Geogebra file, Incident 1

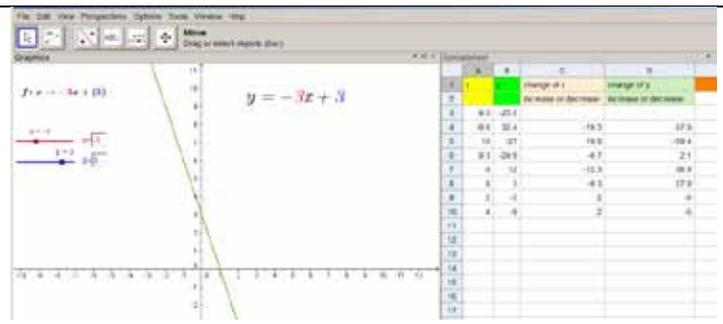

Figure 3: Geogebra file, Incident 2

The teacher has assigned to each group of students different values for a or β . In the spreadsheet, the first four values of x are random numbers, which change with F9 key, whereas the last four values of x are fixed and the same for every group. When the incident starts, students have already filled the columns of y , *change of x* and *change of y* by using the corresponding values of x and they are ready to deal with the task: “List as many observations you can regarding the results in the spreadsheet (try to be analytic in your description)”. The teacher expects that some groups will observe that the change of y is proportional to the change of x and will try to connect the ratio of change of y over change of x with the parameter a or the slope of the graph. Any observation of this type might be helpful to him to introduce students to the monotonicity of functions at a later stage.

During the whole class discussion, a student working in a group with the function $f(x)=0.5x-3$ notices that the values of y have always the same sign with those of x .

The teacher reminds the students that, by pressing F9, the values of x change and that x can be any real number and asks them to think “whether for every value of x the value of $y=0.5x-3$ always have the same sign as x ”. Some students agree, others not. He takes up the challenge and attempts to make students investigate the problem, by encouraging them to make connections among different representations of the function and also to link the solutions of equations and inequalities with points of the graph. A student says that for “every negative value of x this will be true”, another argues that “if $x=0$ then $y=-3$ ”. Other students suggest that there are positive values of x , for which y is negative or positive, “all the values of x for which $0.5x<3$ or $0.5x>3$, respectively”. However, there are students who fail to follow this suggestion. The teacher asks about the graph of the function and draws it roughly on the blackboard, following students’ suggestions regarding the y -intercept and the positive slope of the line. Then, he asks students not participating in the previous conversation to propose positive values of x , for which $y>0$ or $y=0$ or $y<0$, fill a table with the corresponding values of y and plot some corresponding points on the graph.

The initial aim of the teacher was the students to relate the ratio of change of y over change of x with the parameter a or with the slope of the graph. To achieve this, he asks students to work with different values of a and β , in order to observe the pattern in the spreadsheet. However, the open-ended question in the worksheet drives students’ observations to a different direction. By reflecting on his lesson after the session he notes: “The way that the question was posed in the worksheet might have been vague for what I had in mind”. As in the first incident, he takes into account students’ responses – although beyond his aims – and he creates a new teaching goal: to support students to give meaning to the graphical representation of the points (x, y) and relate them to the roots of the corresponding equation and inequality. Nevertheless, some students find it difficult to follow this shift:

Instead of allowing all students to present their results, I grasped the first opportunity offered by the first student’s response: “if for every value of x the value of $y=0.5x-3$ will always have the same sign as x ” and I invited the class to work on this. I saw it as a good opportunity to discuss issues related to the solution of an equation and an inequality and its relation to the corresponding point on the graph. [...] Students found it difficult to shift their attention from the problems they were working on to the specific case [...]

Analyzing the two incidents by the EMT

The two incidents exemplify some of the observations across all the sessions offered by the teacher on linear functions. It seems that his *good* pedagogical intentions were challenged by discrepancies between his and his students’ activities.

The EMT below (see Table 1) is used to interpret the context of the teaching/learning activity that took place across the observation.

Many of the teacher’s decisions, choices and rules are deeply influenced by the Master’s community. He strongly believes that conceptual understanding is the key for learning mathematics and he sets particular rules to provide for this:

After the Master degree, for me, there are no students' simpleminded answers, which could exist because they would not study enough and, therefore, would not understand. My approaches on how I interpret what they do have certainly changed. I saw and realized how complicated things about maths and the various concepts are.

For this reason, he uses new practices and tools he came across, such as group communication and Geogebra tasks, interprets students' responses being informed by research literature and follows a different teaching structure from the one suggested by curriculum. Mathematical learning is being pursued by connections between different representations and contexts and the electronic environment and the questions in the worksheet aimed to facilitate students to make these connections.

<u>Subject:</u>	Teacher	Students
<u>Object:</u>	Should enable all students to: <ul style="list-style-type: none"> • connect symbolic, graphical and tabular representation and the graph of linear function • connect the geometric context and the algebraic context of linear function 	<ul style="list-style-type: none"> • answer the questions of the worksheet.
<u>Tools:</u>	<ul style="list-style-type: none"> • Geogebra file • worksheet 	<ul style="list-style-type: none"> • Geogebra file • worksheet
<u>Community:</u>	<ul style="list-style-type: none"> • classroom community • school community • master's community (researchers, schoolmates, professors) • wider educational community (other textbooks, the internet) • wider social community (relationships with students' parents) 	<ul style="list-style-type: none"> • classroom community • school community • private mathematics lessons • friends • family • wider social community (team sports etc)
<u>Rules:</u>	<ul style="list-style-type: none"> • Different agenda from colleagues and curriculum: open-ended activities in agreement with findings of research literature - emphasis on students' conceptual understanding • group communication • teacher's requirements • exam requirements • pressures of the curriculum particularly with regard to time management • norms regarding working in mathematics and generally in class • norms regarding working in computer laboratory 	<ul style="list-style-type: none"> • At private mathematics lessons and in other classes at the same school: Solving a great number of exercises for procedural understanding and practice. Teaching according to the book and curriculum structure. • examination requirements • peer pressures
<u>Division of labour:</u>	<ul style="list-style-type: none"> • planning the worksheet and Geogebra file • organization of students into groups • support for the students' teamwork • discussion with the whole class at the end of teamwork • consolidation of mathematical meanings 	<ul style="list-style-type: none"> • working in groups • enhance personal meanings concerning the task • contribution to teamwork and the whole class discussion with the teacher

Table 1: EMT describing the context of the teaching/learning activity

However, it seems that the teacher has different objectives and rules from students, whose teaching/learning experience is within the traditional paradigm, which promotes practicing on exercises and developing procedural skills. As a result, although the connections of different contexts and representations are included in the teacher's objectives, these are not visible for the students in advance. In addition, these connections are not included in either students' objectives in practicing procedures of mathematics or school community's practices of teaching and learning.

This contradiction of objectives led, as a consequence, to a contradiction between the teacher's expectations and to what the students actually did. Later on, when the teacher noticed that his students did not make these connections (in discussing with the first author after lesson 10), he reflected:

At the beginning, they had made these tasks with the parameters a and b ... but possibly I did not manage to make these connections apparent... To make them apparent or to let them discover for themselves?... I do not know. This is why today they had this difficulty. They worked rather mechanically with the images, not realizing what the main point was.

DISCUSSION

The teacher's teaching goal is students' conceptual understanding via connections, which must be carried out through investigation. These connections are between different representations of functions (symbolical, graphical and tabular) as well as between different mathematical contexts (algebraic and geometrical). He incorporates technology into his everyday teaching and engages students in group-communication, practices that are new both to him and to his students. In class, the students start directly the investigation, without being informed about their teacher's objectives. The latter frequently experiences situations that he does not expect. He is flexible enough to hear students' voices and adapt his lesson plan accordingly. However, the students, being unfamiliar with this style of teaching and expecting a well-defined teaching agenda known in advance, aren't always able to follow him. Moreover, the exploration allowed by the technological tools makes them feel uncertain about the goals of their activity.

It could be argued that in a teaching approach where technological tools are exploited, students' activity becomes less controlled by the teacher. Furthermore, more layers of complication are added concerning the multiplicity of representations, the interaction with the environment and the dynamics of the emerging constructions. As a result, the meanings shaped by the students might frequently diverge from the meanings intended by the teacher. Many unexpected events may emerge from the students' reactions and the teacher needs to be flexible enough to adapt his/her planned goals and act in-the-moment. These actions require deep mathematical and pedagogical content knowledge for his attempts to effectively promote the mathematical meaning under construction. On the other hand, the openness of the situation, although might motivate students to get involved with the tasks, it is possible to be in conflict with other day-to-day classroom and institutional norms and practices that influence mathematical teaching and learning. Thus, the implementation of technology in the mathematics classroom requires careful consideration of teachers' scaffolding practices, which should aim to gradually introduce students into new ways of being involved with the mathematics classroom activity that promote genuine interactive construction of meaning, challenging them to sensitively explore resistances and resolve conflicts on the way.

This paper focuses on the mathematical knowledge a teacher needs to be able to teach. We give particular consideration to the principles underlying the subdomains making up the model, MTSK (presented in Carrillo, Climent, Contreras and Muñoz-Catalán, 2013), building on the category of Subject Matter Knowledge (Shulman, 1986). We define and analyse three subdomains: Knowledge of Topics (KoT), Knowledge of the Structure of Mathematics (KSM), and Knowledge of the Practice of Mathematics (KPM). We discuss the defining features of these categories, contrasting them with the model of MKT developed by Ball et al (2008), and using examples from our own experience as researchers in the area.

Keywords: MTSK, MKT, knowledge of topics, knowledge of the structure of mathematics, knowledge of the practice of mathematics.

FROM MKT TO MTSK

Ever since Shulman's (1986) seminal work, setting out the knowledge teachers bring into play in the exercise of their profession, a separation has been recognised between Subject Matter Knowledge and Pedagogical Content Knowledge, with seven different categories making up these two main domains. In their construct of Mathematical Knowledge for Teaching (MKT), Ball, Thames, and Phelps (2008), present a classification of mathematical knowledge, following Shulman (1986), and introducing six

¹ This article represents part of the studies into teachers' knowledge by the SIDM group (from the Spanish 'Research Seminar into Mathematics Education') based at the University of Huelva, Spain. It comprises the following researchers: José Carrillo (coordinator), Nuria Climent, Luis C. Contreras, Miguel A. Montes, Álvaro Aguilar, Dinazar I. Escudero, Eric Flores and Enrique Carmona (University of Huelva), M. Cinta Muñoz-Catalán (University of Seville), Pablo Flores, Nielka Rojas and Elisabeth Ramos (University of Granada, Spain), C. Miguel Ribeiro, Rute Monteiro and C. Susana dos Santos (University of the Algarve, Portugal), Leticia Sosa and José L. Huitrado (University of Zacatecas, Mexico), Diana Vasco (State Technological University of Quevedo, Ecuador), and Emma Carreño (University of Piura, Peru).

different subdomains, *Common Content Knowledge* (CCK), *Specialised Content Knowledge* (SCK), *Horizon Content Knowledge* (HCK), making up Subject Matter Knowledge and *Knowledge of Content and Students* (KCS), *Knowledge of Content and Teaching* (KCT) and *Curricular Knowledge*, constituting Pedagogical Content Knowledge. We consider that SCK is particularly relevant as it is considered an area of knowledge exclusive to the profession of mathematics teaching. Despite representing a significant advance in our understanding of mathematics teachers' knowledge, the definition of this subdomain overlaps with others (Flores, E., Escudero, D.I. & Carrillo, J., 2013). Such problems of demarcation between subdomains led to the development of the MTSK framework (Carrillo et al. 2013).

In the following analysis we try to differentiate the specific knowledge that is held by teachers about a mathematical item from the perspective of a pupil (derivatives, for example) from the knowledge of that same item as an element of common knowledge.

Ball et al. (ibid) emphasise the mathematical demands entailed in teaching, which they exemplify with a subtraction computation. The example gives the correct answer to the subtraction $307-168$ via the so-called 'borrowing' algorithm, then considers various typical wrong answers by pupils, to understand the cause of which requires special mathematical reasoning, and finally proposes other non-standard approaches which are often unfamiliar to the teacher. They state that anybody who knows how to solve the calculation can identify when a pupil's answer is incorrect, but that "skilful teaching requires being able to size up the source of a mathematical error" (ibid., p. 396). This kind of teacher knowledge, they add, is complemented by an ability to do such an analysis efficiently and fluently, and to see beyond the errors to the particular problems facing the pupils.

We would agree that identifying a wrong answer of this kind should be considered commonly held basic knowledge, and that it logically forms part of the teacher's knowledge by virtue of the demands of the work of teaching (Common Content Knowledge). However, in the process of analysing the error the teacher brings into play two different types of knowledge. First, in the case of the non-standard approaches, the teacher needs to ask him or herself, "What is going on mathematically in each case?" (ibid., p. 397). The answer to this question implies the mobilisation of intrinsically mathematical knowledge about the significance and implication of each step in the process of subtraction.

Second, in the case of a student arriving at the answer 261, the teacher has to consider "what line of thinking would produce this error" (ibid., p. 396),

and reflect on the nature of the misunderstanding that gave rise to the mistake. In this case, the knowledge brought to bear is not only mathematical, as the item under consideration ceases to be mathematics itself and becomes the cognitive processes called upon when a pupil tackles a mathematics task.

In this paper our interest is in gaining a better understanding of the mathematical knowledge (in the sense of Subject Matter Knowledge (Shulman, 1986)) required by teachers in their day-to-day practice. We approach this interest from the model of Mathematics teacher's specialised knowledge (MTSK) which we present in Carrillo, Climent, Contreras and Muñoz-Catalán (2013, in this volume). MTSK offers a new perspective on the knowledge required in mathematics education, and whilst respecting Shulman's (1986) original division between *Subject Matter Knowledge* and *Pedagogical Content Knowledge*, it brings two fundamental aspects to the fore. First, it adopts the term "specialised" from the model of MKT by Ball et al (2008), but applies it to the whole of the new model. That is, instead of talking about specialised content knowledge, whereby the notion of 'specialised' is applied to content knowledge, the new model concerns the specialised nature of mathematics teacher's knowledge. Secondly, it shifts the focus of study onto the object of the teacher's reflection. Hence, in 'subject matter knowledge' we propose the subdomains *Knowledge of Topics* (KoT), *Knowledge of the Structure of Mathematics* (KSM), and *Knowledge of the Practice of Mathematics* (KPM). In the category *Pedagogical Content knowledge* we include the following subdomains: *Knowledge of Mathematics Teaching* (KMT), *Knowledge of Features of Learning Mathematics* (KFLM) and *Knowledge of Mathematics Learning Standards* (KMLS). For a full description of all these subdomains, see Carrillo et al. (2013), in this volume. Our interest in this paper is to describe the principle features of the subdomains within the first group, giving examples from each.

KNOWLEDGE OF TOPICS

In MTSK (Carrillo et al., 2013, in this volume), the subdomain *Knowledge of Topics* (KoT) represents a new way of viewing the subdomains *Common Content Knowledge* and *Specialized Content Knowledge* (SCK) from the model of MKT.

Ball et al. (2008) define *Common Content Knowledge* (CCK) as "the mathematical knowledge and skill used in settings other than teaching" (p. 399). We can equate this to the mathematics that can be found in mathematics (text) books (at any level). However, although this knowledge might be shared with other professions, we would argue that the teacher

possesses a greater range and depth with regard to this knowledge by virtue of the simple fact that mathematics is the lifeblood of their work. This notion, as suggested above, inspires the idea that “specialised” spreads across the full range of domains in the model of MTSK (Carrillo et al., 2013, in this volume)

With this in mind, we can indicate other aspects of mathematical knowledge which should be included in this subdomain (KoT). To start with, there is the advanced knowledge needed to understand any particular topic. For example, if a teacher is explaining surface integrals at higher secondary level, they will need to know the concept of area, the density of rationals in the set of real numbers, and topological theory, all of which have in common the fact that without them, the topic cannot be understood and which are therefore required within the subdomain. By the same reasoning we would include non-curricular mathematical knowledge such as unconventional procedures for doing mental arithmetic.

Secondly, we also include knowledge about the different meanings a topic might have, as is the case with fractions (Llinares and Sánchez, 1997). A teacher who formulates different problems which can be solved via the same fraction but with different meanings demonstrates considerable reflection on the concept of fractions and their elements, which goes beyond mere problem solving and doing calculations with fractions. We also consider here phenomenological aspects associated with the knowledge of a mathematical item (Freudenthal, 1983; Rico 1997). In the model of MKT, all the above would be included within the subdomain *specialized content knowledge* (SCK). However, bearing in mind that the notion of specialised pertains to the full MTSK model, we consider that this kind of knowledge, being “pure subject matter knowledge” (that is, unalloyed with knowledge of students and pedagogy), belongs within KOT. Put simply, we consider KoT a subdomain containing advanced mathematical knowledge exclusive to the work of teaching.

To recapitulate, the defining features of KoT comprise advanced knowledge of school mathematics topics, along with knowledge of any different meanings involved, and corresponding phenomenological aspects.

KNOWLEDGE OF THE STRUCTURE OF MATHEMATICS

In this section, we focus on the second subdomain within ‘subject matter knowledge’ in the model of MTSK (Carrillo et al., 2013, in this volume) denominated *Knowledge of the Structure of Mathematics* (KSM).

This subdomain emerged as a result of reflecting on Horizon Content Knowledge (HCK) in the MKT model, which is defined as “an awareness

of how mathematical topics are related over the span of mathematics included in the curriculum” (Ball et al. 2008, p. 403). Initially, the authors were unsure whether this category belonged to subject matter knowledge or was spread across several categories. Later, Ball and Bass (2009) proposed subdividing HCK into three related dimensions: HCK - topics (HCK (T)) which concerns connections both within the field of mathematics and with other disciplines; HCK - practice (HCK (P)) dealing with how mathematics is constructed; and HCK - values (HCK (V)) specifying the main values when doing mathematics.

The consideration of how mathematics is interconnected internally is a significant component of KSM as it enables us to understand how teachers construct their mathematical knowledge. Likewise, knowledge of connections with other disciplines enables the teacher to devise mathematics problems drawing on other areas of knowledge. However, for the moment we will leave external connections to one side.

Martínez et al. (2011) consider that the *connections* teachers make between different areas of content (concepts or procedures), whether at the planning stage, during the execution of the lesson, or after the class, can be grouped into three types:

- Intraconceptual connections: connections between different ideas associated with a particular mathematical concept, constituting the essence of mathematics.
- Interconceptual connections: connections to different mathematical concepts.
- Temporal connections: connections between mathematical concepts at different stages of the curriculum, that is between what has been studied and what will be studied.

These connections derive from studies carried out by Fernández et al (2011), in which HCK is considered “not as another subdomain of MKT, but as a mathematical knowledge that actually shapes the MKT from a continuous mathematical education point of view” (p. 2646).

With regard to intraconceptual connections, we have become aware through successive analyses that the connections made are often so closely related within the same topic that we have been led to reconsider the appropriateness of including these within *Knowledge of the Structure of Mathematics* (KSM). The characteristics of such connections are closely linked to the knowledge of the meaning of a specific item, for which reason we consider them as pertaining to the subdomain *Knowledge of Topics* (KoT) presented above.

Interconceptual connections relate one mathematical topic to another or others. These connections are of a different order to intraconceptual connections as they underline that the mathematics teacher is establishing links between different mathematical items, in terms of both concepts and properties between them. The knowledge a teacher demonstrates in developing new mathematical items from existing knowledge is also included.

We include temporal connections in KSM, that is, connections to retrospective and prospective content relative to the current item of study. We can see a convergence here of the idea of *elementary mathematics from an advanced point of view, and advanced mathematics from an elementary point of view*. “These two notions enable two-way connections to be made – prospectively between elementary material at any particular level and its corresponding advanced treatment at later stages, and retrospectively between advanced material and its more basic treatment at lower levels,” (Carrillo et al., 2013, in this volume). In this context, and complementing the idea of connections, we include the concept of increasing complexity (and conversely, simplification). For example, the procedure for classifying two-dimensional shapes is the same at secondary level as it is at infant level, but if teachers at each level were to tackle this area from a perspective of continuity between the two educational levels, each would take a very different mathematical view. The secondary teacher, for example, could deal with the procedure from a complex perspective, suggesting classificatory systems based on two or more criteria at a time or which involved the use of inclusive groups. The infant teacher, for their part, might suggest classificatory strategies that use visual and manipulative cues one after the other to make different groups; they might even use a simplified strategy, such as *identifying* attributes and qualities, or *comparing* shapes (in order to help the pupils at this age to discard their tendency to view the world as a homogeneous whole), which we believe lie at the mathematical heart of the classificatory procedure. In other words, the cline from simple to complex is not cognitive but mathematical; the teacher’s task is to scrutinize the area of study so as to identify those contents which are close or connected and make up a mathematical framework.

Being able to superimpose a more advanced approach to a learning item onto a more basic approach to that item, or put another way, conceptualising an item from both a basic perspective and at the same time a more advanced perspective than that required by the curriculum at that point is one of the key specialised skills a teacher needs to develop.

As mentioned at the start of this section, KSM belongs to the category *Subject Matter Knowledge*, as does KoT. However, while the subdomain

KoT concerns in-depth knowledge of a specific topic (getting to its mathematical heart), KSM concerns knowledge of how topics are interrelated, and this kind of knowledge is based more on a global understanding of the mathematical structure connected to a concept. In the case of KoT, to make an analogy with building a house, we are talking about knowing how to put one brick on top of another, which brick to put and why. In the case of KSM, it is a question of taking a step back to see the girders and joists which make up the framework supporting the house.

KNOWLEDGE OF THE PRACTICE OF MATHEMATICS (KPM)

One of the dimensions of the HCK classification devised by Ball and Bass (2009) is knowledge of the ways of knowing and creating or producing in mathematics (syntactic knowledge). This includes aspects of mathematical communication, reasoning and checking, providing and applying definitions, making connections (between concepts, properties and so on), using correspondences and equivalences, deploying representations, arguing, generalising and exploring. Our perspective is that this categorization corresponds to *Knowledge of the Practice of Mathematics*, that is to say, conceptual knowledge about the rules of syntax themselves, and procedural knowledge about how to do mathematics, in addition to knowledge about the history of the discipline and its relation to other fields (Ball and McDiarmid, 1990). In this respect, we have included *Knowledge of the Practice of Mathematics* (KPM) as the third subdomain making up *Subject Matter Knowledge*.

Again, setting to one side connections with other areas of knowledge as mentioned above, this kind of knowledge is what in large part can be considered “mathematical logic”. We understand that this knowledge, once again, is not exclusive to teaching, but is likely shared by anybody who has wondered about how mathematics is constructed. However, it is specialised in the sense that a teacher should know, for example, when a result with a double implication is fully or only partially demonstrated, and it is knowledge of this kind that enables the teacher to decide this. In short, then, *Knowledge of the Practice of Mathematics* (KPM) concerns reflecting upon ways of doing mathematics.

A group of primary teachers in a collaborative professional development project pondered the question of whether “the addition of a multiple of 2 and a multiple of 10 results in a multiple of 10” (Muñoz-Catalán, 2012). One of the teachers replied that it would need a general demonstration, as sometimes this was the case, but other times it was not. This is an example of knowledge about ways of demonstrating mathematics, which for this teacher seems to consist in checking whether an affirmation that she knows

is not always true, is always true. This knowledge represents an idea of demonstration that is not valid in mathematics, but which we can say is *her* way of understanding what demonstrations are. However, this knowledge is not used in isolation in this case, but in conjunction with the knowledge the teacher has of natural numbers and their properties of divisibility, a fact which underlines how KPM is a subdomain which occurs across domains when the classroom treatment of any mathematical topic is analysed.

CONCLUSION

In this paper we give a detailed characterisation of the subdomains within the MTSK framework (Carrillo et al., 2013, in this volume), corresponding to the category of *Subject Matter Knowledge* proposed by Shulman (1986). We believe that the model of MTSK represents an advance in the process of categorising mathematics teacher's knowledge, which was initiated by Shulman and developed by Ball and the research group at the University of Michigan. It is the result of a considered analysis of the distinct dimensions of knowledge held by mathematics teachers, with the result that the subdomains meet classificatory criteria in terms of the object or aspect of the particular teaching item under consideration. The three subdomains considered here correspond to different objects within mathematics itself: *Knowledge of Topics* (KoT) refers to the knowledge of content itself; *Knowledge of the Structure of Mathematics* (KSM) concerns knowledge of the structure of the content; and *Knowledge of the Practice of Mathematics* (KPM) is knowledge about how mathematics is constructed.

Regarding the dimension of HCK relating to values, we wonder whether the central values inherent to mathematics are really epistemic in nature. Reconsidering the exemplification for this subdomain given by Ball and Bass (2009) which they characterise as 'core mathematical values and sensibilities' we find elements such as 'precision, care with mathematical language, consistency, parsimony, coherence and connections'. We believe that, in the absence of a better characterisation, the items included in this subdomain are conceptions and beliefs about mathematics – such as mathematical attitudes – and towards mathematics, and cannot thus be considered knowledge. Nevertheless, after reviewing numerous works studying knowledge for teaching, we think that extending the framework to include such considerations can only bring a finer-grained sensitivity to the analysis, providing a broader and deeper snapshot of the teacher under study, and consequently of their knowledge for teaching.

With respect to future lines of research relating to this model, we feel that the most important thing is to hone the defining features of the subdomains, working with concrete examples which help to clarify each category, and to

develop suitable methodological questions. An additional area of great interest is the question of what it is to know something, and we would like to undertake a comparison of different approaches to understanding what knowledge is (Meel, 2003), with the hope of arriving at a definition of knowledge in the specific case of a mathematics teacher that would allow us to study the relation between knowledge and conceptions.

PROSPECTIVE TEACHER'S SPECIALIZED CONTENT KNOWLEDGE ON DERIVATIVE

Luis R. Pino-Fan¹, Juan D. Godino¹, Vicenç Font², Walter F. Castro³

¹University of Granada, ²University of Barcelona, ³University of Antioquia

Mathematics teacher knowledge has been widely studied, and recently a remarkable advancement has been reached with the proposal of the “Mathematical Knowledge for Teaching” (MKT) model for describing the complex of knowledge that a teacher should have to teach a specific mathematics topic. Nonetheless there are still questions to be addressed, such as, how or under what criteria can the MKT be assessed? How the teacher educators can help the prospective teacher to develop the different components of the MKT? How are related the different components of MKT? In this report, we have tackled, though partially, such questions, by advancing specific criteria to explore the prospective teachers’ knowledge about the notion of derivative: common, specialized and extended knowledge. In this report we inform specifically on the specialized content knowledge.

BACKGROUND

The mathematical and didactical education of prospective teachers is a very pressing issue for teachers’ educators. One of the problems that have raised a great deal of interest is to identify the didactic-mathematical knowledge required for the prospective teachers to teach mathematics. On this regard, a great deal of research has been conducted to identify the components of the web of knowledge that a teacher should know in order to develop his/her practice efficiently and to facilitate the students’ learning.

Some researchers have proposed a number of alternatives where some features that make up the teachers’ knowledge can be identified. The works of Shulman (1986), Fennema & Franke (1992) and Ball (2000), show a multifaceted vision on the construction of the knowledge required to teach. More recent researches such as those of Ball, Lubienski & Mewborn (2001), Llinares & Krainer (2006), Ponte & Chapman (2006), Philipp (2007), Sowder (2007), Ball, Thames & Phelps (2008), Hill, Ball & Schilling (2008) and Sullivan & Wood (2008), show the nonexistence of an universal agreement on a theoretical frame to describe the mathematics’ teacher knowledge (Rowland & Ruthven, 2011). This fact is a cause of concern not only for the prospective teachers’ education and for the professional development of inservice teachers, but also for the researchers’ community, because it is important to establish a general understanding on what meanings entails the content knowledge and how it affects the practice of teaching. It is difficult to have a coherent approach for a program of teacher education if the role of the teacher knowledge, the features implied and how they interact in the mathematics teaching process (Petrou & Goulding, 2011) are not well understood. The question is: how to determine such didactic-mathematical knowledge based on models that include categories too

“wide”? As Godino (2009) points out, the various models on the mathematical knowledge for teaching, informed by the researches in mathematics education, include categories too “wide” and disjoint, that calls for models that allow conducting a more precise analysis of each knowledge component that are put into effect in an effective teaching of mathematics. Besides, the latter will allow orienting the design of formative actions and the elaboration of tools to assess the mathematics teachers’ knowledge. We consider that the teacher's primary responsibility is to facilitate learning; such a teacher is what we call effective.

In this report we offer a partial answer to questions such as: How or under which criteria can the MKT be assessed? How teachers’ educators can help the prospective teachers to develop the different MKT components? How the different MKT components are related among them? To propose an answer to these questions, we use the theoretic tools provided by the Onto-Semiotic Approach (OSA) (Godino, Batanero & Font, 2007) to knowledge and instruction. We have designed and applied a questionnaire to explore some relevant features of the epistemic facet of the didactic-mathematical knowledge of prospective teachers, on the derivative, which includes, according to the Ball and colleagues’ model, the common content knowledge, specialized content knowledge and extended content knowledge. Specifically, we focus on the specialized content knowledge, for which we propose two levels of analysis and different categories of analysis.

THE DIDACTIC-MATHEMATICAL MODEL

In this research we use the Didactic-Mathematical Knowledge Model (DMK) proposed by Godino (2009) within the Ontosemiotic approach to cognition and instruction (Godino, Batanero & Font, 2007). This model for the DMK includes six facets or dimensions for the didactic-mathematical knowledge, which are involved in the teaching and learning of mathematics specific topics: 1) *Epistemic*: components of the institutional implemented meaning (problems, languages, procedures, definitions, properties, justifications); 2) *Cognitive*: development of the personal meanings (learning); 3) *Affective*: the emotional states (attitudes, emotions, motivations) of each student regarding not only the mathematics objects but also the planned study process, and its distribution over time; 4) *Interactional*: sequence of interactions between the teachers and students, oriented at the fixation and negotiation of meanings; 5) *Mediational*: distribution over time of the technological resources used and distribution of time for the actions and processes involved; and 6) *Ecological*: system of relations with the social, political, economic context that underlies and affects the study process.

For each of the above facets, four levels of analysis are considered. These levels allow the analysis of the teacher’s DMK according to the type of information required to take instructional decisions. The aforementioned levels are: 1) *Mathematical and didactical practices*; description of the actions performed to solve the mathematics tasks proposed to contextualize the content and to promote learning. The general lines of action of the teacher and students are also described; 2)

Configuration of objects and processes (mathematical and didactical), description of mathematics objects and processes that intervene during the mathematics practices, as well as those which emerge out of them. The purpose of this level is to describe the complexity of objects and meanings that intervene in the mathematics and didactics practices. Such complexity is an explanatory factor not only for the meaning conflicts but also for the learning progression; 3) *Norms and meta-norms*, identification of the web of rules, habits, norms that regulate and facilitate the study process, and that affect each facet and its interactions; and 4) *Suitability*, identification of possible improvements of the study process, that increment the didactic suitability.

Due to the fact that our research was carried out with prospective teachers we focus the analysis on the epistemic and cognitive dimensions. We, then, focus on the facets 1) Mathematical and didactical practices; and 2) Configuration of objects and processes taking into account the students' answers to some tasks. Investigating the levels three and four of the analysis described above is beyond the scope of this report.

Subjects and Context

The questionnaire was administered to a sample of 53 students enrolled in the final modules (sixth and eighth semester) of the degree in mathematics teaching offered by the Universidad Autónoma de Yucatán (UADY) in Mexico. This is a four-year degree (8 semesters). The School of Mathematics of the UADY is responsible for training teachers to work at higher secondary or university level in the state of Yucatan (Mexico). The 53 students who responded to the questionnaire had studied differential calculus in the first semester of their degree course, and they had subsequently completed other modules related to mathematical analysis (integral calculus, vector calculus, differential equations, etc.). They had also studied subjects related to the teaching of mathematics. These 53 students constituted the entire population of students with these characteristics in the University of Yucatán.

The EF-DMK-Derivative Questionnaire

The questionnaire, which we have call *EF-DMK-Derivative* (Pino-Fan, Godino, Font and Castro, 2012, pp. 298-299), is made up of seven tasks, and has been designed to assess certain relevant features of the epistemic facet of prospective secondary teachers' didactic-mathematical knowledge (DMK) on the derivative. According to Ball and colleagues model (Ball, Lubienski & Mewborn, 2001; Hill, Ball & Schilling, 2008) this epistemic facet comprises three types of knowledge: common content knowledge, specialized content knowledge and extended content knowledge.

Three criteria were considered for the selection of the seven tasks that make up the questionnaire. The first states that the tasks must include a wide range of meanings related to the derivative; the second states that, for the resolutions, some representation means should be use, and the third states that the type of knowledge must include: common content knowledge, specialized knowledge and extended knowledge. The description of the features and content assessed in every task

included in the questionnaire, can be seen in Pino-Fan, et al., (2012, pp.299-301). The methodological choice to build and implement a written questionnaire has the advantage of being applied to a relatively large sample, compared with study based in interviews to a few students, although it is not possible to deepen in the evaluation of the others facets and nuances of the didactic-mathematical knowledge.

The Specialized Content Knowledge

Ball, Thames and Phelps (2008) propose that the specialized content knowledge is the “mathematical knowledge and skill unique to teaching” (p. 400). This knowledge includes “how to accurately represent mathematical ideas, provide mathematical explanations for common rules and procedures, and examine and understand unusual solution methods to problems” (Hill, Ball y Schilling, 2008, p. 377-378). We agree with this approach to the specialized content knowledge; nonetheless the question that arises is: what specific criteria allow us to analyze and to improve such knowledge required by the prospective teachers? One of the fundamental features of the specialized content knowledge tasks, included in the questionnaire, is the reflection carried out by the prospective teachers, on mathematical objects, its meanings and the complex relations among them. These web of complex relations are put into effect while teaching and learning mathematics. The relationship between objects and meanings are fixed and operationalized by means of the notion *configuration of objects and meanings* (Godino, et al., 2007). Such notion favors not only the systematic identification of a number of procedures to solve the mathematic tasks (including the identification of representations, concepts and properties), but also the identification of both, procedures justifications and properties used in solving them. Additionally, the aforementioned analysis, not only of the tasks but also of the didactic variables that intervene and orient the reflection, on both the possible generalizations, or particularizations, and the connections to other mathematical contents (Godino, 2009).

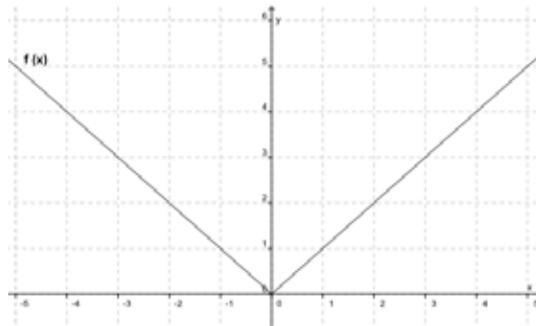

Thus, in our model for the didactic-mathematical knowledge, two levels are proposed for the specialized content knowledge. In the first level, the prospective teachers *should use not only, different* representations, concepts, propositions, procedures, and justifications, but the range of mathematical object’ meanings of the mathematic concept under study – the notion of derivative –. The second level refers to the *teachers’ competency to identify knowledge* (language elements, concepts/ definitions, properties/propositions, procedures and justifications) put into effect during the resolution of tasks on the derivative. It is clear that the specialized content knowledge implies the common content knowledge and some features of the extended knowledge.

The item a) of Task 2 (Fig. 1) assesses the common content knowledge, and the item b) assesses the extended content knowledge. The common content knowledge is used when the prospective teacher answers this item without providing any justifications nor using any representation. The extended content knowledge is assessed when the prospective teacher has to generalize the initial task about the derivability of the

absolute value function at $x=0$, on the basis of valid justifications for the proposition “the graph of a derivable function cannot have peaks” by defining the derivative as the limit of the increment quotient. On one side, items b) and c) refer to the first level of the specialized content knowledge, because prospective teachers may solve them making use of both different representations (graphic, symbolic and verbal), providing valid justifications for their procedures. On the other side, item e) explores the second level of the specialized knowledge, because the prospective teacher must both, solve the aforementioned tasks and identify the web of knowledge that are put into effect in its resolution.

Task 2

Consider the function $f(x) = |x|$ and its graph.

- For what values of x is $f(x)$ derivable?
- If it is possible, calculate $f'(2)$ and draw a graph of your solution? If it is not possible, explain why.
- If it is possible, calculate $f'(0)$ and draw a graph of your solution? If it is not possible, explain why.
- Based on the definition of the derivative, justify why the graph of a derivable function cannot have ‘peaks’ (corners, angles).
- What knowledge is put in to play when solving the above items of this task?

Figure 1: Task 2 from the *EF-DMK-Derivative Questionnaire*

Figure 2 shows Task 5, that assess the first level of the specialized knowledge, for prospective teachers must use different derivative meanings in its resolution: slope of a tangent line and, instant rate of change. At first glance it seems to be one of the “drill exercises” that are commonly found in the high school calculus text books, where it suffices to apply some theorems and propositions on the derivative to solve it. Due to the latter, both item a) and b), individually, assess features of the prospective teachers’ common content knowledge. Nonetheless, the main task objectives are double: first, to explore, globally, the mathematical activity carried out by the prospective teachers, and, second, to test the connections or associations among the different derivative meanings established by them.

Task 5

Given the function $y = x^3 - \frac{x^2}{2} - 2x + 3$

- Find the points on the graph of the function for which the tangent is horizontal.
- At what points is the instantaneous rate of change of y with respect to x equal to zero?

Figure 2: Task 5 from the *EF-DMK-Derivative* Questionnaire**RESULTS: ANALYSIS AND DISCUSSION**

We will present the analysis of an answer provided by a prospective teacher (A), which exemplifies one of the solution typologies identified on the prospective teachers set of solutions to Task 2. On such analysis the primary objects (language, concepts, properties, procedures and justifications), and processes than intervene on both, the statement and on the tasks solutions, are identified. We base our analysis on the levels 1 and 2 of teacher's knowledge described above, which refer, both to *the didactical and mathematical practices*, and to the configuration of objects, respectively. In this section we do not present the "global" results of the entire questionnaire, not even the complete results for the two tasks that we presented. It is because we do pretend to show the usefulness of both the criteria and methodology of analysis proposed; on the other hand, the space constraints make it impossible to present the results in its entire extension.

Analysis to Cognitive Configurations Subjacent of the Task 2

In regard to cognitive configuration used by the prospective teachers to provide a solution to Task 2, three types of resolutions were identified. Each type of configuration is associated to a specific configuration of objects and processes. We have named these three types of cognitive configuration as: *graphic-verbal*, *technic* and *formal*. A high percentage of prospective teachers, 88,6% and 54,7%, respectively, provided a configuration *graphic-verbal* to items a) and c) (e.g., "...it is not derivable at $x=0$ because an infinite number of tangent lines can be traced, to the function on that point"). For section b), the majority of prospective teachers, 62,3%, provided a *technic* configuration (using both the derivative rules and the definition of the absolute value function). One preservice teacher (1,9%) provided a *formal* solution, using the derivative meaning as an instant rate of change (limit of the increment quotient), for the first four items in the task.

Figure 3 shows the solution provided by the prospective teacher that has a *graphic-verbal configuration* associated. In regard to the mathematic practice performed by the prospective teacher (A), it can be observed in Fig.3 that he begins his solution process with a visual justification of the property "the derivability of an absolute value function". Generally speaking, his solution is made of verbal descriptions based on the graph of the function $f(x) = |x|$.

Cognitive Configuration:

In the solution provided by the prospective teacher (A), it is possible to identify the use of a great deal of linguistic features such as: the use of natural language (verbal descriptions), some symbolic entries such as " $\mathcal{R} - \{0\}$ " or the rule of derivation by

parts $f'(x) = \begin{cases} x & \text{si } x > 0 \\ -x & \text{si } x < 0 \\ 0 & \text{si } x = 0 \end{cases}$ of an absolute value function [item c)]. In the same venue,

student (A) uses graphic elements [items b) and c)] to “explain” his analysis. These linguistic elements refer to a group of concepts/definitions, propositions/properties that are illustrated in what follows.

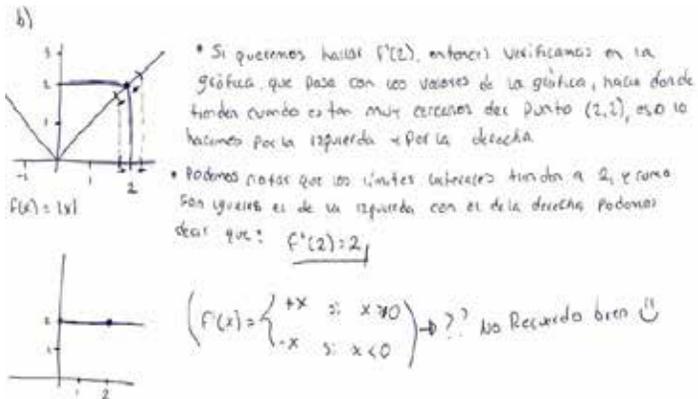

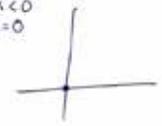

<p>2.- a) La función $f(x) = x$ es diferenciable en todos sus puntos exceptuando donde se encuentra el “pico” de la gráfica, es decir $\mathbb{R} - \{0\}$.</p> <p>b)</p>  <p>* Si queremos hallar $f'(2)$, entonces verificamos en la gráfica que pase con los valores de la gráfica, hacia donde tienden cuando están muy cercanos del punto $(2,2)$, eso lo hacemos por la izquierda y por la derecha.</p> <p>* Podemos notar que los límites laterales tienden a 2, y como son iguales es de la izquierda con el de la derecha, podemos decir que: $f'(2) = 2$.</p> <p>$f(x) = \begin{cases} +x & \text{si } x > 0 \\ -x & \text{si } x < 0 \end{cases} \rightarrow ??$ No Recordado bien :)</p> <p>c)</p> <p>* Siguiendo en razonamiento anterior, debemos ver que cuando nos aproximamos a 0 por números muy pequeños negativos, la gráfica de la función se aproxima a 0 y cuando nos aproximamos a 0 por valores muy pequeños pero positivos también se aproxima a 0. Por lo tanto $f'(0) = 0$.</p> <p>$f(x) = \begin{cases} x & \text{si } x > 0 \\ -x & \text{si } x < 0 \\ 0 & \text{si } x = 0 \end{cases}$</p> 	<p>a) The function $f(x) = x$ is differentiable at all points except where finds the “peak” of the graph, that is $\mathbb{R} - \{0\}$.</p> <p>b) If we want to find $f'(2)$ then we verify in the graph, what happens to the values of the graph, towards where it tends [the values] when they are very close of the point $(2,2)$, we do it that for the left and for the right.</p> <p>We can note [in the graph] that the lateral limits tend to 2, and as they are equal, both to the left and the right, we can say that: $f'(2) = 2$</p> <p>$f'(x) = \begin{cases} +x & \text{si } x \geq 0 \\ -x & \text{si } x < 0 \end{cases} \rightarrow ??$ I do not remember.</p> <p>c) Following the above reasoning, we can see that when we approach to 0 by very small negative numbers, the graphic of the function approaches to 0 and when we approach to 0 by very small positive numbers it also approaches to 0. Therefore $f'(0) = 0$.</p>
--	---

Figure 3: Graphic-verbal resolution of task 2. Student A

Among the concepts and definitions used by the prospective teacher, we can underline those of function (absolute value), domain (of the derivative function and represented by $\mathbb{R} - \{0\}$), approximation (to a specific point of the absolute value function, in this case to $x = 2$ and $x = 0$, taking values close to those points), and the

derivative of the absolute value function (wrongly taken as $f'(x) = \begin{cases} x & \text{si } x > 0 \\ -x & \text{si } x < 0 \\ 0 & \text{si } x = 0 \end{cases}$). The

one side limits, and the bilateral limits, to the points $x = 2$ and $x = 0$, though calculated correctly (if the question were to calculate the limits to the absolute function on such points), based on the graph, were incorrectly used by the prospective teacher (A), when calculating the derivative of the function in the points $x = 2$ and $x = 0$. This misuse of one side limits, to calculate the derivative, seems to be based on the misinterpretation or misunderstanding of a proposition that refers to the

relationship between continuity and derivability: a derivable function is always a continuous function, but a continuous function could be not derivable. This is put in evidence with the procedure and the ensuing justification to calculate $f'(2)$: “If we want to find $f'(2)=2$, then we verify in the graph what happens to the graph values, where do they tend when they are very close to $(2, 2)$; we do it for both sides: left and right. We can see that the lateral limits tend to 2, and due they are the same, both on the left and on the right, we can say that $f'(2) = 2$ ”.

The procedure and justification provided by the prospective teacher to calculate $f'(2)=2$ can also be seen in the graphic representation given to item b) (Fig.3). The misunderstanding is made more evident when the prospective teacher points out both the procedure and the justification to solve item c), which ask for a verification to be carried out on the derivability of the absolute value function at $x=0$. The student says: “Following the preceding reasoning, we can see that when we get close to 0, using very small negative numbers, the graph of the function gets close to 0; and when we get close to 0, using very small but positive numbers, the graph of the function also gets close to 0, thus $f'(0)=0$ ”. Among other properties used in the student’s solution we can highlight the derivability at zero of the absolute value function, which is visually justified, as follows, “The function $f(x)=|x|$ is derivable in every point except in those points where a “corner” is found on the graphic ...”.

The answers that we have included in this type of cognitive configuration, focus on procedures and justifications based on the visual analysis of the graphic features of the function, as in the example provided (Task 2). Another answer type, quite common, were those where the no derivability of the absolute value function, at $x=0$, is justified by tracing an “infinity” number of tangents to the function at that point. Regarding item e), that assesses level two of the specialized content knowledge, it is clear that, as no previous instruction has been offered, to the prospective teachers, on the identification of previous and emerging knowledge involved in the task, only a limited number of concepts, such as function, absolute value and derivative at a point, were provided by the prospective teachers.

FINAL REFLECTIONS

The results obtained through the implementation of the questionnaire *EF-DMK-Derivative* show that the prospective teachers manifest difficulties to solve tasks related, not only to the specialized and extended content knowledge but also, with the common content knowledge. It is clear that the prospective teachers have a better performance when solving tasks that entail the use of the derivative as the slope of a tangent line. This was confirmed when the prospective teachers solve tasks such as the fifth (Fig.2) where their answers show a disconnection among the different derivative meanings. The manifested inadequacies of knowledge, justify the pertinence of designing specific formative actions in order to develop the epistemic facet of the didactic-mathematical knowledge on the derivative. The development could be accomplished first, by designing a teaching process for the derivative, which

stresses the derivative global meaning (Pino-Fan, Godino y Font, 2011). Secondly, the two levels of the specialized content knowledge should be considered, both in its *application level* (use of linguistic elements, concepts, properties, procedures and justifications, as well as the use of different derivative partial meanings to solve the tasks) and in its *identification level*. The latter refers to the competency to identify mathematics objects, their meanings and the relation among them. This prospective teacher's competence would allow a suitable learning management of their future students.

These two levels for the specialized content knowledge are closely related, within the model DMK, to other facets for the teacher's knowledge. The level one, related to the application, is connected to the interactional and mediational facets (knowledge of content and teaching), because the mastery of this level of specialized content knowledge about specific topics, such as the derivative, gives the teacher the resources to perform efficiently his future professional tasks. The level two, identification, is related to the cognitive and affective facets (knowledge of content and students), because it entitles the teacher to detect (previously, during and after the teaching activity) features such as: the mathematical knowledge involved, mathematical objects and meanings, conflicts and mistakes that can arise to his/her future students. This identification competence may lead the prospective teacher to manage the students' learning in a more effective way. Finally, the Didactic-Mathematical Knowledge Model (DMK), offers the tool "configuration of primary mathematics objects" that allows analysing and categorizing some features of the epistemic facet of didactic-mathematical knowledge manifested by prospective teachers. In this report we have focused on the specialized content knowledge, how to analyse it and we have offered suggestions to improve it. The analysis presented herein, as a way of example, is what prospective teachers are expected to demonstrate at the (beginning of, during, and end of) second stage, and its development should begin since the early stages of teacher's professional training.

ACKNOWLEDGEMENTS

This study formed part of two research projects on teaching training: EDU2012-32644 (University of Barcelona) and EDU2012-31869 (University of Granada).

DIDACTIC CODETERMINATION IN THE CREATION OF AN INTEGRATED MATH AND SCIENCE TEACHER EDUCATION: THE CASE OF MATHEMATICS AND GEOGRAPHY

Klaus Rasmussen and Carl Winsløw

Department of Science Education, University of Copenhagen

This paper presents an application of the Anthropological Theory of the Didactic to describe and analyse the genesis of an integrated mathematics and science pre-service teacher education. Reporting from the pre-experimentation phase, it is shown how the levels in the scale of didactic codetermination enable us to understand more clearly how integration is envisaged. We examine more closely the case of a bi-disciplinary teaching-module wherein math plays one part together with geography, and we demonstrate how the scale can be used to explore the precise nature of the intended interaction between the two disciplines.

INTRODUCTION TO THE AMBIGUITIES OF INTEGRATED EDUCATION

At the turn of the century, Czerniak, Weber, Sandmann, and Ahern (1999) made a literature review of science and mathematics integration. They concluded that a lot of “testimonials” existed for the positive benefits of integration, but few empirical studies actually supported this notion that an integrated curriculum is better than a well-designed traditional curriculum. They also emphasised that the term “integrated” was shrouded in ambiguity, with no clear distinction between the diverse labelling of the many-named phenomenon: interdisciplinary, multidisciplinary, cross-disciplinary, trans-disciplinary, thematic or blended, just to mention a few. Ten years later, Stinson, Harkness, Meyer, and Stallworth (2009) reported a similar lack of common characterizations when asking teachers to identify given scenarios as integrated or not. They further concluded that:

“Potential gains from integration (i.e., time savings, improving on student achievement, improving student interest or motivation) are predicated on a common understanding for what integration means. At the very least, curricula or initiatives designed to foster integration must develop operational definitions for integration before laying claims to an integrated approach or product” (p.159)

The problems with specific labels like “multidisciplinary” or “interdisciplinary” are at least twofold: First, as indicated above, we have no commonly acknowledged definitions: In Andresen and Lindenskov (2009) p. 213-214, multidisciplinary was used to signify a cooperation with clear delimitation of the individual disciplines, proposedly in contrast to interdisciplinary where borders *between disciplines are claimed to be more or less cancelled*. In the same article, interdisciplinary is synonymous to cross-disciplinary, and trans-disciplinary is a radical form where no borders between disciplines are acknowledged. Completely opposite distinctions are found in Matthews, Adams, and Goos (2009), p.892, where interdisciplinary refers to curricula in which there is a mixture of science and mathematics although the

boundaries of the two disciplines remain visible, and “integrated” is used to signify the lack thereof. A second, perhaps more profound problem is the principal inability of the labels to specify in any detail how the interaction between the disciplines is carried out, let alone what predicates the conditions of the interaction. For this reason too, we need a precise epistemological model of integrated mathematics and science education.

THEORETICAL FRAMEWORK AND RESEARCH QUESTIONS

In this paper we chose to use the term “integrated” to signify *any* educational setting where two or more institutionally established disciplines are intended to work together in order to bring about learning. It is thus used as an overarching name encompassing all the other labels which are usually employed to signify more specific ways of conducting integrated education. The Anthropological Theory of the Didactic (ATD) describes what happens in educational situations as situated in an institutional ecology. Such an ecology is described by a hierarchy of levels, cf. figure 1. This means that the conditions on one level depend on influences from other levels of the ecology. This interdependency is articulated using a scale of levels of determination (see Artigue & Winsløw, 2010; or Chevallard, 2004 for more details). In integrated education we are considering at least two such ecologies where an explicit decision has been made to cooperate. We can then identify at which level the decision has been made, at which level the cooperation is meant to take place etc. At most times it will be understood that the cooperation is initially defined at the disciplinary level when considering integrated mathematics and science education, but note that our definition of “integrated” also encompasses cooperation initiated on other levels e.g. the math teacher and the science teacher could agree to use “cooperative learning” (Kagan, 1989) during their respective lessons in the same class, thereby situating the integration on the pedagogy level. Focusing on integration at the discipline level, we have the following framework for investigating the disciplinary cooperation, indicated in figure 2. Above the discipline level, the two ecologies are in principle the same, because we are considering the disciplinary interaction *at the*

Figure 1: Mono-disciplinary ecology regarding quadratics. (Taken from Winsløw, 2011, p. 133)

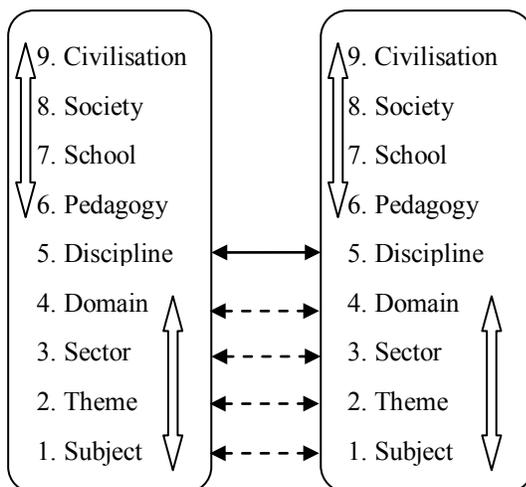

Figure 2: Levels of co-determination for bi-disciplinary ecology

disciplinary level when considering integrated mathematics and science education, but note that our definition of “integrated” also encompasses cooperation initiated on other levels e.g. the math teacher and the science teacher could agree to use “cooperative learning” (Kagan, 1989) during their respective lessons in the same class, thereby situating the integration on the pedagogy level. Focusing on integration at the discipline level, we have the following framework for investigating the disciplinary cooperation, indicated in figure 2. Above the discipline level, the two ecologies are in principle the same, because we are considering the disciplinary interaction *at the*

same institution. It is important to note that “mathematics” and “geography” appears as disciplines in closely related, institutional contexts (such as lower secondary schools, universities, and “university colleges”) and while these appearances are indeed different and bound to the institutions, they are also strongly linked. In this paper we will limit ourselves to look at disciplines inside one institutional context (university college) only. This means that influences from same-name disciplines in another institutional context, like universities, comes into our model at a higher level (mainly society). This we will call *second order influence*. It is now possible to model some of the central questions associated with the two integrated disciplines. The first type of questions concerns the “knowledge to be taught” (Bosch & Gascón, 2006):

“What bodies of knowledge are chosen? How are they named? Why these ones and why with this kind of organisations? What are the reasons to these choices?” (p.56)

The answers to these are determined at the level of the discipline, and the levels above, as indicated by the leftmost vertical arrows.

The second type of questions concerns the levels below the disciplines, where the interaction is realised. These are usually more controlled by the teacher, but still constrained from above (Bosch & Gascón, 2006):

“Why are mathematical contents divided in these or those particular blocks? Which are the criteria for this division and what kind of restrictions on the concrete activity of teachers and students does it cause?” (p.61)

While both types of questions are phrased the same way for mono-disciplinary education, they take on special meaning when more than one discipline is involved. Decisions taken from the perspective of one ecology have to be informed by the other. This is indicated on figure 2 by the horizontal arrows, where the solid one indicates the level at which the cooperation is formally defined, and the dotted ones signify the possibilities of interaction, whose existence and character may be further specified in a particular context, e.g. as part of the planning of an intended curriculum. This leads us to summarise the following research questions: What are the main features of the interplay between institutionalized ecologies in the planning of integrated math and science education? How can we study the “integratedness” in an inductive way, starting with actual and concrete plans for interaction, rather than with general rhetoric that tends to blur the detailed features? What conditions the planning and cooperation in integrated approaches?

OUR CONTEXT AND METHODS

Teacher education in Denmark is institutionally placed at so called “university colleges”, which are higher education institutions independent from research universities. A consortium between the University of Copenhagen, University College Copenhagen and the Metropolitan University College was formed to construct an experimental teacher education program (called ASTE, Advanced

Science Teacher Education). The goal was to investigate, among other things, the synergistic effects of a multi-disciplinary science teacher education. The students are to become teachers of math and science in the lower secondary school, and the design of ASTE has been developed jointly by participating college and university professors. One of the main characteristics of the program is that large proportions of ordinary curricular items have been placed in bi-disciplinary teaching modules. In this paper we will apply the theoretical framework to study the development of the module named: “Geographical Information Systems, data analysis and modelling in geography”, where parts of the math and geography contents are to be taught together. It should be noted that the geography discipline in Danish lower secondary school and at Danish teacher education colleges covers both physical and human geography, and the module we consider here also reflects that.

To shed light on the planning of this interplay we have conducted qualitative interviews with the five developers of this particular module; one math and geography college-professor from each university college (below referred to as CM₁, CM₂, CG₁ and CG₂) and one university-professor from the geography discipline (called UG) and with special interests in education. The institutional affiliations are rather complex in the ASTE-collaboration, but we will present them here because the institutional setting is of importance to our model: The two math college-professors are women, and although at the time of interviews they represented two separate colleges, one of them had only recently changed from one to the other. The two geography college professors, male and female, come from another university-college than the two math professors. It should be noted that it is only the college professors who are expected to do the actual teaching, and the programme is implemented in the *physical* institutional setting of a branch of one of the participating university colleges, to which only one of the college professors (math) belong. The ASTE program comes with its own *formal* institutional settings that are written down in general sections of the curriculum, parts of which are tailored specifically, while others are adopted directly from the ordinary institutional framework.

The interviews were conducted in August 2012, beginning with a pilot interview of one geography college-professor. Informed thereby a scheme of questions were designed, and it was decided to ask the interviewees in advance to think of 1) a concrete activity to undertake in the module and 2) if possible, try to think in broad terms of an “entire” plan of action for the module. This aims to follow the inductive approach, starting with the levels below the discipline level. The interviews were semi-structured and lasted approx. 40 minutes each. They centered on two distinct parts: The design of the specific module as situated in the framework of ASTE and further thoughts on the realisation thereof. There was a focus on the individual respondent’s perceptions and experiences from the curriculum drafting work, seen in relation to their stance in the existing education system.

DATA HANDLING AND RESULTS

All the interviews were recorded electronically and subsequently inventoried minute for minute. The quotations in the following subsections are translated and transcribed from oral Danish by the authors, and are indexed according to their temporal placement in the interviews

Determination of curricular items for bi-disciplinary integration.

Most of the curricular items chosen from each of the disciplines (see figure 3), are recognizable to both mathematics and geography teachers, that is, they have suggestions about what an item from the other discipline could contribute to their own, but generally they do not explicitly acknowledge their lack of expertise in the other discipline e.g.:

My challenge is that I do not know much about the geography discipline in teacher education ...so although I do understand the words, I have difficulties knowing what contents they represent, because I do not know much about geography as a discipline in teacher education. But on the other hand, it is also what makes such cooperation enormously exciting. It is exactly to become knowledgeable about the other disciplines. Are the problems they work with similar to those of math, and how is it about methods? This, I think, could be enormously exciting to get insightful about. (CM₁; 16:11-16:42)

<p>From Geography:</p> <ul style="list-style-type: none"> • Knowledge, theories and problem from physical and human geography • Skills at using geographical sources and methods • IT as integrated part of the discipline in university college and lower secondary school • Knowledge to further students geographic language and "bildung" • Skills to utilize informal arenas of learning and employ investigative methods of inquiry <p>From Math:</p> <ul style="list-style-type: none"> • Geometry, specifically analytic, parametrizations and trigonometry • Using and evaluating appropriate representations • Defining, structuring, mathematizing, interpreting and critique of mathematical models • Skills at planning, organizing and evaluating teaching.
--

Figure 3: Curricular items chosen for the module: "GIS, data analysis and modelling in geography"

This supports the notion that the intended integration, instigated at the discipline level, is indeed formal, but there is the desire to make it real by getting to know the other discipline through cooperation, and this is even seen as a separate advantage. It is also evident that curricular items, formulated along the lines of "the use of IT" are recognizable because they are determined at the school and pedagogy level, which are common to the two disciplines. Then there are some items, the determination of which, are situated exclusively at the level of the discipline: "Using and evaluating appropriate representations" and "skills at using geographical sources and methods" are intrinsic to the disciplines, but they pertain to similar disciplinary categories, such as the use of abstract symbols or graphics to represent data.

One could wonder why, or why only, the geometry domain is mentioned from the math discipline, and not e.g. statistics or functions, which could go well together with "data analysis". The interviewees agree that it is a practical and in a way arbitrary choice, because other domains could be made to work out just as well, but there is

obviousness to the pairing of geometry and physical geography, which in our model can be seen as determined on the civilization level:

“It is something about the measurement of the earth and maps, it all fits together very nicely, scales and similarity, it is nearly obvious! (CM₂ 20:20-20:28)

The etymology of geo-metry and geo-graphy alludes to the kinship between the two and historically, one may contend that the choice of “maps” and “geometry” are the primary domains involved in the interaction, and is indeed natural and reflects culturally rooted views of the two disciplines and the links between them.

Co-determination of concrete activities in the module.

In fact, when it comes to respondents’ ideas for teaching, they are all connected to the notion of maps: The reference to different kinds of maps, the making of maps, maps as a tool for investigation, the historical development of maps. This is determined both at the discipline level, but also conditioned by the requirements of the institution in which the pre-service teachers are going to teach (schools; this second order influence appears at the society level in our model):

“Mathematics sometimes requires practical examples to illustrate what math is, and that is what you can do when working with mapmaking, ...because the math related to that, is also the math you use in lower secondary school” (CG₁ 18:47-19:13)

In figure 4 we have shown an example of how to model the interdependencies surrounding the creation of a physical map, as the subject of a teaching activity. Using this model it is possible to identify possibilities and constraints that one discipline imposes on the other, to the enactment of such an activity: At the domain-level, the choice of geometry, applied to the measurement of the earth, precipitates the restriction to physical geography. This in turn determines what should be the types of maps to work with: e.g. physical or topographic instead of other more culturally oriented maps such as political maps. Then distances could be the information you would like to convey using the map, and the choice of plane geometry might be taken to avoid the time-consuming complication of earth curvature and the different heights of the landscape being drawn on the map, especially if triangles are to be the mathematical theme. Triangles are used when making the measurements of the land considered as a plane surface, and then, by similarity, transferred to the map:

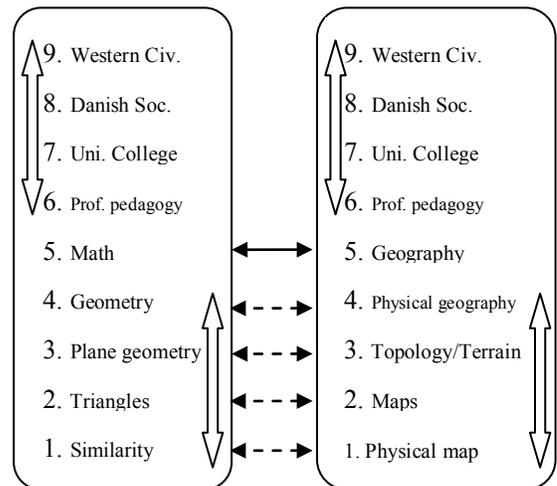

Figure 4 Example of bi-disciplinary ecology inferred from suggestions of interviewees

“yes, that about surveying, at least triangulation and how maps has been made, and how maps look; I don’t know how much surveying per se [they have in geography], when I

think about surveying, it is more from a mathematical point of view, when we go out and construct figures out there” (CM₂ 14:31-15:50]

“It is clear that it would be tempting to measure on a sphere, meaning spherical geometry... but this [module] is not huge, so we have to be careful about how much we can achieve in the given time (CM₂ 24:42-24:57)

It may appear curious that the math teachers so willingly lend their discipline to the making of maps and surveying, but it is a common feature of Danish teacher education that applied math is considered of quite high value, which is also directly reflected in the curriculum description of the mathematics discipline at university colleges:

“The history of the discipline, the discipline’s function as a bearer of culture, and the application of the discipline, is an important part of its identity as a teaching discipline” Undervisningsministeriet (2011, appendix 2, section 3)

Looking at other suggestions to the possible contents of the module we find a lot of references to “problems of flooding and water flow” (CG₁ 5:10, CM₁ 19:20-19:37; 22:10, CM₂ 15:20-16:00; CM₂ 17:55-18:20). These are all strongly influenced by the society level:

“It would be really nice if it [the context for teaching] could be some kind of real problem” (CM₁ 22:21-22:28)

“... but it [the problem of the activity] is strictly a concern for society, it is all concerns for society” (CM₂ 18:30-18:35).

Let us now select two of the concrete examples: 1) Investigating the impact of a new national law, proscribing that no land may be farmed that is closer to a stream than 5 meters. 2) Investigating the flow of water through a lake or stream. Both open up a host of possible teaching avenues, both for math and geography. In figure 5 and 6 we have put this into our model to describe how decisions at higher levels of the scale will interact to produce the possible integrated practice at the subject level. In both examples we recognize the aim to use Geographical Information Systems as a tool to do investigations, but GIS does not appear as an object of knowledge in itself. Therefore it is not mentioned explicitly in the model. It is used at the praxis levels (thematic and subject), and it is conditioned at the discipline level:

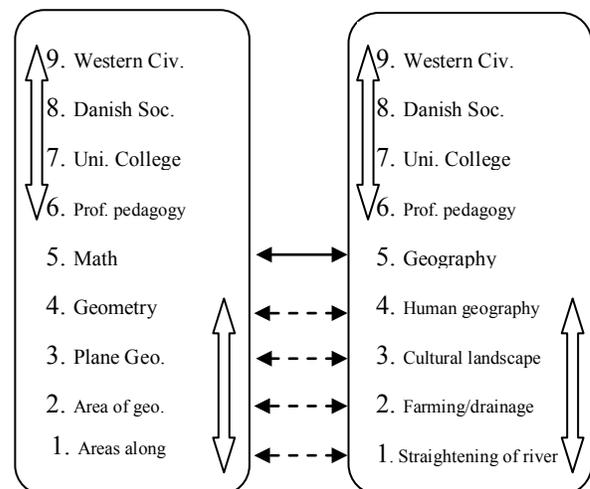

Figure 5 Example of bi-disciplinary ecology
“Investigating impact of new law”

“I think, it is because many who work with geographical information systems believe it is absolutely obvious that the whole world should know about it, because it is so incredibly smart and it appears in so many contexts” (CG₁ 6:14-6:25)

It is worthwhile to notice that CG₁ expresses the desirability to have GIS included at the discipline level of math and geography, in the institutional ecology of the university college, whereas the reasons for the desire is said to come from parts of the society level, namely *those who work with GIS*. This is another example of a second order influence, which comes from an institutional context outside the university college (namely, from the same-name discipline in scientific institutions such as universities). Looking at the first avenue of teaching in figure 5 (example 1 above), we remark that it is directly determined on the society level as the idea originates from the consequences of a political decision. This clearly conditions the domain level to the geographical subfield of human geography, and the sector narrows it down to looking at culturally formed landscapes. Then what can be investigated mathematically is the area of farmland affected by the law, giving rise to the sector of plane geometry. One could hypothesize that the subsequent implications for the economy of the affected farmers could be mathematically considered, *but that would not be in strict accordance with the choice of geometry at the domain level*. As a consequence the theme and subject will, in regards to math, revolve around non-trivial calculations of area alongside curves, which could benefit from the aid of GIS. The geography part could draw on the area calculations and focus on issues of farming and the straightening of rivers (a classical subject of Danish human geography)

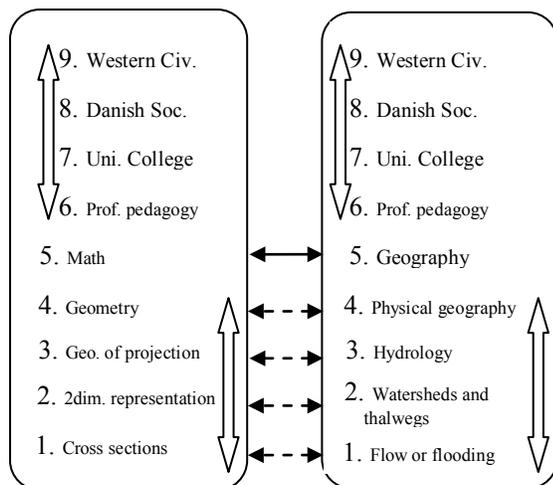

Figure 6 Example of bi-disciplinary ecology
“Flow of water”

The second avenue of teaching (example 2, above) takes us into the “geometry of projections” sector of the chosen mathematical domain. (Figure 6) This is influenced by the choice of hydrology in the physical geographic domain, which has the study of moving water as an object. One theme could be thalwegs, in which two dimensional representations of river cross sections are extensively used. Also the cross section of the inlet and outlet of a lake, will determine the area of the lake surface. Horizontal cross sections of the lake landscape can be used to predict the extension of the lake for different flow rates:

“We talked at some point about the flow through a lake, how the surface area, yeah, could be measured, but also how it changed in accordance with the flow in and out.” (CM₁ 19:13-19:31)

To construct the two dimensional representation, it is suggested that students physically go into the geotope and make the measurements using a mobile phone

application, that can transfer data to a GIS system. Doing investigations in the field is an important part of geography, valued at the discipline level, and the processing of data to make the graphical representations, in this case, of river cross sections, is firmly rooted in the mathematical ecology at university colleges (school and discipline levels). The above quote may also allude to find some relationship or model of the changing lake surface area, expressed in terms of a function, as a pivot for the teaching activity. However, that would conflict with the choice of geometry at the domain level. This choice, if vigorously adhered to, seems indeed to impose rather strong restrictions on the lower levels:

“You could easily get into functions here, and differential equations, if you look at the velocity with which the water runs from the lake. So that could be described in some dynamical systems, but we have nevertheless chosen that it [the module] should take another direction.” [CM₁ 29:15-29:39]

The two above analysed avenues of teaching both have common connection to the concept of “flow”. This reminds us of what Wake (2011) calls a *bridging concept*, which “provide a driver to facilitate cross-disciplinary thinking” (p.1004). But we contend that the interaction among the different levels of didactic codetermination in the bi-disciplinary ecology provides a refined and more precise model of the idea reflected by the term “bridging concept”.

CONCLUSION AND PERSPECTIVES

The way two disciplines, as situated in the institutional ecology of teacher education at university colleges, interact, when trying to establish integrated education, are determined by factors residing at levels above the one immediately considered. The interaction crosses the disciplinary boundaries, meaning e.g. that the domain level of one discipline will influence the theme level of the other. The route of influence, as expressed in interviews with the developers of the integrated math and geography teaching module, can be modelled by the levels of determination, and *it goes by way of the vertically and horizontally indicated directions*. That is, we have seen no determinations that appear to go, for example, directly from the pedagogy level of the math disciplinary ecology to the theme level of the geography ecology. But the possibility of such level crossing codetermination in integrated education needs to be further investigated. This question, and the more general one of seeing borders between disciplines as a criterion of demarcation, is by no means a trivial one when we look at the long ongoing debate about the nature of integrated education. In the illustrations used to represent our model we have what appear to be clear borders between the participating disciplines. This is to recognize that our model *does* operate with disciplines as distinct bodies of knowledge and this also reflect evident conditions in the institutional context studied. Indeed, the curriculum construction in ASTE begins with the existing disciplines, which define relevant positions in the institutional context of the university college. In that fashion the disciplines come

before “big questions” even in the early planning phases. The model is not to be taken normatively, and it does not say to which degrees borders do, or should be discernible, in order to represent “true” integration. It serves simply to organise our analysis of how integration of disciplines takes place, or is planned to take place. Finally it allows us to situate second order influences from same-name “scientific disciplines” and “secondary school disciplines” which co-determine the planning and cooperation in integrated approaches at the university colleges participating in this project. An extension of the model to study these influences further appears of great interest to understand more globally the interplay between participating institutions.

A REFERENCE FRAMEWORK FOR TEACHING THE STANDARD ALGORITHMS OF THE FOUR BASIC ARITHMETIC OPERATIONS: FROM THEORETICAL ANALYSIS TO TASK DESIGN

Ira Raveh^{*} & Boris Koichu^{**}

^{*} *Academic ORT Braude College, Karmiel & Academic College of Education, Tivon, Israel*

^{**} *Technion – Israel Institute of Technology*

The study presented in this paper offers a reference framework for characterizing primary school teachers' mathematical knowledge of the standard algorithms of the four basic arithmetic operations. The framework was first devised theoretically, from mathematical analysis of the algorithms and from past research on knowledge for teaching arithmetic operations with rational numbers. It was then applied to designing tasks for characterizing and deepening the teachers' conceptual understanding of the algorithms. The paper contains examples of tasks related to the knowledge of mathematical principles underlying the algorithms, which were tested with a group of 46 primary school mathematics teachers.

Keywords: *standard algorithms of the four basic arithmetic operations, mathematical knowledge for teaching, task design.*

INTRODUCTION

The four standard algorithms of the four basic arithmetic operations is one of the main topics currently taught in primary school¹. Much time is devoted to teaching this topic, but according to many studies, the pupils have difficulty in performing and understanding it (Fuson, 1992; Fuson et al., 1997; Kilpatrick et al., 2001). There is serious criticism of the way this subject is taught (e.g., Lee, 2007; Ma, 1999; McIntosh, 1998). Many researchers argue that it is taught in a rote manner that does not encourage conceptual understanding. In order to understand the roots of this problem in depth, several studies focusing on the teachers' knowledge of this subject were conducted (e.g., Hill & Ball, 2004; Hill et al., 2008; Kilpatrick, Swafford & Findell, 2001; Ma, 1999; Tchoshanov, 2011).

With few exceptions (e.g., Peled & Zaslavsky, 2008), the recent studies focus on particular algorithms. A framework for characterizing the knowledge for teaching the four standard algorithms as a holistic topic is still missing. The need for such a

¹ This article deals with the four standard algorithms being taught in Israel. These algorithms may have slightly different appearances in different countries.

framework manifests itself due to the broadly recognized importance of emphasizing the connectedness of mathematics (e.g., NCTM, 2000). In addition, and in line with research on other mathematical topics, such a framework is needed for systematic design of mathematical tasks with the potential to characterize and promote the teachers' knowledge of the subject. The present study aims at fulfilling this gap².

Specifically, the goal of the study is to identify, first theoretically, the core components of mathematical knowledge for teaching the standard algorithms of the four basic arithmetic operations, and then to empirically examine the feasibility of the framework by applying it to the design of tasks having the potential to capture variations in the teachers' knowledge.

In the next section we present and theoretically justify the framework. This is followed by examples of tasks related to one of the framework's components, the knowledge of mathematical principles underlying the algorithms. The article is concluded by remarks on applicability of the framework for research and practice.

REFERENCE FRAMEWORK

The framework presented in Table 1 is devised based on juxtaposition of two sources: (1) past studies on the knowledge for teaching the basic arithmetic operations with rational numbers, and (2) analysis of the algorithms in terms of the underlying mathematical principles.

	Component	Operative criteria for component examination
PK	Procedural Knowledge	1. Demonstrated knowledge of the algorithms' steps 2. Performing correct computations
KP	Knowledge of mathematical Principles underlying each algorithm: place-value, number regrouping and distributive law	1. Recognizing mathematical principles, which are violated in students' incorrect performance 2. Explaining the stages of the algorithms using appropriate mathematical principles 3. Recognizing mathematical principles underlying different representation of the algorithms
KS	Knowledge of Similarity between different algorithms based on the common underlying principles	1. Recognizing common principles underlying different algorithms 2. Classification mistakes in the use of different algorithms by pointing out the common mathematical principles violated
KR	Knowledge of different Representations of each algorithm and connections between them	"Translating" standard, vertical, algorithms to horizontal representations

Table 1: Reference framework for teaching the four elementary algorithms

² The paper is based on the PhD research of the first-named author conducted in the Technion under the supervision of the second-named author, Prof. Orit Zaslavsky and Dr. Irit Peled.

Noticeably, the first component corresponds to the notion of procedural understanding, and the next three – to conceptual understanding, as defined by Skemp (1987).

Procedural Knowledge (PK) refers to one's ability to accurately perform the algorithms. This component is not unique for teachers' knowledge. Ball, Hill and Bass (2005) claim that being able to perform the algorithms correctly is essential for teaching, but also insufficient.

Knowledge of mathematical Principles underlying each algorithm (KP) component is included in the framework because, mathematically speaking, the algorithms work based on certain mathematical laws, and it is reasonable to assume that knowledge of these laws is an important part of conceptual understanding the topic. Peled and Zaslavsky (2008) classified this type of knowledge as "local connections between procedures and conceptual knowledge" (p. 28). The principles for the framework were chosen as follows.

First, many researchers assert the role of the *place value principle* in the addition and subtraction algorithms (Ball, Hill & Bass, 2005; Kilpatrick, Swafford & Findell, 2001; Fuson, 1992; Ma, 1999; Thanheiser, 2010); some mention the principle as underlying also the multiplication (Ma, 1999; Kilpatrick, Swafford & Findell, 2001) and the division (Kilpatrick, Swafford & Findell, 2001) algorithms. Second, several researchers point out that the *number regrouping principle* is reflected in addition and subtraction algorithms (Kilpatrick, Swafford & Findell, 2001; Fuson, 1992; Ma, 1999), and it is possible to show that this principle is also involved in the multiplication and division algorithms. Third, Ma (1999) recognizes the *distributive law* as underlying the multiplication algorithm, and it is not difficult to see that it also underlies the division algorithm. In sum, the first two principles underlie all the four algorithms, and the third one – the multiplication and division algorithms.

Knowledge of Similarity (KS) between different algorithms based on the common underlying principles was considered by Peled and Zaslavsky (2008) as a kind of meta-knowledge "about a procedure which includes global aspects underlying a specific procedure or common to a number of procedures" (p. 31). They explored the iterative structure of the standard algorithms as an example of such meta-knowledge and argued that it may emerge in learners based on noticing the iterative structure of each algorithm.

In the proposed framework, we choose to focus on the similarity between the algorithms at the level of the above three mathematical principles. Consequently, there is a sort of hierarchy between the KP and KS components: the KP component is necessary (though not sufficient) for KS.

Our focus on the mathematical principles in the KS component is based on the two-fold argument, as follows. On one hand, a person who studied each algorithm separately and observed that a particular principle repeatedly appears, may use this

observation as a semantic tool for expressing in-depth similarity between the algorithms (cf. Peled & Zaslavsky, 2008, for a compatible argument). On the other hand, a person who learned that the same principle underlies several algorithms may use this knowledge in order to unpack how the principle works in each algorithm.

Knowledge of different Representations (KR) of each algorithm and connections between them component is included in the framework because many researchers accent the importance of knowledge of different representations and models of the subject taught for its conceptual understanding (e.g., Ball, Hill & Bass, 2005; Davis & Simmt, 2006; Hiebert & Carpenter, 1992; Leikin & Levav-Waynberg, 2007; Ma, 1999). Among various representations and models of the four standard algorithms, we choose to focus on translating from the standard, vertical, representation of the algorithms to their horizontal representations. This is because for all four algorithms the translation process is rich with the opportunities to unpack the procedures' steps and reveal how the aforementioned mathematical principles work.

Each knowledge component may be manifested at different levels of depth. The operational criteria for identifying the teachers' knowledge on a *conceptual level* are presented in Table 1. A person may also possess only *rote-level* knowledge of the algorithms. In terms of our framework, the *rote level* of knowledge is manifested when a person, who was encouraged to explicitly use his or her knowledge of the underlying mathematical principles, exposed only the knowledge of the technical-computational aspects in discourse or performance. These two levels of knowledge are exemplified in the next section.

CHARACTERIZING THE COMPONENTS OF KNOWLEDGE BY MEANS OF TASKS

In this section we show how the framework can be applied to the design of tasks having the potential to reveal one's level of knowledge of the algorithms. Due to space constraints, we decided to focus only on the KP component. Three tasks that correspond to three operational criteria characterizing the KP component of knowledge are presented below. The tasks were tested in five 90-minute professional development workshops with two groups of elementary school teachers. Overall, 46 teachers participated in 10 workshops, which were conducted by the first-named author in the framework of a one-year professional development course. The teacher-participants possessed at least B.Ed. degree, had already taught mathematics (among other subjects) in elementary school and wished to be certified as elementary school mathematics teachers.

The principles underlying the four algorithms were discussed with the teachers prior to exposing them to the tasks. The teachers worked on Task 1 and Task 3 in groups of two to four participants; Task 2 was given for individual work. The performance of each group on each task was audio-taped and transcribed; all the written materials were collected. Additional insight on teachers' work on the tasks was received during

individual interviews conducted after the end of the workshop's part dealing with the standard algorithms. The two answers accompanying Task 1 and Task 2 presented below are representative of the edges of the spectrum of the answers: the first points to the rote level and the second to the conceptual level of knowledge. Two answers related to Task 3 exemplify different degrees of conceptual-level knowledge. The examples were chosen in order to demonstrate the range of variations in the teachers' knowledge, which can be captured by the framework.

Task 1: Mistaken computations

The task corresponds to the first operational criteria for the KP component (see Table 1). The teachers were given a series of computations by imaginary pupils containing various violations of the place-value and regrouping principles in the four algorithms³. Four items presented in Figure 1 deal with violations of the place-value principle. For each computation, the teachers were required: (1) to explain the mistake, (2) suggest its possible reason(s), and (3) offer a suitable method to pedagogically treat it. They were asked first to discuss the above three requests, and then to put their agreed responses in writing.

Note that the teachers were not instructed to necessarily use the names of the principles in their written responses, though the principles were emphasized at the beginning of the workshop. Thus, a variation inherited in the task was related to the teachers' choice of whether or not to use the (conceptual) language of the mathematical principles or to use rote language.

Fig. 1: Examples of mistaken computations from Task 1

One group of teachers responded, in writing, to the multiplication item in Figure 1 as follows:

Description of the mistake: The student didn't write the numbers at the right place.

Possible reasons for the mistake: The student forgot to move the numbers (the partial products) to left side.

Possible method to treat the mistake: To remind the technique of the multiplication algorithm.

Noticeably, the teachers choose not to mention the place-value principle in their response and considered only the technical aspect. They did the same with the rest of

³ Some computations were adopted from Zaslavsky (2003) and the others were offered by the first-named author based on mathematical analysis of the algorithms

Teacher B (with reference to Fig. 2)

First of all, you have to explain that we regroup 28 as 20 and 8 and multiply each part separately: $435 \cdot (20+8)$. We then have to remind the distributive law in order to explain the multiplication: $435 \cdot (20+8)$

8 units multiplied by 435 is 3480 units, and 2 tens multiplied by 435 are 870 tens. So we must write the results in the appropriate places. It's the key element of the explanation. Only after understanding this properly you can continue. Finally, you have to add the partial products and pay attention to the units.

In sum, the rote and conceptual level responses were observed at both Task 1 and Task 2. Note however, the following differences in task design: Task 1 addresses imaginary students and Task 2 – an imaginary colleague; Task 1 does not include explicit instruction to mention the mathematical principles underlying the algorithms and Task 2 does. Consequently, one can reasonably suggest the following. Those teachers who responded to at least one of the tasks in a conceptual manner may be characterized as those who possess conceptual-level knowledge of the KP component. Those teachers who responded to both tasks in rote manner, probably not only decided not to mention the principles in the given context, but indeed do not possess conceptual-level knowledge.

Task 3: "Translating" the algorithms into horizontal representation

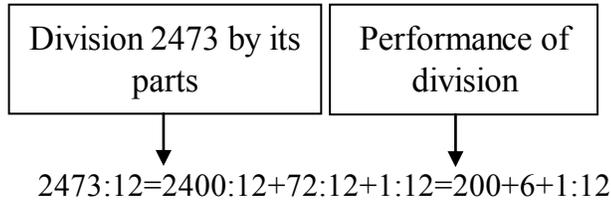

The task was to "translate" all the stages of the computation presented in the standard, vertical, form, into a horizontal row of transformations and justify the validity of each equality sign in the row by the aforementioned mathematical principles. The task included items related to the subtraction, multiplication and division algorithms; each algorithm was dealt with in one 90-minute workshop. The "translating" step of the task corresponded to the KR component (see Table 1) and the "justifying" step corresponded to the third operational criteria for the KP component.

The division algorithm was reserved for the last workshop, so the teachers already knew how to deal with the task in the contexts of the subtraction and multiplication algorithms. Nevertheless, 7 out of 10 groups appeared to be unable to translate the division presented in Fig. 3 and returned empty sheets. Apparently, this occurred because the task was more demanding than the previous ones: only those who possess conceptual knowledge of the division algorithm could write something in response. Two examples below suggest that groups who did respond to the task possessed the required conceptual knowledge, although to different degrees.

$$\begin{array}{r}

 2473 \overline{) 12} \\
 \underline{-24} \\
 073 \\
 \underline{-72} \\
 1
 \end{array}$$

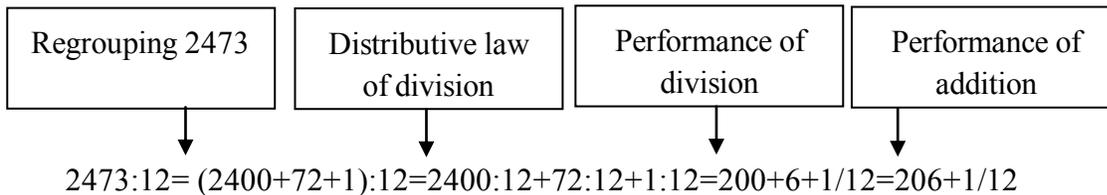

Fig.3: A computation from Task 3

One group of the teachers responded to the task as follows:

As can be seen, the teachers translated the computation using two row transformations and used their own expressions to explain them rather than the names of the aforementioned principles.

The response of another group follows.

This group translated the vertical computation using four row transformations and explained the first two in terms of the intended mathematical principles.

Based on the above written responses, follow-up interviews and a whole-group discussion, we know that the first group chose to translate the vertical computation into a horizontal form straightforwardly, by focusing on particular numbers in the vertical algorithm (i.e., 24, 72 and 1). Then when the teachers tried to explain each horizontal transformation as requested in the task, they observed that the names of the principles did not fit and used their own expressions. The second group began from recalling the relevant principles and decided how many and which transformation to write so they would fit the names of the principles. Consequently, we deem that the response of the second group reflects a higher degree of conceptual knowledge of the division algorithm, in terms of the offered framework, than that of the first one.

SUMMARY AND CONTRIBUTION

Ball, Hill and Bass (2005) point out the teachers' ability to unpack a mathematical subject into related sub-subjects as an important component of mathematics knowledge for teaching. In the context of the standard algorithms of the four basic arithmetic operations, such an unpacking still needs operational conceptualizing. A reference framework presented in this article offers one way of so doing. Based on the above theoretical and task design considerations, we argue that the proposed framework captures the essential components of teaching knowledge of the subject

and can provide a solid basis for teacher preparation programs and for characterizing the teachers' knowledge. Specifically, the framework puts forward the mathematical principles underlying the algorithms as an overarching semantic/mathematical tool for identifying the components of knowledge needed for teaching the algorithms. Consequently, the study continues and advances the research venue started in the studies of Ball, Hill and Bass (2005); Ma (1999) and Peled and Zaslavsky (2008).

Furthermore, the framework includes operational criteria for characterizing the knowledge components at different levels, up to the conceptual level of teaching the algorithms, i.e., teaching with the potential to expose for learners deep mathematical similarities between the algorithms and the connections between their different representations. Thus, the framework addresses the call formulated in Davis and Simmt (2006) and Peled and Zaslavsky (2008). It has been demonstrated that the criteria, in turn, can serve for designing tasks for mathematics teachers' professional development. Three examples of tasks provided in this article have (hopefully) demonstrated the sensitivity of the framework to variations in the teachers' knowledge.

DEVELOPING MATHEMATICS TEACHER EDUCATION PRACTICE AS A CONSEQUENCE OF RESEARCH

Tim Rowland^{a,b}, Fay Turner^a and Anne Thwaites^a

^aUniversity of Cambridge, UK, and ^bUniversity of East Anglia, UK

The authors of this paper are three members of the Cambridge-based research team who developed the Knowledge Quartet (KQ), a theory of mathematics teacher knowledge, with a focus on classroom situations in which this knowledge is applied. At the same time as being researchers, the authors were elementary mathematics teacher education instructors. Despite many years' experience of preparing trainee teachers in elementary mathematics, they found that the KQ research had brought about new awareness of the importance of some components of mathematics didactics, as well as providing new tools for undertaking some aspects of their teacher educator role. The paper explores some of these awarenesses and tools in detail.

Keywords: teacher knowledge, mathematics teacher educator, Knowledge Quartet

INTRODUCTION

This paper is a contribution to a young field of research, which seeks to understand the ways in which teacher educators (specifically, mathematics teacher educators) can gain in wisdom, competence and effectiveness in their work. The state of the art has similarities with the emergence of mathematics teaching as a research field, fuelled by action research, in the 1980s: until then, the research gaze was on students rather than teachers. Likewise, researchers into mathematics teaching, themselves typically mathematics teacher educators, have only recently viewed themselves (or their work) as suitable objects of research, having previously attended to the knowledge and performance of their own 'students'. Even the goals of what we are calling mathematics teacher educator 'development' are, as yet, unclear. In a Special Issue of the *Journal of Mathematics Teacher Education*, Brown and Coles (2010) address the topic in a neutral way, as "change", and ask what it might mean to say that a mathematics teacher educator has "changed". One state with potential for productive change is awareness (Mason, 2008), specifically critical awareness of how mathematics teaching is being modelled, in pre-service teacher education in particular. Adler and Davis (2011) identify three such modelling practices - 'look at my practice', 'look at your practice' and 'look at (mathematics teaching) practice' - and argue that these offer different opportunities for learning about teaching. The first model presents the teacher educator him/herself as example, or role model, as a mathematics teacher might be inclined to do when cast in the role of trainee-mentor (Mason, 2008, p. 50). The second suggests explicit emphasis on critical, constructive examination of one's own teaching practice. It will become apparent that the changes in our own awareness and professional identity relate more to the third model, in which the teaching practice of others provokes awareness of possibilities for the development of one's own teaching.

In their survey of research in mathematics teacher education, Adler, Ball, Krainer, Lin and Novotna (2005) pointed to the importance of the research activity of mathematics teacher educators in helping them to understand and develop their own practice. This link between mathematics teacher educator research and practice is at the heart of this paper, and we turn to it now. The work of University Departments of Education is typically distributed across diverse programs and agendas, including a leading role in the education and professional preparation of prospective teachers. There can be, in the UK at least, and probably elsewhere, a fuzzy divide between faculty engaged in teacher preparation and those engaged in research. Thus, while teacher education is expected to be research-informed, this basis in scholarship most often rests on the research of academics other than those doing the ‘training’. This state of affairs comes about for a number of reasons, and many faculty on both sides of the divide are very content with it. However, the purpose of this paper is to exemplify how mathematics teacher educators can benefit and learn from *their own* research activity, with direct relevance to their teacher education role. In the paper we reflect upon our own experience as education department faculty who have endeavoured to straddle the research-practice divide.

The paper begins with a brief account of a research project on mathematics teacher knowledge, to which each of us made a major contribution. The remainder of the paper is devoted to reflection on, and discussion of, some ways in which the research had a direct impact on our professional work with prospective teachers, thereby (we believe) making us ‘better’ teacher educators. Despite having, between us, over 70 years experience of preparing trainee teachers in elementary mathematics, we found that this particular research activity had given us new awarenesses of the importance of some components of mathematics didactics, as well as providing new tools for undertaking some aspects of our teacher educator role.

We conclude this introduction by articulating an (as yet) unspoken assumption: that knowledge for mathematics teacher education is not quite the same as knowledge for mathematics teaching. This must be the case because the students (student teachers, mathematics students) are intended to be learning different things. It has been pointed out that the ‘community of practice’ model of situated learning does not fit institutional learning very well, precisely because mathematics learners are not apprentice teachers. Mason captures the distinction between teacher and teacher educator in terms of the direction of attention:

Teaching is about directing learner attention [...] about being aware of what learners are not yet aware of, and finding ways to prompt them to become aware. Educating teachers is about directing attention to practices and choices, constructs and theories which can inform choices when teaching (Mason, 2008, pp. 51-2).

The significance of such practices, choices, constructs and theories will become apparent in the narrative to come, in which we ‘make public’ the integration of our research into our teaching.

The Knowledge Quartet

In 2002-03, we undertook some empirical research into mathematics teachers' knowledge, in collaboration with two additional colleagues in Cambridge. Our approach to investigating the relationship between teacher knowledge and classroom practice was to observe and videotape novice teachers teaching. The participants were 12 graduate prospective ('trainee') elementary school teachers in our university faculty of education. We observed and videotaped two mathematics lessons taught by each participant. In the analysis of these videotaped lessons, we identified aspects of trainees' classroom actions that seemed to be informed by their *mathematics* subject matter knowledge or their *mathematical* pedagogical content knowledge (Shulman, 1986). We realised later that most of these related to choices made by the trainee, in their planning or more spontaneously. Each was provisionally assigned an 'invented' code, such as: 'choice of examples'; 'choice of representation'; 'adheres to textbook'; and 'decision about sequencing'. These were grounded in particular moments or episodes in the tapes. This provisional set of codes was rationalised and reduced (e.g. eliminating duplicate codes and marginal events) by negotiation and agreement in the research team. This inductive process generated 20¹ agreed codes, which were subsequently grouped into four broad, super-ordinate categories, or 'dimensions' – hence the 'Quartet'. The four dimensions and the corresponding contributory codes are shown in Table 1.

Dimension	Contributory codes
<i>Foundation:</i>	awareness of purpose; adheres to textbook; concentration on procedures; identifying errors; overt display of subject knowledge; theoretical underpinning of pedagogy; use of mathematical terminology.
<i>Transformation:</i>	choice and use of examples; choice and use of representation; use of instructional materials; teacher demonstration.
<i>Connection:</i>	anticipation of complexity; decisions about sequencing; making connections between procedures; making connections between concepts; recognition of conceptual appropriateness.
<i>Contingency:</i>	deviation from agenda; responding to students' ideas; use of opportunities; teacher insight during instruction.

Table 1: The Knowledge Quartet – dimensions and contributory codes

A brief conceptual outline of the KQ is as follows. The first dimension, *foundation*, consists of teachers' mathematics-related knowledge, beliefs and understanding, incorporating Shulman's (1986) classic taxonomy of *kinds* of knowledge without undue concern for the boundaries between them. The second dimension, *transformation*, concerns knowledge-in-action as demonstrated both in planning to teach and in the act of teaching itself. A central focus is on the representation of ideas to learners in the form of analogies, examples, explanations and demonstrations. The third dimension, *connection*, concerns ways that the teacher achieves coherence within and between lessons: it includes the sequencing of material for instruction, and an awareness of the relative cognitive demands of different topics and tasks. Our final dimension, *contingency*, is witnessed in classroom events that were not planned for. In

commonplace language, it is the ability to ‘think on one’s feet’. More detailed conceptual accounts can be found in Rowland, Huckstep & Thwaites (2005), and in the book Rowland, Turner, Thwaites & Huckstep (2009). Related reports at previous CERME conferences include Huckstep, Rowland & Thwaites (2006). In this paper we also draw upon the longitudinal doctoral research project of the second author (Turner, 2010), in which the findings of the 2002-03 KQ project were applied for the first time; and on continuation projects (e.g. see Rowland, Jared & Thwaites, 2011) in which the scope and methodology of the KQ were extended.

WHAT WE LEARNED FROM THE KQ RESEARCH

We now proceed to describe some of the ways in which the research outlined above brought about new awarenesses, and enabled new approaches, in our professional work as elementary mathematics educators. This will be organised into sections corresponding to specific issues, topics and approaches about which we became more sensitive and knowledgeable as a consequence of the research.

The role of ‘theory’ within pre-service mathematics teacher education

When using the KQ to analyse the practice of beginning teachers, it was salutary to find that they did not draw on what we thought they had learned from our methods courses in the university to the extent that we might have hoped. The mathematical knowledge for teaching (MKT) of beginning teachers might be expected to be mainly *propositional* (Shulman, 1986), i.e. gained from their own mathematics education and from mathematics methods courses during teacher education programmes. There were a number of instances where situations categorised under the *foundation* dimension indicated that, once in the classroom, trainees did not draw on propositional knowledge addressed during their graduate teacher education course. Although there was evidence that this was held as propositional knowledge, these beginning teachers were frequently unable to draw on this knowledge and activate it in their early teaching. Two examples will illustrate this observation.

Amy. During her final school placement, in a lesson about counting with 4–5 year-old children, Amy asked her pupils to write nineteen on their white boards. Several children wrote ‘1P’, at least one wrote ‘99’ and many wrote ‘91’. The trainee teacher focused on the reversal of the nine but did not address the problem of digit order. During the post-lesson interview the trainee teacher was asked why she thought children had reversed the digits:

Because you say nine first, then you say the teen that’s why often they write the nine first they often want to write nine first then write it from right to left instead of left to right. (*Amy*)

Amy clearly knew about the problems children encounter in writing teen numbers (e.g., Anghileri, 2007), but did not apply this knowledge in her practice.

Kate used a number line to help children complete addition calculations such as ‘8 + 8’ and ‘3 + 4’ by beginning at one of the numbers and then counting on the second number. This pre-supposed that children had reached the ‘count on’ stage in addition. However,

observation of the children's independent use of the number lines suggested that some were still at the 'count all' stage (Carpenter and Moser, 1984). Kate was asked if she remembered the stages children go through in learning addition:

At first not knowing that you can just start at numbers, that you have to count the one, two, three ... so you have to count three to get up to three before you can carry on. (Kate)

Although she knew that some children would not be able to understand the addition strategy of starting with one number and then counting on the second number, this propositional knowledge was not drawn on in Kate's teaching.

Analysis of further data using the KQ framework suggested that these beginning teachers became more able to draw on propositional MKT as they gained experience (Turner 2010, pp. 98ff). This suggested that teachers need experience, and focused reflection on their experience, in order to contextualise and make use of the propositional knowledge we present to them in the university. We should not be surprised or disappointed when we find beginning teachers not drawing on this knowledge. We learned that providing the KQ as a tool for reflecting on their teaching helps them to make links to this propositional knowledge and to apply it within the context of their practice.

The use of the KQ to structure review of, and reflection on, teaching

The KQ helped us to observe and to analyse the teaching of our elementary trainee teachers and to give detailed feedback which focused on the mathematical content of their lessons. This detailed analysis of teaching suggested the need to address more explicitly the importance of selecting appropriate examples and representations, as well as making connections and responding contingently to pupils, in our mathematics methods course. Guidelines based on the framework (Rowland et al, 2009, pp. 35-37) were also developed to support university and school-based colleagues working with elementary trainee teachers who were not mathematics education experts. These guidelines were presented and very well received during mentor training sessions at the university, and continue to be available to colleagues.

The usefulness of the framework for supporting observation of, and feedback on, mathematics teaching was explored in a study carried out between 2004 and 2008 (Turner, 2010). It was used as a tool to identify, analyse and chart developments in beginning teachers' MKT, and also as a tool to promote that development. As a tool for development, it was used to frame review discussions of mathematics teaching between teachers and the mathematics teacher educator (MTE) It was also used by the teachers to support individual reflection, helping them identify situations in which their MKT was revealed and to frame their written *reflective* accounts.

In the early phases of the study, the lesson review meetings were intensive and took the form of a stimulated recall interview. The researcher [the second author] used a KQ analysis of the lesson to determine questions to ask and comments to make when the teacher watched the videotape of their lesson. For example, a coding of *choice of examples* (CE) suggested stopping the videotape to ask whether the trainee teacher

thought the examples they had used in their explanation of a mathematical procedure were the most appropriate, or whether they might have caused some confusion. The structure of these initial review meetings would be impossible to sustain across a large number of trainee teachers or with busy practicing teachers. The methods employed in the second stage of the study were therefore more appropriate as a model for scaling up the adoption of the KQ for structuring post-lesson review meetings. Lessons were again observed and videotaped however the review meeting was based on a ‘broad sweep’ KQ analysis of detailed field notes made while observing the lesson. The second author asked questions or commented on significant episodes which had been identified in the analysis and the teachers made observations in relation to the codes and dimensions of the framework with which they were now familiar.

The study also aimed to determine whether the KQ framework supported independent reflection on the mathematical content of teaching. Therefore, during the third phase teachers were not given feedback following their lessons, but were sent DVD copies of the lessons and asked to write reflective accounts independently, structured by the dimensions and codes of the KQ framework. A number of comments made by the teachers demonstrated that they found the framework useful when planning for, and reflecting on, their mathematics teaching. For example:

I often find myself referring to it in my head when I am planning. ...I think the most important effect is having the four headings, makes me more aware of what I am planning and teaching and why. You find yourself questioning yourself and justifying your decisions and choices, it makes you more purposeful in your choices, more precise. (Amy)

From this study we learned that the KQ can be used effectively to frame lesson reviews so that they focus on the MKT of teachers. We also learned that use of the KQ can help teachers to focus their independent reflection on the mathematical content of their teaching.

The role of representations and examples in mathematics teaching

Despite our experience as teacher educators, the KQ research gave us a new appreciation and understanding of the importance of *examples* in mathematics teaching. When teachers teach mathematics they choose and use examples all the time – the relevant code was present in our coding of every lesson. In fact our focus on examples came at an interesting time from a national and international research perspective. While we were building an emergent theory of teacher-chosen examples (e.g. Rowland, Thwaites & Huckstep, 2003), Watson and Mason (2005) were developing a theory of learner-generated examples, applying and extending the ideas of Ference Marton on variation theory. Both of these perspectives were represented in a PME Research Forum (Bills et al., 2006) and in a special issue of *Educational Studies in Mathematics* (Bills & Watson, 2008).

As a consequence of our own research, we realised and understood better the different purposes for which examples are used, and that the choice of examples is far from arbitrary – some examples ‘work’ better than others. These insights have had a

significant effect on our practice in our role as mathematics teacher educators. So whilst formerly we might have spoken in a general way about the importance of choosing examples with care, we are now able to offer our trainee teachers a more analytical account of the choice and use of examples in mathematics teaching and learning. In particular, we identify and exemplify three broad categories of examples that were commonplace in our data, but which, we argue, teachers would do well to avoid. We labelled these categories: examples which confuse the role of variables; examples intended to illustrate a particular procedure, for which another procedure would be more sensible; and randomly generated examples. For details, see e.g. Rowland et al. (2009).

By way of illustration, we exemplify the first of these categories (confusing the role of variables) here, with two excerpts from the classroom data.

Kirsty was reviewing the topic of Cartesian co-ordinates with a class of 10 to 11-year-old pupils. *Kirsty* began by asking the children for a definition of co-ordinates. One child volunteered that “the horizontal line is first and then the vertical line”. *Kirsty* confirmed that this was essentially correct. She then moved on to assessing the pupils’ understanding of this key convention by asking them to identify the co-ordinates of a number of points as she marked them on a co-ordinate grid, projected onto a screen at the front of the classroom. Before marking the first point, she reminded them that “the x -axis goes first”. *Kirsty*’s first example was the point (1, 1). It is interesting to speculate reasons for *Kirsty*’s choice of this example, recognising that these ‘reasons’ might be of different types – pragmatic, pedagogical, affective and so on. In any case, the example would seem to be entirely ineffective in assessing what *Kirsty* wanted to determine: the children’s grasp of the significance of the order of the two elements of the ordered pair.

Michael’s lesson with a Year 4 class was about telling the time with analogue and digital clocks. One group was having difficulty with analogue quarter past, half past and quarter to. *Michael* intervened with this group, showing them first an analogue clock set at six o’clock. He then showed them a quarter past six and half past six. When asked to show half past seven on their clocks, one child put both hands on the seven. We can’t be sure, but the child’s inference from *Michael*’s demonstration example (half past six) seems reasonably clear. Of the twelve possible examples available to exemplify half-past, half past six is arguably the most unhelpful.

The role of *representations* in mathematics teaching has been extensively researched and theorised (e.g. Goldin, 2002). Nevertheless, our research yielded further insights that we were able to bring to our work with trainee teachers. These include the importance of the mathematical appropriateness of representations used for pedagogical purposes. We had observed the trainees’ propensity to choose representations on the basis of their superficial attractiveness at the expense of their mathematical relevance (Turner, 2008). In addition, we are now better placed to emphasise the interplay between choice of representations and choice of examples (e.g. Huckstep et al., 2006).

New uses of classroom video data within initial teacher education

The use of video in mathematics teacher education is well-established (e.g. Borko et al., 2008), and articulates well with case method teacher education pedagogy (Merseth, 1996). In England, the video resources that have been most in evidence in primary teacher education are of the kind developed by a government agency for ‘National Numeracy Strategy’ training (Askew et al, 2004). These tend to feature ‘best practice’ examples of ‘model’ lessons given by experienced teachers, presumably with the intention that other teachers will emulate their example. With the permission of the participants in our research, we use video clips from their lessons in a somewhat different way, and with a rather different purpose. These clips feature novice teachers, not ‘experts’, and as we observe them it is not hard even for trainee teachers to identify things that could be done differently, and maybe should be. We have written about some of these episodes elsewhere (e.g. Huckstep et al., 2006; Rowland, 2010), and there is insufficient space to describe them here. These video stimuli promote lively and thoughtful discussions about what seemed to be successful and what ‘went wrong’, and why, and what these trainees would do themselves to avoid the errors made (in their judgement) so as to improve the instruction. By contrast, we propose that when an expert teacher’s lesson ‘goes well’, the ingredients of its success can often be invisible to the novice trainee. Using our research video data, and in other ways, we now use these authentic classroom scenarios to pose challenging mathematical and didactical problems, and to raise awareness and insight, in our university-based sessions with trainees.

CONCLUSION

Teachers and teacher educators often approach their professional development through action research. This entails investigating one’s own practice, adapting it, and looking for evidence of the impact of this change. The development in our professional practice brought about by our research was a consequence of a very different process. We did not set out with the primary aim of developing our own practice. Rather, our focus was on the practice of trainee teachers as we tried to understand how their MKT was revealed and applied in the act of teaching. However, in investigating the practice of trainee teachers, we developed a way of understanding mathematics teaching which supported our own professional development as teacher educators in a number of different ways.

Developments in our understanding of beginning teachers’ MKT, as revealed through KQ analysis of their practice, led to changes in the content of our methods courses, particularly in relation to the importance of examples and representations. We found that the MKT that was ‘learned’ by trainees in our methods courses was not always available to beginning teachers in their practice. However, we discovered that teachers can be supported in applying this knowledge by providing the KQ as a tool for focused reflection. We improved our teaching placement lesson reviews by using the KQ to focus discussion on the mathematical content of teaching, and began to induct school-

based colleagues in the use of the KQ to support mentoring of trainees. We also presented the KQ framework to trainees themselves to support focused reflection on their mathematics teaching, so as to enable them to continue developing their MKT during school placements and after their mathematics methods courses were completed. We also developed new video resources for primary mathematics teacher education, and new ways of using them. Finally, a bonus in terms of professional development from participating in the KQ research related to the development of understanding and cohesion within the elementary mathematics teaching team.

These outcomes of our study illustrate the possibility of a symbiotic relationship between research into teaching and learning in classrooms and the professional development of teacher educators, demonstrating how the roles of researcher and of teacher educator can be complementary and mutually supportive.

Notes

1. In 2002 there were 18 codes in fact: two more were subsequently added in the light of new data.

This paper presents two episodes of an exploratory study on a prototype of a mathematics curriculum for pre-service teacher education. The focus here is on the way in which students may operationalize mathematical concepts in rational arithmetic thus improving the mathematical quality of their learning. It is claimed in the major research that the curriculum should offer a mathematical matrix strong and flexible enough to enable them to manipulate and create the conditions to teach mathematics with quality as a generalist teacher. The main claim in this paper is the difference between those who relate and compress arithmetic procedures and those who remain in rote learning step-by-step arithmetic procedures, that is called the proceptual divide as showed.

Keywords: Arithmetic's, curriculum, pre-service teacher education, proceptual divide, SOLO levels.

INTRODUCTION

This paper presents an exploratory study of a prototype of a mathematics curriculum for pre-service teacher education. In this prototype it is argued that the mathematics curriculum in pre-service teacher education should offer a mathematical matrix strong and flexible enough to enable them to manipulate and create the conditions for students to learn mathematics.

Students who fail to transform rote-learn arithmetic situations into simpler structures by compressing them into thinkable concepts can't relate them to conceptual learning thus stopping them to generate new knowledge in the sense that Gray & Tall (1994) called the *proceptual divide*. The episodes exemplified in this paper are taken from arithmetic tutoring sessions.

To teach the intuitive arithmetic studied in basic education, future teachers need a foundation or construction following a rational method. This distinction between rational and practical arithmetic does not arise from the nature of the subject, but from the method by which it is structured, founded on a deductive theory based on the boundary between arithmetic and logic by adding scientific rigour to the ability of reasoning that future teachers should have.

This view is in line with the ideas of Tall (2007), in developing his theory of mathematical growth by changing focus from process to concept, called *procept*, and seen as:

An elementary procept is the amalgam of three components: a process which produces a mathematical object, and a symbol which is used to represent either process or object. (Gray & Tall, 1994, p.6)

According to this focus on the complexity of mathematical thought (Tall, 2002) we are trying to understand and find how pre-service teachers operationalize mathematical concepts in arithmetic accessing evidences of the *proceptual divide*.

The implementation of a new mathematical curriculum allows to study, characterize and test that curriculum in various perspectives and at the same time, by analysing the student answers in the various tasks like homework's, quizzes and exams, using as categories the SOLO (*Structure of Observed Learning Outcomes*) model from Biggs and Collis (1982) and Biggs and Tang (2007).

Associating the evolution of their mathematical thinking using Tall theories of *Advanced Mathematical Thinking* (Tall, 2002, 2007) and the concepts of *procept*, *proceptual thinking* and *proceptual divide* (Gray & Tall, 1994) as frameworks to perceive the way students conceptualize mathematical concepts.

BACKGROUND

The introduction of a new mathematics curriculum for Basic Education (pre-service kindergarten, primary and elementary teachers) is reflected in teacher education either by the particular definition of a new kind of student (more proactive ones) or by the need for new methods of teaching and learning of mathematics. This opportunity to change the mathematics curriculum for teachers occurs under a combination of factors: amendments to study plans in higher education; the growing concern with the teaching of mathematics in particular due to the poor results of international studies like PISA (OECD) and a significant change in the mathematics curriculum in elementary education.

Considering all these factors we designed a mathematics curriculum for Basic Education at an institution of higher education in Portugal who wants to combine three levels of intervention: a solid mathematical foundation for all pre-service teachers; a comprehensive training for teaching mathematics connection among knowing and teaching mathematics; a didactics and pedagogical approach about what means to teach mathematics.

The curriculum has been developed taking into account the argument that the pre-service teachers need to have a better understanding of mathematical concepts because it helps them gain a greater understanding of the connections among different areas of mathematics and beyond, taking into account that this course is for generalist teachers.

TEACHING MATHEMATICS TO PRE-SERVICE TEACHERS

Issues related to mathematical preparation of future teachers have been investigated in view of training and teaching on education and not have as much importance as the subject of study for conceptual knowledge of these professionals. Studies on this topic have shown signs of concern, because this kind of mathematical knowledge is not present in many teachers (Veloso, 2004).

To Tall (1989) curriculum development should offer student contexts where they develop mathematical knowledge, leading to a significant growth of their mathematical reasoning. This arduous process of transitioning from a less formal mathematics to a more formalized understanding of mathematical processes and concepts, needs to be assessed by the teacher, both in terms of the complexity of thought highlighted and within the quality of learning.

The traditional concept of a mathematics curriculum structured gradually, starting with familiar elementary concepts and to a gradual complexity of structures has not worked for the simple reason that our brain does not function logically like a computer (Tall, 1989).

In addition, there are several conceptions that advocate that, on the one hand future mathematics teachers must have a broad base of didactics and pedagogical training and the knowledge of the mathematical content will be gained from the experience, on the other hand some argue that they should have a large mathematical training and that the pedagogical aspects are going to be acquired with the experience. In our view, both these dimensions should be balanced, and that should exist a compromise here.

The quality of learning

In this study we consider the quality of learning not only as the quantitative grade a student achieve when answering a question but also to the qualitative process of producing an answer using facts, concepts and skills to achieve the solution to that answer. But this is a complex issue because the quality of learning does not depend exclusively on the student, but there's other dimensions like the quality of the teaching itself, and other like is prior knowledge, motivation, self-regulated learning and so on.

In this paper we are experimenting the hierarchical SOLO model to identify only the process of producing an answer.

The SOLO model

Is the emphasis on the analysis of the quality of the responses from students that make the SOLO model interesting for the study. Throughout the development of the problems the focus is not on correct or incorrect answers, but in the structure (nature) of the responses, encoded in categories based on the SOLO levels enabling a more

detailed description of the development of mathematical thought and the quality of their learning.

Table 1: Description of levels in the SOLO model relating them with the response indicators adapted from Biggs & Collis (1982) and from Ceia (2002)

	Mathematical thinking	Indicators
<i>Extended abstract</i>	Goes beyond the topic, make connections to other concepts and generalizations.	Theory, generalization, hypothesis, reflection. Maximum capacity, uses relevant data and interrelations. No felt need to give closed responses allowing possible alternatives.
<i>Relational</i>	Makes complex connections and synthesizes parts to the overall significance.	Compare, explain the causes, integrate, analyze, report, apply. High capacity, uses relevant data and interrelations. No inconsistencies within the subject, but closure is unique.
<i>Multi-structural</i>	Makes some connections but lack a unifying vision.	Enumerate, classify, describe, list, match, working with algorithms. Medium capacity, can isolate relevant data. Can achieve a different conclusion with the same data.
<i>Uni-structural</i>	Makes simple connections without identifying its importance.	Identify, memorize, perform simple procedures. Low capacity, only one relevant data. Jumps to conclusions on a single aspect.
<i>Pre-structural</i>	Provides information loose and disorganized, not related.	Can not relate. Minimal capacity, confused answer. Inconsistent responses.

This SOLO model becomes a tool which allows a framework which assists the implementation of an educational model based on the mathematical complexity of thought, in view of the quality of their learning and allows to avoid the emphasis on a single learning process.

The *proceptual divide*

The procedural approach of learning mathematics is rooted in positivistic frameworks where, through a set of predefined and outlined procedures, one gets an answer. This appears to be embedded on the idea that by doing sufficient numbers of similar (or even identical) exercises one gets the routines needed to learn mathematics. Although the short-term success of such approach is relatively obvious and educational policies adopt such measures, since they guarantee interesting statistical results (seen in the short term) - for example if a student preparing for an exam, repeating the exercise until exhaustion of previous examinations. In the long term it can be seen the flaws of such an approach, when that same student needs to relate content learned in previous years, so there is not a significant learning.

Gray & Tall (1994) use the concept of encapsulation of a process in a mental object, rooted in the work of Piaget to sustain cycles of building mental structures that in Piaget's theory are cycles of assimilation-accommodation, or reification in Sfard's theory.

The use of symbols, however, have a double meaning, introducing some ambiguity between the procedure and the concept. The way students deal with this ambiguity seems to be the root of a quality learning of mathematics.

We characterize proceptual thinking as the ability to manipulate the symbolism flexibly as process or concept, freely interchanging different symbolisms for the same object. It is proceptual thinking that gives great power through the flexible, ambiguous use of symbolism that represents the duality of process and concept using the same notation. (Gray & Tall, 1994, p.6)

This combination of procedural and conceptual thoughts is called *proceptual thinking*. When there is an inability to relate these two types of thinking making it impossible the development of conceptual thinking.

The dichotomy between those who can and those who can not overcome the barrier of procedural thinking is defined by *proceptual divide*. This is one of the biggest barriers and one of the factors that has most contributed towards the failure of teaching and learning mathematics (Gray & Tall, 1994).

Teaching arithmetic's

The foundation of number theory focuses on, in their essence, in two schools, an Formalist represented by Peano and Hilbert among others, and another Logic represented by mathematicians such as Cantor and Russell. In our curriculum there was no concern of using any of the current theory of the integers or an axiomatic

model. What is required in the course is just an introduction to elementary mathematics. It must be therefore an ordination of the theory in such terms that every proposition is a logical consequence of propositions previously demonstrated. The conceptualization thereby requires the establishment of ideas or primitive concepts defined by axioms leading to choose an approach closer to a formalistic model like Peano axioms.

“The fundamental idea in the development of powerful thinking in mathematics is the compression of knowledge into thinkable concepts.” (Tall, 2007, p.150) This compression of knowledge enable students to relate ideas, concepts and *procepts* allowing them to go beyond rote-learning, that a number of studies show that fails in an unfamiliar context, like is showed in the second episode in this paper.

METHODOLOGICAL APPROACH

The examples in this paper show the process of inquiring and reasoning in action. These episodes are taken from one larger ongoing study in which we analyse and evaluate the mathematics curriculum of pre-service teachers and their learning. The aim of this study was to try to understand the mental construction of mathematical reasoning and, more specifically, to see how a student thinks mathematically taking into account the *proceptual divide* notion, hoping to observe it in action.

This specific experiment was designed based on a tutorial interview in which two students (let's call them Ana and Maria) came to clarify doubts on some issues that had been asked in the exam.

These students attended, and failed, *Mathematics I*, and requested these tutoring sessions to clarify doubts for the upcoming exam, so they had already attended classes, either theoretical either practical matters about these episodes, having made various of the exercises about the issue. These two examples were taken from the exam questions, and have been solved in the tutoring sessions.

In these episodes one of us acted as a teacher and as a researcher and two individual sessions of one hour per student were observed, totalling four hours of work. Both episodes about one exercise of rational arithmetic.

One of the goals of this kind of exercises was to enhance not just the resolution of common arithmetic operations, but to establish a parallelism with aspects of a more formal mathematics, intending to develop mathematical reasoning.

By mathematical reasoning, or demonstration, we understand the combination or joining of two or more propositions to obtain new propositions by means of mathematical reasoning within a finite number of steps deduced from one or more propositions. The method worked is the complete induction (or method of recurrence) and to demonstrate that a given property is true for all integers is enough to demonstrate: (i) is true for 1, (ii) admitted as true for n , is also true for the successor of n (heredity).

Starting from the following proposition that is taken as an axiom:

All property belonging to the integer 1 and the successor of an integer that enjoys this property belongs to all integers (principle of finite induction).

The operations studied were the addition, multiplication and exponentiation and are defined as:

1. Adding two integers - the operation that for each pair of integers a and b matches a given integer $(a + b)$ according to the following conventions:

$$[A1] a + 1 = \text{suc } a$$

$$[A2] a + \text{suc } b = \text{suc } (a + b)$$

2. Multiplication of two integers - the operation that for each pair of integers a and b matches a given integer $(a \cdot b)$, according to the following conventions:

$$[M1] a \cdot 1 = a$$

$$[M2] a \cdot \text{suc } b = a \cdot b + a$$

3. Exponentiation - the operation that for each pair of integers a and n matches a given integer (a^n) , according to the following conventions:

$$[E1] a^1 = a$$

$$[E2] a^{\text{suc } n} = a^n \cdot a$$

Thus, it is necessary that the student in the following problem, realize these recurrence concepts to solve: *Calculate, by recurrence, using the respective axioms $(2+2) \cdot 2^1$*

The categories of analysis of the question and subsequent answers are based on SOLO levels and their attributes and this exercise has been classified as possibly *relational* indicating an orchestration between facts and theories involved, their actions and goals. These kinds of exercises were familiar to both students in the classroom environment although it was the first time they had covered this kind of procedure in mathematics.

To take a deeper analysis we used Tall theories covering an important aspect of the *proceptual divide* since the *procepts* here involved are ambiguous (operations can be viewed either in the field of elementary arithmetic or in the field of rational arithmetic).

EXPECTATIONS FROM THE PROCEPTUAL DIVIDE – TWO EPISODES

For Ana this issue had been solved naturally through elementary arithmetic and had not even noticed that, in the task she was asked to use the rational arithmetics, not understanding her low rating. The dialogue between Ana and Maria and myself was held in Portuguese.

Ana: So, but the account is not right? Gave 8 ...

Teacher: Yes, Ana, but read the statement again ...

Ana: Yes ... and ...

Teacher: We used the axioms?

- Ana: What axioms? ... Ah! ... [reread the sentence, looking at the exam and then back at me with a satisfied air]
- Teacher: ?
- Ana: So I must do like in the classroom, with those axioms of operations, right?
- Teacher: Right. [It is noted then a change in Ana, who quickly wrote on a sheet ... $(2+2).2$ (E1)... $(2+ \text{ suc } 1) . 2$ (A1) ... $(\text{ suc } 2+1) . 2$ (A2)... and so on until the right answer]
- Teacher: Why you do not do that in the exam?
- Ana: Well, I did not read the statement professor ... and it was so easy ...

After seeing her failure, Ana had no difficulty in solving the exercise. This is an example in which, looking at the question (not having read it entirely) and especially to the expression, used a familiar process of elementary arithmetic to solve (correctly) the question ... the issue is that she did not answer the question of the exam.

From the moment she really knows what to do, quickly solves the exercise using rational arithmetic's with axioms relating the properties studied by making a change in how she handles the mathematical objects.

In the exam she focused on the procedures looking for the expression in a disconnected way between number and operation, subsequently, by looking to the expression as a whole, she identified the respective axioms.

In this episode Ana easily surpassed the *proceptual divide* on this issue, rapidly changing their mathematical thinking from procedural to *proceptual* simply by reading again the question. When analysing the responses through the SOLO levels, Ana went from a response classified as a possible *uni-structural* level (in the reply to the exam) by jumping to fast for a conclusion, to a response in possible *relational* level (in the tutoring session) by generalizing within the given context using related aspects which corresponds to the level intended to the question. The next episode with Maria went up differently:

- Maria: Professor I did not understand what it was is that I supposed to do in this exercise ...
- Teacher: So, Maria?
- Maria: asks to do math, but with what axioms?
- Teacher: those who were worked in class, you don't remember?
- ...
- Maria: but this was not just in lectures? I mean we had to decorate these axioms, it could come in a form ...
- Teacher: why?

- Maria: We've done a few of these exercises, and always with an operation only, never with several, so one cannot memorize everything ...
[after almost an hour to explain the resolution and how it should identify the propositions]
- Maria: My head does not give much more, this is very complicated ...
- Teacher: Tell me why?
- Maria: Only theory, when I teach kids, I will not teach so, teaching them only to do the math, none of these things successors and properties and axioms ...
[and we continue with a discussion of what it was to be a teacher ...]

In this example, Maria was so attached to the procedure that after two sessions she still didn't realize that she could not rote this kind of exercise. Even the very procedural knowledge (she couldn't understand the procedure) was deficient because she could even identify the numeric expressions as more complex *procepts*. In this case the *proceptual divide* is in line with the ideas of Gray and Tall when they state that:

This lack of a developing proceptual structure becomes a major tragedy for the less able which we call the proceptual divide. We believe it to be a major contributory factor to widespread failure in mathematics. (Gray & Tall, 1994, p.18)

At the end of the sessions, Maria could solve some issues, but with only two integers and one operation, having been scheduled a third session, with some exercises proposed by the teacher (which never came to happen until the next day of examination). The responses of Maria (on examination and tutoring session) were classified (according to the SOLO levels) as possibly *pre-structural* with great inconsistencies and later *uni-structural* by jumping to fast to conclusions, far from the outcome intended with the exercise.

FINAL REMARKS

In this paper we analysed two episodes in an attempt to expose the conceptualization of Gray and Tall on the *proceptual divide*. The work of Ana and Maria (like all his colleagues) is to overcome the barrier of elementary arithmetic and think mathematically about a set of properties that are common to the operations studied in any circumstance, through the generalization that is possible in the rational arithmetic and this separation was identified by their different characteristics.

The use of the SOLO levels to characterize the questions and answers has the limitation of identifying an image at the moment it is not possible, and in isolation, assess the students' mathematical thinking, hence the necessity to use other methods such as inquiry, to obtain a better understanding of the phenomena under study.

Ana's success depended more on concentration and ability to read the sentence, since after a few questions (directed to read of the sentence and not to the mathematical

content), managed to solve that problem, and others - and subsequently had a positive rating the exam by solving a similar issue using other properties of operations so it's unclear that she crossed the *proceptual divide* by means of the intervention (which was not the aim of this paper) or that she already is using *proceptual thinking* and the problem with the exercise was only due to misreading, Maria failed again in the exam, but in a similar issue she solved partially (only the addition, which was detached), revealing still be using only procedural thinking, having failed to overcome the barrier of *proceptual divide*.

Both examples are used to identify differences in the mathematical thinking related to the same exercise and require further and clearer evidences of the *proceptual divide* that could be an important mechanism for mathematics teachers and researchers in mathematics education.

THE INFLUENCE OF EARLY CHILDHOOD MATHEMATICAL EXPERIENCES ON TEACHERS' BELIEFS AND PRACTICE

Judy Sayers

The University of Northampton

This paper shows how particular forms of formative familial experiences provide prospective teachers with the intellectual tools necessary for undertaking critical analyses of both the received and intended curriculum. Data from a multiple case study shows that beliefs formed through early mathematical experiences stay with individuals to reveal themselves in subsequent beliefs and practice.

Key words: teachers, early childhood, beliefs, practice, norms.

INTRODUCTION

This study follows in the tradition of research into the relationship between teachers' espoused beliefs and their enacted practices (Beswick, 2007; Skott, 2009; Thompson, 1984). It draws on a multiple case study of the whole class interactive phases of the mathematics lessons of six English primary teachers and the rationales they offer for their actions. The data yielded two distinct groups of three teachers, essentially defined, as I explain below, by their early mathematical experiences. All six teachers were similarly qualified, were enthusiastic teachers of mathematics and considered, by their colleagues and others, as ambassadors for the subject. It came as a surprise, therefore, when my analyses highlighted not only substantial differences in practice-related beliefs and the enactment of those beliefs but also the ways in which early childhood influences had moulded such different teachers. Three elements of teachers' practice were identified in the larger study: mathematical intentions, pedagogical approaches and classroom norms. In this paper, due to reasons of space, I report on *classroom norms* (Yackel & Cobb, 1996), and on two of the six teachers, one representative of each group, to highlight the resonance between beliefs, practice, and early childhood experiences.

THEORETICAL BACKGROUND

A number of studies, both theoretical (Ernest, 1989) and empirical (Beswick, 2007; Furinghetti & Pehkonen, 2002; Skott, 2009), have highlighted the influential role of teachers' beliefs on classroom practice. In particular, Ernest argues that teachers' perspectives on the nature of mathematics influence the construction of their mental models of the subject and its teaching. Thus, although subject knowledge is important, it is not sufficient by itself to account for the differences between mathematics teachers. English teachers, the focus of this paper, are typically thought to hold beliefs more in accordance with traditional than reform practice, emphasising the mastery of symbols, skills and procedures (Andrews, 2007).

Warfield et al. (2005) argue that the relationship between "teachers' beliefs and their instruction is not as direct as sometimes thought" (p. 442), stressing that it is not unusual for individuals to hold contradictory beliefs, thereby making it difficult to determine how particular beliefs influence practice. This may be because teachers' mathematics-related beliefs draw on not only beliefs about mathematics and its teaching, but also beliefs about themselves as teachers and the classroom context in which it occurs. Moreover, beliefs about schools, teaching and mathematics will first be formed during childhood. Therefore, understanding teachers' beliefs, which here are construed to be "subjective, experienced based, often implicit knowledge" (Pehkonen & Pietilä, 2003, p. 2), and their genesis about mathematics is important if we are to understand the relationship between beliefs and observed practice.

We know that trainee teachers who experienced failure at school may develop beliefs and practices focused on protecting their students from the pain induced by such experiences. The opposite is also likely to be true; students who recall positive experiences as learners of mathematics will approach teaching positively. Thus, it seems reasonable to assume that mathematics teachers who learned procedural mathematics successfully may have difficulty accepting the validity of alternative practices; their experiences will foster beliefs that will underpin their approaches to mathematics teaching (Handal & Herrington, 2003). Moreover, Muir (2012) has shown how parents influence not only their children's beliefs and attitudes towards mathematics, but also their learning of the subject and the development of their self-efficacy. That is, there appears to be a clear link between parents' attitudes, perceptions and beliefs about mathematics and children's attitudes and performance in mathematics. Yet, little research has explored the nature of parental perceptions of and attitudes towards mathematics in general and its impact on their children's, children who subsequently become teachers, perceptions, values and understanding of the subject.

Consequently, this paper aims to address the following questions: How do primary teachers of mathematics conceptualise the whole class aspect of their work? With sub-questions: 1) What knowledge and beliefs underpin their actions? 2) In what ways do the espoused beliefs resonate with the enacted? 3) What justifications do they present for their actions?

DATA COLLECTION AND ANALYSIS

A number of studies (Thompson, 1984; Beswick, 2007) have shown that case study can facilitate our knowledge and understanding of the relationship between teachers' espoused beliefs and enacted practice. Thus, a multiple exploratory case study (Stake, 2002) was undertaken to examine individual teachers' perceptions of, and justifications for, what they believe they do in the whole class interactive phases of their mathematics lessons. This involved six primary teachers, each considered locally to be an effective teacher of mathematics or, importantly, an ambassador for

the subject. Such an approach controlled for various teacher characteristics such as teacher confidence or indifference towards teaching the subject.

For each teacher, data collection involved an initial semi-structured interview, followed by between three and six, video-recorded, lesson observations. To examine the relationship between espoused and enacted practice recorded lessons were viewed jointly by me and the teacher concerned as components of repeated video stimulated recall interview (SRI). Data were analysed by means of constant comparison (Glaser & Strauss, 1967), a process whereby newly collected data from one lesson were compared with data collected from the previous lessons and interviews, and, in so doing, facilitates the development and refinement of theory. In this paper, due to limitations of space, I discuss two of these teachers; each one being representative of one of the two distinct groups that emerged from the larger study.

THE STUDY RESULTS AND DISCUSSION

In the following I present and discuss a summary of the data on each teacher's *background* and the *classroom norms* that emerged in the observations and explicitly emphasised by the teacher in the interviews that followed. The first section on their background is presented against the three broad headings that structured the interview analyses. Teacher utterances are italicised. These concern the following: 1) Mathematics as a subject; 2) Confidence in mathematics knowledge for teaching; 3) Being a teacher of mathematics.

Mathematics as a subject

Both teachers (Caz and Gary), stated they enjoyed mathematics as a child. However differences between these teachers were only highlighted when specific aspects of their enjoyment were discussed.

Caz believed she had a *natural talent* for mathematics and recalled how she assumed everyone else was enjoying mathematics just as she was. She could not understand why mathematics *wasn't so obvious to everybody at school*. She believed her enjoyment of mathematics stemmed from a family view in which mathematics was challenging but interesting. She spoke much about her engagement in exploring mathematics at home as a young child with her father and younger brother. Believing that the sort of *games found on the Nintendo DS today with puzzles and games and things, were similar to the things we used to do with pencil and paper together at home*. She had always enjoyed playing with, number and logic puzzles, and remained keen to engage her own class in interesting mathematics, like the exploration of the work of Fibonacci that she had experienced as a child with her family. She believed her father had a significant influence in how she viewed mathematics.

Gary in contrast described how he found mathematics unproblematic at school, and could describe very little about family influence regarding the subject. He remembered being good at the subject, and talked about *the rightness and wrongness*

of mathematics. In particular he remembered *he enjoyed working through his text books, getting lots of ticks and feeling very motivated by the correctness of his neatly presented work*. He appeared to enjoy a procedural approach to learning mathematics, appreciating *small steps* and clearly defined levels of progress. Gary remembered learning and *memorising tricks* and talked about how *they worked for me*, and therefore used them in his approach with his class.

Confidence in Mathematical knowledge for Teaching

Both teachers were confident in their mathematical knowledge for teaching. Gary trained as a primary generalist with a mathematics specialism, whereas Caz gained a degree in early child psychology, before gaining her teacher status, where she studied children development and theories of learning which she often referred to in her interviews. Gary remembered how he found the specialism of his degree interesting, but did not remember anything in particular about his training, other than teaching approaches acquired during teaching practice.

Being a Teacher of Mathematics

When discussing being a teacher of mathematics, colleagues' utterances frequently referred to the latest official directives and exploited the vocabulary embedded in them. Admittedly, they were all mathematics specialists, so perhaps this should have been expected. It could be argued that this acceptance and exploitation of vocabulary, only teachers would be expected to understand, reinforces primary teachers' professional identity, not least because "our identities are composed and improvised as we go about living our lives embodying knowledge and engaging in our contexts" (Connelly & Clandinin, 1999, p. 4). That is, continuing participation in this 'nationally led' vocabulary is not only a source of identity within the primary teacher community (Wenger, 1998) but the means by which they remain part of the primary teaching community.

In conclusion, the initial interviews revealed both interesting and pertinent characteristics about the project teachers. When analysing their backgrounds, views and beliefs, a dichotomy of experiences emerged: Caz was representative of one group, and Gary the other. The table below illustrates the very strong differences between these teachers' perception of mathematics.

Experientially-formed beliefs: Beliefs as learner, trainee and experienced teacher.	Teacher	
	Caz	Gary
Believes they have a natural talent for the subject and strongly influenced by family views about the subject	✓	
Found mathematics unproblematic in their own schooling of the subject		✓
Found mathematics challenging but enjoyable in their own learning of the subject	✓	

Enjoyed a mechanical approach to mathematics at school – the challenge of working through text books and levelled cards of questions		✓
Influenced by courses and training in how children learn or the learning of mathematics	✓	
Influenced by teachers they have worked with and Senior management team		✓
Concerns about children’s engagement with the mathematical learning e.g. children groupings and how discussion develops learning	✓	
Concerns about children reaching targets and motivating children to work and achieve		✓
Believes the way mathematics is taught now is much better or more fun than when they were young	✓	✓

Table 1: Differences in perceived beliefs

The results resonate strongly with earlier research highlighting the connections between beliefs formed during the early learning of mathematics and practice (Thompson, 1984; Ernest, 1989). The characteristics of these two groups will be discussed below, but, crudely, the first group, represented by Caz, held a relational perspective on mathematics and its teaching, while the second, represented by Gary, illustrate an instrumental (Skemp, 1976). Moreover, the evidence indicates that the members of both groups still enjoyed the same things as when they were young, and that these formative beliefs are not only deep rooted but reflected in their perspectives on their own classrooms. This perspective will now be presented through the classroom norms emphasised by each teacher in observations and SRIs.

Classroom Norms

Classroom Norms (CN) emerged from the data in all cases of the study which identified a regular pattern to the way in which the teachers conducted their Whole Class Interaction (WCI) in mathematics lessons. Each individual was seen to behave and offer consistent perceptions for that behaviour thus establishing a classroom norm as described by Yackel & Cobb (1996) and Chazan et al. (2012). Utterances made by the teacher are presented in all cases in *italics*.

The teachers fall into the same two groups as presented earlier in their background influences. That is, ‘the understanding that students are expected to explain their solutions and their ways of thinking is a social norm, whereas the understanding of what counts as an acceptable (mathematical) explanation is a sociomathematical norm’ (Yackel & Cobb, 1996, p. 461). There are three main threads to the discussion of classroom norms which are presented in the table (2) below:

Structural Norms	highlight the lesson structures through which teachers present mathematics during WCI phases. For example, the emphasis made on explicit learning objectives and success criteria, discussion, and particular peculiarities of whole
-------------------------	--

	class phases, time and flexibility
Cognitive Norms	encompass the emphasis a teacher makes to developing children as enquirers and problem solvers of mathematics in general, the precision and fluency procedures, and whether an instrumental or a relational approach to teaching and learning is made in WC phases
Attitudinal Norms	illustrate the emphasis the teacher places on developing children's confidence, motivation to learning/mathematical learning, enjoyment of learning/mathematics and the teacher's actions and styles connected to <i>social</i> relationships emphasised by the teacher

Table 2: Classroom norm key threads

Structural norms appeared very similar between teachers, for example, both teachers presented learning objectives (LOs) on their boards, but their rationale for doing so was quite different. In so doing, they exploited routine behaviours familiar to them and their children. Caz, LOs were broad and, I argue, commensurate with her ambitions that her children should remember the mathematics and not the context. For example Caz had asked her class to increase the mass of cake sizes by ten, she said *I want them to remember we were multiplying by 10 and 100 and not learning about cakes!* She consistently encouraged her children to offer ideas and questions about the learning objectives (a social norm). However the manner in which children responded to questions indicated their awareness that they were expected to provide mathematical justifications or reasoning behind their contributions. In short, she presented mathematics as a way of thinking and behaving (sociomathematical norm).

In contrast Gary spent much time emphasising what he intended to be learnt, with between three and six LOs presented every lesson, meticulously going through each in detail. Such actions, while superficially mathematical, concerned the establishment of behavioural, rather than cognitive patterns of working and so, I argue, reflect a social norm, because they are no more than a 'telling' of what children are to learn. This approach was also seen in his use of success criteria (a list of how children will learn the objectives displayed). This is an important distinction and something likely to be hidden from Gary, who believed, as his institutional management team had reiterated, an effective teacher is one who ticks off each of a series of 'teaching skills'. For example: *go through learning objectives with the class – tick. Go through the vocabulary – tick.* It is not wrong it is simply reflective of instrumentally- rather than relationally-focused beliefs (Skemp, 1976).

Discussion was managed in different ways. For Caz discussion frequently included paired talk, questioning and argumentation. She expected children to think and make connections between the mathematics and real-life experiences, as described by Weber et al. (2008). Gary typically followed an Initiation Response and Feedback (IRF) format. The manner, in which this played out in enacted practice, was quick with rapid closed questions answered by selected students. The social norm was for children to sit quietly in front of their teacher and listen and wait to be asked.

To summarise these differences is to acknowledge that children develop learnt behaviours as either autonomous or dependent learners. Autonomous learners ask their teacher questions and offer ideas even if they might be wrong. They talk about their mistakes and misunderstandings publicly. Dependent learners are quiet, essentially passive, but highly attentive to their teacher. The key point however, is directly related to their teacher's approach (Lawson, 2004), and I would argue, their teacher's belief of what it is to be a learner.

Cognitive norms differed greatly between what the teachers perceived as games, and what they understood by whole class discussion. Games were played in both teachers' lessons, and in particular at the beginning. Caz used, for example, speed against the clock games for recalling facts, through perhaps dance routines to jog memory and paired games to develop calculation strategies and vocabulary. She said they *really enjoy playing those sorts of games* (competitive pairs). *They make it really hard for each other too* (with their questions). The emphasis for using games was to make their *children think and talk using new mathematical vocabulary and plan their strategies to win* thus providing an opportunity to behave mathematically (a sociomathematical norm).

Although Gary also used games his rationale was quite different. He frequently used structured tasks, such as writing out times-tables forwards and backwards, which he described as a game. He justified these as time fillers (social norm) and not a sociomathematical norm. At other times he exploited a game called 'popcorn', whereby he calls out a number and, in one variant of the game, children sit if the number is odd and stand if it is even. He varied it so to try to catch children out and, in observed lessons children seemed to enjoy the activity. Interestingly, Gary spoke about it as *breaking up the lesson, to get a bit of movement going, we even go into the millions of whole number, just associating a bit of quick thinking ...that's an even number, I need to stand up, odd numbers oh I sit down*. In such accounts we can see a social rather than mathematical norm where the emphasis was on having fun.

All teachers develop cultural routines and rituals that children come to know (Alexander, 2000) and two such rituals, concerned thinking time. Gary provided short opportunities, typically between three and seven seconds, for children to think about a question before answering. Caz provided several minutes for discussion through whole class or paired talk. Such distinctions typically permeated the lessons of each group.

There has been some discussion in primary education about what pace actually means. Official documentation in England (OfSTED, 2005) indicate that a fast pace is necessary during direct teaching. However, the confidence of the official version of pace is at odds with the literature, e.g. Alexander (2000) write that 'an observer may be deceived into concluding that pace of classroom talk equates with pace of pupil learning' (p. 430), perhaps a pointless exercise if it is not appropriate.

The belief of both project teachers, quite naturally, is that they do what they do because they believe their approaches are effective and educationally beneficial. Yet the research into WCI phases of mathematics lessons (Alexander, 2010) indicates otherwise. In conclusion, the pace and the relationship to the amount of thinking time given to children dichotomised the teachers. Although the time provided for thinking reflected a social norm in each classroom, the conceptions presented by each teacher highlighted differences in a mathematical emphases. Caz believed that children should co-construct their answer to develop mathematical thinking, whereas Gary believed *he* was structuring children's thinking.

Attitudinal norms were presented through their different emphasis on children's enjoyment, confidence and motivation of mathematics. When Caz, emphasised her desire for their children to enjoy mathematics, she did so in relation to their structuring their children's learning of mathematics. It was a cognitive tool rather than an end in itself. Consequently, her ambition reflected a sociomathematical rather than a social norm. Gary, however, discussed enjoyment in very different ways. While it could be argued that his desire for their lessons to be fun helped to maintain his children's focus and concentration, he believed that enjoyment of mathematics would lead to success and increased confidence, as found by Skott's (2009) research on teachers. Gary spoke of how 'target children' were asked lots of questions to build their confidence, for example. Frequently, saying ...*oooh that was a very good answer or good girl or good boy*. Such actions reflect a social norm (Yackel & Cobb, 1996). A justification for his actions may lie in the fact that he paid great attention to the children he perceived as weak. Gary was focussed on progressing all his class two sub-levels in their curricular assessments (as instructed by his senior management) and so worked hard on those at the margin of that.

To summarise classroom norms, important similarities and differences between the teachers' beliefs and practices are highlighted. The classroom norms illustrated in these two classrooms seem in accordance with individual teacher's core beliefs about learning. What is of substantial interest, and an appropriate site for future research, is the clear distinction between the two groups of teachers was either constantly encouraging social norms or encouraging sociomathematical norms. The group, emphasising social norms focus on the achievement of particular behaviours which just happen to be in mathematics, not the mathematics itself. The opposite reflects a more relational learning that is created through sociomathematical norms that encourage a collective, co-constructed learning is rooted in mathematics.

CONCLUSION

Both teachers were, not only considered to be strong mathematically, but leaders of the subject, (according to local definitions) effective teachers of primary mathematics. Yet two distinct groups of teachers consistently emerged through their background perspectives and their classroom norms, despite the fact that all these

teachers are well qualified, there remain substantial differences between them in respect to their early background experiences related to the subject, and how their subject knowledge plays out in the classroom.

This study indicates that what transpires during the whole class interactive phases of a lesson is far more complex than a simple analysis of subject knowledge can reveal (Skott, 2009). Teachers draw on core beliefs about mathematics and mathematics teaching that are frequently immune to change (Handal & Herrington, 2003). The findings of this study, suggest qualitatively different teacher characteristics. On the one hand are teachers who behave autonomously; teachers who mediate the constraints within which they work, and perceive learners to be autonomous. On the other hand teachers who appear dependent are mediated by the constraints within which they work, and emphasise dependent learners in the classroom norms. Of course, this is a simple summary that belies the layers of complexity of what an individual teacher chooses to do in any given set of circumstances. Yet it highlights a strong relationship between how they viewed, valued and played with mathematical ideas at an early age, and continue to manifest this approach in their own teaching.

TEACHING PRACTICES TO ENHANCE STUDENTS' SELF-ASSESSMENT IN MATHEMATICS: PLANNING A FOCUSED INTERVENTION

Sílvia Semana, Leonor Santos

Research Unit of Institute of Education of Lisbon University, Institute of Education of Lisbon University

This paper focus on the planning process of a teaching intervention aimed at promoting students' self-assessment in mathematics. We present an interpretative case study of a collaborative group, planning assessment practices addressed to students' appropriation of assessment criteria in mathematics. The study allow us to: describe the main focus and factors considered in the planning processes; identify the key practices/strategies planned; and understand their foundations. It also highlights the importance of planning formative assessment practices in mathematics and gives some insight into that process.

Keywords: formative assessment practices, planning, self-assessment, assessment criteria, mathematics

INTRODUCTION

Self-assessment is a privileged form of formative assessment (Nunziati, 1990; Santos, 2008) that helps students to take greater responsibility for their own learning (Sadler, 1989) and leads to significant improvements in their achievement, particularly in mathematics (Brookhart *et al.*, 2004). However, the development of self-assessment isn't easy and requires several conditions, which should be promoted by teachers, through formative assessment practices (Wiliam, 2011). To be effective, these practices should be carefully planned.

This study is part of a broader research [1], trying to understand assessment practices of teachers, aimed at promoting students' self-assessment in mathematics. These practices are addressed to: (i) an intentional oral communication during whole-class mathematical discussions; (ii) the appropriation of assessment criteria by students; (iii) the development of students' written self-assessments. They are integrated into a teaching intervention planned in a context of collaborative work involving the first author of this paper (researcher) and four mathematics teachers (grades 7 to 9). In this paper, we focus on the planning process of the teaching intervention, especially with regard to assessment practices addressed to appropriation of assessment criteria, during an initial period of 9 months. We consider the following research questions: (i) What were the main features of the planning process (level of planning, influencing factors and focus)? (ii) What planning decisions were made by the group regarding the definition and implementation of classroom practices? (iii) What reasons have substantiated such planning decisions?

Although the importance of teachers' practices is widely recognized in the context of formative assessment, very few research has been presented in the particular context of mathematics, namely at previous CERME conferences.

THEORETICAL FRAMEWORK

Teachers' practices can be viewed as the activities that they regularly conduct, with certain meanings and intentions, in their working context (Ponte & Chapman, 2006). When teachers develop assessment practices intended to enhance students' learning, we may speak of formative assessment. Formative assessment "accommodate[s] all the ways in which assessment can shape instruction" (William, 2011, p. 40), it involves elicitation, interpretation and use of evidence about students' learning to make founded decisions about teaching and learning (William, 2011).

There are some key strategies that are associated to the territory of formative assessment: (i) clarifying and sharing learning intentions and criteria for success; (ii) engineering effective classroom discussions, questions and learning tasks; (iii) providing feedback that moves learning forward; (iv) activating students as the owners of their own learning; (v) activating students as instructional resources for one another (Leahy, Lyon, Thompson & William, 2005). However, there isn't a *one-size-fits-all package* (Leahy *et al.*, 2005), so it is not enough for teachers to know these strategies. They need to study, and possibly discuss with others, how to implement these strategies in their own classrooms. Otherwise, "without this space for teachers' voices, it seems likely that formative assessment will be enacted more as a set of techniques rather than as a step towards a more dialogic form of teaching" (Hodgen, 2007, p. 1893).

Self-assessment is an internal process of regulation of own thinking and learning (Nunziati, 1990) that is vital for learning (Black & William, 1998). It includes monitoring and action: the student confronts what he/she did with what he/she was expected to do, acknowledging the differences between these two situations, and acts to reduce or eliminate them (Sadler, 1989; Santos, 2008). Therefore, assessment criteria are a reference and a needed condition to self-assessment, but they are just its starting point. They must be legitimate for students and allow them to understand what is expected of them (Hadji, 1994), they must be *appropriated* by students. However, this is quite rare and difficult since the meaning given by students to the criteria may be different from the one given by the teacher (Vial, 2012). Moreover, one must take into account the didactic tension: "the more clearly the teacher indicates the behaviour sought, the easier it is for students to display that behaviour without generating it from understanding" (Mason, 1998, p.2). So, it is necessary to create opportunities for students to really understand the criteria in the context of their work (Black & William, 1998) and to develop ways of promoting a state of *working-on*, instead of *working-through*, in mathematics classroom (Mason, 1998).

Classroom discussions are excellent opportunities for the development of formative assessment practices. In particular, teachers should engage students in discursive practices, encouraging them to develop, explain, justify and assess their ideas and

those of colleagues (Henning *et al.*, 2012); promote the establishment and respect for rules of interaction; and direct the focus of discussion, cautioning the development of important mathematical aspects (Chazan & Ball, 1995).

Given the complexity of effective formative assessment practices, teacher collaboration might be especially useful (Hargreaves, 1998). Besides that, careful planning is essential. In fact, planning processes are central in teachers' practices, but they are typically undervalued (Calderhead, 1996; Clark & Peterson, 1986; Shavelson & Stern, 1981).

Teacher planning is both a psychological process – in which teachers visualizes the future, inventories means and ends, and constructs a framework to guide their action – and a practical activity – the things that teachers do when they say that they are planning (Clark & Peterson, 1986). Planning include three phases: preactive (before teaching), interactive (during teaching) and postactive (after teaching) (Milner, 2001). Calderhead (1996) presents the main features of planning processes: (i) planning occurs at different and interconnected levels, from yearly and long-term plans to lesson plans, and may be seen as “a continuous process of re-examining, refining and adding to previous decisions” (p. 714); (ii) planning is mostly informal, teachers plan by mentality focusing on aspects that need their attention (iii) planning is creative, it does not follow a linear process from specified objectives to activities planned to accomplish them, it has a problem-finding and a problem-solving phase; (iv) planning is knowledge-based, teachers base their planning on different kinds of knowledge (for example, knowledge of subject matter and of students); (v) planning must allow flexibility, to adapt planned activities accordingly to the situations that might emerge; and 6) planning occurs within a practical and ideological context, since there are various factors that influence teachers' planning as policy expectations, textbooks or other materials being used, teachers' experiences and conceptions of mathematics teaching and learning.

METHODOLOGY

This is an interpretative case study (Yin, 2002), being the collaborative group considered as one case. Special attention is given to questions of "how" and "why" the collaborative group plan the teaching intervention aimed at promoting students' self-assessment in mathematics. The collaborative group was constituted to the broad research purpose. The four teachers were chosen to take part in the group, based on the following criteria: to evidence sensitivity concerning issues related to the research aim and openness to consider them in their professional practices; to have different professional experience.

In this study, collaboration is characterized by joint work, in order to provide mutual support and the achievement of goals (not necessarily the same) that benefit all (Boavida & Ponte, 2002). Participants must feel comfortable in their roles (not necessarily the same) and be attentive to the needs of others and open to negotiate understandings emerging from the collaborative effort (Hargreaves, 1998).

Collaborative group meetings lasted a total of 25 months and included the planning of the teaching intervention and assessment of the practices/strategies after implementation in classrooms. The planning process took as starting point the development of a shared understanding regarding the objectives and guidelines that frame the intervention, based on the discussion of various documents, especially associated with formative assessment, oral communication and collective discussions in mathematics classroom. Initially, the researcher played a key role in the collaborative group, being responsible for: (i) negotiate the general goals of the teaching intervention to be planned, (ii) propose documents and materials as basis for discussion and work, (iii) propose points for the agenda of the meetings. Over time, these roles were shared with teachers, as they were feeling more comfortable with the topics addressed and the work was putting focus more on planning and reflection on real classroom practices, rather than on theoretical perspectives.

Data collection includes participant observation of 15 meetings of the collaborative group (meetings were audio recorded; code M1 to M15 is used to identify each meeting), supported by document collection of teachers' planning materials. The process of data analysis included: the transcription of the meetings recorders; the selection of relevant parts of the texts, keeping the coherence of discourse; the interpretation of the texts reduced, taking into account who talks and his/her intention and the context. This interpretation involved the identification of perspectives, ways of being and acting presented in the participants' speech, which led to the identification of themes. In this paper, in particular, is not explicitly compared or contrasted the speech of each participant, but considered the speech of all participants in the construction of a collective discourse of the collaborative group. The transcripts presented in the following section were translated from Portuguese.

ANALYSIS AND RESULTS

Defining assessment criteria in mathematics

The assessment criteria are recognized, by the group, as essential to clarify what is expected of students in mathematics classroom and help them to self-assess accordingly:

Valter: It has to be very clear to them what they're supposed to do.

Researcher: Yeah.

Valter: Because that is what allows them the self-regulation.
(...)

Filipa: We have to give him the assessment criteria (...) for him to know how he will be assessed (...) isn't it? (M5).

In particular with regard to the students' self-assessment, the group agreed that they tend to be not criteria-based (or use criteria different from the ones of the teacher):

I think they have many difficulties ... when I ask them a self-assessment, they are not (...) being more criteria-based when a person asks them: (...) What do you think you can do to improve your learning? It is where ... I think they have difficulties (Filipa, M2).

The group have agreed that the assessment criteria should reveal the expectations concerning the role of students in collective mathematical discussions, in particular as regards to aspects diagnosed as source of resistance and difficulties for students:

[Example 1]

Researcher: I think that if this is a problem in your students [do not value the collective discussion], in the assessment criteria (...) it should be evident that one of the things that they are expected to do is (...) comment or ... whatever ... but ...

Filipa: Yeah, know how to assess...

Joana: Know how to justify his option. (...)

Filipa: ... criticize the other, criticize the speech of the other (M4)

[Example 2]

Filipa: I think it's very important [that they compare, analyse, relate ...]. Because I think that it is what they have more difficulties. (...)

Valter: The ability ... to be able to argue on the basis of the argument presented by another, counter-argue, I find it an asset. To seek to understand the other's perspective (M5).

Furthermore, the group stressed the need for the criteria to put a focus on mathematics: "It's important that there is debate among students, but I have to emphasize that they have... there must be mathematics, if not they will not realize: Well, I participated a lot" (Valter, M4). Thus, the group defined assessment criteria in three domains of mathematics: Concepts and procedures; Strategies and processes of reasoning; Communication.

Working assessment criteria with students

For presenting the criteria, the collaborative group first use a table of descriptors for various levels of performance. But this table was considered too complex for students: "will they understand all this text? The 7th graders? I have some [students] of the 9th grade who will lose themselves (Filipa, M7)". So it was created a simplified assessment grid, presenting a description of what is expected of students for each criterion. To prepare this grid, the group sought to use a language accessible to students:

Valter: They have a restricted code of language. (...)

Filipa: If you put "I make good oral statements", they understand. (...)

Valter: The student must know to what he is answering. (M8)

Aware of the difficulties that some terms could still cause (particularly *systematic solving strategy*), the group considered the importance of negotiating its meaning with students, using concrete examples: “Or give an example (...) They [students] have to realize (...) I think that with an example is better” (Valter, M8).

Following the same assumptions, for a first approach to the assessment criteria in the classroom, the collaborative group decided to involve students in an assessment experience of work samples, using the assessment grid. Strengths and weaknesses should be identified in light of the criteria and a negotiation process should be developed, allowing students to propose changes, but without jeopardizing the key ideas considered by the group:

Researcher: ... the idea was also to leave (...) students, isn't it? ... if necessary, change something. Let them even...

Joana: ... suggest...

Researcher: "So you think that here, perhaps, would be more clear to you this?"

Joana: Sure. (...)

Researcher: Without removing what we consider essential, isn't it?

Joana: I think so. (M7)

In addition, the group realized the need to invest systematically in the appropriation of the criteria, as a whole, in the context for which they were planned – collective mathematical discussions with presentation of students' work. To operationalize this idea, the group planned a first cyclical model of lessons, comprising: (i) performing the task in small groups; (ii) groups' presentations and collective discussion; (iii) students' self-assessment; and (iv) confrontation between students' assessment and the one performed by the teacher, followed by whole-class discussion. In this model, self-assessment is developed by filling the assessment grid, aiming to reinforce the criteria by which students must guide and assess their performance. Self-assessment is asked to groups of students, rather than individually, to encourage discussion and simultaneously not expose individual cases of students who may eventually feel more constrained. The whole-class discussion about teacher's and students' assessments, including teacher feedback, was specially planned to open doors to the negotiation of meanings regarding the criteria and the clarification of what is expected of students, using concrete examples of effectiveness in the classroom, but without constraining students:

Researcher: I think the advantage (...) is that it only speaks...

Sofia: ... who wants, isn't it?

Researcher: ... who feels comfortable to present his case (...) So, we defend cases of students who do not want to expose themselves...

Filipa: Sure.

Researcher: So, they don't feel obligated to do it, but nevertheless they are being confronted with the assessment that the teacher did, and with the examples of others they can... (M9).

Assessing and rethinking practices

To assess the effectiveness of the model and rethink future steps, the group considered to stop/close the corresponding cycle, at proper moments, asking individual written reflections to students as self-assessment.

Filipa: ... what do you think about (...) putting this [model] in all lessons of a [mathematical topic]? (...)

Valter: And, maybe, taking off occasionally to see what is already achieved....

Joana: Yeah. (...)

Researcher: (...) the idea is, later, as Valter said, that they no longer need it [the assessment grid] (...) Maybe it should be interesting (...) after the end of the topic, to ask for a written reflection, for example, no longer...

Valter: ... without the grid in front. (...)

Researcher: And then, through these reflections we can also see if it is necessary (...) to continue or not. (M9)

The group defined a new cyclical model of lessons, similar to the previous one but more flexible, for application when students show a reasonable understanding of the criteria. In this model, self-assessment of students is developed through a written reflection, which may be open or oriented depending on its main purpose:

Researcher: [We want that students] are able to reflect, self-assess their work, also to find strategies to improve (...) maybe in order to a reflection (...) be more useful to them (...) some guidelines may be provided (...)

Valter: This can go through (...) at some point ask for a reflection with some indications (...) And then, later, give again a reflection that is open (...) to see if things meanwhile were being internalized. (M14)

This phase of self-assessment and the next one (whole-class discussion of the assessments) might not happen every time, so they don't become routine procedures that don't raise reflection:

Filipa: ... they [students] do a written reflection for each task and it ends the conversation! (...) is for their own good! (...)

Researcher: It depends (...) Because it may become a tedious process and they are always writing the same thing, you know? Instead of evoking reflection, be...

Filipa: Yes.

Sofia: It becomes routine. (M5)

DISCUSSION AND CONCLUSIONS

In this study, planning has gathered characteristics, mainly, of a long-term planning – a structure of what to do was defined – but also of other levels of planning – how to operationalize some practices/strategies was considered in some detail (Shavelson & Stern, 1981). Thus, different levels of planning were contemplated and have informed each other (Milner, 2001). Nevertheless, since the teaching intervention presupposed the introduction of innovative elements in teachers' practices, long-term planning emerged as the most significant in a first stage (Milner, 2001).

Planning was developed based on different types of knowledge and was influenced by several factors (Calderhead, 1996), in particular: (i) knowledge of mathematics curriculum, literature and teachers' conceptions about teaching and learning mathematics, in order to define the assessment criteria and the expected roles of teacher and students in the intervention lessons; (ii) teachers' previous experiences and knowledge about their students to inform about challenges and difficulties; (iii) research recommendations, namely about formative assessment, and teachers' conceptions and previous experiences to outline practices/strategies and ways of operationalizing them in mathematics classroom.

Regarding classroom practices planned by the collaborative group, they reveal some formative key-strategies (Leahy *et al.*, 2005) and are the result of the collaborative group work, trying to find a suitable way of implementing those broad strategies in the mathematics classroom. The planning process of these practices focus on three main areas: defining assessment criteria in mathematics; working assessment criteria with students; assessing and rethinking practices. Assessment criteria were defined as a powerful resource both to clarify what is expected of students (and indirectly of teacher) in intervention lessons, and to support students' self-assessment (Hadji, 1994). The definition of such criteria was, itself, guided by some criteria, namely: to take into account critical points (in relation to particular difficulties diagnosed) and to put a focus on mathematics. This led to criteria that meet mathematical skills and understandings recognized as essential in mathematics learning (NCTM, 2000): Concepts and procedures, Strategies and processes of reasoning; Communication.

Planning how to *work on* assessment criteria with students (instead of *work through*) has raised new challenges and concerns to the group (Mason, 1998). First, a simplified grid of assessment was prepared so that criteria would become accessible to students. Then, a process of negotiation was conceived, engaging students in the assessment of work samples, with discussion about the strong and weak aspects of each one. Recommendations of several authors were, thereby, considered and combined (Sadler, 1989; Santos, 2008; Wiliam, 2011). For students to understand the criteria in context (Black & William, 1998), a cycle model of practices/strategies was also planned, including students' self-assessment, using the grid, and whole-class discussion about teacher's and students' assessments. Later on, to assess the effectiveness of previous practices in promoting students' appropriation of assessment criteria, the group has planned to ask written reflections to students.

Ultimately, written reflections were integrated in a new model for intervention lessons, as a way to promote and regulate students' self-assessment, which takes into account the didactic tension and the importance of students *working-on* in mathematics classroom (Mason, 1998).

Practices planned by the collaborative group show potential to meet the conditions, identified by Sadler (1989), as supporters of the improvement of students' learning: sharing an idea of quality similar to the one of the teacher, continuous monitoring of work and access to a repertoire of alternative strategies that can be implemented to improve. Naturally, planning should continue, through a cycle of preactive, interactive, and postactive planning (Milner, 2001), readjusting the practices toward the promotion of students' self-assessment in mathematics.

This study presents an innovative character by placing the focus of teacher planning on formative assessment in mathematics and on ways of operationalize such assessment in the classroom, giving some insight into that process. It highlights the importance of, on the one hand, valuing formative assessment in mathematics teachers' planning and, on the other hand, developing a focused and intentional planning of teachers' assessment practices so that they effectively contribute to students' learning in mathematics.

CAPTURING PRE-SERVICE TEACHERS' MATHEMATICAL KNOWLEDGE FOR TEACHING

Ravi B. Somayajulu

Eastern Illinois University, Charleston, USA

This study investigated the change in the Mathematical Knowledge for the Teaching (MKT) of geometry for three preservice teachers over a period of seven months. Data was collected via pre- and post-surveys as well as interviews. Data collection items were specifically designed to elicit preservice teachers' MKT as they responded to items involving the analysis of student work and thinking. The results indicated that there was a significant decrease in preservice teachers' scores on items pertaining to analysis of student work and thinking. Preservice teachers relied on their past experiences as students and on their work experience while making pedagogical decisions. Recommendations for future research in preservice teacher education are discussed.

Keywords: Preservice Teacher Education, Mathematical Knowledge for Teaching, Geometry

INTRODUCTION

Until a few years ago, researchers in the U.S. defined teachers' subject matter knowledge using quantitative means such as number of subject specific courses taken or the teachers' scores on standardized tests (Even, 1993). However, the adequacy of these proxies for measuring mathematical knowledge for teaching has been the subject of controversy and debate (Hill, Rowan, & Ball, 2005). Ball et al. (2005) coined the term Mathematical Knowledge for Teaching (MKT) in order to distinguish a specialized body of knowledge of subject matter that is needed for teaching. MKT consists of not only knowledge of mathematics content, but also how that content is taught. It includes knowledge about which topics or concepts are easy for students to learn and which are difficult. While several studies at the elementary and middle school level have claimed that teachers' MKT is correlated to student achievement, such studies are rare at the secondary school level. One reason for this gap is that high school mathematics consists of a variety of topics and is very complex (McCrory, Ferrini-Mundy, Floden, Reckase, & Senk, 2010). Knowledge about how secondary students think about mathematics is also very limited.

This work is a part of my dissertation study in which I investigated the nature of MKT of secondary preservice teachers by eliciting their reactions to samples of student work included in written surveys, using a case study methodology (Somayajulu, 2012). The following research question guided the data collection and analysis:

What factors do preservice teachers consider when making pedagogical decisions based on analysis of students' mathematical work and thinking?

THEORETICAL FRAMEWORK

In this article, I subscribe MKT to being described as “mathematical knowledge needed to carry out the work of teaching mathematics” (Ball et al., 2008, p. 395). For the purpose of this study I utilized the Knowledge for Algebra Teaching (KAT) (McCrorry et al., 2010, 2012). Although the KAT framework has been designed for assessing algebra teaching, the teaching tasks and the knowledge categories that are highlighted by the framework are applicable to all the areas of mathematics, and in particular to geometry. This framework consists of a two dimensional matrix in which the rows represent the tasks that teachers perform while teaching mathematics and the columns represent the categories of knowledge required to perform those tasks. The specific categories can be seen in detail in Figure 1 below. For the purposes of the current study, I focused on the task of analysing student work and thinking and the knowledge bases required to successfully perform that task.

The framework also consists of three overarching categories: decompressing, bridging and trimming (McCrorry et al., 2010). Decompressing, according to McCrorry et al. (2010) is working from a more compressed understanding of mathematics to a more unsophisticated form. It includes “attaching meaning to symbols and algorithms that are typically employed by sophisticated mathematics users in automatic, unconscious ways” (McCrorry et al., 2010, p. 38). Trimming is a process in which teachers present an advanced or sophisticated mathematical idea to students in a way that the fundamental nature of the topic is preserved but it is now less rigorous (McCrorry et al., 2012). Bridging involves making connections between mathematical topics or between mathematics and other subject areas (McCrorry et al., 2012) which is similar to Shulman’s (1986) notion of lateral and vertical curriculum knowledge. Decompressing and trimming are complementary activities; whereas the former draws on mathematical knowledge to unpack meaning of algorithms, equations, etc, the latter is how a teacher preserves fundamental meaning of advanced mathematical topics in the context of less-advanced classrooms (McCrorry et al., 2012). The KAT framework guided the task selection for the surveys.

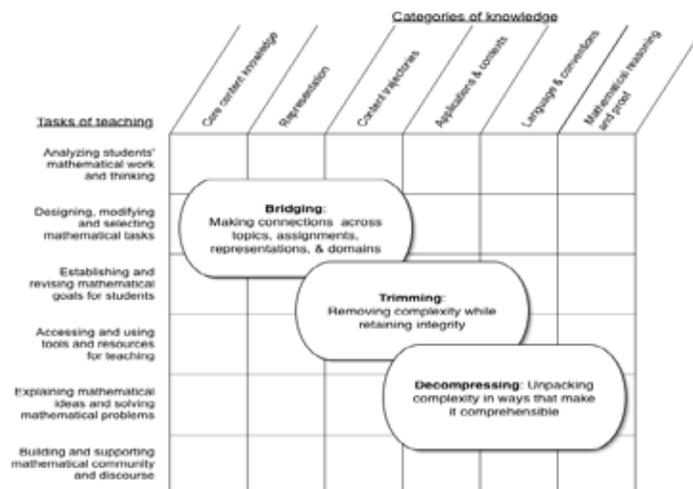

Figure 1: Knowledge for Algebra Teaching (McCrorry et al., 2010, p. 58)

METHODOLOGY

Participants

The original dissertation study involved eight participants: four male and four female enrolled in the Master of Education program seeking licensure to teach 7th to 12th grade mathematics in the U.S. Six of the participants had a bachelor's degree in mathematics and two participants had a background in engineering. For the purpose of this study, I report on an in-depth case study involving three of the participants. The selection of these three participants was done based on Cooney, Shealy and Arvold's (1998) classification of preservice teachers. A brief description of the three case study participants is given below.

Cersei

Cersei had a background in industrial engineering prior to joining the M. Ed. Program. Cersei fell in the isolationist category (Cooney et al., 1998) in that she rejected the beliefs of others. The program had very little effect on Cersei's beliefs about mathematics teaching and learning.

Bran

Bran completed his bachelor's degree in mathematics prior to joining the program. Bran demonstrated the qualities of a naive connectionist (Cooney et al., 1998) in that he was receptive to other's beliefs but is not able to resolve the conflicts between his beliefs and other's beliefs.

Nedd

Nedd was a computer engineer before joining the program. Nedd was a naive idealist (Cooney et al., 1998). He readily accepted other's views and beliefs without questioning them. Unlike the other participants, Nedd opted for an extra year to complete the program.

Data Collection and Instruments

Data collection took place over a period of seven months via pre and post surveys and interviews. The surveys and interviews were designed to capture the preservice teachers' MKT as it pertained to the analysis of student work and thinking via the processes of decompressing, trimming, and bridging. The survey items were taken from previously recorded episodes of student work on geometric tasks consisting of instances of children's thinking and heuristic usage (Manouchehri, 2012). Additionally survey items were chosen from geometric topics common to the U. S. secondary school curriculum. The following is an example of one chosen task:

A student was given the following problem: Consider a cube whose base area is 4 cm^2 . If the area of the base increases to 16 cm^2 , how much does the volume increase?

The student replies by saying that the volume of the cube would increase by 4096 cm^3 . How do you think the child arrived at this answer?

What techniques or tools may be used to help the child understand the solution?

What are some questions you can ask the student to further his understanding on the topic?

The content validity of the survey instrument was verified by obtaining feedback from practicing teachers, mathematics educators, and mathematics education graduate students. The surveys were piloted with graduate students in mathematics education and based on their responses and feedback, necessary modifications were made. Finally the surveys were administered to preservice teachers outside of the sample for this study. Based on their responses final changes were made to the language in order to remove any ambiguities.

Interviews were conducted after the administration of the surveys to gather further information of the participants' responses to the surveys. The interviews were approximately 90 minutes long. The interviews consisted of three parts: (1) obtaining background information from each participant, (2) a self efficacy scale (Tschannen-Moran, & Hoy, 2001), and (3) focused on exploration of survey responses. In this paper, I focus on (1) and (3).

Data Analysis

The data analysis was completed in two phases. During the first phase, the preservice teachers' responses to the surveys were analysed and coded. In order to do this, the survey responses were classified by dividing MKT along two categories of mathematical and pedagogical analysis. I utilized previously identified performance indicators from a study exploring knowledge for teaching (Manouchehri, 2011). The indicators are as follows:

Mathematical Analysis

Articulating basis for mathematical decisions that children make.

Identifying the strengths and weaknesses of ideas from a mathematical point of view.

Identifying content trajectories and using them to assess children's conceptions.

Identifying the sources of children's errors/misconceptions and reasoning how they could have resulted.

Developing mathematically sound instructional strategies.

Pedagogical Analysis

Identifying why certain pedagogical moves are appropriate to pursue with children based on their analysis of student work and thinking

Successfully addressing areas in which children would or would not be able to perform adequately.

Offer a rationale for why certain pedagogical choices should be implemented.

Identifying the advantages and disadvantages of use of instructional tools.

Based on these indicators, I categorized the responses on a continuum from Mathematically and Pedagogically Naïve to Mathematically and Pedagogically Mature. The scoring of the responses is explained in table 1. This resulted in a maximum possible score of 4 and a minimum possible score of 0.

Score	Mathematical Analysis	Pedagogical Analysis
0	Mathematically Naïve	Pedagogically Naïve
1	Mathematically Developing	Pedagogically Developing
2	Mathematically Mature	Pedagogically Mature

Table 1: Scoring Rubric

Since the number of prompts used differed from the pretest to the posttest, I calculated a percentage score for each participant (that is total points scored divided by total points attempted on a particular survey).

The second phase of data analysis involved analysing the interview data. The interviews were transcribed and coded based on the references they made while analysing student work. Once the interviews were coded, percentages of occurrences for each of the coded category were calculated. Those percentage scores were utilized to build an illustrative map of sources that the preservice teachers drew from while analysing student work and thinking. Finally interview data was compared with the responses to the surveys in order to triangulate conclusions. An example of an illustrative map is given below. The map describes the various factors of Cersei's MKT as exemplified through references while analyzing student work and thinking during the pre interview.

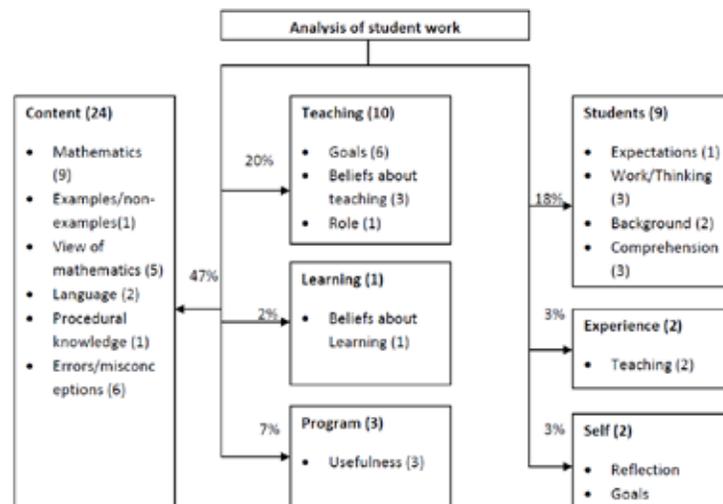

Figure 2: Example of an illustrative map highlighting factors influencing participants decision making

From the above example we see that Cersei made a total of 51 references to student work on geometry during her interview. While commenting on student work, Cersei

referenced the geometric content 24 times and teaching 10 times. She also made 9 references to students. Other references were made to learning, experiences, M. Ed. Program and to self. These categories were further broken down into subcategories. So for example, while commenting on the content, Cersei referenced the mathematics 9 times, while she referred to the child's errors/misconceptions about 6 times.

Such maps were generated for both pre and post surveys for each of the three case study participants. These maps were then used to generate a list of important factors that the preservice teachers consider while making pedagogical decisions and hence what factors might be included in the teachers' MKT.

RESULTS

The findings for each of the three case study participants are discussed below.

Cersei

The major factors affecting Cersei's orientation toward teaching were her experiences both as a learner of the subject as well as her work experience, and her beliefs about the teaching and learning of mathematics. She viewed mathematics teaching as being similar to her job as an industrial engineer. When asked if being an engineer was different/similar to being a teacher she replied:

Cersei: I was always the person that trained the new industrial engineers coming into the department. So I guess I've kind of been teaching all along without really recognizing it but really liked in that whole experience just to being kind of a mentor and helping so many get started into the department.

Analysis of Cersei's responses to the surveys revealed that there was a decrease in her scores for prompts pertaining to analysis of student work and thinking, decompressing, trimming and bridging. After augmenting her interview data with the survey data it was observed that even though her attention to student work had increased, there was a decrease in her attention to the mathematical content. Cersei was also not able to make specific connections to models of assessment and hence was unable to utilize them while analysing student work and thinking.

Bran

The main factors affecting Bran's orientation towards teaching were his experiences as a learner of mathematics as well as his knowledge of the subject matter. Bran acknowledged the connections between his college mathematics courses and high school mathematics and drew on this knowledge of content trajectories while attending to student work. For example, one of the questions on the survey asked the participants to choose two of three topics (similarity, transformations and right triangle trigonometry) such that it would foster student learning. Bran selected transformations and right triangle trigonometry. He did not choose similarity because he felt that it could be derived from transformations.

Researcher: You said similarity can be described through transformations, and how would you go about that?

Bran: I think I'd start with a shape. So a transformation of this would be to make each side longer. So I could keep this here, so I can make everything, like move these points twice as far away from each other. And so I could have two shapes that after the transformation, the shape is still similar. So I can tell that's a special case of transformation when the relationships between the sides and the angles are the same.

Comparison of Bran's pre and posttest survey scores revealed that there was an increase in his scores for prompts pertaining to the analysis of student work and thinking, trimming, and bridging. However, there was a decrease in his scores for prompts pertaining to decompressing. His interview data revealed that his attention to the mathematical content had increased. Bran also demonstrated an increased tendency to try and understand the reasoning behind the student work.

Nedd

Work experience was the biggest factor affecting Nedd's orientation to teaching. Nedd was of the opinion that his job as an engineer had already instilled in him the skills required to be a successful teacher. When I asked Nedd if being a teacher was similar to being an engineer he replied that they required the same set of skills.

Nedd: Yeah. So I think the biggest reason, the biggest thing is, umm, mostly continuous improvement. You know problem solving, adaptability, looking at all the inputs. You know, defining a problem, alternatives, what gets you to that next improvement. I mean, I think those are very drilled into me and I think that's a skill a teacher needs to have.

Nedd also showed a decrease in his scores pertaining to analysis of student work and thinking, decompressing and bridging. From the interview data, I observed that Nedd's attention to student work decreased. Instead the tasks pertaining to student work and thinking served as an avenue for Nedd to reflect on his own mathematical knowledge.

A cross examination of the three cases led to the following findings:

Preservice teachers had trouble decompressing their knowledge while analyzing student work and thinking.

Preservice teachers relied on their experiences while analysing student work and making pedagogical decisions.

Preservice teachers were unable to utilize learning based assessment models such as van Hiele or Pirie-Kieren (Pirie, & Kieren, 1994) to aid in evaluating student work as well as designing instructional tasks.

Knowledge of content and content trajectory had an impact on the participants' analysis of student work and their pedagogical decision-making.

DISCUSSION

Figure 3 illustrates the common factors affecting the preservice teachers' pedagogical decision making. Participants' past experiences along with their beliefs about the teaching and learning of mathematics, and their knowledge of the trajectory of the content were critical factors when making pedagogical decisions while analyzing student work and thinking.

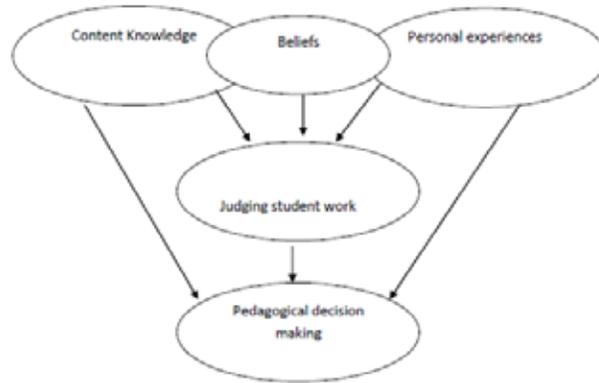

Figure 3: Forces influencing pedagogical decision making (Somayajulu, 2012, p. 282)

Elbaz (1983) demonstrated the interactions between teachers' personal theories and practice, often referred to as teachers' personal theorizing. This study exhibited similar results, where in the preservice teachers relied on their past experiences and their classroom observations of their mentor teachers while making pedagogical decisions. Of these, their past experiences as learners of mathematics and their work experiences had a prominent influence on their decision making. While referring to student work, the preservice teachers almost always made decisions independent of attention to student work and relying mostly on their experience as learners of mathematics. For the participants with engineering backgrounds, work experience was a constant influence on how they viewed the mathematical content.

Several studies have demonstrated the importance of the knowledge of content and its trajectory while making decisions (Aubrey, 1996; Kahan, Cooper, & Bethea, 2003). This study too demonstrated that such knowledge was critical in pedagogical decision making. Preservice teachers, who were not comfortable with the content, were not able to identify the concepts that were central to the topic and hence could not identify the trajectory of contents.

One major concern was that none of the participants were able to connect theory to practice. This concern has been documented by several researchers, in particular by Jaworski (2006). According to Jaworski (2006), this inability to connect theory to practice stems from the fact that even though theories are valuable tools for analysing student work, they do not offer any clear insights to teaching. I observed that none of the preservice teachers in the study were able to apply models of assessment to aid them in their analysis of student work and thinking. One reason for this is that it is unclear how we can measure teachers' development within the realm of a research

based program. It is essential to develop an understanding of teachers' learning trajectories as they are exposed to new knowledge via teacher education programs.

Another concern is the lack of influence of the methods courses on the participants. One likely reason for this is that the methods courses were designed without much sensitivity towards helping the teachers' bridge theory and practice. In light of the findings of this study, I recommend that preservice teacher education programs should take into consideration the prior experiences of teachers as learners and build on them while designing activities that are more effective.

LIMITATIONS

A major limitation of this study was that the analysis was entirely based on the results of the surveys and the interviews. While I observed the participants in their methods courses, I did not analyse the discourse in those environments. Such analysis might help in providing deeper explanations of why certain changes took place.

The survey instrument that was developed covered a limited range of topics. Moreover the surveys were about 150 minutes long and as a result some of the participants left items blank, especially at the end of the post surveys.

RECOMMENDATIONS

There is a need for developing instruments that are capable of capturing the different aspects of MKT in geometry. Such instruments also need to cover a broader range of geometric topics. While doing so, steps need to be taken so that the surveys are not too long. Another recommendation for future work would be to consider the use of interviews as venues for learning and growth of preservice teachers.

Studies analysing classroom discourse and interactions amongst preservice teachers need further attention as they have potential to offer perspectives on how to sequence tasks to better aid in teacher preparation. There is a further need to analyse the interaction between content knowledge and teaching at the secondary school level.

PRE-SERVICE TEACHERS' KNOWLEDGE AND BELIEFS: THEIR ASSOCIATION TO PRACTICE IN THE CONTEXT OF TEACHING FUNCTION WITH ANALOGIES

Behiye Ubuz¹, Utkun Özdil², Ayşegül Eryılmaz Çevirgen³

¹ *Middle East Technical University, Ankara, TR*

² *Muğla Sıtkı Kocman University, Mugla, TR*

³ *Anadolu University, Eskisehir, TR*

The present study concentrates on pre-service teachers' knowledge and beliefs and their association to teaching practice in the context of teaching function with analogies. During the first phase of data collection, pre-service teachers completed a knowledge test concerning the definition of function, its types, and analogy. In the second phase, pre-service teachers were observed and videotaped during their teaching practice. In the last phase, interviews were conducted upon the completion of pre-service teachers' teaching practice to yield data about their beliefs about using analogies. Results revealed that pre-service teacher knowledge and beliefs about function and analogy strongly associated with the nature and the extent of analogy use in teaching the function concept.

Keywords: Function, analogy, pre-service teachers, teacher beliefs

INTRODUCTION

There is an agreement among mathematics educators on the importance of analogies or situations from everyday life within the verbal definitions of the function (Elia, Panaoura, Eracleous, & Gagatsis, 2007), the examples of functions from their applications in real life (Elia & Spyrou, 2006) or the tasks that aim to use the definitions of functions (Christou et al., 2005) because of their valuable opportunities for students to gain understanding in functional thinking (Cooney & Wilson, 1993). An analogy is drawn by transferring ideas from a *familiar* concept to an *unfamiliar* one (Thiele & Treagust, 1995). The familiar concept that provides basis features to interpret the unfamiliar concept is often called the source or analog; whereas the unfamiliar concept to which the information is transferred is called the target (Gentner, 1983). Researchers have basically emphasized a correspondence in some respects from source to target, thus underlined the “*relation*” and “*similarity*” in which the same system of relations holds across different objects (Eid, 2007; Heywood, 2002). Matching the familiar domain to the unfamiliar domain is achieved by accessing the similarities and differences of the domains, and then mapping similar characteristics between the two domains by indicating the breakdown points. Analogy generation is crucial for teaching, the origin of which grounds to the connections between the real world and the target concept that establishes as real world linkage, and which, in general terms, could be said to prompt visualization of abstract concepts that facilitate understanding (Thiele & Treagust, 1992). The sense of this perspective is clearly articulated in recent years, such as that of several

mathematics educators (Fast, 1996; Richland, Holyoak, & Stigler, 2004). Analogical representations such as function machines attempt to move students from an action to a process conception (Selden and Selden 1992). To be able to manage this move, the quantity and quality of teachers' mathematical knowledge on functions and analogy are important aspects. The collection of articles written by Even (1990, 1993, 1998) and by other researchers (Hitt, 1998; Lloyd & Wilson, 1998; Sanchez & Llinares, 2003) pointed out subject matter knowledge and pedagogical content knowledge, as defined by Shulman (1987), essential for teaching the function concept. Moreover, characteristics of teachers' belief systems have also been linked to various components of these knowledge aspects.

Although a few studies investigated pre-service teachers' use of analogies in teaching function concepts (e.g., Ubuz et al., 2009), not much is known about teachers' knowledge, beliefs, and ability to use analogies in teaching functions that are fundamental components of their pedagogical content knowledge. Considering these facts, we aimed to investigate how pre-service teachers' knowledge and belief are associated with how and when they use analogies to teach the idea of functions. Response to this question can provide insight as to possible linkages between teachers' knowledge and beliefs about functions and analogy, and their teaching of functions with analogy.

METHODS

Context and Participants

The participants were all seven pre-service secondary mathematics teachers (PT1, PT2, PT3, PT4, PT5, PT6, and PT7) attending to Master of Science without Thesis Program at Middle East Technical University. All seven of them were the total number of the students in their last term attending to this program. Master of Science without Thesis Program is a three semester certificate program to teach mathematics at secondary school level (grades 9-12). The first three were male and the rest were female. All graduated already from the Department of Mathematics. They all had some previous teaching experience through their participation to the private tutoring programs. Data were collected during *Practice Teaching in Secondary Education* course provided at the last semester including 14 weeks. This course involves practice teaching in classroom environment for acquiring the required skills to become an effective mathematics teacher. Each week PTs spend their six class hours in a classroom environment at an arranged public secondary school, and two class hours at the university. In that two hours period at the university, PTs presented sample lessons one by one to their peers and the instructor. They were required to present the function concept and its types by generating analogies. At this stage, their knowledge on functions and analogy, and their images resulted from their previous experiences in school and university mathematics as well as the method courses offered at the Master of Science without Thesis Program. With regard to functions and analogy, method courses involved history of function, misconceptions about functions, definition of analogy, and importance of analogy for learning and teaching.

At the public school they taught two lessons with presence of the instructor (the first researcher) and the classroom teacher. At other times they presented lessons whenever the classroom teacher allowed them to do. Teaching at the university and the school constituted 30 percent of the course grade. Lesson plans constituted 15 percent of the course grade. While preparing the lesson plans, they mainly focused on objectives, materials, teaching techniques and the development process in the lesson.

Data Collection and Analysis

Knowledge Test: Knowledge test assessed the PTs in two major strands of knowledge prior to their teaching practice: subject matter knowledge and pedagogical knowledge. The item on subject matter knowledge was chosen to test their factual knowledge about functions, particularly the definitions of function and its types (one-to-one, onto, into, and one-to-one and into). The item on pedagogical knowledge was prepared to assess their knowledge on analogy, particularly the definition of it and its characteristics. They were required to complete the test in the presence of the research assistant of the course during the first week of their course and no time limit was imposed. At this week, all PTs, except PT7, were registered on the course, and ultimately the knowledge test data were driven from them. At the add-drop week PT7 registered to the course and were involved in the present study. Themes on PTs' definitions of functions were explored by considering the historical development of functions (Cooney & Wilson, 1993). Reviewing the development, it becomes obvious that development has moved in the direction of including various elements of functions, that is, of the concept of set, arbitrary correspondence, and the requirement that each value of the independent variable has a unique image. These elements on functions provided us to keep track of PTs' knowledge of the function concept and its types. In line with this, the correctness of their definitions was also explored. The underlying ideas of analogy contributed significantly to our analysis and interpretations of the responses given to “*What is analogy? Define and determine the main characteristics of it*”. The responses were categorized under the following descriptors: (1) transferring the familiar domain to the unfamiliar domain, (2) accessing the similarities and differences of the domains, and (3) mapping similar characteristics between the two domains by indicating the breakdown points.

Teaching Practice: At the beginning of the Practice Teaching in Secondary Education course, function topics covered at the 9th grade were assigned to each participant to be presented using analogies, to provide an effective flow of lesson and to cover all topics relevant to functions. Each participant prepared two lesson plans about assigned topics to be presented at the classroom in the university. One of the lesson plans was on function concept and the other on its types. The first author (instructor of the course) and the third author (assistant of the course) observed and videotaped the PTs during their teaching practice experiences to be consulted in further analysis. The teaching practice data were collected from the observations of all the seven PTs. All PTs, except PT7, were observed on two different occasions in terms of teaching function concept and its types within an average duration of 30

minutes. PT7 was observed on a single occasion involving both teaching function concept and its types within 40 minutes period.

Content analysis (Philips & Hardy, 2002) was conducted to discern meaning in teachers' written and spoken expressions. Videotapes of 13 sessions were fully transcribed and considered line by line whilst annotated field notes were used as supplementary sources. The first phase of data analysis included detecting analogy-based teaching instances and identifying source analogies and the target concepts. A portion of the course was considered to be analogical if it was aligned with the working definition stated above and/or it was stated in the lesson as being analogical. Then the spotted cases was scrutinized concerning nature and extent of analogy use, considering analogical relationship, presentational format, level of enrichment, position, and limitations. The framework suggested by Thiele and Treagust (1994) served as a tool for analyzing the spotted cases. In addition, analogies were analyzed through the presence of any limitation and categorized as applicable or not applicable. The ones that are applicable were analyzed in terms of the presence of any stated warnings which highlights to the students where possible attribute mismatches may occur and categorized as specified or not specified. Furthermore, analogical instances were analyzed whether they are generated by listeners (as student) or presenters (as teacher). That is, while one PT as a teacher was presenting a lesson, the others were required to *participate* in that lesson as students. Thus, during the teaching practices all PTs had the opportunity to act as both students (i.e., listeners) and teachers (i.e., presenters).

Interview: A semi-structured interview was conducted by the third author upon the completion of PTs' teaching practice to yield data about each ones espoused (stated) beliefs about using analogies, lasting approximately 17 minutes for each case. The teaching practice of the PTs provide insights into the extent to which espoused beliefs (what they say) support their enacted beliefs (what they do) evidenced in the classroom.

While analyzing the responses given for "At which stage should analogies be used in the teaching process?", we delineated the position aspect of the theoretical framework that was used in analyzing the observations. The analysis brought forth three descriptors: (a) advance organizer, (b) embedded activator, and (c) post-synthesizer. The focus of the analysis on the responses given for "Who should construct the analogies?" was partially attributable to teachers' conceptions on the pedagogy of the analogy-generated lessons. Thus, our analysis of the interview responses focused on finding useful ways to think about the perspectives held by the PTs. This analysis traced perspective characteristic of the construction of analogies within two descriptors (Harrison & Coll, 2008): (a) student-generated analogies, and (b) teacher-generated analogies. The responses given to "*Is it appropriate to use analogies in teaching the function concept?*" were categorized in two descriptors: (a) appropriate and (b) inappropriate. The PTs' value of using analogies was pivotal in our analyses to categorize the responses because it signaled the insight into their conceptions about

analogies and provided an opportunity to inquire into those conceptions in relation to the appropriateness of teaching functions via analogies. While analyzing the responses given to why questions subsequent to each question we did not rely solely on categorizing the aforementioned descriptors rather we sought for the essence of PTs' reasons of their beliefs.

Reliability of Coding

The initial classifications were undertaken by the last two researchers after repeated reading of the knowledge test responses, and teaching and interview transcriptions. Headings were created in relation to the theoretical framework. These analyzed data were then evaluated by the first author who was an expert in teaching functions and analogy. The analyzed data were then subject to discussion by the three members of the research team to further refine the headings. At this meeting, it was decided that all the data will be analyzed by the aid of the matrices comprising the PTs, headings, and descriptors. Subsequently, the independent analyses were carried out by the last two researchers using the matrices for the knowledge test, teaching practice, and interview data in conjunction with the first author's comments. Analyses of the analogies in teaching practice in relation to the two headings - position and level of enrichment - were germane to disagreement. The conflicts were driven from the different conceptualizations of embedded activator and post-synthesizer descriptors in the position heading and the extended descriptor of level of enrichment heading. After consulting with the first author and utilizing the review of literature, embedded activator was restricted to the analog domain be presented after the introduction of the target domain; post-synthesizer was restricted to the analog domain be presented following a complete treatment of the target; and level of enrichment was restricted to the detail of mapping (e.g., expressing the domain, range, process, and the univalence feature) rather than the degree of mapping (e.g., using one analog to express multiple targets and/or multiple analogs to express a single target).

RESULTS

Knowledge of Functions and Analogy

Definition of function and its types. The notion of function as a dependence relation between elements became dominant in the definitions provided for all six PTs. According to their definitions, relations pairing elements of the second set with one or several elements of the first set and each element in the first set has a unique image were considered functions. Analysis of the responses revealed that all of the six PTs approached the types of function from a modern perspective. Their definitions endeavored to reflect function's correspondence perspective referred to as relation between sets. Apparently, the concept of set becomes a fundamental element in the definitions. Further, it was noted in the definitions that the relation or correspondence need not involve numbers but could also involve relationships or correspondences between other elements that vary. Mostly definitions did not illustrate the requirement of a definite "law" correspondence. To summarize, Bourbaki's definition

has remained dominant. The types of functions were also defined correctly referring to their specific characteristics.

Description of analogy. The underlying ideas of analogy under the following descriptors: (1) transferring the familiar domain to the unfamiliar domain, (2) accessing the similarities and differences of the domains, and (3) mapping similar characteristics between the two domains by indicating the breakdown points were emphasized by all PTs in different words. They underlined the fact that an analogy cannot hold all the shared attributes, rather the similarities can be built in terms of particular features of a concept.

Teaching Practice

Amongst the 45 analogies, 26 of them were teacher-generated and the remaining 19 were student-generated. Teacher-generated analogies refer to analogies that are constructed by the presenter either during or before the lesson. Student-generated analogies were developed by the listeners/participants either during or after the lesson mostly with the presenters' initiation during lesson.

Analogical Relationship. Results revealed that the vast majority of analogical relationships were functional (41 of 45, 91%) as they include the behavior of the source shared by the target concept. Only four (9%) analogies shared both functional and structural relationship. Structural-functional analogies were generated considering the spelling and meaning similarities of the terms while teaching types of functions.

Presentation Format. Results indicated that 31 of the 45 identified analogies (69%) were verbal, and only 14 (31%) had a pictorial representation together with the verbal representation. The 10 of the 14 pictorial-verbal analogies (71%) and 16 of the 31 verbal analogies (51%) were generated by the presenters of the lesson. This might be due to the fact that presenters tend to support their teaching to enhance the understanding of the function concept via pictorial-verbal analogies.

Position. Most of the analogies (23 of 45, 51%) were generated prior to the investigation of target concept that referred to as advanced organizer. Twelve of the 45 analogies (27%) acted as post-synthesizers while the remaining 10 (22%) were generated as embedded activators. The 20 of the 23 advance organizers (87%) and two of the 12 post-synthesizer (17%) were generated by the presenters of the lesson.

The Level of Enrichment. According to the "level of enrichment" criteria, it was observed that most of the analogies (20 of 45, 45%) generated were enriched analogies following extended analogies (15 of 45, 33%) and simple analogies (10 of 45, 22%). Further, three of the 10 simple analogies that primitively state that the target is like the source, 10 of the 15 (67%) extended analogies that indicate several shared attributes of a single source used to teach a variety of targets, or a variety of sources used to teach a single target, and 13 of the 20 (65%) enriched analogies in which some shared attributes between the source and target concepts for the

analogical relations are stated, were generated by the presenters themselves. That is, simple analogies were generated mostly by the PTs who were student participants in the class, and enriched and extended analogies were generated mostly by the PTs who are the teachers of the class.

Limitation. Limitations play a central role in the teaching and learning with analogies by contributing to the conceptualization of the links between analog and target. Four of the 45 analogies were discarded from the analyses of this heading since these analogies were mathematically incorrect (see aforementioned section). Of the 41 analogies 24 (59%) were classified as not applicable due to having no limitation; 17 (41%) were reserved for having a limitation among which nine were not specified and eight were specified.

Epistemological Appropriateness. The epistemological appropriateness of the analogies was classified in terms of whether the domain, range, process, univalence, and other features of the target concept correctly mapped to the analog or not. Results documented that 37 of the 45 analogies (82%) were correct and four of the 45 (9%) analogies were incorrect. The rest four (9%) structural-functional analogies cannot be analyzed in terms of epistemological appropriateness as they corresponded to the target concept in terms of their spelling and verbal meaning. As expected, the most of the incorrect analogies (3 of 4, 75 %) were formed by the PTs as student participant with the presenters' initiation during lesson.

Beliefs

When to use analogy? PTs appeared to have an insight into the use of analogy from the introducing of a new concept to the developing an understanding for this new concept. All six PTs indicated that analogies could be used as an *embedded activator* since analogies can be presented as an example at a point after the definition of a concept or at a time when the mathematical content is becoming more abstract or difficult to the students.

Who should construct the analogies? PTs' preference for the teacher-generated analogies was evident during the interviews. The reasons can be illustrated with two underpinnings. In generating the analogy the PTs put emphasis on the importance of the subject matter knowledge and pedagogical knowledge. As teachers have knowledge both on subject and analogies, they can direct students more efficiently, emphasizing similarities and differences between the analog and the target. They deliberately viewed analogy generation as a difficult process since the analogy generation grounds explicitly on the connectedness between the source and target concepts.

The Use of Analogies in Teaching Functions. The use of analogies in teaching functions was greatly valued and instigated in the comments of all PTs except PT3. They clearly found them appropriate as functions are difficult for students and engenders anxiety among them as it was introduced for the first time at the 9th grade. They articulated that analogies help conceptualization because correspondence

between analogy or familiar concept and function concept requires students to extend their understandings in a meaningful way.

DISCUSSION

This study's foregoing findings lend credence to the consistent associations between PTs' subject matter knowledge, pedagogical knowledge, beliefs, and their practices advanced by Fennema and Franke (1992). In terms of practical implications, the findings of this study clearly support the need for developing PT knowledge and beliefs as they have an association on PTs' teaching practice.

Knowledge test and teaching practice data revealed that all PTs tended to use similar definitions on functions. This implies that PTs were consistent in their knowledge and teaching practice. PTs' understandings clearly articulated that they were able to reconcile the analogical approach to functions with the prominent features of their own knowledge on functions. However, they were limited in their attempts to generate analogies in scientific contexts. This supplied evidence that generating an effective analogy requires not only knowledge of mathematics but also the knowledge of interdisciplinary subjects that can furthermore support the development of new mathematics concepts in real-life contexts. This thereby illustrates that PTs' knowledge of functions and other subjects acted as a filter for the interpretation and a springboard for epistemologically appropriate analogies.

PTs tend to think of analogy as a tool with the descriptors of transferring the familiar domain to the unfamiliar domain, accessing the similarities and differences of the domains, and mapping similar characteristics between the two domains by indicating the breakdown points. This indicates, for example, that the pre-service teachers knew the importance of stating the limitations of an analogy by putting particular emphasis on the breakdown points. This also was observed in the teaching practice where mostly all exhibited a fulfilled intention of discussing where their analogies break down. Only PT7 and PT4 exhibited an unfulfilled intention of discussing where their analogies break down. This might be attributable to two reasons: First, PT7 and PT4 might assume that their peers themselves were capable of building the analogical relationships between analog and target concepts and therefore they might not have teaching concerns. And secondly, although they, as a teacher, were indeed aware of indicating where the analogy breakdowns, they might fail to transform this knowledge and integrate it into the analogical context.

These foregoing findings lend credence to the consistent associations between PTs' espoused beliefs (what they say) and enacted beliefs (what they do). The more they valued and instigated the use of analogies in teaching functions in their comments, the higher number of analogies they generated in their teaching practices. Some of the PTs (i.e., PT1) underlined that there may be times where students should construct their own analogies and in their teaching practice they encouraged the classroom to think about the analogies and to propose new analogical relations to the classroom. Furthermore, PT3 stated that analogies definitely should not be used as a

starting point for the introduction of a new concept and therefore as a teacher used analogies only as post-synthesizer.

“Analogies should not be used at the very beginning of the lesson. I mean, while introducing a new concept. Rather, they should be used somewhere during instruction while giving explanations. I mean, you should generate an analogy in order to score a goal, not to get into a position.” PT3

Although association was evident between teachers’ knowledge, beliefs, and teaching practice, what teachers teach is mediated by the external factors such as textbooks since teachers’ thinking about functions is based on how functions are presented in school textbooks (Cooney & Wilson, 1993). Thus, future research can explore the textbooks and to what extent teachers can enhance the treatment presented by a textbook in order to accommodate particular objectives.

UNDERSTANDING PROFESSIONAL DEVELOPMENT FROM THE PERSPECTIVE OF SOCIAL LEARNING THEORY

Steven Watson

Centre for Research in Mathematics Education, University of Nottingham

This paper considers professional development (PD) from the perspective of Social Learning Theory (SLT). While a single component of SLT, self-efficacy, is frequently referred to in teacher education research, the full theory has not been used in this field previously. In this paper SLT is evaluated in terms of the extent to which it is able to describe and explain the phenomena of professional learning. An example of reform-oriented PD is used for this purpose. SLT provides an integrated view of learning, accounting for individual, cognitive aspects of learning, such as knowledge and beliefs as well as social and participatory aspects of learning. This study demonstrates that SLT provides a potentially useful theoretical approach in the context of teachers' professional learning.

Keywords: Professional development, professional learning, self-efficacy, Social Learning Theory

INTRODUCTION

It is argued that theories of professional development need to include both cognitive and social aspects of learning (Borko, 2004). However, theory has tended to focus on either cognitive or social perspectives. Cognitive perspectives have centred on notions of changes in teachers' beliefs or knowledge. Social perspectives have considered professional learning through participation (Lave & Wenger, 1991). Social Learning Theory (SLT) (Bandura, 1977) provides a theoretical approach that integrates cognitive aspects and social effects in learning. While an important sub-construct of SLT, self-efficacy, has been used extensively in theorising teacher education, there are no examples, to the author's knowledge, of research that draws on the full theory.

In this paper the potential use of SLT is explored by interpreting the effects of a professional development (PD) programme that was designed to support teachers in using student-centred problem-solving (SCPS) approaches in their teaching. SCPS is an approach to teaching that is characterised by student collaboration and discussion in the process of solving open-ended tasks and activities. This contrasts with traditional teacher-centred teaching, which is characterised by the teaching of mathematical methods and routines, this is the prevailing approach in England's secondary schools (Ofsted, 2008, 2012). The importance of SCPS is in fostering deeper understanding of mathematics as well as in improving motivation and engagement (Rocard, 2007).

Schoenfeld's (2002) criteria for assessing a model or theory were used to guide the evaluation of the viability of SLT in the context of PD. The criteria used are based on

the qualitative assessment of the *descriptive* and *explanatory power* of the theory. In other words, to what extent can SLT effectively account for the observed phenomena? This is part of ongoing work in the development of SLT in the context of PD. Further assessments are being undertaken; this paper reports on the extent to which SLT can describe and explain PD. Schoenfeld (2002) explains *descriptive power* as the extent to which the theory captures “‘what counts” in ways that seem faithful to the phenomena being described’ (p. 488). *Explanatory power* refers to the extent to which theory provides a description of the way in which things work (p. 489). While Schoenfeld (2002) proffers further criteria, these two were chosen as the most important at this stage and are also consistent with Sriraman and English’s (2010) functional criteria for theory.

SOCIAL LEARNING THEORY

From the perspective of SLT, the mechanism of learning and the formation of individual knowledge is through observation (Bandura, 1977). SLT posits a sophisticated mental modelling of observed behaviours and subsequent construction of novel behaviours, but this does not necessarily mean direct imitation of others’ behaviours. Observational learning has been found to be an important mechanism in teacher development (Lortie, 2002), as has the importance of a mental model or a picture of the lesson as the teacher enters a classroom (Rowlands, Thwaites, & Jared, 2011). The way in which teachers choose and construct behaviours is influenced by the extent to which they believe they will be successful with a course of action in a particular context. This self-regulatory process within SLT is referred to as self-efficacy. It is the belief an individual has in the level of success they will experience when they act in certain ways in specific contexts. Self-efficacy reflects cognitive capacities and underlying skills, it also incorporates affective components such as confidence, motivation and willingness to innovate (Bandura, 1997). Previous research has found teachers’ self-efficacy to be related to positive teaching behaviours and student achievement. Teachers with lower levels of efficacy are more pessimistic about student motivation and believe in strict classroom regulation and rely on extrinsic inducements and negative sanctions to get students to study (Woolfolk, Rosoff, & Hoy, 1990). Self-efficacy is an important dimension but it is the broader theoretical framework that is being considered in this study.

The core component of SLT, as referred to above, is observational learning and the mental modelling of observed behaviours. Teachers (re)construct behaviours to implement in classroom. Much behaviour, according to Bandura (1977, 1997), becomes routine and does not require prior modelling and planning. Teachers at the beginning of their careers observe and model the practice of other teachers, adapt them and (re)produce them in the classroom (Lortie, 2002), this is consistent with SLT. Feedback and response as well as self-assessment by the individual teacher influence the formation of their teaching behaviours (Lave & Wenger, 1991). In time, practices become largely routine (Bandura, 1997; Cuban, 2009; Wake, 2011). As

teachers, we observe the largely traditional teaching of more experienced colleagues, we reconstruct this, knowing that it represents a safe and stable practice. Thus we enter into a well-established didactic contract (Brousseau, 1997) based on traditional and conservative teaching approaches. Wake (2011) argues that the introduction of SCPS approaches requires a change or renegotiation of this contract. According to SLT then, the facilitation of this renegotiation is reliant upon teachers having the appropriate pedagogical knowledge – in the form of mental models of possible and alternate practices, pedagogies and behaviours (Bandura, 1997) – combined with a level of self-efficacy in order to be able to implement such approaches (Guskey, 1988).

It is important to be reminded of the social and contextual effects that present a challenge to innovation. Within SLT these act in a regulatory way, mediated through self-efficacy. If our behaviours are challenged then we may begin to doubt their ultimate success, we may modify our behaviour. Similarly, as teachers, if we introduce an innovative pedagogy and it is challenged or it is responded to unfavourably by students, parents and colleagues, then it is likely that we will be less confident with the approach. Ultimately we may change our behaviour to an approach that we believe will be more acceptable. The kinds of teachers that persist with innovation have been shown to demonstrate high levels of self-efficacy in the context of teaching (Berman & McLaughlin, 1978). Beyond the effects of others in influencing behaviour, there are also the effects of the working conditions, the demands of the job, the nature of teaching and the institution in which it takes place. It has been recognised that these environmental effects also have a strong influence on the way teachers teach (Cuban, 2009; Leinhardt, 1988).

At a theoretical level, SLT appears to offer a useful framework for describing and explaining professional learning – from the above description it appears to have good *descriptive power*. In order to test this further and test SLT's *explanatory power*, a study involving a PD programme was undertaken. Three components were derived from SLT and through an iterative analysis of the data. These were, 1) *Teacher knowledge*, 2) *Teacher self-efficacy beliefs* and 3) *Social, contextual and environmental effects*. *Teacher knowledge* corresponds with aspects of data where the teacher refers to their knowledge and the effects on their knowledge in the context of the PD and their teaching. In terms of SLT, knowledge is conceived of as mental models of potential behaviours. If SLT provides a reasonable descriptive and explanatory capability then there may also be suggestion of observational learning and the modelling of behaviours. For *teacher self-efficacy beliefs*, examples might feature direct references to confidence, motivation or expressions of willingness to include innovative processes in their teaching. Alternatively, there might be negative effects on self-efficacy. *Social, contextual and environmental effects* refer to aspects of the PD and teachers' experience that are related to student, parent or colleague expectations that may have a bearing on what the teacher does in the classroom. In addition, the aspects that relate to the effects of the nature of the job of teaching are

also accounted for in this component. The three components provide the means through which data taken from the PD example can be related to SLT.

THE PROFESSIONAL DEVELOPMENT

The PD programme was designed to support teachers in the teaching of SCPS. In England's secondary schools teaching is largely traditional – teacher-led and focussed on the teaching of methods (Ofsted, 2008, 2012). However, the English National Curriculum stresses the importance of problem-solving. This PD was designed to support the teaching of problem-solving. It was also designed to enable groups of teachers to work together with one teacher leading the PD. There are seven modules, each focusses on one aspect of pedagogy. Module themes include, promoting student collaboration and group work; developing questioning to promote student reasoning; and formative assessment – all in the context of using ‘rich’ and open-ended problem-solving tasks. All modules have the same structure: an *introductory session*, *into-the-classroom* and a *follow-up session*. In the *introductory session*, teachers consider the ideas in the module – for example, student collaboration – they attempt tasks and lesson activities provided with the PD materials, they watch edited videos of real lessons in which the focus of the module is exemplified. Teachers are encouraged to reflect on and discuss the ideas presented. They then collaboratively plan a lesson based on the tasks in the PD materials and teach the lesson in the *into-the-classroom* phase. In the *follow-up session*, teachers review and reflect upon their experience and look at further videos and materials. Each of the PD sessions lasts about one-hour. The professional learning theory underpinning the design is based on teachers' beliefs. The PD is intended to provide a supportive setting in which teachers can try out a different approach and have the opportunity to develop different beliefs – more oriented toward SCPS than traditional teacher-centred approaches (For more details about the design philosophy behind the PD materials see Swan, 2006). Observations made during a pilot study involving the evaluation of the PD indicated that this theoretical approach did not provide sufficient descriptive or explanatory power and a more sophisticated model was needed. This prompted the investigation of SLT as an alternative theoretical framework.

METHODOLOGY

The study took place in mathematics departments in four schools in England. The University of Nottingham has partnerships with schools for the purposes of pre-service training of teachers, 86 of the secondary schools were contacted and invited to take part in the study. Twelve schools expressed an interest in the project. After initial meetings with the schools, four schools agreed to take part. The PD programme took place over two terms. Schools completed a module (*introductory* and *follow-up sessions*) each term, all teachers in the department were encouraged to take part: most teachers (over 90%) attended the PD sessions.

This multi-site case study was guided by the need to address questions such as ‘how’ and ‘why’ in a naturalistic setting (Yin, 2009) and in the context of professional learning. The aim of the research was to develop an in-depth understanding of the effects of the PD on teachers’ beliefs and practices. Data were collected through questionnaires, observations of PD sessions, observations of lessons and interviews with individual teachers and heads of departments. Eleven teachers were involved in the video-study, three teachers in three of the schools and two from the smaller of the four schools. At the start of the project the teachers were asked to teach a problem-solving lesson, they were interviewed before and after the lesson, it was videoed and student work also collected. As soon as was convenient the mathematics departments ran the introductory session of the first PD module, this was video recorded and the head of department and PD leader were interviewed. Teachers then taught the lesson they had planned in the PD, this lesson was videoed and a post lesson interview was conducted. The same procedure was repeated in the follow-up session. A final problem-solving lesson was taught by the video-study teachers and they were interviewed again. They were asked about the aspects of the PD they had used in the observed lesson and the extent to which the PD influenced their views and the way they taught. The same process was repeated with a different PD module in the second term. Eleven teachers were observed and interviewed five times through the project. Data were collected using questionnaires from over 90% of the mathematics teachers (n=37) in all four schools. The research design involved the mathematics department as a whole but observing a smaller number of teachers in more detail in the video-study.

The overall strategy was built around drawing conclusions from the large amount of data, which included interview data, lesson video, video of PD sessions and questionnaires. The primary source of data for analysis was the interview data. Unstructured interviews were used in the initial rounds of post-lesson interviews, these were transcribed and analysed and semi-structured interviews were developed at each successive round of interviews. In this way a constant comparative approach was used in the data collection. A method was developed for systematically summarising lesson content and PD session content (Watson & Evans, 2012). Analysis was conducted with reference to what was observed in lessons and in PD sessions. Analyses of teacher interviews were cross-referenced with observations of lessons and the analysis of interviews with the head of department. This provided a network of triangulation and enhanced the trustworthiness of results. The three components of SLT, 1) *Teacher knowledge*, 2) *Teacher self-efficacy beliefs* and 3) *Social, contextual and environmental effects* were used to code the data in order to analyse the PD from the perspective of SLT. The aim was to assess the descriptive and explanatory power of SLT in this particular context.

RESULTS

In this section, a theoretical analysis of the PD is presented from the perspective of SLT. The results are presented in terms of the three themes described above.

Teacher knowledge

The most important aspect of teacher knowledge was the development of pedagogic knowledge. This was often very specific aspects of pedagogy and was often treated as models that could be adapted and developed for use in the teacher's own classroom. As an example of this, two schools used the PD module which focussed on student collaboration, teachers who took part in the PD were interested in approaches to groupwork. They were concerned with how to promote the full participation of students working collaboratively on an open-ended and unfamiliar problem. Of particular interest were techniques to assign different roles to the group members or setting up 'ground rules' for discussion.

[Students] do not always know how to work in groups. To have the rules was good because they all knew they all had to take part. It was not one person who could take over and one person sit back and not say anything. They all knew that they had to listen to each other. They were all clear on expectations so they knew what was acceptable and what was not. (Sally, Hilltown School, year 8, high-ability).

The introduction of pedagogic moves and techniques, as in the above example, was often related to structuring a more student-centred lesson. The knowledge that teachers most often applied in observed lessons were associated with techniques and pedagogic passages they had observed in the PD sessions or that was described in the accompanying printed materials.

There were examples of observational learning. Video examples of lessons were shown in the PD sessions. It was quite common to see teachers use elements of what they had seen. For example, in the PD module on questioning and reasoning, there is a video of a lesson where the teacher, having given students a little time to work on an open-ended problem in pairs, asks students to explain their approaches while she summarises each idea in a sentence or two on the whiteboard. This was recreated in an observed lesson. The way in which teachers' acquired models of teaching was not limited to the videos. Detailed lesson plans also provided them with models and structures, which they would follow to help them in developing their own approaches to SCPS.

Teacher self-efficacy beliefs

Teachers were asked about their experiences of the PD and how their perspectives may have changed as a result. A common feature of their responses was concerned with their confidence in connection with incorporating SCPS into their teaching. In many cases, the PD had supported increased motivation and confidence to include SCPS in their teaching. In some examples, especially where the teacher was working with lower ability groups, it was evident that the teacher had become less confident.

The self-efficacy of each teacher was explored, through the study, with individual teachers, however it was also valuable to consider the heads of departments' perspectives of teachers and compare these with individual explanations.

They were asked to consider which teachers would find it more or less difficult to use the ideas of the PD and what sorts of characteristics were important. The issues they raised were to do with confidence and motivation.

[It] is the comfort-zone that is quite hard for them to break out of. To have things like children working in groups, that is quite difficult. Children may be diverging in the ways they are doing things and they can't plan for every way they might do it. The teacher can't have a written answer to give them confidence in what is going to happen. They are going to have to think on their feet and follow the way the children are going. (Anne, Head of Mathematics, Norman Fletcher School).

I would have said Barry, me, Kate, Lizzie do these activities with a certain degree of confidence, because I think we like to try things like that. And we don't mind if it goes wrong. (Deborah, head of mathematics, Barrington School)

The efficacious teachers were more willing to take risks in their classrooms. This was also supported by observations of lessons, the efficacious teachers seemed more at ease with a student-centred approach. "Loss of control" or "out of my comfort-zone" were phrases used by teachers in describing how they felt about the approach. The video-study teachers, particularly with higher ability group, felt that the PD programme had helped them become more confident in giving students greater control over their learning. This was supported by observations of their teaching over the course of the PD – teachers became more comfortable with the approach. This was also consistent with the observations of heads of departments.

There was no reference to changes in beliefs about mathematics or the teaching and learning of mathematics. It appeared that many teachers did not see beliefs about teaching as a barrier to taking a more open-ended approach. In the following the head of department explained that she thought that many of the teachers had appropriate beliefs to teach in the way suggested by the PD. The barriers appeared related to self-efficacy.

They come with a lot of the points [to do with questioning to promote reasoning in the context of problem-solving] that are there anyway. It's just a case of consciously thinking about it. A lot of the things we know we don't necessarily put into practice (Anne, head of mathematics, Norman Fletcher School).

There were two aspects to self-efficacy, the first is that the more efficacious were more willing to experiment with their teaching. Second, the data suggests that the PD had an effect on teachers' self-efficacy. Often this was positive but if teachers had a bad experience with SCPS as part of the PD it could undermine confidence and diminish self-efficacy.

Social, contextual and environmental effects

There were references to the social, environmental and contextual factors that limited teachers' capacity to incorporate student-centred problem-solving into their teaching. Teachers often referred to the having to 'cover' or get through the scheme of work or curriculum in order to prepare students for examination. In addition, they suggested that because students were not used to working in a SCPS way – particularly in the lower ability classes – this presented barriers to teaching in that way. Some teachers and most of the heads of departments also expressed concerns about parental expectations in what mathematics teaching should be like. The approaches suggested in the PD were often perceived to be contrary to the expectations of students, parents and sometimes colleagues in the wider school. In one school, teachers were particularly concerned how the inspectorate would judge their teaching if they were observed teaching in the ways suggested in the PD programme. However, teachers, particularly those in the video-study, acknowledged that the PD and lessons they had tried out had given them space to experiment with and explore different ways of teaching. It had given them 'permission' to do something different.

All heads of departments explained how difficult it had been to fit in meeting time to hold the PD sessions. One school had to hold the sessions during lunch breaks another had to do the sessions in scheduled department meeting time but found issues that had been put to one side for the PD still needed to be communicated and discussed. At the same time they all valued the opportunity that the PD created: to meet, discuss and explore teaching and learning as a department. They felt that being part of the project had made them, as a department, think and try out lessons and different approaches. However, in one of the schools it was clear that only the teachers involved in the video-study were actually trying out the planned lesson with their own classes.

DISCUSSION

This preliminary analysis demonstrates that SLT has both *descriptive* and *explanatory power* in the context of this PD. This could be further developed through more analysis. Schoenfeld (2002) describes *descriptive power* in terms of the theory's capacity to capture "what counts" *or* the extent to which the theory takes the right factors into account? (p. 488). It appears that teacher knowledge, self-efficacy beliefs and the social and contextual effects, represent the 'right factors'. Schoenfeld (2002) contrasts description and explanation: 'It is one thing to say that people will or will not be able to do certain kinds of tasks, or even to describe what they do on a blow-by-blow basis; it is quite another thing to explain why' (p. 489). The analysis of SLT presented through this papers suggests SLT offers a viable explanation of professional learning from both the cognitive perspectives of teacher knowledge and beliefs as well as the social and situated aspects of professional learning. SLT also addresses learning processes in terms of observational learning which appears consistent with other studies (See, for example, Lortie, 2002).

CONCLUSION

SLT appears to offer a useful theoretical framework that integrates cognitive and social aspects of professional learning. SLT accounts for teachers' pedagogic knowledge in terms of mental models of behaviour that have been acquired through observational processes. The way in which pedagogic knowledge is applied in the classroom is influenced by the teachers' level of self-efficacy as well as the social and contextual setting. SLT could provide an improved theoretical framework that has the potential to enhance the design and evaluation of PD. However, this is a preliminary exercise in testing the potential of SLT. SLT has been considered against two criteria: *descriptive* and *explanatory power*. Schoenfeld (2002) suggests further criteria, further research is required to assess SLT against these additional criteria. Although, at this stage it is reasonable to conclude that SLT has potential in theorising teachers' professional learning.

WHAT CAN WE LEARN FROM OTHER DISCIPLINES ABOUT THE SUSTAINABLE IMPACT OF PROFESSIONAL DEVELOPMENT PROGRAMMES?

Stefan Zehetmeier

University of Klagenfurt, Austria

This paper deals with the sustainable impact of professional development programmes. While research on this issue is rather scarce in mathematics teacher education, some other domains like health care or development aid are well grounded in research results regarding this topic. This paper gives an insight into the other disciplines' knowledge concerning the impact of innovations and professional development programmes and the respective fostering factors. Moreover, possible implications for mathematics teacher education are discussed.

INTRODUCTION

The question of how to promote mathematics teachers' professional development is of great interest and discussed in various papers (e.g., Krainer & Zehetmeier, 2008; Loucks-Horsley, Stiles, & Hewson, 1996; Maldonado, 2002; Sowder, 2007; Zehetmeier, 2010; Zehetmeier & Krainer, 2011). In this context, the question of sustainability is of particular relevance. Despite its central importance for both, teachers and teacher educators, research on sustainable impact is generally lacking within teacher education disciplines (Datnow, 2006; Rogers, 2003).

However, a sound knowledge base concerning the issue of sustainability would be useful for understanding the long-term impact of teacher professional development programmes. At the same time, this knowledge would allow thorough discussions regarding implications for upcoming professional development programmes' planning, implementation, and evaluation. The aim of this paper is to provide other disciplines' knowledge concerning this issue. For this, an extensive literature was carried out; using qualitative content analysis (Mayring, 2003), relevant topics were identified and clustered. The following sections provide other disciplines' knowledge regarding factors that foster the sustainability of professional development programmes' impact.

This raises the question: Who are the others? Health care disciplines come with a relative long tradition of researching the topic of professional development's sustainable impact. This led to a widespread body of research findings concerning this issue. Besides the health care disciplines also research on development aid or public service evaluation has available interesting findings; they also can be used as focal points for discussing and reflecting sustainability in mathematics teacher education. Thus, this paper's literature review is based particularly on research findings from health care disciplines (e.g., Scheirer, 2005). Moreover, results from

disciplines like development aid (e.g., van den Berg, 2006) or public service evaluation (e.g., Savaya, Elsworth, & Rogers, 2009) are provided.

THE OTHERS' FOSTERING FACTORS

Literature regarding conceptual or empirical knowledge of factors that may foster the sustainability of innovations is rather sparse (Johnson et al., 2004). However, “the question of what factors contribute to or detract from program sustainability is important because ... it cannot be assumed that proven success in achieving its goals ensures a program’s continuation beyond its initial funding” (Savaya et al., 2009, p. 2). The question which factors help increase the likelihood of sustainability is particularly addressed in literature regarding the institutionalization of programmes within organizations: “This issue is of central importance when one is planning for program sustainability, when it is helpful to know what processes and other influences need to be considered to extend the delivery of program activities” (Scheirer, 2005, p. 324).

This paper uses a qualitative analysis of literature (Mayring, 2003): Eight central factors, which foster the sustainability of programmes, were categorized. The following factors are central, because they were found to be influential more often than other ones: perceived benefit, innovation champions, mutual fitting, institutional support, sufficient resources, networking, ownership, and integration of rules. The following paragraphs provide an overview concerning these central factors.

Perceived benefit

One of the central factors fostering the sustainability of programmes is “the perceived benefit from the programme” (Amazigo et al., 2007, p. 2080) for the people involved. This implies in particular that “attention to the needs, attitudes, and perceptions of adopters is critical to their sustained use of an innovation” (Johnson et al., 2004, p. 143). And further: “Users must perceive a benefit to the innovation beyond that of current practices. ... Adopters are also more likely to sustain an innovation if they believe it is effective” (Johnson et al., 2004, p. 145). Baum et al. (2006) state that some “initiatives were often only felt to have happened because of the previous collaborations. ... In effect these had laid the seed bed on which future projects grew” (p. 262).

In particular, the “evidence that the model works ... and the ability to document positive client outcomes” (Blasinsky et al., 2006, p. 721) represents a strong fostering factor. On the other hand, Scheirer (2005) highlights that these “benefits to staff members and/or clients ... are readily perceived, but not necessarily documented via formal evaluation” (p. 339). This issue points to benefits and outcomes which may not have been intended or expected in a programme’s conception; and which may – thus – not be considered in project evaluations or research efforts.

Pluye, Potvin, Denis, Pelletier, and Mannoni (2005) found incentives to be a factor fostering the sustainability of innovations: “The promotion of personnel (into positions of greater responsibility and power) encouraged the routinization of innovations. ... Adding concrete benefits to human resources also constitutes an incentive (for example, in the form of convenience or reduced effort)” (p. 125).

Innovation champions

Another central factor that supports the sustainability of programmes is “the presence of champions for an innovation” (Johnson et al., 2004, p. 138). Similarly, Scheirer (2005) highlights “the key role of a program champion” (p. 339). Also Savaya et al. (2009) state that “program champions who promote the program in the organization and the community can contribute to program sustainability” (p. 2).

These champions are “formal and informal leaders within adopting systems ... who proactively promote an innovation from inside or outside of a system” (Johnson et al., 2004, p. 143). They “are critical to creating an environment that supports and facilitates sustaining innovations. ... Such champions can serve as brokers on behalf of the innovation with other decisionmakers” (Johnson et al., 2004). Johnson et al. (2004) describe in detail: “Essential skills for innovation champions include communicating their commitment to the innovation, ... engaging others, overcoming barriers, building infrastructure, thinking and learning reflectively, summarizing and communicating, coaching for sustainability, and building further organizational capacity to spread the innovation” (p. 144).

Blasinsky et al. (2006) point to the importance of staff members who are “already trained [in the programme]” and are “available not only to continue [the programme] but also to train others in the intervention” (p. 726).

Mutual fitting

Yet another central factor fostering sustainability is the fitting of innovations and adopting institutions. For example, “when program objectives fit with the values of the organization and staff” (Pluye et al., 2005, p. 125). Or “when cultural artifacts from program activities are shared with organizational artifacts” (Pluye et al., 2005, p. 125); here, artifacts are defined as myths, symbols, metaphors and rituals that express a set of organizational values, beliefs and feelings. Another kind of fitting is represented by “the adaptation of activities according to their context or environment” (Pluye et al., 2005); in this case, adaptation means the adjustment of activities regarding local contexts and environmental variations. In sum, this refers to introducing innovations into organisations without “disruption of the operating work flow” (p. 126).

Johnson et al. (2004) state that sustainability is fostered when innovative programmes are “compatible with the philosophical orientation ... and internal agenda of users” (p. 145). Similarly, Scheirer (2005) claims for “a substantial fit with the underlying organization’s mission and procedures” (p. 339). This challenges both

the organisations' stability and flexibility: "The stability of an organization and its ability to change significantly contribute to the sustainability of new programs" (Savaya et al., 2009, p. 2).

Institutional support

Institutional support is another central factor that supports the sustainability of programmes. This can be mirrored by the "willingness of the organization to promote change" (Blasinsky et al., 2006, p. 726). Or when organisations take the risk of supporting innovative programme activities: Because then organisations "build confidence among actors involved in activities and encourage the routinization of programs" (Pluye et al., 2005, p. 124).

For this, the administration of organisations "must have the structures and capacity necessary to carry out administrative functions related to an innovation responsively, effectively, and efficiently" (Johnson et al., 2004, p. 144). In this regard, it is important to know that "systems that focus on strengthening administrative capacity to support an innovation during its initial implementation are more successful at sustaining the innovation once the initial trial ends" (Johnson et al., 2004, p. 144).

Sufficient resources

Yet another central factor fostering sustainability is the availability of resources. Johnson et al. (2004) state that "sustainability research clearly identifies resources as important to sustaining innovations" (p. 143). These resources include human, physical, technological, financial and informational resources (Pluye et al., 2005; Johnson et al., 2004). Sufficient resources can support the sustainability of programmes in the case of "equipment turnover (renewal of material resources when needed)" or of "turnover in key personnel (change of original personnel after an appropriate period of time)" (Pluye et al., 2005, p. 124). To ensure the availability of sufficient resources, programmes can "have multiple sources of funding", and/or "the project leaders can plan to raise resources for the future, when fund raising starts early on" (Savaya et al., 2009, p. 2).

Networking

Savaya et al. (2009) highlight the importance of networking: "Self-contained programs are less likely to be sustained than are programs that are well integrated with existing systems" (p. 2). In this regard, Pluye et al. (2005) state "that transparent communication between the actors is necessary to achieve congruence among objectives, to share cultural artifacts, and to take corrective actions, thus promoting routinization" (p. 125). For networking, some "positive relationships among key implementers" (Johnson et al., 2004, p. 138) are useful: "Collaboration between program developers and teachers who are implementing the program appeared to increase their commitment and desire to implement the new procedures. A supportive peer network among implementers of an innovation is also important for sustaining innovations" (Johnson et al., 2004, p. 138).

Ownership

Savaya et al. (2009) point to the factor ownership as being central for sustainability: They found “greater sustainability of programs that were developed and implemented with the involvement and support of community bodies” (p. 2). Also Johnson et al. (2004) indicate the importance of “ownership by ... system stakeholders” (p. 138) as factor fostering the sustainability of innovative programmes. Similarly, Amazigo et al. (2007) point to the fostering influence of “community leaders [who] show appreciation” (p. 2080) for the programmes.

Integration of rules

Research findings of Johnson et al. (2004) suggest that the integration of rules is another fostering factor: “Policies and procedures ... assure that the innovation remains part of the routine practice of the organization, even after the top management who advocated sustaining the innovation leaves the organization” (p. 143). For Yin (1981), sustainability is fostered when “program functions become part of job descriptions and prerequisites” or when “the use of innovation becomes part of statute, regulation, manual, etc.” (p. 63).

DISCUSSION AND IMPLICATIONS

This section links the others’ fostering factors to mathematics teacher education. Communalities can indicate possible affirmations and validations of our discipline’s knowledge. Differences may point to aspects worth being challenged and reconsidered.

Communalities

The other disciplines identified several factors that foster the sustainability of programmes (see the others’ factors above). In a meta-analysis concerning factors in the teacher education disciplines, Zehetmeier (2008) found yet similar, but not the same factors. For example, mutual fitting, ownership, and networking turned out to be central fostering factors in both the others’ and teacher education literature. Therefore, it seems reasonable to facilitate factors identified by both domains.

Zehetmeier and Krainer (2011) highlight in particular the outstanding relevance of contextual factors. Similarly, a study of Nickerson and Moriarty (2005) points to organizational conditions (e.g., teachers’ relationships with the school administration) being highly relevant for the further development of schools. Since contextual factors contribute particularly to sustainable impact, organisational development should be part of any professional development programme. This means, that not only mathematics teachers should be seen as a programme’s target group, but also the teachers’ contexts (e.g., colleagues, pupils, principals, parents, policies, etc...). Therefore, professional development and school development should be considered as concomitant processes. This relevance of contextual factors

is also highlighted in the other disciplines (see section “institutional support”, above).

Rogers (2003) highlights that the diffusion of an innovation depends on different characteristics: Relative advantage, compatibility, complexity, trialability, and observability. Fullan (2001) describes similar characteristics (need, clarity, complexity, quality, and practicality) influencing the acceptance and impact of innovations. Relative Advantage includes the perceived advantage of the innovation (which is not necessarily the same as the objective one). Compatibility and need denote the degree to which the innovation is perceived by the adopters as consistent with their needs, values and experiences. Complexity and clarity include teachers’ perception of how difficult the innovation is to be understood or used. Trialability denotes the opportunity of participating teachers to experiment and test the innovation (at least on a limited basis). Quality and practicality make an impact on the change process. Observability points to the claim that innovations should be visible to other stakeholders. Therefore, when aiming at sustainable impact, the following implications should be considered: An innovation with greater relative advantage will be adopted more rapidly. This issue is also addressed by the other disciplines’ factor “perceived benefit” (see above). More complex innovations are adopted rather slowly, compared to less complicated ones. Innovations that can be tested in small steps represent less uncertainty and will be adopted as a whole more rapidly. High quality innovations that are easily applicable in practice are more rapidly accepted. Innovations which are visible to other persons and organisations are more likely to be rapidly accepted and adopted. These implications are closely linked to the others’ fostering factor “integrations of rules” (see above).

Shediac-Rizkallah and Bone (1998) categorized three groups of factors that foster or hamper programmes’ sustainability: (a) factors pertaining to the project; (b) factors within the organizational setting, and (c) factors in the broader community environment. Zehetmeier and Krainer (2011) try to reduce the multiple factors’ complexity by clustering them into three dimensions (the three Cs; see Krainer, 2006): Content (high level and balance of subject-related action and reflection), Community (high level and balance of individual and social activities, in particular fostering community-building within and outside the professional development programme), and Context (high level and balance of internal and external support). Thus, both domains acknowledge the rather complex system of factors and try to establish useful and suitable models. Therefore, if professional development programmes are aimed to be sustainable, it seems crucial to carefully consider and facilitate these fostering factors. If some of these factors are dependent from the programmes’ existence, then these factors may be substituted with alternative ones that are less or not at all connected to the programmes’ existence.

Differences

Leadership as fostering factor is not really a topic in the others' disciplines. Indeed, Johnson et al. (2004) point to "effective leadership" (p. 138) being a fostering factor. However, it remains unclear, what this notion may mean. By contrast, within the teacher education disciplines the issue of leadership is of great importance. The results of several studies suggest the central influence of school leadership to the (sustainable) impact of school innovation initiatives (e.g., Fullan, 2006; Owston, 2007): Fullan (2006) proposes a direct correlation between the sustainability of innovations and the new role of school leadership: "This new leadership, if enduring, large scale change is desired, needs to go beyond the successes of increasing student achievement and move toward leading organizations to sustainability" (p. 113). These new leaders focus on systemic relationships to foster sustainability not only on the individual level, but also on the levels of organisations or educational systems. "Such leaders widen their sphere of engagement by interacting with other schools in a process we call lateral capacity building. When several leaders act this way they actually change the context in which they work" (Fullan, 2006, p. 113). Fullan (2006) calls this new type of leadership "system thinkers in action" ("they have the capacity to be simultaneously on the dance floor and the balcony", p. 114). Similarly, Owston (2007) states: "Support from the school principal is another essential factor that contributes to sustainability" (p. 70). He distinguishes three types of administrative support: Neutral leaders (who meet innovations rather passive without promoting or prohibiting); Supportive principals (who create and support beneficial environments for innovations); And actively involved leaders (who are driving visionary ideas, identify personally with innovations and motivate other teachers for the innovation). Therefore, for programmes aiming at sustainable impact, it seems indicated to foster and support this kind of leadership.

The presence of an innovation champion as fostering factor is rather no big topic in mathematics teacher education disciplines. However, Cobb and Smith (2008) highlight the important role of "brokers" (as do Johnson et al., 2004, see above) for the development of a shared instructional vision of high quality mathematics instruction. They describe brokers as people "who can facilitate the development of a shared instructional vision by bridging between perspectives and agendas of different role groups. Brokers are people who participate at least peripherally in the activities of two or more groups, and thus have access to the perspectives and meanings of each group" (p. 238).

SUMMARY

This literature review revealed other disciplines' knowledge regarding the sustainability of professional development programmes' impact. With regard to mathematics teacher education the following implications can be deduced: Teachers, facilitators, and researchers of professional development programmes should

- plan for sustainability from the very start,
- take systematically into account the unintended and unexpected impacts,
- consider professional development and school development as concomitant processes,
- foster and support sustainable leadership,
- foster and support innovation champions,
- focus on factors that are less dependent from the programme's existence.

When discussing and researching professional development programmes' sustainable impact, the fostering factors are playing the central role. Knowing and being sensible for them is prerequisite for any conceptualization, implementation and evaluation of future professional development programmes which aim at sustainable impact. Thus, further, broader as well as deeper research of professional development programmes' sustainable impact and their respective fostering factors appears to be promising from both scientific and practical perspectives.

Another felicitous sentence concerning the complexity of fostering and hindering factors is provided by Slavin (2004): "With the many ways that innovations can be undone, it is perhaps more surprising when they do maintain over time than when they do not" (p. 61). Therefore, each programme has to carefully consider its respective fostering factors regarding the sustainability of impact, since each professional development programme has its own and particular objectives, contents, methods, and environments. Considering these factors in the programme's planning may help to establish sustainable impact.

NOTE

This paper is a modified and shortened version of Zehetmeier (in press). In this aforesaid paper, also the others' rationales, definitions, theories, research methods, and discussions are provided.

SPECIALIZED CONTENT KNOWLEDGE OF MATHEMATICS TEACHERS IN UAE CONTEXT

Ismail O. Zembat

Mevlana (Rumi) University, Faculty of Education, Konya, Turkey

This study aimed to characterize the gap between the mathematics teachers' current knowledge of mathematics and the ideal mathematical understanding for teaching in the UAE context. Specifically, it aims to investigate this gap by focusing on the specialized content knowledge of mathematics teachers in UAE. A fairly representative sample was chosen from UAE public schools and a questionnaire including open-ended and multiple-choice questions was applied to 142 mathematics teachers from grade 1-12. The results suggest that there is quite a gap between the current and ideal levels in terms of understanding core mathematical ideas, interpreting student work and knowledge, understanding purpose of assessment and conceptualizing the development of mathematics curriculum.

INTRODUCTION

The purpose of this research project¹ was to characterize the mathematics teachers' knowledge of mathematics in UAE public schools in order to portray the gap between what mathematics teachers should know and what they already know. For this purpose, I sampled a number of teachers from different public schools of United Arab Emirates (UAE) and applied a comprehensive research-based mathematics questionnaire assessing their knowledge of and about mathematics.

RELEVANT LITERATURE AND RESEARCH QUESTIONS

Even though there is not much solid research-based evidence, it is the perception shared in the relevant research literature that teacher knowledge has an impact on students' understanding, especially in the field of mathematics education (Ball & Forzani, 2009). Such shared belief in this area puts extra responsibilities on the shoulders of researchers' to investigate the relationship between teacher knowledge and student success. However, before doing so, researchers need to learn more about the nature of teacher knowledge so that they can then use it to pursue the aforesaid endeavor. Therefore, in this study, I aimed to investigate the following research questions in a geographic region whose voice has not been heard well enough in the relevant literature, specifically UAE. The research questions for this study were:

1. How do in-service mathematics teachers understand and think about fundamental mathematical ideas in major strands (geometry, algebra, measurement, probability and statistics, and numbers)?"?
2. What is the nature of the gap between 'what teachers currently know' and 'what they should know' to teach mathematics effectively in UAE schools?

In light of these research questions the current study aimed to contribute to the field's understanding of mathematics teacher knowledge and its nature. To pursue these

research questions I used the following framework and methodology. The data analysis is still in progress but some of the results will be shared in this article.

THEORETICAL FRAMEWORK

Searching through the relevant research literature gave me the chance to identify the types of knowledge (in mathematics) and the ideal qualities of mathematics teachers with respect to these knowledge types. Following on Shulman's (1986) previously proposed knowledge types, Ball and her colleagues in a number of studies (e.g., Ball, Lubienski, & Mewborn, 2001; Hill, Schilling, & Ball, 2004; Hill, Ball, & Schilling, 2008; Ball, Thames, & Phelps, 2008) identified the types of knowledge teachers should have that is required in teaching mathematics, called mathematical knowledge for teaching (MKT). In this framework, MKT consists of two major components, namely subject matter knowledge (SMK) and pedagogical content knowledge (PCK). PCK consists of knowledge of content and students, knowledge of content and teaching and knowledge of curriculum. SMK consists of common content knowledge, mathematical knowledge at the horizon and specialized content knowledge (SCK). The subcomponent SCK is the focus of attention for this study since it is directly related to teachers' mathematics subject matter knowledge and it is the most essential one. SCK refers to the "mathematical knowledge that allows teachers to engage in particular *teaching* tasks, including how to accurately represent mathematical ideas, provide mathematical explanations for common rules and procedures, and examine and understand unusual solution methods to problems" (Hill et al., 2008, p.378). This account of SCK was initially described in Ball et al. (2005). In explaining SCK, Ball and her colleagues working on teacher knowledge suggested that teachers should have some SCK that is required to manage everyday tasks of teaching mathematics. Even though these tasks of teaching mathematics vary a lot and these scholars did not provide a complete list in a single publication, it was possible to compile a list of these everyday tasks of teaching from their writings that have previously appeared in different publications (e.g., Ball, Lubienski, & Mewborn, 2001; Hill, Schilling, & Ball, 2004; Ball, Hill, & Bass, 2005; Hill, Ball, & Schilling, 2008; Ball, Thames, & Phelps, 2008). Below is a list of tasks mathematics teachers need to deal with regularly, which require special kind of knowledge (especially SCK) on the part of the teachers. According to Ball and her colleagues mathematics teachers who have SCK have the knowledge of or ability to do the following:

SCK#1: Unpack" mathematical knowledge in order to provide meaning for learners; **SCK#2:** Have knowledge of interpretations and contexts; knowledge of common errors; diagnosing errors in student work; **SCK#3:** Design mathematically accurate explanations that are comprehensible and useful for students; **SCK#4:** Know mathematical explanations for common rules, procedures or algorithms; represent mathematical ideas (and operations) carefully; **SCK#5:** Provide explanations and justifications for mathematical ideas and procedures; evaluate mathematical explanations; present mathematical ideas; **SCK#6:**

Generate examples; find an example to make a specific mathematical point; **SCK#7:** Analyze mathematical treatments in textbooks; Appraise and adapt the mathematical content of textbooks; deploy mathematical definitions or proofs in accurate yet also grade-level-appropriate ways; **SCK#8:** Build connections among mathematical ideas; know underlying mathematical structures; **SCK#9:** Interpret and make mathematical and pedagogical judgments about students' questions, solutions, problems and insights (both predictable and unusual); respond to students' "why" questions; **SCK#10:** Assess aspects of understandings students show; listen to and interpret students' responses; analyze student work; pose questions; (+recognize what is involved in using a particular representation; select representations for particular purposes); **SCK#11:** Analyze a superficial understanding of an idea; be able to respond productively to students' mathematical questions and curiosities; evaluate the plausibility of students' claims (often quickly); attend to ambiguity of specific words; make mathematical practices explicit; **SCK#12:** Choose and develop useable definitions; use mathematically appropriate and comprehensible definitions; **SCK#13:** Connect a topic being taught to topics from prior or future years; sequence ideas; **SCK#14:** Think about multiple representations; map between a physical or graphical model, the symbolic notation and the operation or process, and make connections among the representations; link representations to underlying ideas and to other representations; construct and/or link non-symbolic representations of mathematical subject matter; use mathematical notation and language and critique its use; **SCK#15:** Inspect equivalencies; **SCK#16:** Know alternative solution methods, and claims; evaluate mathematical methods, claims and (alternative) solutions.

In the current study, this list of competencies is considered to be "what mathematics teachers should know." To learn about teachers' current competencies in each of the above issues (what they currently know), I designed a questionnaire consisting of questions with several subquestions per competency, the details of which are given in the following section. Such design helped me to identify the gap in between what mathematics teachers already know and what they should know.

METHOD

A questionnaire testing the aforesaid competencies was generated based on the relevant research literature and my own experiences about teacher knowledge, and applied to a sample of teachers. The sample was chosen from among all public schools throughout UAE. I used proportional stratified sampling to sample 100 schools out of 499 by considering cycles, gender, and region. Even though I sampled 100 schools out of all UAE public schools I could only work with volunteered teachers from 55 of those 100 schools because of bureaucratic limitations. The distribution of participant teachers is illustrated in Table 1.

City name / Cycle	Cycle 1 (Gr.1-5)	Cycle 2 (Gr.6-8)	Cycle 3 (Gr.9-12)	Common Cycle (Gr.1-12)	Total
Al Ain	12	25	11	17	65
Western Region	0	1	4	22	27
Abu Dhabi	12	23	15	0	50
Total	24	49	30	39	142

Table 1: Participant mathematics teacher distribution based on cycle and region

This sample is about the 10% of the whole school population and mathematics teacher population. The sample of teachers is fairly representative of the public school mathematics teacher population. The participants were 85 male (60%) and 57 (40%) female mathematics teachers.

SOME OF THE QUESTIONS ASKED IN THE QUESTIONNAIRE

Once those competencies (as laid out in the Theoretical Framework section) were identified, I developed a questionnaire targeting each competency (group). Then these questions were piloted on mathematics teacher groups online the results of which helped in revising and finalizing the questionnaire. Some of the questions from this questionnaire and their corresponding competencies are given within the results.

DATA ANALYSIS PROCEDURE

The gathered data included two main sections; one is about demographics and the other is about mathematical knowledge. Demographic information is analyzed to highlight the background characteristics of the participant teachers, which is partly shared in the Method section. The data about mathematical knowledge was mainly qualitative but to save time in overall data analysis process, I transformed this data into quantitative form and make the necessary analyses using SPSS. For example, in analyzing the participant answers about the division of fractions problems (targeting SCK#4, as explained in page 8 of this paper), the responses were coded as follows: "1 = "Completely wrong answer and/or rationale", 2 = "Says "it is right" but no rationale", 3 = "Turn it into invert-multiply and find solution", 4 = "Size or division matches rationale", 5 = "Size and division match rationale", 9 = "No answer". Once such coding is completed for this question, I then checked the frequencies of different responses and then move into the qualitative analysis of these responses to learn more about the nature of participants' SCK. A detailed qualitative and quantitative analyses are still ongoing. Because of space limitations, the nature of this data analysis is briefly included in the paper. Some of the results are highlighted and briefly discussed in the following section.

BRIEF DISCUSSION OF SOME OF THE MAJOR RESULTS

The current study revealed that in-service mathematics teachers in UAE have significant problems regarding mathematics content, analyzing student work,

curricular issues and assessment. This also suggests that there is quite a gap between where they are and the ideal SCK that they should have. Therefore, this paper only highlights the weaknesses of the participant teachers to reveal the nature of the aforesaid gap. The results about these issues are briefly explained below.

ISSUES RELATED TO CONTENT

Participant in-service mathematics teachers can mostly carry out the basic mathematical procedures (e.g., finding solution of a basic division problem), which is a strength on their part, but most of them have serious problems with interpreting the conceptual meanings embedded in those procedures. For example, in analyzing whether a given 3-dimensional graphical representation for $g(x, y) = xy$ as in Figure 1 represents a function (targeting SCK#13), almost 90% of the teachers mentioned that a 3-dimensional graph cannot represent a function, which is also one of the major misconceptions seen among students. In earlier grades whether a given graph represents function is tested through vertical line test (VLT). However, when the given representation is a three-dimensional (3D) graph, as given in higher grade mathematics classes, the participants had a hard time applying this VLT to the given graph. They even left VLT aside and think that a 3D graph cannot represent a function. This seems to be because it is a challenging task for them to connect a topic being taught in early grades to topics from future years (a requirement for SCK#13).

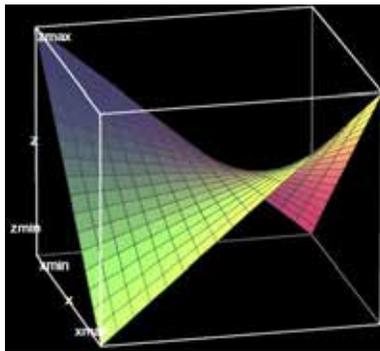

Figure 1: A given 3-dimensional graphical representation for $g(x, y) = xy$. [Note that this question was originally developed in a project, conducted within Mid-Atlantic Center, supervised by Prof. Kathleen Heid from The Pennsylvania State University in USA]

The participant teachers, for example, analyze equations through a single lens, mostly through algebra, as opposed to referring to several lenses including geometry. In analyzing a given first degree equation, $2x+4 = 3x+8$ (targeting SCK#15), about 95% of the teachers found its solution as $x=-4$, which is a strength on the teachers' part, but could not provide another way to analyze it (e.g., as a point of intersection of two lines). This suggests that their analysis of equivalencies is limited (opposite to the requirement of SC#15) and they did not seem to be able to interpret equivalencies, such as $2x+4 = 3x+8$, by referring to different domains like analytic geometry.

One final example that illustrates a challenge for participants regarding conceptual meanings of mathematical ideas is the way they approach to the concept of parallelism. In one of the questions, the participants were given a drawing-a-

parallelogram scenario in a dynamic geometry software environment (DGS) (with pictures as illustrated in Figure 2 in order). In this scenario the participants were told that a student, Ahmed, was going through the following steps. In a dynamic geometry environment, called Wingeom, a line is drawn (passing through two arbitrary points, A and B), then a point (out of line AB) is put on screen (point C), and the program is asked to draw a parallel line (passing through that outside point) to the initially drawn line. Then the DGS draws a parallel line passing through the initial point (point C) but it automatically puts another point on this newly drawn line (point D).

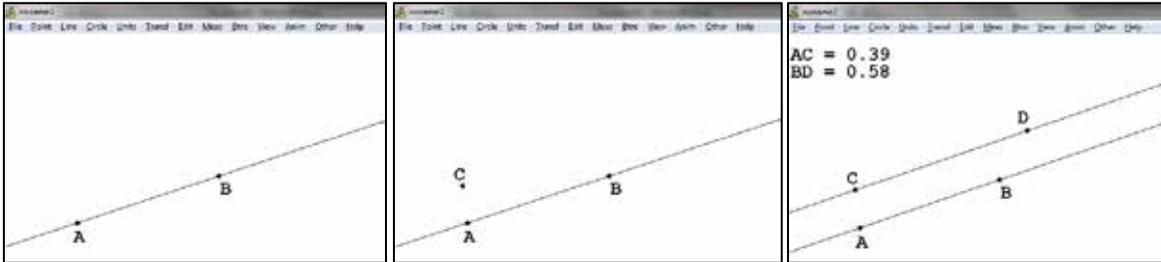

Figure 2: Pictures given in question #9 targeting SCK#9.

They are then asked: “After going through Step#3 and finding the measures for AC and BD, he got puzzled. He thought to himself, “If Wingeom did not draw the parallel line based on the distances between A and C, and B and D, how did it decide on how to draw the parallel line CD? On what basis did the program created this extra point (point D) automatically?” If Ahmed was in your class, how would you explain the answers to these two questions mathematically to Ahmed?”

It is obvious from the participants’ responses that they could only think about parallelism by focusing on the distance between the two lines or the ratios of distances AB , AC , CD and DB . A sample response from one of the participants is as follows: “I confess utter confusion as to the reason Wingeom would create such a pt. D at exactly the place it did. However, it could have picked a random point on \overleftrightarrow{AB} and gone 0.3 inches away to put a point D and then draw the parallel line. It may have created point D so that the ratio of \overline{AB} to \overline{CD} was equal to AC to DB but without knowing the values of \overline{AB} and \overline{CD} . I cannot verify such a claim.”

The above response suggests that this teacher focused his attention to the distance between the two lines as well as the ratios of certain distances in the given scenario, whereas he ignored the fact that parallelism also requires same sloped lines. The participant teachers had difficulty in interpreting and making mathematical and pedagogical judgments about hypothetical unusual student questions and in responding to students’ “why” questions - a requirement for SCK#9.

As seen in these given examples, interpreting the mathematical meanings of core mathematical ideas is quite a challenge for the participant mathematics teachers.

ISSUES RELATED TO ANALYSIS OF STUDENT WORK

The participants’ analysis of student work is not at a desired level when it comes to an alternative solution method. For example, when given a scenario about a fraction

division solution, like $\frac{3}{8} \div \frac{1}{3} = \frac{9}{24} \div \frac{8}{24} = \frac{9}{8}$ (called common denominator algorithm), they only turned it into a well-known invert-and-multiply algorithm to check whether it is accurate or not instead of analyzing the accuracy of the given method. This suggests that their ability to provide mathematical explanations for common algorithms, which is a requirement for SCK#4, falls short in reaching the ideal level.

The study also revealed that the participant mathematics teachers are also quite weak in identifying possible student errors for a given problem situation. They were asked to talk about possible student errors for the following problem targeting SCK#2:

Question #2: *A computer game store is having a sale. They have advertised 10% off everything in the store. They also have just purchased a new shipment of computer games. These games cost the store 32.11AED each. They want to price the game so that they will make at least a 40% profit, even at the sale price. What is the lowest regular selling price for the game that will allow this profit? (Bair & Rich, 2011)*

a) *If a student brings this question to your mathematics class, to what extent would you feel confident (or comfortable) in analyzing this problem situation before you actually solve it?*

- 5-highly confident 4-somewhat confident 3-confident
 2-little confident 1-not confident

b) *What mathematical knowledge or understandings are required to solve this problem? [Please be specific in your answer. For example, saying that it requires algebra or geometry is not informative! If you need, you can solve the problem here and then talk about the mathematical components of it!]*

c) *What common mathematical errors (or mistakes) would you expect from students in solving such a problem?*

In approaching such a problem, instead of focusing on the student errors, participants mostly solved the problem first, and then talk very superficially about possible student errors such as “students will most like make calculation errors.” This suggests that the participant mathematics teachers need significant support in how to analyze student work in mathematics classes. Such support can be in a form where they are given opportunities to “listen” to the student ideas, interpret those ideas, and think about what it means to think like a student in certain problem situations.

ISSUES RELATED TO ASSESSMENT

The study revealed an interesting result about mathematics teachers’ understanding of assessment. When participants were asked to choose from among three assessment items so as to test student understanding of infinity (given below), about 95% of the participant teachers chose the easiest to handle representation to ask, Example 3. A typical response given by the participants who chose Example 2 or 3 as the best one to ask students are: “Since sets are given side by side [in Example 1], students can’t really analyze them” and “Because it is well cleared [in Example 3] to the student that both groups are infinite.”

Question #10 (targeting SCK#10): Which of the following sample questions would be nice to assess student understanding of infinity? In answering the question please also consider the way the questions are represented. (Tsamir & Dreyfus, 2002)

1-Example#1 2-Example#2 3-Example#3

Example #1: Consider the following sets. Which one do you think has more elements than the other?

$$A = \{1, 2, 3, 4, 5, 6, \dots\}; B = \{1, 4, 9, 16, 25, 36, \dots\}$$

Example #2: Consider the following sets. Which one do you think has more elements than the other?

$$A = \{1, 2, 3, 4, 5, 6, \dots\}$$

$$B = \{1, 4, 9, 16, 25, 36, \dots\}$$

Example #3: Consider the following sets. Which one do you think has more elements than the other?

$$A = \{1, 2, 3, 4, 5, 6, \dots\}$$

$$B = \{1^2, 2^2, 3^2, 4^2, 5^2, 6^2, \dots\}$$

Such focus on the teachers' part suggests that the participants think about assessment in mathematics as a way to help students as opposed to as a way to test knowledge of students. One of the purposes of assessment is to figure out how and to what extent students understand a targeted concept (Airasian & Russell, 2008) and a teacher can assess students' knowledge through probing questions that do not include any hints about the solution of the problem. The fact that almost every participant choose the easiest-to-handle question to ask students to figure out how students think about infinity suggests that they seem to misinterpret the purpose of assessment in mathematics classes.

ISSUES RELATED TO CURRICULUM

From curricular standpoint, almost all of the participant teachers follow the traditional ways to explain curricular decisions made in the books. For example, they think about trapezoid by referring to exclusive definitions (definition #1 as given below) rather than inclusive definitions (definition #2 as given below).

Question #7 (targeting SCK#7): A well-known mathematics educator in USA, Zal Usiskin, checked through the geometry textbooks used in USA since 1800s and realized that there are mainly two definitions given for "trapezoid" as shown below.

Definition #1: Trapezoid is a quadrilateral with exactly one pair of parallel sides.

Definition #2: Trapezoid is a quadrilateral with at least one pair of parallel sides.

A) If we accept Definition #1 which one of the following figure(s) would be considered as trapezoids? Mark all that apply.

1-Parallelogram 2-Rectangle 3-Rhombus 4-Square 5-Isosceles Trapezoid

Why?

B) If we accept Definition #2 which one of the following figures would be considered as trapezoids? Mark all that apply.

1-Parallelogram 2-Rectangle 3-Rhombus 4-Square 5-Isosceles Trapezoid

Why?

C) If you were to use one of these definitions to teach students in your math classes, which definition would you use?

1) Definition#1 2) Definition#2

Why?

In addition to this, when they need to make curricular decisions about the sequence of mathematical topics (e.g., which topic should come first, triangles or circles?), their decisions do not reflect a solid understanding of those mathematical concepts. For example, most of them do not know that having the knowledge of circle is necessary to make sense of triangles, and therefore, it may be appropriate to teach circles first and then triangles. Therefore, their responses suggest that their analysis of the mathematical treatments in textbooks and deploying mathematical definitions in accurate and grade-level-appropriate ways, as suggested by SCK#7, need to be improved in ways that allow them to critique mathematical definitions and their treatments in textbooks.

IMPLICATIONS AND RECOMMENDATIONS FOR FUTURE RESEARCH

Considering the above general results about mathematics teacher knowledge, there seems to be a considerably negative large gap between where teachers are and where they should be – teachers currently teaching mathematics in UAE are quite weak in understanding the core mathematical ideas they teach, in interpreting and analyzing student work, in the assessment of understanding mathematical ideas, and finally in making and criticizing curricular decisions. Their SCK needs to be improved in order to close this gap. Therefore, considering their background information it seems quite reasonable to think that teachers who currently teach mathematics in UAE public schools need considerable professional development support in the aforesaid areas. The nature of this support will depend on identifying the weaknesses of the teachers, which was partially done through the current research study, and then preparing professional development programs that specifically address those needs and weaknesses throughout long term programs.

These results also suggest that teachers are not prepared well throughout the Education and Science faculties of the universities in the Gulf region. This is not to say that they do not learn anything from those programs. It is rather saying that the experiences teachers gain from their undergraduate education does not seem to support them well for the aforesaid areas. Obviously teaching the subject for many years (some teachers have the experience of 20 years of teaching) or having extra credentials (e.g., master, PhD) did not help them improve their understanding of the core mathematical ideas either. Neither the academic background nor the teaching experience that they had helped them in answering even very simple questions about core mathematical ideas such as drawing a triangle (e.g., one question was about investigation of whether given three side measures helps one draw a triangle) or interpreting a first degree equation.

Finally, the mathematics teacher competencies should be carefully reconsidered and revised. The SCK construct seems to be useful in targeting certain competencies for mathematics teachers regarding their content knowledge and in generating questions to test those competencies. However, to what extent these competencies and testing of them would tell us about student success is not clear. The connection between student success and these competencies is beyond the scope of this paper.

NOTES

1. The current paper describes part of a major research study funded by United Arab Emirates University with the fund number 31D000 for the years 2010-2012 and includes some preliminary results about mathematics teacher knowledge.

PROFESSIONAL DEVELOPMENT PROGRAM IN FORMATIVE ASSESSMENT

Catarina Andersson and Lotta Vingsle

Umeå Mathematics Education Research Centre, Umeå University, Sweden.

Key words; Professional development, formative assessment, mathematics education

BACKGROUND

Several studies have demonstrated that substantial learning gains are possible when teacher introduce effective formative assessment into their classroom practice (e.g. Black & Wiliam, 1998; Hattie, 2009; National Mathematics Advisory Panel, 2008), but a strong research base supporting how effectively help teachers to implement a formative assessment practice is lacking (Schneider & Randel, 2010; Wiliam 2010).

Effective formative assessment (FA) can be conceptualized as practice based on an adherence to the “big idea” of using evidence about student learning to adjust instruction to better meet student needs, and a competent use of the following five key strategies (Wiliam 2010);

1. Clarifying, sharing and understanding learning intentions and criteria for success;
2. Engineering effective classroom discussions, questions, and tasks that elicit evidence of learning;
3. Providing feedback that moves learners forward;
4. Activating students as instructional resources for one and another;
5. Activating students as the owners of their own learning.

PROJECT DESCRIPTION

We are part of a larger project that uses an experimental design, with 40 randomly selected teachers in grade 4 and 7, to investigate the impact of a comprehensive (one day a week in 20 weeks) professional development program (PDP) in formative assessment on teachers’ implementation of FA and on student achievement and motivation. In our part of the project we will investigate in which ways the teachers change their classroom practice, with respect to FA. An aim is to evaluate to what extent the PDP can be used to help teachers develop their formative assessment practice. Another aim is to contribute to the understanding of factors that are significant in the support of teachers’ implementation of effective FA. The teachers’ classroom practices have been observed and teachers have been interviewed before and after the PDP. The teachers’ have also answered a questionnaire as an evaluation of the PDP. The framework of FA suggested by Wiliam and colleagues (see above) form the basis for analysis of the teachers’ practices before and after the PDP.

EXPECTED RESULTS

We expect to identify interesting changes with respect to FA in the participating teachers' classroom practices, over time and between teachers. The identification of similarities, differences and patterns will help us understand the reasons for these possible changes, and offer indications for improved FA-programs in the future. The collection of data is completed and in February we expect to be able to present some preliminary results.

DISCUSSION – THE PROJECT CONTINUES

Based on the results and conclusions from this project, professional development program in formative assessment will be developed and researched.

On the poster, the content will be presented with the same structure as above; this will be done by text, photos and pictures. Preliminary results might be presented with tables.

STATISTICAL KNOWLEDGE AND TEACHING PRACTICES OF ELEMENTARY SCHOOL TEACHERS IN THE CONTEXT OF COLLABORATIVE WORK

Ana Caseiro

Escola Superior de Educação do Instituto Politécnico de Lisboa

João Pedro da Ponte

Instituto de Educação da Universidade de Lisboa

Cecília Monteiro

Escola Superior de Educação do Instituto Politécnico de Lisboa

Keywords: *Teachers' knowledge; Teachers' practices, Statistics education*

SUMMARY OF THE POSTER

Statistics is an important topic in today's world. An active participation in society requires the ability to analyze and interpret statistical data represented in many different ways. In addition, statistics has an important role in several school subjects and supports the development of students' critical reasoning (Batanero, Godino & Roa, 2004). This leads statistics to receive an increased emphasis in the school curriculum. The main aim of its teaching is the development of students' statistical literacy, from an early age (Ponte & Sousa, 2010).

Teachers' mathematical knowledge is an important research topic (Ball, Hill & Bass, 2005). Groth (2007) indicates that, among all the mathematical topics, usually it is in statistics that teachers have weakest knowledge. Since teachers' knowledge is one of the most influential bases for effective teaching, it is necessary to investigate the knowledge needed to teach this topic and how it may develop (Fennema & Franke, 1992; Groth, 2007). As students' learning derives from the way teachers plan lessons, conduct such lessons, and reflect on the whole process of teaching and learning, the study of teachers' practices is also crucial. As teachers' practices are deeply intertwined with teachers' knowledge for teaching, thus this study aims at understanding the development of specialized knowledge for teaching and of knowledge regarding practical instruction of elementary school teachers in terms of statistics education, in their mutual relationship, in a collaborative work context.

The study is based on a collaborative context since this is an important support for teachers to deal with professional problems (Ponte & Serrazina, 2004) as well as an useful strategy for carrying out investigations into professional practice (Boavida & Ponte, 2002). In a collaborative environment the process of joint reflection is likely to support teachers' professional development, as it allows an analysis and discussion of their practices, leading to the clarification of some aspects and contributing for new actions to emerge.

The study follows a qualitative and interpretative methodology, with three case studies of grade 3 and 4 teachers of two different schools. The working sessions group will focus on collaborative discussion and reflection on current curriculum guidelines, as well as on articles and other documents relating to the teaching and learning of Statistics in elementary grades. During these sessions teachers plan lessons for their students which will be screened (via videotaped excerpts) and discussed in order to promote a constant joint reflection. It is expected that collaborative work will promote the development of teacher's knowledge for teaching. Data collection includes participant observation of collaborative work sessions and of teachers' classes (with audio and video recording); semi-structured interviews with participating teachers, one at the beginning of investigation and another at the end (with audio recording) and the collection of written documents (teachers' diaries, documents produced by teachers and students during classes and documents produced in the collaborative group). Data analysis will be made according to categories of analysis related to teachers' knowledge and practices and statistical education issues, taking into account the theoretical framework and the research questions.

The poster, supported by graphical elements, will present the goals and main ideas of the theoretical framework regarding both teachers' knowledge and practices and statistical education. It will also describe the method used in the study and present some preliminary results.

THE TRIGONOMETRIC FUNCTIONS - CONCEPT IMAGES OF PRE-SERVICE MATHEMATICS TEACHERS

Aleksandra Čizmešija

Željka Milin Šipuš

University of Zagreb, Croatia

University of Zagreb, Croatia

Abstract. According to the present Croatian curriculum for secondary education, substantial time is allocated to the trigonometric functions of real argument. However, results of the Croatian State Matura show that students' performance on tasks involving this mathematical content is unsatisfactory. In order to gain a deeper insight into causes of this discrepancy in the context of the Croatian educational tradition, we have conducted a survey of basic concepts related to trigonometric functions of university mathematics education students in Croatia.

Key words: pre-service teachers, concept image, trigonometric functions

THE STUDY AND RESULTS

In our study, we were focused on concepts such as the radian measure, as well as sine, cosine and tangent function and the way they are used in solving simple trigonometric equations and inequalities (e.g. $\sin x < \cos x$, $\tan x > -1$). In order to describe dominant cognitive structure associated with the concept, the results obtained are analyzed against the theoretical framework of concept image vs. concept definition (Tall & Vinner, 1981) and the notion of procept (Gray & Tall, 1994) which is as well concerned with predominance of procedural knowledge over conceptual. Our research questions were: What kinds of concept images of radian and of trigonometric functions do pre-service teachers have? What kind of understanding of radian and trigonometric functions do pre-service teachers have: dominantly procedural or dominantly conceptual? In our study, we have collected data over entire populations of 79 students of the 3rd year and 26 students of the 5th year of university mathematics education programmes at the largest Croatian university. They completed a one-hour questionnaire with 13 open-ended questions addressing their understanding of the concepts mentioned above. Students' responses to each question were classified and the code plan has been developed accordingly. Based on the most typical concept images detected and strategies used to solve given problems, 8 students (4 from each group) were selected for semi-structure interviews on the same and some additional questions. Interviews were audio recorded and then analyzed.

In our poster, we present findings with major contribution to the research questions posed. Results suggest that pre-service teachers relate radian measure dominantly to rectangular coordinate system, circle trigonometry, as well as to trigonometric functions, whereas right triangle trigonometry and degree measure make significant part of their concept images of sine and cosine functions. On the contrary, tangent

function is seen dominantly only as a ratio of sine and cosine, without referring to its geometric interpretation in circle trigonometry. Pre-service teachers refer to π as the unit for radian measurements, while real numbers not being of the form $q\pi, q \in \mathbb{Q}$, are not recognized as the radian measures of an angle. Moreover, degree angle measure dominates students' conceptions of angle measure. For example, to find a length of an arc subtending central angle given in radians, they preferably convert radians into degrees, neglecting the definition of a radian measure. This reveals also a students' need to use conversion formulas, emphasizing their procedural knowledge. Dominance of procedural knowledge over conceptual is also seen regarding basic trigonometric inequalities. Some of these findings on Croatian dataset confirm earlier findings in Fi, 2006, Topçu, Akkoç, Yılmaz & Önder, 2006, and Chin & Tall, 2012. Our results evidently show that a change in Croatian initial mathematics teacher education should be made to promote pre-service teachers' conceptual knowledge on radian measure and trigonometry functions of real argument. Radian measure should be more explicitly related to angles and arc length, while values of basic trigonometric functions (especially of tangent function) should be recognized as coordinates of points in rectangular coordinate system. Our study is the first research on students' understanding of trigonometry concepts in Croatia.

MATHEMATICS TEACHERS' UNDERSTANDING AND INTERPRETATION OF THEIR OWN LEARNING AND CLASSROOM PRACTICE

Malin Lindwall Ehrnlund

Department of Teacher Education, Halmstad University, Sweden

SUMMARY

Educational systems around the world are at the moment in the center of numerous reforms in order to improve schools and students achievement (Roesken, 2011). In the Swedish context the reforms requires interpretation and implementation of changed curricula grounded in learning and teaching paradigms that may challenge and question mathematics teachers' present beliefs and teaching practices. In order to meet these requirements teachers play a central role in gaining adequate professional development; to participate in and obtain qualified and continuing learning opportunities (Borko, 2004). Several contextual conditions are identified by international research as promoting principles for teacher learning; providing ongoing opportunities for teachers to collaborate and learn together, content focused school-based professional developmental activities based on experiences and incorporating inquiries into teachers own practice and learning (Loucks-Horsley, Love, Stiles, Mundry & Hewson, 2010, Borko, 2004). The aim of this study is to examine Swedish mathematics teachers understanding and interpretation of their own learning and classroom practice during learning activities designed according to the consensus criteria mentioned above.

Two teachers in a local mathematics team participated in a 3 year-long PD-project, initiated by the teachers, the school-leader and a local resource teacher, who also joint facilitated the learning activities. The PD-initiative was raised after mutual identification of an escalating need for improving students result in mathematics. The intervention was designed by the researcher, the teachers, a resource teacher and the school leader and consisted of further improving the mathematics teachers' content knowledge and pedagogical knowledge through a number of PD activities (i.e. workshops, network meetings, collegial reflections) on a regular basis.

In 2010 semi-structured interviews with two participating teachers were conducted and video-recorded in order to capture the teachers' understanding and interpretation of their classroom practice and their own learning needs. During 2010 and 2011 artifacts were collected from practice, for example classroom videos of teaching sequences concerning number sense and arithmetic, students work, assessment data, teachers planning. In 2012 Video Stimulated Reflection (VSR) was used on the same participating teachers. Through VSR, supplemented with artifacts from practice, the participating teachers collaboratively reflected upon the film-clips from 2010 concerning (a) the classroom practice and (b) their own pedagogical reasoning as mentioned above.

Preliminary findings indicates (and to some extent confirms previous research) that in this meta-cognitive process of sharing reflections on authentic video-recordings, supplemented with other artifacts from practice, the teachers interpret their own learning and classroom practice and become aware of their own progress and learning needs. They also re-interpret the students' conceptual understanding, learning and learning needs. The collaborative conversations and the contextual setting of the intervention seem to be motivators and key-factors for establishing a systematic approach to teachers' reflection on their own practice, teaching concerns and needs in relation to their students' learning needs. *During the autumn of 2012 the interconnected model (Clarke and Hollingsworth, 2002) is adapted to the data in order to analyze the complexity of teachers' professional growth.*

This study has implications for research into the professional learning of mathematics teachers as well as for the design of school-based PD. Even though an international need for mathematics teachers' professional development is identified and expressed, we know little about the precise challenges, needs and possibilities related to mathematics teachers' continuing professional learning in and for practice in local contexts. Jaworski (2011) stresses that "we know much less than we should about teachers' learning from experience; whether teachers learn, what they learn and what supports learning from experience." (p. 11).

Keywords: Professional development, mathematics teacher learning, artifacts from practice

The poster-content will be presented using the IMRAD-model. Short, but clear and concisely introduction (I) and statement of aims. The method section (M) will be brief. The result section (R) will be the major part, visualized and illustrated with cites and representations in the middle of the poster. The discussion section (D) will be brief and sited on the right side of the poster.

THE MATHEMATICAL KNOWLEDGE FOR TEACHING

A view from the Onto-Semiotic Approach to Mathematical Knowledge and Instruction

Juan D. Godino and Luis R. Pino-Fan

University of Granada, Spain

Keywords: teachers' training, teacher's knowledge, mathematical knowledge for teaching, onto-semiotic approach, didactic-mathematical model.

One of the problematics that has drawn a lot of attention from both researches community and policy makers alike, is the identification and characterization of the knowledge web that a mathematics teacher should have in order to teach effectively and to facilitate their students' learning on specific mathematics topics. One proposal on the teachers' knowledge that is widely accepted, is the model called "Mathematical Knowledge for Teaching (MKT)", developed by Ball and colleagues (Ball, Lubienski & Mewborn, 2001; Hill, Ball y Schilling, 2008; Ball, Thames & Phelps, 2008). This proposal is a remarkable advancement for describing the complex of knowledge that a teacher should have to teach mathematics. Nonetheless, despite the advances that the MKT model represents, there are still questions to be addressed, such as: how to identify the teachers' didactic-mathematical knowledge when the teachers' knowledge models include categories too wide? Specifically, under what criteria can the MKT be evaluated? How can the teachers be supported to acquire or to develop the MKT components? In general, as Godino (2009) points out, both the MKT model and the others various models on the mathematical knowledge for teaching, informed by the researches in mathematics education, include categories too "wide" and disjoint, that call for models that allow conducting a more precise analysis of each knowledge component that are put into effect in an effective teaching of mathematics. The latter will allow orienting to the design of formative actions and the elaboration of tools to assess the mathematics teachers' knowledge.

Thus, in this work, based on both the Onto-Semiotic Approach to Mathematical Knowledge and Instruction (OSA) (Godino, Batanero & Font, 2007) and the categories of didactic-mathematical teacher's knowledge (Godino, 2009), we propose a model called "Didactic-Mathematical Knowledge (DMK)". This model proposes six facets or dimensions to analyse the teacher's didactic-mathematical knowledge about a specific mathematical topic (Godino et al, 2011, p. 278-279): 1) *Epistemic Facet*: The intended and implemented institutional meaning for a given mathematical content, that is, the set of problems, procedures, concepts, properties, language, and arguments included in the teaching and its distribution over the time; 2) *Cognitive facet*: Students' levels of development and understanding of the topic, and students' strategies, difficulties, and errors as regards the intended content (personal meaning); 3) *Affective facet*: Students' attitudes, emotions, and motivations regarding the content and the study process; 4) *Mediational facet*: Didactic and technological resources available for teaching and the possible ways to use and distribute these

resources over time; 5) *Interactional facet*: Possible organisations of the classroom discourse and the interactions between the teacher and the students that help solve the students' difficulties and conflicts; 6) *Ecological facet*: Relationships of the topic with the official curriculum, other mathematical themes and with the social, political, and economical settings that support and condition the teaching and learning. These facets reinterpret and organize the different components of the MKT. Furthermore, to each of the said facets the OSA provides theoretical and methodological tools that allow more detailed analysis. For example, for the epistemic and cognitive facets the tool "objects and processes configuration" is proposed, which refers to the detailed and systematic description of the linguistic elements, concepts, propositions, procedures and arguments, involved in the mathematical activity. An example of application of this tool can be seen in Pino, et al. (2012). The relationships between the components of MKT and the facets and levels of analysis of the DMK will be graphically illustrated in the poster.

ACKNOWLEDGEMENTS

This study formed part of two research projects on teaching training: EDU2012-32644 (University of Barcelona) and EDU2012-31869 (University of Granada).

MATHEMATICAL KNOWLEDGE FOR TEACHING AS A MEASURE OF COHERENCE IN INSTRUCTION MATERIALS PRODUCED BY TEACHERS ON THE INTERNET

Yvonne Liljekvist & Jorryt van Bommel

Karlstad University, Sweden

KEYWORDS

Didactical Engineering, Mathematical Knowledge for Teaching, Teacher-shared instructions on the Internet

SUMMARY

In the poster, a plan for upcoming research is presented as a result of two previous studies. A first study revealed a discrepancy between instruction materials in mathematics shared by teachers through the Internet (Liljekvist, 2012, in preparation). In that study the didactical message was analysed, such as, topic-specific features related to syllabus, mathematical ideas, competencies, cognitive demands, and degree of devolution. Further on, an analysis was conducted on in what way these task-features could be understood as representations of didactical engineering. In a second study, lesson plans produced by student teachers were analysed and coherence was used as a measure of student teachers' Mathematical Knowledge for Teaching (MKT) (van Bommel, 2012a, 2012b). The study indicated that MKT influenced the degree of coherence within the produced lesson plans.

In the suggested upcoming research the coherence and lack of coherence within the analysed instruction materials made by teachers will be analysed using the MKT framework. In the poster, two examples will be presented to show in what way MKT could explain the degree of coherence within each example. Furthermore, the concept Didactical engineering and the framework MKT will be outlined.

CONCEPTUAL FRAMEWORK

Didactical engineering “deals with the production of the possible and available meanings of a students’ activity“ (Herbst & Kilpatrick, 1999, p. 7), hence, a teacher has the didactical responsibility to outline a task, or adopt it (Brousseau, 1997, Kieran, 1998) and thereby orchestrate a didactical situation to address, for instance, goals in syllabus.

MKT can be described as the mathematical knowledge needed to carry out the work of teaching mathematics (Ball, Phelps, Thames, 2008). The MKT model consists of 6 domains and complemented the PCK notion suggested by Shulman (1986). As a result, items were developed to be able to study the relationship between teacher knowledge and pupils’ achievement. In this study the MKT model will be used to study the relationship between teachers’ apparent knowledge and coherence in their produced materials. The relevance of the connections between features within the produced instruction materials, determine the degree of coherence.

RESEARCH QUESTION

How can the degree of coherence in teacher-shared instruction material on the Internet, be understood in terms of MKT?

PRE-SERVICE ELEMENTARY TEACHERS' PROCEDURAL KNOWLEDGE OF THE GREATEST COMMON FACTOR AND LEAST COMMON MULTIPLE

Jeffrey A. McLean

Syracuse University

Pre-service elementary teachers in the United States demonstrated on a survey and follow-up interviews what I categorized as either superficial procedural knowledge or deep procedural knowledge of the greatest common factor (GCF) and least common multiple (LCM). Those exhibiting deep procedural knowledge varied the processes used to find the GCF and LCM based on the numbers' representation. Those exhibiting superficial procedural knowledge followed the same procedure regardless of the numbers' representation. Statistically significant evidence suggested that pre-service elementary teachers who define the GCF (and LCM) through the relationships between two or more numbers and their GCF (and LCM) also demonstrate deep procedural knowledge of the GCF (and LCM).

REVIEW OF LITERATURE

Zazkis and Campbell (1996) investigated pre-service elementary teachers' understanding of elementary number theory concepts and determined that their respondents showed a disposition towards procedural thinking, even when they displayed a conceptual understanding of the topic. Hiebert and Lefevre (1986) characterize procedural knowledge as memorization of facts and algorithms used to solve mathematical tasks (1986). Star (2005) later argued for a reconceptualization of procedural knowledge and asserted that a distinction must be made between those learners with superficial and deep procedural knowledge: "There are subtle interactions among the problem's characteristics, one's knowledge of procedures, and one's problem-solving goals that might lead a solver to implement a particular series of procedural actions" (p. 409). If a solver possesses a superficial knowledge of the procedures s/he may fall back on the known standard procedure to solve the problem, regardless if it is the most efficient process. If the solver instead possesses deep procedural knowledge, s/he may use various techniques to produce a solution that best matches the form of the problem.

FINDINGS

Through use of a survey instrument and interviews, I assessed 48 pre-service elementary teachers' knowledge of the GCF and the LCM. The respondents demonstrated what I categorized as either superficial procedural knowledge or deep procedural knowledge. Items on the survey asked the participants to determine the GCF and LCM of two numbers given various representations of the numbers, such as the numbers' prime factorizations, lists of each number's factors, or lists containing

the first 10 multiples of the numbers. The participants classified as demonstrating superficial procedural knowledge of the GCF and LCM applied the same procedure to each survey item regardless of the numbers' representation. Those exhibiting deep procedural knowledge varied the processes used to determine the GCF and LCM and applied more efficient methods based on the numbers' representation. For instance, a survey item asked respondents to find the GCF of two numbers that were represented by lists containing all of their factors. Those that I classified as demonstrating superficial procedural knowledge did not utilize this list, found the prime factorization for each number, and then used these prime factorizations to determine the GCF. Those that I classified as demonstrating deep procedural knowledge exhibited an understanding that the representation of two numbers as lists of their factors is transparent with respect to their GCF, and determined the GCF by finding the largest factor shared on each list of factors.

The survey also asked the participants to define the GCF and LCM. The responses fell into the following two categories: (1) those describing the relationship between two or more numbers and their GCF and LCM, and (2) those detailing a process that can determine the GCF and LCM for two or more whole numbers involving the numbers' prime factorizations. Using Fisher's exact test, I compared the relationship between the respondents' definitions of the GCF and LCM with the form of procedural knowledge that they demonstrated. The data revealed statistically significant evidence ($p=0.03$) suggesting that pre-service elementary teachers who define the GCF correctly through relationships also exhibit deep procedural knowledge of the GCF. Similarly, the data revealed statistically significant evidence ($p=0.04$) suggesting that pre-service elementary teachers who define the LCM correctly through relationships also exhibit deep procedural knowledge of the LCM.

POSTER FORMAT

In the poster I will explain my methodology, display the survey instrument with typical participant responses, and discuss my rationale for classifying these responses as demonstrating superficial or deep procedural knowledge.

THE RELATIONSHIPS BETWEEN THE TRADITIONAL BELIEFS AND PRACTICE OF MATHEMATICS TEACHERS AND THEIR STUDENTS' ACHIEVEMENTS

Alesja Šapkova

Daugavpils University, Latvia

The importance of teachers' beliefs for students' learning is highlighted from different sources showing that teachers' beliefs affect their teaching approach that, in turn, affects students' achievement. The studies of mathematics teachers' beliefs in Latvia brought out a contradiction between teachers' constructivist beliefs on teaching and learning and their traditional routine work while revealing match between some traditional beliefs on teaching and learning and traditionally-oriented instructional practice. The aim of the present study is to explore the possible relationships between the traditional beliefs and practice of mathematics teachers and their students' achievement in mathematics. For this purpose the Latvian data from two international research projects were analyzed. The sample included 190 mathematics teachers and their 2828 students from grade 9 representing different regions of Latvia, schools with different programs of education, rural areas and cities. The results suggest that the traditional beliefs of teachers are connected with lower students' achievement in mathematics test, while teachers' traditionally oriented self-reported practice is positively related to the achievement of their students.

Key words: *teachers' espoused beliefs, reported practice, students' achievement.*

THEORETICAL FRAMEWORK

Belief entails individual, seldom – stable subjective knowledge that includes person's feelings or care (Pehkonen, 1994). The given study is focused on teachers' beliefs. We will single out teachers' espoused beliefs from all the diverse other beliefs of teachers. Teachers' espoused beliefs (what is said) about teaching are what teachers think about the impact of teaching in general, as well as their understanding of how children learn (McMullen, Elicker et al., 2006). It is important to pay attention, along with teachers' espoused beliefs, to their reported practice. In the given research, exactly due to these reasons survey on reported practice followed in a common package with the survey of teachers' beliefs. Teachers' reported practice (what is done) is teacher's recognition of methods used in class and the frequency of using them (almost every lesson, at about half of lessons, in some lessons, never).

The world educational research has recently manifested a dichotomous division of teachers' beliefs and approaches to teaching and learning: *the traditional beliefs* and *the constructivist beliefs* (OECD, 2009).

The aim of the present research is to make out whether there is correlation between the *traditional* orientation in *teachers' espoused beliefs* and reported practice and the achievements in mathematics of these teachers' students. Two research questions were set: 1) what relationships exist between the traditional espoused beliefs of teachers on teaching mathematics and their students' achievement in mathematics? 2) What relationships exist between the traditional

orientation of teachers in self-reported practice and their students' achievements in mathematics?

METHOD

The given research has used data of two international studies: Singapore National Education Institute project “Non-Cognitive Skills and Singapore Learners – an international comparison” and NorBa project “Nordic-Baltic comparative research in mathematics education”. The following methods of statistical analysis were used for data processing: Kolmogorov-Smirnov test to assess the distribution of data, descriptive statistics, frequencies, two step cluster analysis, factor analysis, hi-quadrangle criterion, Wilcoxon criterion, Kruskal-Wallis criterion, Mann-Whitney criterion as well as Cronbach Alpha to assess the reliability.

RESULTS

The research data base shows that there exist correlation between Latvian teachers' espoused traditional beliefs on teaching mathematics and their students' achievements in doing mathematics tasks: the more distinct teachers' espoused traditional beliefs, the lower their students' achievements. On the other hand teachers' traditional inclinations in their reported practice have a positive impact on their students' achievements. Completely different tendencies of teachers' espoused beliefs and reported practice may be accounted for by the fact that the major factor of influence on learner's achievement is not the teacher's beliefs but readiness to change, i.e. to change his/her beliefs as well as an ability to adapt his/her practice to the learners' intellectual level, needs, motivation. At the same time these teachers continue to use traditional methods gradually introducing new ones in their work. Despite the fact that the education philosophy reflected in the State Education standard is oriented toward the process of learning, in reality the mathematics education in Latvia is measured by students' achievement that, in turn, is characteristic of the traditional paradigm of education. Indeed, after every three years every learner in Latvia must take a compulsory centralized test or state examination in mathematics, regular mathematics Olympiads have been organized on local and state level. Learners' achievements in Olympiads and examinations are the basis of mathematics teacher ratings. This may account for the great influence of traditional reported practice on learners' achievements.

TEACHER LEARNING

WITHIN THE CONTEXT OF LESSON STUDY

Daan van Smaalen

University of Twente, The Netherlands

Lesson study is a professional development strategy that is grounded in daily practice. A team of teachers collaboratively studies teaching and learning through examining single lessons. By means of live classroom observations and post-lesson discussions, student learning is related to the lesson design and the course of the lesson. Lesson study cases from Dutch secondary schools will be presented during the CERME. In those cases, the professional learning of (mathematics) teachers is captured and will be related to the core of lesson study - observation and discussion - completed with teaching and collaborative planning.

Keywords: lesson study; teacher learning; secondary education

Lesson study is a professional development strategy in which teachers collaboratively study teaching and learning by means of live classroom observations and post-lesson discussions (e.g., Fernandez & Yoshida, 2004; Saito, 2012). Lesson study originated over a century ago in Japan where it is widely viewed as the foremost professional development strategy for teachers (Fernandez & Yoshida, 2004; Stigler & Hiebert, 1999). By the end of the '90s, lesson study gained worldwide attention and spread over different Western countries.

The goal of my research is to gain understanding of what and how teachers learn when participating in lesson study. On the basis of previous research, Lewis (2009) presents a schematic that can be used to address the impact of lesson study on teachers and instruction. The schematic explicitly links lesson study to teacher learning but it does not elucidate the influence of different activities in the lesson study process on teacher learning. This has become an important focus of my research.

By means of a single case study, we investigated a secondary school mathematics teacher's learning outcomes - particularly changes in pedagogical content knowledge (PCK) - and related those to teachers' learning activities within the context of lesson study (Van Smaalen, Verhoef, Yoshida, & Pieters, 2012). This exploratory study shows (a) the importance of live classroom observation for developing knowledge of student learning, and (b) the significance of imagination when creating a (research) lesson.

In a current follow-up study, which started in 2011, we broadened our view from PCK development to professional learning: the development of knowledge, skills, and habits of mind necessary to professional thinking and practice, and (intentions

for) changes in practice itself. Fifteen secondary school teachers - including nine mathematics teachers - participate in this study. To gain a deeper understanding of teachers' learning - especially the relation between lesson study activities and teacher learning outcomes - we asked the participants to fill in a learner report (e.g., Van Kesteren, 1993) after each lesson study activity (planning, teaching or observing, and discussing). Besides this, we recorded the teachers' joint reflection at the end of each lesson study cycle. We are currently analyzing the data that has been collected so far (data belonging to six lesson study cycles), describing diversity of learning experiences (i.e. learning outcomes related to lesson study activities) using qualitative survey analysis (Jansen, 2010).

During the CERME, I will present the results of both the single case study and the follow-up study. The poster starts with the conceptual framework (i.e., lesson study and professional learning) and the research questions. Next, the method will be presented, in particular the learner report and qualitative survey analysis. Then the results will be described by picturing the diversity of learning outcomes (e.g., knowledge of student learning) and their relation to lesson study activities (i.e., collaborative planning, teaching, live classroom observation, and post-lesson discussion). The poster ends with the findings of the study (e.g., the importance of live classroom observation) and points for discussion.

USAGE OF TASKS DURING PROFESSIONAL DEVELOPMENT OF IN-SERVICE MATHEMATICS TEACHERS

Ján Šunderlík, Soňa Čeretková

Constantine the Philosopher University in Nitra, Slovakia

In the poster we describe the searching process of the mathematical tasks and design materials optimal usage for in-service teacher during professional development course. Based on the analysis of needs and interconnected model (Clark & Hollingsworth, 2002) we interpret teachers' usage of tasks and identify their way of learning. The main focus is on the transformation between learning in content knowledge and pedagogical content knowledge (Ball et al., 2008). According to the findings we suggest the new design of the continuing professional development course.

Key words: teachers' learning, CPD, inquiry based tasks

FOCUS OF THE POSTER

Our poster presents some study findings in which we were piloting different approaches of in-service mathematics teachers' usage of student oriented tasks during continuing professional development (CPD) course. The content of CPD was focused on introduction of constructivists' approach to teaching, development of competences and inquiry based learning supported by ICT. According to the usage of tasks we identified several approaches to in-service teachers' learning. Our research question was: "How was teachers' usage of tasks evolving during CPD course and what supported this change?"

THEORETICAL FRAMEWORK

Since 2009, there have been established new CPD courses for in-service teachers. In Slovak context most of the CPD courses were designed in implicit model. In the observed CPD courses we firstly focused on identification of necessary content knowledge (CK) and then we connected it with appropriate pedagogical content knowledge (PCK) (Shulman, 1986, Ball *et al.*, 2008). We analysed the trajectory of teachers' learning according to the interconnected model (Clark & Hollingsworth, 2002) and based on the findings we redesigned the model of the new planned CPD course.

METHODS AND DATA ANALYSIS

In our study three groups of lower secondary mathematics teachers 28 teachers in total were observed during the five whole day CPD sessions. One of the researchers was a lecturer of the CPD course. Some of the parts of the courses were videotaped.

Teachers were supposed to create and submit written assignments that contain some part of lesson planning after each session and the final assignment. All the written assignments were analysed. All sessions were transcribed and coded. Based on the data we identified events from CPDs that were in any way “critical” in connections with usage of tasks by the teachers. These events were interpreted within our theoretical framework.

INDICATION AND JUSTIFICATION OF THE CONTENT

The poster consists of introduction, theoretical framework, methodology, results that include examples of tasks and discussion with new design of the CPD. We observed that the settings of CPD and tasks usage in many cases were not sufficient for changes within domain of practice as well as domain of consequence. However, some teachers demonstrate positive results of inquiry tasks development. Based on these findings and theoretical framework from project PRIMAS we present new design of CPD model that more accurately addresses the difficulties that teachers had while implementing the innovative curriculum material into practice.

FORMAT OF THE POSTER

The poster will have a prescribed rectangular format 70 cm x 90 cm and will be printed on one piece of paper. Data will be optically organised and clearly described.

1. This work was supported in part by the EU, within the 7FP project, under grant agreement 244380 "PRIMAS – Promoting Inquiry In Mathematics And Science Education."
2. The actual poster presented at CERME8 may be obtained from the author by emailing them to <jsunderlik@ukf.sk; sceretkova@ukf.sk>

PROFESSIONAL MATHEMATICS TEACHER IDENTITY: AN EXAMPLE WITH TELESECUNDARIA SYSTEM TEACHERS IN MEXICO

Erika García Torres, Ricardo Cantoral Uriza

Centro de Investigación y de Estudios Avanzados del Instituto Politécnico Nacional
CINVESTAV-IPN, México

The aim of this poster is to discuss about the constitution of professional identity, taking into account that the profesional identity is shaped through the participation in a collaborative learning network. The participants are Mexican teachers that belong to the telesecundaria system, who work in rural or marginalized urban zones. The online work promotes a reflection about mathematics tasks that are in textbooks and the way that they have to apply in the contexts from her/his students.

INTRODUCTION

This study focuses on the analysis of the relationship between teachers' identity and teachers' practices. If the social environment is considered a contextual variable that has an impact on how a person acts, how does it come to affect identity formation?

The aim of our work is to identify the "professional mathematics teacher identity" of Mexican teacher of "Telesecundaria system" and create a collaborative learning network, which helps and also increases his professional identity.

The poster will include three sections: first the research problem, second the theoretical framework and finally the methodological advances.

CONCEPTUAL FRAMEWORK

Based on reviewing research into professional identity in relation to teachers and teacher education, Beijaard, Meijer & Verloop (2004) concluded that often lacks a clear definition of professional identity.

The notion of mathematics teacher identity is considered a social construct that describes not only a human group but also determines their actions. It means that the teachers' identity is not only the possession of a defined set of assets required for the profession. For instance, Gee (2001) says: "Being recognized as a certain kind of person, in a given contexts, is what I mean...by identity" (p.99). Identities are not stable but dynamic and situated, emerging in talk in different situations of everyday life. Ponte and Chapman (2008) suggest that this construct, professional mathematics teacher identity, may be seen as the teacher's "professional self" or an instance of a social identity. We consider that professional mathematics teacher identity emerges and changes in significant social experiences that define identity indicators. The analysis of the development of this construct allows also to recognize and explain the actions of teachers from their perspective.

METHODOLOGY

The participants in this investigation are teachers that work in an educational program in secondary level called “Telesecundaria”. This program offers coverage in urban or rural areas in the secondary level (25% of the population) and students receive instruction in all subjects from a single teacher. Instruction is delivered through three mechanisms: television broadcasts, teachers and texts. Sometimes the teachers do not identify themselves as mathematics teachers. Rather, they must master the disciplinary knowledge of all subjects that are included in the school curriculum.

We will use reflective narratives (Bjuland, Cestari & Borgersen, 2012) to identify the identity of the teachers from four areas: personal history, their initial training in their daily work and professional development spaces in which they have participated as well as from their participation in the collaborative learning network.

Telesecundaria’s teachers around Mexico as well as researchers and teacher educators will be those that constitute the collaborative network of teachers. The working methodology is to conduct a joint reflection on the design of learning tasks that are based on their textbooks for using in the classroom. This research encourages teachers to question the use of mathematics concepts, strategies and tools designed to affect the learning of their students.

FINAL DISCUSSION

The analyzed data suggest that there is not unique professional identity of telesecundaria’s teachers. The diversity of the initial training of teachers influences how they guide the students’ learning. Teachers should make adjustments to the curriculum according to the telesecundaria’s context and student difficulties. In our opinion, the study of professional mathematics teacher identity provides a different approach to the professional development of teachers. It implies an approximation of the teacher’s reality from their perspective, to explain from “there” their practices.

INTERACTION SUITABILITY ANALYSIS WITH PROSPECTIVE MATHEMATICS TEACHERS

Yuly Marsela Vanegas, Joaquin Giménez, Vicenç Font

Barcelona University

We study how the development of four professional tasks focused on the analysis of mathematics class interactions, may influence the reflection and evaluation of own practice done by future secondary mathematics teachers. We describe the tasks and we show its specific impact on these reflections.

KEY WORDS: Interaction suitability analysis, Teacher development

INTRODUCTION

The training program for prospective teachers of mathematics at the University of Barcelona is looking to develop various competencies, including competence didactic analysis. Our study is assumed as a teaching experiment in which design, plan, implement and evaluate a set of professional tasks. Four professional tasks focused on the analysis of the interactions in the mathematics classroom will be presented, by using case studies, with theoretical underpinnings. It is intended that future teachers develop tools for critical thinking and research attitudes. In task 1, future teachers must review the process of solving a geometrical problem, developed by a couple of students aged 16, with reference to the analysis of interactions proposed by Cobo & Fortuny (2010). In the second, was asked to analyze an episode of one class of measurement developed with students of 12-13 years, with reference to another episode analyzed using the proposal from Vanegas, Font y Giménez (2009). The third task is the analysis of a debate in a class of beginning algebra, having as a reference the proposal given by Vanegas, Giménez & Font (2012), by characterizing democratic mathematical practices. In the fourth task, we did a joint reflection among future teachers and trainers, on the notion of quality of interaction analysis, by using an ontosemiotic approach (OSA).

To analyze how the proposed tasks have influenced the thinking process of the practice of future teachers, we identify written productions, class discussions, and particularly in the Master Thesis (MT): a) if it appears a collaborative work and reasoning, b) if teaching purposes are clearly described, c) the type of didactical configuration is identified, d) the importance of recognizing the teacher's role in generating teaching situations that allow the development of mathematical democratic practices is revised and it appear some criteria used to assess the quality of their practice.

DISCUSSION AND CONCLUSIONS

All students interested in the analysis of the interaction in the reflection of their own practice, as an important aspect of class management analysis. The first reflections

immediately after the school practice, are characterized by superficial and descriptive comments focused on the action, with little justification argument.

“... in the activity with more implication, in which the students participate more actively was a "role-play", in which students are points. The teacher says an inequality with two unknown, then the students raise...” (Student A)

When analyzing MT productions, value judgments prevail. 88% of prospective teachers recognize different performances which has enabled or not promoted the interaction. Only 24% identify concrete situations of their own practice as justification. 16% of the students allude to the quality of the interaction to reflect on how to improve aspects of their own practice. The following example refers to both the proposed mathematical democratic practices (Task 3) as a means of intervention raised in Task 2.

“This is to allow more time for students to think about how to get to the solution of problems... On the other hand, it has also changed the role of the teacher giving students proper tracks looking to reflect rather than closer to the procedure or solution ... The role of the teacher can encourage students' reasoning or else cut their reflections. So the teacher has to act as a guide but let the student take responsibility at all times” (Student B)

Only one student proposes a creative graph to represent the evaluation of different aspects of their practice, using some of the criteria proposed by the EOS and noting what was their level of achievement in different practice sessions.

Finally, we recognize that the use of different theoretical framework for analyzing the interaction allowed some improvements in the reflection of the actual practice of future teachers. Meanwhile, they were considered more variables to characterize the interaction, were incorporated in certain cases the categories proposed by the authors studied, and it is reflected on the importance of analyzing the development of these processes in math class. We suggest that more time is needed to have more influence, and the need to have a common discussion about own reflection.
