In this problem, students are asked to construct a midpoint and a circle. Starting from the logic analysis the concepts of circle, we shall attempt to bring out *a priori* the potential of frequentation modes which could be considered for the geometrical objects involved in the problem set. This will provide an analysis framework which will be used, during the progress of the sequence, to identify coexisting divergent interpretations of the situation and will help to better understand how they evolve. We will observe the students' gestures and procedures as well as the dialogues between them and with the teacher.

CONSTRUCTING THE MIDPOINT

A priori analysis

A line segment may be seen in different ways: it may be seen as a part of a straight line or as a pair of points. In the first case, the midpoint of a line segment is characterized by a binary relation between two objects, a geometrical object of dimension 1 – the line segment – and an object of dimension 0 – the midpoint (example of statement of the relation: the midpoint is the point of the line segment that splits it into two parts of equal lengths). In the second case, it can be characterized by a ternary relation between three objects of dimension 0: the end points of the line segment and the midpoint (example of statement of the relation: the midpoint is the point aligned and equidistant with the two end points). These two ways of seeing call for objects which differ in number and nature (in dimension). From a physical action standpoint, there are many possible construction procedures. In the first grades of secondary school, the more usual method involves using a graduated ruler (to measure the length of the line segment and to plot half of the length from one of the ends). The property explicitly studied in this procedure is the fact that the midpoint M of a line segment $[AB]$ fits the equality $AM = \frac{1}{2} AB$. Questions such as the alignment of the midpoint with the end points or the midpoint belonging to the line segment are hidden by using the graduated ruler. Another method will be used later: plotting the perpendicular bisector using a ruler and a compass. In the present situation, the rope can be used as an artefact to split the length and check the alignment. The construction requires to explicitly account for both alignment and equidistance properties. It should be noted that the construction program proposed (annex) does not explicitly require plotting the line segment involved. There are several procedures available. We shall describe three of them:

P1. The first procedure consists of plotting the line segment on the ground by stretching out the rope, identifying the ends if necessary and then folding the rope in two equal parts. The midpoint is obtained by plotting the length from one of the ends. In this case, the property under which the midpoint belongs to the line segment is no more explicit than in the ruler procedure, since the question of alignment (or of belonging to the line segment) is evened out by the plotting of the line segment that is made independently of the construction of the midpoint.

P2. If the line segment has not been previously plotted, the rope can be laid in a straight line on the ground and then be folded in two parts by moving only one of its ends, the other end staying in the same place. Therefore, the midpoint is placed at the end of the new line segment thus obtained. Theoretically, this procedure does not call for the issues about alignment or belonging to the line segment, but the question arises from a practical standpoint, since it is difficult to move half of the rope while the other end stays still.

P3. The third procedure explicitly accounts for the alignment property. It starts by laying the rope on the ground as described in the procedure P2 and by identifying the

ends. Then the rope is folded in two equal parts and the new length is used to plot an arc of a circle, the centre of which is one of the ends of the line segment. The midpoint is obtained by determining, using the rope, the point on this arc which is aligned with the identified ends (the line segment can be plotted or not).

We consider that the distinction made between the different conceptions of the notion of midpoint, in terms of binary or ternary relations, in addition to the *a priori* analysis of possible procedures, may contribute to demonstrate the potential of frequentation modes which could be considered for the midpoint (of a line segment) object. The following *a posteriori* analysis should identify the frequentation modes in which the students stand, detect the possible coexistence of different frequentation modes and intend to better understand how the change towards a frequentation mode of the midpoint notion in line with the school expectations at this educational level operates.

***A posteriori* analysis**

In this paper, we shall focus on the physical and dialogical practices of a group of three students (E1, E2 and E3) and their interactions with the teacher (H) about the construction of the midpoint of line segment $[OE]$. The three points O , E and I are identified by a cross and by their corresponding letter on the playground. The line segment $[OE]$ is not plotted and the three points O , E and I do not seem to be aligned. Then, the teacher intervenes and asks the students to explain how they have proceeded. E1 "shows" the way they used to construct the point. He starts by joining the two ends of the rope, joining both his hands to openly show the half-length obtained. This means that the group perceives the length constraints imposed on the construction of the midpoint. Then he lays a part of the rope on the ground. One end of the rope is placed in O , while the other end stays in E1's hand and the rope is laid so that it passes by O and by I (but it does not pass by E). Now, he folds the end he holds towards point O , without exerting any other pressure on the rope. It seems that this group has used procedure P2, in a more or less successful manner. The interactions proceed in the following way:

- H: No, no, but ... have we got a means to check if it is the midpoint?
- E1: Why, yes
- H: What could we do?
- E1: Plot a line.
- H: A line? [...] Check there... How, how did you place your rope to check that this is the midpoint? [Pause] How will you proceed?
- E3: We lay it/ [E3 points his finger towards O]
- H: Therefore, we put one end here and then the other end/ [E1 puts an end of the rope in O]
- E3: We fold it
- H: Yes, and the other end? You must stand...
- E1: We fold it like that [E1 follows the procedure described above]

H: Well, this is not what I want

We can assume that H checks the control procedure which consists of using the rope as an artefact to check that the three points E , O and I are aligned. As for the students, they seem to be in a frequentation mode that is definitely different from the notion of midpoint. They focus on the distance constraints and they only consider global perceptive retroactions which cannot invalidate their construction strategy. This misunderstanding appears in the form of language interactions. For example, when H says "and then the other end" then goes on with "Yes, and the other end", it seems that he expects an answer with something like a specification of the position where the other end of the rope should be placed. The students' answers are in the action field, to fold the rope in a certain manner, rather than in the place field. This extract shows how language interactions may be a place of confrontation between conflicting frequentation modes and an (attempt of) negotiation towards a shared frequentation mode. For example, when the teacher repeats E1's statement "we lay it there" by saying "Therefore, we put one end here and then the other end", he attempts to direct the students' look towards the ends of the line segment and introduces the end E as a reference of a position. Thus, he intends to lead the students towards an interpretation of the "midpoint" object defined by a ternary relation between three points. The technique implemented by the teacher aims at pointing out that point E should be taken into consideration. The purpose is to set a shared objects field from which construction language games could be compared. Nevertheless, students are not able to put on language indicators used by the teacher and they do not recognize the specific form of language game he wants them to play. Finally, this misunderstanding leads the teacher to artificially put aside the strategy of this group. Therefore he decides to introduce by himself the third point necessary to make them shift to the punctual standpoint:

H: [H puts his forefinger on point E] Yes but here, in relation to this point, is there a means to check that your point placed there will be the middle point, the midpoint of your line segment?

E3: Well, we plot er... the rope.

However, it is difficult for students to use the rope as a geometrical artefact to plot straight lines. So far, the rope has been laid on the ground in an approximate straight line, without exerting special pressure on its ends. Now, the teacher takes over a more important part of the problem. He uses the language to simultaneously set in action the three points the alignment of which is to be questioned and clarifies the fact that they must be linked by a specific relation.

H: If your point is the midpoint, how should these three points be?

E1: On the same straight line

H: On the same straight line, well then have we got a means to check your three points are really on the same line? What can we do?

E1: Oh no, there are like this! [E1 shows that the points are not aligned]

- H: Well, how can we check then, how can we be sure it will be placed correctly? [...] You cannot see how we can check the points alignment?
- E3: Er... no
- H: Well, your task will be... You have to find the way, just think, sort it out yourselves, find how to check that your three points are correctly aligned, that's all [H goes to another group].

This time the students see the necessity to align the points, thus focusing on the line segment, to the exclusive consideration of the lines and lengths by a punctual look, inducing a possible questioning on the points alignment.

In this first example, we have tried to point out the consistency between the modalities of physical action, the discourse and the way of looking at the figure for a given group of students, even when this consistency is disturbed by the teacher's intervention. Let us now present a second example.

PLOTTING A CIRCLE

A priori analysis

From a logical and mathematical standpoint, the circle can mainly be seen (for other characterizations of the circle, cf. Artigue & Robinet, 1982) as:

- a set of points characterized by a relation: the fact that they are at a given distance (radius) from a given point (centre). This representation corresponds to a plot using a compass or a rope, but also a "point-by-point" plotting (plotting multiple points at a given distance from the centre, then plotting a line if necessary, or linked line segments)
- a continuous line with constant curving. This vision of a circle is hardly operational except for freehand plotting (it can be combined with plotting a few points or few diameters then applying the point-by-point plotting described above), this characterization can also be used for checking a freehand plotting (or using artefacts if necessary)
- the given length line which contains the largest surface area (not quite operational, somewhat corresponding to the circle of a children's dance)
- a line with infinite number of axes of symmetry (not quite operational but it can be used to check during plotting)

It should be noted that the first characterization calls for a relation between objects of dimension 0 (points, including the midpoint which is "exterior" to the graph) whereas the three other points use properties applicable to a single object of dimension 1 (the line).

Of course, the rope can be used to plot circles (or arcs of a circle). This construction requires to follow the same preliminary steps as for plotting with a compass (this artefact is almost always used for plotting circles in a classroom): decision of the radius length to be used (if necessary, selection of the line segment to be plotted, or modalities of length measurement if the length is given with a numerical value) and

of the centre around which the circle must be plotted. If the rope is used to plot, it might be difficult to hold one of its ends in a fixed point during rotation. With a compass, when the space between the legs has been fixed, the equidistance property of the points of the circle, or from the line to the centre, is accounted for by the stiffness of the artefact itself. In the context of plotting with the rope, this property is tightly linked with the fact that the rope must be held tight during the whole plotting process. It is physically felt by the student who makes the plot of the circle and it is the required condition to plot the circle. Plotting with a rope usually corresponds to plotting in the meso-space, whereas the compass is commonly used in the micro-space of the sheet of paper. This parameter induces different gestures: plotting with a compass requires hand work, while plotting with a rope requires moving the body and the arms and sometimes the intervention of two students is needed (one student keeps one end of the rope on the centre of the circle whereas the other holds the tight rope and draws the required circle with the other end).

In this case, the links between characterizations and modalities of construction clearly appear, as well as the links between the characterization and the nature of the circle object. The objects explicitly or implicitly handled and the nature of their relations (binary relation, property, etc.) differs from one characterization to the other. What is considered: the centre? the radius? Is the circle seen as a set of points? a line?

A posteriori analysis

In this part, we shall focus on the analysis of the sequence with the work of a second group, again made up of three students. The students are going to plot the circle with the line segment [OE] as a diameter.

The analysis of language interactions shows us that without their usual artefacts the students cannot instinctively adopt a mathematical frequentation mode. They suggest to draw "a round shape" and even a "normal round shape", i.e. a round shape which does not refer to mathematics but rather to what they usually use outside the specific approach of spatial issues raised in geometry. This justifies freehand plotting here. The standpoint on the circle adopted is that of a rounded shape made of a line (a closed line, characterized by its constant curvature and/or its symmetries for example). This is a global rather than a local point of view, since it calls for lines and not for points (and the centre of the circle is not evoked). The teacher's interventions can be seen as attempts to (re)-position the students in a frequentation mode of the circle object which is more in line with the school mathematical expectations, to guide them to express their practical concerns through a mathematical questioning of the properties of the objects and artefacts involved, using a language suitable for the school mathematical context. The background movement that the teacher attempts to bring about is stimulated by the questions: "A circle, what is it? What is a circle?". Raised by the teacher, these questions call for a change in the students' way of seeing. The questions on the nature of the circle are not only or mainly aimed at obtaining a definition of the circle in return. The objective is to lead the students to "see" the circle as it is usually seen in the school mathematics context. Some of the

answers given by the students may seem to be tautological ("A circle", "It's a circle", "Well, it's a circle") and useless in the context of knowledge. The students seem to be aware of it, but it is not the case if they are analyzed considering how the dialogue works and how the practices are inserted in the required context. These language interactions show a change in position. This movement is also revealed by the fact that, in other following answers, terms which are specific to mathematical vocabulary are introduced (centre, diameter and radius).

With the term "the-circle-with-a-centre-X-and-a-radius-Y" (used twice in an identical manner) and the explicit allusion to the «definition» of the circle, the teacher clearly introduces a formal dimension (Hache, in press), above all in relation to the situation of the exercise and the supposed frequentation mode of students. Besides, from the knowledge standpoint, the teacher, by using the words "centres" and "radius" for example, refers to the prevailing definition of the circle in the school context, i.e. the circle seen as a set of points placed at a same distance of a given point. As already mentioned, this characterization calls for a property which is made natural by using a compass in the usual situations of plotting. On the other hand, it differs from the instinctive characterization adopted so far by the students, which rather seemed to lie on the circle as a line, characterized by its constant curvature. In practice, shifting from one conception to another is not instinctive (Artigue & Robinet, p. 49), all the more as the characterizations appeal to students to have different looks on the figures (Duval & Godin, 2006). The last teacher's intervention in the above extract can be understood as an inducement to fit the way of seeing ("therefore, is formed by what?") with the way of speaking ("the circle with a centre O and a 3 cm radius").

CONCLUSION

The purpose of this paper was to describe and analyse the confrontation and changing processes of frequentation modes of 1st grade students (10-11 years old) during two geometric construction tasks. This work was based on a logic analysis of the mathematical concepts involved: the midpoint of a line segment and the circle. In both cases, according to the adopted standpoint, the mathematical concepts can be described from different categories of logic (property, binary or ternary relation) on objects different in number and nature. This analysis, although it was quite brief, seemed to be useful to consider the consistency and practical harmonization of the three dimensions "seeing – acting – speaking" we called for to describe the frequentation modes (Moschkovich, 2007, would maybe have said a *Discourse*). We could thus observe that the change in the way of seeing ("Oh no, there are like this!") of the students who worked on the construction of the midpoint was produced by the teacher's language action aimed at setting the objects *ends of the line segment* as references for some words in the language games specific to the geometry practice at school. This change in their way of seeing is associated with new possible uses of the artefact *rope* (physical dimension of geometry practice). As for the plotting of the circle, we attempted to show how the language practices could be linked with the plotting methods. It seems that the expression "a normal round shape" can be related

to extra-school practices which justify the "freehand" plotting that we compared with a global vision of the circle as a rounded shape. If this approach is somewhat justified, the related vision is not that in use in mathematics at secondary school. On the contrary, the language game which calls for the expression "the circle with a centre O and a 3cm radius", and which is initiated by the teacher, introduces some elements required for invoking a punctual standpoint on the circle, in particular the centre of the circle. This centre, exterior to the line actually plotted, must be taken into consideration to implement the techniques which call for the equidistance relation.

We are just at the start of our research and we are not sure to be able to offer a pertinent discussion of these results. Nevertheless, we will try to situate it inside the today well-established *discursive framework* in mathematics education (Sfard, 2013). Our feeling is that the former semantic and dialogic perspective could be one way to consider both social and external aspects of language. Mathematical language games could be *outdoor games* (Hintikka, 1996), i.e. games involving the objects of the language one speaks. Analysis of communication quite often emphasizes interpersonal interactions. In this work, we think it necessary to integrate a specific focus on the interaction between students and external (even if dialogically constructed) mathematical objects, with the help of a logic analysis of the concepts at stake. Of course, all of this is nothing new. For instance, the Theory of Didactical Situation tradition in France has a long time ago pointed out the educational interest of the students-*milieu* interactions (Brousseau, 1997) and inside the communicational approach, Sfard (2001) clearly accounts for the "object-level aspects of discourse". We only hope that this research, relying on logic analysis, could contribute to the content related dimension of language games understanding.

ANNEX

Construction program and example of the expected figure

Stretch out a rope the length of which must correspond to the side of the square to be constructed.

On the ground, mark its ends O and E and its midpoint I.

Plot the circle with a diameter [OE] and circles with radii [OE].

These two large circles are crossed in U and V.

Stretch out a rope between U and V.

Mark as N and S its intersection points with the small circle.

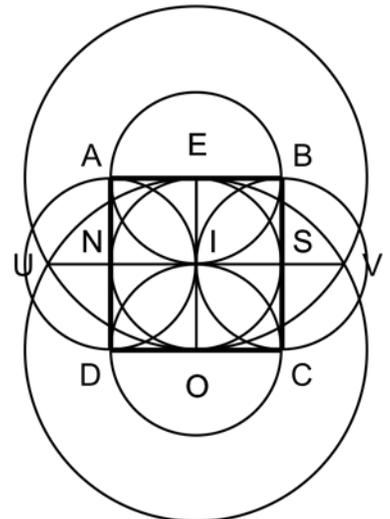

Points U, N, I, S and V are aligned in this order.

Plot the circles with respective centres E, O, N and S the radius of which should measure half the EO length.

These four large circles are crossed two by two in A, B, C and D.

These four points are the vertices of the square.

Follow these instructions and construct a square using the artefacts given to you.

A LINGUISTIC ANALYSIS OF THE DIDACTICAL ENVIRONMENT IN SUPPORT OF THE SCAFFOLDING CONCEPT

Thierry Dias & Chantal Tièche Christinat

University of Teacher Education, Switzerland

Can the didactical environment be conceptualised as a constant evolving process due to all the protagonists' contributions such as: signs, actions, interactions, and language games? If the didactical environment during mathematical problem solving is without doubt composed of cognitive destabilizing elements, these must be compensated by resources required for supporting the learning process by adaptation. This is particularly important in the context of special needs education. In order to complete our studies of didactical environments, our different observations and analyses of interactions occurring during classroom situations, bring us to reflect on language acts. A linguistic analysis using the syntactic, semantic and pragmatic register is suggested. Its possible contribution to our understanding of didactical environments is discussed.

VERBAL SCAFFOLDING AND THE SEARCH FOR BALANCE

Our research explores various language interactions encountered during mathematical problem solving activities through a didactical dimension related to the notion of environment ("milieu") (Brousseau, 1990). Language phenomena that are responsible for the evolution of an environment suitable for the construction of mathematical knowledge in the specific context of special needs education are investigated. Hence our objective is to make the distinction between:

- What pertains to antagonism (the Piagetian unbalance) in mathematical problem solving activities: uncertainty, the masking of objects of knowledge, the need for verbal exchanges and the rupture of a didactical contract.
- What pertains to compensation or adaptation: for example by basing ourselves on the functions of scaffolding (Wood, Bruner, & Ross, 1976).

Our hypothesis is that the search for balance (or unbalance) by means of control or regulation of didactical situations is mainly possible by resorting to the scaffolding functions defined by Wood et al. (1976) The latter describes scaffolding as the resources employed by an adult or a specialist to help someone less competent (Wood et al., p. 89). After observing pupils and tutors in a problem solving activity, we identified six categories of scaffolding functions: 1. Recruiting; 2. Reduction in degrees of freedom; 3. Direction maintenance; 4. Marking critical features; 5. Frustration control; 6. Demonstration.

We expect that this model is coherent with the practice of special education teacher and it can be used with the notion of adaptation. During a learning situation in mathematics, these scaffolding functions may be correlated to linguistic processes. In our research project the following research questions are investigated:

- 1) Do special education teachers resort to all the six scaffolding functions during mathematical problem solving activities? Do they give priority to some scaffolding functions and why?
- 2) Can a linguistic analysis of discourse provide a better awareness of the progressive dimension of the didactical situations analysed through a semiotic process?

During this communication, preliminary results related to research question 1 and 2 will be presented and their implications discussed.

THE SPECIFICITY OF THE DIDACTICAL ENVIRONMENT IN SPECIAL EDUCATION

The concept of the didactical environment stems from the theory of didactical situations (Brousseau, 1998). According to this theory, the use of antagonistic situations (didactical situations creating an unbalance), are crucial for learning. The pupil learns thanks to a process of adaptation to an environment characterised by contradictions, difficulties and unbalance (Brousseau, p. 325). In these situations, learning is made possible thanks to successive adaptations of the didactical environment. In this model, regulations and retroactions provided by teachers are at the heart of didactical concern. Teachers have to anticipate the instructional components that will allow their students to be self-regulated and autonomous. One of the specificities that we observed in the context of special needs education, was that if the didactical environment contained elements producing a cognitive destabilisation, the teacher must compensate it by providing resources and educative alliances. It is necessary for the teachers to anticipate the student's diverse reactions. Indeed, some of the students with special educational needs can ignore the retroactions of the didactical milieu and never take active part in the learning process. The goal of the adaptive learning model is in such cases unachieved, unless complementary or compensatory resources scaffolding the adaptive learning process are provided. The challenge in teaching pupils with special educational needs is to control the progression of the didactical time, and at the same time the maintenance of a pedagogical and relational balance, crucial in the context of special education. The teacher has to submit complex situations to the students in order to involve different kinds of knowledge, without decreasing his requirement and without distorting the didactical environment.

3. LINGUISTIC ANALYSIS

To date, the study of the didactical environments (Brousseau, 1990) does not seem neither completed, nor complete. We wish to explore another approach of the distinctive elements of learning situations in the context of special needs education.

Based on the observations and analysis of classroom interactions during mathematics instruction conducted in our previous studies (Dias, 2007), a language analysis based on speech acts theory (Kerbrat-Orecchioni, 2001) is proposed in order to enhance our comprehension of the didactical environment. Three distinctive dimensions of discourse will be analysed: syntactic, semantic and pragmatic. As defined by Morris (1938) in his classic presentation of semiotics, syntax is described as the study of the formal relations and combinations of signs. Semantics refers to the relations existing between signs and objects to which the signs are applicable (their "designate"). Pragmatics describes the study of «the relations between signs and interpreters» (Morris, 1938, p. 6). These dimensions have been used by many scientists interested in language (linguistic, semiotic and communication). The theoretical framework for the linguistic analysis of didactical situations in our study refers essentially to Morris' work (1974).

Morris' model assimilates semiosis to a dynamic process, similar to the pragmatic approach developed by Peirce (1978). It seems therefore particularly appropriate for gaining a better understanding of the various mechanisms involved in the interactions emerging during mathematical problem solving activities. This reference to behaviour suggests that the pragmatic dimension of discourse is essential in understanding the classroom's dynamic. The syntactic dimension is a "hidden dimension" for the students. Indeed, only the rules structuring discourse are explicit. In Morris' model all the signs do not necessarily refer to a real, tangible and perceptible thing. These "vehicles of signs" are mediators of knowledge in didactical situations.

The semantic dimension refers to the assignment of meaning(s) to the expressions of a discourse. In other words, this is the dimension where interpretation of discourse takes place. Because of the complexity of the relations existing between mathematical objects and their perception and comprehension, this is the main difficulty in mathematics instruction. It is in this dimension of discourse that the stakes of constructing meaning are the highest. Indeed, during mathematics instruction several actors interact with similar objects, which are not always interpreted in the same way (Dias, 2008). The verbal exchanges between the actors can lead to a consensus on the meaning of these objects, or not. This depends on the teachers' skills in regulating the dynamics of the didactical environments (retroactions and antagonisms). If the teacher wants his pupils to interpret correctly his instructions, he must ensure that they are conveyed in the pupils' comprehension zone. The objects present in the didactical environment, which are conveyed as signs to be interpreted, are essential elements of this comprehension zone. The main issue at stake in this semantic dimension is the construction of a shared understanding of reality (Lelong, 2004).

4. THE RELEVANCE OF A LINGUISTIC ANALYSIS

During communicative situations in the classroom, teachers often discuss with their pupils but also sometimes struggle with meaning in a "language game" (Durand-

Guerrier, Heraud, & Tisseron, 2006). The pragmatic dimension of discourse described in Morris' model, is based on the notion of "language in action". It defines the relation between language and its functional use by the speaker in communicative situations. The pragmatic dimension is essentially contextual, as it refers to the interactions between participants in communicative situations. It can therefore be described as having a psychosocial nature. This dimension is highly relevant in didactical situations in the context of special needs education. Indeed, if a teacher wants to change the behaviour or enhance the knowledge of his pupils, he must necessarily build a social cooperation with his pupils.

In our opinion, interactions are neither dependent, nor independent of their context of production. They are constructions of the context itself as well as manifestations of it. It seems to us that studying this pragmatic dimension of discourse is important to gain a more comprehensive understanding of didactical situations. In our linguistic analysis of discourse during interactions in pedagogical environments, the following references are used:

- The pragmatic register (Morris, 1938): analysis of the effects of the different utterances on the actors in the communicative situation
- The speech act theory (Austin, 1970; Searle, 1976). Austin and Searle distanced themselves from the syntactic and the semantic studies conducted by structuralists, which assume that every utterance implies an effect of this utterance, voluntary or not.
- The interactionist pragmatic (Kerbrat-Orecchioni, 2001), which studies the effects of the language acts during conversations and shows that the effects of some utterances are not consistent with their form. The interactionist analysis of language acts can highlight misunderstandings between teachers and pupils that can reinforce the disequilibrium present in didactical environments. This type of analysis seems particularly promising and could serve to identify several essential factors impacting on student-teacher interactions and their didactical relationship.

AN EXAMPLE OF CONTENT ANALYSIS OF A CORPUS

The example of content analysis presented in this section is based on an audio-recorded lesson, which took place in a self-contained classroom for pupils with special educational needs in the spring of 2011. The teacher had presented to her students a mathematical open-ended problem that they had to solve (Arsac & Mante, 2007). In order to solve this type of complex problems, pupils have to conduct an arithmetical investigation and use their knowledge of several mathematic facts.

The problem:

In a desert of 1000 km, you have to carry 3000 bananas with a camel. This camel can carry 1000 bananas on his back. We know that it consumes 1 banana per kilometre.

What is the largest number of bananas that you can get to the end of the desert?

Characterisation of scaffolding with Bruner's (1983) model

A content analysis in two steps is used in order to distinguish the exhaustive analysis of the teachers' verbal scaffolding and their linguistic interpretation.

Step 1: analysis of the teacher's interventions

The teacher's verbal interventions are systematically identified. Each language act is associated to a scaffolding function, based on Bruner's (1983) model and they are coded with the same numerals used by Bruner for each scaffolding function in his study.

When necessary, the audio-recorded conversations were re-heard to enrich the reading of their transcription. The non-verbal explicit acts (gestures and looks) could not be taken into account in the analysis, because the lessons were not videotaped.

Step 2: Sequencing scaffolding interventions

The transcription of the lesson is then divided into short episodes corresponding to communication sequences. This allows the identification of chains of scaffolding interventions that are used preferentially or at least recurrently by teachers. The goal is to establish a profile of teacher's monitoring of the progression of didactical time.

Episodes	lines	Scaffolding functions
1.	line 1 to 9	2-3-3-4-2
2.	line 9 to 19	1-3-3-4-2-2-(4)
3.	line 20 to 37	1-3-3-5-3-3-5-2-2
4.	line 38 to 47	1-3-3-2-(4)
5.	line 47 to 52	1-3-4-2
6.	line 55 to 63	1-4-(2)-6-5
7.	line 63 to 76	1-5-4-4-2-4-3-(4)-2

Table 1. Example of an analysis of content from a corpus

Our analysis shows a frequent use of function 3 (direction maintenance as sustaining the pursuit of the goal) during the first episodes of the activity. The teacher seems to compensate for the antagonism of the milieu created by the complexity of the mathematical problem that the pupils were asked to solve. Indeed, because there is no obvious solution to open-ended problems, pupils are confronted with mathematical retroactions synonymous with temporary failures. It seems therefore normal that the teacher tries to sustain her pupils' orientation on the task, in order to avoid that they abandon their search for a solution out of discouragement. Through this scaffolding technique she also aims at exerting a didactical control on the problem solving process.

An analysis of these episodes also highlights that the function 2 (mainly by simplifying the task) has a conclusive impact on communication. This may be a phenomenon very specific to mathematics teaching in the context of problem solving activities. Indeed, the use of this type of scaffolding is not anticipated in a learning situation which promotes pupils' search of a solution and the production of statements, whose validity is postponed. During the phase of *formulation* (Brousseau, 1990), only the retroactions of the didactical environment can foster the verbalization of knowledge. The teacher's simplification of the task does not play this role and stops the verbal exchanges between pupils.

In this extract, an evolution of the types of scaffolding functions used by the teacher can be observed in accordance with the progression of the problem solving procedure and the progression of the didactical time. Function 4 (identified mainly by pointing out critical features) appears progressively, as a manifestation of the teacher's will to stabilize the pupils' hypotheses and findings. In our opinion, this could be a phenomenon specific to problem solving situations in the context of special needs education. Special education teachers often observe that their pupils have difficulties in identifying the important elements in terms of knowledge after spending time trying to solve a problem. The profusion of information and the absence of identification of their domain of validity is a source of difficulties for pupils.

Scaffolding function 5 (Controlling frustration) appears belatedly in the succession of episodes. This confirms the teacher's willingness to loose progressively her control of the progress of problem solving. This could be described as a professional skill. It could be interesting to highlight it in a context of pre-service or in-service training for teachers.

The implicit character of language acts and disequilibrium in the didactical environment

This second type of analysis is related to our hypothesis that some of the teachers' interventions during mathematical problem solving activities are intended to scaffold pupils' learning, but are not perceived as such by the pupils themselves. Because of these miscomprehensions, elements creating disequilibrium and antagonism, which are not always consciously wished by the teachers, are introduced in the didactical environment. The following extract is an example of this type of perturbation.

- | | | |
|----|---------|--|
| 20 | teacher | this is not... Someone else ? Quentin ? |
| 21 | student | I calculated that for one banana the camel had to walk one kilometre, so I calculated 1000×1 , which makes 1000 |
| 22 | teacher | yeah |
| 23 | student | then I divided 3000 by 1000, which makes 3 camels. |
| 24 | teacher | yeah |
| 25 | student | then, as we know that one camel eats 1000 bananas, I calculated 1000 bananas for one camel, and then subtracted 1000 to 3000, which makes 2000 |

- 26 teacher yeah
- 27 student then as 2000 bananas were left, I sent another camel with 1000 bananas.
- 28 teacher how much?
- 29 student 1000 bananas
- 30 teacher ah yeah, 1000 bananas
- 31 student then I did 2000 minus 1000 makes 1000 bananas
- 32 teacher but your 1000 bananas stayed at the entrance of the desert ?

An analysis of the language acts identified as creating imbalance in the above mentioned extract yields the following findings.

line 22: interpretation of the answer «Yeah»

This first «yeah» is an assertion (statement presented as true). The illocutionary value is an affirmation, but the perlocutionary effect is to point out to the pupil that the teacher heard him and at the same time that he agrees with the content of his statement and enjoins him to continue his reasoning.

line 24: interpretation of the answer «Yeah»

With this second «Yeah», the teacher agrees with the operation performed by the pupil, but creates confusion because her illocutionary act validates the entire proposition. She intended to validate only the result of the division but not the pupil's proposal to use 3 camels. The assertion of this pupil's answer creates confusion, because it does not respect the constraints given in the instructions of the problem (only one camel can be used). Because of the teacher's assertion of this answer with a «yeah», the entire proposition of this pupil will be followed by his classmates in their reasoning during several rows of conversation. This will last some time, before the teacher realizes this confusion and reminds her pupils that they have the right to use only one camel (line 59 of the corpus).

line 30:

The teacher uses the word «Yeah» for the third time. It has the value of an assertion: the locutor commits himself in recognising the truth of the proposal expressed by the pupil. However, this answer creates/sustains the disequilibrium because it was already used previously on two occasions with another linguistic value. Therefore, it is unlikely that the pupils will be able to interpret this intervention correctly on a semantic level.

line 32:

This intervention suggests that the teacher misunderstood the pupils reasoning. A true disequilibrium is created in the didactical environment and is followed by a time of latency showing the ambiguity of the communicative situation.

CONCLUSION

The preliminary analysis of this corpus highlights the impact of the verbal interactions on the didactical environment, and particularly on its antagonist characteristics. The interplay of interactions related to scaffolding functions contributes to the modification, enrichment, or complication of the didactical environment. It renders it either more accessible, or more opaque for the pupils. The teacher's use, or non-use, of the six scaffolding functions seems to depend from the specificities of the didactical environment, as well as from the didactical time.

The different scaffolding functions identified by Bruner seem to be located in the chronology of interactions and form sequences comprising a succession of scaffolding interventions. These sequences can be clearly identified and seem to be provided in a relatively stable way. Some functions are used more scarcely; probably by fear of a modification of the characteristics of the didactical environment, in particular the fear to make it an ally.

In our corpus, scaffolding seems to be related to the progress of the didactical time. The real function of scaffolding interventions depends on the perlocutionary effect of the language act. Thus, the pragmatic analysis of discourse that we adopted seems to contribute to a relevant identification of the real effects of verbal scaffoldings.

MEANINGS OF THE CONCEPT OF FINITE LIMIT OF A FUNCTION AT A POINT: BACKGROUND AND RESULTS

José Antonio Fernández-Plaza, Luis Rico, & Juan Francisco Ruiz-Hidalgo

University of Granada, Spain

In this paper we present a description of previous work carried out by the authors on the general issue of designing and implementing a didactical planning for Spanish students from non-compulsory secondary education, 16-17 years old. The current research has as its aim to describe the meanings that students associate to specific terms from the language, such as, “to approach,” “to tend,” “to reach,” “to exceed,” and “to converge.” Prior to the study, we reviewed the mathematical use of these terms and we contrast this with the colloquial use of the terms. From the semi-structured interviews used to gather information, we provide an analysis of the written data. It is important to highlight that students have contributed with a variety of meanings, in addition to those from the previous review.

INTRODUCTION

Since the academic year 2009/2010 we have been interested in investigating some problems related to the teaching and learning of the concept of the limit of a function at a point. This concept is important because it is necessary for the learning of the derivative and integral concepts and is more complex than the concept of limit for sequences. Furthermore, it is one of the key concepts that mark off the transition towards the advanced mathematical thinking. By exploring several textbooks we observed a large number of routine tasks about calculating the limit following an intuitive definition based on the idea of approximation. So we carried out an exploratory study about the intuitive meanings that students have about the concept of a finite limit of a function at a point. The students are given tasks using different representations such as verbal, graphic and symbolic representations (Fernández-Plaza, 2011). Some of the results have been presented before both at national and international conferences (Fernández-Plaza, Ruiz-Hidalgo, & Rico, 2011, 2012a, 2012b, 2012c).

Recently, we have gathered information by means of interviews in order to contrast our interpretation of the written records from students and to deepen the personal conceptions that students associate with the following terms from calculus: “limit,” “to approach,” “to tend,” “to converge,” “to reach” and “to exceed”. The colloquial meaning of these terms has been shown to influence the understanding and this has been reported in several studies (Cornu, 1991; Monaghan, 1991). In (Fernández-Plaza, 2011), the effective use of these terms and other synonyms has been explored, but not the specific meaning implemented by students. By effective use of a term, we mean that students in fact use this term, and not a synonym. For example, for the specific term “to approach”, a student may use “to get close” or “to approximate,”

among others. This does not count as effective use but it is related to “to approach.” Below, we describe the main achieved results so far.

MAIN ACHIEVED RESULTS

We summarize the most important results we have found out until the present moment. Firstly, we observed a persistence of misconceptions related to the limit as a non exceedable and unreachable value. This result is consistent with those from Cornu (1991) and Monaghan (1991). Here, we go deeper into the topic in the sense that, some students suggested a link between exceedability and reachability. We consider that this kind of misconceptions could arise from an overgeneralization of the particular case of monotone convergence.

Secondly, we discriminate between *process conceptions*, *object conceptions* and *dual conceptions* of the concept of limit. As *process conceptions*, we understand conceptions where the limit is closely related to a procedure about how to find it. With an *object conception*, the student is able to identify properties of the limit without depending on the process involved. Intermediate conceptions between these two are called *dual conceptions*. Thus when students were requested to discuss about the statement “The limit describes how a function $f(x)$ moves when x moves to certain point,” the most of arguments could be classified as one of these three options depending on whether students interpreted the limit as “how” (process conceptions) or “where” (object and dual conceptions) a function moves.

Thirdly, we found conflicts with the arbitrary accuracy of approximation to the limit. Expressions such as “limit can be approximated *as much as you wish*” are taken to mean that some students think that accuracy is bounded in the practical process. We suggest that the ambiguity of the underlined expression could have made students do a crucial distinction between the potential infinite character of the process and its implementation in practice.

Finally, we pointed out the conflicts with the exact or indefinite character of the limit value.

Some subjects considered a limit as an exact number whereas others considered that the limit is an “approximate” number. We suggest, according to Sierpiska (1987), that the latter subjects do not know the exact value of the limit, but only approximations to it, that is to say, the limit is undetermined. The progressive improvement in the interpretation of these results gave rise to talking about *structural aspects*, such as object/process duality of the concept, exact/approximate character of the limit, potential infinite/finite character of the limiting process, reachability and exceedability of the limit. These structural aspects were used to characterize and establish connections between different conceptions about the concept of limit (Fernández-Plaza et al., 2012a). At the same time we tried to characterize the terminology used by students in their answers. We selected the terms “to approach,” “to tend,” “to reach,” “to exceed” and “to converge” among other reasons because they are used in the technical language and they describe different aspects of the

concept of limit. Moreover, the influence of their colloquial meanings and everyday use on students' understanding have been reported in the literature. This problem leads us to three questions:

- Which are the different meanings and uses that these terms have in Spanish language?
- What is the terminology that students effectively use to explain their answers?
- What are the explicit definitions and meanings that students associate to these specific terms?

The treatment of the two first questions can be consulted in (Fernández-Plaza, 2011; Fernández-Plaza et al., 2011, 2012b). In the following section we are going to focus on giving answers to the third question.

DESCRIPTION OF THE CURRENT STUDY

We propose to describe how students explicitly define some specific terms from calculus in contrast with the colloquial and technical meanings of these terms. The chosen terms are “to approach,” “to tend,” “to reach,” “to exceed” and “to converge.”

Theoretical framework and prior research

We position this study in the research agenda of *Advanced Mathematical Thinking*, from the international group on the Psychology of Mathematics Education (Gutiérrez & Boero, 2006, pp. 147-172). There is no agreement to establish the transition from elementary to advanced mathematical thinking.

The educational stage analyzed assumes a period of transition in which students use elementary techniques to tackle mathematical contents whose development historically, epistemologically, and didactically has an advanced status.

Rico (2012) developed the notion of meaning of a school mathematical concept, based on reference, sign and sense. We analyze the systems of representation, formal aspects or references of the concept, and the phenomena that provides its meaning.

Three components constitute the basis of the meaning of a school mathematical concept:

- *Systems of representation* (sign), defined by a set of signs, graphics and rules, to express and highlight aspects of the abstract concept and to establish relationships with other concepts.
- The *conceptual structure* (reference) that comprises concepts and properties, the derived arguments and propositions and their truth criteria.
- *Phenomenology* (sense) that includes those phenomena (contexts, situations or problems), which are at the centre of the concept and provide sense to it. (Rico, 2012, pp. 52-53)

The mathematical language related to the concept of the limit of a function at a point includes the terms “to approach,” “to tend,” “to reach,” “to exceed” and “to

converge.” We chose these terms, among other reasons because each of them refers in part to properties and modes of usage associated with the concept of limit, that is to say, the phenomena involved (see Fernández-Plaza, 2011, pp. 14-21).

Conceptual analysis of specific terms

By a conceptual analysis we understand the procedure that leads to establishing the mathematical use of the terms and we want to contrast this use with the colloquial use or use in other disciplines.

We describe the chosen terms below and we also include the colloquial meaning of the term “limit.” Monaghan (1991, p. 23) notes that to a mathematician tends to, approaches, converges, and limit are interchangeable. In Spanish “*aproximar*” has two different meanings; the first one expressed by “to approach,” (dynamic) and the second one expressed by “to approximate” (static) (Fernández-Plaza, 2011, p. 16).

The sentence “to tend toward a value” means “to approach gradually but never reach the value” (Real Academia Española [RAE], 2001) and expresses a very specific form of approach. Blázquez, Gatica and Ortega (2009) argue that a sequence of numbers approaches a number as a limit if the difference between the terms of the sequence and the limit decreases gradually, but they also argue that a sequence “tends toward a limit” if any arbitrary approximation to the limit can be improved by the terms of the sequence.

A study by Monaghan (1991) concludes that many students do not distinguish between “to tend” and “to approach” in a mathematical context. In a formal sense, to tend toward or to approach a limit is said of a sequence (e.g. the sequence 0.9, 0.99, 0.999... tends toward 1, but also that sequence approaches number 2) according to the definition of limit, but “to approximate” a limit is to give any of the terms of a convergent sequence (“0.999 approximates 1 with an error less than 0.01”). We justify the different distinction between these terms only for Non-University High Education because both of them are applied to the same object (a sequence).

The expression “ $f(x)$ tends toward L , when x tends toward a ” may cause cognitive conflicts, as Tall and Vinner (1981) note, because x never equals a , so students may consider that $f(x)$ never equals L .

“To reach” means colloquially “to arrive at” or “to come to touch” (RAE, 2001). We interpret the mathematical meaning of “reach” to be that a function reaches the limit if the limit value is the image of the x -point at which the limit is studied (continuity); by extension, the limit can be the image of any other x -value in the domain.

We see that “to exceed” means colloquially “to be above an upper level” (RAE, 2001), excluding the meaning “to be below a lower level”. We will say that the limit of a function may be exceeded if we can construct two successive monotone sequences of images that converge to the limit, one ascending and the other descending, for appropriate sequences of values of x that converge at the point at which the limit is studied. The reachability or exceedability of the finite limit of a

function can be easily interpreted as global or local concepts, but there is no logical implication of the two concepts.

The term “to converge” means colloquially “to come together from different directions”. In mathematics, this term is equivalent to “to tend” and normally is applied to the limit of sequences and series and is not so often used in connection with the limit of a function at a point. We expected that students could invent a definition for this term in this new mathematical context.

Furthermore, the term “limit” has colloquial meanings that interfere with students’ conceptions of this term, such as ideas of ending, boundary, and what cannot be exceeded (RAE, 2001). The term’s scientific-technical use is related in some disciplines to a subject matter or extreme state in which the behaviour of specific systems changes abruptly (Real Academia de las Ciencias [RAC], 1990).

Prior Research

Monaghan (1991) studied the influence of language on the ideas that students have about the terms mentioned above, when the terms were used in connection with different graphs of functions and examples that school students verbally explained. We underline as a limitation of the approach adopted in this case, that the key terms that the students were asked to use were defined a priori, instead of enabling students to use their own words freely and spontaneously and to infer the appropriate nuances a posteriori.

In previous CERME proceedings there has been published papers related to the learning of the concept of limit of a function. The most relevant one in relation to this study is by Juter (2007) who investigated, among other aspects, how students interpreted the reachability of the limit in a problem solving context.

Method

A semi-structured interview was conducted in an ordinary classroom. The protocol of implementation was the prior request to the students to write their answers on the sheet provided, and the discussion of the answers was audio recorded. The subjects were organised into nine groups with 3-5 in each, in order to facilitate the interaction between the subjects and the researcher.

We focus on the following common question:

Describe how you understand the following terms: “to approach”, “to tend”, “to reach”, “to exceed”, “to converge” in the context of a finite limit of a function at a point.

In order to help the students to better express their conceptions during discussion, we showed them some graphics of functions so that some other characteristics of meaning of these terms could emerge, especially with the terms “to reach” and “to exceed”.

33 subjects out of a total of 36 from the previous study (Fernández-Plaza, 2011) were selected. They were chosen deliberately, according to their previous answers and based on their availability. The subjects attended the second year of non-compulsory secondary school study (17-18 years of age) and they were all studying mathematics. They had received the instruction on the concept of limit according to the current curriculum.

Preliminary results and discussion

We are going to show some preliminary results from the analysis of the written records. Table 1 shows a classification of meanings and frequencies of the selected specific terms. According to these categories, we classify the definitions provided by the students by the codes (Ai, Bj, Ck, Dl, Em) (Note that each student produced at most five definitions). Only 2 out of 33 of the individual productions (the set of their five definitions) have the same code, therefore the differences are relevant (any two students could define 1, 2, 3, 4 or 5 specific terms in a different way).

We observe that 23 out of 33 individual productions establish some distinctions between “to approach” and “to tend.” The most relevant differences of meaning between these terms are as follows:

- The possibility of not to reach or exceed the limit. In particular, some students used expressions such as “to approach more and more” to point out a potential infinite character of the process “to tend.”
- The technical usage and the subjective view of the term “to tend.”

Specific terms	Meanings	Frequencies
To approach	A1. To get as close as possible	14
	A1.1. Not to reach the limit	10
	A1.2. Not to reach and not to exceed the limit	2
	A1.3. To reach but not to exceed the limit	2
	A2. To establish the closest value to the limit	4
	A3. No answer	1
To tend	B1. To approach	5
	B1.1. Not to reach the limit	7
	B1.2. To approach more and more	4
	B2. Technical usage	8
	B3. Subjective	2
	B4. Other	5
	B5. No answer	2

	C1. To arrive at or to touch the limit	27
	C1.1. Not to exceed the limit	3
To reach	C2. To know the exact value of the limit	2
	C3. To know the value of $f(x)$ for a given x	1
	D1. To surpass the limit of the function $f(x)$	19
	D2. To surpass the x -value.	7
To exceed	D3. To reach the limit and continue (To pass through the limit or x -value)	4
	D4. No answer	3
	E1. The function is above the limit all the time	2
	E2. The function is below the limit all the time	2
	E3. To tend	1
	E4. To reach	1
To converge	E5. The right and left-hand limits are the same.	3
	E6. The function takes the same value than the limit	1
	E7. Two functions or straight lines intersect at one point	9
	E8. Other	4
	E9. No answer	10

Table 1: Classification of meanings and frequencies about the selected specific terms

Below we exemplify answers from some categories in order to clarify their denomination. The other categories are denoted by a “representative” definition, for example, category A1 includes those definitions that express the idea or use the expression “to get as close as possible”, so we do not consider it necessary to exemplify all of them:

- **Category B2: Technical usage.** An example of an answer is “*This term is used to indicate the value that x takes in a limit*”. It does not state anything about the specific meaning of the action “to tend,” that is, it is only a technical word; an agreement. Another answer is “*to tend to a number is to use the closest number to it, for example, if $x \rightarrow 1$ from the left, we use 0.9. From the right, we use 1.1.*” The term is used to describe a personal rule to calculate a limit.
- **Category B3: Subjective.** Examples of answers are: “*To approach to that number without being aware of it (without intending to obtain it)*” and “*To approach it as much as we want*” indicate a subjective aspect of the definition of the term “to tend.”

From Table 1 we discuss the global results:

Most subjects (14 out of 33) consider “to approach” as *to get as close as possible*. Although it is relevant that 10 out of 33 subjects also consider that the function cannot reach the limit. Only 2 out of 33 admitted in addition that the function could in fact reach the limit but never exceed it. In general, “to approach” is considered as an intuitive and incomplete process.

However, the term “to tend” has some particular characteristics different from “to approach”, such as a subjective view of its definition (2 out 33) (“*To approach it as much as we want*”) or a technical usage (8 out 33) (“*This term is used to indicate the value that x takes in a limit.*”), that is it is an agreement in mathematics.

Regarding “to reach”, most subjects (27 out of 33) consider it simply as *to arrive at or to get to touch the limit*. Only 3 out of 33 considered that the limit must not be exceeded. On the other hand, only two subjects considered that the limit is reachable if we can calculate the exact value, while only one subject stated that “to reach” is to know the value of $f(x)$ for a given x , so there could be a possible identification between the limit and the image.

“To exceed” is basically *to surpass the limit or the x -value given* (19 and 7 out of 33), although some subjects (4 out of 33) gave more complete answers, in the sense that a limit or a given x -value are exceeded *if the function reaches them and continues, both above and below them*.

At the beginning, students recognised not to know the term “to converge” in the context of a finite limit of a function at a point. In fact, 9 out of 33 did not answer this question, so the researcher had to encourage them to write whatever they could imagine about any other situation and to invent a definition. Only one subject defined this term as “to tend”, and the most frequent meaning (6 out of 33) was *two functions intersect at one point*, and 5 out of 33 define “to converge” as *the right and left-hand limits are the same*, a definition that could be considered suitable in this context. On the other hand, several subjects described situations where the *function is all the time above or below the limit*, that is to say, an asymptotic behaviour of the function, for example, $f(x) = 1/x$ converges to 0 when x tends to $\pm\infty$.

Preliminary conclusions

According to the discussion of the results from Table 1 and the aim proposed at the beginning; to describe how students define explicitly some specific terms from calculus in contrast with a previous conceptual analysis of these terms, we draw the following conclusions about their achievement.

Students interpret the meaning of the selected terms in many different ways, most of them extracted from everyday situations, so we agree with Monaghan (1991) and Cornu (1991) that conflicts between colloquial and formal language are still occurring.

The review of the use of specific terms has predicted partially the meanings that students were going to provide, above all the colloquial meanings. The technical use of the term “to tend” had been conjectured by Fernández-Plaza (2011, p. 36). The observed difficulty some students had to distinguish between “to approach” and “to tend” is consistent with Monaghan (1991) and Blázquez, Gatica and Ortega (2009). All the new meanings of these terms should contribute to enrich this review in order to increase its explicative power.

At the beginning, the term “to converge” had been considered unknown by students in the context of finite limit of a function at a point, but they were able to invent a possible definition for the new context.

It is relevant that exceedability and reachability of the limit are especially connected to the students’ conceptions of the terms “to approach” and “to tend” according to Fernández-Plaza (2011, p. 40).

THE INFLUENCE OF HOW TEACHERS INTERACTIONALLY MANAGE MATHEMATICAL MISTAKES ON THE MATHEMATICS THAT STUDENTS EXPERIENCE

Jenni Ingram, Fay Baldry, & Andrea Pitt

University of Warwick, UK

Making mistakes is an essential aspect of learning mathematics, both for the teacher and for learners. Teachers are generally encouraged to use students' mistakes as teaching points particularly in order to expose common misconceptions. However, teachers use a wide variety of interactional techniques to avoid directly and explicitly negatively evaluating a student's mistake during whole class interactions. This gives the implicit message that mistakes are embarrassing and problematic (Seedhouse, 2001). So, whilst teachers may explicitly state that making mistakes is part of learning mathematics, interactionally they are saying that they are problems and are to be avoided.

Making mistakes is an integral part of learning mathematics and many recent initiatives have advocated teachers using mistakes in their teaching, particularly to expose frequent misconceptions and mistakes to avoid. However, because of the interactional structure of the classroom, teachers often avoid explicitly negatively evaluating students' mistakes or mitigate their negative evaluations in some way. This avoidance of explicit and direct negative evaluation portrays the interactional impression that mistakes are to be avoided. Hence, the pedagogical messages surrounding the role of mistakes in learning conflict with the interactional messages given by teachers when they handle these mistakes.

In this paper, the structure of sequences of interactions in which a mathematical mistake occurs are described in detail to reveal the conflict between the pedagogical and interactional messages.

METHODOLOGY

This study uses a Conversation Analysis (CA) approach, particularly drawing upon the CA literature and studies on the preference organisation of repair in interactions. Conversation analysis is an unusual methodological approach in the social sciences in that it is not driven by research questions or a priori analysis. Rather, it studies the social organisation of 'talk-in-interaction' (ten Have, 1990) with the aim to explicate the structures that the participants themselves orient to in the interaction. This paper focuses on describing and explicating the interactional strategies teachers and students use when a mathematical mistake occurs in the interaction.

Repair can be defined as the treatment of trouble in speaking, hearing, or understanding (Schegloff, Jefferson, & Sacks, 1977). Trouble can take the form of a mistake or error, but is also used more broadly to include any difficulties occurring in the interaction (Seedhouse, 1996). In this article we will only be considering the

treatment of mathematical mistakes and errors. The repair of trouble consists of three parts: the trouble source; the initiation of the repair; and the outcome of the repair. The person in whose turn the trouble occurs and the person who initiates the repair and the person who performs the repair may or may not be the same person. For example, the trouble could occur in Jane's turn, John could initiate a repair on the trouble in Jane's turn, but it might be Peter who actually performs the repair.

A great deal of research has been conducted into the structure of repair in different interactional contexts, in particular the preference organisation of sequences of interactions that follow a trouble source. The notion of preference is complex and is not used consistently within the CA literature. The term preference as originally used by Harvey Sacks (1995), refers to the structural features of turn organisation in interactions rather than the psychological meaning of preferring one thing over another. However, this distinction is difficult to make. Most authors focus on describing the common features of preferred and dispreferred responses rather than defining preference explicitly. These features include the markedness of responses, the frequency of types of responses and issues relating to face (Sifianou, 2012). Preferred responses are often unmarked, occur frequently and are not face-threatening. Dispreferred responses, on the other hand, are often marked, given hesitantly or delayed in some way, are seen rarely in interaction and can be interpreted as face threatening acts (Schegloff, 2007). Bilmes (1988) argues that there is an association between these features of responses but does not accept these as defining features. He argues instead that they indicate a reluctance by the speaker to give the response. This leads to many authors discussing how speakers 'avoid' dispreferred responses (Levinson, 1983; Mey, 1993). Bilmes argues that a response that would be noticeably absent if not given could be considered as an alternative indicator of a preferred response.

McHoul (1990) examined the preference organisation of repair in geography lessons and showed that the number of other-initiated repairs was greater than self-initiated repairs. This contrasts with ordinary conversation where there the frequency of self-initiated self-repairs is far higher (Schegloff et al., 1977) i.e. the same person in whose turn the trouble occurs initiates and performs the repair. However, even though other-initiated repairs appear more frequently in classroom interaction, self-initiated repairs are still preferred structurally.

When considering preferred and dispreferred responses in this paper, a response given by a student is considered a preferred response if it is treated as such in the turn that follows. Thus a mathematical mistake could be treated as a preferred response if the teacher accepts it without hesitation, or marking his response in some way. Thus, when teachers use mistakes as teaching points, the occurrence of a particular mistake might be the preferred response. Equally a mathematically correct and appropriate response could be dispreferred if the turn that follows treats it as such. In the data from the study used in this paper, there is an example where the teacher has asked for the mean, median and mode of a set of data and a student correctly gives the median

and the calculation made to find it, but the teacher treats it as dispreferred and continues to talk about the previous student's calculation of the mean.

A conversation analytic approach focuses on the contextual information that the participants themselves see as relevant. In the interactions presented here, the roles of teacher and student are oriented to in the interactions and the context of the mathematics classroom is clearly relevant. Other contextual information, such as details of the sample such as the gender of the teacher or the nature of the school are not oriented to in the data and thus are not included in this paper except to say that all the classrooms were in England. The extracts used in this article are taken from a study of seventeen mathematics lessons involving four teachers from four different schools and students aged between 12 and 14 years. The lessons were video recorded and are naturally occurring. These recordings were then transcribed using the Jefferson transcription system (2004), but for ease of reading only some of the details of this transcription are included in this paper. This article focuses only on the structure of repair of students' turns that contain a source of trouble that relates to the mathematics.

HOW MISTAKES ARE HANDLED IN WHOLE-CLASS INTERACTIONS:

When students give a preferred response, the teacher often positively evaluates this response immediately and without any markers or hesitations, using terms such as 'good', 'yes', 'ok' and 'that's right'. In the two examples that follow, the students' responses are correct responses and are treated as preferred by the teacher. The example below is taken from the third lesson recorded with Edward's class.

- 1 Kieren: it could be either because like th- the chance is even.
- 2 Edward: okay good. ...

Edward lesson 3.

Teachers also often repeat the preferred response, which can occur with or without a positive evaluation:

- 3 Richard: ... ok so um you said that micro means what?
- 4 Sasha: um millionth
- 5 Richard: a millionth very good. ...

Richard lesson 1.

However, when the students' response contains a mathematical mistake, the teacher tends to avoid direct and explicit negative evaluation. It is very rare to see an immediate 'no' to a student's response. Teachers generally use a wide variety of methods to avoid an unmitigated explicit negative evaluation, they are "doing interactional work specifically in order to avoid using unmitigated negative evaluation" (Seedhouse, 2001, p. 355). In other words, there is a dispreference for direct and explicit negative evaluations of students' mistakes.

Bald negative evaluations

In this study, there were only two examples where a mathematical mistake was treated as a preferred response in the turn that follows. These both occur in Tim's lessons:

- 21 Tim: ... if I did that in one operation, if I did that in one swift move, what am I actually doing
- 22 Nic: dividing by five
- 23 Tim: no

Tim lesson 4.

In the situation above, Tim has asked what dividing by 3 and then dividing by 2 would be if you did it as one operation. The task that the students have been working for the remainder of the interaction focuses on limits of sequences, and in this case what happens if you continue to divide by 3 and then divide by 2. The mathematics in this exchange was not central to the task that the students have been working on for the remainder of the interaction, which focuses on limits of sequences. The other occurrence is during an interaction about the probability of picking a particular cup out of a row of ten cups and Tim asks questions about probabilities related to the rolling of two dice. In neither of these exchanges, when incorrect answers resulted in unmarked negative evaluations in the teacher's responses, were the questions directly related to the overarching task. In other words, the mistakes made were not directly relevant to the learning objectives of the tasks within which they occurred.

In general, teachers use a wide variety of interactional strategies to avoid bald negative evaluations of students' turns. These strategies that teachers use to avoid negatively evaluating a student's mathematical mistake include:

Delaying or mitigating an evaluation

- 10 Sandy: it's got a plus sign, you've got to like (.) take it off, but if it's like a minus you like (.) add it on
- 11 Edward: (0.6) not quite, what is it about this that means that you have to take it away

Edward lesson 1.

In the extract from Edward's lesson there is a negative evaluations but it is delayed as it follows a pause of 0.6 seconds, and is not a bald 'no' but a mitigating 'not quite'. The initiation of repairs can take place over a series of turns, with the teacher offering multiple opportunities for a student to self-repair.

Initiating a repair

- 6 Tim: ... what fraction of that triangle have I actually shaded. Alex?
- 7 Alex: um a half.
- 8 Tim: have I shaded a half?
- 9 Alex: no

Tim lesson 1.

In this extract from Tim's lesson, Alex has given the answer of a half which is not the answer Tim is looking for and Tim initiates a repair by rephrasing Alex's response as a question and returning the turn to Alex. There is no explicit negative evaluation of Alex's response and Alex is given the opportunity to repair (or alter) his response. By initiating a repair of the student's turn no explicit evaluation of the turn is made but it does indicate that there is some form of trouble with the student's turn and it offers the student the opportunity to self-repair.

There are many different strategies a teacher could use to initiate a repair, including repeating the question, or repeating the students' response (part or whole) but phrasing it as a question as in the extract above. Each of these does not explicitly evaluate the student's turn and offers the student the opportunity to self-repair, treating the student's turn as dispreferred. Many of these strategies can also result in other-repairs, where another student or the teacher themselves provides the correct answer.

- 12 Drew: is the range a hundred and seven- seventeen
 13 Simon: range a hundred and seventeen. the range is the biggest number take away the smallest number. the biggest number is a hundred and twenty five, the smallest number is eight, a hundred and twenty five take away eight. Ashley.
 14 Ashley: no because the the range is going to be in days absent so it'll be eight

Simon lesson 1.

The teacher could also offer an explanation of why the student has made a mistake without explicitly stating that their response included a mistake.

- 15 Richard: ... what names would you give to these things that are in the squares. I'm looking for the technical term for them. Chris?
 16 Chris: formulas
 17 Richard: formulas, you could say. formula often has equals in it, doesn't it like the formula for speed equals distance divided by time...

Richard lesson 4.

In the extract from Richard's lesson, Richard accepts the response but explains why it is not the response he was looking for before repeating the question.

The teacher could also accept the response given by the student but in revoicing it (O'Connor & Michaels, 1993) supply the correct answer:

- 18 Simon: ... quarter of a hundred and nine?
 19 George: twenty seven. point
 20 Simon: twenty seven point two five. twenty seven point two five going across.
 ...

Simon lesson 4.

Questioning Strategies

Teachers have a wide variety of other strategies that they can use to handle mathematical mistakes whilst avoiding explicit negative evaluation. The teacher could, for example, begin a sequence of simpler questions that enable the students to be ‘led’ to the appropriate answer, a technique often referred to as ‘funneling’ (Wood, 1998). This does not mean to say that teachers do not negatively evaluate students’ responses, just that when they do they are usually delayed or mitigated in some way, indicating that they the previous turn was dispreferred. Direct, explicit and immediate negative evaluations are very rare.

THE ROLE OF MAKING MISTAKES IN LEARNING MATHEMATICS:

Mistakes and misconceptions have come to be seen as essential in the learning of mathematics. This is both from the perspective of the teacher and the learner. From the teacher’s perspective, they can be “a powerful tool to diagnose learning difficulties” (Borasi, 1987, p. 2) but can also give insight into how learners are thinking about the mathematics. This is particularly important where learners’ conceptions of mathematical ideas differ from those “generally accepted versions of the same ideas” (Sfard, 2008, p. 16).

It is through making mistakes or considering different conceptions that a great deal of mathematics has been developed (Tall, 1990). Burton’s (2004) description of professional mathematical behaviour includes making mistakes and using them to learn new things. Borasi (1987) offers examples of how mistakes and errors can be used within a mathematics lesson to initiate enquiry and enhance learning.

Traditionally mistakes and misconceptions were seen as something to avoid in the mathematics classroom, but Piaget’s influence and the influence of constructivist theories of learning began to challenge this and studies, such as those by Askew and Wiliam (1995) and Swan (2001) showed greater learning gains when mistakes and misconceptions were confronted and discussed than when they were avoided. From the perspective of the learner, making mistakes or confronting misconceptions and adapting understanding in light of these is fundamental to constructivist principals of learning.

Many authors emphasise the role of the classroom environment in the handling of students’ mistakes. The emphasis being placed on creating an environment where students feel safe to make errors and it is a classroom norm to discuss and explore errors (Schleppenbach, Flevares, Sims, & Perry, 2007). Several studies have introduced or developed rules for interaction to establish an environment where learners feel safe making mistakes and discussing them (Mercer & Sams, 2006; Ryan & Williams, 2001). However, it is important to note that student errors do not necessarily mean a lack of knowledge or understanding (Mehan, 1980).

O’Connor (2001) explores the decisions teachers need to make about whether they correct a mistake or not and raised some interesting questions about the role of the

purpose of the activity and the role of the mistake within the interaction. This article is not concerned with these conscious decisions that teachers must make but instead looks at how the interactional norms of conversation and classroom discourse may influence how students may interpret the teacher's actions, both when a mistake is corrected and when it is ignored.

The conflict

By treating mistakes as dispreferred responses to questions, teachers are interactionally telling students that making mistakes is embarrassing and face-threatening and to be avoided. There is a conflict between the pedagogical message that making mistakes is an essential part of learning mathematics and the interactional message that mistakes are to be avoided (Seedhouse, 2001).

“Teachers are avoiding direct and overt negative evaluation of learners’ ...errors with the best intentions in the world, namely to avoid embarrassing and demotivating them. However, in doing so, they are interactionally marking ... errors as embarrassing and problematic.” (Seedhouse, 2001, pp. 368-369)

So, whilst teachers are not explicitly telling students that making mistakes or errors is embarrassing and problematic, the way that they handle these in whole class interactions implicitly tells the students that they are. The very responses such as partial agreement or mitigation, that may be intended to allow incorrect answers to contribute to learning, are also the ones that give the interactional message that these errors are to be avoided.

Conclusion

The purpose of this paper was to describe the interactional structure of repair in mathematics classrooms when mathematical mistakes are made. This has revealed a conflict between the interactional messages which treat mistakes as something to be avoided and the pedagogical message that mistakes are an essential part of learning. Teachers use a wide range of interactional strategies to avoid baldly negatively evaluating a student's turn, treating mistakes as dispreferred responses, and hence a source of trouble. However, this paper does not suggest that teachers should baldly negatively evaluate students' mistakes more frequently. Further research is needed to explore the influence of varying these interactional and pedagogical messages may have on the learning of mathematics. Indeed, the implications of raising teachers' awareness of this conflict needs exploration. It may be that this conflict is part of the norms of classroom interaction in the same way that teachers asking questions to which they already know the answer to is. The influence this conflict has on student and teacher interactional behaviour still needs to be explored.

WRITER IDENTITY AS AN ANALYTICAL TOOL TO EXPLORE STUDENTS' MATHEMATICAL WRITING

Steffen M. Iversen

University of Southern Denmark, Denmark

Learning to communicate in, with and about mathematics is a key part of learning mathematics (Niss & Højgaard, 2011). Therefore, understanding how students' mathematical writing is shaped is important to mathematics education research. In this paper the notion of 'writer identity' (Burgess & Ivanič, 2010; Ivanič, 1998) is introduced and operationalised in relation to students' mathematical writing and through a case study it is illustrated how this analytic tool can facilitate valuable insights when exploring students' mathematical writing.

Keywords: Identity, mathematical writing, analytical tools.

INTRODUCTION

In recent years the notion of *identity* has received increased attention in the field of mathematics education research. Despite of this Steentoft and Valero conclude that “identity is still only emerging in mathematics education research and is far from explored in full.” (Steentoft & Valero, 2009, p. 76). As argued by Sfard and Prusak (2005) one of the key challenges in this endeavour is to provide operational definitions of the notion of identity itself.

How writers construct their identities in texts has been the focal point of several studies in the field of writing research. In fact in his overview of writing research Hyland (2009) notes this as one of the key issues to be addressed in writing research and point to the works of Ivanič (1998) as a major contribution in this context.

In this paper I will argue that Ivanič's notion of *writer identity* (Burgess & Ivanič, 2010; Ivanič, 1998) can in fact provide a useful way of operationalizing the notion of identity in relation to students' mathematical writing. In order to do so, I will initially introduce the notion of writer identity as outlined by Ivanič and elaborate on how this can be operationalised. Following this I will demonstrate the usefulness of these analytical tools by applying them to two different mathematical texts written by the same student. The center of attention will be how, and why, the student changes his way of representing himself as a writer of mathematical writing.

To sum up, the two research questions leading this paper will be: (1) *how can the notion of identity be operationalised in relation to students' mathematical writing, and (2) what kinds of insights can an identity perspective on students' mathematical writing provide?*¹

THEORETICAL FRAMEWORK – THE NOTION OF WRITER IDENTITY

Ivanič distinguishes between four interrelated aspects or meanings of *writer identity* and characterizes these as “ways of thinking of a person’s identity in the act of writing” (Ivanič, 1998, p. 23). As such the notion of writer identity is a *social* notion, which concerns the many ways in which writers position themselves through their use of semiotic resources.

Discoursal self. This aspect of writer identity is concerned with the impression that writers convey of themselves in a particular text. Writing mathematical texts is not just about getting the calculations right. A written text, mathematical or not, also leaves the reader with an impression of who the author is or perhaps wants to be. The discoursal self is constructed by the text characteristics of the particular text, but is closely related to the values, beliefs and power relations embedded in the discourses² that are present of the social context of the writers.

Authorial self or *self as author* as Ivanič prefers to call it, is the way writers appear as authors in particular texts. This involves in which ways, and to what extent, writers attribute the choice of content and form of the texts to themselves or to other authorities. Some writers of mathematics present the content of their writing as platonic truths while other writers present it as being the work of their own. As both the discoursal self and the authorial self are identities that are inscribed in particular texts they can both be analyzed using text analysis.

Autobiographical self. The third aspect focuses on the personal stories the writers bring with them to the act of writing. This involves norms, values and beliefs related to the writing of mathematical texts and as such this aspect will be shaped by the writers’ previous encounters with writing events that involved mathematics. Obviously this aspect of writer identity cannot be disclosed through analysis of students’ written texts alone, but can instead be further explored through interviews with the students.

Possibilities of selfhood. In any social context *possibilities of selfhood*, or *subject positions*, will be available to the writers in the act of writing. Students’ mathematical writing in most cases takes place in the institutional context of school and is as such embedded in the various possible discourses of school mathematics. These discourses in turn shape the possibilities of self-hood available to the writers. This aspect of writer identity can be explored through classroom observations, studies of institutional texts such as curricula and by interviewing both students and teachers.

METHODOLOGY

Underlying the notion of writer identity is an understanding of writing as a *social act*. This fundamental assumption has methodological consequences both on the level of research design and for the use of analytical tools. In both cases the goal is to minimize the gap between text and social context by using context sensitive approaches when exploring students’ mathematical writing. On the level of research

design Lillis (2008) argues that this can be done by adopting ethnography as a research methodology. The two texts analyzed below are drawn from a one year long ethnographic longitudinal study that explored how upper secondary school students develop writing competences in the subject of mathematics.

Analytical tools for text analysis

Understanding students' mathematical writing as a social act has in this case led to a text analysis based on *systemic functional linguistics* (e.g. Halliday, 1978). A significant contribution as to how such analytic tools can be applied to mathematical texts is developed by Burton and Morgan (2000), Morgan (1998, 2006) and O'Halloran (2005). As noted by Burton and Morgan (2000, p. 430):

Although sometimes seen to be peripheral to the main mathematical content natural language serves in the construction of the identities of the author and reader and of the epistemological and ontological assumptions underlying the writing.

Against this backdrop I will in this paper restrict the focus of the text analysis to the *mathematical language* of students' texts thus leaving out the *visual mediators* (Sfard, 2008) from the analysis although they too can contribute to identity construction in written mathematical texts.

Textual characteristics of the discoursal self

Characterizing writers' discoursal selves involves analyzing how the writers represent, or portrays, themselves in their mathematical texts. According to Hyland "[a]n example is the extent to which a writer takes on the practices of the community he or she is writing for, adopting its conventions to claim membership" (Hyland, 2009, p. 73).

An integral part of this would be to explore in what ways and to what extent writers make *use of mathematical vocabulary and conventional forms of mathematical language* (e.g. use of characteristic grammatical structures) (Morgan, 1998, p. 97), when we analyze how students try to claim membership to some sort of mathematical community in their texts. Another important aspect of how writers construct their discoursal self concerns their use of *personal pronouns* (Burton & Morgan, 2000; Rowland, 1999). Moreover, writers can direct the attention to themselves in their mathematical texts by *referring to their own actions and cognitive processes*. As with the use of the personal pronoun *I* this text feature can, I suggest, in a school setting be understood as students' way to accommodate to a demand of *showing their own understanding* of the mathematical issues or problems elaborated in the texts.

Textual characteristics of the authorial self

One way that writers can convey their authority is by using words or phrases that signal different kinds of *ownership*. As noted by Burton and Morgan (2000) this can be studied in mathematical texts by attending to the use of *modality*, which includes the use of *adverbs* (e.g. *almost, always, certainly, clearly, easily, nearly, potentially,*

possible), *adjectives* (e.g. ‘*the derivative is easily calculated in this case.*’) or *modal auxiliary adverbs* (e.g. *must, can, may, could*). Another, perhaps more subtle, way of expressing authority is by making it clear what is *not* in the particular text. Purposefully *omitting* more or less obvious parts of calculations or symbolic manipulations, and perhaps even underlining that this is the case, is a well known way of claiming authority in the field of mathematics. As the authorial self is closely connected to the writers’ willingness to get behind claims or arguments that are put forward in the text, again another way of signaling authority in a text can be to explicitly express different kind of *choices* that has been made by the author. This could, for example, include choices regarding the mathematical content or style of the text (Hyland, 2009).

THE CASE OF CHRISTOPHER

Christopher is a student at a Higher Technical School (htx), which is one of the four upper secondary school programs in Denmark (grade 11-13). A review of the mathematical texts Christopher has produced as a student at htx shows that he has gradually found a way to construct his identity as a writer of mathematics that is quite *stable* with regard to how he represents himself in his texts. The extract of text shown below in Figure 1 is chosen because it illustrates how he typically does this³.

The different assignments that Christopher works with during his time as a htx-student can roughly be divided into three categories: (1) *Home assignments* that typically consisted of a collection of separated word problems, (2) *Project assignments* that usually were constructed around one guiding problem, and (3) *Presentation assignments* that were tasks where the primary goal was to present some sort of mathematical topic or idea. The two text extracts below is taken from Christopher’s responses to a home assignment (Figure 1) and a presentation assignment (Figure 2) respectively. In both cases the text was produced at the end of the school year and had to be handed in to the teacher who evaluated it afterwards

In several interviews I talked to Christopher about his perception of the different kinds of assignments in order to get some insight in to his *autobiographical self*. Home assignments are for Christopher associated with *training* and *standardization* and he describes these as *controlled* by the teacher. Regarding project assignments the converse seems to be the case. Christopher characterizes these with expressions like *independence* and *a possibility of putting the mathematics into a larger perspective*. In both cases the relations between type of assignment and the associated discourse seems locked for Christopher. This might be an important part of the explanation as to why he had continuously constructed similar types of discourses and authorial selves in his mathematical texts in the last year of htx.

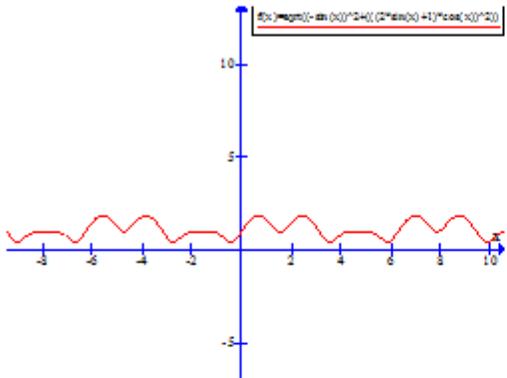

The *home assignment* consisted of a set of word problems or tasks, which had been posed at a written national examination in mathematics some years before. In the extract we see Christopher’s answer to one of the tasks. The purpose was to

determine the maximum speed of a moving particle whose motion is described by a vector-valued function. When we enter Christopher's text he has just found the derivative of the vector-valued function – the velocity vector. Notice how Christopher is clearly present as an acting agent in his own text.

1 Now where I have to find the maximum speed, I should start by calculating the length of my
 2 velocity vector, because the speed is defined like this.

3 $|v(t)| = \sqrt{x'(t)^2 + y'(t)^2} \Leftrightarrow |v(t)| = \sqrt{(-\sin(t))^2 + ((2 \cdot \sin(t) + 1) \cdot \cos(t))^2}$

4 By inserting it to Graph¹, I can get an overview of the various possible vertices.

5

6 This doesn't look all wrong, because I can imagine that the two big 'sharp' turns that appears in the
 7 first graph is what gives the two turns on this graph. The spaces between the two major vertices
 8 correspond to the major loop before the turn's returns on the original graph. By taking the
 9 derivative of the speed function I can find out where the vertices can be found.

10 $|v'(t)| = \frac{2 \cdot \cos(t) \cdot ((2 \cdot \sin(t) + 1) \cdot (\cos(t))^2 - 2 \cdot (\sin(t))^2 \cdot (\sin(t) + 1))}{\sqrt{(4 \cdot (\sin(t))^2 + 4 \cdot \sin(t) + 1) \cdot (\cos(t))^2 + (\sin(t))^2}}$

As this should be taking the derivative equal to zero, then the numerator has to be 0 before the whole fraction can and therefore I can just solve t in the numerator.

--

The equation I solve is this:

14 $2 \cdot \cos(t) \cdot ((2 \cdot \sin(t) + 1) \cdot (\cos(t))^2 - 2 \cdot (\sin(t))^2 \cdot (\sin(t) + 1)) = 0$

--

I get 5 solutions, which indicates for which value of t there is a turning point:

16 $t = 0,695 \quad t = \frac{\pi}{2} \quad t = 2,44 \quad t = \frac{3\pi}{2} \quad t = 5,88$

--

By evaluating my graph I found out that $t=0,695$ and $t=2,44$ both were vertices. Those values have the same kind of vertices, and therefore, I can just insert one of the values in my speed function:

19 $|v_{\max}(t)| = \sqrt{(-\sin(0,695))^2 + ((2 \cdot \sin(0,695) + 1) \cdot \cos(0,695))^2} = \underline{\underline{1,865}}$

Figure 1: Extract from Christopher's written answer to a home assignment

In the *presentation assignment* each of the students was assigned a specific mathematical topic, and their job was to present it in the best way possible to the other students. Christopher was assigned the topic *vector-valued functions*, and the text shown in Figure 2 is taken from a paragraph where he writes about *the straight*

line. As we enter Christopher's text he has just sketched a graph of $f(x)=\frac{1}{2}x+3$ in a coordinate system.

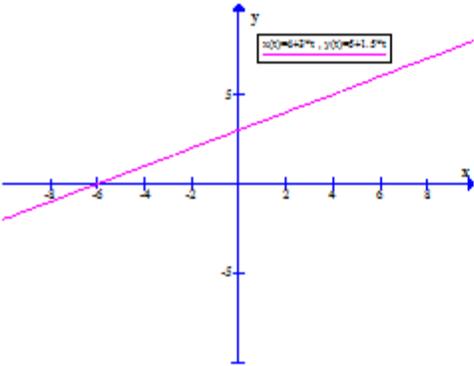

1 As an example, we look at the line drawn earlier on. The line is passing through two

2 points $A=(1;3,5)$ and $B=(4;5)$. These points are used to describe a direction vector:

3 $\vec{r} = \vec{OB} - \vec{OA} \Leftrightarrow \vec{r} = \begin{pmatrix} 4 \\ 5 \end{pmatrix} - \begin{pmatrix} 1 \\ 3,5 \end{pmatrix} = \begin{pmatrix} 3 \\ 1,5 \end{pmatrix}$

4 Using the point B as P_0 we can write the vector function:

5 $\vec{OP}(t) = \begin{pmatrix} x(t) \\ y(t) \end{pmatrix} = \begin{pmatrix} 4 \\ 5 \end{pmatrix} + \begin{pmatrix} 3 \\ 1,5 \end{pmatrix} \cdot t = \begin{pmatrix} 4+3t \\ 5+1,5t \end{pmatrix}$

6

7 If we want our parametric equation for the line to look like the original function for a

8 straight line $y=ax+b$, then we have to eliminate the parameter t .

9 Here, the prior example is used as a basis:

10 $f(t) = \begin{pmatrix} 4+3t \\ 5+1,5t \end{pmatrix}$

11 To eliminate t , we isolate t in either the x -part or the y -part:

12

13 $x = 4 + 3t \Leftrightarrow t = \frac{x-4}{3}$

14 This is then inserted to the y -part:

15 $y = 5 + 1,5t \Leftrightarrow y = 5 + 1,5 \cdot \left(\frac{x-4}{3}\right) = \underline{\underline{0,5x + 3}}$

Figure 2: Extract from Christopher's written answer to a presentation assignment

Construction of identities in the two texts

Due to limited space, the analysis will focus only on the most significant *differences* between Christopher's two texts. These are displayed in Table 1. Numbers in brackets refer to the line numbers in Figure 1 and 2 respectively.

Textual characteristics	Home assignment text (Figure 1)	Presentation assignment text (Figure 2)
<i>Use of personal pronouns</i>	Example – use of ‘I’ and ‘my’: ‘The equation I solve is this:’ (13) ‘... my velocity vector...’ (1-2)	Example – use of ‘we’ ‘As an example, we look at the line drawn earlier on.’ (1)
<i>Reference to own actions and cognitive processes</i>	Example – actions ‘By evaluating my graph I found out that $t=0,695$ and $t=2,44$ both where vertices’ (17) Example – cognitive processes ‘This doesn’t look all wrong, because I can imagine that...’ (6)	No explicit reference to own actions and/or cognitive processes
<i>Signals of authority</i>	Example – omitting and modality ‘... therefore I can just solve t in the numerator.’ (12)	No direct use of words and phrases that signals authority and/or use of modality
<i>Use of conventional forms of mathematical language</i>	Example – ‘spoken’ language: ‘As this should be taking the derivative equal to zero, then the numerator has to be 0 before the whole fraction can and therefore I can just solve t in the numerator.’ (11-12)	Example - ‘textbook’ language ‘If we want our parametric equation for the line to look like the original function for a straight line $y=ax+b$, then we have to eliminate the parameter t ’ (7-8)

Table 1: Summary of significant differences between the two texts

So what kind of identities does Christopher seem to construct in his two texts? In the first text the discorsal and authorial selves are characterized by an explicit presence of Christopher appearing as an active and visible agent in his own text. It is Christopher himself as a person who appears as the source of the mathematical actions performed and the new knowledge presented. Christopher seems to construct an identity as *a writer who wants to make clear to his reader: (1) how he himself as a person is able to solve the task he is given, and (2) what he thinks while doing this*. It is a very different discorsal and authorial self we encounter in Christopher’s second text. His own clear presence as a person in the text is gone, and instead an identity as *a neutral mathematical communicator* using the voice of a mathematical textbook is constructed.

One of the most remarkable differences in the way Christopher constructs his identity in the two texts is the alternating use of personal pronouns. In an interview at the end

of the school year I asked Christopher to comment on this difference between the two texts.

- 1 Christopher: I believe it is when you are thinking that you are writing some mathematics to somebody else who understands mathematics, then you are kind of saying ‘Now we do this’ or ... but sometimes I also say ‘I’ and I cannot really explain why. But in this case, I think I can ...
- 2 Interviewer: With these notes [*the presentation assignment text* [4]]?
- 3 Christopher: Yes, because now it’s not for one person, that I have to imagine that this is for, but generally for somebody who doesn’t understand it, and then it might sound a bit stupid to say: ‘I’m doing this’ because it’s not me, who does it. It’s ... generally you can do it like this. That’s also why I wrote ‘a vector-valued function is described’ instead of ‘I describe a vector-valued function’. It is, I guess, not me who has found it or ... and sometimes I also just think that ‘we’ is just ... It’s just a better way of writing it than using ‘I’. I think it sounds a little ... In the home assignments ... there I know that it’s me who makes it, I mean calculates this stuff. So there I think it fits better than as for example in this paper, even though it is me who has done it. But that’s not what’s important for the purpose of this text.

In the interview Christopher gives three different reasons for his replacement of the personal and for him habitual, *I* with the more neutral *we*.

Community with the reader: The use of *we* indicates that both writer and reader are part of the same community, and Christopher does in fact himself point to the fact that an equal relation with the reader (‘... *somebody else who understands mathematics...*’) give rise to the use of *we* in his texts. At the same time he is aware that in other texts, which are only read by his teacher, he most often uses *I* and not *we* in his wording. This seems to leave him doubtful (‘...*I cannot really explain why.*’).

The source of knowledge: The use of *we* instead of *I* contributes to a linguistic move of responsibility away from the writer as a person, and this seems crucial to Christopher in this case. He recognizes, of course, that he is the author of both texts, but underline that in the case of the text on vector-valued functions this is not essential in relation to the purpose of the text (‘...*it is me who has done it. But that’s not what’s important for the purpose of this text*’).

Sounding in the right way: The third reason is affective in nature. Christopher states that ‘*It’s just a better way of writing it than using ‘I.’*’ and continues ‘*I think it sounds a little ...*’ referring to the use of *I*. What is meant by ‘*just a better way*’ is of course not transparent, but it seems plausible that Christopher in this case, consciously or unconsciously, identifies with some sort of mathematical community, where the use of *we* would be regarded as more appropriate than the use of *I*.

CONCLUSIONS

In this paper one way of operationalizing the notion of identity in relation to students' mathematical writing has been presented. When producing mathematical texts students need to be able to decode and navigate in the purposes and possibilities of selfhood associated with writing in the mathematical classroom, and to construct identities that are perceived as *appropriate* in the given context. As pointed out by Morgan (2006, p. 239):

While establishing appropriate identities is of importance to participants in any situation, it is of critical importance to students at all levels whose oral and written productions are to be assessed.

Different types of writing assignments offer different possibilities of selfhood to the students in the mathematical classroom and Christopher in the presented case reacts by constructing different kinds of identities in his two texts. For him *purpose* of the writing assignment and *audience* of the text seems to have a specific influence on the way he constructs his identity as a mathematical writer.

In this way the case illustrates how varying the writing assignments of the mathematical classroom hold a potentially strong possibility of forming students' ability to develop their style of writing in mathematics. The analysis shows that an identity perspective on students' mathematical writing can provide valuable insights about, what students want to achieve with their writing, how they understand the role and function of writing in mathematics education, and how this understanding can shape the way they express themselves in their mathematical texts. Such insights can be an important step towards providing better opportunities for students to develop linguistic and communicative competences in mathematics.

NOTES

1. The study presented in this paper is part of the research project *Writing to learn, learning to write – Literacy and disciplinarity in Danish upper secondary education* supported by the Danish Agency for Science, Technology, and Innovation. For additional information please go to www.sdu.dk/fos.
2. Throughout the paper I use the notion of discourse as Gee (1996, p. 131) defines *Discourse* (with a capital D).
3. In both text extracts the original layout has been changed slightly. Christopher inserts a line break when he uses the sign for material equivalence \Leftrightarrow . For the sake of saving space I have removed these line breaks simply letting the calculations continue horizontally. I do not analyze the layout of Christopher's texts in this paper.
4. My insertion in square brackets.

DESIGN AND VALIDATION OF A TOOL FOR THE ANALYSIS OF WHOLE GROUP DISCUSSIONS IN THE MATHEMATICS CLASSROOM

Laura Morera, Núria Planas & Josep M. Fortuny

Universitat Autònoma de Barcelona, Spain

We present an analytical tool to characterise whole group discussions in mathematics classrooms. Following an exploratory study with 8th grade students, our interest lies in identifying and characterising interactional episodes and certain actions that support them. It has been confirmed (Morera & Fortuny, 2012) that the tool helps to detect what we call Mathematical Learning Opportunities –MLO. It shows not only what participants are doing in the course of their interaction, but also which the potential learning contents are. From a methodological point of view, the tool appears to operate in different didactical settings. We provide an example of its use in a teaching and learning setting of mathematical work mediated by a DGS instrument.

INTRODUCTION

Learning can be viewed as one of the ultimate reasons behind the actions of the students and the teacher in the mathematics classroom. In the context of whole group discussion, it is important to identify the various actions that have a role in framing the students' learning. Morera and Fortuny (2012) have argued that the identification of these actions and its development in whole group may serve to reach evidence of learning. While existing research has placed much emphasis on the presentation of pedagogies and practices that teachers can learn in order to improve the didactical effects of classroom conversations (Stein & Smith, 2011), developing systematic research on the potential of whole group discussions is a relatively new endeavour. Further investigation is needed to carry out an in-depth study of the nature of such discussions from an analytical perspective.

The goal of our research is to create and apply an analytical tool to identify and characterise: a) episodes of whole group discussion involving mathematical work, b) actions by the participants in these episodes, and c) opportunities in terms of potential contributions to the students' mathematical learning. This triple examination of episodes, actions and opportunities leads to a more global characterisation of whole group discussions in the mathematics classroom, under the assumption that whole group promotes episodes of mathematical learning. We are aware that the underlying notion of Mathematical Learning Opportunities –MLO– is itself critical in that one can imagine almost any situation to be a potential scenario for learning. What is scientifically useful for us is to view the sets of learning opportunities as an initial step toward the search for evidences of effective mathematical learning on the part of the students. This report provides an overview of the process that has been followed

to create the tool, including examples with classroom data, and a summary of the current refinement being developed around methodological considerations.

Context of the research

For the research, ten class sessions of an experienced grade 8 teacher were chosen. A sequence of five inquiry problems was designed to study isometries in a collaborative way using DGS. After the students had solved a problem in pairs, the teacher led a 50-minute whole group discussion. DGS was involved in the students working in pairs and the whole group interaction. During the whole group discussions, the teacher and the students were observed and video-taped with three video cameras and several additional voice recorders to capture all actions in detail. The attention was focused on the interactions between the participants and the software as well as on all different series of significant actions produced by both the teacher and the students.

After data collection, qualitative data analysis software was used to organise and codify the whole group videos. The three authors worked together on carrying out the codification. The codification of videos was primarily expected to provide a general picture of the interaction. Since a very early stage of the research, the purpose was to create a well-established analytical tool to better understand how interactions between actions, which are the main components of an episode, support MLO.

EPISODES, ACTIONS, AND MLOs

A theoretical approach has been developed to help determine the relationships between the *actions* of an *episode* that support *mathematical learning opportunities*. In this section we explore the nature of these key constructs, and see them as highly interrelated. On the one hand, when a MLO occurs in an episode, it is appropriate to ask what actions are behind the creation of such opportunity. On the other hand, when certain actions take place in an episode, it is also appropriate to look for the possibility of emerging MLOs. In the interactional and critical approaches to mathematical learning (Planas & Civil, 2010), one of the main focuses is to understand how sequences of actions are to be enacted in ways that promote a sort of correspondence between actions and learning. Although each action is singular in that it is mainly enacted by one participant, its implications do not refer to concrete individuals but rather involve the different participants having a role in the discussion.

Identifying and characterising episodes

It is part of the tradition of interactional theories to take episodes as organised units of data. When deciding what to take into account in the identification of classroom episodes, the organisation of units of data was framed by criteria of topic cohesion. In the context of a whole group discussion, we focus on those episodes most likely to influence the students' learning by promoting qualitative shifts in the mathematical thinking over the course of collective participation around a concrete curricular topic.

The qualitative shifts were considered in the sense developed by Saxe and colleagues (2009) when talking about “the travel of ideas” in the classroom.

To characterise the selected episodes of the whole group discussion orchestrated by the teacher, we take the instrumental and the discursive dimensions. Concerning the instrumental dimension, we draw on the types of instrumental orchestration by Drijvers and colleagues (2010): *Technical-demo*, which refers to the demonstration of artefact techniques by the teacher; *Explain-the-screen*, which refers to whole-class explanation by the teacher, guided by what happens on the computer screen; *Link-screen-board*, where the teacher emphasises the relationship between what happens in the technological environment and how this is represented in conventional mathematics of paper, book and blackboard; *Discuss the-screen*, which involves a whole-class discussion about what happens on the computer screen; *Spot-and-show*, where student reasoning is brought to the fore through the identification of interesting student work during preparation of the lesson, and its deliberate use in a classroom discussion, and *Sherpa-at-work*, where a so-called Sherpa-student uses the technology to present their work, or to carry out actions requested by the teacher. We adapt this typology to broadly classify the nature of the episodes according to the didactical performance of a discussion in which the artefact is not necessarily given by a DGS instrument. Our types are the following: *Explaining the artefact*, *Explaining through the artefact*, *Linking artefacts*, *Discussing the artefact*, *Discovering through the artefact*, and *Experiencing the instrument*. The first three types are dominated by the teacher’s actions, while the last three types are dominated by the students.

Concerning the discursive dimension in the characterisation of episodes, we draw on types that have been grounded throughout the evolution of the process of our research. After having examined all the mathematical concepts and procedures in all the selected episodes (see Morera, Fortuny & Planas, 2012, for details of the discursive dimension of a particular episode), an effort was made to search for common patterns that might help to understand a generic development of the episodes and the particularities that are shared by most of them. Although any episode can be distinguished from other episodes of the same lesson, the search for discursive commonalities among them has allowed determining a linear sequence of types for general orientation: *Situation of the problem*, *Presentation of one solution*, *Examination of resolution strategies*, *Examination of particular and/or extreme cases*, *Consideration of cases*, *Examination of different solutions*, *Connections*, and *Generalization*. This linear pattern refers to commonalities arisen from episodes with a specific kind of mathematical problems that foster both particularization and generalization. A different kind of problems would have probably led to a different discursive characterisation. Nevertheless, the sequence above is expected to represent whole group discussion around a set of mathematical tasks that goes beyond the concrete geometrical problems on isometries in our study. As it will be shown later in this report, the characterisation of an episode by means of a series of discursive and

instrumental types gives a complex picture of the interaction among participants, along with the contents and the direction of the interaction.

Identifying and characterising actions from the episodes

Episodes have been taken to be instrumental and discursive units of data. But if we go deeper inside their structure, we need to add a complementary characterisation based on the actions that constitute the episodes. In summary, we have first developed a major characterisation of episodes by means of instrumental and discursive types, and then have looked at them in terms of the actions that frame the two types.

To search for significant actions that include the participants' interventions and the instrumented acts related to the use of a particular artefact, we draw on the mediational approach to the teaching and learning of mathematics by Mariotti (2012). The emphasis on the relationships between humans and artefacts was initially fostered by our use of DGS environments, but has now turned to be generalised to any context of teaching and learning. We agree that knowledge is socially constructed by subjects involving the media because the participants collaborate to re-organise thinking with a different role than that assumed by written or oral language. The relation between different significant actions in an episode may provide opportunities to greatly enhance students' learning. Thus, we classify the significant actions within episodes as follows: Students' actions considered as *Thinking-Math Interventions*; Teacher's actions, considered as *Didactical Interventions*; and *Instrumented Actions* performed by the participants and centred on their use of artefacts. While the Thinking-Math and the Didactical Interventions are rather located in the discursive dimension, the Instrumented Actions are better thought of as related to the instrumental dimension. The relationship between the instrumental types (from the major characterisation of episodes) and the Instrumented Actions is highly complex and needs to be explored through the representation of the analytical tool. Similarly, the relationship between the discursive types (from the major characterisation of episodes) and the Thinking-Math and Didactical Interventions are also part of what is expected to be illustrated through the representation of the analytical tool.

Identifying and characterising MLOs

The identification and characterisation of episodes and actions is followed by the identification and characterisation of learning opportunities. We assume that the teaching and learning of mathematics take place in settings in which an important variation in the amount of MLOs exists. Moreover, we assume that such variation has an influence on the achievement of individual students depending on the quantity of MLOs in the specific settings of mathematical practice, together with the social conditions that qualitatively mediate such quantity. By either promoting or reducing the amount of MLOs, a change is made in the students' actual learning experiences. This is part of our argument for organising the search for mathematical learning in relation to the search for learning opportunities.

To make the notion of MLO operational, we take it on the form of opportunities for participation in a classroom discourse in which certain actions are oriented toward the discussion of specific *Mathematical Contents*, *Thinking Strategies*, and/or *Self-Regulating Activities*. In our study, actions by individuals are interpreted as potential contributors to the mathematical learning in groups. Through the three types of actions around ‘contents’, ‘strategies’ and ‘activities’, students develop their knowledge in interaction with other participants and build concrete relationships that help the classroom discussion to focus on the mathematics. Consequently, we see learning as a qualitative change in the contents, strategies and activities developed by a student (i.e. a learner) to become or keep being a participant of a community that has its own institutionalized repertoire, like it is the case with the mathematics classroom.

We structure the analysis of opportunities by establishing these three types that, in turn, may respectively favour conceptual (e.g., the notion of homothety), procedural (e.g., the practice of conjecturing) and regulative (e.g., the norm of justifying) mathematical learning. The MLOs of an episode are also more broadly characterised through the types of actions that frame opportunities. This complementary characterisation is helpful in that it relates, for instance, the Thinking Strategy that is to be learnt with the students’ and the teacher’s actions that are enhancing the consideration of that particular strategy. Furthermore, two MLOs that are equally characterised as Mathematical Content and have the same conceptual content of reference can be distinguished by means of the complementary characterisation in terms of the actions in the episode that frame each MLO. The understanding of a MLO depends on both the contents for potential learning and the actions that contribute to making these contents emerge. On the other hand, the relationships between the MLOs and the actions in an episode point to the impact of the whole group dynamics on the students’ learning.

THE RESULTING ANALYTICAL TOOL

The resulting analytical tool that has been created organises the characterisation of the whole group discussion throughout the characterisation of episodes, actions and MLOs. A complex representation of the whole group interaction is developed to inform about the richness of the discussion in terms of the amount of diverse MLOs. In this section, we explain the tool and then exemplify its effectiveness.

The representation of the episodes of a whole group discussion

For a concrete whole group discussion and as it has been argued earlier, the nature of the episodes is characterised through the instrumental and the discursive dimensions. Figure 1 illustrates the structure of the whole group discussion exemplified in this report. We claim that all the episodes identified in a whole group discussion can be represented in a two-dimensional matrix that suggests a coordinate system. Each episode is located in the system with two coordinates that determine its position, but the position is not uniquely determined as more than one episode may own the same

two coordinates. The use of this representation allows whole group discussion to be interpreted in terms of a sequence of episodes with changing particularities concerning the use of artefacts and the interaction with the mathematical task.

Once the episodes have been defined and the whole group discussion has been structured as a sequence of characterised episodes, an in-depth study of the actions involved in each episode is required.

Whole-group discussion (Problem 3)	Situation of the problem	Presentation of one solution	Examination of resolution strategies	Examination and/or extreme cases	Consideration of cases	Examination of different solutions	Connections	Generalization	(Discursive types)
Explaining the artifact									
Explaining through the artifact									(e ₁₁)

Figure 1: Representation of the episodes (e_i) involved in a whole group discussion
(Subscript *i* helps to follow the episodes chronologically)

The representation of the actions within each episode

The actions involved in the episodes are defined only by one element. As presented in the theoretical framework, the nature of this element differs depending on the agent (i.e. students' actions considered as Thinking-Math Interventions –TMI; teacher's actions considered as Didactical Interventions –DI; and Instrumented Actions –IA– performed by the participants and centred on the uses of particular artefacts). When an action has been characterised by considering the agent, it is codified to describe its nature in more detail. Apart from the chronological succession of actions, the relationships between them also have to be taken into account. Thus, we add oriented segments to connect the actions that are influenced by others. Finally, a structure is created to summarise all this information: a) the nature of all actions, b) the participants who are performing each action, c) the time sequence when the actions occur, and d) the oriented segments that relate the different actions (Figure 2).

We exemplify the use of the tool in the characterisation of the actions of one of the episodes in Figure 1. The episode comes from the 50-minute whole group discussion around the third problem of the sequence. The problem asks to find the centre of a rotation mapping two line segments given in the plane. We present the analysis of the first episode identified in the discussion. The episode presented (e₁) is characterised as “Experiencing the instrument”. Two students are using the DGS technology to present their work and to carry out actions requested by the teacher. In the transcription, we can observe the participants involved and the different nature of their actions. Each action is linked to one of the three types presented above.

Student 1: We decided to do a perpendicular bisector between a point and its homologous. Then we tried this intersection and we realised that it coincided and that it was the right rotation centre.

TMI: To explain a procedure to reach a solution

Student 2: [While Student 1 explains their solution, Student 2 constructs the situation with DGS]

IA: To complete an explanation with visual construction

Teacher: Now that you know that this point is right, could you argue why?

DI: To ask for a mathematical argument

Student 2: If two points, when we rotate a piece, coincide, it means that they are at the same distance from that point. So if they are at the same distance, for example, the perpendicular bisector is the locus point of all equidistant points between the two original ones.

TMI: To elaborate on a deductive justification

Teacher: The locus.

DI: To reformulate technical vocabulary

Student 2: Ah, yes! The locus.

TMI: To correct technical vocabulary

Student 2: [While Student 2 expresses the justification, he uses visual DGS figures that are on the screen for his explanation]

IA: To draw on visual DGS figures

After having identified the types of actions involved in the episode, the situation is represented in a visual diagram that incorporates preliminary oriented segments (Figure 2). It is particularly important to have these segments triangulated.

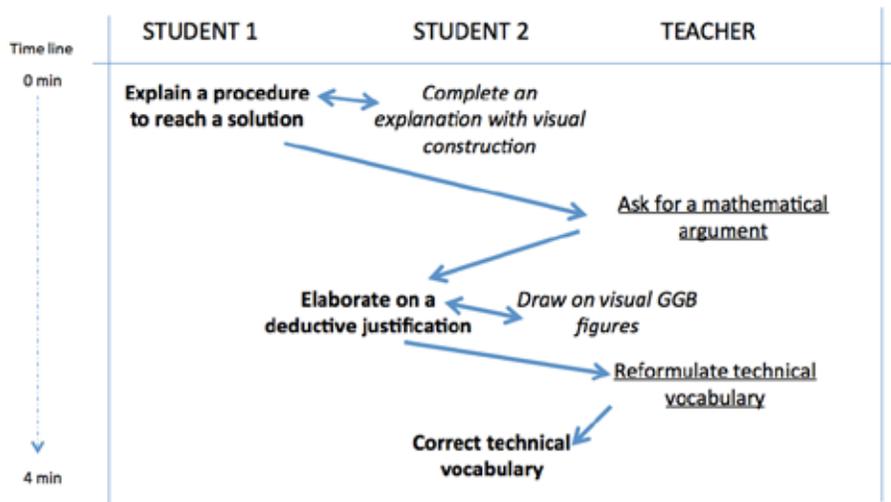

Figure 2: Visual representation of episode 1 (e_1)

The participants involved in this four-minute episode are two students and the teacher. If we focus on the nature of the actions, the students' Thinking-Math Interventions (bold) are central. We also observe that the Didactical Interventions (cursive) by the teacher are equally important. In his first intervention, he asks for an argument and in the second one, he makes a vocabulary correction of the expression "locus". The students' use of the software is crucial too. In the transcription, we see that they first use the software to make a construction and then, point to the screen and show the completed construction, which are considered Instrumented Actions (underline).

The representation of the MLOs within each episode

The final use of the analytical tool is to identify rich situations that can influence the learning process in a middle-term perspective. In the selected episode, three situations that can enhance the students' mathematical learning are interpreted in terms of MLOs. The first two rich situations are derived from relationships between Thinking-Math and Didactical Interventions, and the third rich situation is derived from relationships between Thinking-Math and Instrumented Actions. Following the characterisation of MLOs in three possible types, for this episode we find a dominance of Self-Regulating Activities. The contents of the interaction suggest the type of learning involved in the regulation of the task performance in the mathematics classroom. The following three MLOs are not based, for instance, on the mathematically correct performance of explanations, and justifications, but rather on the production of consciousness around the importance of such practices in the context of school mathematics.

- *MLO₁ –Importance of explaining through communicative skills and technology*

The fact that the students use software every time they want to explain or show something to the class, as occurs twice in this episode, is a significant relationship between the Thinking-Maths Intervention and the Instrumented Actions around the uses of DGS. The students complement their explanations by drawing on visual DGS figures: Student 1 explains the procedure to reach the solution and Student 2 develops a deductive justification. We consider that this situation gives importance to the dual explanation through a combination of communicative and technological skills. In further research, we will have to assess the possibility of being influenced by this episode when a student later uses the DGS to complement a written or oral solution.

- *MLO₂ –Importance of reasoning and justifying*

The fact that the students are asked for a mathematical argument after the presentation of incomplete solutions is illustrated in this episode by Student 1, who points out the importance of arguing the solutions for any mathematical problem. Moreover, in this situation, the correct justification is given by Student 2. This action also enhances the potential for learning because it provides specific knowledge (the correct argumentation) that may influence the understanding by other participants that have listened to the contribution made public by Student 2.

- *MLO₃ –Importance of correctly using the mathematical language*

The fact that the teacher corrects the mathematical expression “locus point” after its inappropriate use by Student 2 during his argumentation creates a rich situation in which the importance of using correct vocabulary is modelled. Student 2 reacts to the teacher’s intervention by correcting his expression and showing a more accurate use of the mathematical language. Thus the positive influence of the intervention is evident, and we can suggest that more students may be positively influenced by this situation.

In this episode we have identified three potentially rich situations that can be seen as MLOs and can enhance the mathematical progress of the students. With this example, we show that analysing the episodes with our tool provides an overall view of how the actions of an episode interact. This overview facilitates the detection of potential situations emerging as a convergence of different agents involved in the episode.

DISCUSSION

For the investigation of whole group interaction in the mathematics classroom, systematic methods are needed. We have presented an analytical tool to facilitate this investigation. We have summarised the design and validation of the tool, whose main objective is to identify rich situations that may enhance the students’ mathematical learning during whole group discussions. Its effectiveness has been illustrated by applying it to data from a transcript. The tool analyses whole group discussions from multiple perspectives. On the one hand, the framework of the instrumental orchestration by Drijvers and colleagues (2010) provides an episode-structure of the discussions. On the other, the findings about the actions involved in the episodes further support the humans-with-media theoretical approach that considers the subject and the tool involved in a mathematical activity (Mariotti, 2012). These results are consistent with our assumption of students’ progress being not only caused by verbal interactions, but also by artefact manipulations and nonverbal actions.

We are concerned with the problem of applying the tool to any setting of teaching and learning mathematics. The applicability of the tool can be expected to be improved by reconstructing some of the types for the instrumental and the discursive dimensions from a more global perspective. Nevertheless, it is not easy to broaden the definitions of these dimensions to include situations in which the artefacts are less visible and the tasks are less argumentative. At this moment, therefore, the tool still has limitations that constrain its generalisation. It has emerged from the analysis of discussions with particular teacher, students and tasks. Despite these limitations and others that may appear, we conjecture that the tool could be applicable, after minor adaptation, outside the scope of this study with a design experiment involving other contents and technical environments. It would be worthwhile to explore the effectiveness of the tool in various contexts such as discussions involving different teachers and students, other kinds of problems, and particularly other kinds of artefacts. Further research will help to refine the tool and carry out a careful analysis

of its potential and reliability to explore whole group discussions in the mathematics classroom.

READING STORIES TO WORK ON PROBLEM SOLVING SKILLS

Marianne Moulin, Virginie Deloustal-Jorrand, & Eric Triquet
University Claude Bernard Lyon 1, France

As part of a research on mediation through stories in the mathematics class, we present a didactic engineering (Artigue, 1988) built on two storybooks about problem solving. To characterise proper reading and understanding of mathematics problems, we define a reading-contract of the problem instructions, based on Brousseau's didactic contract (1998) and Eco's fictional reading contract (1994). We assume that the exploration of plots and alternative worlds in stories about problem solving, leads children to develop problem solving skills. Our study is backed by an experiment in a fifth grade class of a primary school. The storybook approach points out benefits of mediation through stories in problem solving.

INTRODUCTION

This work is part of a research exploring science's mediation through stories led by a multidisciplinary team from the S2HEP Laboratory (Sciences & Société: Histoire, Épistémologie et Pratiques). Based upon the heuristic power of stories (Bruner, 2003), this research points out some benefits of studying stories in experimental science classes. Following our results, we aim to extend mediation through stories to mathematics. In the context of the doctoral work of the first author, we examine problem solving in two complementary ways. The first one involves story-reading and the second one story-writing. With this guideline, we try to open a new field in the French Mathematics Didactics.

The main goal of this paper is to disclose benefits of mediation through story-reading in problem solving, especially on problem instruction understanding skills such as the selection of data. We focus here on a didactic engineering (Artigue, 1988), designed for 10 to 11 year-old children (primary school), involving the study of two French storybooks. We assume that the study of storybooks allows children to develop a proper reading and understanding of mathematic problems. More generally, we assume that stories have a heuristic potential that we can rely on to make children work on their problem solving skills (both understanding and solving).

We first present educational elements, with the analysis of curricula and mathematics textbooks, to frame our work. We then share items of our understanding of problem solving and mediation through stories. We introduce the engineering with the study of the storybooks. Finally, we highlight representative exchanges that occurred in the classroom and extracts by the children to expose some of the main results.

EDUCATIONAL ELEMENTS AND OBJECTIVES

Various curricula interpret problem solving as a key activity of school mathematics. It aims at improving reasoning and logical skills to bring meaning to mathematical objects. The French curriculum for primary school insists on the fact that problem-solving may “increase pupils’ knowledge, reinforce sense’s control and develop rigour and interest in reasoning” (Bulletin Officiel, 2008, p. 23). Indeed, problem solving implies devising a plan based on mathematical reasoning. Referring to Polya’s (1945) four-phase model of problem solving, the first step is to understand the problem. We focus on this initial stage and try to figure out what a proper reading and understanding of the instructions for a mathematics problem must be. We consider instructions like specific texts because they are academic texts written as short stories. Following Jacobi (1987), they require specific techniques to be read and understood.

Having in mind Brousseau’s didactic contract (1998), we question the existence of a specific (implicit or explicit) contract for reading and understanding problem instructions. We have analysed some French mathematics textbooks in order to see how school problem narratives are drawn up and how problem reading and understanding are taught. Using linguistic tools (Larivaille, 1974; Reuter, 2009), we have disclosed some limits in problem narrative structures. We have pointed out a lack of complexity in the narrative backing the problem. Even if they look like short stories, school problems are missing the main characteristic of a story: the disrupting factor. There is only one question to ask and only one way to solve the problem. The path through problem solving is mapped out (Moulin, Triquet, Deloustal-Jorrand, & Bruguière, 2012). Consequently there is no need for pupils to build mathematical reasoning. They can rely on automatic procedures without reading the instructions. Figure 1 illustrates two examples of stereotypical problems.

<p>During two night walks, a bunny brings 57 carrots back home. During the second night, he brings 31 carrots back. How many carrots did he bring back on the first night?</p>	<p>To help his friend, a squirrel took 17 hazelnuts from his supplies. He said: “I still have 41 left.” How many hazelnuts did he have in his supplies?</p>
--	---

Figure 1. Examples of stereotypical problems

In the exemplified problems above, numbers are in the right order to answer the questions: 57 minus 31, and 17 plus 41. When you are expected to do a subtraction the first number is bigger than the second one, and when you need to do an addition it is the opposite. Many problems are built using this structure. We can guess that this choice is made to help children to solve problems.

But this kind of structures allows children to go on with an “incidental solving” and prevent them from working on reading and understanding skills. Children need to practice those skills to be able to solve mathematics problems with a plan based on reasoning. They need to embed what we call proper reading and understanding.

Castellani (1995) says that good command of disciplinary support, as problem narratives, is crucial to acquire knowledge of the discipline. Since instructions are built as stories, we rely on Eco's fictional reading contract (1994) to build a "reading contract" for the problem instructions. We take the two following rules as the most important: 1) The world described in the instructions is not the real world but an idealized world to make calculations easier; 2) The instructions include what belongs to the story's context and what belongs to the data, so that a distinction is required.

We choose an approach based on storybooks in order to lead children to make these rules explicit. Stories have a heuristic potential, and relying on this characteristic, we assume that studying a story about problem solving can lead children to question their conceptions of such activity. One experimental assumption in our work is that the confrontation between the solving activity and the students' behaviour while doing it might create debates about problem solving in the class. Storybook reading and studying is not a usual approach but it fits in the French curricula: "They [children] have to interpret and build an argument in the literary field but also in the scientific field. They have to train in order to mobilize knowledge in complex situations to question, to search and to reason" (Bulletin Officiel, 2008, p. 10).

In brief, our main goal is to study characteristics of mediation through storybooks reading. So, we need to identify stories with a mathematics teaching potential (around problem solving activity), and we have to determine didactical and epistemological conditions for mediation through stories in the mathematics class.

THEORETICAL FRAMEWORK

Our choice to link literary work with mathematical work is mostly due to the fact that the French curriculum recommends language work in each discipline. Furthermore, mediation through stories produced interesting results in the experiment that we carried out in the science class. Bruguière and Herault (2007) show how pupils' first conceptions can be questioned through stories and Triquet (2007) points out that a narrative plot can be a powerful tool for knowledge building.

When referring to the stories' characteristics and educational potential, Bruner (1996/2008, 2003) claims that stories bring us to question behaviours. Additionally, Tauveron (2003) claims that understanding implicit data in a story involves cognitive and cultural work. A common point linking these works is that fictional stories suggest alternative worlds. Those worlds can lead the reader to have some "thought experiment" and question her/his own relation to objects (Triquet & Bruguière, 2010). In a mathematical story context, the "thought experiment" and the questioning must be about mathematical objects. Relying on this context, we made the following two assumptions: 1) If alternative worlds and implicit data of the story are linked with mathematics and problem solving activity, the reader has to begin a mathematical work to understand these elements; 2) Studying storybooks with a mathematical context and a plot about problem solving activity leads children to question and then to improve their problem solving skills.

To test the two assumptions above, we build an experiment based on the “didactical engineering” methodology (Artigue, 1988). This kind of methodology relies on an internal validation. As we previously did, it is necessary to establish some hypotheses. Then a plan is to be built to test each of them. The validation is made by the confrontation between an *a priori* analysis of the plan (with the corresponding epistemological, didactic and/or cognitive study of tasks) and an *a posteriori* analysis (with the corresponding lesson observations and children productions).

We also rely on Brousseau’s Theory of Didactical Situations (1998) and especially on the concepts of environment, action phase, formulation phase and validation phase to build our engineering. For this particular work and hypotheses, our engineering consists in a plan of four sessions based upon two storybooks for children. We present the books in the next section. The two plots rely on mathematical problem solving and the characters’ ways to solve it have an interrogative potential.

DIDACTIC ENGINEERING

So far we have established the general hypothesis that story-reading can be a way to make children improve their problem solving skills. In order to test this hypothesis, we build a didactic engineering involving work on a tale named *Le Problème* (Aymé, 1944/2002) and a play also named *Le Problème* (Lamblin, 2000). Aymé’s *problème* is the following: “The woods of the town are 16 hectares. Knowing that each are is planted with 3 oaks, 2 beeches and 1 birch, how many trees are there in the woods of the town?” While Lamblin’s *problème* is the following: “My daddy buys a strawberry pie and cuts it in 4 slices. Knowing that the pie’s weight is 800g, how heavy is each slice?”

Storybooks’ presentation

We need storybooks with a heuristic potential around problem solving. As shown by their titles, both stories are built on mathematical problems in a classroom. Children characters have to solve a mathematical problem given by the teacher. This is a necessary characteristic about the plots. The two of them rely on the mix-up between reality (characters’ real world) and the mathematical world (the instructions). The characters merge some elements of the problem with their equivalents into reality and propose an unusual problem solving method. In Aymé’s tale, the characters go to a forest to count trees because their problem begins with “the woods of the town” and ends with “how many trees are there in the woods of the town?” In Lamblin’s play, the fact that the problem includes the words “my daddy” leads children to convert all elements in the instructions to make them identical to their reality.

The authors of the two stories used the possible mix-up between the sense and the signification of some words. This characteristic allows a work on the explanation of “games of language”, and this explanation can be in turn productive of knowledge (Durand-Guerrier, Hérault, & Tisseron, 2006). Because of this mix-up, characters make confusion between data and context elements in the instructions. Then rules of proper reading, as we defined them, are broken. In our engineering we want to make

children work on these ruptures. Some elements, linked to mathematics and problem solving, explaining these ruptures remain hidden in the stories. So relying on Tauveron (2003), we assume that working on this mix-up may bring children to improve their problem solving skills as we want them to.

Hypotheses, tasks, and some methods

We worked with a class of 28 10-11 year-old pupils during four sessions of 50 minutes each. The tasks (shown below in this section) were given on four different sheets (one per session). In this way we could examine the evolution of the children's answers through the study of the story plots. The analysis of the answers complemented by the audio recording of the four sessions allowed us to explore some relevant characteristics and to support our hypothesis about mediation through story-reading.

We lead children to study the characters' problem solving activity in two ways: in relation to the plot and also in relation to the problem instructions. So, we came up with two specific hypotheses for this engineering:

H1: Studying alternative worlds, linked to the mix up between the real and the mathematical world and working on implicit elements linked to the characters' reasoning, imply mathematical work about problem solving activity.

H2: Fiction and "language games" allow a questioning on the nature of the different words included in the instructions and the referential function of words in mathematical problem instructions.

By going deeper into the analysis of the plot, children might link their problem solving activity to the way used by the characters to work on mathematical problems.

We focused on two activities, each one linked to a rule of our "reading contract for word problem instructions" presented in our objectives about problem solving.

The first activity relies on the study of the disrupting factors which are the same in both stories: the mix-up between the real word and the mathematical word. In Aymé's tale it occurs when a character suggests going into the forest to count the trees. In Lamblin's play it happens when one child asks the teacher if the problem is about an arbitrary dad or about her/his own dad. We can assume that studying the characters' reasoning and results can bring children to build judgment about the links between real world and its modelling in mathematic problem instructions. We suggest one set of three tasks to enable debates in the classroom. Our hypothesis is that arguments will evolve with the analysis of the two stories. So, each debate is preceded by individual work with stories' comprehension and questions. In the following lines we present the main task preceding each debate and the main question.

First debate: What can you say about the characters' methodology to solve the problem? What can you say about their result? We wanted children to build judgment

about the result and the methodology engaged and then to be able to argue about criticisms that can be addressed to the characters.

Second debate: What is the characters' reasoning (which is implicit in the story and relies on the links between the real world and the mathematical world)? We want children to debate about the relevance of this reasoning.

Third debate: After reading Lamblin's play, what can you say about the character's attitude (which is to make problem's instruction look like her/his real world)?

For the second rule of our "reading contract", we wanted children to work on the referential function of the words in the instructions. For them the goal of this set of activities is to identify data and context elements in some instructions and to learn their function in a problem solving activity. We assume that studying the characters' points of view, which rely on opposite attitudes toward the words included in the instruction, can bring children to understand these two notions. To test this hypothesis, we ask children to select data and context elements in Aymé's problem at three different times and we study the evolution of their selection.

Lesson 1 with Aymé's tale: After reading Aymé's tale, the children have to select in the instruction what they would use to solve the problem. Then, after solving it they have to select the elements they have actually used.

Lesson 2 with Lamblin's play: The pupils have to study how the characters modify the instructions and what are the consequences of those changes in the problem solving. Each change in the instruction brings a new word problem. We ask the pupils to solve all problems to see evolution (when changes concern data the solving is altered whereas when it is about context elements the solving is identical). The aim for them is to identify different natures of words: data and context elements. Then, we ask them to determine in Aymé's instruction what belongs to data and what belongs to context.

Lesson 3: We ask children to rewrite the problem instruction to work on data selection and context elements.

RESULTS

In this section we highlight some results showing how mediation, through the two storybooks, operates in the class. As we said in the previous section, we focused our analysis on two sets of tasks, each about one of the hypotheses (H1 and H2).

About the first hypothesis implying alternative worlds (H1)

Our first hypothesis is about the links between the real and the mathematical world. In the two stories alternative ways of solving and reasoning are brought up. We assume that the confrontation between the characters' solving and the children's behaviour will create debates about problem solving in the class.

During the debate session, one of the topics discussed was about the difference between "real problem" (in a real situation), "realistic problem" (inspired by a real situation) and "fictive problem" (on fictional elements)". Children in the class

established a distinction among these three types. To go further with the first rule of our “reading contract”, concerning links between reality and mathematical world, we can also say that children reflect on how the real world is included in word problem instructions. Between the two first debates, pupils’ criticisms against the characters’ methodology evolved in an interesting way. They included modelling and mathematical characteristics in their arguments, as can be seen in Table 1.

Before the first debate	Before the second debate
<ul style="list-style-type: none"> - The result is wrong because they counted the real trees of the forest. - The result is right because they were careful when they counted and other characters found the same result. - The methodology is wrong because a problem is unreal. - The methodology is wrong because you have to do calculations in order to solve a problem. 	<ul style="list-style-type: none"> - The woods in the problem are not supposed to be realistic. By counting the real trees instead of doing a calculation, characters made a mistake. - A problem is not real (...) it is precise; in each part you know exactly how many trees there are. But in real forests there is not always the same amount of trees in each part. - The methodology is incorrect; there are too many places for mistakes because their forest is not the same as the one in the problem. They spend all day counting and doing calculation is faster.

Table 1. Evolution of pupil’s criticisms between the debates

The evolution is due to the study of the tale. Pupils criticized the modelling of the world into the mathematical world. They realized that problem instructions are not identical to reality: the mathematical world is idealized, and overall simplified. They were able to critically reflect on the other storybook, reinvesting knowledge about links between mathematics and reality in mathematics problems for the last session.

About the second hypothesis implying fiction and games of language (H2)

Concerning the second rule of our “reading contract”, which implies the characterization of data and context elements, we can say that the study of these two books made pupils understand these concepts.

During lesson 1, pupils were unable to make a selection of data in the instructions even after they solved the problem. 21 pupils (out of 26) were unable to distinguish between data and context in Aymé’s problem. During the engineering, the confrontation between the characters’ points of view and the study of the evolutions linked to the changes in Lamblin’s story, helped children to separate data from context. We translate underneath an exchange that happened during lesson 2:

Student: At the beginning they are complaining that ... on daddy is strawberry intolerant so they change it for apples.

(...) *Work about problem solving with apple instead of strawberry in the instructions.*

Tutor: Ok ...so, does it change something to solve the problem?

Class: No.

Tutor: Why? Why do we change?

Student 1: Taste! Flavour!

Student 2: Context!

Tutor: Yes, this is a context element. It's like the presentation of data.

Other exchanges involving the same knowledge occurred during that time. After this work (Lesson 2), almost all children were able to distinguish data from context in Aymé's problem (only six of them made a wrong selection). They also succeeded in rewriting the activity and made context and data changes as they were asked.

CONCLUSION AND PERSPECTIVES

The work conducted in class confirms our hypotheses. The study of the two storybooks helped children to establish some rules of proper reading of mathematics problem instructions. Their answers show that questioning the plot, understanding the stories' problematic and comparing the characters' points of views allow children to develop problem solving skills. As we assumed, mediation through stories reading seems to be efficient in the mathematic class.

We are also working on mediation through story writing. We assume that stages in reasoning-making can interact with stages in story-writing. We link the action time, the formulation time and the validation time described in Brousseau's Theory of Didactical Situations (1998) with story-writing seen as an action description (action and validation), or an action anticipation (formulation and validation).

Regarding Scardamalia and Bereiter (1987, 1998), we assume that building a story including mathematical elements will lead children to build a reasoning linked to this story. These authors point out that interaction between the rhetorical space (within which the story is built) and the problem space (within the field of mathematics) leads the writer to improve knowledge and skills by processes of knowledge transforming. We rely on this framework to carry on our work about mediation through stories.

CHOICE OF NOTATION IN THE PROCESS OF ABSTRACTION

Mona Nosrati

University of Cambridge, UK

This paper focuses on the notation invented and used by students in a study concerning the process of abstraction. Participants were asked to identify the symmetries of a square, and to further investigate the various properties of the group formed under composition of the identified elements. Particular attention will here be paid to the differences in approach by academic track and vocational track high-school students in embracing the task, a difference which appeared to stem largely from the creation and use of notation for representing the members of the group.

INTRODUCTION

The underlying methodology of the project has been grounded theory (Glaser & Strauss, 1967) which emphasizes the generation of theory from immersion in collected data. This process has so far resulted in 22 clinical interviews with high-school students (aged 16-19) in Oslo (Norway), with roughly half of the participants from each of the academic and vocational high-school tracks. Both paired and individual work has been considered, with three of the interviews for each track involving two students working together. *Task based clinical interviews* have been used for data collection, which involve intensive interactions with the individual participant, extended dialogues between interviewer and interviewee and careful observations of the interviewee's work with 'concrete' intellectual objects (Ginsburg, 1997).

As a whole, the study from which this paper derives is an exploration of post-compulsory students' strategies for investigating and organizing abstract mathematical structures when engaging with an unseen task. More specifically it is a consideration of Norwegian students' encounters with the symmetry group of a square. As such a number of issues and questions have emerged, however this paper will concentrate on the differences in invention and subsequent use of notation by the two groups of students. Some of these differences will be discussed in light of APOS theory - as a framework for abstraction, and Duval's analysis of problems of comprehension arising from semiotic representations (Duval, 2006). The former thus provides an outline of the stages involved in moving from the concrete to the abstract, whereas the latter explores potential barriers in the transition between these stages. This study suggests that considering these theories together in an interwoven manner can be a useful step towards understanding certain students' seeming difficulties with abstract mathematics.

THEORETICAL BACKGROUND

Piaget proposed the term 'reflective abstraction' to describe the construction of logico-mathematical structures by an individual during the course of cognitive development (Dubinsky, 1991). Reflective abstraction is characterised by the fact that

It does not proceed from a series of observations of contingent events or objects. Rather, it is a process of interiorizing our physical operations on objects. As we move sets of objects about ... we interiorize properties of mathematical operations rather than objects; we acquire implicit understanding of commutativity, associativity, and reversibility (Noddings, 1990, p.9).

This idea has featured prominently in Freudenthal's (1973) analysis of mathematical development, where he notes that "the activity of the lower level ... becomes an object of analysis on the higher level" (p.125). Other mathematics educators working in the Piagetian tradition have called this process 'entification' (Kaput, 1982), 'integration' (Steffe, Glasersfeld, Richards, & Cobb, 1983) or 'encapsulation' (Dubinsky, 1991). There are subtle variations within these definitions, but in essence they all describe "the process of forming a static, conceptual entity from a dynamic process" (Gray & Tall, 1994, p. 118). There is widespread recognition, both within cognitive psychology and mathematics education, of reflective abstraction as an essential focus for educators, a key to fostering understanding and development of intellectual thought (Simon, Tzur, Heinz, & Kinzel, 2004), and a crucial skill for a meaningful engagement with mathematics (Hazzan, 2005).

Much of the research on abstraction in mathematics has been carried out with a focus on young children, and the majority of Piaget's own work (on which much of the later research is based) was concentrated on the development of mathematical knowledge at the early ages (e.g. Piaget, Wedgwood & Blanchet, 1976; Piaget & Pomerans, 1978), rarely going beyond adolescence or basic mathematical structures. He did however suggest that the same ideas could be extended to apply for older subjects dealing with increasingly advanced mathematical concepts. This is the context most relevant to this study, and the chosen framework for analysis has therefore been 'APOS theory' (Asiala et al., 1996), which was specifically developed to address this less investigated avenue of abstraction in more advanced mathematical situations. APOS theory is based on Piaget's principle that an individual learns by applying certain mental mechanisms to build specific mental structures and subsequently uses these structures to deal with mathematical problem situations. APOS is an acronym for Actions, Processes, Objects and Schemas (Dubinsky & Moses, 2003, p. 403), and these can be described as follows:

- 1) A mathematical concept begins to be formed as one applies a transformation on objects to obtain other objects. A transformation is first conceived as an **action**, in that it requires specific instruction as well as the ability to perform each step of the transformation explicitly.
- 2) As an individual repeats and reflects on an action, it may be interiorized into a mental process. A **process** is a mental structure that performs the same operation as the action being interiorized, but wholly in the mind of the individual, thus enabling her or him to imagine performing the transformation without having to execute each step explicitly. Given a process structure, one can reverse it to obtain a new process or even coordinate two or more processes to form a new process via composition.

3) If one becomes aware of a process as a totality, realizes that transformations can act on that totality and can actually construct such transformations, then we say the individual has encapsulated the process into a cognitive **object**.

4) A mathematical topic often involves many actions, processes, and objects that need to be organized and linked into a coherent framework, which is called a **schema**.

As has been pointed out (Dubinsky & McDonald, 2002), these stages need not be linear or even exact descriptions of a learning process. However the theory as a whole provides a useful framework for analysis of qualitative data, and it is in this capacity that it has been and will continue to be used for the purposes of this study.

THE STUDY

Mathematical framework

The concepts that have served as a mathematical framework rest largely on group theory and will be introduced here in brief. Formally a mathematical group can be defined in the following way (Smith, 1998):

A set G equipped with a binary operation \cdot is called a group if all of the following axioms are satisfied:

- Closure: For every $a, b \in G$ their product $a \cdot b$ is in G .
- Associativity: For every $a, b, c \in G$ it follows that $(a \cdot b) \cdot c = a \cdot (b \cdot c)$.
- Identity: There is $e \in G$, such that $e \cdot a = a \cdot e = a$ whenever $a \in G$.
- Inverses: Given any $a \in G$, there is $b \in G$ such that $a \cdot b = e = b \cdot a$.

The group that has played a particularly central role in this study is the symmetry group of a square, often denoted D_4 , which is a member of the ‘dihedral groups’ (the groups of symmetries of a regular polygon). This group has been suitable for interview purposes for a number of reasons: It is unfamiliar to the students, and yet it involves a range of concepts that undoubtedly (implicitly or explicitly) form part of school mathematics, such as rotations, reflections, symmetry, identity and inverses, just to mention a few. Furthermore, the group has eight elements - a number large enough that it is not necessarily immediately obvious what these are, and yet small enough that within a reasonable time students can find these elements themselves by inspection, rather than being presented with them; the task is simultaneously attainable and challenging. Moreover, the group as a whole is not commutative. That is, $a \cdot b$ (a followed by b) is not *necessarily* the same as $b \cdot a$ (b followed by a) for two elements a and b in the group.

It should be emphasized that although group theory has been utilized as an underlying framework for the project, it has never been made explicit to the students. Rather it has provided points of reference along the way in the design of tasks and in the analysis of the data, much as APOS theory has been, and will continue to be, used as a supportive framework in the process of analysis.

The interview process

Interviews (lasting up to two hours including short breaks) were recorded on a laptop web-camera. The reason for this choice was that a laptop is such a familiar part of everyday life that it is far less obtrusive than a video camera being pointed at the participants. Moreover it is easy to carry around between interviews, and has left no improvement in quality of image or sound to be desired.

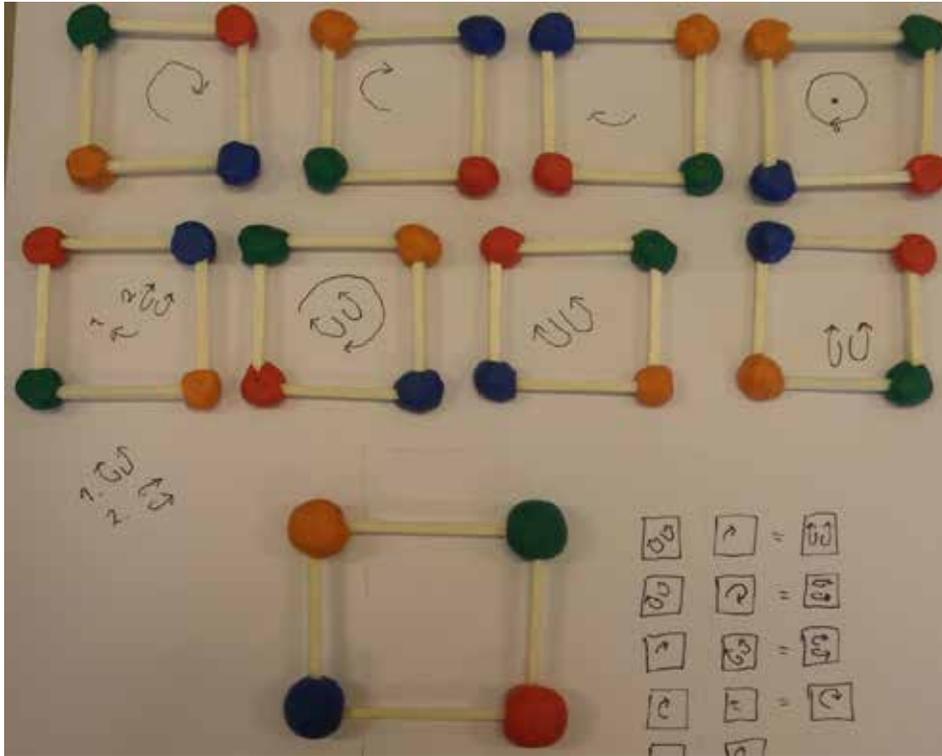

Figure 1

The interviewees had pen and paper available and were encouraged to think out loud and to write down their ideas. They were presented with a square with coloured corners (see figure 1), and were asked to ‘play’ with this figure under certain ‘rules’ which commanded firstly that it would have to end in the plane, and secondly that the symmetry of the figure had to be preserved. Each time a new move was performed, the students would record it by placing a smaller version of the square on the paper, showing the new position of the colours, and they would further describe, using notation of their choice, the motion that had been performed. The square was always returned to its original position before the next move, and participants were asked to find as many configurations as possible. When they were happy with the number of possibilities found, the students were asked to combine pairs of moves, writing down what they did as they went along, and to comment on the results. The relationships between the elements of this new ‘system’ were discussed, during which the students were encouraged to lead the conversation, and they were subsequently given the freedom to explore any aspect of the system that caught their attention. For the initial record kept by one of the interviewees, see Figure 1.

PRELIMINARY RESULTS

The students' initial engagements with the square were mostly at a concrete level, with attention paid to its physical appearance and the position of the colours. However, while identifying all the elements of the group was largely an action based endeavour, investigations became increasingly abstract and towards the end of their interviews many students were touching upon concepts such as inverses and identity elements, identifying subgroups and looking for overall behaviours of the system. For example, many participants established that D_4 as a whole is not commutative, and additionally tried to determine a pattern for this 'non-commutativity'. Several students considered questions such as: which elements commute? And perhaps more strikingly: When two elements fail to commute, what is the 'difference' between the outcomes? And, is this difference always the same for non-commuting elements? It transpired that this 'difference' is always one of 180 degrees. That is, if $a \cdot b = c$ and $b \cdot a = d$ (for distinct elements a, b, c, d in the group), then in order to get from c to d (or d to c), a rotation of 180 degrees is required, a result with which I was unfamiliar before the interviews. Indeed, while this and other student discoveries merit further elaboration, limitations of space prevent it. I mention them to illustrate clear shifts from physical actions and attributes towards abstract structures.

However before reaching this level of abstraction, participants had to choose some notation for the elements of D_4 that they identified, so that this notation could later be used when operating with the members of the group (i.e. when combining two elements as shown in Figure 1). It is this specific aspect of the investigations that will be presented here, and it was largely in this process that a marked difference could be perceived between the academic and vocational tracks.

Figures 2a and 2b show the notation chosen by an individually interviewed academic and vocational track student respectively.

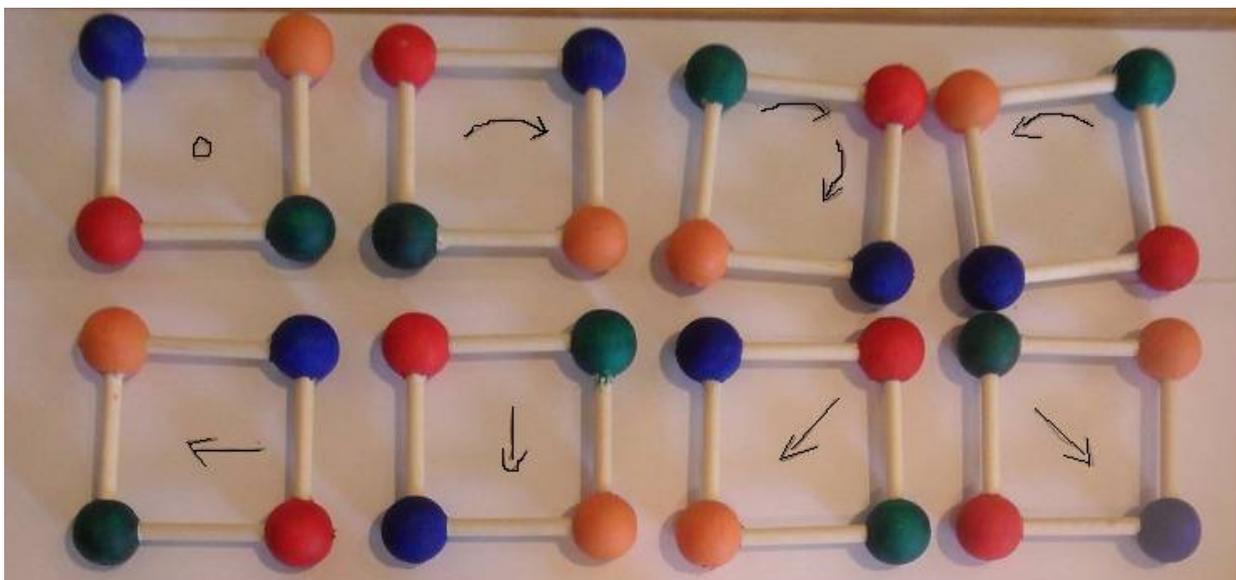

Figure 2a: Academic track student (individual interview)

you'd get it [asking Jonathan]? For me it would be to take the top right bit and pull it down to the left bottom bit...

Jonathan: what right and left though? ... I like using a, b, c, d and draw a picture of a square and show what goes where.

Alex: yeh... but what if you don't have a picture of the square...

After further elaborate negotiations and various drawings, their final result was that drawn in the third square from the left on the second row in Figure 3 (The writing translates to: 'swap places with each other').

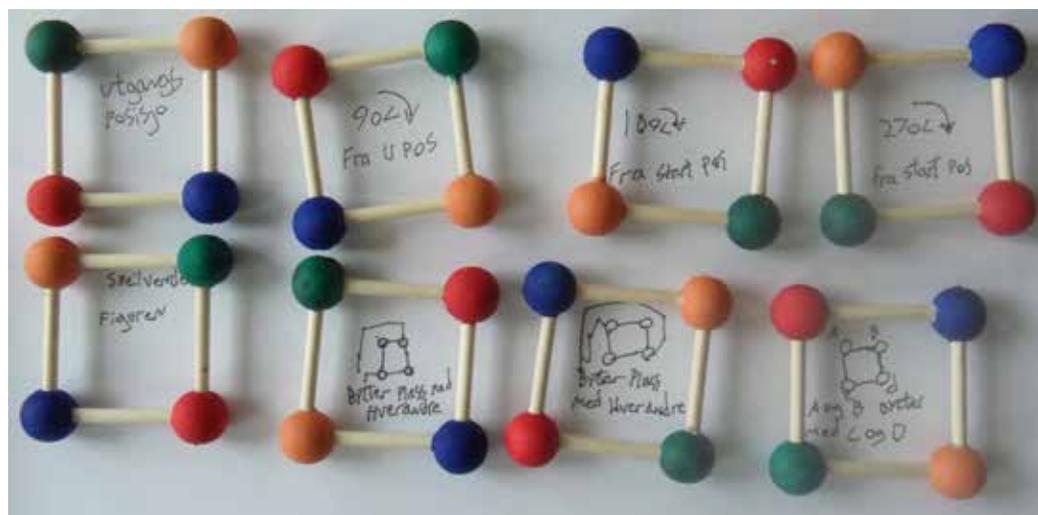

Figure 3

DISCUSSION

So what exactly are the differences between the chosen notations? Coherence and simplicity appear to be central issues. The academic track students tended to choose the same 'kind' of notation for the elements of D_4 (such as seen in Figure 2a). This gave them an overview of the number of elements; for instance, once they had drawn one diagonal arrow, they naturally realised that the other 'diagonal move' would also give a member of the group. Moreover these simple arrows, where they continued to use them, facilitated further exploration of the system, particularly when pairs of moves were combined. The vocational track notation tended to lack both coherence and simplicity. As shown in Figure 2b, there was no 'single kind' of notation, but a mixture of drawings and words, which often hindered the identification of all the elements. Moreover, as shown in Figure 3, many students insisted on keeping a small drawing of a square as part of each notation. This underpinned their lingering dependence on the physical attributes of the concrete artefact, and additionally made the subsequent exploration of the system slow and cumbersome to keep track of.

It should however be noted that problems of notation were not limited to the vocational track students. The academic track participants were all fairly confident and coherent in the *invention* of notation; however it is important to distinguish between mere invention and invention followed by appropriate application. To illustrate this, the work in Figure 4 might be considered.

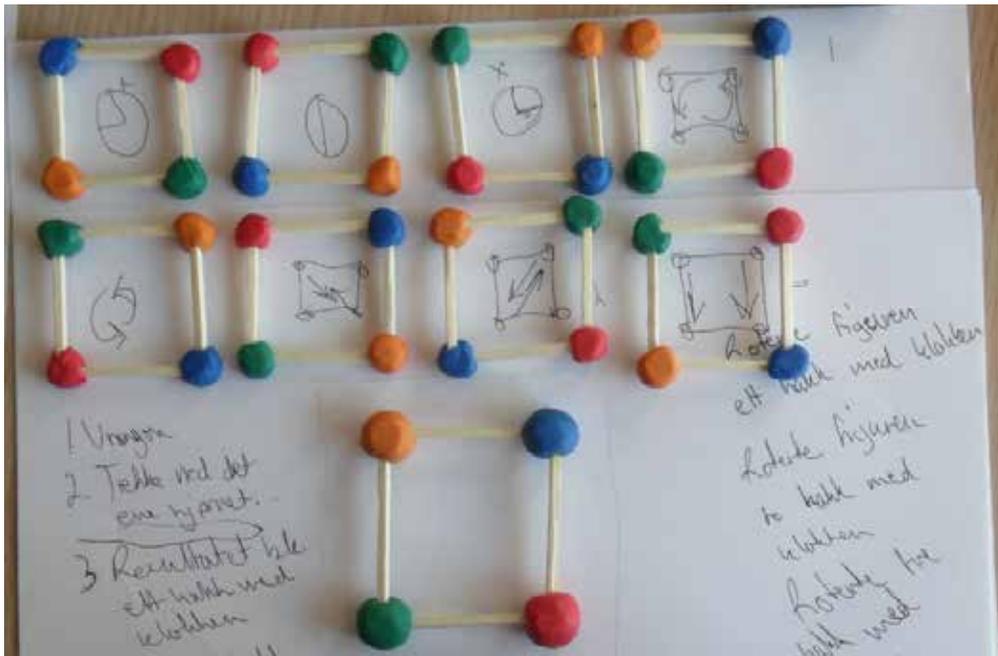

Figure 4

It can be seen that the student has succeeded in creating largely coherent and descriptive symbols for each element, however when he moves on to combining pairs of elements below, he does not think to *use* the symbols, but rather writes his operations and results out in words, a process which is time consuming and inefficient for exploring the abstract structures of the system further.

In the context of APOS theory, the issues described above are closely related to the first two steps of *action* and *process*, and how they can lead to *object* ($AP \rightarrow O$). The preliminary observations and analysis of collected data suggest that at these stages serious barriers might occur, and that the speed at which these barriers are overcome depends largely on the invention and use of notation. (Once guided to overcome these difficulties, the explorations by both sets of students were rather impressive). The study thus indicates that it might be appropriate to consider APOS theory in conjunction with theories of semiotics, where for instance Duval (2006) contends that

representations can ... be signs and their complex associations, which are produced according to rules and which allow the description of a system, a process, a set of phenomena. There *the semiotic representations, including language, appear as common tools for producing new knowledge and not only for communicating any particular mental representation.* (Duval, 2006, p. 104, italics added)

Moreover he explicitly asks: “What cognitive systems are required and mobilized to give access to mathematical objects and at the same time make it possible to carry out multiple transformations that constitute mathematical processes?” (p. 104). Here it could be argued that a different way of posing this question might be: what cognitive systems lend themselves to facilitate student’s transitions between the stages proposed by APOS theory in the process of abstraction? One answer might be that signs and semiotic systems of representation are needed, not only to label objects at the action stage, but to promote the transition to thinking in terms of processes and

encapsulating these processes into objects in their own right, or as Duval puts it: “to work on mathematical objects and with them” (p.107). Now whereas this idea has been researched in various ways in relation to the learning of basic mathematical structures by young children, there appears to be less focus on the interplay between theories of abstraction and theories of semiotics in more advanced mathematical situations.

The study presented here, though very much a ‘work in progress’, suggests that more careful consideration ought to be given to the semiotic resources drawn upon by older students, and that the ways in which these resources are used (or neglected) can give insight into barriers that students meet in the later stages of abstraction. Although further analyses will be necessary, these preliminary results suggest there is reason to believe that the students who struggled to invent and use notation appropriately during the task under consideration, might also struggle in other mathematical situations, as symbol use is crucial in the development of abstract mathematical proficiency, particularly in algebra where Norwegian students are repeatedly shown to perform poorly (Grønmo, Onstad, & Pedersen, 2010). And when considered against the backdrop of other research on students’ proficiency (or lack thereof) in abstraction and algebra (e.g. Breiteig & Grevholm, 2006) this study underpins a need to improve the situation. Initiatives and approaches such as suggested in the ‘Trip Line’, an algebra module designed for the high-school curriculum as part of part of ‘The algebra Project, Inc.’ (The Algebra Project, 2010), might well be worthwhile to pursue, as it unlike many current teaching plans pays explicit attention to the invention and use of symbols in algebra. It thus integrates Halliday’s (1993, p. 93) proposition that a good strategy for understanding human learning in general, would be to pay attention to “how people construe their resources for meaning - how they simultaneously engage in ‘learning language’ and ‘learning through language’”.

AN INVESTIGATION INTO THE TENSION ARISING BETWEEN NATURAL LANGUAGE AND MATHEMATICAL LANGUAGE EXPERIENCED BY MECHANICAL ENGINEERING STUDENTS.

Michael D. Peters¹ & Ted Graham²

¹Aston University, UK

²University of Plymouth, UK

This investigation is grounded within the concept of embodied cognition where the mind is considered to be part of a biological system. A first year undergraduate Mechanical Engineering cohort of students was tasked with explaining the behaviour of three balls of different masses being rolled down a ramp. The explanations given by the students highlighted the cognitive conflict between the everyday interpretation of the word energy and its mathematical use. The results showed that even after many years of schooling, students found it challenging to interpret the mathematics they had learned and relied upon pseudo-scientific notions to account for the behaviour of the balls.

INTRODUCTION

The purpose of this paper is to report upon a study which investigated how a group of first year undergraduate Mechanical Engineering students conceptually interpreted mathematics. The students were presented with a physical system which comprised of a ramp on which three different mass balls were rolled down. One half of the class was asked to predict where the balls would land relative to one another, the other half were given a composite photograph of the balls landing and asked to explain this behaviour. The students' analysis of the system was used to investigate the tension that arises from the everyday meaning attached to scientific terms and the precise mathematics definition. The concept and interpretation of the word energy was used to facilitate this study. This report first provides a brief discussion of some of the issues around the interpretation of mathematical language. It then goes on to discuss the investigation and finally, the conclusions draw together the theoretical and experimental aspects discussed in the paper. The conclusions also highlight the importance of the use of language in the learning and teaching of mathematics and why a conceptual approach to aid the interpretation of mathematics is important.

BACKGROUND

Mathematics, as an intellectual discipline, can be thought of has two interdependent aspects: the language element and the computational element. This interdependency is at the root of the difficulties experienced by many learners and indeed by mathematicians at all levels. The difficulties faced by learners can be eloquently summed up by Davis and Hunting:

To put it in a simple form that highlights the students' dilemma: they need to know the language of mathematics in order to know what mathematics is about; conversely, they need to know what mathematics is about in order to know how to use the language. (1990, p. 117)

Natural language is used as the medium to convey and learn mathematics. The development of natural language relies upon forming a link between the three dimensional 'concrete' world we live in and the conceptual world of our minds. In terms of embodied cognition, one could say that perceptions are mediated by language to form conceptions, which in turn are used to interpret perceptions. Thus, as conceptions become more refined, perceptions can be interpreted in a more meaningful way. In the early stages of development a child learns to form the link between an object and the name given to it by the society the child lives in. This is evident when a child first learns to count in that a number name (a numeral) is attached to an object. The child also learns that once all of the objects have been counted, the last number indicates the quantity of the objects (the cardinal number).

Lakoff and Núñez (2000) suggested that this process of attaching meaning can be explained by the use of metaphors and conceptual metaphors. A metaphor defined to be the linguistic construction used to describe a subject in terms of another unrelated object and a conceptual metaphor to be where one idea is understood in terms of another unrelated idea. Lakoff and Núñez would explain the scenario of the child counting objects as an 'arithmetic as object collection' conceptual metaphor. As the child progressed more conceptual metaphors would be developed in order to sensibly interpret the world. This process of developing conceptual metaphors is reinforced by the use of metaphorical language extensively used in the teaching of mathematics. It is quite common when teaching children about numbers to employ the use of a 'measuring stick' metaphor to explain the relationship between numbers. In a similar way, the use of an 'arithmetic as motion along a path' metaphor is employed to explain negative numbers. The use of conceptual metaphors has been shown to be problematic within the classroom (Doritou & Gray, 2007).

The learner at some stage has to realise that concrete objects are not necessarily the subject of mathematical operations. For example, the arithmetic as object collection metaphor can prove to be problematic when the learner is faced with set theory where the natural numbers are described in terms of the empty set, that is, \emptyset maps to 0, $\{\emptyset\}$ maps to 1, $\{\emptyset, \{\emptyset\}, \{\emptyset, \{\emptyset\}\}$ maps to 0, 1 and 2, since the empty set is the fundamental 'unit' and not a physical object. This highlights the problem that the learner can, in some instances, attaching a name to a concept at one stage in their mathematical development, but at a later stage the concept is modified but the familiar name is still used or a familiar concept is given a different name (e.g. the equation $y = 3x + 2$ becomes the function $f(x) = 3x + 2$).

THE BASIS OF COMMUNICATION

Two models of linguistic communication that stand in sharp contrast are the classical code model where sentences are comprised of sound-meaning pairs and the more recent inferential model where the sentence provides a semantic structure from which the meaning can be inferred (Sperber & Origgi, 2010). In order to communicate, according to the code model, the speaker and listener must interpret the sentences in precisely the same way. In contrast to this the inferential model acknowledges that ambiguity can arise from the listener misinterpreting the speaker's message. In this model, understanding the speaker's meaning is an inferential process using a common grammar which assigns semantic properties to the sentence and uses context to aid interpretation. As an example of the inferential model, Anderson (1997) studied two working environments: a garage and a postal service. He discovered that in many cases the workers would use words and phrases that did not conform to the standard natural language, but instead used abbreviated sentences and sometimes just words to make a request or convey an instruction. Since the workers were in the same environment, ambiguities did not arise.

Within a mathematics classroom environment it cannot be assumed that the learners possess the same lexicon as the educator, since in the context of mathematics, the language used is often inferential. In one respect the novice mathematician develops a form of proto-language where a lexicon of coded concepts is built where these concepts, to a certain extent, are independent of one another. It is not until a later stage that links are formed between these concepts and then, what could be termed, super concepts are created (Sfard, 1991). It could be said that the symbol reifies the concept in the sense that it can be manipulated and used to investigate both physical artefacts and abstract concepts. From the learners' perspective, the interpretation of these symbols can be a difficult and cognitively demanding process especially when the fundamental concepts rely upon a conceptual metaphor grounded in the 'real' world.

Nowak, Komarova and Niyogi (2001), in their discussion of cognitive development in humans, suggested that the brain developed as a modular system. They suggested that skills like reading and other more sophisticated object recognition processes that are constantly being used, develop their own modules based on ones in which similar processes already exist. Fodor (1983) suggested that modules must fulfill certain properties to a lesser or greater degree: they must be domain specific, they use encapsulated information, they are activated without conscious control (Fodor called them mandatory), their outputs are shallow, they are quick to process pertinent data, they have characteristic breakdown patterns and the neural architecture is fixed. Two of the key criteria suggested by him were domain specificity and encapsulation. Domain specificity is defined to be the class of information that the module is designed to accept or operate upon. Encapsulation refers to the notion that modules are not influenced by information or processes external to it. Pinker (1998) suggested

that a module should be defined by the specific operations they perform on the information they receive.

For example in the case of mathematics; in order for a learner to make sense of vectors, some idea of what ‘moving’ means and what ‘direction’ means is crucial. The information gathered from the ‘real world’ experience activates certain modules which in turn enable a cognitive link to be made between the physical world and the mathematics used to interpret it (concept formation). At an intuitive level the concepts of speed and velocity are interchangeable and indeed in many mathematics problems the learner does not need to distinguish between them. The challenge comes when circular motion has to be studied. In this instance the object moving along a circular path is subject to continuous directional changes and hence must be described by velocity not speed. This creates a conflict for the learner who now either has to adapt a deeply ingrained concept to include the notion of changing direction or else has to separate the two concepts and rely upon semantic processing to correctly resolve any problems. This conflict was evident in an investigation carried by Peters and Graham (2009) where a group of trainee teachers were asked to explain the forces acting on an imaginary object suspended without any support in mid-air. This investigation demonstrated the cognitive conflict experienced by some teachers when attempting to use Newton’s third law of motion to explain the problem. They could not identify the relationship between the object and the Earth in terms of forces and attempted to modify their learned concepts to allow for an object to be suspended without physical support.

The issues around the learning and teaching of energy are well reported at the secondary level of education (Millar, 2005; Sefton, 1998; Soloman, 1983; Trumper & Gorsky, 1993,). As Sefton points out there is no unique definition of energy and the one normally taught in schools is ‘the capacity of a system to do work’. In this report energy is treated as a value which cannot change (first law of thermodynamics). In most cases, when teaching about energy, a transfer or a transform metaphor is used to explain how a system works rather than a process of conversion. This approach, along with intuitive ideas, leaves learners with the impression that ‘energy is what makes things happen’ (Ogborn, 1986).

When learners arrive at university to study, not only do they bring with them intuitive ideas of how the world works but also the conceptions or misconceptions developed from their previous educational experiences. In many cases, the students are able to solve mathematics questions procedurally but have great difficulty in solving problems at a conceptual level. As Vigeant, Prince, Nottis and Miller (2012) pointed out; one of the major differences between novices and experts is that experts are able to organize their approaches conceptually. In order to facilitate the journey from novice to expert, the need to develop a conceptually understanding is vital.

EXPERIMENTAL DESIGN

The group for this research comprised of 44 first year undergraduate Mechanical Engineering students. They had all studied mathematics to an advanced level during their secondary education. The investigation was carried out in the second semester of their first year. The group was divided into two subgroups and placed in different rooms. Once in their designated rooms they were seated so that they were unable to see their immediate neighbour's response.

Group A had a total of four tasks to complete. The first two were based on their observation of the first ball being allowed to roll down the ramp. The remaining tasks asked them to use their knowledge of mathematics to select pertinent equations which they could use to offer an explanation of the behaviour of the balls. Finally they were asked to draw conclusions about the important factors that determined the behavior of the balls.

In the first instance they were shown a small ball (tennis ball) rolling down a ramp (Figure 1). They were then asked to predict where a 'heavier' ball would land relative to the first one. Finally they were asked to predict where a third ball ('heaviest') would land relative to the other two. They were given the opportunity to request additional information. To facilitate this, the researcher had brought along a tape measure and a set of electronic scales which were initially hidden from view so the learners would not be given a false prompt that they required additional information. In order to record their responses they were given prepared sheets with the pertinent questions. A typical question was, "You have seen a ball being rolled down a ramp and made a note of where it landed. If another heavier ball was to be rolled down the ramp, would it land: (a) In front of the lighter ball or (b) behind the lighter ball?" The option 'land in the same place' was not given since the idea behind the investigation was to test the students' deep learning of interpreting equations but they could have stated, in the space provided for them to explain their answers, that the balls would land in the same place. The individual sheets were handed out at the appropriate time and collected in after each response. This was done so that as the investigation progressed the learners would be unable to modify their previous answers.

The second group, group B, was shown a composite photograph of all three balls leaving the ramp and landing in the same place (Figure 2). They were also given four tasks. The first task was to look at the photograph and offer an explanation as to why the balls landed in the same place. The remaining tasks were the same as group A in that they were asked to select equations that could be used to explain the behavior of the balls. These tasks were centred on them knowing the end result and having to provide reasons why this outcome occurred. In a similar way to the first group, their answer sheets were collected in after each task.

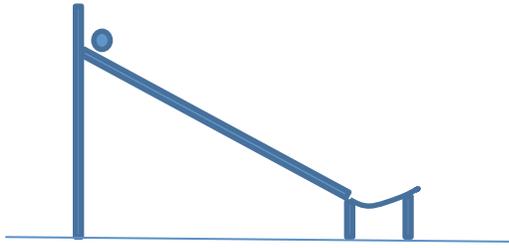

Figure 1: Ramp Configuration

Figure 2: Composite Photograph of Landing Balls

RESULTS

The results of the investigation were collated into a spread sheet. The student answers were coded with respect to the key words or phrases they used within their explanations. The most frequently used key words were then summed. If the student did not provide an answer it was coded as ‘no explanation’ and if they admitted to guessing or not knowing an answer, this was coded as ‘don’t know/guess’. An example of the method used for recording and analyzing the results is given in Table 1. This table shows the collated student responses from group A to task 4, part 1, which asked them to select equations from a list that could be used to predict where the balls would land relative to each other. Part 2 of this question then asked them to justify their selection.

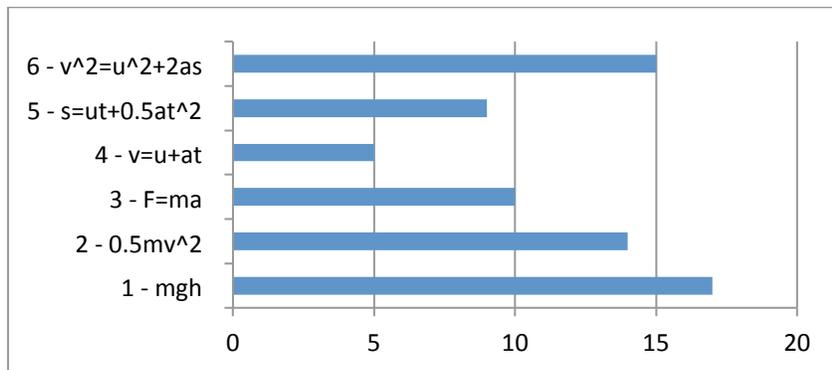

Table 1: Student responses to Task 4, part 1.

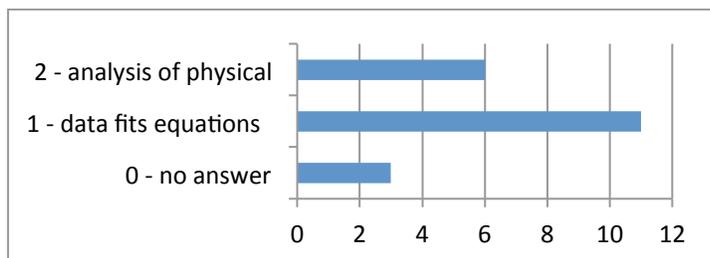

Table 2: Student responses to Task 4, part 2.**DISCUSSION OF RESULTS**

It was evident from their responses that when studying mathematics and, in particular mechanics, they were used to a procedural approach where they used certain equations to analyse the components of a system rather than a conceptual approach.

One student wrote “The mass of the ball, the initial and final velocity and the displacement are the key values....” This suggested that the student was going to apply a series of steps, rather than taking the more holistic energy approach. The student's answers to task 4 part 2 reinforces this in that when asked why they chose certain equations they could use to predict where the balls would land relative to one another, they chose the ones which would be required to calculate where the balls would land. The emphasis of the tasks was on the relative positions of the balls and not on calculating their positions. In order to be able to explain the behaviour of the balls the students should have focussed on the equations related to the conversion of energy from potential to kinetic. This would have required them to have a clear understanding of the concept of energy, its conversion from one form to another and be able to interpret the equations which described the relationship between potential and kinetic energy.

In their answers some of them talked about the energy of the ball as if energy was a physical thing rather than an abstract mathematical concept used to analyse physical systems. In effect these students had been taught in a way that the concept of energy had become reified and was a commodity that was physically transferrable between the different components of a system. This is not surprising since in every day conversations the word energy is used in a variety of contexts. For example, it is quite common to talk about how much energy a person gains from eating certain foods, or the cost of energy to heat a home. These, and similar statements, imply that energy is something that is consumed. In terms of using conceptual metaphors, the students employed a container metaphor in that energy was contained within a vessel and the only way it could be transferred was by emptying the contents from one container into another. For example, a typical response was “When the balls reached the bottom of the ramp, the potential energy was transferred to the kinetic energy of the ball...” Most of the students were aware of potential and kinetic energies and how energy can be converted from one form to the other. Although the equation for potential energy includes height, the students seemed unable to realise that this implied that for potential energy to exist a system is required. If one looks at the two equations, $PE = mgh$ and $KE = \frac{1}{2}mv^2$, it is evident that the common factor of m (mass) has no effect on the conversion of energy and consequently the velocity of the ball is only reliant upon the initial height from which the ball was released. Typical approaches when asked to justify their answers mathematically, were to calculate the

PE when the ball was stationary at the top of the ramp and use this to calculate a value for the KE and subsequently find the velocity of the balls. One student followed this procedure but still insisted that the mass was the major factor in determining how far the balls would travel. This insistence was linked to earlier statements made when they were asked to explain the behaviour of the balls without the use of mathematics. The empirical context of the investigation, that is a mechanics class, primed the students to think they were expected to calculate values (procedural approach), rather than to think conceptually. This was evident from the way many of the students wrote down a list of every equation they could remember involving forces (Newton's 2nd Law), displacement, time and acceleration equations (eg. $s = ut + \frac{1}{2}at^2$), energy (PE and KE) and attempted to fit the data they had to one or more of the equations rather than use the relevant equations to explain the scenario. One student wrote, "This equation covers all aspects of this experiment such as height of the object above ground level, acceleration due to gravity, etc to make the balls behave the way they do."

The second group were shown a composite photograph of all three balls leaving the ramp and landing in the same place. They were asked, using their knowledge of mathematics, how this could be explained. This form of the experiment involved the students in being able to 'reverse engineer' a system given the final outcome. The majority of responses from this group were similar to the ones given by the first group. For example, one student wrote, "The heavier ball has to overcome more friction and has more gravity acting on it, meaning it falls to the ground faster." Another student wrote, even after seeing the outcome, "If the ball has more mass it will gain more momentum on the way down the slope and so will travel further." When asked which were the most important factors influencing the balls, the height the balls were released from, the distance the balls travelled and their mass were considered the key ones. When asked to write down any conclusions regarding the behaviour of the balls, such things as the final velocity of the balls, the time of travel, mass, initial velocity and acceleration were considered the factors which determined where the balls would land.

CONCLUSIONS

This investigation explored students' interpretation of the word energy within the context of a physical system. The purpose of the investigation was to explore the tensions between the intuitive interpretation of the word energy and its mathematical interpretation.

The results indicate that after many years of education, students still rely upon intuitive explanations. It also revealed that in some cases students were unable to use an equation or set of equations to conceptually interpret a system. In this investigation, the everyday interpretation of the word energy has obscured, for many students the scientific notion of energy in the sense that they reify the concept of

energy and employ a container metaphor to analyse a system involving energy conversion. Although this investigation centred around the interpretation of energy, the issues it raises can be applied to mathematics in general, for example, the interpretation of the word ‘set’, the language used in the teaching of the calculus (the theory of limits). In addition to the students’ interpretation of the word energy, the language used within the task sheets would have some influence on how they approached the tasks. In order to assist students on their journey from novices to experts, educators must be careful in their use of language when teaching and place a greater emphasis on the interpretation and meaning of equations in order to develop conceptual learning.

THE PRODUCTIVE ROLE OF INTERACTION: STUDENTS' ALGEBRAIC THINKING IN LARGE GROUP WORK

Núria Planas and Judit Chico

Universitat Autònoma de Barcelona, Spain

We report preliminary results from a design research of six lessons in a mathematics classroom with students aged 15 to 16. The emergence of relationships between mathematical learning opportunities and students' interaction has been examined. The idea of Learning Opportunity Environments –LOEs plays a significant role in the study, as we consider it useful to better understand the social aspects of mathematical learning. Our results suggest, but do not demonstrate, progress in the students' algebraic thinking, as regards generalization processes that were fostered at different points of the interaction. We use data from the episodes to illustrate two major themes that are central to what takes place in large group work. More generally, these episodes bring up reflection on what LOEs are and what they are not, and for whom.

INTRODUCTION

Large group work has become a common practice with a modest amount of research compared to pair work. This report describes a study linking task-related interaction to mathematical learning in a large group. At the moment learning is not actually examined, but learning opportunities pretend to be demonstrated as having taken place. The motivation for the study is the increasing use of collaborative classroom settings, along with the need to refine scientific arguments around them. Following analyses of students interacting in small group more than twenty years ago (Cobb, Yackel, & Wood, 1991), we aim to examine the potential of large groups from the perspective of creating learning opportunities in the mathematics classroom. For the last two decades, research has pointed to the impact of social interaction on mathematical learning (Brandt, 2007). Other outcomes have pointed to unintended consequences of being involved in interactive settings (Gresalfi, Barnes, & Cross, 2012). We undertake to develop an analysis of large group processes that helps to understand the complexity of creating learning opportunities in the interaction with *many others*.

In what follows, we present our view of mathematical learning as a socially mediated process, and briefly introduce the methods applied in the research. In the last part of the report we comment on two episodes to illustrate major themes that point to the creation of Learning Opportunity Environments –LOEs. The episodes provide an indication of what we call “large group work”. There is no data in this report to determine the extent to which learning took place across the large group or even to verify that others learned in response to comments that were made by the students who interacted. Moreover, although we focus the discussion on two episodes, we attempt to note complexities arising from scenarios with similar didactical and pedagogical orientations.

THEORETICAL FRAMEWORK

In this section we briefly present what we mean by social interaction and mathematical learning opportunities. Then we refer to the domain that frames the objects of teaching and learning in the design research, namely the transition from arithmetic to algebra.

The joint construction of social interaction and LOEs

Social interaction may lead to oriented actions for performance improvement in the teaching and learning of mathematics. The ideal of interaction as a cultural practice has survived to become a tool for potential learning and for group development so that it makes sense to interpret the notions of learning and learning opportunities as conceptually and empirically similar. Both refer to the favourable negotiation of circumstances toward the construction of knowledge. Cobb, Yackel and Wood (1991) suggested the value of thinking of learning at an operational level in terms of what we refer to as LOEs. We view students' learning as a product of their involvement in LOEs, and of their ability to optimize the interaction with others to improve mathematical discussion. In our study we focus on LOEs that may contribute to learning during the course of students' interactions despite minimum intervention from the teacher. Missed learning opportunities may occur due to the lack of active guidance provided by the teacher, but students have the potential to make the most of many other opportunities by themselves. LOEs still are an in-construction theoretical notion in that we need more examination on what they are, and more important, what they are not.

Our understanding of mediation points to the mutual influence of different realities in the accomplishment of specific goals and tasks. We see mediation as a culturally-based practice embedded in learning and group development, with the underlying assumption that individuals and groups are ready to (consciously) move their roles and positions in the interaction with others. In our work, mediation is explored in terms of the actions of participants in a mathematics classroom in which the creation of LOEs through peer interaction is expected to lead to the development of mathematical discussions. Moreover, our idea of mediation coincides with the selection of certain participants and issues that will receive more attention than others in the interaction. It is this discursive nature that raises a problem for the practice and theory of social interaction as a mediator of mathematical learning: what to do with and how to explain LOEs in which communication is not always successful, and/or is not well addressed in the direction of sharing knowledge. In response to this problem, it makes sense to develop studies that are built on the search for collective situations in which students make the most of a LOE to achieve learning, together with others in which they miss the opportunity at a given point of the interaction. In this report, we focus on the first type of situations.

The difficulties of students in the transition from arithmetic to algebra

Algebraic thinking is the activity of doing, thinking and talking about mathematics from a generalized and relational perspective. In the transition from arithmetic to

early algebra, one of the initial difficulties for students has to do with the learning of the language conventions underlying this mathematical domain. Algebraic symbols like an n become rather sophisticated, and in the resolution of a problem tend to be misinterpreted and misused. On the other hand, Lins and Kaput (2004) argue that an early favourable start to the learning of algebra is possible by leading the students to foster a particular kind of generality through the use of a problem-solving approach with generalized arithmetic. The reasoning required to solve certain problems can be expanded from concrete arithmetic situations to more complex situations that include the ability to use abstraction. We state that a problem involving several stages of algebraic thinking, from near to far generalization, helps students to adjust their reasoning from meaningful numerical cases to algebraic symbolism and mathematical abstraction. Thus three levels of reasoning may be recommended to represent a problem: a) concrete (considering small quantities), b) semi-concrete (considering big quantities), and c) abstract (using symbols).

Together with the three levels above, the exploration of visual growing patterns is another recommended way to introduce algebraic expressions (Warren, 2000). Many students experience difficulties with the understanding of geometric patterns as algebraic functions. Some of these difficulties come from the lack of an appropriate language to describe relationships between variables, the inability to visualize and complete patterns, and the complexity to connect verbal, visual and algebraic representations. Consequently, tasks that encourage visual strategies and relate number and geometric contexts are crucial in the early learning of algebra. For the design of the tasks in our research, we have considered the combination of concrete, semi-concrete and abstract levels of reasoning, and the combination of verbal, visual, numerical and algebraic representations to mathematically model regular situations of change.

RESEARCH CONTEXT AND METHODS

The investigation consisted of preparing and analyzing six lessons in a classroom with a group of students aged 15 to 16, and the teacher. The students were used to pair work and large group discussion. They were also used to problem-solving dynamics, to listening to each other, and to communicating their mathematical ideas. The research question was: *How does large group work contribute to the creation of mathematical learning opportunities in problem solving classroom environments?*

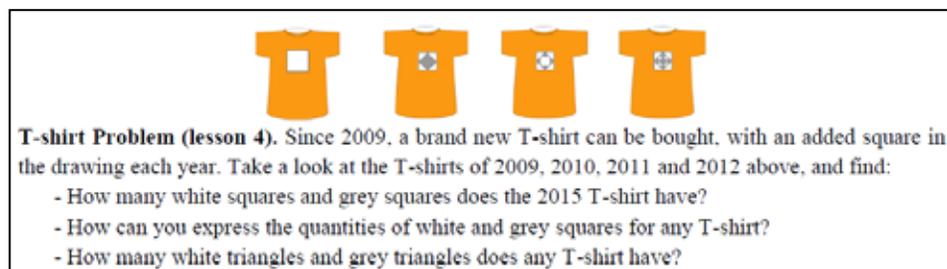

Figure 1. Example of task from the problem sequence

To prepare the experiment, we elaborated a coherent and focused sequence of six word problems about generalization that helped to create a LOE. Coherence was based on the control of a progressive difficulty in the problems from the perspective of algebra, and also on how a problem was mathematically related to the next one in the sequence. The problems presented were challenging in many respects. For instance, the example in Figure 1 was intentionally complex from the perspective of the wording, in particular with regard to the expression “any T-shirt”. The T-shirts seem to be defined by the year, but it is not immediately clear if “any” means “any year T-shirt”.

For each fifty-minute lesson, one problem was presented by the teacher and then discussed by the students in pairs. The last thirty minutes were devoted to large group work. The teacher acted as a facilitator of the students’ interactions, and circulated around the room during pair work. Thirty minutes is a lot of time so that much pressure was on the quality of large group work, especially for the teacher to orchestrate it.

Data collection consisted of audio and video recordings of class discussions. We began by transforming audio and video files into transcripts. It took time to decide which type of transcription would better suit the aims of the research, while remaining an adequate representation of data with a double emphasis on the interaction and the mathematics. After having examined various options, we looked for key episodes in the videos and elaborated transcripts that illustrated interactional and mathematical features. To determine where transcripts of episodes begin and end, we gave priority to the mathematics. We identified large group moments in which mathematical practices were at the core of the discussion due to the existence of diverse meanings or the difficulty in understanding a mathematical reasoning. Thematic boundaries and learning opportunities may be differently perceived by different researchers, but the two authors’ agreement was guaranteed, along with a third researcher who intervened when it was difficult to reach agreement in the analysis of a specific episode.

Having constructed the set of episodes and reviewed the videos several times, we began a process of comparative and inductive analysis (Glaser, 1969) among episodes from the same lesson and then from the total set of lessons. We aimed to elaborate mathematical memos and interactional codes to mark changes in the students’ meanings, as well as changes in the direction of interactions. The direction of social interaction depends on whether participants direct their actions toward someone in particular, and whether such actions involve intentions concerning the interpretations under discussion. In an episode with practices of cross multiplication, for example, interactional codes may consider verbal actions by one student aimed at seeking others who share similar ways of making sense of cross multiplication. Other codes may be related to verbal actions aimed at helping each other to understand cross multiplication. There may be codes that point to students asking for clarification of ideas, and so on.

Any social interaction is a combination of interactional codes, and thus it is not possible to have key episodes that are univocally related to single codes. However, an exhaustive attribution of codes to episodes was not attempted. We gave priority to detecting one (possibly two) code(s) that influenced the evolution of the mathematical activity. Next we summarize the direction for two interactional codes that were constructed in advanced phases of the analysis in relation to key episodes. The following codes were developed in an on-going way as the analysis of new episodes contributed different codes and until there was a stable set:

- *Sharing responsibility* -A student follows up a mathematical explanation given by the peer in pair work and gives further information.
- *Expressing confusion* -A student reacts to a prior intervention by claiming lack of understanding with respect to a mathematical reasoning.

Throughout the analysis, interactional codes were completed with mathematical actions. Our use of the term mathematical action echoes the notion of mathematical practice by Godino, Batanero and Font (2007, p. 3): “Any action or manifestation (linguistic or otherwise) carried out by somebody to solve mathematical problems, to communicate the solution to other people, so as to validate and generalize that solution to other contexts and problems.” The attention to mathematical actions led to the elaboration of what we call mathematical memos. There was no limit on the length of memos. Nevertheless, we intended to summarize mathematical characteristics in the actions of students in an episode in about one paragraph (see next section). By providing codes and memos, we advanced toward the construction of themes in order to obtain cases of episodes. The creation of a theme involved specifying two components: i) the mathematical actions at that point in the lesson, and ii) the interactions that appeared connected to the realization of such actions. Emerging themes were expected to inform about learning opportunities in terms of relevant mathematical actions and interactions. Various themes were constructed and, as more data were analyzed, some of them came to assume a greater importance and constituted major themes. Some early themes were either discarded as the analysis progressed, or absorbed into more accurate descriptors. A final group of major themes comprises the preliminary findings of the study. Next we summarize two of these themes.

SHARING RESPONSIBILITY AND MAKING SENSE OF ALGEBRA

The excerpt below reproduces part of an episode in which two students are discussing the third question of the T-shirt Problem, “How many white triangles and grey triangles does any T-shirt have?” The T-shirt design pattern refers to an arrangement of squares inside each other. The midpoints of each side of the outer square are joined to make a smaller square inside it and so on. Jose and Gabriel worked together during pair time, and they are now explaining part of the solution in the large group.

Jose: If n is the number of the T-shirt, n equals the quantity of squares in that T-shirt. The first T-shirt has one square, the second has two, the third has

three... But as said before, one square has no triangles. Then you need to take the number of T-shirts minus one, and multiply it by four because each square leads to four triangles. That's the total. If n is even, you divide the total by two and get the white and the grey triangles. When n is even, you get the same quantity of white and of grey squares. You've taken one out, and get the same quantity of white and of grey triangles.

Gabriel: No, this happens when n is odd, no... Yes, when n minus one is odd.

Jose: Yes, it is n minus one, odd.

Gabriel: When n minus one is odd. We made a mistake, when n is odd you get one more white square. It leads to the same quantity of white and grey triangles.

Jose: Yes. If n is odd, you divide it by two and get the number of the two types of triangles.

While in the first lessons the wording of the problems stresses one of the variables with the algebraic use of the letter n , the fourth problem requires the symbolic representation of the variables by the students. Jose uses the n to distinguish the location of the T-shirt, established at the start of his reasoning. To reach the unknown quantity of colored triangles, he gives the expression $4(n-1)/2$ for the special particular case of n odd. Despite the confusion between even and odd T-shirts, he progressively constructs the pattern with the support of algebraic language and visual thinking. Gabriel points to the issue of even and odd numbers having an influence on the adequacy of the pattern. The two students, however, seem not to be clear about the need to use n or $n-1$. In a former episode from the lesson, some students discuss whether the 2015 year T-shirt is the seventh in the collection, while some others consider it to be the sixth due to incorrectly interpreting the year subtraction, 2015 minus 2009. Such a difference also has to do with taking either 1 or 0 as the initial value for n . Gabriel looks at the drawing of the third T-shirt and concludes that the pattern by Jose works for the odd cases. He justifies his reasoning on the basis of the characteristics embedded in the general case given by the set of odd T-shirts.

In the end, both students seem to make sense of algebra by using the symbolic convention for the generic representation of natural numbers. But still another interpretation is plausible. We may see two students who are, at the moment of the episode, wrestling with their own ideas and who might want to resolve their personal understanding before attending to anyone else's answer or approach. If their focus is on individually reaching a solution, then it is quite conceivable that they will not, and will not want to, interact with anyone who might "spoil" their quest for untangling their ideas. Thus we wonder if learning would actually be taking place for Gabriel if he just accepts the reasoning posed by his peer. To generate a more precise understanding of the social aspects of the mathematical learning it is necessary to know more about the students who are involved in such learning, and the meanings given by them to pair and large group interaction with peers.

Sharing responsibility here represents situations in which a student follows up a mathematical explanation given by the peer in pair work and provides further information. The student feels that s/he should respond to what the peer says and does in some appropriate way. Gabriel and Jose share the responsibility of making sense of the algebraic pattern in the context of the T-shirt Problem. This code calls for responsibility based on joint efforts during pair work. For the different lessons, we often see students in the large group behaving as individuals still belonging to a pair structure. Students take more responsibility for what their peers in pair work say in the large group, compared to what other students say and do, for whom the main responsibility is expected to be assumed by the teacher. Although our analysis focuses on large group and all students showed different ways of participation, the influence of the pair work dynamics appears to be relevant in that it is a locus of responsibility. It can be argued that this sort of student-student collaboration would not be so present if large group discussion had not been preceded by pair work.

This episode illustrates how large group work can enhance learning opportunities by making public an error in relation to the algebraic use of n . The intervention by Gabriel makes the incorrect use of the variable explicit, which comes with a clarification of the connections among the value for n , the position of the T-shirt in the sequence and the appropriate pattern. By having the two students sharing responsibility for this discussion in the large group, the creation of a learning opportunity may be facilitated. If Gabriel had not paid attention to his peer, the mathematical error might have been overlooked. In other episodes, *Sharing responsibility* also acts as a mediator in the understanding and manipulation of algebraic expressions. In the same lesson and with respect to the same pair, when discussing the answer to the first question in the problem, Gabriel clarifies some of the words said by Jose concerning the connection between the value for n and the position of the T-shirt.

EXPRESSING CONFUSION AND LINKING REPRESENTATIONS

The episode partially reproduced below is an immediate continuation of the previous episode. Both take place in the fourth lesson around the solution of the third question of the T-shirt Problem. The following conversation helps to illustrate the fact that an expression of misunderstanding can become a resource to be exploited by students to optimize the creation of learning opportunities.

Teacher: Have you understood? Maria [a student], can you explain it?

Maria: Woops! I have understood nothing!

Jose: If they tell you that there are three T-shirts, one, two and three... This one, the third, has three squares because each year you have one more square.

Maria: It will have as many white triangles as grey triangles...

Jose: We'll talk about that later. Now, you have three squares in the T-shirt but one square does not generate triangles, the one in the middle. So you take one out.

- Maria: Why do you take one out?
- Jose: The one in the middle does not generate triangles. You take these two squares that do generate triangles. You multiply them by four. Each square generates four triangles [pointing to the third T-shirt]
- Maria: Okay.
- Jose: That's the total amount of triangles. Three squares minus one are two, multiplied by four is eight, the total. You don't know how many are grey and how many white. You only know that eight is the total. But the n is odd, and it's the same quantity for white and grey. You divide it by two and get the quantity of white and grey triangles.

A few minutes before, Jose had explained the pattern for the special particular case representing the odd T-shirts, $4(n-1)/2$. He was aware of the two special cases introduced by the particularity of a number being either even or odd. There was an initial algebraic approach to the explanation of the general pattern, that may be viewed as a mere symbol manipulation instead of an expression that shows relationships between the location of the T-shirt in the collection and the number of squares and triangles in the design. Such manipulation seemed to hinder Maria's understanding. Jose reacted by linking algebraic language with natural language and including references to the visual context of the problem. On a second attempt to clarify his explanation, he took the case of the third T-shirt, as a generic example to illustrate regularities that support his pattern. The episode suggests that Maria came to see the generality in the pattern through the particular case provided by Jose. The only evidence for this assertion is that Maria says "Okay" in response to the second part of Jose's explanation. We do not even know what Maria thinks about Jose's final contribution, and so we have no evidence for her understanding of that part. Of course, saying "Okay" is not evidence of understanding, and indeed in another episode we see how Maria says "Yes" in response to a question by the teacher and, two lines later, we discover that she has not understood what is under discussion. This is why our analysis points to the creation of LOEs but does not guarantee the identification of learning.

Expressing confusion here represents the actions of a student who reacts to an intervention by claiming lack of understanding with respect to a mathematical reasoning that has been exposed. Maria is the student who expresses such confusion. Although the term confusion rather suggests the individual dimension, it may arise from non-internal reasons such as people poorly communicating their ideas. A student may suppress information that the addressees need to make sense of what is being said. As part of an interaction, confusion is to be seen in terms of a collective challenge with people involved in the completion of a shared task. A student expressing confusion is not a guarantee of participants exploring the problem-solving processes. Such actions become unproblematic as long as participants are willing to help each other to understand mathematical contents by checking meanings. Understanding is facilitated when communication is seen as possible because

participants are considered to be competent. Jose might not have provided examples for his mathematical thinking if he had interpreted Maria's intervention only as an expression of difficulties in the understanding. And vice versa: Maria might not have shown confusion if she had not seen Jose as sufficiently competent to follow her arguments.

We interpret here large group as a LOE in which learning opportunities are provided through making public the incompleteness of a mathematical reasoning. The fact that Maria publicly shares her confusion leads Jose to explain again his reasoning including, on this occasion, newer connections between visual reasoning and verbal patterns. Thus the opportunity to link different representations (verbal, visual, numerical, and algebraic) appears. The actions by the teacher are also relevant in the creation of this LOE. The teacher promotes the tacit demand from Maria, which becomes effective in the configuration of the turns that makes the mathematics evolve. In other episodes from this lesson, the study of the T-shirt sequence reinforces the opportunity to learn that there is more than one correct way to express the same relationship between two variables. This is a common learning opportunity arising from the six lessons: students realizing that two or more differently looking arithmetic expressions are equivalent and mathematically model the same realistic situation.

METHODOLOGICAL ISSUES AND PROSPECTIVE

The goal of this report was to describe how we have proceeded in the analysis of learning opportunities around the construction of algebraic thinking in the context of classroom large group work with other students and during problem solving. The identification of mathematical learning opportunities in episodes, which is in turn related to the identification of LOEs, is theoretically grounded on the recognition of opportunities as being influential in the promotion of mathematical learning. We assume that the awareness of learning opportunities in the classroom discourse is a condition to use them for learning. Thus the ideal of identifying students' learning is being first approached through searching learning opportunities. It is our position that learning becomes more or less fostered depending on the participation in LOEs and the exposition to learning opportunities. Consequently, learning can be understood as an increase in the exposition to such opportunities.

What are the criteria for us to claim the existence of certain learning opportunities? Even though we have not always evidence of students taking advantage of particular opportunities, and experiencing processes of learning something new (Jose, Gabriel, Maria... for instance, may be already aware of a mathematical knowledge and they may be merely reminded of it by another participant), we sustain the idea of identifying potential opportunities for learning as useful. This option brings up the substantial problem of reaching a multiplicity of learning opportunities, some of which do not necessarily contribute to the construction of mathematical learning. We see the current final set of multiple mathematical learning opportunities as the starting point for the second part of our study. We plan to explore connections

between learning and learning opportunities. So far, our analysis of classroom episodes has consisted of two main dimensions that have been articulated through the identification of interactional codes and learning opportunities. It is interesting to include a third dimension that helps examine the ways in which the students are supported in their mathematical learning by means of the exposition to certain social environments. Such prospective might serve as a basis to more precisely conceptualize LOEs, as well as to construct a typology of mathematical learning opportunities.

PLACE OF THE CONVERSION OF SEMIOTIC REPRESENTATIONS IN THE DIDACTIC FRAMEWORK R^2C^2

Maryvonne Priolet

Université Reims Champagne Ardenne, France

This article is about the place that I have allocated to the conversion of semiotic representations at the heart of the didactic framework R^2C^2 . Ten 3rd year primary school classes were involved in this study: eight in France and two in the Czech Republic. This framework was tested in four of the eight French classes.

After having presented the theoretical framework, I describe the methodology, based essentially on the analysis of professional practice of teachers, using video recordings of sessions as well as interviews. Then I try to highlight to what extent the principle of conversion of representations can encourage the conceptualization process among pupils.

INTRODUCTION

Whereas in more than three classes out of four, the teachers declare that at least once a week they present their pupils to numerical problem solving (Priolet, 2000), the pupils' competences in this field remain very variable. This has also been reported by the General Inspectorate of National Education (IGEN, 2006).

Pupils' recurrent difficulties in learning numerical problem solving led me to focus this research on the observation and analysis of the teaching practices in primary school classes and on the implementation of a didactic framework.

THEORETICAL FRAMEWORK

As soon as I started this research on numerical problem solving in primary school (Priolet, 2000), I focused on the teaching practises. I wondered to what extent the pupils are effectively exposed to the conversion of semiotic representations, which is considered fundamental by Duval (1995) in the comprehension process enabling pupils to access mathematical objects. All mathematical objects, including numbers, are not directly accessible by perception or observable with instruments; their accessibility is possible by semiotic representations belonging to a system with its own meaning and functioning constraints (Duval, 2001).

Semiotic representations can be discursive (e.g. native and formal language) or non-discursive (e.g. figures, graphs, charts). Duval classifies these representations in registers and, according to him, the originality of the mathematical activity lies in the coordination of at least two registers of representation at the same time and in the possibility of changing between them.

He defines *conversion* as a transformation that consists in changing registers while keeping the same objects and *treatment* as a transformation within the same register. He considers as fundamental for the construction of a concept the ability to perform conversions between several registers of semiotic representation of the same mathematical object (Duval, 1995).

Each time a change of register proves to be necessary or that two registers must be mobilised simultaneously, we face a rise in the number of pupils' failures or blocks, at all teaching levels (Duval, 2006).

Novotná (2003) observed that if the graphic language is not presented previously by the teacher, it is rarely used by the pupils. She showed, in particular, the help that a chart can bring to problem-solving (Novotná, 2001). However, she warns against the risk of imposing such support, given the fact that individual differences exist in the manner of treating semiotic representations.

Apart from Novotná's work, my theoretical framework is also based on Glaeser's work (1973) which insists on the necessity of effectively putting pupils in situations to search solutions to a given problem. Of importance is also Brousseau's theory of didactical situations (Brousseau, 1990), in particular for managing the teaching and learning experiences by the teacher and for the concept of devolving some decision making to students. My approach also encapsulates contributions from the cognitive psychology by Vergnaud (1990) on the importance of the categorisation of problem-situations according to the mathematical relations at stake.

R²C² DIDACTIC FRAMEWORK AND RESEARCH HYPOTHESIS

This research on learning and teaching mathematical problem solving in primary school leads me to venture the following hypothesis.

The learning of numerical problem solving can be enhanced if the pupil is exposed to four principles: P1: Looking for solutions to problems; P2: Networking of knowledge; P3: Conversion of semiotic representations; P4: Categorisation of problem situations.

The teaching of problem solving, when putting together these four principles and looking at their devolution to the pupil, may contribute to teachers' professionalization. It may develop teachers' reflective attitude on how they teach problem solving and especially on how they devolve to the pupil the responsibility for solving the problem.

Linking to the various theoretical works mentioned, and in order to test my research hypothesis I have conceived and tested a didactic framework given the acronym R²C² (Research, networking (Réseau), Conversion, Categorization). This framework is based on the implementation of the four principles (P1, P2, P3, P4), under the conditions of their coexistence, of their regularity and of their devolution to the pupil.

This article aims to analyse and describe more specifically the implementation of principle P3.

EXPERIMENTATION

Ten third year primary school classes (eight in France and two in the Czech Republic) were involved in this study. The experiment followed three main phases:

In the first stage, at the start of the school year, I observed and analysed problem solving sessions laid out by ten teachers. The observations of these sessions, known as initial sessions, were filmed (type n°1 recording). Then, all the pupils were given a pre-test made up of 12 numerical problems.

In the second stage, from January to March, four classes in France selected randomly among the eight were exposed to the didactic framework R^2C^2 . Problem-solving sessions were carried out in these four classes that formed the experimental group. These were also recorded (recording n°2).

The four other classes, which formed the control group in France, continued the work planned by the teacher within the framework of their usual problem solving teaching. At the end of the academic year, the pupils were exposed to a post-test exactly identical to the pre-test.

Simultaneously to this experimentation in French classes, with the help of Jarmila Novotná, I extended the observations to include two Czech classes. The pupils in both classes were given the same test (translated into Czech language) as the eight French classes.

Artefacts introduced in the operationalization of the R^2C^2 framework

The implementation of the R^2C^2 framework includes the introduction and use of artefacts denoted «reference boxes» and «reference dictionaries». They lead teachers to implement the four principles (P1, P2, P3 and P4) in the teaching of the pupils.

Each pupil in each experimental class has a reference box that can be either an envelope, an exercise book or a cardboard box. The reference boxes are intended to support, without imposing it, the linking of verbal statements and various representations; operation, drawing, graph, text etc., in order to foster the conversion from one register to another (Duval, 1995). The basis of solved problems which will grow little by little will link to networking and categorisation activities. Then, each reference box becomes a reference for each class of problems (Vergnaud, 1990).

Another artefact, the reference dictionary was used in organising teaching and learning, as conceived by Brousseau (1990). A dictionary was developed collectively in each of the four classes of the experimental group as verbal difficulties arose.

DISCUSSION

Description and analysis of usual problem-solving teaching in the 8 classes in France. The place of the conversion of representations.

The observations of Type 1 sessions, as well as the self-reflective interviews, show that pupils were mainly exposed to the use of the textual and numeric register, registers between which conversions occur when doing problem solving. The iconic

register was essentially mobilised during correction stages, under the teacher's control. It was introduced by the teachers when collecting pupils' work, or by a pupil showing at the board the iconic representations traced in his/her book during the resolution of the problem. In conclusion, and in the limits of this experiment, it turns out that teachers endeavour most of the time but not exclusively to put their pupils in a position to look for solutions to problems.

The responsibility for linking students' previous knowledge as well as for the conversion of representations mainly belonged to the teacher. However, during the sessions, I noticed that not every teacher practiced at the same time the networking and the conversion. No categorisation activities were noticed during these observations.

After the analysis of the usual problem solving teaching practices of these eight teachers I focus on the implementation of the P3 principle in the didactic framework R^2C^2 in the four classes of the experimental group.

Interpretation of the implementation of the principle of the Conversion of Semiotic Representations (principle P3 of the didactic framework R^2C^2)

In the Type 2 sessions, due to the implementation of the didactic framework R^2C^2 , I notice that it is the teacher who defines the rule and it is the pupil who has got the responsibility to choose what to do during the searching stage: drawing, writing, directly calculating. Through the use of reference boxes pupils are invited to use the iconic register, on the one hand to elaborate on a drawn representation of the situation described in the problem title and on the other hand, to schematise and model the situation. Before coming back to more general considerations on the implementation of principle P3, I will deal with the recourse to drawings and then the recourse to the graph drawing.

Resorting to a drawing:

Pupils are in presence of a textual utterance which presents a situation to be solved. In referring to work from learning psychology, I consider that this situation, even in the case where it is about a daily life situation, must be reconstructed by the reader in order to elaborate a mental representation (Johnson-Laird, 1983). Resorting to the drawing seems to force the pupil to do a step by step reading of the textual utterance, or several readings which could suggest a better identification of the data. We concur with Novotná (2003) who develops the view point that the construction of the mental representation of the situation could be facilitated by resorting to a drawing which would allow less work for the memory.

Resorting to drawn graphs:

If one is interested in the representation of diagram types in the Vergnaud sense, one can consider (Novotná, 2003), that resorting to a drawn graph is going to facilitate the

heuristic process thanks to the manipulation, in written form, of mathematical relationships.

In this didactic framework, the material form of the reference box a blank box planned for a diagram, invites the pupil to produce it. According to Novotná (2003), without a previous presentation by the teacher, the graphic language is rarely used by pupils. In the R^2C^2 framework, the use of the artefact reference box makes the appeal to the recourse to this kind of conversion explicit. Nevertheless, I drew the teachers' attention to the possibility to run the risk, as Novotná points out, to compel the pupils to fill in all the squares of the reference box.

After having considered more in detail the traces belonging to the iconic register I consider the implementation conditions of the P3 principle.

Problem 3 (translated):

Last Friday, the president of the Amicale Laïque association came to give us sweets to congratulate us with the good results we had at the Foulées Vertes. On the package was written '100 sweets'. That day, three pupils were absent from our class.

In order to share the sweets equally between all the children present on that day, how many sweets should we give to each pupil?

Problème n°3 :
Vendredi dernier, le président de l'Amicale Laïque est venu nous donner des bonbons pour nous féliciter de nos bons résultats aux Foulées Vertes. Sur le paquet, il était écrit 100 bonbons. Ce jour-là, il y avait 3 absents dans notre classe.
Pour partager équitablement les bonbons entre tous les enfants présents ce jour-là, combien fallait-il distribuer de bonbons à chacun ?

		5 → la réponse $\begin{array}{r} \times 20 \\ \hline 100 \end{array}$	pour partager équitablement il faut donner 5 bonbons à chacun des élèves						
	$\left. \begin{array}{l} ? \\ \times \\ ? \end{array} \right\} = 100$	$23 - 3 = 20$ $\dots 5 \times 20 = 100$	Il faut distribuer 5 bonbons à chacun						
	<table border="1" style="display: inline-table; vertical-align: middle;"> <thead> <tr> <th>a</th> <th>b</th> </tr> </thead> <tbody> <tr> <td>1</td> <td>?</td> </tr> <tr> <td>20</td> <td>100</td> </tr> </tbody> </table>	a	b	1	?	20	100	erreur de calcul 	il fallait distribuer 5 bonbons à chacun
a	b								
1	?								
20	100								

Figure 1: Resorting to the conversion of representations : Answers from three pupils in the same class of the experimental group.

I have chosen to illustrate the variety of the recourse to conversions of representations (calculation, drawing, diagram, text), through the work of three pupils, selected randomly, among those who had completed all the squares of the referent box (Figure 1). This selection must not hide the fact that the instructions in relation to the use of the artefact reference box specify that it is not imperative to fill in all the squares and then the recourse to the set of mentioned registers is not needed.

The regularity imposed in the use of reference boxes aims also to induce regularity in linking several registers. This regular implementation condition, mixing a variety of treatment tasks and register conversions, is mentioned by Pluvinaud (1998). I am interested in the place of these operations in learning about problem solving. Duval (1995) points out the fundamental role played by conversion tasks between several registers of semiotic representations for the same mathematical object when constructing a concept.

The film recordings n°2 show a more personal involvement from the pupils, some involving themselves more in the conversion of representations, others not resorting to it because they proceed directly to problem-solving using an expert process. Others still feel authorised to use drawings or graphs. These observations show how the teachers take into account the conversion of representations (P3 principle) in the devolution to the pupils.

It also seems to me that the implementation of the P3 principle can have influence on the didactic contract (Brousseau, 1980) insofar as the pupil is now exposed to different representation possibilities accepted by the teacher. The analysis of Type 1 sessions revealed homogeneity in the initial practices of teachers, who demanded going through the normal presentation form solution/operation. This form, centred on a unique approach of resolution based on resorting to calculating mode, seems to me to encourage the use of the arithmetical operational technique during the learning stage (Priolet, 2008).

One can then consider that the fact of establishing, during Type 2 sessions, the use of different registers of representation modifies the didactic contract. However, the analysis of the documents that have been filmed, shows that some pupils produce an iconic type representation after having given the solution to the problem. One can see here again the effect of the didactic contract. The pupil wants to respond to the request to use different registers and fills in all the available boxes. It seems essential to consider, referring to Vergnaud (1997), that these drawings or graphs have a transitory status and that they are meant to be gradually forgotten as problems get mastered.

MAIN RESULTS

The quantitative analysis of the effects of the R^2C^2 didactic framework implemented in the four classes of the experimental group in France has been carried out by comparing the results of the pupils belonging to the control group to those of the pupils belonging to the experimental group during a pre-test and a post-test made up

of the same twelve numerical problems. There were six problems concerning simple proportionality, one problem concerning multiplicative comparison and five problems requiring intermediate calculations. The score of each pupil was calculated by taking the number of attainments into account.

		Number of Pupils	Total score		Average		Difference
			Pre-test	Post-test	Pre-test	Post-test	
Groups	Control	65	304	364	4,68	5,60	0,92
	Experimental	72	315	457	4,38	6,35	1,97

Figure 2: Results from pre- and post-tests.

The difference (1,05) between the averages obtained at the pre-test and at the post-test (1,97 for the experimental group and 0,92 for the control-group) is significant:

$$t_{\text{Student}} = 2,94 > 2,61 ; \text{ddl} = 135 ; p < 0,01.$$

This study showed convincing results: the performances noticed in the control group increase by about one more problem solved, whereas the ones observed in the experimental group increase by about two more problems solved.

The pupils in the two Czech classes, not exposed to the R²C² didactical framework, have also been given the same test with twelve numerical problems.

For these two Czech classes, the results of the test are better compared to those of the French experimental group (7,67 vs 6,35).

CONCLUSION

The main qualitative and quantitative results which emerge from this study come to reinforce the hypotheses I have stated.

The possibility of the possibility of using reference boxes encourages the pupil to the conversion (principle P3) between the textual, numerical and iconic registers, and thus favors the production of representations. I consider these productions, associated with a reading of the text and the drawing of diagrams, allowing to visualize the mathematical relationships at play, facilitate the construction of a mental pattern (Johnson-Laird, 1993).

The introduction of the artefact reference box makes it possible to consider a double networking: the networking of problems, according to underlying mathematical relationships (Vergnaud, 1997), which leads the pupils to an activity of categorization; the networking of diagrams which aims at the drafting of a model of these mathematical relationships. I can consider that the principle P3, thanks to the categorization and the establishment of a model, constitutes an element allowing to generate the process of conceptualization among pupils.

It should be mentioned that the results of the experimental group in France are inferior to those of the two Czech Republic classes observed in the framework of

ordinary practices and not exposed to the R^2C^2 didactic framework. The pupils of the two Czech Republic classes considered it natural to work with similar problems, to try to use the register of representation best adapted to their problem solving strategy, to break down a new problem in several simple sub problems which they already knew how to solve (Priolet & Novotná, 2007). I notice similarities with the principles of the R^2C^2 didactic framework implemented in the four classes of our experimental group in France. That can explain the significant improvement compared to the four classes of the control group. However, the pupils in the French experimental group have only been exposed to the four principles of the R^2C^2 didactic framework for three months, whereas the practices observed in the Czech Republic were implemented each year and regularly throughout the school year. I attribute the superiority of the performances of the two Czech Republic classes to the long-term systematic work undertaken since the start of compulsory schooling.

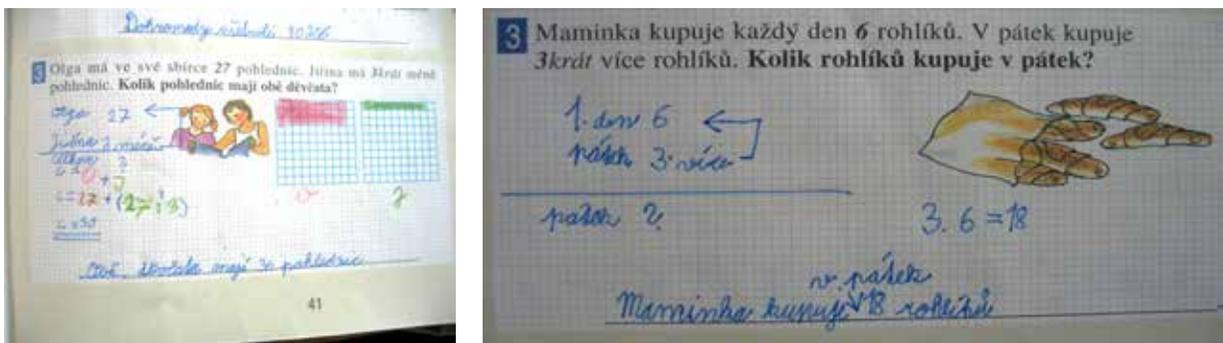

Figure 3: Czech Republic exercise books showing that pupils refer to different semiotic registers

The example below is extracted from a reflective interview and shows that the implementation of the P3 principle (the conversion of representations) had effectively brought to the teachers' awareness the consequences of the use of the presentation «solution-operation» that they imposed on their pupils. Indeed, this normal presentation, limited to textual and numeric registers leaves little place for conversions between registers.

Teacher 5: I gave up the rigorous presentation «solution – operations» because I became aware that they thought they had to do operations with the numbers and that it translated by an operation and not necessarily by the right answer.

In conclusion, by a systemic approach, I can consider that the implementation of the R^2C^2 didactical framework favoured the process of conceptualization among pupils, however on approval that the principles are devolved to the pupil.

THE USE OF ICT TO SUPPORT CHILDREN'S REFLECTIVE LANGUAGE

Eva Riesbeck

Malmö University, Sweden

The importance of language and learning with different artifacts in mathematics education is the focus in this paper. The language in the communicated situation or activity can be understood as a means of constructing meaning. The importance of context, different artifacts and communication in the teaching of mathematics is visualized through analyses of preschool, year 1 and year 2 in students' work with numbers and place value. Through participation and interaction, through dialogue and using different kinds of artifacts, students develop new patterns of meaning that may facilitate their learning of mathematics.

INTRODUCTION

My interest is in how students in school learn or are taught number sense and place value problems. A socio-cultural perspective (Säljö, 2000; Vygotsky, 1986; Wertsch, 1991) on human development, reasoning and arguing calls for the use of linguistic and physical tools to analyze and make claims about events in the world. From this, I am interested in how people reason and argue and how they quantify and mathematize. In particular, how mathematizing and reasoning are connected when making a claim or by proving a point in a conversation involves people moving between everyday discourse and analytical languages.

In the new Swedish curriculum (Skolverket, 2011), students are expected to formulate and solve problems with mathematics, to formulate strategies and methods, to use and analyze mathematical concepts and relations between concepts and to use the language of mathematics in order to explain and justify what they have done. To see how different artifacts and communication influence the gaining of this knowledge is important for teachers.

Learning and knowledge about the surrounding world begins in what can be called the life world. Nevertheless, the dissonance between the environment inside and outside school is very distinct, especially with regard to mathematics as a school subject. Consequently, students' interpretations of real life problems may become an obstacle for their learning in mathematics. The focus of this paper is how the language and physical tools in the communicative situation or activity could be understood as leading to the construction of meaning. The importance of context, tools and communication in the teaching of mathematics is visualized through analyses of first and second grade students' work with number sense, place value and different tools.

In a socio-cultural perspective, the question is about how knowledge and information are learned and how this learning changes in new surroundings (Lave & Wenger, 1991). All activity, including the mental processes of thinking and reasoning, is

mediated by tools and signs. Knowledge is developed through the cultural tools that are in the society (Vygotsky, 1978). Students in school have an ability to use artifacts that come from the real world. The artifacts are central because they change relationships between people and the world around them. For example, when teachers are introducing signs and symbols in the teaching of mathematics they try to mediate from a reality to a mathematical model. The teachers use language, such as pictures, symbols, signs, words and so on, when working with physical tools in order to get students to understand mathematical modeling. However, in spite of the use of these common artifacts, students have difficulties learning mathematics, because they are not able to use their knowledge and see mental pictures. In this study I describe different artifacts and discuss how students mediate with artifacts and with each other. In a socio-cultural perspective the mediation is very important. Therefore, the research question is: how does the interaction between students and their choice of language change when they use different artifacts in mathematics?

DIFFERENT KINDS OF ARTIFACTS

Wartofsky describes three different kinds of artifacts which are used in learning. These are categorized as primary, secondary and tertiary (Wartofsky, 1979).

Primary artifacts can be tools like axes, clubs, hammers, pins, computers, and mobile phones. They can be used directly in production processes and are based on utilizing people's strength to solve different kinds of problems. However, understanding how to use those artifacts involves understanding the special surroundings where they are used. In this way, they help people to understand their world and to participate in the life that they live. In schools, there are many primary artifacts, usually called concrete materials that are used in the teaching and learning of mathematics. These include stones, bottle tops and Cuisenaire rods. Primary artifacts can be used without knowing how they help to complete the task that they are used for. They can also be talked about without knowing how they perform the teaching and learning job that we expect of them. However, this complicates the teaching and learning process when the purpose of the tools remains unspecified.

In the present day and age, it is necessary to understand how to use tools such as the computer and the Ipad in order to learn how to live in the world. Thus, communication and knowledge change with these new artifacts. To use a mobile phone, the user has to understand how to handle it and to do this he/she has to study the instruction manual. This requires having the knowledge to comprehend what is read and then translate this into an understanding of how to use the mobile phone. Secondary artifacts are tools that provide models for how to use tools and how to think about how to use those tools. They are externally embodied representations that collect and describe information. Secondary artifacts control decision making and planning processes. There are many of them in everyday life, such as recipes, drafts, designs and ways of classifying the world. In mathematics education, secondary artifacts are things such as mathematics textbooks. The pupils learn how to study a math problem from the textbook and also how to solve it.

However, when primary and secondary artifacts are used at the same time, the result could be that the teacher is teaching in one way and the students are learning in another. This can be seen in the following example.

In this example, the teacher provides a primary artifact such as base ten arithmetic blocks which the students are expected to use to illustrate whole numbers and decimal fractions. The instruction is:

2,1

1,9

0,8

0,01

1,25

Use the material to represent these numbers, then have a friend write the amount that they see as numbers with decimal fraction parts. Discuss!

Write your own five numbers and let a friend put it in a place value table. Discuss!

The students listen to the teacher and try to translate the information into specific actions. To do this, they must position the material (the primary artifact) appropriately, study the written instructions (the secondary artifact) and discuss what they are doing. In the second part of the activity, they still use a secondary artifact, the written instructions, but this time they produce new numbers which a friend must then illustrate with the blocks. The exercise could be changed so that the students would need to use new tools. For example, the students could use an empty number line on which they would have to put out their own numbers and find the difference between the numbers. Alternatively, they could work with computers to construct, change and compare the numbers and talk about what happens and why. When the students have been using a variety of tools and language they can start reflecting and talking about their knowledge of decimal fractions (Riesbeck, 2011).

Tertiary artifacts are tools that help people to construct new knowledge. They support people's reflection and communicating skills. In order to learn mathematics students need not only to see and translate information but to know how to mediate knowledge with tertiary artifacts so that they develop their thoughts and representations of their understandings. Thus, it is important for teachers to understand how to move from having students use primary artifacts to developing their reflective skills from using tertiary artifacts.

For example, if students can construct geometrical figures using a computer program, they can think and talk together including critically discussing issues as they arise and finding new forms of arguing. Communication and language are very important to all human learning and it is through new language and tools we develop new knowledge. Through using language as a tool human beings can understand and construct new knowledge (Säljö, 2005).

Wartofsky (1979) suggests that people are dependent on artifacts in their doing and thinking. Primary artifacts help when people want to have a better understanding of the physical meanings connected to the world. On the other hand, secondary artifacts helps us in our communication and understanding of the world and the physical tools and the tertiary artifact is a thinking and creative tool.

THE DIFFERENT LANGUAGES CONNECTED TO THE ARTIFACTS.

The descriptions of the three kinds of artifacts suggest that all artifacts are needed for learning but the tertiary artifacts have extra significance, because of the sort of language associated with them, reflective language, and how this contributes to learning. When mathematics education expects students to learn only with books the language and thinking are connected solely to that of the secondary artifacts. Students can work with primary artifacts, such as the book doing the same type of exercises without thinking or reflecting (Johansson, 2005). They can become familiar with the problem in the textbook, if they can translate the text into actions, thus using the textbook as a secondary artifact.

However, when the goal is to learn mathematics, students need to talk about what they have read and they need to understand the new knowledge specified in the curriculum. In this case, it is necessary to work with tertiary artifacts. Pimm (1987) suggested that in any mathematics classroom there are many different languages. Students use conversational language which they have learnt at home or with friends. Students will also use a more mathematical language when they talk to each other while using concrete materials to learn and do mathematics. There is also the symbolic language of mathematics being used when students have to use concepts from mathematics and to argue and talk about how to solve the problems. There is also evidence of a reflective language when the students in the dialogue discuss and answer questions about why a specific answer is correct or if the solution is sufficient (Verschaffel, 2002).

The use of different artifacts will affect what languages are used. As Vygotsky (1986) put it, thought and language is a parallel project. In this perspective knowledge develops in interaction between people and between people and tools (Kozulin, 1998; Vygotsky, 1978). A dialogic nature to discourse, where students learn to question, argue, explain, justify and generalize will be achieved through the models provided by teachers and others in interactions with different artifacts (Riesbeck, 2008). Through using different kinds of reflecting questions, classrooms of mathematical inquiry which support language and thinking can develop (Hunter, 2007). Therefore, when students learn mathematics they also will use different languages depending on what kind of mediating tools they use.

The concepts of context, mediation and artifacts are central to the sociocultural perspective. The concept of context can be described as being the environment where the action takes place. Mediation implies that human beings interact with external tools in their perception of the world around them. Linguistic as well as physical artifacts are created by people to perform actions and solve problems. Using semiotic tools one can demonstrate how a linguistic element is connected to its meaning.

The semiotic triangle is made up of concept, symbols and objects which illustrate the possibilities for mediation. The semiotic triangle is used when analyzing interaction of the students when they are talking about numbers and place value.

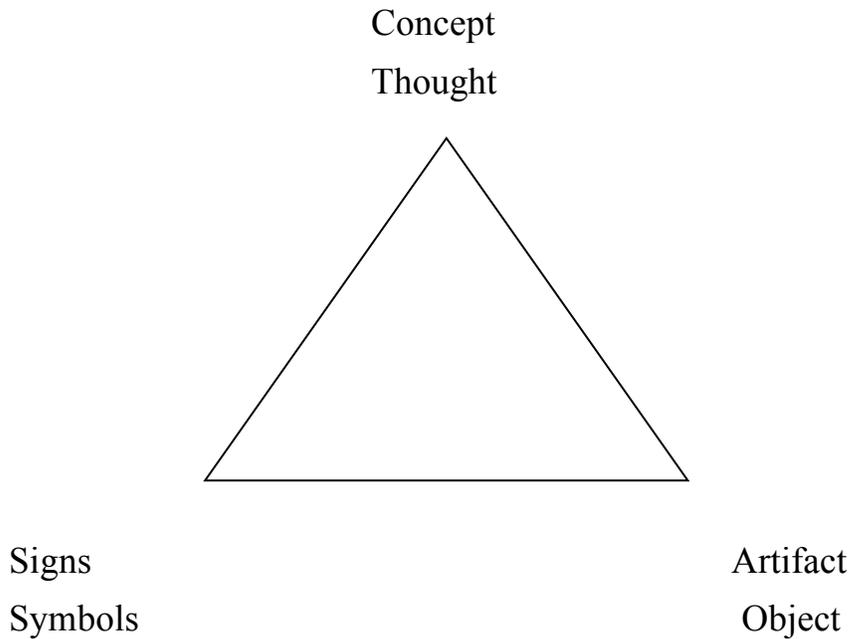

Figure 1. The semiotic triangle.

The semiotic triangle (Johnsen-Høines, 2000; Mellin-Olsen, 1984; Ogden & Richards, 1923) helps us to mediate from all three angles and is a tool to analyze the material in this study. This means that the teacher choose an artifact for the children when they for example work with blocks on the computer to understand place value and you analyze what kind of symbols or concepts there are when they are talking in this situation. What and in what ways are the children talking about math with different artifacts?

METHODOLOGY – THE STUDY

The study investigates the same set of pupils and their teacher as they moved between grade 0 (preschool class), 1 and 2 in a Swedish school for three years. Audio and video recordings were used to collect the discussions in interactive situations between teacher – children or child - child. In this paper a small part of the study is going to show how different tools can support different languages.

The children were six years old when the study began. The recorded lessons were about numbers and the teacher stood at the front of the class and used an interactive whiteboard. The sign 5 appeared on the interactive white board. The teacher and the children talked about this number five and the children told the teacher about pictures of different things. They went up to the board and moved pictures like rabbits, dogs and so on whilst they counted one, two, three, four and five. Then they sat in groups with concrete material talking and manipulating the material. The teacher followed this up by returning to the interactive whiteboard to show a film about the number five. During this year when the children were in preschool class, lessons using the interactive whiteboard and the teacher having a dialogue with the pupils about numbers appeared every week. The mediating process was about numbers and

pictures and using the interactive board and the language was mostly everyday language.

In the following year when the children were seven years old, the teacher started one lesson about the little zero using the interactive board. The transcript is an excerpt from that lesson. In the transcript, L stands for the teacher whilst E stands for various pupils.

- L: Do you remember the book we read about the little zero and the pictures we looked at? How was the little zero? How did the little zero feel in the beginning? Tell me!
- E: It felt very lonely.
- L: How did the little zero feel when he had said hello to everybody in the houses? What did all the other numbers say to him?
- E: That he was nothing.
- E: You are only a zero.
- L: What happened later on? Where did the little zero go? The zero walked away to places where none of the other numbers could go. Where did the zero go?
- E: Into the cave.
- E: The zero was so upset.
- L: Why?
- E: He could not find a zero so he could count his money.
- L: The zeros that could stand after the numbers so we can find big numbers. If a number stands for himself he isn't worth so much. But if you put several numbers together they can be worth much.

In the first part of the teacher- pupil interaction the language is about the real world and they are talking about feelings for the little zero. But here the teacher works further on and begins talking about where to put the zero and what can happen with the value of the money. They are on their way to a more mathematical language. They were later on in the lesson sitting in front of the computer two by two, talking about where to put the zero and what numbers are in this place value table. Here they use a mathematical language.

In another situation the teacher and the pupils are working in a program showing blocks of one and blocks of ten. The pupils put the numbers under right block.

- L: I put in ones and tens . What is the number?
- E: The number is three.
- L: Yes if you add it together. But I mean if you write it together as one number. What is the number?

- E: The number is twelve.
- L: How many tens are there in twelve?
- E: One one and two tens.
- L: But you can also write another number with those numbers.
- E: Three
- E: 21
- L: How many tens are there in twenty?
- E: Two
- L: How many ones?
- E: One

The teacher has several of this kind of lessons, interacting with the interactive whiteboard and the students. The pupils now are on their way to the language of mathematics. They get some help from the program on the interactive board and the discussions between the teacher and the pupils. In another lesson, the children were sitting in pairs in front of the computer working in the same program as they had done together with the interactive whiteboard but now they are going to use addition and subtraction. The numbers are $56+23$. First they find 50, say that it is five tens and take five ten blocks on the computer to show. After that you can see the pupils say twenty and put two tens on the program to show each other and then they take in six and three unit blocks. They have a paper and they have to write down the answer and say how they got to the answer.

In the program on the computer the pupils show how they place the numbers under the right place value and talk about it. The different kinds of artifact change the pupils' use of language.

Another example from the class is when the pupils use Ipad. In pairs, they had to explain place value using mathematical words and using the program on the computer and then they are going to film with the Ipad. They practiced this together several times and when they were ready they used the Ipad as a video camera and filmed each other. This communication had to be perfect, so they worked hard and filmed each other several times until they thought it was good enough to show to the teacher and the rest of the class. The next transcript illustrates how one boy, was discussing place value in relation to addition and subtraction on the Ipad as the teacher was watching.

- E: Hello, my name is Adam and I will show you how I've learnt place value.
- E: The addition is $78+21$.
- E: I first take seven tens and then eight ones and then I take two tens and then it is 98 and after that I add one one and then it is 99.

- E: The subtraction is 49-36.
- E: First I take four tens and then nine ones and then I take away three tens and then I have 19 and after that, no I don't know. We do it again!
- L: But you have 19 and you should take away 6 ones.
- E: But I made it in a wrong way.
- They do it again. Another pupil is counting and talking in front of the Ipad.
- E: I first take four tens and then nine ones and after that I take away three tens and then it is 19 and then.....
- L: And then you have to take away six ones.
- E: But I never put them in there.
- L: You had 49 from the beginning and take away three tens.
- E.: And take away six ones.

Most of the students were doing this in pairs and they were filming until they were convinced that everything was perfect. To use an Ipad filming the pupils' understanding of place value is one step to the tertiary artifact when the pupils learn to reflect on what they know and why they know it.

The different artifacts, interactive board, computer and Ipad, that the teacher used showed that the pupils were in different contexts and their language changed when they used different kinds of artifacts. If you use tools from daily life contexts or from mathematics contexts you get different language and learning. From a mathematical perspective the pupils show that they share the mathematical language and understanding of the signs and symbols of mathematics and they can in their talking use tens and hundreds.

DISCUSSION

If teachers are to support students using more abstract language and thoughts in mathematics, then there is a need to understand the impact of different artifacts in the classroom. When teachers use primary artifacts like concrete materials and computers, they have to think of the dialogue they want to develop. If the material is to be translated to a secondary artifact, then the students need to learn how to translate from the concrete material to the mathematical concepts. They also have to learn to write and reflect on their knowledge and ask questions like why is this answer right, or describe the process they have used and their decisions for using a particular model. The students must also actively engage with the language and the artifact at the same time through dialogue. Then it is possible for you to say that you have started to learn mathematics. Figure 2 sums up how using an artifact can support students developing their knowledge of mathematical concepts. Before arriving in the middle it is necessary to know things from the other blocks.

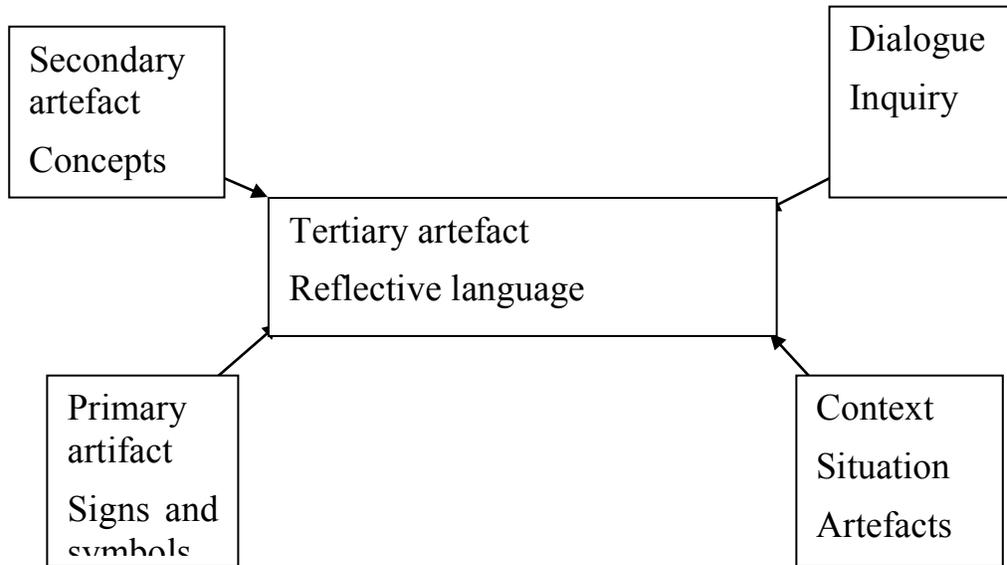

Figure 2. The reflective language as a tertiary artifact

In the middle is the tertiary artifact where the teacher and the students are reflecting and talking with the mathematical language in dialogue. Here they use signs, symbols and concepts from mathematics. In this study one can find the program the teachers and pupils are working with to support the reflective language.

The students are going to develop a language not to talk about their doing but talking about why the process or the product could be like that and they also document their new knowledge in mathematics.

Use of a tertiary artifact can be recognized in the qualities of language, tools and knowledge both from having a picture from the everyday world and also from the mathematical sphere. In this context, quality means that students communicate around a sign, a concept and a situation by looking critically at it, putting forth arguments for and against and document their own learning. To further their acquisition of new knowledge develops into an issue of learning to apply abstract and complex intellectual and practical tools, and to accomplish this the more essential it becomes to engage in communicative practices with different tools (Riesbeck, 2011).

A COMPARISON OF IRISH AND ENGLISH LANGUAGE FEATURES AND THE POTENTIAL IMPACT ON MATHEMATICAL PROCESSING

Máire Ní Ríordáin

National University of Ireland, Ireland

This paper presents some insights into the syntactical and semantic differences between Irish and English, and the potential impact on mathematical processing. Previous research suggests that learning mathematics through the medium of Irish at primary level education may enhance mathematical understanding (Gilleece, Shiel, Clerkin, & Millar, 2011; Ní Ríordáin, 2011). A key question being addressed here is whether characteristics of the Irish language potentially have a different effect on students' mathematical processing of text. No examination has been undertaken on the Irish language and its potential impact on cognitive processing. This initial analysis is striving to provide some useful insights for further investigation.

INTRODUCTION

Recent studies conducted in Ireland into Irish-medium education have demonstrated positive cognitive advantages in relation to mathematical and English reading attainment in comparison to students who attend all-English medium education (Gilleece, Shiel, Clerkin, & Millar, 2011; Ní Ríordáin, 2011). These investigations accentuate the positive benefits that can be reaped from being bilingual and are consistent with international findings in relation to the benefits of bilingual and immersion education (e.g. Bourton-Trites & Reeder, 2001; Clarkson, 2007; Genessee, 1987; Turnbull, Hart, & Lapkin, 2000). For Gaeilgeoirí (students who learn through the medium of Irish) in the transition from primary (Irish-medium) to second level (English-medium) mathematics education a significant relationship exists between their performance on the mathematical word problems through the medium of English and their Irish language proficiency (Ní Ríordáin, 2011). Gaeilgeoirí with high proficiency in both languages, and those who were dominant in Irish, performed mathematically better than their monolingual peers. This suggests that learning mathematics through the medium of Irish at primary level education may enhance mathematical understanding. A recommendation arising from my study was to review the Irish language with respect to the effect on the understanding and processing of mathematical text. This paper presents an initial analysis of the Irish language and its differences with the English language in relation to some grammatical features.

THE ROLE OF LANGUAGE IN MATHEMATICS

Language and communication are essential elements of learning and teaching mathematics (Gorgorió & Planas, 2001) and thus the language we initially learn

mathematics through will provide the foundations to be built upon and developed within that language. Language is employed as a communication tool and facilitates the transmission of (mathematical) knowledge. We consider mathematical language as a distinct ‘register’ within a natural language e.g. Gaeilge or English, which is described by Halliday (1975, p. 65) as “a set of meanings that is appropriate to a particular function of language, together with the words and structures which express these meanings.” Each language will have its own distinct mathematics register and ways in which mathematical meaning is expressed in that language.

Vygotsky was one of the earliest theorists to begin researching the area of learning and its association with language. He concluded that language is inextricably linked with thought – “the concept does not attain to individual and independent life until it had found a distinct linguistic embodiment” (Vygotsky, 1962, p. 4). Although a thought comes to life in external speech, in inner speech energy is focused on words to facilitate the generation of a thought. If this is the case, it raises an important question – does the nature of the language used affect the nature of the thought processes themselves? The transition from thought to language is complex as thought has its own structure. It is not an automatic process and thought only comes into being through meaning and fulfils itself in words. Thought is mediated both externally by signs and internally by word meanings (Vygotsky, 1962). Communication is only achieved by the thought first passing through meanings and then through words. Therefore, language will play a significant role in the processing of mathematical text and the development of understanding (Hoosain, 1991).

Mathematics is not “language free” and due to its particular vocabulary, syntax and discourse it can cause problems for students learning and the development of understanding (Barton & Neville-Barton, 2003). A number of mathematics education researchers have identified characteristics of the English language that may impede mathematical learning (e.g. Austin & Howson, 1979; Durkin & Shire, 1991; Rudner, 1978; Wareham, 1993). In her review article, Galligan (2001) highlights the differences between Chinese and English in terms of vocabulary, word-order, use of prepositions and other grammatical features, and their impact on the understanding and processing of mathematical word problems. It raises the question of whether the language of learning impacts on mathematical ability and the processing of text. Other studies have highlighted a Chinese language advantage in relation to number sense (Fuson & Kwong, 1991), fractions (Bell, 1995) and logical connectives (Zepp, Monin, & Lei, 1987). It is important to note that when comparing mathematics processing in different languages and across different cultures, that there are many factors to consider e.g. social, political or pedagogical differences (Setati & Planas, 2012). However, what is of concern to the author is whether the Irish language potentially has a different effect on student attainment in mathematics. As Barton (2008, p.11) states “languages are examined not so much for their linguistic characteristics, but for their mathematical ones.” No examination has been undertaken on the Irish language and its potential impact on mathematical cognitive

processing – this initial analysis is striving to provide some useful *insights* for further investigation and some explanations for previous findings within the Irish context.

DEVELOPMENT OF THE RESEARCH

The research undertaken stems from the author's PhD studies (Ní Ríordáin, 2011). In this study the relationship between mathematics and language proficiency in Irish/English was examined, with psycholinguistic theories informing research practices. The findings provide support for Cummins Threshold Hypothesis in that Gaeilgeoirí with a high proficiency in both languages performed mathematically better than those dominant in one language and better than their monolingual peers. At second level education high competence in Irish was shown to facilitate the transition to English medium education (Ní Ríordáin & O'Donoghue, 2009). The study also found that Gaeilgeoirí encounter difficulties with the syntax, semantics and mathematics vocabulary of the English mathematics register (Ní Ríordáin & O'Donoghue, 2011). Gilleece et al. (2011) studied primary pupils' performance on national mathematics and English reading assessments and found that Gaeilgeoirí in 2nd class (approx. age 8) and 6th class (approx. age 12) in Irish-medium education are performing the same, or better, than their monolingual peers nationally in mathematics and in English reading.

More recent research investigating a bilingual approach (English and Irish) in third level mathematics education in Ireland, demonstrates that on average bilingual students performed better mathematically than those choosing a monolingual approach (Ní Ríordáin & McCluckey, 2012). The studies undertaken in the Irish context suggests that there are advantages associated with having two languages (Irish and English) for mathematics learning, and that learning mathematics through Irish may lead to cognitive advantages for these students. Therefore, this study goes some way in identifying some of the potential advantages that these students may experience by utilising Irish when engaged in mathematical problem solving.

METHODOLOGY

The list of differences between Irish and English are the consequences of a bibliographical review on several works around learning mathematics and language use. In particular, studies addressing mathematical processing in English (e.g. Austin & Howson, 1979; Galligan, 2001; Li & Thompson, 1981, Wareham, 1993) were of significance, as well as studies highlighting the key characteristics of the Irish language (e.g. Hickey, 1985; Mac Murchú, 1997). By utilising these studies I was provided with a foundation and framework for progressing with an initial analysis of the Irish language and its potential impact upon mathematical processing. Mathematics state examination papers (available in English and Irish) and mathematics textbooks (available in English and Irish) were analyzed in relation to the identified features arising from the literature review.

DIFFERENCES BETWEEN IRISH AND ENGLISH

In this section I summarise some of the key differences between the Irish and English languages, drawing on previous research. A comparison is undertaken in terms of some of the key features associated with the syntax and semantics of both languages.

Subordinate clauses and sentence length

In modern Irish, longer sentences are common, with the use of subordinate clauses. However, in many of the mathematical examples studied in current textbooks and state examination papers, shorter sentences are apparent. For example:

Tá poll in aice leis an mbun in umar sorcóireach oscailte d'uisce. Is é ga an umair ná 52cm.

Translation (T): There is hole near bottom in tank cylindrical open of water. It is radius of the tank 52cm.

English (E): An open cylindrical tank of water has a hole near the bottom, with a radius of 52cm.

Shorter sentences lend to an easier understanding of mathematical text and are a desirable feature (Austin & Howson, 1979; Wareham, 1993).

Topic prominence

English is classified as a subject prominent language (Li & Thompson, 1981), whereas Irish tends to be a topic prominent language. For example:

Is slánuimhir é ceann amháin de na luachanna sin.

T: It integer is one of the values these.

E: One of these values is an integer.

In this example the Irish reader's attention is drawn to the *integer*, whereas the English reader is drawn to the *value*. Therefore, the Irish reader is pointed to the topic of the sentence (Galligan, 2001).

Word order

Irish possesses the unusual word order Verb (V) – Subject (S) – Object (O), whereas English is classified as SVO (Galligan, 2001). For example:

Faigh comhordanáidí an dá phointe ina dtrasnaíonn na cuair $y = f(x)$ agus $y = g(x)$ a chéile.

T: Find coordinates the two points intersect the curves $y = f(x)$ and $y = g(x)$ each other

E: Find the coordinates of the two points where the curves $y = f(x)$ and $y = g(x)$ intersect.

The placing of information and the unknown in sentences may have an impact on the ease of processing the sentence (Galligan, 2001; MacGregor, 1993). From the above

example, English readers have a greater cognitive processing load in that they must hold in memory *co-ordinates of the two points* before reading the words *curves...intersect*. Whereas Irish readers are drawn to the key information of the sentence and this suggests a difference in mathematical processing in Irish.

Question structure

Irish has no words for “yes” and “no”. The answer to a question contains a repetition of the verb, either with or without a negative particle (Hickey, 1985). For example:

An éisteann Seán lena mháthair riamh? - “Does Seán ever listen to his mother?”

- *Éisteann* - “Yes , he does”
- *Ní éisteann* – “No, he doesn’t”

In Irish, the question word tends to be placed at the start of a mathematical sentence and the syntactic structure is simpler when compared to English. Following Galligan (2001, p.117), “English question structure is more varied, and the change from the question to the answer requires changes to word structure and verb morphology.”

Passive voice

Irish commonly uses the impersonal form (also known as the autonomous form) instead of the passive voice. For example:

Líonadh an umar le h-uisce.

T: One filled the tank with water.

E: Someone filled the tank with water/The tank was filled with water.

The word endings ‘adh’/’eadh’ are used to indicate the passive (Mac Murchú, 1997), and therefore provides students with a strong cue when engaged in mathematical problem solving. English mathematical word problems have been criticised for difficult passive constructions (see Slobin, 1973 – reversible sentences), thus impacting the processing of mathematical text.

Redundancy

Rudner (1978) found that inferential and low information pronouns are sources of difficulty and hinder students’ interpretation and understanding of English mathematical word problems. Mathematical text in Irish tends to be more wordy, thus impacting on reading time, but understanding may be clearer (Galligan, 2001). For example:

Cé mhéad soicind a bheidh caite nuair a bheidh aired 64cm ag an dromchla?

T: How many seconds will have passed when height 64cm has surface?

E: After how many seconds will it be a height of 64cm?

Dialects

There are three dialects of spoken Irish – Munster, Connacht and Ulster. Some spelling conventions are common to all the dialects, while others vary from dialect to dialect (Mac Murchú, 1997). In addition, individual words may have in any given dialect a pronunciation that is not reflected by the spelling. Therefore, Irish can be a difficult language to interpret due to variation. Accordingly Irish students may need to engage more with a written mathematical problem due to the diverse nature of the Irish language. Consequently Gaeilgeoirí may develop stronger mathematical problem skills relating to comprehension and transformation.

Alphabet

The Irish alphabet consists of (Mac Murchú, 1997):

- Vowels **a, e, i, o, u**

With an acute accent (sineadh fada) shows the length of the vowel **á, é, í, ó, ú**

- Consonants **b, c, d, f, g, h, l, m, n, p, r, s, t**

The constant **h** serves as a notation lenition (bh, ch, dh, etc.) and as the h-prefix (ha, he, etc.).

Given that there are fewer characters used to write Irish, the meanings are more variable and hence context is more important when dealing with mathematical text.

Access to meaning

Orthography plays a key role in reading and processing mathematical text (Galligan, 2001). The nature of some of the Irish mathematics vocabulary allows readers to access the direct meaning of the words. For example, the word in Irish for velocity is ‘treoluas’ (direction speed) and parallel is ‘comhthreomhar’ (equal directionality). Many of the Irish words describe concepts/objects as opposed to just labelling them. Given that the more easily and quickly the meaning of words is activated, the simpler it is to process mathematical text. It may help to retrieve all the words associated with the concept thus enhancing the total cognitive structure (Galligan, 2001).

DISCUSSION

This initial comparison of the Irish and English language demonstrates that there are differences between the two languages. However, what is difficult to interpret is whether differences between the languages have a differential impact upon cognitive processing (Galligan, 2001). The syntactical structure of the Irish language in terms of sentence length, topical prominence and word order, appears to lend itself to easier interpretation of mathematical meaning in comparison to English. Accordingly, Irish may lend itself to easier mathematical word problem solving and the acquisition of enhanced processing skills. In particular it raises the question of whether Gaeilgeoirí have faster and more accurate access to mathematical text and accordingly strategies for arriving at a solution.

A significant insight from the analysis is that some Irish words assist in conveying meaning and/or permit the concept to be formed more readily. Similarly the sentence structure allows access to key information. Given that Irish readers are drawn to the key information of the sentence, and that this suggests a difference in mathematical processing in Irish, these surface features may aid mathematical problem solving, while providing a support for developing a deeper understanding of the word problem.

Also, context plays a key role in mathematics and in the interpretation of mathematical text. Given that the meanings are more variable in Irish and hence context is more important when dealing with mathematical text, this may lead to the development of better mathematical problem solving skills for Gaeilgeoirí. In particular, the author would suggest that it may lead to Gaeilgeoirí “reading more carefully and accurately because they have to rely on context more” (Galligan, 2001, p.126).

When comparing English and Irish, visually they do not appear to be significantly different. However, the syntax and semantics of a language plays a crucial role in interpreting mathematical text and developing meaning (Galligan, 2001). A key question arising from this analysis is do students who learn through the medium of Irish employ different processing strategies when interpreting mathematical text, and consequently does this impact on mathematical attainment and understanding?

I propose that proficiency in Irish and experience of learning mathematics through Irish may lead to cognitive advantages and enhanced processing of mathematical text (as outlined in previous sections) and accordingly may contribute to the development of this additive bilingualism. Additive bilingualism results when a second language and culture have been acquired without loss or displacement of an individual’s first language and culture, and a positive self-concept is correlated with this form of bilingualism (Baker, 1996). However, subtractive bilingualism results when an individual’s first language and culture are replaced by the new language and culture, usually occurring in a pressurised environment. As a consequence a negative self-concept may develop due to loss of culture and identity (Baker, 1996). Within the Irish context additive bilingualism is fostered through Immersion (Irish-medium) education at both primary and post-primary levels (Ní Ríordáin, 2011). High ability Irish bilingual students (additive bilingualism) display an enhanced meta-cognitive ability demonstrating flexibility in thinking and reasoning, self-correction, and an ability to select appropriate features for problem solving (Ní Ríordáin & McCluskey, 2012). This reinforces the point that bilingualism in Irish and English has the potential to enhance mathematical teaching and learning, while doing mathematics through the medium of Irish may contribute to enhance mathematical processing.

CONCLUSION

This paper presents an initial analysis of the comparison between Irish and English language and its potential impact on mathematical processing. Some promising

insights are emerging, suggesting that students who learn through the medium of Irish may experience advantages in terms of processing mathematical text. Clearly further research is warranted in this area. Further analysis is needed into whether Irish language processing strategies have an impact on the way Gaeilgeoirí understand mathematical text and solve mathematical word problems. Moreover, do these processing skills transfer to a new language of learning and to the development of additive bilingualism? In particular, investigation is needed into how a particular language and its syntactical structure may impact on mathematical activity and reasoning (Morgan, Tang, & Sfard, 2011). The mathematics register is more than just the language medium of learning and therefore development of this study needs to incorporate other areas of study such as discourse analysis, socio-cultural aspects, linguistic theory, and semiotics. Moreover, there is a clear need for the development of descriptive tools/frameworks for the analysis of mathematical registers, in order to assess their impact on cognitive processing and mathematical reasoning, and to aid comparisons of different/multiple languages for learning mathematics. An in-depth study into the nature of the Irish language and its mathematical register could contribute to significant insights into the cognitive benefits reaped from being bilingual, whilst developing valuable analytical tools to be utilised in other contexts.

MAKING SENSE OF FRACTIONS GIVEN WITH DIFFERENT SEMIOTIC REPRESENTATIONS

Frode Rønning

Sør-Trøndelag University College, Norway

This paper is based on observations of a group of 20 pupils in grade four in a Norwegian primary school. The pupils are presented with a task involving fractions. In the task the pupils are asked to judge the relative size of some simple fractions and also to identify equivalent fractions. The fractions in the task are linked to a context about milk boxes with different volume and the task also involves conversions between measuring units. These pupils are at a very early stage in their learning of fractions and my interest is mainly in inquiring into how they make sense of the situations they are exposed to, with special emphasis on semiotic representations.

Keywords: Fractions, semiotic representations, mediating artefacts.

INTRODUCTION

In a previous paper for CERME (Rønning, 2010) I have reported on a study of grade 4 children involved in the practical task of measuring out 15 dl of milk from boxes containing a quarter of a litre. The boxes were labelled $\frac{1}{4}$ liter¹ and in that paper I discussed how the children interpreted the sign $\frac{1}{4}$ and to what extent the interpretation had any effect on completing the measuring task. I showed that the presence of a measuring beaker as a mediating artefact to a large extent made it redundant to actually make sense of the sign $\frac{1}{4}$. In this paper I report on a study of the exact same pupils, grouped in the same groups as before, working on a task that is mathematically similar to the measuring task reported on before but in terms of the representations used it is quite different. Here the children are presented with a task, given as a text accompanied by pictures, which they are asked to discuss and solve. My main research question is how the children make sense of the fractions given with different representations. I am in particular interested in how the children argue about the relative size of the fractions, how they argue about equivalent fractions, and how they handle fractions larger than 1. I will make connections to the situation described in (Rønning, 2010) and compare this to the situation described here.

THEORETICAL FRAMEWORK

In this study the notion of a sign is central. According to Steinbring a sign typically has two functions, a semiotic function; “something that stands for something else”, and an epistemological function, indicating “possibilities with which the signs are endowed as means of knowing the objects of knowledge” (Steinbring, 2006, p. 134). What is special for mathematics, in contrast to other subjects in school, is that all the objects of study are abstract and that they can only be accessed using signs and semiotic representations (Duval, 2006, p. 107). Despite the abstract nature of the

mathematical objects, mathematics is used as a tool to describe and make predictions about real life situations. A sign can therefore refer both to a mathematical concept as well as to a real life situation. In this study this dual nature can be exemplified through the sign $1/4$, used as a representation for the mathematical concept “the fraction one over four”, as well as for an actual quantity of milk, contained in a real or imaginary milk box. Using Steinbring’s construct *The epistemological triangle* (2006, p. 135) the amount of milk in one box is the object or reference context and the concept is the idea of the fraction $1/4$.

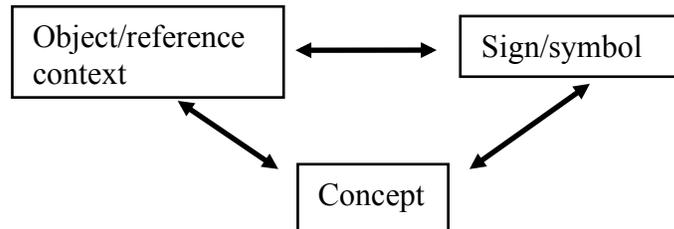

Figure 1: The epistemological triangle

In most cases a mathematical concept can have multiple representations with different characteristics. According to Peirce a sign can be an *icon*, which stands for its object by likeness; an *index*, which stands for its object by some real connection with it; or a *symbol*, which is only connected to the object it represents by habit or by convention (Peirce, 1998, pp. 13-17, 272-275). Successful learning of mathematics is often linked to the ability to switch between different representations of the same mathematical object. Being able to do this and keeping the connection to the same object is, according to Duval (2006), one of the most important obstacles to learning mathematics. In my paper iconic (depictive) and symbolic (descriptive) representations will play the main role. Depictive representations possess inherent structural features making it possible to extract relational information but they do not contain symbols for these relations. Descriptive representations also contain information about relations but to extract this information it is necessary to know the conventions embedded in the symbols (Schnotz & Bannert, 2003, p. 143).

Making sense of conventional representations can be thought of as creating strong links between the corners of the epistemological triangle. In the process of creating such links the learner often uses *hedge words* (Lakoff, 1973; Rowland, 2000) as an indicator of uncertainty, lack of a precise language, or as a search for approval from e.g. a teacher. Rowland groups hedge words into two main categories, *shields* and *approximators* (2000, pp. 60-61). In brief, shields indicate a vagueness on behalf of the speaker, that he or she does not guarantee the truth of the proposition to follow, whereas approximators indicate a vagueness in the proposition (that the speaker is aware of).

Much research has been done on learning with multiple representations and it has been claimed that using multiple representations will enhance learning. Susan Ainsworth has identified three main functions of using multiple representations;

complementary roles, to constrain interpretation, and to construct deeper understanding (Ainsworth, 1999, p. 134, 2006, p. 187). The first function is to use representations containing complementary information or supporting complementary cognitive processes. The second function is to use one representation to constrain learners' interpretation of another representation, e.g. to support the interpretation of an abstract representation. The third function has to do with encouraging learners to construct a deeper understanding of a situation.

In school mathematics fractions are in most respects taken to be equivalent to positive rational numbers. Many authors have described subconstructs of rational numbers and the list of subconstructs varies among different authors. Behr, Lesh, Post, and Silver (1983) claim that one can identify at least six different subconstructs: a part-to-whole comparison, a decimal, a ratio, an indicated division, an operator, and a measure of continuous or discrete quantities. According to Behr et al. the part-whole subconstruct is fundamental to all later interpretations and these authors also suggest a reconceptualisation of this subconstruct into what they denote as *the fractional measure subconstruct*. Previous studies about the learning of fractions have often been of a quantitative nature and focussed on the various subconstructs of rational numbers (see e.g. Behr et al., 1983). Recently there seems to have developed a stronger interest in looking at the learning of fractions through transformations between multiple forms of representation (see e.g. Ebbelind, Roos, & Nilsson, 2012). This study shares much of its theoretical foundation with my study.

METHOD

The 20 pupils in the class were grouped into four groups, each consisting of five pupils. Each group left the regular teaching in the class and came to a nearby room where I was waiting for them. I sat together with the children around a table and each child received a sheet of paper with the task written on it. They had not seen the task before or been given any information about what they were going to work on together with me. They could draw and write on the task sheet as well as on blank sheets that were available on the table. No concrete material was available. The episode was recorded by a video camera standing in a fixed position on a tripod. Each group of pupils got approximately 30 minutes for the task. The data for the analysis consist of the video recordings as well as the sheets of paper that the children used to write and draw on. Since I was actively taking part in the conversation I did not have the possibility to shift the position of the camera. It is directed towards the table and since the groups are so small it is to some extent possible to discern from the video the actual process when the children make drawings and link this to what was actually said at the same time.

To analyse the data I looked at the recordings and made summaries from the activities in each group, looking in particular for episodes that I considered important in relation to my research question. These episodes were transcribed, first in a style close to the spoken dialect and later to standard written Norwegian. For the purpose of this paper, parts of the transcriptions have been translated into English. Each

section of utterances are given an internal numbering. All the children have been given English pseudonyms. The same child carries the same pseudonym in this article as in (Rønning, 2010). My analysis of the data is based on the pupils' utterances and their writings and drawings during the process, and through an interpretative process I will make some statements about the pupils' sense making of fractions. As an analytic tool I rely in particular on elements from semiotic theory and multimodal representations as well as theory about subconstructs of rational numbers.

In the task the pupils were presented with drawings of four different situations, each described by a figure as shown in Figure 2.

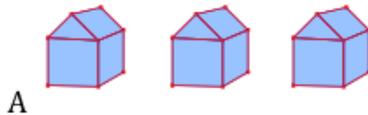

Figure 2: Situation

from the pupils' task

In the text it was explained that the pictures illustrated milk boxes, blue and red. It was explained that each blue box contained $\frac{1}{3}$ litre of milk, and each red box $\frac{1}{4}$ litre² of milk. Situation A showed three blue boxes, situation B four blue boxes, situation C four red boxes, and situation D three red boxes. The questions in the task are reproduced below.

- Which box, red or blue, contains most milk?
- Which situation, A, B, C or D, represents the largest quantity of milk?
- And which situation represents the smallest quantity of milk?
- Are there any situations with the same amount of milk?
- How many decilitres of milk are there in situation D?
- You need 15 decilitres of milk and you have boxes containing $\frac{1}{4}$ litre, hence red boxes. How many boxes do you need?

COMPARING FRACTIONS

The question of finding out which box, red or blue, contains most milk immediately turns into a question of comparing the fractions $\frac{1}{3}$ and $\frac{1}{4}$, where the context with the milk boxes plays no role. The children introduce a new context where the fractions are represented by rectangular shaped figures, divided into parts in different ways. To illustrate $\frac{1}{3}$ Fran draws a rectangle, divides it into three parts. Then she divides one of the three parts into two and shades this part to illustrate $\frac{1}{4}$. Chris has a similar illustration of $\frac{1}{4}$ as showed in Figure 3. An excerpt from a discussion in one of the groups is presented below.

Figure 3: Chris' illustration of $\frac{1}{4}$

- 1.1 Fran: Because, when it is, in a way, a third, then it is divided into slightly larger pieces, but when it is a fourth, it is smaller. So there is more space in a third.
- 1.2 Chloe: If they get thirds, they get more, if they get fourths, they get less.
- 1.3 Chris: The larger the number below, the smaller is the actual part.
- 1.4 Frode: Yes, the smaller is the actual part.
- 1.5 Chris: It is almost like this. Then it is almost as if we split this one [points to the shaded part of Figure 3], making it even smaller.

The children create iconic signs (Peirce, 1998) to link to a reference context having to do with dividing a whole into pieces. The numerator (“the number below”, #1.2) is linked to the number of pieces and the size of each piece is linked to the size of the fraction in an inverse way. This is most clearly expressed by Chris when he states, “the larger the number below, the smaller is the actual part” (#1.3). When Chris links his statement about the numbers in the fraction (#1.3) to the illustration he is using hedge words, “almost like this” and “almost as if” (#1.5). I interpret these words to be *rounder approximators* whose effect is to “modify (as opposed to comment on) the proposition” (Rowland, 2000, p. 60). In his statement (#1.3) Chris shows no indication of vagueness, and therefore I interpret his statement (#1.5) not to be taken as an exact representation of a smaller fraction but as an approximation.

The signs $\frac{1}{3}$ and $\frac{1}{4}$ can be placed in an epistemological triangle dealing with the concept volume of one box where the blue and red boxes are placed in the reference context corner. Then the connection between sign and reference context is just a “communicative agreement” (Steinbring, 1998, p. 173). In order to reason about the relative size of the fractions it is necessary to introduce a new sign, the partitioned rectangles, that can function as a reference context for the signs $\frac{1}{3}$ and $\frac{1}{4}$. Then there is a structural reference between the sign and the reference context, “the connection between symbol and referent is indirectly mediated by syntactical and logical structures on the symbol level and the referent level” (Steinbring, 1998, p. 179). (See Figure 4. The sign $>$ was not used in the interaction with the children.)

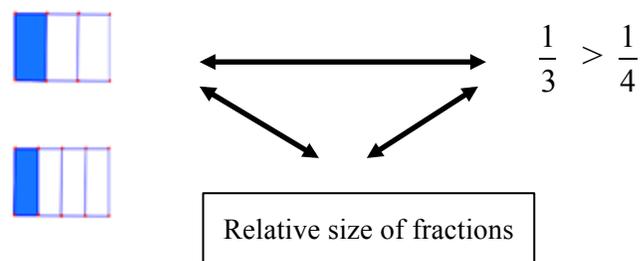

Figure 4: Comparing fractions

In the dialogue above Fran said that in $\frac{1}{3}$ “it is divided into slightly larger pieces” (#1.1). In order to determine whether there are situations containing the same amount of milk a need to quantify the difference arises, *how much* larger is a blue box than a red box? Jessica and Ellie have suggested that situation A has the same amount of milk as situation C and in the dialogue below they justify their argument.

- 2.1 Jessica: The blue one is in a way one more, I nearly said.
 2.2 Ellie: Then it is the same amount such that it is one more.
 2.3 Jessica: Yes. And then I think that the blues are almost one more than the reds.
 2.4 Frode: Yes ...
 2.5 Jessica: One box more, yes there are three there [points to A] ... and then you can in a way draw one more.

They agree that each blue box contains one third, and that the only possible solution, if any at all, is A and C.

- 2.6 Ellie: But it is, the blue ones there [points to B], compared to the red ones, [points to C] there are five, and there are four, so it is like one more.
 2.7 Frode: OK.

The pupils have previously agreed that $1/3$ is larger than $1/4$ but how much larger? The answer given to this is that it is “one more” (#2.1). Also here the hedge words are interesting, e.g. when Jessica says that the blue box is “in a way one more” (#2.1) and “the blues are almost one more than the reds” (#2.3). This argument gives as a result that four red boxes are equal to three blue boxes. In this discussion I interpret the hedge words to be of the type that Rowland refers to as *adaptor approximators* (2000, pp. 60-61). Jessica attaches vagueness to the proposition (one more), not in the sense of a rounder (approximately one more) but in the sense that she does not have good way of expressing exactly how much larger $1/3$ is than $1/4$, so it is “in a way one more”. One may claim that Jessica, knowing that 4 is one more than 3 and that $1/3 > 1/4$, the latter relation has a certain degree of “one more-ness” to it, albeit in a reciprocal way. The relation belongs, to a certain degree, to a category consisting of objects $\{a, b\}$ where a is one more than b (Lakoff, 1973).

The argument is developed further into concluding that four blue boxes correspond to five red boxes, when Ellie says that “the blue ones there, compared to the red ones, there are five and there are four, so it is like one more” (#2.6). It is not clear what is meant by *one more* but I interpret Ellie’s utterance to mean that four blue boxes correspond to five red boxes. Her reasoning works in the particular cases given by situation B and situation C but not in general. If v_r denotes the volume of one red box and v_b denotes the volume of one blue box, and n_r and n_b denote the number of red and blue boxes, respectively, then the total volume will be the same if $n_r \cdot v_r = n_b \cdot v_b$, or $n_r = \frac{v_b}{v_r} \cdot n_b$. Hence, the relation is a multiplicative one, whereas the pupils suggest that an additive relation, $n_r = n_b + 1$, will give the same volume.

LACK OF FLEXIBILITY IN THE REPRESENTATIONS

In the second question of the task the pupils were asked to identify the situation containing the largest amount of milk. Prior to this it had been established that the blue box contained the largest quantity of milk and the pupils quickly suggest that situation B has the largest amount of milk. Fran starts to justify this suggestion but soon she begins to object to her own suggestion.

- 3.1 Fran: Because there [in B] there are many blue ones. The more blue ones, the ... But really, it is not possible because the blue one is one third and this one is four thirds, so it really is not possible.
- 3.2 Frode: Not possible. Why not?
- 3.3 Fran: Because then there is one too many. Is it.
- 3.4 Chris: That is why A is the largest. There there are three thirds.
- 3.5 Frode: In A, yes.
- 3.6 Fran: Because it is not possible with four thirds. That is not possible. If it had been fourths, then it had been possible.
- 3.7 Chloe: There is only room for three in one litre. If it had been written four it would be possible. That is why it is possible in C.
- 3.8 Fran: It is not possible to take one more box than what in a way is there.
- 3.9 Chloe: So it is possible with one fourth but not with one third.
- 3.10 Fran: So really, it is A.

There seems to develop a reluctance to accept situation B in this context, when Fran explicitly says “four thirds, so really it is not possible” (#3.1). Looking at the previous attempts of explaining fractions (see e.g. Figure 3) this reluctance is understandable. The fraction is compared to a fixed quantity, the unit, in this case drawn like an almost rectangular figure. The concept of fraction is taken as the part-whole subconstruct (Behr et al., 1983), meaning that there is a certain number of parts, n , and one of those is “one n th”. And it does not make sense to take $n + 1$ because the unit (the whole) does not contain more than n parts. “It is not possible to take one more box than what in a way is there”, as Fran puts it (#3.8). Or, “there is only room for three in one litre” (Chloe in #3.7). Here 1 litre is the limit, the whole. This shows the limitations involved when looking at fractions only as parts of a whole and how the representation given by partitioning a given unit is not sufficiently flexible.

To make sense of the symbolic representation $\frac{1}{n}$ all the pupils use a representation of the type shown in Figure 3, i.e. a rectangular shape partitioned into n stripes. This is an example of a depictive (iconic) representation that enables the pupils to achieve insight into the descriptive (symbolic) representation. In this way the multiple representations can be said to have a constructive function (Ainsworth, 1999, 2006). However, the iconic representation also has a constraining function, and in this case a constraining function that goes too far. Ainsworth describes the constraining function as being of help in the meaning making stating that it entails using one representation “to constrain possible (mis)interpretations in the use of another” (1999, p. 134). In the excerpt above one can see that the constraining is too strong in the sense that it does not allow for the sign “four thirds”. Situation B is a depiction of four blue boxes and this is expressed by Fran as being “four thirds”. This sign is never expressed in symbolic form. Chris writes $\frac{3}{3}$ next to the three blue boxes in Situation A and in

Situation B he draws a curve around three of the boxes and another curve around the fourth box, and says that “A is the largest” (#3.4).

A multiple representation for Situation B could be as shown in Figure 5.

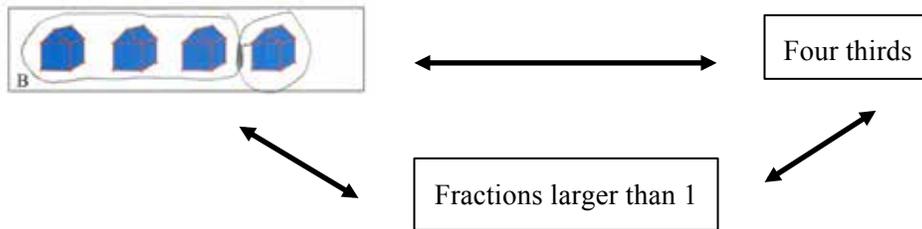

Figure 5: Reference context for fractions larger than one

Although the pupils use the verbal sign four thirds to represent Situation B, this is not accepted as a solution in this particular context, which we at an early stage in the conversation had agreed was about fractions. The epistemological triangle shown in Figure 5 for fractions larger than 1 is not established in the given situation. The pupils link the sign to the reference context but they cannot link this to a concept of fractions. Earlier they have linked the sign for the fraction (spoken or written) to the partitioned rectangle. The partitioned rectangle does not function as a link between the sign and the reference context in Figure 5 because the partitioned rectangle does not make sense in the case of four boxes of $\frac{1}{3}$ each. Therefore there is a lack of flexibility in the representation, since one box corresponds to one stripe in the rectangle and there are only three stripes, so “it is not possible to take one more box than what in a way is there”, as Fran puts it (#3.8). Therefore, “really it is A [that has the largest amount of milk]” (#3.10).

In one of the other groups identifying the situation with the largest amount of milk presented no difficulties. Jessica read the question “Which situation, A, B, C, or D, contains the largest amount of milk?” and she immediately answers that it is B. This is repeated by Ellie and one of the other pupils. When asked why this is the case, Ellie says “because it is the largest number...”. Ellie is interrupted by Jessica who gives the following explanation.

Jessica: Besides, you can see that it is most, and the reds are as many as the blues, so then you think, and here you said that blue was most, and it has to be blue which is most of red and blue there also.

Jessica accompanies her argumentation by pointing with her pencil to the task sheet and by combining what she says with the pointing that can be observed on the video I interpret her statement in the following way. She first verifies that the number of red boxes in C is the same as the number of blue boxes in B. Then she refers back to what we already had agreed on, that one blue box is more than one red box. Then she concludes that it must be the situation with four blue boxes (B) that contains the largest amount. I take it that she has tacitly assumed that none of the situations with three boxes could be a candidate for the largest amount.

Jessica's argument here does not need the concept of fractions larger than 1 so she does not face the same problems as the group with Fran, Chris and Chloe did. Jessica builds on previous knowledge that one blue box is larger than one red box ($v_b > v_r$) and for this the representations in Figure 3 can be used. Furthermore, by counting, it is clear that the number of blue boxes in B is equal to the number of red boxes in C ($n_b = n_r = n$). From this she concludes that $n v_b > n v_r$.

DISCUSSION

In this paper I have showed how representations that resonate strongly with the aspect of fraction as a part-whole relationship can be limiting and restrictive, in particular when it comes to dealing with fractions larger than 1. In a context, which in itself would be expected to be a familiar one (boxes of milk), one situation consisting of $4/3$ litre was dismissed as being “not possible” and my interpretation of this is that because the task has to do with fractions, the pupils cannot accept four thirds, whereas they are happy to accept four fourths. It would have been of interest to pursue the statement “not possible” further by asking “what is not possible?” Instead I only ask “why it is not possible”, assuming that we all have the same understanding of what “it” is. This can however, not be taken for granted.

Although mathematically the tasks for the pupils presented in this paper are quite similar to the ones discussed in (Rønning, 2010), there is one important difference. In the situation described in the previous paper the pupils had measuring devices available that functioned as mediating artefacts between the signs and the reference context. The presence of the mediating artefacts strongly reduced the need of making sense of the signs. Therefore some of the pupils read $1/4$ as “one comma four³”, and says “two comma eight” after having poured two $1/4$ litre boxes of milk into the measuring beaker. One of the pupils saying “one comma four” is corrected by one of the other pupils who says that the sign / is not a comma but a slash (Rønning, 2010, p. 1018). The first pupil readily admits that she doesn't have a clue to what “one slash four litres” means but nevertheless the pupils in the group have no problems finishing the measuring task because they are guided by the measuring beaker where the scale has the function of an indexical sign (Peirce, 1998).

In the situation presented in this paper the depictions of the milk boxes in the task were not helpful in making sense of the fraction signs. Therefore the pupils created other signs that they could use but these signs turned out not to be sufficiently flexible to deal with the situations, in particular not in cases of fractions larger than 1.

NOTES

¹ Norwegian spelling of litre.

² In the text presented to the pupils the signs $\frac{1}{4}$ and $\frac{1}{3}$ were used.

³ In Norwegian a comma is used for the decimal point so “one comma four” means 1.4.

PRIMAPODCASTS – VOCAL REPRESENTATION IN MATHEMATICS

Christof Schreiber

Justus Liebig Universität Gießen, Germany

After having investigated written and graphical-based communication I focus on vocal representations of mathematical contents. The mathematical podcasts were made by primary school children and therefore they are called PriMaPodcasts. The relationship to written and graphical representations, the special setting to produce the podcasts with primary pupils and an example is depicted in this paper. The different steps of production of the PriMaPodcast are classified in reference to the special relation of vocal and written communication. It is a first classification according to the linguistic model of Koch and Oesterreicher. Furthermore some interests of investigation concerning the use of PriMaPodcasts, the acquisition of competences, semiotic analyses and the use of digital media in teacher education are briefly described.

MOTIVATION

Our special interest in vocal representations of mathematical contents aroused from the investigation of written and graphical-based communication in the project ‘Math-Chat’ (Schreiber, 2010, 2013, see next section). A first conception was developed (Schreiber, 2011) to create podcasts about mathematical contents with primary school pupils, which was modified later (Schreiber, 2012a). In this project only audio-podcasts are produced, so the use of written and graphical elements is not possible and this kind of representation must be ‘replaced’ in some way by the primary pupils. Three different aims are crucial:

- The learning can be fostered because of the requirement of not using any written or graphical representation but only vocal representation for the description of mathematical contents.
- The level of the pupils’ skills in reference to their mathematical expression, both spontaneous and planned, can be identified by analysing all products during the production of the podcasts.
- This is very promising for the purpose of investigation because it is possible to see what is used to replace the written and graphical representation when only vocal representation is possible.

Not only the product but also all steps in the production of PriMaPodcasts are of interest. There are seven different steps and the written and vocal representations are interwoven permanently. The written and vocal parts of this process are classified by the two-dimensional model of medial and conceptual orality and writtenness (Koch & Oesterreicher, 1985).

ANCESTOR PROJECT

The ancestor project ‘Math-Chat’ [1] was about the genesis of ‘mathematical inscriptions’ (Latour, 1987; Latour & Woolgar, 1986) in primary education: In an experimental situation, an internet-chat setting, the communication between pupils solving together given word-problems depended on the use of written and graphical representations. This setting offered insights into the learning of mathematics because mathematics depends on written forms of communication (Pimm, 1987). Writing constitutes an integral part of mathematical communication. Fixing ideas in a written form changes their status and makes them more explicit and conveyable, see Bruner's approach of the "externalization tenet" (Bruner, 1996, pp. 22-25). The focus on the medial written form of language in problem-solving situations in mathematics was the special issue of ‘Math-Chat’ (see Schreiber, 2005). In the ‘Math-Chat’ project a semiotic instrument for analysing inscription-based mathematical problem-solving processes has been developed. These processes are described as “Semiotic Process-Cards” (Schreiber, 2010, 2013).

PRODUCTION OF PRIMAPODCAST

According to the latest conception (Schreiber 2012a, 2012b) there are seven steps in the process of production of the so-called ‘PriMaPodcast’ (see Fig. 1):

1. Spontaneous Recording: The pupils have to answer a question or to react to a stimulus about mathematical terms like ‘infinite’, ‘greater than’, ‘less than’, or calculation methods like addition or subtraction or about geometrical objects like a circle or a cuboid. Their first spontaneous reaction is recorded with a voice recorder. This is like a brainstorming about the mathematical content and can be used in the further process because it is recorded and available for the pupils.
2. Manuscript I: The pupils have to plan an audio-podcast, which is to explain this content to others. For this they can and they should now take some notes and make a kind of manuscript for their recording. They are free to make it more or less detailed, to decide who is saying which part or to make more or less a rough draft.
3. Audio-podcast: The recorded audio-podcast should begin with the same question or stimulus as in the first step. It will be recorded based on the pupils’ manuscript. Depending on this manuscript it can be read out or the pupils speak freely.
4. Editorial Meeting: Two different groups meet here together with the teacher to give one another feedback to the created audio-podcasts. The feedback can be about the content, formal aspects or the choreography of the whole audio-podcast. These two groups decide with the help of the teacher if the created audio-podcasts are ready to be published or if there are changes to be needed.

5. Manuscript II: In connection with the editorial meeting the manuscript has to be revised. This way, the final version is initiated.

6. PriMaPodcast: The pupils take a final recording of their audio-podcast. Afterwards, it is ready to be published.

7. Publication: After the release of the PriMaPodcast, an administrator publishes them in a blog on the internet, <http://blog.studiumdigitale.uni-frankfurt.de/primapodcast/> (in German). The advantage of publishing the PriMaPodcasts in a blog is the categorising of the several podcasts in main-theme and sub-theme categories which makes it easy to manage for a group of researchers.

Fig. 1: Steps to produce a mathematical podcast with primary pupils - PriMaPodcast

Similar to the ‚Math-Chat-Project‘, in which there is a link between medially graphical but conceptually oral communication, there is a link between the two kinds of communication in PriMaPodcast production, too. As it is explained below, orality and writtenness are present in the different parts of the production of PriMaPodcasts in different manners and both are interwoven.

CONFLICTING FIELDS OF WRITTENNESS AND ORALITY

To explain more about the interwoven use of oral and written communication in a medial and conceptual manner, I use the linguistic model of orality and writtenness of Koch and Oesterreicher (1985), well explained by Fetzer (2007, p. 79) as the “two dimensions of orality and writtenness (translated by the author: „Zwei Dimensionen von Mündlichkeit und Schriftlichkeit“).

Koch and Oesterreicher (1985) have developed a model of communication that distinguishes between medial phonic and medial graphic communication and between communicative immediacy and communicative distance. The medial phonic and the medial graphic realization of communication are dichotomous, whereas the conceptual realization can be placed on a scale between the communicative immediacy and the communicative distance (see Fig. 2).

As an example a personal talk is not only medial phonic, there is an emotional closeness to the dialogue partner and thus conceptual oral. Writing in a diary is in a conceptual sense also oral, not formal and characterised by the ‘closeness’ to the reader, but it is medially graphical. An administrative directive in contrast is medially graphical and also conceptually an example for communicative distance. The

language is strictly formalised in this case. If this administrative directive will be read aloud, it will be medially phonic, but conceptually it continues to be written. The language is still the same and characterised by distance and formalism.

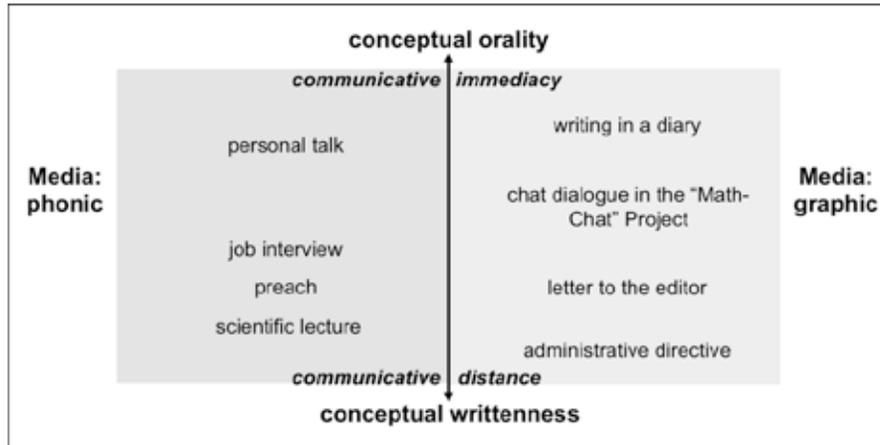

Fig. 2: Koch and Oesterreicher's model according to Fetzer (2007, p. 79; translation by the author)

EMPIRICAL EXAMPLE

A couple of PriMaPodcasts have been made in German and also a few in a bilingual German-Spanish and a bilingual German-English class. The PriMaPodcasts in German language are available in this blog: <http://blog.studiumdigitale.uni-frankfurt.de/primapodcast/>, the examples in Spanish and in English language are also available in blogs [2]. Further examples will be added to these two blogs. A blog in Greek and one in Turkish are planned.

In the PriMaPodcast which is presented here, the question was ‘What is so special about a square in comparison to the other quadrangles?’ This PriMaPodcast was developed by one girl and two boys in grade four and the recordings were led by a teacher-student. At first the transcript of the spontaneous recording is given [3]. After that the manuscript is depicted, which is written by one of the pupils as agreed with the others. Then the audio-podcast, which is based on this manuscript, is exhibited as transcript. The improved recording, the PriMaPodcast, is also documented as a transcript. It conforms to the manuscript, even though there are some different intonations and it is not fluently read in all cases. For my analysis this is of interest. All citations of the transcript are marked in squared brackets <like this>.

Spontaneous Recording:

At first pupil 1 (the girl) asks ‘What is so special about a square in comparison to the other quadrangles?’ <sp1> and pupil 2 answers spontaneously <sp2>, that he knows an answer. But it is pupil 3, who explains that there is a difference in terms of spelling <sp3>. He remarks that the capital letters of the two words are different. This assumption is correct even though his spelling of the second word is wrong. Pupil 2 takes the turn and has a content-related point of view and claims that the sides of a

square are of equal length. To this he gives an example <sp4>. Pupil 3 adds another example to confirm the statement <sp5>.

- sp1 00.00 p1 What is so special about a square in comparison to the other quadrangles
- sp2 00.07 p2 Okay I know
- sp3 00.10 p3 A square (*in German Quadrat*) is spelled with Q and the quadrangles (*in German Vierecke*) are spelled with F
- sp4 00.14 p2 Squares have on each s. on each side a square is of equal length that means when one side is five centimetres the other sides of the square are five centimetres too
- sp5 00.29 p3 And when it's one centimetre the other side is one centimetre too (*colloquial*)

You can see here that pupil 2 and pupil 3 both focus on the sides and on the shape of the square. With their utterances they do not actually compare the differences between a square and the other quadrangles. The pupils only describe the characteristics of a square. Other characteristics of a square, for example symmetry or angles, are not taken into consideration. Pupil 1 does not add another content-related argument either.

Manuscript:

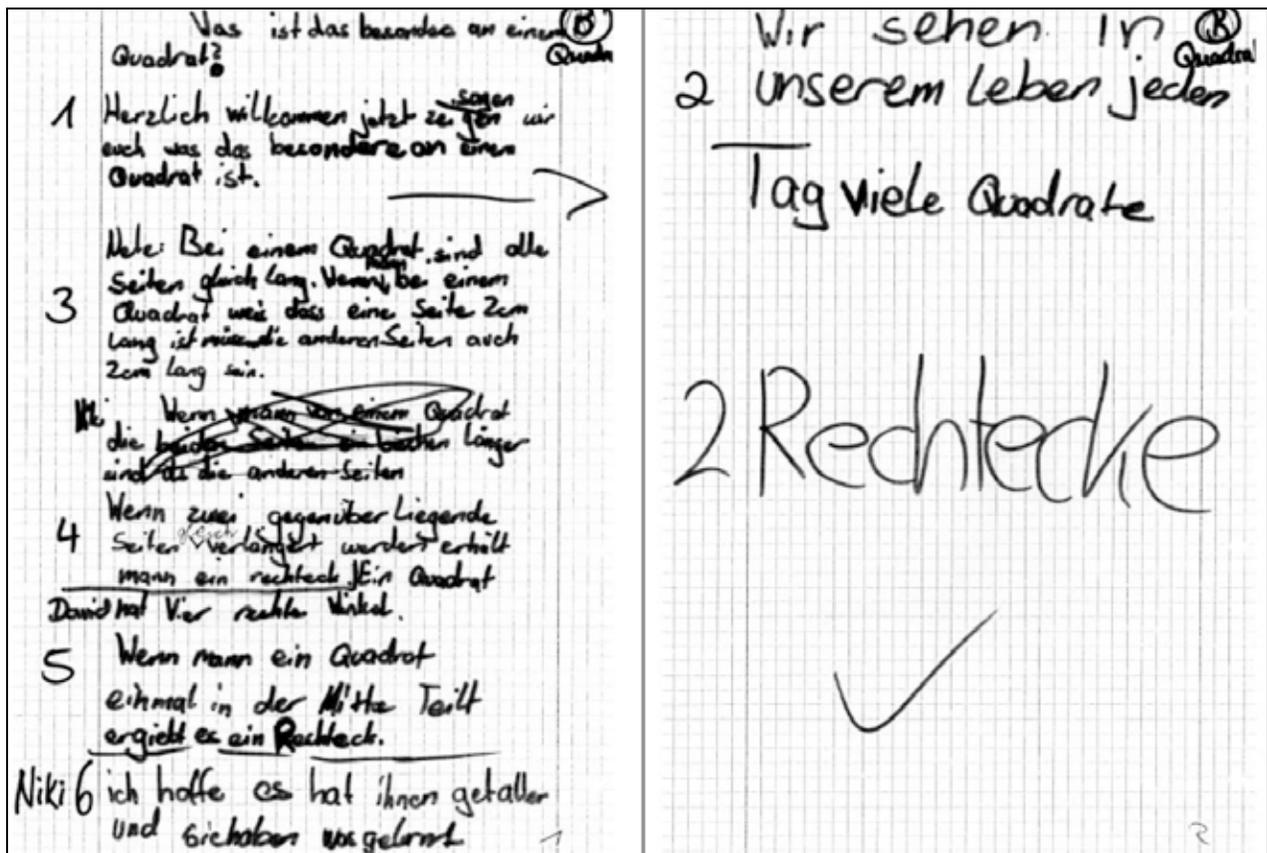

Fig. 3: Manuscript of the PriMaPodcasts (originally two pages in A4)

Here I give the translation of the manuscript (see Fig. 3):

<p>What is so special about a square?</p> <p>1 Welcome now we are going to tell you what is so special about a square.</p> <p>3 Nele: A square has got four sides of equal length. When you know that a square has one side of 2 cm all the other sides have to be of 2 cm, too.</p> <p>When both sides of a square are a bit longer and the other sides</p> <p>4 When two facing sides are lengthened equally you get a rectangle.</p> <p>David 5 A square has got four right angles. When you split a square in the middle, you get two rectangles.</p> <p>Niki 6 I hope you liked it and you have learnt something</p>	<p>2 Every day we see many squares around us</p> <p>2 rectangles</p> <p style="text-align: center;">✓</p>
--	---

Audio-Podcast:

At first they welcome the audience of their audio-Podcast by presenting their topic <a1>. Then they make clear, where you can find squares in the “every . day” <a2> world. After that, they take an utterance of the spontaneous recording and focus again on the length of the sides of a square <a3> with the help of an example. In utterance <a4> they explain how to transfer a square into a rectangle and utterance <a5> is another way of transformation. The right angles are mentioned in this context, too <a5>. With their statements in <a6> and <a7> they refer again to their audience.

- a1 00.00 p1 Welcome now we are going to tell you what is so special about a square
- a2 00.04 p3 Every . day we see many squares cede covers glazed tiles squared paper (*Hessian accent*) in our Maths school books around us .
- a3 00.13 p1 A square has got four sides of equal length when you know that a square has one side of two centimetres all the other sides have to be of 2 centimetres too
- a4 00.22 p2 When two facing sides are lengthened equally you get a rectangle
- a5 00.28 p3 A square has got four right angles when you split it in the middle vertically or horizontally you get two .. rectangles (*Hessian accent*)
- a6 00.37 p2 I hope you liked it and you have learnt something ..
- a7 00.42 all p By-yee

In this version, the pupils think of an audience of their work <a1>. This is different to the spontaneous recording and makes their work ‘public’. So it changes the status of the spoken text, which bases on the manuscript. With the first content-related statement they make clear what the question means in their “every . day” life <a2>. This shows their personal interest of the question. By taking an utterance of the spontaneous recording they focus another time on the length of the sides <a3>. And this shows that they are still aware of their first ideas. They do not only take over this idea, but they are able to generalise it and to add an example. For the first time, in utterance <a4> they make a difference and also a connection between squares and other quadrangles. It is not any quadrangle but a special one, a rectangle. They show the connection and the difference by using two modifications of the square: In the first case, it is a modification by changing the length of “two facing sides” <a4> and in the second case by splitting into two equal parts <a5>. Moreover, the pupils mention one more detail of the square by focussing on the angles <a5> and they are able to use the terms ‘vertically’ and ‘horizontally’ to explain the directions <a5>. In utterance <a6> they emphasize that their aim was to let the audience learn something.

PriMaPodcast:

After the editorial meeting the PriMaPodcast is recorded. It still bases on the same manuscript. Mostly all parts of the audio-podcast are in this PriMaPodcast version. The pupils only change details like leaving out the examples from every day life <pr3> and adding their names <pr7>.

- | | | | |
|-----|-------|-------|---|
| pr1 | 00.00 | p1 | Welcome . Now we are going to tell you what is so special about a square |
| pr2 | 00.04 | p3 | Every day we see many squares around us |
| pr3 | 00.08 | p1 | A square has got four sides of equal length if you know that a square has one side of two centimetres all the other sides have to be of 2 centimetres too |
| pr4 | 00.17 | p2 | If two facing sides are lengthened you get a rectangle |
| pr5 | 00.22 | p3 | A square has got four right angles when you split it in the middle vertically or horizontally you get two rectangles (<i>Hessian accent</i>) |
| pr6 | 00.29 | p2 | I hope you liked it and you have learnt a lot. |
| pr7 | 00.33 | p3 | This commentary was given by Nele Niklas und David .. |
| pr8 | 00.37 | all p | By-yee |

In the PriMaPodcast version the pupils are aware of the imaginary audience <pr1>. This is clear because this version is for publication in the blog and the children were told this before. So their recordings will be made ‘public’ indeed. In this version the pupils read it out louder and more fluently than in the audio-podcast version. Leaving out the examples from every day life is an important change. Up to now it was of great interest for the children and they put emphasis on it by mentioning it at the beginning of the audio-podcast. But from their point of view it is not so important for the imaginary audience. All the other arguments are repeated <pr3; pr4; pr5>, which shows that the pupils see their relevance for the audience. The children were not

asked to mention their names, but this seems of interest, too <pr7>. The pupils can identify with their PriMaPodcast and they finish it jointly.

CLASSIFYING IN THE CONFLICTING FIELDS

The communication in the ‘Math-Chat’ Project is medially graphical, but conceptually oral, because it is in a high range interactive, synchronous and little formal. The classification of the different phases of the development of PriMaPodcast consists of three parts: The spontaneous recording, which is medially phonic and conceptually oral too. The utterances are little formal and not very elaborated. The manuscript, which is the base for the later recording of the PriMaPodcast, is medially written but conceptually – depending on the kind of manuscript – it should be classified more to the vocal pole. The so developed PriMaPodcast is medially phonic and conceptually nearer on the oral pole than the manuscript.

The overlapping areas mean that, e.g., a manuscript for the PriMaPodcast can be conceptually more oral, than the medially graphical interaction in the Math-Chat project, which is in its part also conceptually oral. As well a PriMaPodcast can be conceptually nearer to oral than the spontaneous recording.

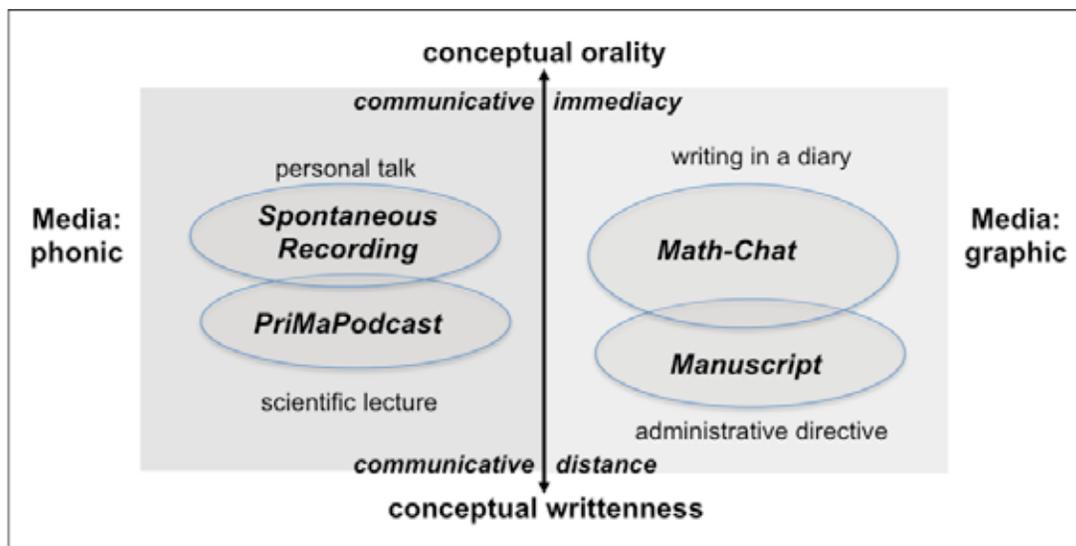

Fig. 4: Examples classified in the conflicting field of writing and speech (see also Schreiber, 2012a)

FURTHER INTERESTS OF INVESTIGATION

Here I want to highlight three aspects of interests of investigation:

- The acquisition of competence in mathematical learning
- Semiotic analyses of vocal representation
- Digital resources in teacher-education and mathematical learning

Communication is one of the mathematical competencies. It is overlapping with representation and also with argumentation. If we want to foster the acquisition of

these competencies, we have to find a task in which they are required aligned and in variations. So for the empirical investigation there is a special requirement. I want to investigate this field by video analyses and explore, in what extent it is possible to foster this competencies acquirement. Especially the connection between written and vocal representation in the production of the PriMaPodcasts is of interest. This can help to identify the importance of the different models of communication.

As always in the field of reconstructive social investigation this investigative work should amplify the repertoire of methods: the vocal products in connection with the before created manuscript are subjected to a semiotic analysis. For this the analyses-method of the Semiotic Process-Cards is developed further to be used for vocal forms of communication. The goal of the more differentiated theory is to examine the semiotic aspects of interaction in mathematical classroom activities. Up to now they were limited to inscriptional aspects of mathematical communication (Schreiber 2010) and they are used for Gestures in this context (Huth, in press).

If it is true, that there is a deficit of use of digital media in primary mathematics classes (at least in Germany) like Mitzlaff (2008) and Ladel and Schreiber (2011) affirm, then we as educators in mathematics should close this gap. Especially for project-oriented mathematical education we have to create and to prove scenarios for all-day use in primary classes. This is what happens in the above described scenario of creating PriMaPodcasts. They can serve as a scenario to teach and learn mathematics and also as a possibility for investigative learning for the teacher students of primary education.

NOTES

LINGUISTIC INTERCOURSE WITH SPATIAL PERCEPTION COMPARATIVE ANALYSIS IN PRIMARY SCHOOL, INFANT SCHOOL AND THE FAMILY

Marcus Schuette

University of Hamburg and Goethe-University Frankfurt am Main, Germany

Many mathematical abilities as well as general cognitive abilities have come to be understood in the context of spatial perception. According to Newcombe and Huttenlocher (2006), a key aspect of improving spatial-geometrical ability lies in the linguistic coding of space – yet this linguistic intercourse with spatial perception remains unfulfilled. Research in the field of mathematics education indicates that this can be explained by a tendency to interpret situations in arithmetical terms, or to employ more deictically characterised, implicit forms of mediation. The following report presents a video-based empirical study, which attempts to reconstruct and compare linguistic intercourse with spatial perception in different places in which children learn – infant school, primary school, and family.

THEORETICAL BACKGROUND AND RESEARCH FOCUS

According to Hostetter et al. (2006), gestures of teachers are habitual and some of them tend to be conscious. Thus teachers are capable of actively influencing the gestures they produce. They can decide to increase their use of gestures or to stop using gestures altogether. Using this idea, the present study aims to establish how parents, educators and teachers construct the learning of spatial-geometrical mathematical content in linguistic terms. It also aims to identify and reconstruct differences in this respect that exist between the distinct places of learning. The goal of the study is to identify opportunities and risks through an integrated examination of linguistic intercourse with spatial perception, and to use it to develop a training concept to support parents and infant and primary school teachers in the fostering of spatial thinking. The research question is the following: Which kinds of linguistic intercourse with spatial perception can be reconstructed in the three distinct places of learning: family, infant school, and primary school?

The significance of perceptions of space in the learning of mathematics

The spatial world we live in requires the development of spatial perception. Almost every action of individuals takes place in the spatial world, and consequently cognitive or mathematical abilities are increasingly being understood in the context of spatial thinking. Here it is important to note that a broad competency in spatial thinking early in life not only has positive effects on a child's later capacities for thinking in spatial terms, but also on the proficiency in other areas of mathematics (Lüthje, 2010; Stern, Felbrich, & Schneider, 2006). Größing (2002), and Clements and Sarama (2011) have made observations that support the assumption that there is a positive correlation between spatial perception and mathematical achievement:

Spatial thinking is an essential human ability that contributes to mathematical ability. ... Further, mathematics achievement is related to spatial abilities (Clements & Sarama, 2011, p. 134)

These observations are supported by a similar negative correlation. Several studies have reached the conclusion that a lack of ability in spatial perception is linked to dyscalculia, and vice versa (Maier, 1999). Spatial perceptions determine thought and language. Spatial concepts are used in many of our everyday metaphors, for example “high-spirited”, “on top of the world”, “to take up a lot of space”. Language is seeking here to describe abstract situations or feelings by using concrete concepts from the world of spatial perception (Fthenakis et al., 2009). Spatial ability is thus essential for children’s development. Little attention is paid however to spatial-geometrical content in German schools. An inadequate system and an underestimation of its importance seem to have led to an aversion to the theme in the teaching community. For a long time, German geometry teaching has focused almost exclusively on the study of form, and on looking at the world from a two-dimensional perspective (Lüthje, 2010; Winter, 1976). Consequently, a number of authors have criticised modern geometry teaching:

Spatial geometry is, as a rule, the learning of vocabulary, arithmetic and algebra. (Maier, 1999, p. 8, translated by the author)

Authors like Maier (1999) have demanded a restructuring of the current primary school curriculum that will make nurturing spatial perception a specific goal of geometry teaching. If we take the importance of focusing on ability in spatial perception in the development of children seriously, according to Fthenakis et al. (2009) we have to ask what the requirements are for teaching it in the places in which children learn. Henceforth we shall consider that the development of spatial-geometrical perception does not begin in primary school, but far earlier, in the family and in infant school, and that “effective learning depends on the support given to all those places where children learn and develop” (Fthenakis et al., 2009, pp. 38-39, translated by the author). Clements and Sarama (2011) have observed that, at earlier stages of children’s education too, little or no time is devoted to geometry and spatial perception. They suggest failures in teacher training as a possible cause for this.

Language and the learning of mathematics

It is a fundamental goal of mathematics education to enable children to understand and experience the world with the help of a mathematical perspective. Since many mathematical objects and areas are represented in language, it is also a question of developing linguistic abilities that are linked to mathematics. In a number of approaches to mathematics education, language and communicative competence are accorded particular importance with regard to learning. Above all in primary school, according to Maier (2006), teachers often attempt to introduce concepts through visualisations with the help of illustrative models; that is to say, the form of “iconic” representations. There is an inherent problem here, because these visual techniques do not allow a comprehensive understanding of mathematical concepts. This is true above

all because mathematical objects are abstract, and it is therefore difficult to access these objects sensually through enactive and iconic visualisations. This dilemma can only be resolved through the use of language and symbols, underlining the importance of language in the learning of mathematics:

As fundamentally abstract concepts, [mathematical concepts] can only be legitimately handled and represented on a linguistic-symbolic level. (Maier, 1986, p. 137, translated by the author)

According to Maier (1986, 2006), intensive verbal communication is an indispensable educational tool when introducing new mathematical concepts. Pimm (1987) goes one step further, and considers mathematics as a social activity that is structurally closely linked to verbal communication. From this standpoint he uses the metaphor “Mathematics is a language?” (ibid., p. XiV) to raise the question of whether mathematics may be considered as, if not a natural language, a unique style of language. His concern is to structure the concept of mathematics partly in linguistic categories, with the principal goal of rendering the teaching and learning of mathematics easier to explain (Pimm, pp. 14-15). Returning to the area of geometry in the light of this idea, it is worth referring to Newcombe and Huttenlocher (2006), who have remarked that the linguistic coding of space is a central competency with relation to spatial thinking. Although the literature places great importance on linguistic intercourse with mathematics, particularly with relation to spatial perception, so far I have noted the following: in German schools, spatial-geometrical content barely appears to feature, whilst outside of school in the family a linguistic intercourse with space is frequently neglected. At the time of writing the author is unaware of any experiments that have been carried out on spatial perception in German infant schools.

Support in learning situations containing an element of mathematics

In infant school, primary school and in the family, children are involved in processes of negotiation of meaning through which they become increasingly familiar with mathematical content. Tiedemann (2012) interprets these processes as “support”. She draws a link to Bruner’s (1983) concept of a support system whereby children are involved in repeating models of interaction, which leads to their becoming increasingly autonomous actors in their cultural environment. A crucial point here is that support can be understood as an interactional phenomenon produced by adult and child together. Whilst the adult assists, the child orients the adult’s utterances and actions by his or her reactions in the situation of negotiation of meaning. Tiedemann (2012) adapts this approach for mother-child mathematical discourses, and reconstructs different aspects and methods of support. Therefore, linguistic intercourse with spatial perception in primary school, infant school and the family as described in this study can be reconstructed and understood as “support”. One can explore, in the three different places of learning, forms of support that can be observed in processes of negotiation of meaning relating to spatial perception.

Research gap and focus of the study

Anderson (1997) investigated the parent-child interaction of 21 four-year-old children and their parents in situations containing elements of mathematics. An incidental result of her study is relevant to the present paper. In Anderson's study families were given multilink blocks, a child's book, blank paper, and preschool worksheets, and a fifteen-minute audio recording was made of each family as they began to try and solve the puzzles. It was found that the parent-child interaction included a wide range of mathematical approaches of various levels of sophistication, showing counting as the core mathematical skill. Interestingly however, she could not find virtually any explicit verbalisation of spatial description in the interaction between parent and child. This suggests that verbalisations of spatial descriptions were compensated for or replaced by deictic gestures in order to resolve the situation.

In relation to recent research on indicative gesture, the most important works in English include above all Alibali (2005), Alibali and Nathan (2007) and Hostetter et al. (2006). Following these authors, gesture can be differentiated to support both teacher behaviour and interaction with spatial perception. Alibali and Nathan (2007) emphasise that gesture is a means of communication which can be employed by teachers, like language, to support the understanding of their pupils. Therefore, on the one hand gesture can be used to clarify something that has already been portrayed in language. On the other hand, according to Alibali (2005), deictic gesture is used to convey information that has not been linguistically expressed. From an educational perspective, this fact seems to contain a crucial problem. Approaches to mathematics which focus on the senses are problematic because mathematical objects are abstract, and it is difficult to access them sensually through visualisations. A deictically characterised form of support however lends itself to precisely the visual approaches which cannot communicate mathematical concepts.

If we take learning to be a process of dialogue, which may only be described in the course of coordinating the mental activities of at least two individuals, and whose components, in the sense of genetic interactionism (Miller, 1986), are anchored in the activities of the collective, all participants in the dialogue must adapt and re-adapt their interpretations of situations in order for processes of negotiation of meaning to successfully make progress. Usually only a small functional adaptation of individual interpretations is required from the participants in the dialogue to move the interaction forward. This kind of temporary adaptation of meaning is called "working consensus" (Krummheuer, 1992, p. 25; on the concept see Goffman, 1959, pp. 9-10). According to Krummheuer and Brandt (2001), learning can be understood in this light as the increasingly active participation in the asymmetrical processes of the negotiation of meaning, so that the conditions of autonomy of the adult can be translated to the children. The question is whether this kind of short-term working consensus and opportunities for learning through gaining autonomy can still be realistic goals if, during negotiation of meaning in asymmetrical interaction, aspects of mathematical issues are expressed by the adult through deictic gesture instead of

language. These gestures could result in a vague situation where the subject of negotiation is often implicitly obscured, and where the children are barely given any opportunity for more active participation (“Implizite Pädagogik”, in Schütte, 2009, p. 191; or “Implicit Pedagogy” in Schütte & Kaiser, 2011, p. 247).

Even when learning is anchored in the mental constitution of the individual, and the individual participants are accorded every decisive mechanism and process in Piaget’s sense of genetic individualism (Miller, 1986), a further problem emerges. If language is understood in this way, most learning does not take place in processes of negotiation of meaning between participants in a dialogue: instead, learning processes are portrayed by the individual constructs of the individual participants. It is not only that processes of negotiation of meaning remain vague when certain aspects are not linguistically expressed. Opportunities to access processes for creating mental constructs can also be hampered and restricted, since deictic gesture is far from being unambiguous or self-explanatory. In addition, it can be concluded with Huttenlocher and Newcombe (2006) that the use by adults of deictic gesture as a substitute for vocalisation will give children less opportunity to learn the linguistic coding of space.

In some mathematical topics gesture plays an especially large role in teaching. Unlike in other mathematical areas, negotiation on spatial information seems to demand the use of gesture. Conclusions drawn by Acar (2011) also point towards a neglect of spatial perception in everyday family interaction. Looking at various play-situations, Acar shows that parents approach building games – which belong in the realm of spatial perception from a mathematical point of view – in such a way as to make them exercises in arithmetic. They thus focus the support they give to the child on counting the wooden blocks, whilst spatial-geometrical application remains lacking.

METHODOLOGY AND METHODS

The basis for this study is qualitatively oriented, both in and outside a school environment; more precisely, it represents an interactionistic approach of interpretive education research in the field of mathematics education (Tiedemann, 2012). Video recordings form the empirical basis for the study. The research questions will be adapted according to an innovation in perspectives: the research will simultaneously look at children of similar ages (5-7 years) in primary school, infant school and in families. A comparison of these different places of learning takes the different kinds of development in children into account, and at the same time gives a comprehensive base for proposals regarding the development of spatial thinking. It is assumed that the individuals under observation, in view and in spite of the potentially new situation (study materials, camera, etc.), nevertheless resort to routines of behaviour and interaction that they have previously found to be successful. On this basis the observed situations are taken to represent the everyday in the schools, infant schools and families studied (Schuette, 2009). In this sense, the study that forms the basis for this paper aims to help initiate a shift in the focus of research, or at least to reveal possibilities for such a shift. With reference to Krummheuer and Naujok (1999), the present paper aims

to identify conditions under which teaching can be altered; it also attempts to discover possibilities for altering behaviour in adults that may be habitual and is not rationalised by the presence of a fixed aim.

Methods of data collection

The study is planned as a cross-sectional video-study. Data are collected in infant and primary schools as well as the respective families of the infant and primary school pupils. In the infant school, on two respective visits two different play and discovery exercises were carried out with one teacher and two children. Similar play and discovery exercises were carried out, also over two visits, in the families of the children. In the families the situations were played out with a parent and the respective children; in the primary school, however, the procedure was different, since the children are taught by teachers with mathematical didactical expertise. This meant everyday teaching was investigated in relation to the central ideas of space and form. Teachers were given thematic areas around which to independently plan and deliver a lesson, without any further external input. The families of the primary school pupils were given tasks fundamentally similar to those given to the families of the infant school pupils, only adapted to suit the older age-group. The characterisation of components of spatial perception is based on a model by Maier (2001, pp. 71-72), which is founded on: (1) spatial perception, (2) visualisation, (3) mental rotation, (4) spatial relations and (5) spatial orientation. On the one hand these components can be categorised such that the “outside position” refers to the participants in the dialogue; that is, whether an inside or outside position is adopted. On the other, we can differentiate between static and dynamic mental processes. Every play and discovery situation was divided up into three tasks. The first situation could be categorised as a building situation, and was developed on the model of the spatial geometrical game “PotzKlotz”. The skills demanded were spatial geometrical areas, spatial relations, mental rotation and visualisation. The thematic focuses of the three parts of the exercise given in the infant school and in the families of the infant school pupils were as follows: (1) working together to build a copy of a model, (2) building from instruction, (3) building a model and then reconstructing it. For the families of the primary school pupils the focus was slightly different: (1) building from instruction, (2) building a model and reconstructing it, (3) comparing buildings. An example of building from instruction for the families of the infant school pupils is given below.

PotzKlotz - Building and Discovering Together (2 Players)

You need some building cards and 5 building blocks. Choose one of the cards, and work together to build the structure that is shown on it. Repeat 3 times.

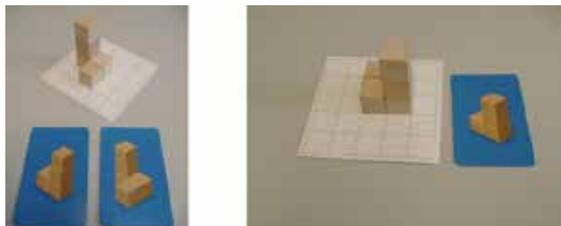

Figure 1. Building from instruction

The second play and discovery situation can be understood as an adaptation of Piaget and Inhelder's "Three Mountains" test (1971, p. 251, cf. Grüßing, 2002). The situation demands skills of spatial orientation. The three foci for infant school and infant school families were: (1) reconstruction from a photograph, (2) orientation from a given position, (3) search of positions from a given orientation.

Methods of data analysis

The analysis of the interaction units in the video-recorded situations aligns itself with a reconstructive-interpretive methodology and a central element of the Grounded Theory research method, namely the methodical approach of comparative analysis (Strauss & Corbin, 1996). In the analysis of the linguistic intercourse with spatial perception, video sequences are analysed with the help of interactional analysis (Krummheuer & Brandt, 2001). The interactional analysis allows the constitution of negotiations of meaning in interaction between individuals to be reconstructed. In order to reconstruct additional common structural features in the linguistic intercourse with spatial perception in the different institutions and with different adults, the video-recorded situations are systematically compared using the comparative analysis methods.

RESULTS

Analysis of the linguistic processes of negotiation in the families yields interesting results. Similarly to the results in Schütte (2009), the mothers' behaviour can be described with the help of the theoretical concept of "Implicit Pedagogy". As they work through the tasks, the mothers hardly ever use conceptual terms like "block", "build", or "building" (in relation to learning environment 1), instead using indexical expressions such as "here", "that", "there", etc.

- 6-9 <N: that's how that is supposed to look...can we do that/
- 13 <N: can we put that on that, too\ can you put it on that/
- 20 <N: that's right\ where should we put the others now/
- 66 I: first let's put that on the ground

It might be assumed that the young children guess these concepts and begin to use them. This would correspond to the procedure in the Year 4 classes, analysed by Schütte (2009) in a range of different aspects, in which the achievement of the goal of introducing a mathematical concept appears to lie above all in its naming. However, if one examines this through the theoretical lens of Bruner's language acquisition approaches (1983), there is a clear difference to the processes of negotiation in the Year 4 classes. According to Bruner, children require a linguistic model, whose linguistic behaviour they can begin imitating. Over time they then lastingly integrate linguistic patterns, concepts, etc. into their own patterns of linguistic behaviour, actively using them more and more by themselves. In this way, children also imitate the linguistically reduced behaviour of the mothers described above, leading to a

negative spiral in the linguistic level of negotiation. It could be argued that the children here are very young, and that a more elaborate linguistic negotiation is therefore neither appropriate nor to be expected. But something interesting occurs in the breaks between tasks, where the mothers are no longer directing the actions in the learning environment: suddenly, they start to use concepts, and their linguistic behaviour becomes more elaborate.

51 <N: now let's find another new one/ ok then squash the blocks again

How can this behaviour be explained? If we stay with the theory of Implicit Pedagogy, it can be concluded that the mothers seem not to want to “give away” concepts to their children when they perceive that they are in a learning environment. It seems important that the children guess these concepts, and are then the first to use them, which would contradict the above-mentioned language acquisition theories. Similar behaviour was observed in Year 4 teachers during the introduction of new mathematical concepts. In this case, the behaviour appeared as specific to teachers. But these parallels to the linguistic structuring used by the mothers indicate that this understanding of teaching, which could be characterised as a vulgarisation of active discovery learning, should not be ascribed to a professional pedagogical teaching approach. Rather, it emerges from an everyday perception of teaching and learning, that is, that in all kinds of learning processes, one should not “give away” concepts to children. In relation to the discovery of mathematical patterns and structures, this is surely correct. It is not possible, however, to simply “discover” concepts or special linguistic features or conventions. For this purpose, children require a person offering an advanced interaction by which they can orient themselves, and who serves as a (linguistic) model.

PERCEIVING CALCULUS IDEAS IN A DYNAMIC AND MULTI-SEMIOTIC ENVIRONMENT- THE CASE OF THE ANTIDERIVATIVE¹

Osama Swidan

University of Haifa Mandel Leadership Institute, Israel.

The present case study was designed to analyze the objectification processes of making sense of the antiderivative concept when it is being studied graphically in a dynamic and multi-semiotic technological environment. This study is guided by sociocultural theory, which considers artifacts to be fundamental to cognition and views learning as the process of becoming aware of the knowledge that exists within a culture. The case study focuses on two seventeen-year-old students. In the course of the discourse micro-analysis I identified three essential foci in the objectification processes 1) objectifying the relationship between a function and its derivative 2) objectifying the relationship between a function and its antiderivative 3) objectifying the vertical transformation of the antiderivative graph.

INTRODUCTION

The integral concept is considered to be central to learning calculus and I cannot imagine any curriculum in calculus not containing the integral concept. The integral consists of two essential concepts – the antiderivative and the definite integral. The fundamental theorem of calculus connects these two concepts. Therefore, significant learning of the integral concept must encompass the learning of the conceptual aspects of both these concepts (Thompson, Byerley, and Hatfield, in press). Thompson and Silverman (2008) suggested to introduce the accumulation function as a tool to connect these two concepts. Thompson et al. (in press) have proposed a didactical sequence that serves to emphasize the conceptual aspects of the integral concept when taught to college students as the accumulation function, and using technological tools. Following Thompson and Silverman (2008) and Thompson et al. (in press), I propose a learning unit composed of five sessions, in order to improve the understanding of the processes involved when high school students are learning the integral as accumulation using graphical means. This learning unit is based on graphic and numeric signs and dynamic interfaces, which consider the graph of the accumulation function as central in conceptualizing the integral concept. Yerushalmy and Swidan (2012) have analyzed and identified processes of making sense of the definite integral as accumulation in a dynamic and multi-semiotic environment among high school students.

Few research studies have examined the learning of the antiderivative concept in general, and among high school students in particular. For example, Haciomeroglu,

¹ This case study is part of a PhD study under supervision of Prof. Michal Yerushalmy, university of Haifa - Israel.

Aspinwall, and Presmeg (2010) have examined the mental processes and images used by three university students to create meaning for graphs of the antiderivative function. Berry and Nyman (2003) have studied college students' understanding of the relationship between a function and its antiderivative function while drawing graphs of functions from graphs of the derivative by using a sensory calculator (CBR²). The scarcity of studies dealing with the process of learning of the antiderivative concept by high school students and the usefulness of graphical tools such as graphic interfaces in teaching the conceptual aspects of calculus is what motivated me to design the current study. This study aims to analyze the processes involved in high-school students' learning of the antiderivative concept graphically as accumulation function, using graphical and dynamical tools.

THEORETICAL FRAMEWORK

According to sociocultural theory artifacts of any kind are central and play a fundamental role in cognition. It has been claimed that, within the social use of an artifact to accomplish a task, shared signs, which relate to the artifact, are produced and may be related to the content intended to be learned (Bartolini Bussi and Mariotti, 2008). The relationship between an artifact and knowledge is expressed by culturally determined signs. The relationship between an artifact and accomplishing a task is expressed by signs such as gestures, speech and drawing.

Signs in general, and mathematical signs in particular, play two roles. Radford, Bardini, Sabena, Diallo, and Simbagoye (2005) define these roles as “social objects in that they are bearers of culturally objective facts in the world that transcend the will of the individual. They are subjective products in that in using them, the individual expresses subjective and personal intentions” (p. 117). Berger (2004), who studied the functional use of mathematical signs, suggests a twofold interpretation of the meaning of signs and objects: a personal meaning, “to refer to a state in which a learner believes/feels/thinks (tacitly or explicitly) that he has grasped the cultural meaning of an object (whether he has or has not),” and a cultural meaning, “to the extent that its usage is congruent with its usage by the mathematical community” (p. 83). In the context of using artifacts, Bartolini Bussi and Mariotti (2008) describe the relationship between the personal and the mathematical meaning as a double semiotic relationship: “On the one hand, personal meanings are related to the use of the artifact, in particular in relation to the aim of accomplishing the task; on the other hand, mathematical meanings may be related to the artifact and its use.” (p. 754). Adopting these terms, I define the double semiotic relationship as the semiotic potential of an artifact, and assume that the potential is defined with respect to a particular design and pedagogical goals.

² Calculator based ranger is a motion sensor device that can collect and represent real-world motion data, such as distance or velocity.

Learning in this setting means participating in an active process that leads to making sense of the elements, and bringing about an encounter between personal and mathematical meanings. In other words, to learn something, the learner must attend to the existence of the knowledge within the culture and become aware of its existence (Radford, Bardini, and Sabena, 2007). The attention and awareness processes of an existing mathematical object require engagement in a mathematical activity to grant meaning to the object. (Radford, 2003) called this process an objectification process. Objectification requires making use, in a creative way, of different semiotic tools such as words, symbols, and gestures available in the universe of the discourse (Radford, 2003). Semiotic tools play a central role in the objectification processes of knowledge. To examine the objectification processes of learning the antiderivative concept graphically, I intend to answer the following question: How do the personal meanings that emerge from accomplishing a task with a dynamic artifact take on mathematical significance for a pair of high school students?

THE MATHEMATICS, PEDAGOGY AND SEMIOTICS OF THE ARTIFACT

The artifact used in this study was *The Calculus Integral Sketcher* (CIS) (Shternberg, Yerushalmy, and Zilber, 2004) (Fig. 1). As a multi-semiotic system, the CIS contains different types of signs that can be grouped into two categories:

1. **Cartesian Graphing system:** Two Cartesian coordinate systems, one above the other, coordinated horizontally. The curve in the upper Cartesian system signifies a function f . The curve in the lower system signifies the values of $\int_a^x f(u)du = g(x) - g(a)$ where the derivative of g is the function f .

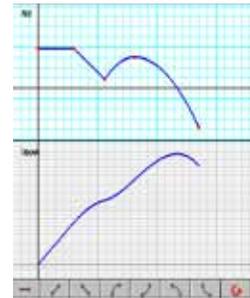

Fig. 1

2. **Iconic Graphing tools:** Students choose the graph in the upper Cartesian system by pressing an icon at the bottom of the CIS. Schwartz and Yerushalmy (1995) describe this set of icons as a mediating language for modeling consisting of segments from a wide range of single variable functions.

Sketching the graph of a function f in the CIS is carried out by choosing an icon from the icons applet, placing it into the upper Cartesian system, and manipulating it by dragging the segments or their end points. Fig. 1 shows a curve drawn using multiple icons (linear and nonlinear), and its antiderivative graph g is produced by the CIS in the lower system. The tool allows dragging f freely and the g changes accordingly. Dragging the g is permitted only vertically (shifted by a constant) and therefore f does not change.

THE DESIGN OF THE STUDY

This case study is part of a longitudinal study that aims to analyze the learning processes of the integral concept graphically. This study explored about one hour of learning by Mohamed and Ahmed, two seventeen-year-old students in the mathematics class taught by the author. The episode took place in the computer lab at

the students' school. At the time of the episode, the students had already acquired the concepts of function and derivative, but not that of the integral³. The students were familiar with performing differentiation symbolically. The two students shared a computer, and the researcher introduced them briefly to the interface.

To explore the processes of making sense of the antiderivative graphically, I asked the students to interpret the mathematical relationships between the graphs that appeared on the computer screen. To cover the majority of the cases of one variable functions, I asked the students to create graphs using either a single icon or multiple icons. The students were given the following instructions:

To complete the task, you will use the Integral tools of CIS. You are invited to create graphs of single icon and multiple icons. Your task is to come up with a conjecture and explanation about the mathematical relations between the upper and lower graphs. You can work as long as you want, until you feel that you can sketch a graph without any tool that will appear in the lower window for a given function graph.

The students were video-recorded and their computer screens were captured. The video recording was achieved by software which captured the footage in two different windows: the computer screen and the students' body. The researcher was present as an observer and available to provide technical and miscellaneous clarifications.

DATA ANALYSIS

I used *attention* and *awareness*, Radford's (2003) categories of objectification of knowledge, to analyse the evolving processes of personal and mathematical meanings. I identified *attention* as a declaration about the existence of a mathematical relationship between objects in the semiotic system. In the present study, declarations about the existence of mathematical relationships tended to be based on visual considerations. Justifications and interpretations based on mathematical considerations of the mathematical relationships students had noticed were defined as *awareness*.

I present here the second round of analysis. The first round consisted of reiterative watching of the video, concentrating on students' actions with the tools, their repeated gestures, argumentation, and interpretations. The second round involved searching for and classifying the transcripts into three main categories which were taken from the data: 1) objectifying the relationship between a function and its derivative 2) objectifying the vertical transformation of the antiderivative graph 3) objectifying the relationship between a function and its antiderivative. Therefore, I collated chronologically the utterances and gestures in the discourse that were related to these categories.

³ They had encountered the integral symbol and its computational uses in their physics and electronics lessons

OBJECTIFYING THE RELATIONSHIP BETWEEN A FUNCTION AND ITS DERIVATIVE

The attention of the relationship between the lower graph as a function and the upper graph as its derivative

- 12 Mohamed: [while they drag the graph of f] Constant function parallel to x-axis [initially (Fig. 2) appears; then, as f is dragged vertically, there appears on the screen a constant function in the upper Cartesian system and a linear function in the lower Cartesian system (Fig. 3)]
- 13 Ahmed: This is a function [the lower graph] and that is its derivative [the upper graph].

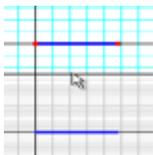

Fig 2

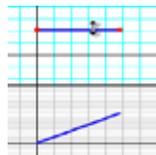

Fig 3

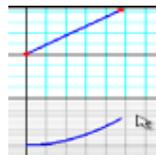

Fig 4

Fig 5

Fig 6

The students create a semiotic system, which contains two constant zero functions by the first icon  of the CIS [12]. When they drag f in the upper Cartesian system vertically they create a new semiotic system which contains a constant function in the upper Cartesian system and a non-constant linear function in the lower Cartesian system [12]. Immediately, the students declared a correlation between the two graphs – function and derivative. This suggests that the semiotic systems they create help them to pay attention to the correlation between the graphs, while their dragging of f vertically and the corresponding change of g suggests that the students become aware of the correlation between the slope of the linear function and the y-value of the constant function. This is shown in the next transcript.

The awareness of the relationship between ‘g’ graph and ‘f’ graph

- 18 Ahmed: The slope is increasing [tracing the graph in the lower Cartesian system (Fig. 4) with the mouse] increasing, increasing
- 19 Mohamed: You must consider from here to here [trace the interval (0,1) on the x-axis in the lower Cartesian system]. How much is the slope? From here to here [indicates with the mouse on the x-axis from the origin up to one, then goes up vertically to reach the graph in the lower system] it is about one.
- 20 Ahmed: It is about one [pointing with the mouse to a point its y-value is one on the upper Cartesian system] ... how much here?
- 21 Mohamed: From here to here are two three... Ahh... It is increasing... the slope will behave like this [gestures with his hand (Fig. 5)] its slope is increasing [makes a gesture with two fingers, emulating the linear function (Fig. 6)]

In this excerpt, the students create a linear function in the upper Cartesian system and the graph of a quadratic function appears in the lower system. Ahmed starts to make sense of the connection between the two graphs. He describes the tangent slope of the quadratic by tracing it on the graph with the mouse and by using rhythmic speech “increasing, increasing, increasing” [18]. The words [How much is the slope? From here to here] and the gestures [indicates with the mouse on the x-axis from the origin up to one, then goes up vertically to reach the graph] performed by Mohamed in [19] suggest that he is describing the rate of change of the quadratic function at several points. In [20] Ahmed starts to describe the connection between the two graphs for a specific value of x that the two graphs share. They correlate the tangent slope value in a point where its x coordinate is one in the lower graph to the y -value of the function in the upper graph for the same x coordinate [20]. Mohamed’s gestures and words suggest that he is becoming aware of the behaviour of the tangent’s slope of the quadratic function. The gestures performed by Mohamed – the first gesture signifying the tangent slope of the quadratic function and the second gesture signifying the linear function graph in the upper Cartesian system- together with Pointing by the mouse to the point whose y -value is one on the upper graph. Suggest that the students are becoming aware that the behaviour of tangent slope value of the lower function on points is the same behaviour of the y - value of the upper graph at the same x -coordinate [21].

OBJECTIFYING THE VERTICAL TRANSFORMATION OF THE g GRAPH

The attention and awareness to dragging the g graph vertically

36 Mohamed: There is no difference between the slopes of the graphs when we drag them up and down. We get the same slope if we drag it like that [drags ‘ g ’ vertically – (Fig. 7)]

37 Ahmed: What is the value of this point? [The intersection point with the y -axes]

38 Mohamed: It is not the matter of the value of the point...The matter is considering the slope of the lower function, for example the slope is one [makes a motion with the mouse like a tangent line at a point on the lower graph] here is one [points toward the coordinate point in the upper graph]. The slope here is two [makes a motion with the mouse like a tangent line at a point on the lower graph and simultaneously he points toward a coordinate point in the upper graph]

39 Ahmed: I don’t agree with you

40 Mohamed: It is correct. The slope of the lower graph isn’t changing even if you drag it [dragging ‘ g ’ vertically], the slope will not change

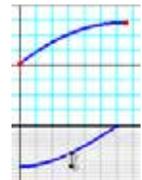

Fig 7

The students drag g vertically. They observe that f is not moving. Mohamed observes that the shape of g does not change when they drag g vertically. Mohamed demonstrates his awareness of this fact by using the word ‘slope’. His vertical

dragging action, the words he is using, the gestures he is performing on the lower graph and the pointing gestures he is performing on the upper graph in [36] and [38] suggest that he is ‘seeing’ the tangent’s slope of g in different points and coordinates the tangent slope value to y -value of points on the upper system. He is repeating this process for other graphs which differ by a constant.

OBJECTIFYING THE RELATIONSHIP BETWEEN f AND g

First phase: Objectifying the function change

In this excerpt the students are discussing ways to describe how the tangent slope is behaving. While Ahmed claims that the slope of the tangent to the left of the minimum point is decreasing (Fig. 8) Mohamed is explaining how he sees the increase of the tangent slope.

- 62 Mohamed: It is minus two; minus one [y - values of f from left to right] it is increasing [points to f].
- 63 Ahmed: It is the derivative [points to f]
- 64 Mohamed: This graph [f] describes the slope of the function [f]
- 65 Ahmed: Wait a moment... here it is a function [f]... how much is the slope? [Tracing the left side to the minimum point on [g], it is decreasing until it becomes zero
- 66 Mohamed: It means increasing
- 67 Ahmed: Correct! It is increasing [tracing f until the intersection point of f with the x -axis]...when it becomes zero [f] it gets this point [he connects, with the mouse, the intersection point in the upper graph with the minimum point of g]
- 68 Mohamed: When the slope is zero [traces with the mouse the minimum point of g] it intersects the x -axis [indicates the point where f intersects the x -axis]

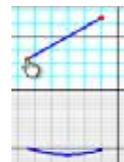

Fig 8

The semiotic system of graphs, the gestures and the words in [62] suggest that Mohamed is considering, for the first time, the graph of f and reading two consecutive y -coordinates, as a way to explain the increase of the tangent slope. While, Ahmed still maintains the view - the graph in the lower system is a function and in the upper system it is a derivative - which mentioned and analysed in the last excerpt. Mohamed’s declaration in [64] suggests that he has seen the connection between the y -values of the graph in the upper Cartesian system and the tangent slope value of the lower graph. In [65] Ahmed is checking Mohamed’s claims by tracing the lower graph up to the minimum point. His tracing gesture imitates the behaviour of the tangent of the graph. The mismatch between Ahmed’s tracing gesture and his statement “It is decreasing until it becomes zero” suggests that Ahmed has a difficulty describing the process where a negative tangent slope is increasing [65, 66]. In [67] Ahmed leaves the ‘ g ’ graph and concentrates on describing the upper graph, noticing that the intersection point between the upper graph and the x -axis

corresponds to the minimum point in g graph. In line [68] Mohamed explains this correspondence by identifying the slope of the minimum point as zero. This explanation suggests the role the word “slope” plays in correlating both graphs and in conceptualizing the idea of the antiderivative.

Second phase- objectifying the rate of change of ‘f’

The students use the fourth icon  to create an increasing function graph with a decreasing rate of change in the upper Cartesian system (concave down Fig. 10). For g , they obtained an increasing graph with an increasing rate of change (concave up) in the lower Cartesian system. The students are confused about having two increasing graphs where one has an increasing rate of change g and the other, a decreasing rate of change f . In the next excerpt, I analyse the processes and the emergence of the new semiotic means that enable them to solve this matter.

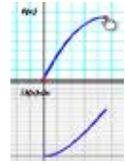

Fig 10

101 Ahmed: [Fig. 11 appears on the screen] It is the derivative [f]

102 Mohamed: It is zero. Okay? Here it is two... If the value is two what does it mean in the integral? The slope of the integral function at this point is two... What have we got here? Three. It is decreasing at three.

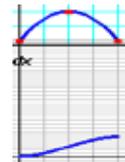

Fig 11

103 Ahmed: It is decreasing. The slope is decreasing

104 Mohamed: Look here [he deletes the right branch of Fig 11 and drags the right red point diagonally to get Fig. 10] [Silent for 10 seconds] I got the idea... wait a moment... when x is one the value is three [indicates the point (1,3) in the upper graph] Therefore, the slope is also three when x is one. [Points to lower graph] here it is four [points to the point (2,4) on the upper graph] thus the slope here is also four [makes a gesture like a segment on the lower graph]. Here its value is five plus [points to the point where x is 3 in the upper graph] thus its slope is five plus.

After they encountered difficulties interpreting the concavity of the integral graph [Fig. 10], the students made a new graph, using two different icons in the upper graph [Fig. 11]. The left icon is increasing graph and concave down, and the right icon is decreasing graph and concave down [Fig. 11]. Initially Ahmed signified the function graph as derivative [101]. Mohamed adapts Ahmed’s claim as he is determining three y -values of the function graph. The students are well aware that each y -value in the function graph is the value of the slope of the tangent in the integral graph [102], and they are using the y -value of the function and the tangent slope of the integral function graph as means of semiotic mediation to explain the mathematical relationship between the two graphs. The use of these means is well illustrated in [104], where Mohamed interprets the relationship between the function graph and the integral graph.

DISCUSSION

Through the semiotic lens I determine three essential foci of objectifying the antiderivative concept. The first focus is objectifying the relationship between a function and its derivative. The constant function icon plays a central role in objectifying the relationship between the graph in the lower Cartesian system and the graph in the upper Cartesian system. The vertical dragging of the constant function graph performed by the students allows them to create an additional similar semiotic system, while linking the graphs according to the cultural meaning of the antiderivative helps them notice the difference in the similar semiotic systems. Once they notice that, the connection between the antiderivative graph slope value and the y-value of the constant function becomes apparent. Changing the semiotic system to include a linear function and a quadratic antiderivative produced changes in the semiotic resources the students used to objectify the relationship between the function and the antiderivative graph. Utilizing additional semiotic resources allows me to suggest that the slope of the graph in the new situation is not obvious to the students, unlike in the constant function case. In order to make this obvious they use rhythmic speech to describe the behaviour of the tangent's slope, and gestures to objectify the change of the tangent slope. The second focus considers the objectification of the vertical transformation of the antiderivative function. Dragging the antiderivative function graph vertically by the artifact and noticing that the function graph is fixed help the students become aware of an essential mathematical element of the antiderivative concept. The little variety of the semiotic resources used in this focus allows me to claim that objectifying the mathematical fact that the antiderivative of a function is a family of antiderivative functions is actually quite simple. The third focus considers the objectification of the antiderivative idea. That is, the y-value of a point on a function's graph is the tangent's slope value of the antiderivative function's graph for the same x-value. The current focus consists of two phases: objectifying the change of the function and objectifying the rate of change of the function. The first phase emerges through the students' confusion in describing the behaviour of a tangent slope of a decreasing graph with an increasing rate of change. This confusion has helped them leave the lower Cartesian system in favour of the top one. I assume that this happened because of the linearity of the function graph in the upper Cartesian system. The second phase does not refer to the shape of the antiderivative function behaviour only, but does refer to how the shape of the graph behaves. This phase emerged when the students created two contrasting graphs, one concave up and the other concave down.

FACTORS AFFECTING THE ESTABLISHMENT OF SOCIAL AND SOCIOMATHEMATICAL NORMS

Konstantinos Tatsis

University of Ioannina, Greece

The present paper initially examines the concept of norm as it has been implemented in mathematics education. A sample excerpt is then used to demonstrate that the analysis of norm establishment would be better accompanied by the consideration of the face-saving needs of the participants. The relevant sociological and linguistic theories are also presented in order to provide the background for that claim.

INTRODUCTION

One of the main current trends in mathematics education research puts the emphasis on collaborative learning environments. In line with sociocultural views on learning been directly related to the societal contexts, numerous studies have been made. It is noteworthy, however, that there are voices that call for attention in the mere acceptance of any teaching/research approach, just because it belongs to the mentioned trend: “the current obsession in mathematics education with group work and discussion is not, and cannot be, a panacea” (Mason, 2004/2008, p. 1). The present paper is the product of the author’s interest in the interactional processes that constitute or assist the establishment of taken-as-shared mathematical meanings (Cobb, Wood, Yackel, & McNeal, 1992). In the relevant literature a number of theoretical constructs have been used in order to assist the researchers to describe and interpret the observed phenomena. Among these, I am mostly interested in the concepts of the social and sociomathematical norms as they have been introduced for mathematics education by Paul Cobb and his colleagues (e.g. Cobb & Yackel, 1996; Yackel & Cobb, 1996). These concepts have been used quite extensively in studies that vary from classroom interactions (McClain & Cobb, 2001) to collaborative student pairs (Tatsis & Koleza, 2008) and from kindergarten (Tatsis, Skoumpourdi, & Kafoussi, 2008) to university (Yackel & Rasmussen, 2002). My aim here is to examine whether these concepts suffice to account for the establishment of mathematical knowledge. The answer to this question may be of interest to the researcher or the teacher who wants to interpret the participants’ actions while they interact in a mathematical environment. I have to stress though that I do not aim to offer a novel approach in interpreting interactions; I merely wish to examine the complementarity of particular existing theories.

SOCIAL AND SOCIOMATHEMATICAL NORMS

The concept of norm is derived from the broader notion of *prescriptions* which are: “behaviours that indicate that other behaviours should (or ought to) be engaged in. Prescriptions may be specified further as demands or norms, depending upon whether they are overt or covert, respectively” (Biddle & Thomas, 1966a, p. 103). A similar

concept to that of the norm is the *obligation* (Voigt, 1994) which connects the various routines of the classroom and regulate the students' and the teacher's actions. Different typologies for the norms have been proposed by sociologists, each based on different criteria; Morris (1966) groups the various criteria into four sets:

- (a) distribution of the norm (extent of: knowledge, acceptance and application of the norm),
- (b) mode of enforcement of the norm (reward-punishment, severity of sanction, enforcing agency, extent of enforcement, source of authority, degree of internalization by objects),
- (c) transmission of the norm (socialization process, degree of reinforcement by subjects),
- (d) conformity to the norm (amount of conformity attempted by objects, amount of deviance by objects, kind of deviance).

The above typology was not created to be implemented as a whole; it is rather the researcher's decision on which criteria to use. For example, the distribution of the norm is related to, among others, the extent of knowledge of the norm by subjects (those who set the norm) and by objects (those to whom the norm applies). Thus, in the case of (mathematics) education, a researcher who is interested in the distribution of a norm within a classroom may focus on the objects (students), while one who is interested in the distribution of a norm within the mathematicians' community may focus on the subjects. Yackel and Cobb (1996), while observing an 'inquiry-oriented' mathematics classroom have made another distinction, between social and sociomathematical norms. The former are related to the general structure of classroom activity and some examples are: "explaining and justifying solutions, attempting to make sense of explanations given by others, indicating agreement and disagreement, and questioning alternatives in situations in which a conflict in interpretations or solutions had become apparent" (Cobb & Yackel, 1996, p. 178). The latter are specific to mathematical activity and relate to which contribution counts as "a different mathematical solution, an insightful mathematical solution, an efficient mathematical solution, and an acceptable mathematical explanation" (Cobb & Yackel, 1996, p. 179). The authors relate the process of establishing norms to the process of constructing mathematical beliefs and values, thus attempting to connect a sociological with a psychological approach. Similar to the concept of norm is that of the *metadiscursive rules* "that is, mostly tacit navigational principles that seem to underlie any discursive decision of the interlocutors" (Sfard, 2002, p. 324). Although Sfard considers norms as a sub-case of rules¹, she offers some useful (for the teacher and the researcher) characteristics of the metadiscursive rules:

[M]etadiscursive rules may *evolve* over time (as opposed to the object-level rules of mathematics, which, once formulated, remain more or less immutable). Metarules are also made distinct by being mainly *tacit*, and by being perceived as *normative* and value-laden whenever made explicit. Finally, metarules are *constraining* rather than

deterministic and are *contingent* rather than necessary. (Sfard, 2008, p. 202, emphasis by the author)

Finally, one could mention the notion of the *didactical contract* introduced by Brousseau (1997), which refers to specific habits of the students that are expected by the teacher and vice-versa. The responsibility of knowledge construction is seen as shared between the teacher and the students and the didactical contract assists that process. However, a familiar didactical contract can also create problems for the students, especially when they enter a situation where the contract changes considerably, e.g. by entering the university.

ROLE THEORY AND THE NOTION OF FACE

All the approaches mentioned in the previous section are to some extent related to a sociological theory. What is common in them (and in other approaches of the same tradition) is the focus on the interactional aspects of the activities that take place in educational settings. The human agent (teacher, student or researcher) is present, but the actions of these agents are usually analysed under the lens of the mathematical activity, e.g. examining the changes in students' knowledge or beliefs about mathematics. What seems to be missing is a consideration of the fact that all participants in any interaction can be viewed as some kind of actors, and sometimes the whole 'scene' is set before them. People's behaviours, seen under this interpretive model, form the research ground for *role theory* as set by Biddle and Thomas (1966b) and exemplified by Goffmann (1971, 1972). The central concepts in that theory are *face* and *role performance*. Face is defined as "the positive social value a person effectively claims for himself by the line others assume he has taken during a particular contact" (Goffman, 1972, p. 5) and can be further categorised into positive and negative: positive face is related to a person's need for social approval, whereas negative face is related to a person's need for freedom of action (Brown & Levinson, 1987). The participants not only have these needs, but recognise that others have them too; moreover, they recognise that the satisfaction of their own face needs is, in part, achieved by the acknowledgement of those of others. All these affect the role performance which is defined as "all the activity of a given participant on a given occasion which serves to influence in any way any of the other participants" (Goffman, 1971, p. 26). For example, when a student enters the mathematics classroom s/he is primarily concerned about maintaining face; in order to achieve that s/he has to deploy various linguistic and non-linguistic strategies. The same is the case for the teacher. Each communicational move may be initially characterised as face saving or face threatening for the speaker and/or the listener. A request or a question from the teacher for example, is considered a face threatening act; a student's wrong answer on the other hand, may or may not be face-damaging, depending on the classroom's established norms. The effect of the consideration of face can be seen in the use of vague language (Rowland, 2000), which in turn affects the 'quality' of mathematical propositions, thus the learning of mathematics itself. But why would someone use vague language, especially in the mathematics

classroom? A comprehensive list is given by Channell (1985, 1990, 1994, as quoted in Rowland, 2000, p. 67):

- giving the right amount of information;
- deliberately withholding information;
- saying what you don't know how to say;
- covering for lack of specific information;
- acknowledging and achieving an informal atmosphere;
- expressing uncertainty;
- downgrading the importance of something as to highlight something else;
- expressing politeness, especially deference;
- protecting oneself against making mistakes.

The above list provides, among others, direct links with the concept of face (positive and negative) and its protection against possible threats. It also stresses the point that I made at the beginning of the section that participants in any interaction, including students in the mathematics classrooms, may be viewed as persons with aims similar to those of any other person. Sometimes, for example, a student might feel the need to not convey the information requested by the teacher; and this might be due to some (inter)personal reasons, related to saving face. In the next section I will present an example of the implementation of these theories; my aim is to demonstrate their compatibility with the concepts of social and sociomathematical norm.

AN EXAMPLE

Mathematical concepts are (or should be) clearly defined; the same is the case with the rules of logic, which assist the mathematicians in expressing conjectures, proving theorems and generally conducting research in pure mathematics. The rules related to these processes can be referred to as object-level rules (Sfard, 2008). However, the interactions taking place in a mathematics classroom or in any other research setting are governed by metarules and norms, whose main characteristics, as they have been already described, are quite far from being fixed. I believe that what provides these norms with their flexibility is the fact that human agents are involved in their establishment. The needs of these agents may evolve over time, thus the norms have to be renegotiated or even replaced. For example, turn-taking – or, more generally, who has the right to speak – may be of high importance in the first years of schooling, but, as students mature, the norm of the quality of one's contribution should be valued. This could be seen as an example of a social norm (on turn-taking) being transformed into a sociomathematical norm.

Two issues need to be addressed at this point. The first is that an established norm does not necessarily have to be a desirable one; in other words, a norm might hinder – instead of assist – mathematics learning. A characteristic example is the

‘mathematical differentiation norm’ (Tatsis & Koleza, 2008) according to which mathematics is comprised of distinct, non-overlapping fields, such as algebra and geometry; there is also a distinction between mathematical and practical solutions. In the following excerpt two female student teachers have just found the answer to the following problem: *Figure 1 shows a triangle in which three lines are drawn to one or the other of the opposing sides from each of two vertices. This divides the triangle into 16 non-overlapping sections. If 14 lines are drawn in the same way, how many non-overlapping sections will the triangle have?* The interaction takes place in a laboratory setting and the researcher has taken a passive stance throughout the interaction by choosing not to intervene or assist the student teachers.

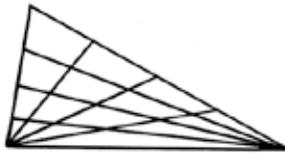

Figure 1: Number of non-overlapping sections

- 134 Student A: Okay, if we draw three segments we have four triangles. But this is practical. You may say that in three, if you draw three line segments from the one side and also from the other, it created four line segments, four triangles, with four sections each. Right? So, in total the overlapping will be four times four, 16. If you draw 14 line segments you will create 15 triangles with 15 overlapping sections. So, okay, does this have 100 % proof? And if someone tells you: I with 60? It will... 61 triangles that will be created, with 61 non-overlapping sections. So, indeed it will be 16 here, so indeed it'll be 225 here, so indeed 3600 and so on.
- 135 Student B: Good, if we justify about 15, let the other one with the 60 bother for that.
- 136 Student A: Do we have an eraser or something?
- 137 Student B: Why, does it necessarily have to be like that?
- 138 Student A: What?
- 139 Student B: A formula?
- 140 Student A: We are not talking mathematically, that's all, okay? And what I say is correct, to say: since with three is the immediate larger in 16...

The two students agree to write down the solution, but when student B starts writing, the following exchange takes place:

- 149 Student A: It can't be. Something else must be happening here. You keep writing, keep writing.
- 150 Student B: What was Thales's Theorem about? It doesn't fit.
- 151 Student A: For parallels, angles... let it go. It can't have theorems, here it's a practical issue.
- 152 Student B: If it's practical, the way found is correct.

The above excerpt can be seen under many different lenses, but for the purpose of the present paper I focus only on the norms which are evident from the students' contributions. The most apparent is the norm of cooperation, according to which the students are expected to work together to solve the given problem; this is evident by the use of the first plural form 'we' in most utterances. What is also evident throughout this brief excerpt is the students' need to 'mathematise' either by creating a formula or by proving their conjecture that the number of non-overlapping sections equals to the number of lines drawn increased by 1 in the power of two. These are manifestations of the norm related to the mathematical efficiency of a solution as described by Yackel and Cobb (1996). Finally, we may observe the norm of mathematical differentiation mentioned before, especially in [134], [140] and [151]-[152]. At the same time, there are some utterances that can't be fully interpreted by the concepts of norms; a characteristic case is [150] where student B asks a question which she immediately withdraws. One may wonder why she did not care to wait for her colleague's response. At a first glance, mentioning a theorem can be related to the norm of mathematical efficiency, interpreted as: "all propositions should be justified".² The student, struggling between a 'practical' solution (since they had to draw few cases to justify their answer) and a 'theoretical' background that characterizes school geometry, comes up with one of the most familiar theorems. She has the need to contribute to the common task of writing an efficient solution and she offers the best she can at the given moment: Thales Theorem. By proposing something so novel at that moment she is exposed in front of her colleague, but mainly in front of the researcher, who was present. This is a typical face threatening act; and student B in order to minimize the potential damage to her positive face (in case her suggestion is proved to be inadequate) she immediately adds that "It doesn't fit". Student A, who seems to know the theorem, quickly rejects the plausibility of the theorem and they move on. Such exchanges are frequent in educational settings where many students feel that their positive face will be damaged in case of a wrong answer; and sometimes they choose to be silent and this has serious implications for their learning, but also for the establishment of the whole learning community.

Another remark on the given excerpt may come from the observation that student A seems to be in charge of the process; she expresses verbally the solution in [134], leaving to student B the role of merely writing it down, even when she thinks that their solution might not be complete [149]. The small excerpt contains some face empowering verbal acts, such as "what I say is correct" [140] and some face threatening acts for student B in [149] and [151]. Tatsis and Koleza (2006) while analyzing the interactions of three meetings of pairs of preservice teachers, observed the following roles:

- (a) The dominant initiator: makes many suggestions, rarely asks for the partner's opinion and always tries to maintain face; demonstrates a low level of conformity to most social and sociomathematical norms, sometimes adjusts a

norm by his/her acts. Whenever in a difficult position, attributes it to external factors (e.g. the difficulty of the task or even the inability of the partner).

- (b) The collaborative initiator: makes many suggestions, asks for the partner's opinion, gives information whenever necessary and – most of the times – tries to maintain face; is ready to withdraw a suggestion but only if the opposing one is strongly grounded; generally demonstrates a high level of conformity to the social and sociomathematical norms established.
- (c) The collaborative evaluator: makes relatively fewer suggestions compared to the previous roles, always gives information (whether asked or not) and tries to maintain face when s/he believes that it is not against any norm; thus, s/he shows a high level of conformity to the norms established and his/her acts demonstrate a high level of uniformity and facilitation to the partner's acts.
- (d) The insecure conciliator: makes few suggestions and does not try to maintain face in an explicit way; shows a low level of conformity to most norms as s/he accepts his/her partner's suggestions without evaluating them; demonstrates the highest level of facilitation to the partner's acts. Whenever in a difficult position, attributes it to uncontrollable factors, such as ability or task difficulty.

The small presented excerpt does not provide sufficient amount of information to lead us to a valid characterization of the two students' roles. However, we may infer that student A is an initiator, and possibly a dominant one. Student B's behaviour, on the other hand, provides indications that she is a collaborative partner, but we cannot conclude whether she is an initiator or an evaluator.

Generally, in role theory, role performance is conceived as highly situated, thus the roles described before aimed to interpret the participants' act in the particular context (collaborative problem solving). What is important, however, is the fact that these roles are described in relation to the social and sociomathematical norms which are established. The importance of this fact lies in the realization that, while the role of the teacher is seen as central in the process of establishing the desired norms (Sfard, 2008), the actual process is much more complex due to the face needs of the participants (who fulfil these needs by performing various roles). I will return to this point in the final section of the paper.

The second issue that needs to be addressed is that a norm does not have to be accepted by all members of a community to be considered as such. Actually, as I already mentioned, the distribution and the conformity are just two attributes that can be used to describe a norm. This idea is not taken up by many contemporary researchers, who usually see a norm as a characteristic of the whole community of the classroom.³ The first implication of this view is that other, 'minor' norms, which are enacted by few participants, are not given much attention. The second implication is that it creates an assumption that all norms which are desirable by the teacher are efficient for all students. Let me elaborate on this, by using as an example the norm of what counts as an insightful mathematical solution (Cobb & Yackel, 1996). It is

quite apparent that the notion of ‘insightful solution’ is a rather subjective one, and even if the teacher establishes some metarules on that, there will still be some students for whom these rules will be inadequate.

CONCLUSIONS – AN ATTEMPT TO RECONCILE

In the preceding sections I have attempted to briefly present the basic characteristics of the concept of norm and then role theory with its relevant concept of face. I have also demonstrated how these concepts seem compatible, or even more, complementary, since they can be jointly applied in the analysis of interactions. A question might then arise: is such an approach justified by the theoretical assumptions of the relevant theories? The answer is positive, and it can be derived by examining some of the references in the papers mentioned before; they seem to have a common interest in the importance of interactions and many cite the theory of symbolic interactionism (Blumer, 1969). According to that theory, the role of symbols, especially language, is vital for the process of interactions; it is through symbols that people establish shared meanings and define the situation they are involved with. The person is not treated as a passive receiver of society’s influences, but as an active participant who takes part in the formulation and negotiation of shared knowledge during the process of symbolic interaction.

The concept of norm is a fine tool for the researcher at the initial stage of the analysis, or for the teacher who wants to establish a feasible didactical contract with the students. However, once the researcher reaches the micro-level of utterances, s/he will probably notice that some of them do not seem to fit to any established norms; the researcher may also encounter some utterances that were not supposed to be heard in a mathematics classroom (e.g. because they are vague), which at the same time seem to be effective from a communicational point of view. The teacher might have more pragmatic worries concerning the enactment of the norms that should be established. How shall s/he deal with utterances like: “The maximum will probably be, er, the least ’ll probably be ’bout fifteen.” (Rowland, 2000, p. 1)? This utterance clearly violates the sociomathematical norm of clarity; however, this consideration cannot assist the teacher in establishing that norm, unless s/he becomes aware of the fact that the student might be using these linguistic forms in order to protect his face. Thus, acknowledging the face-saving needs of the participants might be of great importance in the mathematical classroom and particularly, in the establishment of social and sociomathematical norms.

NOTES

1. According to Sfard (2008) a rule is considered a norm only if it fulfils two conditions: it must be widely enacted within the discursive community and it must be endorsed by almost all members of that community, especially those considered as experts.
2. This can be also seen as an example of a negative influence of an established norm.

3. However, there is research (Planas & Gorgorió, 2004) indicating that in multi-ethnic mathematics classrooms students adhere to different sets of norms, which in turn results in learning obstacles for some of them.

STUDYING THE DISCOURSE OF SCHOOL MATHEMATICS OVER TIME: SOME METHODOLOGICAL ISSUES AND RESULTS

Candia Morgan¹, Sarah Tang¹, & Anna Sfard²

¹Institute of Education, University of London, UK

²University of Haifa, Israel

The project “The Evolution of the Discourse of School Mathematics”¹ seeks to investigate how the nature of participation in mathematical discourse expected of students in England has changed over the past three decades. We have chosen to use the examinations taken by almost all students at the end of compulsory schooling (aged 16 years) as our lens. The General Certificate of Secondary Education (GCSE) examination is widely used as a gatekeeper for further education and employment as well as being a key accountability measure for schools. It thus has high-stakes consequences for schools, teachers and students and, as such, has a strong influence on the curriculum and pedagogy experienced by students through much of their secondary school career (Broadfoot, 1996).

The project rests on a theoretical orientation that understands doing mathematics as participating in mathematical forms of discourse (as a consumer and producer). Hence our analytic approach focuses on discourse, examining the forms of language and other communicative modes involved in engaging with the examinations. In our poster at CERME7 (Morgan & Sfard, 2011), we presented a preliminary analytical framework for identifying characteristics of examination texts. The overall structure of this framework was based on Sfard’s characterisation of mathematical discourse as consisting of vocabulary and syntax, visual mediators, routines and endorsed narratives (Sfard, 2008). This was augmented by questions to be posed to the texts and detailed analytical tools also derived from Sfard’s communicative theory of mathematical activity and from multimodal social semiotics and systemic functional linguistics (Halliday, 1978, 1985; Kress & van Leeuwen, 2001; Morgan, 2006).

A major challenge in beginning this project, however, was to develop this framework into an analytical tool with a sufficient degree of delicacy to distinguish between texts and sufficient robustness to enable it to be applied efficiently and reliably. See Tang, Morgan and Sfard (2012) for an account of the process of development of the framework, focusing in detail on the analytical categories *specialisation* and *objectification* of discourse. Since beginning the project we have come to realise more clearly the challenges it poses and the complexity of the variables involved. Time is a crucial variable defined by our original aims. We have therefore sampled

¹ Funded by the Economic and Social Research Council, grant no. RES=062-23-2880

examination papers from eight points in time between 1980 and 2011, chosen following a review of curriculum and assessment policy and practices in order to capture key changes during the period. This sample consists of 31 question papers containing a total of 558 questions. On the one hand this is a large sample of questions, yet, as the questions range across all parts of the school curriculum, the number of questions on any topic area is relatively small and, even within a single area of the curriculum, the mathematical focus of questions set in different papers can vary considerably. In attempting to look at variation over time, therefore, it has been necessary to find a way of looking that enables comparisons across the full range of the curriculum.

In this poster presentation we will exemplify a small part of the developed analytic framework, focusing on the specialised mathematical nature of the discourse. The fundamental question with which we interrogate the data is: to what extent and in which ways do the examinations demand that students participate in specialised mathematical discourse, using and producing texts with characteristics of such a discourse. We will present indicators used to address this question, exemplifying their application to examination questions from different years and topic areas, together with quantitative results showing variation in this aspect over time.

ANALYZING TEACHERS' FOLLOW UPS AND FEED FORWARDS, SEEN AS A WAY TO ENABLE STUDENTS' PARTICIPATION IN MATHEMATICAL REASONING

Anna-Karin Nordin

Department of Mathematics and Science Education, Stockholm University

In an on-going study, mathematics teachers' communications with students are investigated, with an interest in how teachers' acts respond to, interact with and take forward students' mathematical reasoning. To analyze this, an analytical framework, combining follow up and feed forward, separately used in earlier studies (Boistrup, 2010; Brodie, 2010) will be proposed. The follow ups and feed forwards are seen as providing students with opportunities, in different ways, to participate in mathematical reasoning. The framework is to be used for studying teacher-student interaction as well as interaction in whole class discussions.

INTRODUCTION

Mathematical reasoning is seen in many international frameworks as crucial for becoming mathematically proficient. My interest lies in how teachers can enable students to participate in mathematical reasoning and thereby develop their competence to justify ideas and conclusions, to create arguments and improve their conceptual understanding.

A Swedish study showed (with several exceptions and some variation) that students, in general, are offered limited opportunities to develop their competence in reasoning (Bergqvist et al., 2009). Generally, activities in the classroom focus mainly on routine tasks and mathematical procedures.

The purpose of this poster will be to propose a basis for an analytical framework that will be used in an ongoing study with an interest in mathematical reasoning.

THE STUDY

The aim of the study is to examine the teachers' use of follow up and feed forward as a means to enable student participation in mathematical reasoning and the possible effect it has on students' reasoning. Follow up is a notion used by Brodie (2010) to describe teachers' responses to students' contribution. Follow up is aiming to respond to, interact with and take forward student contributions. Feed forward is a notion that has been used by Boistrup (2010) as an act related to future acts by the student and/or the teacher, which can create opportunities for mathematical reasoning.

Research questions

- How does the use of different types of follow up and feed forward enable student participation in mathematical reasoning?
- Does the use of follow up and feed forward change when the teachers participate in a collaborative development project?

- How do the different types of follow up and feed forward affect students' reasoning?

METHODOLOGY AND ANALYTICAL FRAMEWORK

Data is gathered from school development projects, seeing collaborative learning as a means to improve teaching. Lessons are video recorded in such a way that the teacher's actions, when interacting with individual students and in whole class discussion, will be captured together with chosen students' interaction with each other.

For analyzing the follow up and feed forward provided by the teachers, notions from earlier studies will be combined in an analytical framework. Some follow ups (Brodie, 2010) attempt to transform the student contribution. It could be by asking the student to elaborate on his/her idea or by the teacher contributing something new which the student uses or by the teacher making her own mathematical contribution. Other follow ups maintain student contribution, without any intervention, in the public realm for others to elaborate on. To the analytical framework will also be added notions presented by Boistrup (2010), for example feed forward as guiding and challenging. The above-mentioned types of follow up and feed forward will, from a socio cultural perspective (Lerman, 1996), be seen as enabling student participation in mathematical reasoning and learning.

Students' ability to reason, as a possible effect of the follow up and feed forward given by the teacher, will be analysed adopting a multimodal perspective where the use of different communicative modes will be taking account for (see e. g. Boistrup, 2010).

TEXTBOOKS AND LOGBOOKS IN MATHEMATICS

Cecilia Segerby

Malmö University, Sweden

This poster presents the main themes found in a literature review about logbooks and their impact on helping students to gain more information from reading mathematical textbooks. Previous research in years 3 and 4 has shown connections between reading skills and mathematical skills. Logbooks are suggested to overcome these difficulties.

In Sweden, recent research has shown that a dominant practice in mathematics education involves students working individually in textbooks (Johansson, 2006; Myndigheten för skolutveckling, 2007).

To gain meaning from textbooks, students need to read and locate specific information. However, not all students possess the skills necessary to do this and struggle to gain anything from their textbooks except the location of the exercises (Weinberg & Wiesner, 2011). According to Johansson's (2006) analysis of Swedish mathematical textbooks, the textbooks lacked important parts and did not provide possibilities to reflect and ask questions on the content of the text or to discuss the role of mathematics in daily life and society.

There is a clear need for students to use and develop the mathematical language used in the textbooks. One way for students to do this is to use logbooks to reflect on what they are reading in textbooks (Borasi & Rose, 1989). However, little research has been done that shows how logbooks can be used to support students' reading of their textbooks.

Consequently, I suggest the need to research the following questions:

- In what ways, can writing in mathematics support the students' understanding of what they read in their textbooks?
- How can writing in logbooks contribute to communicating about mathematics more generally?

READING AND WRITING IN MATHEMATICS

Möllehed's (2001) study in years 4-9 showed an interrelation between mathematics word problem solving performance and reading comprehension skills. In particular, vocabulary is considered to be a key factor in reading comprehension (Westlund, 2009). In reading mathematics textbooks this may be especially important because the vocabulary can be difficult for the students to comprehend because there are terms that can be found only in the mathematics. Some of the mathematical words can also have a different meaning in the

natural language, for example odd and volume (Lee, 2006; Myndigheten för skolutveckling, 2007).

In year 4, mathematics is considered to become much more difficult for Swedish students when many new concepts are introduced and the amount of text in the tasks increases and becomes more advanced (Myndigheten för skolutveckling, 2007). Therefore, I would suggest that the research study be situated in a year four classroom, when most students are about 10 years old.

In the mathematical logbook, students can express and reflect on their feelings, process, knowledge, and beliefs about mathematics (Borasi & Rose, 1989). According to Lundberg and Sterner (2006), the logbooks can also become mathematical dictionaries for the students, where they continuously supplement new words and explanations in order to develop their mathematical language.

INTRODUCTION TO THE PAPERS AND POSTERS OF WG10: CULTURAL DIVERSITY AND MATHEMATICS EDUCATION

Alexandre Pais, Sarah Crafter, Hauke Straehler-Pohl & Mônica Mesquita

Keywords: Inclusion; exclusion; politics; agency; participation; dialogical self; foreground; ethnomathematics; critical mathematics education; non-school mathematics

The work and the discussions that animated the activities of WG10 sought to position mathematics education within the realms of culture, society, the political and the historical. Participants in WG10 presuppose that mathematics education refers to more than the encounter between an individual and a mathematical object. The process of teaching and learning mathematics occurs within a culture that both influences and is influenced by the workings of mathematics education. This way, the group was interested in understanding learning and teaching mathematics in culturally diverse schools, classrooms and other educational settings, by analysing the variety of sites where mathematics education takes place and the differences in the organization and structure of practice in such contexts. On the other hand, it is assumed that research is not an innocent activity producing a diagnosis of the state of mathematics education practices or proposing solutions to the problems of practice. Rather, it is an active participant in shaping, discursively, the possibilities of seeing and inventing practice. It was the focus of the group also to cover research and its discourses, and the way in which such discourses contribute to the formation of particular subjectivities and ideologies in and through mathematics education. As a way to address both the teaching and learning of mathematics and the research done on this issue, the group privileged theories and methodologies that explicitly connect what is usually called the micro level—people interacting with mathematics—with the macro level—culture, society and the political. Inter-disciplinary perspectives including fields such as socio-cultural and discursive psychology, cultural studies, history, anthropology, linguistics, sociology, discourse studies, political sciences, psychoanalysis and philosophy are among the most prolific theoretical frames used by the participants of WG10 to attain such a goal.

Against this background, the diversity, both methodologically and theoretically, of the 17 papers and 3 posters submitted allowed participants to tackle a set of problems that, although highly influential in the teaching and learning of

mathematics, often remain understated in mathematics education research. These problems were brought forth by an emphasis on the sociopolitical dimension of mathematics education, and by the use of broader theoretical frames than the ones provided by mathematics, didactics and psychology. The theories used by participants ranged from modern influences such as the works of Bourdieu (e.g., Johansson & Boistrup) and Bernstein (e.g., Bohlmann, Hinkelammert, Rhein, & Straehler-Pohl) to more postmodern approaches such as the philosophy of Žižek (Straehler-Pohl & Pais) and Foucault (Valero). We also had works using discourse analysis to investigate the practices of school mathematics (e.g., Doğan & Haser, Che & Bridges), as well as social psychology, in particular the notion of dialogism (e.g., Abreu, Crafter, Gorgorio & Prat; Machado & César; Newton & Abreu). Some of the papers took advantage of philosophical thought to engage in a theoretical discussion about the possibilities and limits of mathematics education and its research (e.g., Kollosche; Valero; François & Pinxten). On the other hand, we also had participants taking advantage of theories already developed within mathematics education. This was the case with ethnomathematics and critical mathematics education, two fields concerned with the sociopolitical dimension of mathematics education, and which have been in the last two decades gaining importance within the field. Some of the participants based their research within one of these two approaches (e.g., Domite; Campos, Jacobini, Wodewotzki & Ferreira; Fernandes; Martins; Hochmuth), and some sought for an articulation between the two (e.g., François & Pinxten).

While most of the participants take advantage of empirical classroom material to develop their argumentations, there were a significant number of papers dealing with mathematics education from a strictly theoretical perspective (e.g. Valero; Kollosche). The majority of the papers and posters presented, however, focus its analysis in diverse classroom episodes. We had the opportunity to discuss classroom situations involving immigrant students in Catalonia (Abreu, Crafter, Gorgorio & Prat), low income students in Turkey (Doğan & Haser), a combination of the two in a German context (Straehler-Pohl & Pais) and deaf mathematics students in Portugal (Borges & César). Another set of papers focused on the relations between school and out of school mathematics, whether we are talking about adult education (Fantinato; Johansson & Boistrup) or the relevance of the family context to the learning of mathematics (César, Machado & Borges; Newton & Abreu). Together, these works offered a fruitful basis for

comparing and discussing the cultural, social and political roles that mathematics education is asked to perform in diverse contexts.

The method we use to organize the work in the working group emphasizes discussion and collaboration between the participants. Since CERME 7, WG10 adopts a way of presenting papers where it is not the author of the paper who presents it, but another member of the group. That is, each of the authors has the task of presenting another individual's paper, and to elaborate a set of comments or questions in order to initiate a general discussion. The presentation should not exceed 5 minutes—something hard to do when it is the author of the paper presenting, but fairly easy when another one is doing it—allowing 25 minutes for discussion. This proved to be a good strategy to guarantee an informed and enthusiastic discussion between the participants. Furthermore, this form of organisation helped promote links, searching for connections and working out synthesis and contradictions across papers.

The nature of the papers presented in this group allowed for a discussion of mathematics education beyond a strictly didactical approach. Participants in WG10 are interested in investigating not only the particularities of the teaching and learning of mathematics, where an individual subject encounters a mathematical object, but also the broader cultural, social and political context that crucially influences what is happening in a classroom. Bringing these dimensions into play requires not only broader theoretical frames (as the ones we indicated before), but also a broader questioning of the societal role of mathematics education, as well as our role as researchers in addressing pressing social problems as the worldwide failure in this school subject. During the five days of work, we had the opportunity to discuss some of the political problems involving mathematics education and its research. As a suggestion for further discussions within WG10, we list some of the questions that occasioned lively discussions among the participants:

- 1) Is failure a necessity of schooling and, if so, how can we develop research taking this into consideration? This was a recurrent question among participants, and one addressed in some of the papers. If we accept that current schooling needs failure as an inherent sign of its success, that is, if we assume that schools today have an important economic role in the way they exclude and select people, how is it possible to map the role of research when addressing this reality? Can an educational enterprise solve problems that are, in their very

nature, political and economical ones? Perhaps more and better research in mathematics education is not enough when addressing the persistent problem of failure in this school subject.

2) What kind of theories and methodologies are needed to address the political dimension of a classroom? If we recognize that there are sociopolitical factors that influence what is happening in mathematics classrooms, how to develop research that can take into account these broader societal dimension? What kind of theories can allow us to “see” the political operating in the classroom? These questions emerge after one realizes that many of the problems that both teachers and students experience when teaching and learning mathematics are not didactical ones, in the sense that they can be approached by better ways of teaching and learning mathematics, but political ones, having to do, among other things, with the economical organization of schooling.

3) What do we gain from investigating experiences of success? What do we gain from investigating experiences of failure? Mathematics education research is often interested in reporting experiences of success. After a problem has been identified, an analysis is carried out and a way to solve the problem is proposed. This approach has been, however, criticized for not having in consideration the gap between the aseptic environment of research and the real, messy, nature of schools. Can it be that more important than reporting experiences of success is to investigate failure, namely, the reasons why well-elaborated strategies tend to fail when implemented in the normal, daily work of schools? On the other hand, how can we, then, maintain faith in the possibility of change? Can successful participatory research in real school settings be a catalyst for change? If so, is the next step, then, to report on moments that contributed to succeed or to reflect on those moments that failed?

4) Is mathematics in reality or in our gaze? This question aroused when discussing the (ir)relevance of real-life problems for the learning of mathematics. Some of the research in ethnomathematics or in critical mathematics education claims for the importance of connecting school mathematics with real world situations. It is argued that such connection can make mathematics more meaningful for students, as well as allowing them the contact with what some authors call “mathematics in action”, that is, mathematics as it is used in broader society. The discussions have problematised how researchers assume that turning mathematics more “real” can allow students to learn it better. Researchers “see” mathematics in reality

because they have a “trained eye” that allows them to identify as mathematics something that, for a student, is just a part of her or his routine. What are the effects of imposing our “mathematician view” on aspects of reality (like the construction of an indigenous house, in the case of ethnomathematics) that have yet not at all been related to mathematics for the students?

5) How to grasp students’ identity or “self”? These question emerge from the set of papers we discussed dealing with social psychology. Participants raised the question of how to be sure about the fidelity of students as well as teachers’ speech? How to interpret the speech of the participants in our research? Shall we go in depth into their inner self meanings, or shall we posit the discourse within the sociopolitical arena and interpret it as a symptom of broader ideologies?

Each paper, in one way or another, tackled some of these major issues, which were recurrent in our discussions. We list them here because we think they deserve reflection from a research community that too often leaves these broader (political) questions unaddressed. It is our wish that the next WG10 continues exploring these burning questions, together with the development of methods and theories that can allow us to tackle the political diversity of school mathematics.

This paper examines the transitions that immigrant students experience as mathematical learners in schools and investigates conceptual and methodological tools that contribute to the understanding of the transition processes that promote or hinder students' success in the host culture schools. From a psychological point of view, the study of the transition processes requires a consideration of the person's subjective experience. To help our discussion we will borrow from Dialogical Self 'I' positions theory to examine interview data. We will examine a case study, that of Felipe, an immigrant student who saw himself as liking mathematics and doing well in the subject in Chile, until the moment he realized that as an immigrant student in Catalonia he failed maths.

INTRODUCTION

This paper examines the transitions that immigrant students experience as mathematical learners in schools. Our aim is to investigate conceptual and methodological tools that contribute to the understanding of the transition processes (Zittoun, 2009) that promote or hinder students' success in the host culture schools. For Zittoun (2009) "Transitions can be defined as processes of catalysed change due to a rupture, and aiming at a new sustainable fit between the person and her current environment" (p. 410). Often, a starting point in the study of processes of transition is external criteria imposed by researchers. From a psychological point of view, however, the study of the transition processes requires a consideration of the person's subjective experience. In Zittoun's words "If an event is studied as a rupture that is likely to bring a person or an organism to engage in changes, then the organism or the person under study must perceive the event as a rupture, in some respect" (p. 412). If rupture is a central feature of the analytic process of studying shifts one must re-cast or re-think what is meant by the rupture by addressing sense making such as markers of identity (me/my), relationships (reference to others), disruptions in time, distance from the experience and hypothetical thinking about alternative trajectories.

We wish to tackle what is meant by a perceived rupture. This is a methodological challenge as most of the time, research has focused on transitions that occurred in the past and therefore the person under study has to be able to recount past events and

experiences and how they made sense of these. In addition, the researcher has to have the methodological tools to examine the processes. To help our discussions about ‘points of shift’ in interview data and transitional ruptures we will borrow from Dialogical Self ‘I’ positions theory (DST) (Hermans, 2003) to look at verbal shifts whereby participants go from non-elaboration, to suspension of the voice to a re-engagement. The reason to borrow from this theory is that it allows us to explore the shifts and dialogues between I positions that are voiced by the individual when recounting how they experienced certain events and trajectories in their lives. Drawing on James’ (1890) concept of the “I” (self-as-subject) and “Me” (self-as-object) and on Bakhtin’s (1973) metaphor of the “multi-voiced” (or polyphonic) novel, the DS Dialogical Self is conceptualized as a multiplicity of “identity positions”, self (internal positions) and positions that speak for significant others (external positions).

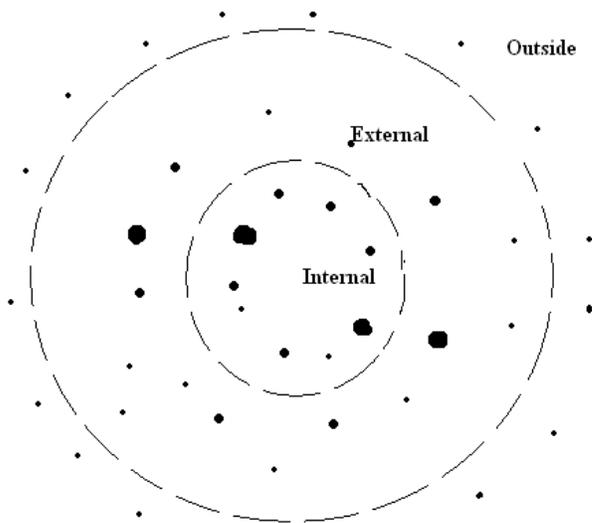

Figure 1: Positions in a multi-voiced self (Hermans, 2001)

The “I” is always positioned in space and time, and these locations result in movement and dialogue between “I” positions. (For more detailed descriptions of the theory see Hermans 2001, 2003, and how it can be applied to immigrant transitions of young people in schools Britain see Abreu, O’Sullivan-Lago & Hale, 2012, Prokopiou, Cline & Abreu, in press). It is precisely the potential to examine the shifts and dialogues in “I” positions, both overtime and across practices (in this case mathematical practices) that makes us believe that examining “I” positions will enable the identification of:

- (i) what is/was experienced by the self as rupture;
- (ii) which strategies were used to protect the self (e.g. suspending, giving up studying mathematics);

- (iii) what was experienced by the self as restoring continuity (e.g. engaging in transitions processes).

THE CASE OF FELIPE

In this paper we will examine the case study of Felipe, an immigrant student who saw himself as liking mathematics and doing well in the subject in Chile, until the moment he realized that as an immigrant student in Catalonia he failed math. The data examined was obtained in an interview carried out in Catalonia by one of the authors of this paper. This is one of the most common methods to elicit memories of one's life trajectories. In our research we have used a specific type of psychological interview that attempts to elicit both narrative and episodic data. Felipe was born in 1993 and spent his early childhood in Chile. In 2008 he moved to Spain (Barcelona) where he continued his education. He arrived in Barcelona during the middle of the academic year and was recommended by the school to go back and repeat the year. He was educated in a private school in Chile but went into a state school in Spain. Felipe provides a useful case study around which to explicate theoretical ideas of rupture and 'I' positions because he has a positive mathematical identity before the transition to a new country, which is disrupted by the move. It is this conflict and tension to the 'I' as a good mathematics student that we explore in more depth here.

ANALYSIS

When Felipe arrived in Barcelona he was surprised to find, like many other immigrant students, that mathematical operations and strategies were not the same as he has experienced in his first country of education (Gorgorio & Abreu, 2009). In this first extract Felipe attempts to reconcile the rupture to his sense of self as a good mathematics student:

Felipe: I couldn't believe it, because I told him it's not that I couldn't, **I failed with sickening grades** and he tells me [his previous maths teacher], but that's not possible, you had good grades and this and that. It's that there was a big jump in level and said that on top of that, it was a big mistake to go to a public school because achievement dropped a lot and I couldn't, **I just couldn't fit in my idea was to study the sciences and because of math I couldn't really do it and now I'm hanging** here in humanities, I don't know.

Felipe attempts to bridge his pre-transition self with his 'new' self by talking to his previous mathematics teacher who is surprised that his student is struggling when he had been successful in Chile. Felipe provides himself with a number of plausible explanations for struggling with mathematics in Spain: a change in level of mathematical difficulty, the move from private to state school and in another part of the interview, learning a new language in the form of Catalan.

The realization of the “**I failed maths**” is the marker of the disruptive moment for the self, and takes center stage in our analysis, as failing math results in a disruption of what Felipe has planned as his academic career.

Felipe: I wanted to study something related with biology, with cellular biology or with genetic modification or whatever, but related with that and then (???) possibilities it's that now **I see myself without options**, my grades are really low and it seems really hard...

The disruption to the self has far reaching implications beyond the here-and-the-now in the student's life. Felipe's failure to maintain his I position as a good mathematics students forced him to re-think his future career. Theoretically this is prolepsis in action. The notion of prolepsis borrowed from Cole (1995) can be used to explore the way the imagined future, which is framed by past experiences, mediates and constrains the world of the present. Felipe's imagined future is constrained by his past transitional move to a new country and his subsequent failure to succeed in mathematics learning in a new system of education.

What strategies were used to protect the self

Felipe tries retrospectively to make sense of what happened to him and in doing so recounts strategies to protect the self from the disruption. At the early stages of arrival, he saw the self as foregrounding I-positions, such as 'I as closed', 'I as afraid of voicing my problems', as the 'I did not know the other' (the teacher, and the colleagues). Not knowing the new cultural others made Felipe worried that making his problems visible will have the same reaction as in Chile (ridiculing the self), and was a reason for withdrawing. Retrospectively he realizes this would not have been the case, but this knowledge about the new cultural others comes later to be useful for the self at arrival.

Interviewer: You said, I mean, you said, hey, you work differently here. Did you give them some kind of signal, did you let them know?

Felipe: The thing is, **the first few months I think you get here like a little closed because**, well, you're new and **you're nervous, you don't know people**, and on top of that they have a very different lifestyle, at least here in Sant Cugat....

Interviewer: How?

Felipe: Well, people are more, for example, **if a kid in Chile**, for example, if he had said he didn't understand or something, **they'd start to make fun** and other stuff, but here I saw, I don't know, people are like, ok, no problem, you know?

Interviewer: Well, this is good, this is a good thing

Felipe: But that's good, but, well, **I didn't think that way** and **I just kept quiet**.

Interviewer: You were a little...

Felipe: **I kept quiet out of fear of looking bad or I don't know**, because **I was embarrassed**, because **I'd been here for a very short time** and **I didn't know...**

The process of withdrawing offers the self some protection from the new and unknown (as also discussed in Abreu & Hale, 2009). Felipe has assumed that ways of thinking and behaving in Barcelona would be similar to Chile and so feared that people would make fun of him. It took him time to realize the differences in the way people would react to him. He shows retrospective awareness of the importance time plays in the process and returns to the subject when asked his views about the teachers and students in here (Barcelona) and there (Chile).

Interviewer: And what do you think of the teachers here, the relationship between the teachers with the students in, for example, a math class. How do you see them? Does it seem like over there, like a private school in general, or like public?

Felipe: No, I think the relationship between the teacher and students is the same but the thing is this relationship grows in strength as time passes, right? And what you know about the teacher, if you arrived and you met him two days ago, it's difficult to get close to him in a way where he'd help you with something you don't understand or don't know (...) and so one doesn't know he's going to react or anything, he's an unknown person for you and it's hard to take the step to...

Another strategy for protecting the self during transitional rupture was to suspend aspects of the self which were vulnerable.

Interviewer: And you've stopped doing, I mean, you've changed, in the year, the two years you did ESO here, if you change the way you do operations, for example, or did you continue with the way you did them in Chile?

Felipe: The truth is **I got off track right away**, I think **I stopped** and left it behind, that's what I tend to do, the truth is when I don't get something, I leave it aside and I say there'll be time later and I focus on other things, and in the **end I left it aside** and **I just ignored it totally to not cause any trouble**, and I saw it really high, you know, and so I didn't understand and then the time comes when, damn, if you don't understand a second-grade equation, you're stuck there.

As Felipe recounts "I stopped", "I left it aside", "I just ignored it totally", and he makes sense of this suspension in terms of "not to cause any trouble". Suspending is a strategy he describes as part of the way he reacts to this type of situations "that's what I tend to do". It may well be that this is a common strategy for the self to deal with a rupture and gain time to work out transitions. However, later he realizes that suspending his engagement with the mathematical learning has specific

consequences for future learning, as he realizes that “if you don't understand a second-grade equation, you're stuck there”.

What was experienced by the self as restoring continuity (e.g. engaging in transitions processes)

Felipe's final phase of his initial post-transition rupture is to let go of his 'I' as a good mathematics learner self.

Felipe: Exactly, I mean, it was a question of grades because, like I told you, if a teacher is impressed because I have good grades or even if my classmates, because **in the end I told them that I no longer was doing math.**

Interviewer: Illogical.

Felipe: Yes, because **I've always liked it, liked it... from since I was little** and then of course the sciences use all that, right?

Felipe implies here that either the teacher or his classmates could have played a role in restoring his 'I' as a good mathematics student self-identity position. In the end Felipe lets go of the mathematics identity developed in Chile and re-positions his relationship with school mathematics, with the 'I' position he acquired during the period of rupture, “I no longer was doing math”. This resulted in Felipe following a different pathway in his studies, “I took another option”. For his baccalaureate “maths” was replaced by Latin. However, his desire to follow a scientific career remained and contact with older friends already at University started pointing out options of re-engaging with mathematics at University...

Felipe: ... in the end I took another option... and (it was a) disaster... I left maths... and now I do latin... but some friends of mine... older that are already at the uni tell me things... they said to me that they give you some options, that you can do maths as a propedeutical subject... or biology... and if this is true, yes, this is a possibility... is a good alternative... but I'm not well... but if this is so...

When Felipe reflects on his approach to his learning following his transition to Barcelona, he returns to the issue of irreversible time to explain his experiences. He used the example of his younger sister to suggest that his transition could have been more positive and successful if they had been addressed by significant others, such as teachers and parents, at an earlier time.

CONCLUSIONS

Using dialogical self “I positions” as a conceptual and methodological tool in this paper we examined the ruptures an immigrant student experienced in the transition across school mathematical practices from one country to another. We have used a case study approach to explore changes in mathematics identity positions when an identity position, in this case the “I as a good mathematics student” is under threat.

We first examined the student descriptions of “I-positions” that reflected a rupture to the self. Then we examined the “I-positions” involved in coming to grips with a new and unfamiliar sense of self (e.g. being no longer good at maths) and trying to provide the self with explanations for the change. This involved three specific dialogical self strategies: withdrawing of self, suspending of the self, and a letting off the old mathematical self go. This process also meant the student had to engage with a distinct change to their imagined future, as the imagined “I-position” as studying a scientific subject at University became uncertain (not possible). We argue that the transition process involved dialogical self work to restore some continuity in the self. In this case continuity was not afforded by the new mathematical I position (I as failing mathematics), thus the perceived alternative, was to give up school mathematics. This refers to a specific time in the experience of the student, and it is interesting to consider two aspects on Felipe’s reflection. One aspect refers to his reflections on the way “time” impacts on the dialogical self work. As he stresses that in the initial stages the key others (teachers and colleagues) are unknown to the self. Thus, the self dialogues are still drawing on images from the past (schools in the home country). The other aspect refers to Felipe reflection that significant others parents and teachers can play a role on the impact of time by becoming aware and addressing issues at the earlier stage. To briefly think about future research: we know quite a bit about the disruption to the self and learning post immigration transition but there is still little practical guidance for significant others on how to help their children and students in this process.

REFLECTIONS ON RECONTEXTUALISING BERNSTEIN'S SOCIOLOGY IN TEACHERS' INSTRUCTIONAL STRATEGIES

Nina Bohlmann, Johannes Hinkelammert, Felix A. Rhein, & Hauke Straehler-Pohl

Freie Universität, Germany

In this paper we discuss the complex process of developing an in-service teacher-training program that aims at promoting teachers' explication strategies. Therefore, we critically examine this process from the sociological perspective that has provided the theoretical basic tenets for our work. Following Basil Bernstein's sociology of education, these basic tenets are, 1) that the recontextualisation of knowledge in schools creates a social order, 2) that the hierarchising of meanings that permeates this process is constructed in social arenas outside school, and 3.) that a mathematics education for social justice requires the explicating of hierarchies of meanings in school. An analysis of one teacher's realization of instructional explication strategies will build the grounds for this reflection.

INTRODUCTION

In the last decades, the amount of research on the social and political dimensions of mathematics education has significantly increased. One of the theories that is often applied as a frame of reference is Basil Bernstein's sociology of education. In this paper we want to present and reflect first attempts to recontextualise research-findings from our research-group (e.g. Gellert & Hümmer, 2008; Gellert, 2009, Gellert & Straehler-Pohl, 2011; Straehler-Pohl & Gellert, 2012) that stem from this theory in classroom practice. A crucial component of a pedagogy that bears the potential for social change on the school level is to make the criteria for evaluation explicit and visible for all learners, while keeping a high level of conceptual demand (e.g. Morais, 2002; Gellert, 2009). At the same time, we maintain that this abstract claim is not a general rule in the sense that it can be applied in the same way at any place at any time. Rather, the meanings of *explication* and *high level of conceptual demand* call for a sensible recontextualisation respecting the particularities of actual educational contexts. Recontextualisation of pedagogic theory into practice can never be a direct transfer that is independent of the particularities of the target-context. Making our research findings that operate on a high level of abstraction accessible for teaching practice therefore calls for a cautious reflection on the potentially emerging boundaries within particular contexts. For example, research all across the world has shown that in contexts of low-ability expectations or in contexts of low-class (while the former are not seldom a result of the latter) teachers tend to draw too extensively on students' supposed experiential environments (e.g. Hoadley, 2007 for South Africa; Straehler-Pohl, Fernandes, Gellert & Figueiras, forthcoming for Spain). In order to transform these tendencies, it does not suffice to declare the reduction or abandonment of real-world contexts in mathematics classrooms with lower-class learners. The documented cross-contextual similarities in the teachers' discourses should rather make us aware, that there might be structural reasons within *and* across

the teaching-contexts that reinforce these teachers to teach in the way they do. We try to target exactly these institutional contexts with students who are supposedly *inferiorly able* and *socially disadvantaged*. Thus, our didactical aim is to help teachers to comprehend their interactional routines and transform them in a more empowering way. We sought to approach this by designing an in-service training for practically promoting a pedagogy that we theoretically have identified as favorable for students of marginalised backgrounds. These students have to be regarded as a 'risk-group' concerning their further educational and vocational opportunities and whose social participation is massively jeopardised. We argue, that this is not solely a matter of more or less effective learning but has to do with a differential distribution of different kinds of knowledge to different social groups. With the *pedagogic device*, Basil Bernstein provides a conceptual frame, how this process *is structured* and in turn *structures* pedagogic practice. The pedagogic device enables us to understand, why it is important for teachers to develop instructional explication strategies in order to do more than just lifting the mathematics achievement of at-risk students to a basic-competence-level, but making accessible a code that is a carrier of *power* within *and* outside the mathematics classroom.

THE PEDAGOGIC DEVICE

The pedagogic device comprises three rules that constitute the basis for any pedagogic discourse: the distributive rules, the recontextualising rules and the evaluative rules. All three rules are hierarchically interrelated with the distributive rules being at the top. *Distributive rules* regulate the formation of systems of meaning through the production of specialised knowledge and thus hierarchise different forms of knowledge. According to Bernstein (2000), the distributive rules constitute a social arena in which meaning hierarchies are negotiated and determined. Following Durkheim, he differentiates between two general forms of knowledge. On the one hand, there is *esoteric* knowledge that has a more distant relation to a material base and is thus less context specific. *Mundane* forms of knowledge, on the other hand, have a closer connection to a specific context due to their proximity to a material base. On the level of the distributive rules esoteric knowledge is categorized in a higher hierarchical position than mundane knowledge. This is important for the level of the *recontextualising rules* where the reproduction of knowledge is regulated. Here, meaning hierarchies are again negotiated but in dependency on the distributive rules. While, from a theoretical perspective, the recontextualisation is reliant on, but not determined by the distributive rules, empirically, the recontextualising rules seem to reproduce the hierarchies agreed upon on the distributive level. The re-structuring of categories of knowledge by recontextualisation does not follow the intrinsic rules of the original discourse but takes place according to a specific logic of transmission. Thus, meanings are again hierarchised and structured, but in a way distinctly different from the original discourse. In contrast to the higher-level rules, the *evaluative rules* do not regulate how forms of knowledge are hierarchised but make the hierarchical relations visible by means of evaluation. Evaluative rules become visible for example

in standardized assessments or in teaching practice. In the context of pedagogical practice, evaluative rules evoke a transformation of knowledge into consciousness of the individual, that is to say knowledge is reproduced. In order to allow students to perform successfully in school, the intrinsic rules of the pedagogic device need to be explicated. We conclude that, *within* the classroom, teachers cannot effectively challenge hierarchies of meanings that operate *outside* the classroom. *Within* the classroom, their agency is restricted to the level of the evaluative rules: They may or may not realise a pedagogic practice that explicates the hierarchies that are the outcomes of the pedagogic device in its present state; they may give access to dominant discourses or to dominated discourses.

Gellert (2009) makes us aware that keeping particular *rules of the game* implicit and leaving it to the students to independently make their way from the mundane to the esoteric (or fail at it) is a part of the common sense on teaching mathematics. However, if teachers aim at offering all students the same chance to successfully partake in socially valued forms of classroom activities, they need to make the outcomes of the device transparent, so that the hierarchy of esoteric and mundane forms of meanings and knowledge can become visible for all students. Gellert (2009) suggests that the rules that need to be made explicit permeate the pedagogical practice in mathematics classrooms on the following levels:

1. which area of mathematics is taught (algorithms, tasks drawing on real-life experiences, heuristics etc.),
2. if and in what way school mathematics is related to academic mathematics or to everyday knowledge,
3. what constitutes a successful participation in mathematics lessons and which criteria a student's contribution in class has to fulfil.

In one way or another, all these levels contain a relationship between the mundane and the esoteric. Consequently, we encourage teachers to depart from the common sense of leaving certain rules of the pedagogical game implicit in order to enable more students to become successful learners in the mathematics classroom. When we take into consideration the research, exemplarily referenced above, we need to be aware that implementing a pedagogy that explicates the hierarchy of the esoteric and the mundane without disempowering and alienating students and teachers is a sensitive and long-term endeavour.

PROMOTING INSTRUCTIONAL EXPLICATION STRATEGIES

Our project's goal was to design an in-service teacher-training program where teachers develop strategies and practices of explicating implicit rules of school mathematics. This training is explicitly not aimed at providing materials, influencing teachers' beliefs or transmitting knowledge, but seeks to build on teachers' existent interactional routines. Brought to consciousness, we argue that these routines can provide the basis for the development of effective explication strategies. As Bernstein

(2000) makes us aware, the move from decontextualised meanings (e.g. sociological theory) to contextualised meanings (e.g. pedagogic practice) is never a matter of direct transfer but inevitably follows a recontextualisation process, where relations of meanings are re-ordered and re-negotiated (see recontextualising rules above). In order to realize such a negotiation process and to integrate it in the concept of the teacher-training we involved experienced teachers in the designing process. This is in line with research results indicating that participants of such programs accept and apply the suggested ideas more likely when other teachers partake in the designing-process of the program (e.g. Lipowsky, 2010). We invited six teachers who work with ‘at-risk students’ in their daily practice to join us in the process of planning the teacher-training program. Over a period of four months we convened three meetings that took a whole weekend each. At the beginning stood an introduction to the general problematic of implicitness of evaluative criteria and the challenge to explicate them, inspired by recent sociological research in mathematics education (e.g. Dowling, 1998; Cooper & Dunne, 2000; Gellert, 2009;). Based on this introduction, a discussion was initiated in which we could relate our rather theoretical perspective to the teachers' everyday practical experience and vice versa. This discussion resulted in the choice of four domains that all of us consensually regarded as crucial for explicating the dominant code: a) verbal modes of expression, b) modalities of documenting learning processes, c) everyday context problems, and d) mathematical games.

- a) The domain ‘verbal modes of expression’ shall enable learners to recognize and realize utterances within a school mathematics register in delineation of an everyday or common sense register;
- b) In the domain ‘modalities of documenting learning processes’ the main aim is to make individual learning processes visible by opening up discussions about evaluative criteria;
- c) The *right amount* of reality to take into account when dealing with ‘everyday context problems’ is not a fixed quality depending on the given problem *sui generis*. Rather it may vary with different contexts (e.g. "problem of the week" might differ from standardized tests). The ability to recognize and realize this right amount is a crucial condition for achievement.
- d) The domain ‘mathematical games’ is concerned with the use of games in the mathematics classroom and aims at revealing the boundary between *a logic of play* and *a logic of school mathematics* in order to enable learning for those who tend not to recognize this boundary.

In each domain we figured out possibilities of implementing interactional explication strategies in the mathematics classroom. The teachers then tried to put these ideas into practice. First attempts of this recontextualising of the theory into the context of the teachers' particular situations were videotaped in order to attain two objectives: Firstly, we aimed to reflect on the potentials and boundaries that emerged. Secondly,

sequences of the videotapes shall be used in the in-service teacher-training program for the purpose of illustrating and reflecting on the recontextualisation.

ANALYSIS

In the following we will present and analyse a case study on Paul, one of the six teachers, who took part in the project so far. We will start with a brief introduction of Paul, based on our shared experiences in the run-up of the lesson. Paul gave this lesson in order to provide us with videotaped illustrative material for the planned teacher-training program. Then we will briefly present the mathematical game Paul chose for his lesson and finally analyse his approach on explicating implicit rules of school mathematics from our perspective.

The case of Paul

Paul works as a teacher in the 8th and 9th grade (in the age of 13 to 15) at a “Förderschule”, a school that exists beside the regular school system and brings together children with socio-emotional ‘disorders’ and cognitive learning disabilities. Additionally, a high migration rate and a low socio-economic structure in the feeding area affect the school’s daily routine. Paul teaches all subjects in his classes. He did not study mathematics as an academic subject. We experienced Paul as a very calm and patient person, who does not let himself be disturbed when being challenged or questioned. We would describe him as ‘down-to-earth’ with a close contact to the students’ realities. His motivation for taking part in the project is rather a general openness and the motivation to improve himself as a (mathematics) teacher. Paul chose the domain of mathematical games for his lesson.

Paul’s game: Nummero

For his lesson Paul chose the game “Nummero”. In this game each participant selects a number between one and one hundred. S/he keeps the number secret. The other participant will have to find out this number by asking questions about it. There is a fixed set of allowed questions that are printed on game-cards, such as “Is it an even number?” or “Is the number between ... and ... ?” (the students have to fill the gaps on their own). On the basis of the given answer, the asking participant can eliminate an amount of impossible numbers by crossing them out on a hundred board (see Fig. 1) in order to keep track of the numbers already eliminated. The participants alternate with asking a question. Whoever finds out his opponent’s number first is the winner of the game.

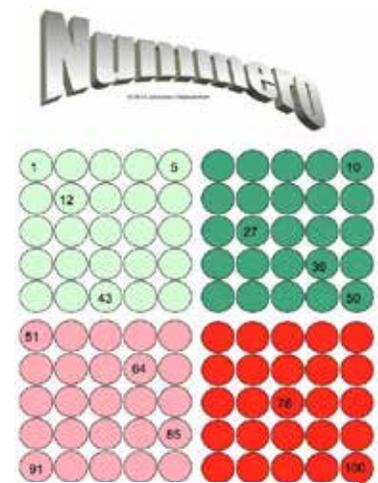

Fig. 1: Nummero

Discussing the game

As Paul and the research team considered the game as not challenging enough for his own 8th and 9th grade classes, Paul asked a colleague in a 5th grade (students are in the age of 10 to 11) for permission to take over one lesson. While his colleague agreed,

he expressed serious concerns that the game would be too demanding for his students. As it was not his own classroom, Paul agreed on choosing another, much less demanding game. However, this game proved to be free from any impulses for mathematical reasoning and hence was entirely unsuitable for the declared purpose of explicating the hierarchy of a logic of play and a mathematical logic within the mathematics classroom. Finally, we presented Paul's colleague the choice to either let Paul proceed with the more challenging game or to cancel the lesson. Paul seemed pleased to have the opportunity to try to prove his less optimistic colleague that the students can do more than he expected.

Paul's lesson: Data and Analysis

Interaction I: Paul opened the lesson by announcing that they will play a game. He emphasised that besides playing, his students are supposed to "learn something". In a short conversation Paul introduced a hundred board (see Fig. 1), where he asked some students to fill out missing numbers. He announced that he would explain the rules of the game by means of playing a first round with the whole class against the teacher. He showed them a piece of paper on which he had noted a number that they were supposed to find out. Thereupon Paul asked a student, Sven, also to choose a number. Doing so, Sven wrote down '86' and fixed it in a way that his classmates could see it, but not Paul. After this, Paul introduced the game-cards with the questions. The first card enabled Paul to ask for a specific figure contained in his number. Accordingly, Paul questioned if 'five' is contained what the students negated.

Paul: Well, then I can cross off some numbers that are not possible any more. • ... • So the five is not contained. Then, of course it can't be the fifteen either, can it? • *He starts crossing 5 and 15 by drawing a line* •

Students: No. [...]

Paul: And twenty-five, thirty-fi-, forty-five they are all impossible. [*He crosses out the column from 5 to 95*] Okay. And... but the fifty-one isn't possible either, is it?

Students: No. [...]

Paul: Fifty-one is impossible. Exactly. Then I'll cross it as well. [*He starts crossing the row from 51 to 59, and then, asked by a student, he also crosses 50*]

Analysis: The teacher chose a trajectory from a school mathematics content to the mathematical game. Thus he first drew the attention to the hundred board and just then shifted to the rules of the game. We interpret this as a sign of sensitivity for providing a dominant space for the mathematical side of the activity. When taking the first game-card, the instructions on the card triggered off a conversation between the

teacher and the students, in which the teacher offered an insight into his thoughts. He asked his students questions in order to involve them in the game and simultaneously to share his ideas. This decision to openly discuss a strategy is characteristic of a school mathematical logic. In everyday contexts, competing participants of a game would not be expected to uncover their thoughts or even to help each other. However, even though Paul brought up the situation of sharing thoughts on strategies, he did not delineate it from the logic of play since he did not contrast his approach to playing games outside the classroom. In addition, he did not initiate a discussion about the meaning of crossing a whole row or column, but only verbalized the crossing out of single numbers. Thus the school mathematics' aim of reasoning ran danger of fading behind the need to proceed in the game.

Interaction II: The students picked a card saying “Is the number greater than...?”.

Sven: Is the number greater than... seventeen?

Paul: Than?

Sven: Is the number greater than... fifty-seven?

Paul: Than fifty-seven. No, it is less. Okay, now you have to cross out your numbers. [...] The number is less than fifty-seven.

Sven: [*shows with his pen somewhere between 46 and 47:*] Up to here.

Paul: No, less! Listen. Is the number less... what did you ask?

Sven: Than fifty-seven.

Paul: Is the number greater than fifty-seven. And I said no, means it is less.

Sven then started crossing out numbers that are greater than 57, but left out the 88 and instead, falsely crossed out 51 to 56. A discussion on which numbers need to be crossed out emerged between the teacher and the students.

Analysis: The discussion between the students and the teacher revolved around the question whether the numbers less or greater than '57' need to be crossed out. This resulted in a strong emphasis on a game-procedure, while the reasoning on strategies (e.g. why to choose 57) completely faded into the background. Emphasising the dominance of a mathematical logic, Sven would have had to explain his strategy behind choosing the number '57'. However, the teacher did not ask Sven to explain but instead instantly requested him to cross out his numbers. Thus, at this point, the implicit expectations within the mathematics classroom of unfolding mathematical strategies in order to 'improve the success' in playing was not made visible to the students. Instead, the emphasis was on following the playing routine. However, we can interpret the discussion about the meaning of 'less than' and 'greater than' as an effort to keep a mathematical frame of reference by emphasizing a mathematics *content*.

Interaction III: Paul's next card asked whether his number was located on the light-coloured half of the hundred board, which was approved by the students.

Paul: My number is located on the light-coloured half, right? · ... · Well, then I can cross all dark.

Sven: On the dark · *pointing on the dark-coloured half* · ... ·

Student: (...) on the dark side?

Student: On the light side.

Paul: Have a look, you wrote down a number for me. And this one is located on the dark, isn't it?

Analysis: The students seemed to have difficulties with deciding whether the teacher should erase the light-coloured or the dark-coloured half. The teacher repeatedly pointed out the number chosen by the students, thus trying to help them make their decision. At this point, again, the discussion focussed on a question exclusively tied to game-procedures, i.e. which part of the hundred board can be crossed out. Following a logic of school mathematics, it would have been fruitful to discuss what "dark side" and "light side" meant mathematically and how this knowledge could promote making a decision without searching the particular number in the hundred board. However, the students were not asked to explain or to justify their decision for one half of the game board. The focus on game-procedures again seemed to emphasize the logic of play while neglecting a school mathematical logic, thus giving the students a certain impression of how they are expected to think and behave in the mathematics classroom. That the hierarchy of these two discourses is actually the other way around is left implicit.

DISCUSSION

In this paper, we aimed to critically reflect on the potentials of recontextualising Basil Bernstein's sociology of education in interactional strategies for teaching that systematically strive for an explication of rules and criteria. Usually they remain implicit in mathematics classroom discourse, which hinders students from disadvantaged backgrounds to recognize what counts as a legitimate contribution and a desirable learning outcome. While research produces more and more evidence on how these processes occur in regular classrooms, our intention was to analyse intentionally created teaching-contexts in which explication is a conscious point on the teacher's agenda. In order to be able to evaluate the capacities of interactional explication strategies on a broader scale, this appeared to us as a necessary first step. We expect that confronting ourselves with the boundaries that emerge in such a process helps us canalizing our efforts.

Our analysis of Paul illustrates that reflecting on explicitness and its sociological relevance and bringing it to consciousness is a step into the right direction, however it

proved to be a very first in a bigger number of necessary steps. The least we can say about the success of Paul's intervention is that it released the students from excessively lowered expectations. Still, we cannot conclude to having provoked a full suspension of a discourse of low expectations. For example, Paul's strong insistence on procedural aspects of the game is characteristic for such a discourse. Even though Paul has sensitized himself in the meetings and in our discussions to the importance of explicating the dominance of the logic of mathematics *within* the mathematical game by an emphasis on reasoning, he frequently missed out on situations that bore the potential for such an explication. We tend to see this contradiction not as a result of an inadequate realization of the aims that Paul set himself but rather as a result of the very structural intricacies that inevitably arise when using situations that *usually* are characterised by *implicitness* to *explicate* something. Taking up Bernstein's concept of classification, using games in order to explicate structural rules of school mathematics means juxtaposing a weakly classified activity with a strongly classified activity in order to explicate the boundaries that characterize the latter. This inevitably creates a situation, where the strong classification of the latter is challenged. As Bernstein (2000) makes us aware, classifications create a "*psychic system of defence*" (p. 12). A challenge of classifications initiates a threat to this system. So it appears quite comprehensible that the more and more Paul and his students proceed in the game, the more and more he loses track of explication and the more and more he is drawn towards a logic of play. However, we do not see this process as inevitable and conclude by giving up our belief in teacher agency. Rather, the analysis of the case of Paul has provided us with new insights, of which we can now effectively take advantage in the upcoming teacher-training program. Further, the existence of video-taped material gives us the opportunity to contextualize our findings for the participating teachers and thus going one step further in the recontextualisation of Bernstein's sociology in interactional explication strategies. In order to overcome a "psychic system of defence", one needs to be aware of it.

DEAF STUDENTS AND MATHEMATICS LEARNING: PROMOTING INCLUSION AND PARTICIPATION

Inês Borges* & Margarida César**

**Universidade Nova de Lisboa, Faculdade de Ciências e Tecnologia, Unidade de Investigação Educação e Desenvolvimento, Portugal; **Universidade de Lisboa, Instituto de Educação, Portugal*

Including students who need special educational support in mainstream schools brought new challenges to teachers. Assuming an interpretative paradigm and an intrinsic case study design, we focus on the adaptations so that two 12th grade Deaf students could learn mathematics with their classmates. The participants were these Deaf students, their classmates, and their mathematics and special education teachers. Data collecting instruments were observation, interviews, informal conversations, students' protocols and documents. Data were analysed through a narrative content analysis from which inductive categories emerged. Results focus on five interactive patterns used in classes. They facilitated the mathematics communication and learning of the two Deaf students and their inclusion.

INTRODUCTION

The sound cultural diversity that characterises Portuguese schools grew in the last decades (César & Oliveira, 2005). It brought additional challenges and responsibilities to teachers (César, 2009, in press). They are expected to rethink the curriculum and their practices having in mind students' characteristics, needs and interests (Allan & Slee, 2008; César & Ainscow, 2006). Vulnerable minorities need special attention and inclusion should fit the different characteristics of the countries and cultures (Timmons & Walsh, 2010). National and international policy educational documents stress the need to promote a more inclusive education (ME, 2008; UNESCO, 1994). But despite legislation, students needing special educational supports still face barriers (César & Ainscow, 2006). Deaf students experience high underachievement and school dropout rates and they are one of the smallest groups at Lisbon University (Almeida, 2009). Due to their specific communicational characteristics their hearing peers and teachers undervalue their (mathematical) performances (Borges, 2009; Borges, César, & Matos, 2012).

The designation of inclusive education is often used. It assumes different meanings. All of them concern social justice, equity in the access to school achievement and the promotion of students' participation in school activities, namely in mathematics (César & Ainscow, 2006). But the focus and the ways to achieve these goals are different. Ainscow and César (2006) designate these differences as “a typology of five ways of thinking about inclusion” (p. 233). We assume a position connecting the last and third ways of thinking. The aim is to achieve a quality education for all (the fifth way of thinking). But to achieve this, we need to pay close attention to all

vulnerable groups and to promote equity (the third one). As Clapton (2009) claims, we need a transformatory ethic of inclusion, rupturing with the previous concepts of disability and inclusion. Thus, we follow the recommendations from UNESCO (1994). We conceive school inclusion/exclusion as a contribution to students' life trajectories of participation which are shaped by inter- and intra-empowerment mechanisms developed – or not – through school practices (César, 2013).

Adapting the curriculum to each and every student (César & Santos, 2006; Rose, 2002), respecting and valuing their participation in different cultures (César, 2009, 2013, in press), and allowing them to give a meaning to school knowledge (Bakhtin, 1929/1981) is more striking when it comes to mathematics. This subject is associated with high academic underachievement, rejection, negative social representations and low positive self-esteem (Machado & César, 2012). Giving a meaning facilitates knowledge appropriation and the transitions between contexts, scenarios or situations (Abreu, Bishop, & Presmeg, 2002; César, 2009). It involves reflecting on classroom practices, including the nature of the tasks, working instructions, interactive patterns, didactic contract, evaluating system, regulatory dynamics and inter- and intra-empowerment mechanisms (César, 2009, 2013, in press). Thus, every teacher can use the curriculum as a vehicle for inclusion or as a lever for exclusion (Rose, 2002).

Policy educational documents point to mathematics communication as one main goal (e.g., Abrantes, Serrazina, & Oliveira, 1999; NCTM, 2000). Elaborating and testing conjectures, producing sustained argumentations, establishing connections, or being critical about mathematical issues regarding society are significant aspects in mathematics learning (Alrø, Ravn, & Valero, 2010; Matos, 2009). A communicational common basis is needed, creating intersubjectivities and making mathematical messages understandable (Borges & César, 2011, 2012; Borges et al., 2012). Students need learning opportunities, support and adaptations that are adequate to their uniqueness, including their cultural diversity, that facilitate meaningful mathematics learning and proficiency. Assuming a historical-cultural approach and knowing students' zone of proximal development (Vygotsky, 1934/1962) facilitates the promotion of transitions from their solving strategies and ways of thinking into more formalised mathematical conceptualisations (César, 2009; César & Santos, 2006; Roth & Radford, 2011).

Like Sfard (2008), we assume learning and thinking as communicating. Thus, social interactions play an essential role in mathematics education and teachers' practices need to promote students' participation and their engagement in school mathematics activities. Investigating adaptations performed when Deaf students participate in mainstream classes assumes relevance as Deaf experience particular communicational barriers that often compromise their school achievement (Borges, 2009). They must communicate and think mathematically and be able to make transitions regarding their (mathematical) knowledge, abilities and competencies.

METHOD

The problem that originated this research regards the barriers to communication and to the access to the mathematical cultural tools (Vygotsky, 1934/1962) that Deaf students experience when included in the mainstream educational system. This work is part of a broader study (Borges, 2009). In this paper we focus in two of the four research questions: (1) What adaptations are performed by this teacher in this 12th grade class that includes Deaf and hearing teenagers?; and (2) What changes are performed by the hearing students in their communication while working and interacting with these Deaf students? These questions do not focus on mathematics learning directly, but we observed mathematics classes. We studied the participation of two pre-lingual profound and severe oralist Deaf students in their 12th grade mathematics classes: Dário and Artur (false names). They were achieving cases as they had the expected age and planned to go to university. The disclosure of successful cases contributes to a more inclusive education (Allan & Slee, 2008; César, 2009; César & Santos, 2006).

We assume an interpretative paradigm (Denzin, 2002) and an intrinsic case study design (Stake, 1995). The participants were these two Deaf students, their classmates, their mathematics teacher (Mariana) and their special education teacher. Mariana had taught other Deaf students in previous school years and she was particularly sensitive to their needs. The data collecting instruments were: participant observation (audio recorded and registered in the researcher's diary); interviews; informal conversations; students' protocols; and documents. The observation included the attendance of one class per week (November to June, a total of 17 classes). The numbers in the codes refer to the observed lesson – 1 to 17. The contents were mainly functions. Data treatment and analysis used a narrative content analysis (Clandinin & Connelly, 1998), starting with a floating reading. More in-depth readings included the search of interactive patterns. Inductive categories emerged (César, 2009), such as the interactive patterns used in mathematics classes (Borges, 2009).

RESULTS

The analysis of some episodes and empirical evidences allowed for the recognition of five interactive patterns used in these mathematics classes: (1) spatial regulation; (2) working rhythm regulation mechanisms; (3) reinforcement schemes; (4) tutorial co-construction; and (5) clarification of doubts. These patterns played an important role in the inclusion process and in mathematics knowledge appropriation.

Spatial regulation

A teacher can walk around the classroom, be in a backlit position, and speak while writing on the blackboard or consulting a book without stopping a hearing student from following his speech, such as in the examples illuminated by Machado and César (2013). But as an oralist Deaf student uses lip reading as his/her main way of communicating with hearing people, a simple rotation of the face, a misarticulated word or a too speedy sentence breaks the communication. Mariana's ways of acting illuminate she was concerned with these details: "Mariana mentions the number of

the lesson and dictates the summary. (...) She repeats near Dário (...) slower. She does the same near Artur” (15th lesson, May 13, 2009, p. 137). These were essential features for these two Deaf students. A less rigorous diction or the omission of syllables turn lip reading into an impossible task. This was an essential move to allow these Deaf students’ access to mathematical cultural tools (Vygotsky, 1934/1962). Their hearing classmates also used adaptations in communication and so enable peer interactions: “Núria, who arrived a little late, asked Dário about the summary. He does not understand and she repeats only the word summary, rotating completely her face towards him and speaking the word a little slower” (15th lesson, May 13, 2009, p. 138).

In the communication between Deaf and hearing people, the oral information can be complemented with gestures and/or other visual aids. Besides the blackboard, we observed the use of technologies like the viewscreen, the interactive board, and the graphing calculator. In one class, while using a computer program that allows visualising the image of a graphing calculator in the interactive board, we registered: “Mariana starts giving instructions about the definitions of the calculator, exemplifying in the projection in the interactive board. Students repeat the procedures in their calculators” (11th lesson, April 22, 2009, p. 109). Thus, the oral instructions were complemented with the use of the virtual calculator, facilitating mathematical learning. These resources are useful for any student but they are particularly important for the Deaf, as sight is their privileged means when communicating, and as Sfard (2008) underlined, communication is a main mediating tool for mathematics learning. These complements benefit the hearing and Deaf students as intended by the inclusive education approach (Borges, 2009).

Working rhythm regulation mechanisms

In these mathematics classes some working rhythm regulation mechanisms emerged and played an important role in students’ engagement in these school mathematics tasks. This teacher used them often. Those mechanisms were similar both for Deaf and hearing students. But they were used much more often with the Deaf, as she knew that the communicating characteristics of the Deaf may exclude them from what is going on in the class, particularly in whole group discussions and, as stated by Borges (2009), they also get distracted more easily.

Mariana [to Artur]: Haven’t you done [exercise] b?

Artur: That’s for homework.

Mariana: For homework? Oh, you are always watching the clock! Then, write it down. Your homework is the [exercise] 300, Paragraph b, c, and d; Test 9, Page 14. [The bell rings. Mariana speaks to the whole class] Finish [exercise] 300 and do Test 9. [Mariana goes near Dário and repeats the homework] (7th lesson, March 4, 2009, p. 77)

Besides the instructions given specifically to the two Deaf students and to the whole class, the teacher chose to ask students about their progression in their solving

strategies to promote their working rhythm. Thus, instead of telling them to work or to be quiet, Mariana led the students' attention to the mathematical tasks and alerted them, in a subtle way, whenever they needed to work faster.

Another mechanism to regulate the working rhythm had to do with teacher's positioning. By moving around between the students' desks while they were doing autonomous work, Mariana got closer to them and saw how they were progressing. This way of acting was more frequent with the two Deaf students as she wanted to keep them in a similar rhythm and to know if they were struggling with any difficulty. This particular attention to students' performances is mentioned in other researches as an essential feature for school achievement, particularly in mathematics (César, 2009; Machado & César, 2012). Sometimes Mariana remained longer next to a particular student to be sure s/he would keep working. This often happened with Artur who would easily get distracted: "(...) Artur starts talking to his right side. Mariana walks by and says «Well?» and stays next to him following his work, preventing him from being distracted again" (6th lesson, February 11, 2009, p. 65).

It was curious to see that the hearing classmates would also regulate Deaf students' working rhythm. Sometimes the classmate that shared Artur's desk brought his attention back to work, illuminating the peers' role in students' performances, as also stated by César (2013). The intersubjectivity they developed enabled her to do so only using non-verbal language: "Artur has "his head in the clouds" and Melissa taps him on his shoulder and, without saying anything else, he understands the message and returns to work" (17th lesson, June 3, 2009, p. 158). From what we have observed, Artur did not feel embarrassed or displeased with these small remarks. Their special education teacher (SET) also mentioned this: "Artur accepts perfectly (...) the criticism, quotation marks, of him being inattentive, not very concentrated (...)" (SET, interview, p. 14). Thus, with the help of his mathematics teacher and peers, Artur's working rhythm improved as well as his mathematical performances.

Reinforcement schemes

The mathematics teacher introduced simple, discrete and efficient reinforcement schemes. For instance, she would confirm the steps used in a particular solving strategy. The teacher could say: "Mariana [to Dário]: That's it" (1st lesson, November 26, 2008, p. 17). Other times students requested these reinforcement mechanisms:

[Artur asks if what he has done is correct. Mariana says it is]

Artur: Did I get away with it?

Mariana: You did. [Laughs] (3rd lesson, January 14, 2009, p. 39)

Classmates also used reinforcement among themselves, encouraging each other. Sometimes, after seeking together for an answer they would share the pleasure of finding it, as also stated in other researches (César, 2013; Machado & César, 2012). In this episode Artur and his classmate, after discussing about the correct option for a multiple-choice exercise, participate in the general discussion:

Mariana: (...) therefore the answer is...?

Melissa and Artur: It's D.

Mariana: It's D. [Melissa and Artur celebrate by hitting each other's right hand in the air – a "high five"] (3rd lesson, January 14, 2009, p. 38)

After discussing the task, these students felt confident to answer to a question asked to the whole class. Some authors claim this is a clear sign of their participation (e.g. Sfard, 2008). These Deaf students often volunteered to answer to questions during the general discussion. This illuminates how they felt included in the mathematical activities. This celebration illuminates a well-accomplished socialisation. Artur participates in a teenagers' typical way of acting. We infer a high level of inclusion in their peer groups, desirable in an inclusive education (UNESCO, 1994).

Tutorial co-construction

As observers we often saw the elaboration of an answer or solving strategy including an interaction engaging two persons (teacher/student or student/student) or the whole class, in general discussions (teacher/class). This illuminates the central role played by social interactions in mathematics learning as stated by Roth and Radford (2011). Mariana's interventions were mainly questions or suggestions – which constitute an interactive pattern that characterises her practices, and was also mentioned in other researches (Machado & César, 2012). There was a clear effort to avoid giving the answers to students. She preferred to give students time and space (César, 2009, 2013) so that they could find the answers on their own, allowing them to mobilise and develop their mental tools (Vygotsky, 1934/1962).

Mariana: What is the first thing that you have to do here? U_n tends to what value?

Artur: This is really confusing.

Mariana: It may be confusing at first but then the conclusions are the same. Remember what we did a while ago. (...) It tends to...?

Artur: They become really small.

Mariana: It tends to...?

Artur: -5, no?

Mariana: No. (...) Try to find it using the calculator. [Mariana goes near Artur and helps him constructing the graph in the calculator] (4th lesson, January 21, 2009, pp. 45-46)

The teacher does not contradict Artur when he says that this content is confusing. She tells him that it can be confusing only at the beginning, which implicitly conveys the message that she believes he will understand that topic if he goes on trying. Implicit messages are very strong elements in (mathematics) learning as well as in students' commitment/rejection towards it (César, 2009; César & Santos, 2006). Implicit messages are essential regarding these students' processes of inclusion.

Another detail is the improvement of Artur's mathematical communication, an

essential feature according to Sfard (2008). He states the succession tends to “really small” values. Mariana, without criticising him, repeats the question asking for an accurate answer. When Artur guesses one value, Mariana could have given him the answer. But she suggests he should try to find the expected number in his graphing calculator. She continues to push Artur to find the answer by himself and, once again, that brings an implicit message: she believes he can find the answer on his own and improve his mathematical performances. She believes that he can learn – an essential aspect to achieve students’ engagement as also stated by César (2009, 2013) and Roth and Radford (2011).

Clarification of doubts

As we mentioned before, during the moments of autonomous work the mathematics teacher used to walk around between the students’ desks. By doing so, two patterns of doubt clarification emerged, according to who initiated this interactive pattern: the teacher; or the students.

Dário raises his arm. Mariana does not notice it and goes near Artur to become aware of his progress [regarding his work]. Dário lowers his arm. Mariana clarifies another student’s doubt and when she has finished Dário raises his arm again. Mariana goes near him and confirms what he has already done and the next step as Dário asks her if his idea is correct, or not. (2nd lesson, January 7, 2009, p. 29)

We can infer a safe class culture characterised by tolerance and the absence of a competition level harmful for the students’ learning. When Mariana is unaware Dário had requested her help, she first walks and goes near another classmate. Thus, Dário lowers his arm, waits, and when she is available he calls her again. This happened without any manifestation of unpleasantness and he keeps on working while waiting.

During the observations we also realised that students shared what they knew and co-constructed their answers in a similar way as described by Roth and Radford (2011). Usually they only requested their teacher’s help when they could not go further on their own. The teacher respected these clarifications of doubts among classmates: “[Mariana] comes back, near Dário, who is talking to Melissa about the exercise. She waits until Melissa finishes her explanation and only then she participates in their discussion” (5th lesson, February 4, 2009, p. 57). With this kind of acting the teacher encourages autonomy (an essential competency for students who are preparing themselves to go to higher education or to start working), promotes mutual help and respect, creating more inclusive spaces and times.

Sometimes individual clarification of doubts could originate useful contributions:

[Dário looks a little longer to the resolution in the blackboard, while he bites a nail and says to Núria, with a worried look]

Dário: I didn’t understand! [Mariana is explaining something to Alexandra and when she returns to the blackboard she adds the rule for deriving the exponential [function]. Dário makes a face that seems to tell us that this detail was what was missing for him to

understand the solving strategy]

(9th lesson, March 25, 2009, p. 90)

The doubt of Alexandra gave rise to a collective enlightenment. It led the teacher to infer that remembering the exponential function derived rule was probably going to benefit other students. Looking at Dário's facial expression, she was right.

FINAL REMARKS

The results illuminate a well-accomplished inclusion process regarding these two Deaf students, both as mathematics students and as youngsters in peer groups. This class constitutes an example of what is recommended by UNESCO (1994). Deaf people tend to have some difficulties due to the communicative characteristics associated with profound and severe deafness. But, in these cases, they participated in their peers' extra-classes activities, like going to esplanades or to the movies which illuminates their inclusion process and socialisation, as stated also by César and Santos (2006) in another research.

The main adaptations this mathematics teacher introduced in her practices had to do with her spatial positioning and the care with the speed and articulation of words. It was intended for Dário and Artur to participate in the mathematics classes. Knowing the access to the Portuguese oral language is a further challenge to the Deaf, she often passed by their desks, making sure they were progressing in the tasks with an adequate rhythm, and that they were not getting blocked by linguistic barriers, such as an unknown word, or a new mathematical designation. Perhaps because it was a 12th grade class, we were unaware of changes in the nature of the tasks or in their instructions. Nevertheless, there was clear concern, both from the teacher and the classmates, to make Dário and Artur feel like legitimate participants, and to respect their characteristics, interests and needs. The importance of legitimate participation in mathematics classes is also underlined by César (2009, 2013) and by Machado & César (2012).

It was interesting to observe that the hearing classmates adopted ways of acting and communicating with Dário and Artur similar to the ones used by their teacher: being careful with the articulation and speed of the oral speech, turning their face to them, simplifying the vocabulary whenever it was needed. This way of mimicking the teacher's adaptations draws attention to the importance and influence of the role of the educator as a facilitator (or blocker) of a more inclusive education, as also mentioned by César and Santos (2006). The horizontal interactions played several roles: contributed to the development of the students' autonomy; promoted mutual help, facilitating the inclusion of the Deaf (and other) students; helped developing aspects related to the socialisation and to create a relaxed and healthy way of Dário and Artur experiencing their deafness. In short: as mentioned by Sfard (2008), communication played an essential role in mathematics learning, particularly in formal educational scenarios. We would like to stress that the inclusion of these two Deaf students in a mainstream class was not only beneficial for them. Their presence in the classroom asked for a particular care with communication and that also

facilitated hearing students' mathematical learning. The diversification of ways of communicating made this experience a very rich one for them all in what regards socialisation and citizenship.

ACKNOWLEDGEMENTS

Our gratitude goes to the school, teachers, students and families who helped make this work come true, and also to Professor Joseph Conboy who edited this paper.

SOCIAL-POLITICAL INTERFACES IN TEACHING STATISTICS

Celso Ribeiro Campos*; Otávio Roberto Jacobini**; Maria Lúcia Lorenzetti
Wodewotzki*** & Denise Helena Lombardo Ferreira****

*PUC-São Paulo, Brazil; **PUC-Campinas, Brazil; ***UNESP-Rio Claro, Brazil;
****PUC-Campinas, Brazil

The objective of this article is, based on the assumptions of Critical Statistics Education, to value the social-political interfaces in teaching Statistics by modeling projects. For this, we present a practical case, one in which we address the issue of corruption in Brazil, placed in the context of the teaching of index numbers, within the discipline of statistics in an undergraduate course in Economic Sciences.

INTRODUCTION

Political awareness and the discussion of social issues related to a student's reality are the main goals of Critical Education (CE) at any level of schooling. In our view, as in the opinion of the main organizers of this theory, such a goal can be pursued regardless of the syllabus of the subjects. We understand that educators can build adaptations to embrace themes that facilitate discussion of political and social issues which are relevant to the student's reality.

Critical Statistics Education (CSE), as presented by Campos (2007), shows the possibilities of integration and combination of objectives between these approaches by connecting the fundamentals of Statistics Education (SE) and CE. In this context we take the foundations of CSE to highlight and deepen the possibilities of enhancing the socio-political interfaces within the teaching of undergraduate courses in Statistics. For this purpose, we present a fragment of the theoretical basis of CSE and show how it is possible to obtain positive results with this integration, by using a mathematical modeling project that we had developed within the discipline of Statistics and applied in an undergraduate course in economics.

Another aspect that seemed relevant in this approach was the ability to assemble multiple media types within this modeling environment. Jacobini (2011) shows us that this congregation helps to motivate students to immerse themselves in a research environment. He also pointed out that it widens and diversifies the universe of opinions on the issues worked, enriching and stimulating classroom discussions.

CE, SE, AND CSE

As a development of critical thinking, CE has emerged in opposition to traditionalism in the educational system, and its foundations can be credited mainly to Jurgen Habermas in Germany and Paulo Freire in Latin America. Freire's work, which proposes emancipatory knowledge, inspired Giroux (1997), who extended the idea of democratization and politicization of education, within a vision of the teacher as an intellectual transformer: "essential for the category of intellectual transformer is

the need to make the pedagogical more political and the political more pedagogical” (p. 163). Giroux emphasized a perspective from which "critical reflection and action become part of the fundamental social project to help students to develop a deep and abiding faith in the struggle to overcome economic, political, and social injustices and further humanize themselves as part of this struggle" (p. 163). Thus, Giroux defended the use of “pedagogies that incorporate political interests that have an emancipatory nature, i.e., the use of pedagogical forms that treat students as critical agents, making knowledge problematic, using affirmative and critical dialogue, and arguing for a qualitatively better world for all people" (p. 163).

Skovsmose, in turn, incorporated these concepts, and progressed in the development of CE. He stated that "it is essential that the issues relate to fundamental social conflicts and situations and it is important that students can recognize problems as their own problems" (Skovsmose, 2004, p. 24). Centered around the question of democracy, Skovsmose emphasized that this issue must be present in mathematics education and thus he worked towards a Critical Mathematics Education, in which working with modeling projects is valued.

Mainly developed since the 1990s, SE was conceived in a context of unease, trying to question and reflect over problems related with the teaching and learning of this discipline. This education was ignited by the difficulties that students have in thinking or reasoning statistically even when they show calculation skills. Seeking to differentiate the pedagogical problems presented by Statistics from those presented by the teaching of Mathematics, several authors converged on the idea that the teaching of Statistics should focus on the development of three specific skills: statistical thinking, statistical reasoning, and statistical literacy.

Statistical literacy has been well characterized by Gal (2004), who emphasized two interrelated components:

- a) people's ability to interpret and critically evaluate statistical information, arguments relating to data from research and stochastic phenomena found in different contexts;
- b) people's ability to discuss or communicate their reactions to this statistical information, along with their interpretations, opinions, and understandings.

According to Gal, in order to develop these abilities the educators must promote activities such as dialogues and discussions to encourage the students and their ideas when faced with real-world data containing statistical elements.

Statistical thinking is linked to the idea of evaluating the statistical problem globally, understanding how and why statistical analyses are important. Thus, statistical thinking is related to the ability to identify the statistical concepts involved in the investigations and problems dealt with, including the nature of data variability— the uncertainty, how and when to properly use the methods of analysis and estimation, etc. According to Chance (2002), this capacity provides the student with the ability

to explore the data in order to extrapolate what is given in the texts and to generate new questions beyond those indicated in the research.

Pfannkuch and Wild (2004) have gone further in the study of this ability and have identified five types of thought which they consider essential for Statistics:

- a) Recognition of the need for data: proper obtainment of data is a basic requirement for a correct judgment in real situations.
- b) Transnumeration: changing registers of representation to facilitate understanding.
- c) Variation consideration: to observe the data variation in a real situation in order to guide the strategies for studying them.
- d) Reasoning with statistical models: refers to thinking about the global data behavior.
- e) Statistical contextual integration: identified as a fundamental element of statistical thought. Results must be analyzed within the problem context and they are validated in accordance with the knowledge related to this context.

In order to develop these types of thought, Falk and Konold (1992) believe that the students shall be guided to make an internal revolution in their ways of thought, leaving behind the idea of seeing the world in a deterministic way.

The way in which people reason with statistical concepts composes what is generally called statistical reasoning. According to Garfield (2002), to reason statistically means doing appropriate interpretations of a certain data set, to represent or summarize the data correctly, to make connections between the concepts involved in a problem, or to combine ideas involving variability, uncertainty, and probability.

The development of statistical reasoning should lead the student to be able to understand, interpret, and explain a statistical process based on real data. Ben-Zvi (2008) emphasizes the importance of this capability. He states that all citizens should have it and that it should be a standard ingredient in education.

As we can see by the brief descriptions above, there are many commonalities between the three capabilities, especially between statistical thinking and reasoning. The cited authors categorize thinking and reasoning quite similarly and, in attempting to explain them, show a convergence of cognitive and conceptual aspects among them. In our view, rather than highlighting the differences among these capabilities, statistical educators must undertake further research on how to develop them in students. Campos (2007) gave some suggestions for classroom works:

- a) work with real data and relate it to the context in which it is involved;
- b) encourage students to interpret, explain, criticize, justify, and evaluate the results, preferably working in groups and discussing and sharing opinions.

We understand that these suggestions can be supplemented to address major aspects of CE, and with this in mind, Campos, Wodewotzi and Jacobini (2011) suggest the following actions:

- a) problematize teaching, work on statistics through projects contextualized within a reality consistent with the student's;
- b) promote debates and dialogues among students and between them and the teacher, assuming a pedagogical democratic attitude;
- c) thematize the teaching by prioritizing activities that enable the discussion of important social and political issues;
- d) use technology in teaching, valuing skills of instrumental character;
- e) adopt a flexible pace for developing the themes;
- f) discuss the curriculum and the pedagogical structure adopted.

According to Campos (2007), by adopting these actions in the educational process, we will be practicing a CSE that goes against the traditional teaching model, which follows an alienating path by assuming a false political neutrality.

Campos (2007), Campos, Wodewotzi and Jacobini (2011), and Campos, Jacobini, Wodewotzki and Ferreira (2011) have argued that working with mathematical modeling projects comprises an appropriate pedagogical strategy to carry out CSE. With modeling we create motivation, facilitate learning, give meaning to the contents worked, value the concepts' applicability, and develop students' thinking that is critical and transformative of their reality, and we also promote the understanding of the political and social role of statistics. We understand that CSE worked through mathematical modeling is an efficient way for the articulation between theory and practice, and favors the breakup of arbitrary boundaries between disciplines, allowing a broader and more effective scope.

DESCRIPTION OF THE SETTING

In an Economic Statistics discipline, taught in an Economic Sciences course by the first author of this paper, one of the program contents is that of Economic Indices, which include index numbers and others socioeconomic indices. Throughout the discussion of these indices in the class a question arose about the possible existence of a corruption index. As this is a controversial subject and has generated much debate, we proposed an activity be held related to the subject, organizing groups, and selecting topics for each group to prepare a presentation. The 30 students in the class were divided into six groups and chose the following topics:

- 1) Misuse of public funds
- 2) Bids and overbilling
- 3) Movies about corruption

- 4) Books about corruption in Brazil
- 5) Corruption on the Internet
- 6) Corruption Index

It was suggested that students prepare a brief report on the research topic, in addition to a presentation, preferably with the aid of the Power Point program that might contain snippets of audio and/or video. After a period of two weeks the groups performed the presentations, which were followed by a session of questions and discussions. After the last presentation there was an intense debate and the students decided to undertake some actions to repudiate the corruption problem:

- a) to disclose the sites to fight corruption on their Facebook pages;
- b) to support the protests against corruption marked for the international day against corruption (December 9);
- c) to sign a petition against the unfair increase of the parliamentarians' salaries [1].

DESCRIPTION OF PRESENTATIONS

Group 1 - Misuse of public funds

The group presented a definition of corruption and quoted the DESVIÔMETRO, a kind of monitor or counter of the misuse of public funds, available on Facebook [2]. A study by FIESP (São Paulo's Industry Federation) was presented, entitled "Corruption: economic costs and proposals to combat it" which projects an average cost of corruption in Brazil of 2.3% of GDP [3]. Some graphs and tables were shown giving data on corruption in Brazil. The group displayed a video from YouTube, wherein a state Representative denounces corruption [4].

Group 2 - Bids and overbilling

This group explained what overpricing is and mentioned a report issued by the Federal Police, reporting that overbilling of about R\$ 700 million was found in 303 public works inspected. They showed a chart comparing some market prices as opposed to inflated prices. A video, available on YouTube was shown by the group, pointing out some suspected fraud in bids [5].

Group 3 - Movies and documentaries on corruption

This group presented a brief analysis of three films, which are summarized below. An excerpt of each movie was presented, and a debate enriched the explanations.

“Quanto Vale ou É por Quilo?” (How much is it worth or is it by weight?) Directed by Sergio Bianchi, this 2005 production features a parallel between the slave trade in Brazil and the fake NGOs that exploit poverty.

“Brasília 18%”. Directed by Nelson Pereira dos Santos, this 2006 movie is a fiction about the disappearance of a parliamentary staff member. With a plot full of corruption, the film reveals a disbelief in the punishment of crimes committed by politicians.

“Tropa de Elite 2” (Elite Troop 2). Launched in 2010, this film, directed by José Padilha, shows the clash between the Special Operations Battalion (BOPE) and drug trafficking in Rio de Janeiro. The film shows the involvement of police and corrupt politicians with the militias that exploit poor communities in Rio.

Group 4 - Books about corruption in Brazil

This group chose two books to analyze and do a presentation. These works, summarized below, report corruption cases that occurred over the last 20 years.

“A Privatária Tucana” (The Toucan Pirate-Privatization). Written by Amaury Ribeiro Jr. and edited by Geração Editorial, this book exposes the irregularities in the privatization of state enterprises that took place in Brazil during the 1990s.

“Sanguessugas do Brasil” (Brazil’s Bloodsuckers). Edited by Geração Editorial, this book was written by Lucio Vaz in order to report the misuse of public money and to recount the history of corrupt politicians and businessmen.

Group 5 - Corruption on the Internet

The goal of this group was to show how the issue of corruption is addressed on the Internet. The group presented several examples, like news sites, denunciation sites, and others [6].

Group 6 - Corruption index

The group mentioned Transparency International, an NGO that fights against corruption [7]. This organization produces an annual report which highlights the indices of perceived corruption in several countries around the world. The group explained that the index is composed of a combination of studies linking corruption to data collected from various institutions. The corruption perception index (CPI) of 2011 is based on 17 data sources from 13 institutions and their scale is from 0 to 10, where 0 means that a country is perceived as highly corrupt and 10 indicates the country is very transparent and not corrupt. According to the CPI, Brazil is in 73rd position and has a score of 3.8, considered by the index to be very corrupt.

ANALYSIS

In this project, the statistical content worked on was an index calculation. Realizing its complexity, the group that presented this issue only superficially addressed the methodology for calculating this corruption index. They discussed the possibility of creating a simpler and more objective index. However, it was understood that the lack of data on levels of corruption in the countries complicates this task. We understood that the study of corruption index deepened students' knowledge about

this type of calculation. However, we must emphasize that the objective of the activity was to involve the students in a discussion of a socio-political problem rather than to deepen their procedural knowledge of Statistics.

For the three skills cited by SE's theoretical foundations, we had observed that working with the real situations involved in the corruption index calculation allowed students to have an overview of the problem. This overview manifested itself when we proposed a problem (to develop an index calculation) and the students needed to research a calculation methodology, as well as find a way to obtain the necessary data and, in addition, to proceed with an analysis of the results. As we said on the description of SE theory, statistical thought is related to the idea of making a global evaluation of a problem, and understanding how and why statistical analyses are important. In this way, like we said, statistical thinking is connected to the capability of identifying statistical concepts involved in the investigations and in the problems worked. This was accomplished in this activity when students were able to see the difficulties that surround the complexity of this index and followed some statistical tools used in its determination. Thus, we understand that this activity advanced their development of statistical thought.

In the theoretical part of this work we had observed that the development of statistical reasoning should lead students to be able to understand, interpret, and explain a real data-based statistical process. The group that researched the corruption index experienced this process, including doing their interpretations and explanations about the studied content. The other groups were able to follow the reports and presentations, as well as take part in the discussions and debates. Thus, we believe that this activity favored the development of statistical reasoning, especially that identified by Pfannkuch and Wild in the (a) item.

As we described in the theoretical part of this work, statistical literacy manifests itself by someone's ability to discuss or communicate their reactions to statistical information, and render their interpretations, opinions and understandings. In this context, we understand that the group who presented the corruption index work had advanced in the development of statistical literacy, as they had elaborated a report which contained statistical data and calculation methodologies of the index. They also made a theme presentation, putting their arguments into words, based on statistical information, using their own vocabulary to do so.

Concerning the other groups, we could observe in the reports and in the presentations the use of typical expressions and terminologies from statistics. Also, we observed some graphs and tables presented, which makes us believe that a contribution had been made to advance this literacy.

We would like to point out that there is no objective methodology capable of measuring the development of the three capacities yet. Thus, the only thing we can

do is to observe whether we are stimulating their development or not, based on the theoretical indications that we had presented.

Regarding CE, we understand that we had highlighted it in many ways. Both in the analysis of films and of books, at various opportunities students were placed face to face with the problem of human poverty, of social and racial discrimination. The discussions showed a sense of rebellion and rejection of humiliating and degrading situations that were shown by groups 3 and 4. The social problem of unequal distribution of wealth in the country was wide open to students, who reacted angrily. The problem of misuse of public money for illicit enrichment by politicians, businessmen, and their allies was highlighted in the presentations of groups 1 and 2, generating intense debate and discussions to bring to the forefront the idea that people can and should unite themselves against rampant corruption. Full of indignation for the many examples of the misuse of public money that were presented, with the presentation of group 5, students could realize that there are tools to combat the crimes committed by those engaged in corruption, especially if people united themselves around actions ranging from public protests to the drafting of petitions that could become law by popular initiative against politicians and corrupt businessmen. Students realized that social networks and the Internet can be powerful allies for this purpose.

As for CSE, we see that throughout the project we were on the path traced by the theoretical considerations foreseen by Campos, Wodewotzi and Jacobini (2011), because:

- a) we had problematized the course, working topics related to Statistics through contextualized projects, linked to a reality consistent with that of the student;
- b) we had encouraged the debates and discussions among students and between them and the teacher, thus taking a pedagogically democratic posture;
- c) we thematized the teaching and focused the activities that emphasized the debate of several important social and political issues;
- d) we used a technological basis in the education and valued the skills of an instrumental nature to the student who lives in a highly technological society;
- e) we adopted a flexible pace in implementing the work presentations.

FINAL CONSIDERATIONS

In carrying out educational activities related to the project described here, we sought to show one possibility of working at the insertion of CSE into the content of the discipline of Statistics in an undergraduate course. In this context, we emphasized the interfaces involved in the proposed socio-political themes, which emerged from the pedagogical environment experienced by the teacher. Our interest in reporting this experience was to show that opportunities to introduce a theme related to social and political problems occur at various times in the pedagogical process, and it is up

to the educator to take advantage of these situations to encourage critical, investigative, and challenging thoughts among the students who excel when they are placed face to face with a social problem that involves their realities.

It should be emphasized that throughout the project execution reported here we observed that the diverse media used as a research source (books, movies, and Internet), combined with the possibility of integrating several technological devices (the use of software, audio, video and slide projections) enriched the themes as they showed the reality closest to the student, increasing their involvement and causing their reaction, maximizing the enhancement of the analyses and discussions.

Without losing focus on the statistical contents, we believe that adopting the CSE in a multimedia environment can greatly enrich the education process. Thus, we give the students the opportunity to better understand their own reality and to find the paths that can lead them to actions against the unjust and unequal system in which they live. Thus, we understand that the teacher performs a much broader role and makes their education more meaningful, interesting, and true.

SCHOOL AND FAMILY INTERPLAYS: SOME CHALLENGES REGARDING MATHEMATICS EDUCATION

Margarida César*, Ricardo Machado** , & Inês Borges**

** Universidade de Lisboa, Instituto de Educação, Portugal; ** Universidade Nova de Lisboa, Faculdade de Ciências e Tecnologia, Unidade de Investigação Educação e Desenvolvimento, Portugal*

Policy documents and research regarding mathematics education stress the need to overcome underachievement and students' rejection. They also claim about the essential role played by families in order to achieve this. This work is from FAMA – Family Math for Adult Learners project. We assumed an interpretative paradigm and developed a case study in Portugal. The participants were mathematics teachers (N=28), 8th graders (N=108), and their families (N=52) who answered to a questionnaire. Some were selected for an interview and for focus groups. Data were treated through descriptive statistics and a content analysis. Results illuminate different expectations from these groups and also the lack of possibilities to act as legitimate participants felt by poorly literate parents from vulnerable minorities.

INTRODUCTION

Portuguese educational statistics show the most important criteria to predict students' marks is their parents' level of literacy (César, 2013). This clearly illustrates the essential role played by the cultural background and by family support towards schooling. It underlines the privileged life trajectory of participation (César, 2013), particularly in school, that is experienced by students whose families accomplished a long schooling path. These families usually participate in the mainstream culture (Favilli, César, & Oliveras, 2004). The majority of the school contents, vocabulary, tasks and examples, both used by teachers and in the textbooks, are well adapted to students from towns in the seaside – the richest and most developed part of the country – and from the mainstream culture. Many other students participating in vulnerable cultures – usually socially undervalued – often experience school underachievement and early school dropouts (César, 2009, 2013). Thus, at schools affected by poverty, whose students' families did not accomplish a long schooling and participate in cultures far away from the mainstream, the need for regulatory dynamics between school and families is particularly intense (César, in press).

Families play a very important role in students' life trajectory of participation (César, 2013), in and outside school, and in their engagement in school activities, namely in mathematics (Borges, César, & Matos, 2012; César, 1987, in press; Sheldon & Epstein, 2005). Regarding life trajectories of participation, some families expect their children to accomplish university studies and that school will play a main role in their professional opportunities, while others believe their children's future is much

more related to working experiences than to school knowledge. Thus, expectancies regarding schooling, achievement, and future opportunities to get better life conditions vary a lot. Another important issue is that parents get involved in mathematics activities in different ways according to their mathematics knowledge, and their previous experiences (Díez-Palomar, 2008; Green & Hoover-Dempsey, 2007). Their positive self-esteem, the way they perceive their empowerment, or if they assume themselves as legitimate participants (César, 2009; Lave & Wenger, 1991), believing they have a voice that can be expressed and respected, or as peripheral participants who are often silenced and have less opportunities to express themselves and be listened to, also shape the way they help – or feel unable to help – their children when they are studying mathematics at home. As mathematics is one of the most rejected subjects, presenting high levels of underachievement and playing a decisive role for students' vocational choices and future professional lives, it is also the subject that is more affected by parents' levels of literacy and by their previous experiences as mathematics learners.

The development of negative social representations about mathematics and themselves as mathematics learners is connected to students' and parents' experiences of school failure and underachievement (César, 2009, 2011). Changing these negative social representations is an important step in order to promote students' access to mathematics cultural tools and also to school and social achievement and inclusion (César, 2009, 2013). It is also an essential move in order to construct their identities and to allow them to experience learning opportunities based in equity (César, 2009, 2013; Cobb & Hodge, 2007).

METHOD

This work is part of FAMA – *Family Math for Adult Learners* – an international project involving countries like Spain, France, United Kingdom, Switzerland, Portugal and Italy. We focus on the Portuguese data and in the third specific goal: to support people from socially vulnerable groups who are part of marginalized social settings, particularly immigrants, persons affected by poverty and women. We began by collecting accounts from three groups: teachers, students, and their families. Data collection lasted from November 2010 until March 2011. FAMA team agreed that in countries collecting data from mainstream schools, students should be mainly 13/14 years old. In Portugal this corresponded to students attending the 8th grade. Compulsory education has long ago regarded students until they were 15 years old (AR, 1986), i.e., those considered in this study.

We assumed an interpretative paradigm (Denzin, 2002) and an intrinsic case study design (Stake, 1995). FAMA project included multiple cases (one in each country participating in it). The criteria to choose the schools were that they should be multicultural settings, from poor backgrounds and including students and families from diverse vulnerable minorities. In Portugal we selected a school in the

surroundings of Lisbon. But as no school had as many mathematics teachers as we needed (at least 25 per country), we used other schools with similar characteristics, regarding the mentioned criteria, and in the same region, in order to collect the teachers' questionnaires. In the Portuguese case study the participants were 28 teachers, 108 students, i.e., all 8th grade classes from that school, and 52 family members. The majority of the family members were parents. There were many more mothers (87%) than fathers (13%) acting as responsible for students' schooling (*encarregados de educação*), and more female (75%) than male teachers (22%) [3% did not state their gender]. This is usual in Portuguese schools. Regarding students who answered to the questionnaire, 46% were male, 53% were female and one did not mention his/her gender.

All the participants answered to a questionnaire, specific for each group: teachers, students, and families. Then, we selected 5 teachers (all those teaching the 8th grade), 22 students, and their 22 family members for an interview. The criteria to select students were: (a) only children, others with only older or younger brothers/sisters, and those who had them both; (b) high, medium and low achievement, particularly in mathematics (it also meant different ages); (c) different parents' schooling levels; (d) diverse cultural backgrounds; and (e) gender. We interviewed all parents from the selected students. Finally, we had a focus group for teachers (N=5), three for students (N=3, N=6 and N=8, in a total of 17 students), and another three for families (N=3, N=5 and N=5, in a total of 13 family members, two of them being the mother and the father of the same student). Due to external constraints we could not have in the focus groups all those we interviewed. We must underline the huge effort these families made in order to participate. All the interviews and focus groups took place in the school and they had to conjugate their schedules with ours. As many of them had temporary and badly paid jobs, they were not allowed to leave earlier or to ask for a free mid-day. Thus, many had to use a holiday day or meet us late, at night. This is a sign of their engagement in this work and in their children's schooling. We could get 17 students and 13 family members for the focus groups, although none of them explicitly told us s/he did not want to participate. Those who did not participate were sick or had last minute issues that did not allow them to participate at the scheduled time and place. As focus groups involved several students or parents at once, they were not as easy to reschedule as interviews.

Data treatment and analysis was based in descriptive statistics (questionnaires) and in a narrative content analysis (Clandinin & Connelly, 2000), based in successive readings, regarding the open questions of the questionnaires, the interviews and the focus groups. The FAMA team previously decided the six categories of analysis. Thus, they were deductive categories, based in the literature review. They were the same for all countries and case studies: affect, cognition, teaching and learning, contents, participation, and structure. All interviews and focus groups were fully transcribed. This allowed for an in-depth analysis, trying to understand these

persons' life trajectory of participation (César, 2013), particularly at school and at these students' homes. For each category we marked each part of the transcripts that illustrated it, and also if they contradicted other parts of the interview or focus group. We focus on the participation category. In order to maintain their anonymous participation, as recommended by ethical principles, we used a code system that still allows readers to pair students and families: the number of the students and respective families are the same (e.g., Mother 3 is the mother of Student 3). Confronting different papers (César, 2012; César & Machado, 2012) and the National Report (César, 2011) this allows for a better comprehension of the participants life trajectories of participation (César, 2013).

RESULTS

Regarding participation, teachers mainly stated: (1) parents' lack of time to come to school; (2) their wishes regarding marks and students' progression, but their lack of concern about their (mathematics) knowledge; and (3) the discouraging role played by complains in what regards parents' participation in school. These three points are illustrated in the next excerpts, in the order we mentioned them.

12 T3 – (...) It's difficult to bring parents to school because sometimes they aren't even at home. (...) In this sense and in these cases, I believe that school has to take the first step and it must help parents realise that it's worthwhile coming to school and know what's going on... Or even know it from home. To keep informed about what's going on with their children... Ah... (...) But there are very complicated situations! In which family's engagement is set up in a very difficult way in school (...). (Teacher 3, Interview, Turn 12, pp. 2-3)

This first excerpt also mentions a very important topic: the school should do the first move, should be aware of parents difficulties and should turn coming to school into something appealing. Other researches by César (in press), César and Oliveira (2005) or Sheldon and Epstein (2005) also illuminate the role played by school and teachers in parents' engagement in their children's schooling. We would add that it is also needed to empower parents so that they feel themselves as legitimate participants (César, in press). Otherwise, when they feel afraid of talking to teachers because those ones have a better argumentation and know school rules better, or when they feel helpless in changing their children underachievement and/or way of acting, they will avoid coming to school, as mentioned in other studies (César, 2009, 2013; Favilli et al., 2004).

14 T5 – That is... it's a subject... a very worrying [subject]!... Because... the... family engagement in school when "our son is getting well", when he is praised and shines at school, it's an easy engagement. That doesn't happen when "our son" is... acts the other way around!... i.e., when we are called to school for those reasons we should never be called, we tend to get away from school... Ah... How do we fight against this? I don't have the slightest idea... (...) I don't have

any answer... [The tone of voice denotes a smile]

15 R – And the school? Are there any dialogue spaces between the family and the school?

16 T5 – The school tries to! The school tries to... But... Ah... It's complicated... There's this need, but in practical terms, that need is... Then, there are too many barriers: or it's because the timetables aren't compatible ones, or because we've two hours to talk about five hundred subjects... (Teacher 5, Interview, Turns 14-16, pp. 2-3)

This excerpt states once again that teachers' and school practices facilitate parents' participation. But this teacher accounts that he does not have any possible moves to attract parents to come to school when there are difficult situations that need to be solved in a collaborative way. Once again he points up the lack of time, both from parents and teachers. Thus, what comes from this excerpt is also that there is a gap between discourses – parents should participate in schools – and practices, as timetables, spaces, or what are regarded as the most important issues to be addressed, do not include parents' participation in the school life. Overcoming this gap is possible, through the development of regulatory dynamics between schools and families, as illustrated by César (in press). But this means a huge effort from the directive board of the schools and also from teachers and families. Schools clearly have to do the first moves.

The focus groups allowed for a more in-depth understanding of the difficulties experienced by parents regarding their participation. All teachers mentioned the importance of parents' schooling when they are helping their children studying mathematics. But they also mentioned that the economical background also played an important role, as private lessons (*explicações*) are expensive but are also quite common in Portugal. What is interesting is that no teacher mentioned that the need for those private lessons also meant that schools were not working so well, i.e., there is a lack of a more critical approach to the educational system itself.

7 T1 – (...) But probably a student from a superior socio-economical context has more potentialities regarding private lessons, regarding extra work, that allows, isn't it? The parents' schooling itself can also allow, according to having time or not, to help children at home, while here probably it isn't so... it's not like that. There are many parents who during the day are working and are away and – isn't it? – they're trying to earn some money, and they can't... (Teacher 1, Focus Group, Turn 7, p. 2)

Participation was also discussed in what regards the times teachers try to contact some parents, particularly those whose children are in trouble and who do not answer the phone when they realise that it is a call from the school. Thus, participation is also shaped by expectancies, as shown by César (2013) or Green and Hoover-Dempsey (2007). If parents expect teachers to tease them, they tend to ignore the call

and they do not contact the school. Thus, teachers need to find ways to ask parents to come to school also to listen to nice comments and not only that their children are in trouble, as mentioned by Favilli and his associates (2004), or by César (in press).

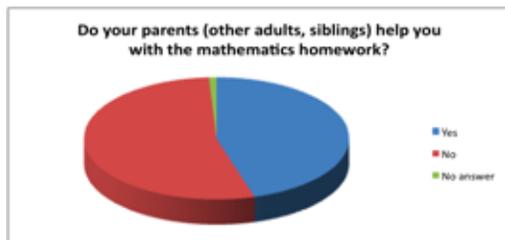

51 T2 – That depends because – and now I’m putting things a bit my way – there are parents that we contact and they simply have the school number in their cell phone memory, and they just ignore it, they don’t answer that call. They answer if it’s an unknown number.

52 R – Hum, hum.

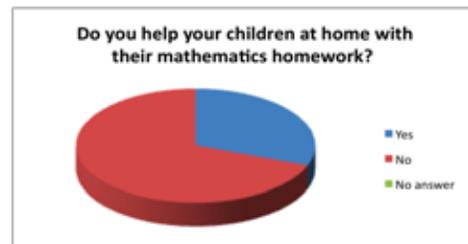

53 T2 – That reveals a lot, regarding some of the parents. Others call us regularly. This I’m reporting as director of the class (...). (Teacher 2, Focus Group, Turns 51-53, p. 5)

When they discussed possible ways of overcoming this problem, they mentioned the emails, or a platform in the internet. But due to the poverty that affected many students’ families they also claimed that many of them did not have internet at home and these solutions did not prove to be efficient ones.

Regarding participation students never mentioned if their parents went or did not go to school. What they mentioned was if they participated in their mathematics work when they were doing it at home. Fifty-eight students (54%) state that their parents do not help them (see Graph 1). But even more parents (N=36, corresponding to 69%) claim that they do not help their children (see Graph 2). This is also mentioned in the interviews and in the focus groups: many parents do not feel competent to help their children when they are doing mathematics activities at home.

Graph 1 – Students’ questionnaire

Graph 2 – Families’ questionnaire

In the interviews it was clear that those whose parents did not help them reported that their level of schooling and time were the main motives to explain their lack of participation in their mathematics activities.

21 S6 – They don’t remember anything from school! They try! But they don’t always succeed. Sometimes I have to be the one who teaches them... [Ironic smile] (Student 6, Interview, Turn 21, p. 2)

In these cases students have to rely on themselves to study mathematics at home, unless they go to private lessons or to an after school centre of studies. It is mentioned by those whose families help them that this is an advantage. Some account that their older siblings have an easier way of explaining mathematics –

using what they call “a teenager language” – and others stress that it is very good to have a family that studies with them because many colleagues do not have this privilege.

42 S15 – Because I understand well what they [referring to his brother and his parents] mean... because sometimes – how can I say that – they explain more with “teenagers’ language”.

43 R – And at school, you don’t get that?

44 S15 – I also get it at school. Sometimes. Also in the books, there are contents that are less explained, let’s put it like this... If this is the case, he [referring to his brother] helps me better. To understand it better. (Student 15, Interview, Turns 42-44, p. 3)

This excerpt illuminates how important it is to have family support when studying mathematics, as it also allows students to understand better the contents that are less clear or less explored in the textbooks. This support is not only important for students who do not use the textbooks to study. It is important for all of them, as shown in the last excerpt below. Thus, we can understand better the Portuguese educational statistics results which expressed that the most important criteria for getting high marks were parents’ levels of schooling (Rodrigues et al., 2010).

32 S7 – I don’t know... It’s so cute. To see that I can count on them for this! To see they’re interested! About my school path, about... about me! They’ve interest! Isn’t it? It’s good to know I’ve someone that I can count on this issue, about school, that I don’t have, as I know that most of my colleagues have to do it all by themselves, they have no one at home that helps them and so I value my family very much! (Student 7, Interview, Turn 32, p. 4)

Summing up, students who can count on their families to work with them when they are studying mathematics at home are supported in what concerns knowledge. But the important point is that this participation in their school life also makes them feel more secure emotionally and more able to develop their own abilities and competencies. As this study was developed in a setting affected by poverty, some students valued a lot their families and the chance they had, as they were able to share their home activities with them each time they felt any kind of difficulty regarding their studies. But the differences between those who have support and those who cannot count on it are also visible in the focus groups:

185 R – Yes. And when you have homework and you have some doubts what do you do?

186 S4 – I don’t do. (...)

188 S7 – I ask for help. (Students, Focus Group 2, Turns 185-186 and 188, p. 8)

These very short but also very quick answers explained it all: those who have family support when they are studying mathematics, when they experience a difficulty they

ask for help and they get helped. But those who cannot count on their families to study mathematics, they simply do not do their homework or they stop studying it.

When confronting students' accounts to their families' accounts it is important to be aware that they confirm each other. For instance, Mother 6 told us that she experienced a lot of difficulties regarding mathematics and her son had reported that sometimes he was the one who had to teach his parents (see Student 6 excerpt above). Mother 6 is already attending the 12th grade, but she failed in mathematics and this subject makes her feel uneasy, as she stated:

2 M6 – I'm going to be honest: mathematics it's not and it never was my strongest [subject]. My mathematics is delayed since my 10th grade. I still did not accomplish the 12th grade, but it is still delayed, mathematics is not my strong [point]. We try to help him in what we are able to, in what we remember, me and my three sisters [Says her sister's name] already finished her university graduation recently, but... it's not our strong point. He does things on his own and he learns by himself. It doesn't come from us. (Mother 6, Interview, Turn 2, p. 1)

Father 7 also as a very similar discourse to the one we reproduced above (see Student 7 excerpt). He also states that having family support when they are studying is a very important issue.

4 F7 – Or when I pass and ask, '[Says the name of his daughter], do you need anything?'. She sometimes says yes, other times she says no... Ahm... But whenever is possible, yeah, I do help [her]. (...)

18 F7 – ... mathematics is a subject... peaceful! Thus in [says his daughter's name]'s evolution.

19 R – And in your view, should the family or is it profitable that the family gets engaged in their children's mathematics learning?

20 F7 – I think so, I mean... It's helpful we become involved in all their process of education, right? Educative. Ahm... Both in mathematics and in other subjects whatsoever. I think it's worthwhile. For everyone. And if they need help when they ask for help, a... In part it's good, and it's great to know that we can help. (Father 7, Interview, Turns 4, and 18-20, pp. 1-2)

This account illuminates two important features of this father's participation: (1) he is attentive to his daughter's needs and sometimes he asks her if she needs anything; and (2) he feels confident about his competencies to help her. His daughter showed a similar high positive self-esteem and calm way of facing school evaluations and daily work. Thus, confronting families and students' accounts allowed for a better understanding of their life trajectories of participation, in and outside school.

FINAL REMARKS

Promoting parents' participation in their children's home mathematics activities and in schools is a complex issue. Despite their wish to help their children their low schooling levels associated to their lack of time and confidence as mathematics users makes them feel unsecure and uncomfortable when their children ask for their help. Teachers are aware of their difficulties and their rejection of mathematics activities, but they do not realise how much effort some of them put into helping their children.

Parents' abilities and competencies play an essential role in their participation. Some of them assume themselves as legitimate participants and that facilitates their children's development of a positive self-esteem. Their children also show higher expectations towards their own performances. But many parents feel unable to help their children and act as peripheral participants. In these cases schools need to be able to develop regulatory dynamics (César, in press), particularly in order to empower families and to distribute power, allowing them to have a more active role in their children's schooling, and promoting equity regarding school achievement.

ACKNOWLEDGEMENTS

FAMA – *Family Math for Adult Learners* project was partially supported by UE (contract n.º 504135-LLP-1-2009-1-ES-GRUNDTIVG-GMP) and by UIDEF - *Unidade de Investigação e Desenvolvimento em Educação e Formação*. Our gratitude goes to the teachers, particularly Teresa Batista, students and families who helped make this work come true.

THE GAP BETWEEN MATHEMATICS EDUCATION AND LOW-INCOME STUDENTS' REAL LIFE: A CASE FROM TURKEY

Oğuzhan DOĞAN*, Çiğdem HASER**

* *Yeditepe University*, ** *Middle East Technical University, Turkey*

The purpose of this study was to trace the reflections of cultural differences based on social class in the elementary mathematics education in Turkey. Critical discourse analysis was conducted to examine these possible reflections. By researching mathematics education from a critical perspective, this study aimed to contribute constructing a starting point for socially responsible mathematics education. Elementary mathematics curriculum, textbooks, classroom practices, and teacher interviews were the main data sources. The discourse analysis of mathematics education contexts implied that elementary mathematics discourse replaced the 'real life' in mathematics problems with the life of middle and upper middle classes and ignored the low-income students' cultural backgrounds.

Keywords: Elementary Mathematics Education, Cultural Differences, Real Life Problems, Critical Discourse Analysis

THEORETICAL FRAMEWORK AND PURPOSE OF THE STUDY

The difference in educational outcomes of students coming from different race, ethnicity, class, gender, and language backgrounds were commonly researched and discussed in international education community. For many years, researchers have highlighted that public education systems did not produce equal outcomes for all students. Significant differences in students' achievements, graduation rates, and university attendance were continually observable among groups classifiable by race, ethnicity, class, gender, and language background (Gregson, 2007).

These highlighted differences have directed critical education researches to examine how class, race, and gender are represented and struggled over in schools, in education programs, textbooks, and teaching practices. The deficiencies in the representations of class, race, and gender in education materials were underlined as one of the blockades to their accessibility to high quality education (Gutstein, 2006). This paper specifically focuses on the representations of different social classes in elementary mathematics education discourse.

'Class culture', in the context of this study, was used to examine whether different cultural/social practices of different social/socio-economical classes were valued in a different way so as to provide a ground for inequalities in the mathematics education or not. 'Class culture' issue was examined with the help of the concept of 'cultural capital'.

The literature on cultural capital and its relationship to educational inequality was inspired largely by the work of Pierre Bourdieu. As described by Bourdieu (Bourdieu, 1977; Bourdieu and Passeron, 1977), cultural capital is the vehicle

through which background inequalities in students' life are translated into differential academic rewards. The cultural capital theory argues that the culture transmitted and rewarded by the educational system reflects the culture of the dominant class. To acquire cultural capital, the student must have the capacity to receive and decode it. The acquisition of cultural capital depends on the cultural capital transmitted by the family. Consequently, the higher the social class of the family, the closer the culture it transmits is to the dominant culture and the greater the resultant academic rewards (Bourdieu, 1977; Bourdieu and Passeron, 1977).

'Cultural capital' concept's major insights on educational inequality is that students with more valuable social and cultural capital become more successful in school than do their peers with less valuable social and cultural capital. This perspective is very useful in attempts to gain a better understanding of how class influences the transmission of educational inequality (Lareau & Horvat, 1999).

In the light of cultural capital literature, the main purpose of this study was to investigate how social class differences are addressed in elementary mathematics education in Turkey. Parallel to this aim, this study intended to extend the understanding of the relationship between mathematics education and social/cultural differences and of teachers' views about this relationship.

METHODOLOGY

In line with the purpose of the study, the following research questions were formulated:

- To what extent are elementary mathematics curriculum, elementary mathematics textbooks, and elementary mathematics classroom practices in Turkey free from cultural values?
- How are the different cultural values and practices of different social classes reflected and addressed in the elementary mathematics curriculum, textbooks, and classroom practices?
- What are the perceptions of mathematics teachers about the relationship between mathematics education and dominant cultural values?

Since how power relations are produced, maintained, and challenged through texts and the practices is one of the main concern of CDA (Locke, 2004), it was used as a research methodology of this study. The study employed critical discourse analysis in investigating these research questions and included curriculum documents and implementation, textbooks, and teachers interviews as data sources.

This study investigated the elementary mathematics curriculum (from 6th to 8th grade), elementary mathematics education textbooks (from 6th to 8th grade), an elementary mathematics classroom [one 7th grade classroom (28 students at the age of 13)], and views of an elementary mathematics teacher.

Participant School and Classroom

The study was conducted in a public school in the second semester of 2009 – 2010 academic year. Although the participant school was not far from the city center, the district was composed of Gecekondus (poor quality houses constructed without any proper plan and infrastructure and occupied by very low income families) and lower middle class and middle class apartments. According to school's Strategic Planning Report, most of schools' students were living in Gecekondus near the school district. The families were coming from rural areas of Ankara and near cities, and they maintained their close links to their home towns. While most of students' fathers were working at temporary jobs with minimum wages, their mothers were generally house wives.

The socio-economic conditions of the students in the participant classroom reflected the socio-economic conditions of the district in which school was placed. Most of the fathers were working as driver or construction worker with minimum wage. Only three of the mothers were working as officers (office staff in a state institution), the others were housewives.

Data Collection

There were three main data sources for the investigation of these research questions. The first data source of the study was the curricular materials in elementary mathematics education, such as elementary mathematics curriculum, guidelines/booklet /guide book, textbooks, and teachers' reference books for 6th, 7th, and 8th grades published by the Ministry of National Education. The second data source was the practices and interactions including explanations, examples and questions, teacher-students interactions, homework, and projects in a mathematics classroom which were observed in the second semester of 2009-2010 academic year. The third data source was pre- and post-interviews with the participating teacher. Mathematics teachers' views about relationship between critical issues and mathematics teaching were explored through these interviews.

Data Analysis

The analysis of the data started with the construction of a sample code list after the classroom observations were completed. The content of the curriculum and textbooks was analyzed with this preliminary code list. This code list was composed of textbooks and classroom examples which had reference to daily life situations. This pre-analysis resulted in some improvements in the code list: Three main categories emerged in this pre-analysis. Classroom observations were coded with this improved code list. It appeared that this improved code list was sufficient to analyze the context of the classroom observations. A part of this code list was provided in Table 1.

Up to this point, all data of the study was coded by only the researcher. After the construction of this final code list, the whole data was coded by both the researcher and another elementary mathematics education researcher to address the reliability

concerns. The general objectives, specific learning outcomes, the vision of the elementary mathematics curriculum and sample activities and lesson plans in the curriculum, the homework projects, the examples and questions in the textbooks, the content of the classroom activities and teacher-students interactions were analysed with this final code list by two researchers.

While coding, the researchers read each material individually and coded the critical expressions in the documents. After coding individually, they compared their codings to see whether they were parallel or not. The researchers reached over 85% agreement in assigning codes. When there were differences between the results of coding, researchers discussed the existence of a critical meaning in the statement and decided whether to include these statements in data analysis or not. The controversial statements about which researchers did not convince each other were not presented as a finding of this study. These controversial statements constructed 4% of total data coded.

Theme	Codes/Categories	Examples
Class Culture	Family Life	Mert, his wife and their two children participate different activities such as theater, cinema, and exhibitions every weekend. Cansu takes a lot of photos in her visit to Çanakkale Cemetery on summer holiday with his family Esen family redecorates their house that they newly bought
	Adult Life	Mr. Ali cares for his health. He decided to buy a summer house to escape from stressful pace of everyday life Mr. Okan wanted to get a camera and investigated the prices of different trademarks and models of cameras Mr. Hasan wants to rent a car before for his summer vacation
	Children Life	The following paragraph describes the help of 6.grade students to a poor school. Pınar is going to French course in half of the month Sengul will buy fruit juice, chocolate and candies from shop for her birthday party

Table 1: Code List for the Analysis of the Data

The pre- and post-interviews with the teacher were also analysed with the help of the second coder. Additional to emerged categories (listed in the table as family, adult, and children life), analysis of teacher's interviews was composed of her comments about these categories. The questions in the pre-interview were basically about teacher's general views about the relationship between mathematics education and dominant political, cultural, and patriarchal views and values. For example, one of the pre-interview questions was about the relationship between politics and mathematics education: "When you consider mathematics education in general, such as the explanations in curriculum, examples in textbooks or activities in your classrooms, how do you assess the neutrality of these contexts in terms of political and cultural views?". Post-interview questions, on the other hand, basically addressed teacher's views about my specific inferences from the curriculum, textbooks, and classroom observation analyses. For instance, one of the post-interview questions was about the gap between mathematics problems and students' cultures: "Context of some of the textbook examples seemed considerably far from the students' real life, for example, students were expected to behave as a manager in a bus company in one of the examples. What is your perception of such examples? Can you assess your examples in the classroom in terms of this perspective?".

RESULTS

The main issue investigated in the study was whether different socio-cultural practices of different social classes were valued in a different way so as to provide a ground for inequalities in the mathematics education or not. Possible findings would also answer the question "Whose lives were presented in mathematics education discourse?"

The analysis started with the curriculum's emphasis on (i) the importance of the relationship between mathematics education and students' real/daily life and (ii) the importance of the solving real-life problems. The vision of the curriculum indicated that mathematics should be taught based on concrete and finite-life models. In addition, raising students with the ability of using mathematics in their daily life and appreciating mathematics as an important tool in real life was defined as the prior objectives of curriculum. I concluded that 'solving real life problems' was placed at the heart of elementary mathematics teaching. However, I also concluded that the questions 'what is real life' and 'whose life will be served as real life' were not satisfactorily answered in the program. I pointed out that these unanswered questions would imply that lower social classes which had a limited/restricted voice in both social life and educational organizations can face with the risk that their silence will continue in mathematics classrooms.

The analysis of curricular materials showed that this risk turned into reality in the context of the textbooks. The daily life problems in the textbooks were analyzed under three main headings: (i) The problems based on life/activity of whole family; (ii) The problems based on off-class activity of children/students; and (iii) The problems based on life/activity of an adult character. Based on the findings describing

a families', children' or adults' life, I tried to draw a profile of 'daily/real life' in the problems. This constructed daily life profile was examined for whether it reflected a 'daily life' of specific social classes or not.

The analysis of textbooks specified that 'the family' in the problems were the ones who participate in different activities such as theatre, cinema, and exhibitions. At every weekend, characters visited grandfather, grandmother, or eldest of the family in national holidays, travels different resorts/seaside during the summer vacation, and builds/bought a new house or redecorates the existing one.

'The child' in the problems was the one who would go to different courses through the year, such as a language course or a musical instrument course, or a sport course, participate different out-door activities with his/her friends such as going to swimming or taking a trip, go to shopping for his/her birthday party, have a computer and a bookcase, and s/he would organize with his/her small size classroom either a trip to touristic destination or a campaign to help for a poor school.

Finally, 'the adult' in the problems was the one, who would care for his health either by buying a summer house to escape from stressful pace of everyday life or becoming a member of a sports club, and investigate the prices of different technological devices. In line with these descriptions, I concluded that the 'real life' in mathematics problems was replaced with the lives of middle and upper middle class individuals.

The replacement of 'real life' with the middle-class social life in the textbooks could be considered as the consequences of the asserted deficiencies in the curriculum. When all the expressions about 'real life' in the curriculum and the replacement of 'real life' with the middle-class social life in the textbooks were considered, it seemed that it hid complicated realities, especially for the working-class students.

Moreover, observations of classroom practices implied that the questions solved in the classroom were very similar with the textbooks' examples in terms of the class culture they represented. The families who saved up money to make investment, who loaned a credit from a bank to meet your needs, who went for a holiday or who paid their automobile insurance were not similar to the families of participant students. However, detailed description of classroom practices indicated that the focuses of problem solving procedures were mainly centred on the basic calculations and the cultural contexts of the problems were near to vanish. Classroom observations implied that although the influences of class culture were reduced in the classroom with respect to textbooks, there was still no reference to the lives of participant students in the classroom activities.

Lastly, teacher interviews pointed out that participant teacher's views about class culture issue were parallel to her views of politically neutral mathematics. Although my analysis of textbooks and classroom practices provided counter examples, the teacher believed that different cultural values and practices were respected similarly in schools. In the light of teacher's responses, I also tried to discuss the warnings of

cultural capital literature about the possible inequalities that the difference in cultural resources would bring to classroom whether teachers are aware of these inequalities or not. Teacher's answers also underlined two reasons for limited usage of real life examples in the classroom: (i) Her view that the effects of real life examples is generally overestimated and applicable to only successful students; and (ii) Her view that finding a common concept for all students in the classroom is very difficult task.

CONCLUSION

To conclude, the overall context of elementary mathematics education replaced the 'real life' in mathematics problems with the life of middle and upper middle classes. 'Real life' problems in mathematics textbooks were not prepared to serve appropriately for working class students and they provided middle class students a cultural advantage. The congruence between the life of middle class students and the life presented in mathematical problems could make these problems easier for them in comparison to their lower class peers. When it was considered that middle and upper middle class students already had economic advantage, this cultural advantage would increase the achievement gap between lower classes students and them. It could be claimed that more working class students would be compelled to failure in this unequal cultural and economic conditions. The possible failure was not the only result of this middle class domination for working classes students; they would also have very limited opportunities to comprehend their live conditions through mathematics and so limited chance to take action against these conditions. While mathematics education had the possibility to make them aware of their lives, this possibility was vanished in the realm of middle class culture.

Based on the findings of this study and with reference to current critical mathematics education literature, the following implications could be stated for teachers, teacher educators, curriculum developers, textbook writers, and policy makers.

First of all, the emphasis of the curriculum on the importance of 'real life' and 'problem solving' should be protected; however, there should also be specific directions about integrating the life, culture, and problems of different social classes - especially the lower classes- which had a limited/restricted voice in both social life and educational organizations. Although transforming curriculum is necessary for transforming curricular materials, such as textbooks and workbooks, it will be not sufficient. Textbooks are one of the bridges between curricula and students (and also teachers). Therefore, there is a need for special consideration/attention to address their deficiencies. Integrating the daily life of working class students into mathematics textbooks and focusing on their social and economic problems in mathematics problems will also be helpful for conducting socially just mathematics.

Neither reforming curriculum nor revising textbooks would promise the positive changes in classroom practices. Transforming classroom practices is strongly linked to the change in teachers' perceptions about the relationship between mathematics education and critical issues. Teachers' perception of neoliberal view of education as

a 'common sense' and their perception of mathematics education as politically and culturally neutral would be one of the reasons of the reproduction of social inequalities through mathematics education. Therefore, educating in-service and pre-service mathematics teachers about class- and culture-sensitive mathematics would be a barrier for this reproduction. Although mathematics teacher curricula emphasize teachers' content, pedagogic, and pedagogical content knowledge, there are not sufficient courses or content in other related courses addressing the role of mathematics education in social justice. Teacher education programs should cover possible links between mathematics education and cultural diversity, gender equity and social justice. Teacher education students, as future teachers, ideally could be able to use strategies for identifying their students' social and cultural environment to make them cope with their problems.

This study tried to portray current standings of mathematics education in terms of class culture. Although I pointed out some alternatives above, a comprehensive answer of what could be done to establish improvements in these issues was not the scope of this study. In the light of critical mathematics education literature, there can be an attempt to construct a class- and culture-sensitive mathematics curriculum. Investigating the possible impacts of such program on students' attitudes towards mathematics and towards these critical issues will greatly enrich the related literature.

ETHNOMATHEMATICS AND TEACHER EDUCATION: REASONING OVER THE MEANING OF THE STUDENTS' PREREQUISITE AND THE TEACHER'S LISTENING

Maria do Carmo S. Domite

Faculty of Education, University of São Paulo, Brasil

This paper investigates an approach between ethnomathematics and the mathematics learning processes in the scholarly context – however it does this from an ethnomathematician's perspective, not that of a cognitive psychologist. I have been developing research in the area of teacher education with the objectives of: a) recognizing how much mathematics teachers are aware of the movement/literature on teacher education and, b) searching an understanding how and to what extent they are available/able to appreciate and legitimize the first/previous knowledge of the students. With the help of the results from this research, I have focused on two aspects of mathematics education processes - the notion of the student's prerequisite and the notion of the teacher's "listening" (Freire, 1996) – that play a key role in the mentioned ethnomathematics approach and mathematics learning processes.

INTRODUCTION

Ethnomathematics, as a movement in the contemporary world, brings out, according to Vergani, one approach with the most promising currents of critical and transdisciplinary in today's thinking like sociolinguistics, cognitive linguistics, phenomenology, biology of knowledge, semiotics, symbology, holistic paradigm and complexity (Vergani, 2003, p.127). Such recognition from an intense researcher who has been for a long time involved in ethnomathematics studies – as a link and holder of current critical-holistic thinking – means a lot to mathematics education both in terms of historic comprehension of knowledge and of political-practical-theoretical tools for other movements on this perspective. Indeed, the importance of ethnomathematics' recognition resides in the fact that, thanks to that approach, today many of us can get space to exercise the struggle against formal disciplines superiority – which, assuming the character of knowledge, exclude the rest – those who do not participate in the formal (academic) sphere.

However, if on the one hand it has been accepted to recognize such potential of Ethnomathematics in the political-philosophical sphere, it has been a consensus, among educators involved in these studies, that to take ethnomathematics as a way/method to school education is a highly complex proposal. In a certain sense, this paper aims to developing the thinking about how this might be achieved through the analysis of teacher educator responses to ethnomathematical problems.

In fact, ethnomathematics has been, on the one hand, very successful in developing itself in education as a way to explicit/legitimate spatial and quantitative relationships implicit on the know-how of one group, revealing – from technique to meaning - the differences, from a social-ethnic group to another, in respect to mathematical relationships. On the other hand, even to D’Ambrósio (1990), the biggest concern in the educational point of view, as well as the essential step to ethnomathematics’ diffusion is to take it to the classroom, it is possible to say that the movement of ethnomathematics as a pedagogical practice is still crawling. Why is it so? What happens in the school operational dynamics that could make ethnomathematics assumptions difficult to be incorporated?

An attempt to answer the question above may be the fact that in the school educational environment, some educators seem to be indifferent to the influence of culture in the understanding of mathematics ideas. Such concern really seems to be a waste of time and effort, important only to anthropologists or, at best, to mathematics education researchers who have not discussed earlier and/or closer on the psychology of mathematics education studies (Meira, 1993). Indeed, from our search for such value among mathematics educators (research results shown ahead), some of them seem indifferent to distinctions of social class and culture, while others seem to wish the elimination of these distinctions. And, naturally, among the latter, there is the questioning if what is worth preserving can be re-built/transmitted by teachings via school.

Although I have chosen this approach to start a discussion about ethnomathematics, I do not intend to leave the subject in this rather negative and explanatory tone. After all, I really believe that the teacher should treat school education via cultural patterns of behavior and knowledge, both because, agreeing with Fasheh, it helps the student to become more attentive, critical, appreciative and more confident to face the mathematical relationships the teacher wants to develop as well as help them to build new perspectives and search new alternatives, “and, we hope to help them to transform some existing structures and relationships”. (Fasheh, 1982, p.8)

ETHNOMATHEMATICS: A POINT OF VIEW

From my point of view, one of ethnomathematics founding basis is the belief that different mathematical relationships or mathematical practices can be generated, organized and transmitted informally, like language, to solve immediate needs. And like an operational means of doing, in the center of the know-do processes of a community, mathematics is part of what we call culture. From this point of view, I not only consider ethnomathematics as the area of study that reflects on the cultural roots of mathematical knowledge, but also as the set of quantitative and spatial relationships, generated in the heart of the cultural community, which compose, frequently, what has been theorized as mathematics.

This ethnomathematical perspective is related to the understanding of the meaning of culture, which has passed by innumerable interpretations over the last century, a plot of signs with which people mean objects, happenings, situations and other people around them – and, each individual possessing the code moves easily in the universe of his/her culture, acts on the certainty of having his/her behavior confirmed by the group (Silva, 1993, p.28). In this sense, the relationships involved/built in both fields – cultural and mathematical are structured, naturally in different levels of epistemological complexity but, certainly, including mathematical objects in the (cultural) plot “of signs with which people mean the objects” (Silva, 1993, p.28).

From what was considered, facing the question “Ethnomathematics, how to interpret it?”, it can be recognized as a line of mathematical education research that investigates the cultural roots of mathematical ideas, indispensable to a better understanding/meaning of one of the education areas – the mathematical education – and the assumptions generating its construction such as, contact with other areas of knowledge, cultural contact, values among others. Ethnomathematical studies, somehow, try to follow the path of anthropology, searching to identify (mathematical) problems from the “other one” knowledge, in the sense of understanding the knowledge of the “other one”. In terms of school, for ethnomathematics the teacher would find meaning in the teaching and learning action if he/she takes as starting point the group’s cultural patterns – not an easy task, because - as mentioned - it is as if he/she were searching to identify and interpret an amount of meaningful (ordained) symbols to “another one” different from him/her.

And, once again, what is this? What different manifestation can we meet in the “other group” that is both essential in terms of cognition and difficult to be incorporated? Based on my experience – with an ethnomathematical view on mathematical education and the teacher’s education context – we frequently meet situations in which different inclinations and different choices manifest – all of them conditioned by cultural values. And, recognize certain aspect of things as a cultural value consists in taking it into account in the decision making, that is, in being inclined to use it as something to take into account upon choice and orientation we give to problem solutions, to ourselves and to others. The following situation reveals this condition well:

The indigenous teacher Maximino, of Guarani-Kayowa ethnicity, when asked by participants of the Studies Research Group in Ethnomathematics-GEPem-FEUSP about the nature of arithmetic operations to the Guarani-Kayowa, reveals very well the value put into counting, which by itself is already differentiated from the universal way. Maximino Kayowa explains:

“[...] a family invites another family to have lunch at their home... and when the wife asks the husband “How many people are coming?”, he can answer like this: “they are four and four means the father, the mother, two sons (counting like one) and two daughters (counting like one). “The same sex they are one”. Maximino continues: “maybe the husband answers three, what means the father, the mother and four children, if they are the same blood they are one. (FEUSP, 11 de abril de 2002)

From the discussion so far, we can recognize that whereas ethnomathematical view searches for detachment necessary not to explain all perceived relations linked to academic/universalized mathematics, maybe we always have to question ourselves - when the discussion context is ethnomathematics - about the existing relation between my knowledge and values and those of the others and about which relations should be established or are established between collective and individual knowledge and values.

This way, facing the question “Ethnomathematics, how to interpret it?”, the answers should have more in view the question “How to interpret the(ethno)mathematics to be worked at school?” - it would be more valuable to mathematical learning that they did not come specially from discussions of mathematics philosophy, but of mathematical education. That is, we do not want to interpret it as a set of disciplines and/or a scientific activity, but as a social-cultural product, opening the way to talk about cultural diversity, difference, interculturality.

FOCUS OF INTEREST: TEACHER EDUCATION

As indicated on the title, one of the focuses of interest in this work is related to teacher education from the ethnomathematics perspective. And from this point of view we have tried to call the attention of educators to the fact that in this immense volume of investigations about teacher education – most of them already concerned not only with the student’s intellectual needs but also with education’s social functions - “the student has not been out of the teacher education proposals, but he/she has not been in either”. (Domite, 2000, p 44).

In some way, we must encourage the teachers to want to understand more and more, and deeper, the school where they work and the students they receive, that is, generate bigger availability to formulate questions “school, who are you?”, as well as “who are our teachers?” and “who are our students?”. Being able to recognize beforehand who is part of the group, what they know and how they know, can make the teacher notice the potential of taking into account student’s culture in the pedagogical doing process.

From the mentioned perspective - a perspective closer to the wishes of ethnomathematical studies - some initiatives in the teacher education have been precious, specially those ones inspired by Freire’s and Schön’s original ideas.

Freire brings and opens to (school) education the proposal of situating the educational action in the student's culture. To Freire, the consideration and respect to the student's "first knowledge" and "the culture that each one brings inside him/herself are the goals of a teacher who sees education under the liberating point of view" (Freire, 1967), that is, recognize it as means to generate a structural change in an oppressive society – although Freire states that (school) education does not reach that objective immediately and, even less, alone. Schön, in turn, brought to educators the assumption that it is from the teacher's reflection about his/her own practice that transformations can happen, suggesting to the educator to take the teacher to ways of reflection operation in action and of reflection about action (Schön, 1987). According to the author, it is from reflection about our own practice that transformations can happen.

From what was considered and trying to understand what can be done on the interface of teacher education and ethnomathematics, I came closer and closer to Paulo Freire's studies, choosing him as basic theorist to answer to my questionings. My highest intent is to propitiate a transformation of the relation we have, as teachers, with ignorance about **who our students are, what they know and how they know about them.**

With these concerns and since one of the basic presuppositions of ethnomathematics is in focusing/identifying/legitimizing the quantitative and spatial relationships based on the knowledge of the "other one", I have been developing research in the scope of teacher education with these objectives: a) recognizing how much teachers are aware of the movement/literature on teacher education in the mathematics educational field; b) searching an understanding of the conceptions of the teachers on education and culture and/or how much they are available/able to appreciate and legitimize the first/previous knowledge of the students; c) problematizing issues/processes that emerge in the social reality of a classroom, in which the knowledge of the student becomes (by force of circumstances) the axis of the teacher's concern; d) understanding the possible connections between Ethnomathematics and the movement of Teacher Education and, e) to better understand what the ethnomathematics educators would like to see in the movement of teacher education.

This research tried to collect information on the basis of two proposals. The first (Part I) was constituted of interviewing mathematics in-service teachers and postgraduates, supported by questions about teacher education. The second proposal (part II), and here is the main focus of this research, was to request the manifestation of the investigated individuals, based on the confrontation with a situation that is distinct from those of regular standards. It is worth highlighting here that this second part of the research was born from my consideration, beforehand, about the lack of deepness of the answers to be given to the third question of part I - that is, I suspected that the set of ideas that are there had not had an impact on their professional lives' histories. The prepared script is as follows:

Part I - Interview with mathematics in service teachers and postgraduates from these questions: 1) What have you heard about Teacher Education?; 2) Write/explicit some ideas, challenges or suggestions you have seen or heard related to teacher education and, 3) In your opinion, what are the main features we, teachers, have to have/develop when we decide to put in the center of the process of teaching-learning our student's previous feelings, attitudes, opinions, culture and knowledge?

Part II - How would you go forward/continue the lessons like these that were presented to teacher Mário and teacher Janaína (two cases coming out in two different public school classrooms in São Paulo city).

<p>Situation 1 - teacher Mário begins, in one of his 5th grades, a conversation with his students on the calculating division, by asking:</p> <p>Teacher: How do you calculate 125 divided by 8?</p> <p>José (student), who sells bubblegum at the traffic light downtown, starts speaking:</p> <p>José: We are more or less 10 "guys", almost all day long, some boys and some girls. Then, we divide like this: more for the girls, who are more responsible than the boys, more for the taller ones than the smaller ones".</p> <p>Teacher: Give us an example, José. For example, how was the division yesterday or the day before?</p> <p>José: Ah! Like this ... there were 4 girls, one of which is small; 6 were tall boys and 2 more or less small. Then we were 12 and the gums were 60. Then, it was given half and half, a little more for the girls. The small girl ended up with 3 and the others with 6 or 7, I do not remember well... The boys...</p> <p>Now you have to put yourself</p>	<p>Situation 2 - teacher Janaina begins, in one of her Adult Education Course classrooms, a conversation with the students on the percent calculation:</p> <p>Teacher: What do you know about percentage? How do you do the calculation of a percentage?</p> <p>Luiz: Even today I needed to make a calculation... 35% of 195 and I did like this... $19 + 19 + 19$ and then plus 9,5. It's 30 plus 27 ... more or less 10.</p> <p>Teacher: How did you get 19? Tell us a little about your way of calculating.</p> <p>Luiz: Ah! I do not know why I did it like this... every time that percentage appears I divide by ten because somebody taught me this way, and I add the times that it appears... like this... 30% I add three times, 40% I add four times.</p> <p>Teacher: And how did you get 9,5? Tell me the way you thought to do this.</p> <p>Luiz: I know that one has to divide by two when it is 25% or 35% or 45%, but I do not know why I do this</p> <p>Now you have to put yourself</p>
--	---

in teacher Mário's position and continue the class...	in teacher Janaina's position and continue the class...
--	--

So far, questions related to Part II of the research were examined with the analysis of 48 answers, all in-service mathematics teachers. Among these 48 teachers, 28 are public school teachers with more than 10 years of experience, 11 with less than 10 years (3 of them also in private schools) and the last 9 are also postgraduates.

In order to analyze the answers, we took into account two types of constraints: first, the teacher's perceptions (the one who should continue the "started class") on the situational processes of teacher-students and students-students interactions, and second, how and to what extent the content of such situations have been perceived by the subject teachers and what he/she does in order to take it into account the scholar instructional movement and/or do not distort it. Then, the passages collected under such conditions - grouped and regrouped by similarities of the teachers' attitudes - lead to the configuration of three thematic axis.

The first axis comes from the teacher's desire to transform the real situation into an exercise or mathematical problem - looking towards the teaching of a mathematical content. One of the teachers reacted like this: "Very interesting José, very interesting! But let us think about the division in equal parts...". The second reveals the reflective/interrogative teacher getting into a problematization process trying to recognize what happens in the confrontation between universalized mathematical knowledge and the contradictions that emerge from reality. One representative of this group/axis reaction: "If we take into account the contextualized knowledge of students like José and Luiz, are we contributing to a more meaningful learning of mathematics?". The third axe represents the teacher's beliefs, values, collectivity and power relationships, somehow related to the pedagogical practice. One of the teachers: "This is a terrible political issue... our students selling bubblegum at the traffic light... what are those children doing there?"

And, what have we learned from this ongoing research? How does this add to our understanding of the teachers' attitude issue of taking into account the "first knowledge" of students in a classroom? I would say that my first comprehension of this process - from this research on - is directly focused on a process developed by the teacher - his/her **listening** - the development of his/her availability to listen to the student. As Freire points out, the teacher should develop an "opening to the speech of the other, to the gesture of the other, to the differences of the other, and (...) this does not mean, evidently, that listening requires from those who really listen his/her reduction to what the other speaks (...) this would not be listening, but self-effacement". (Freire, 1996, p. 135).

Listening to the students, according to Freire, is really, speaking “with” them, while simply speaking “to” them would be a way of not listening to them. And here is a great challenge: our **listening** as (mathematics) teachers. Usually, we, as teachers, educated by the so called traditional school, are not prepared to listen – and then, to speak “with” the other – once our teachers’ pedagogical practices were almost always related to “**explanations**” or presentation of **questions already formulated by them**. In fact, as Freire & Faundez state, “the educator, in a general way, already brings the answer when nobody has asked him/her anything”! (Freire & Faundez, 1986, p.53).

The observation of these attitudes by the teachers – taking onto account the student’s “first knowledge” and “listening” – became one of the aspects that we try to insert/explore/include in our investigations on (ethno) mathematical education and teacher education. In both cases, I believe I can declare that a lot of mathematics learning difficulties occur due to the lack of emotional and intellectual involvement of students in the preparation of the problems they solve. On the one hand, the teacher seems not to consider that the student, adult or child, has a conception of one aspect of knowledge that resulted from his/her learning history – first knowledge - and, it is this knowledge, as it is, that will do the filtering between him/her and new knowledge. On the other hand, the issues that instigate the mathematical thinking action and that can lead to mathematical problems posing is not shown to the students. And then, if everything is defined and ready, how can what the students have to say about mathematics be important? Is it worth listening to them?

The second attitude to be developed in us, mathematics educators, when the purpose is to train teachers in order to take into account the student’s “first knowledge” in a classroom, is to rethink with and among teachers **another notion of prerequisite** – like that knowledge that serve as filter/support to the learning of (new) ideas in mathematics.

In general, the idea of **prerequisite** traditionally employed in mathematical education is like a basis of logical order, indicated by the mathematician, as a *necessary* fact to the knowledge of the item to be studied. **Prerequisite** in this new vision refers to teacher’s efforts in understanding how the student understands this or that (mathematical) idea, how he/she makes meaningful relations around a mathematical idea/content – how such mathematical knowledge is to the student... how he uses it, manages.

If we return, for example, to teacher Janaina’s classroom and really take as a starting point the way the adult student Luiz uses the idea “every time that percentage appears I divide by ten and I add the times that it appears... like this... 30% I add three times, 40% I add four times...” (because somebody taught me so), we would have something valuable to start a meaningful process in terms of percentage. What would be necessary to be awakened to the teacher in terms of attitude? Naturally, even if it is a poorly elaborated attitude for us mathematics teachers, we should observe that from the

information - acquired in social/familiar environment- what Luiz brings about the subject is full of memory, symbols and reasoning.

Luiz's intervention elucidate, somehow, the new meaning and role of what we have called pre-requisite, especially when we are in the field of action of mathematics teaching in primary school. The meaning is in showing/discussing the value of taking the knowledge the student already brings/manages/uses for the construction of mathematical relations traditionally expected by conventional school education.

From our point of view, the understanding of a new vision, by teachers, of **pre-requisite** – as what the student knows how to use, whatever logic/rationality and terms of this use – should be one of the aspects to be especially inserted/explored/included in the Ethnomathematical and Teacher Education investigations.

CONCLUSION

This article's intent was to look back at problems and solutions of the middle way between Teacher Education and Ethnomathematics, as well as put some problems for us to reflect about this possible interaction. Trying to reflect on such interface, I realized that we need to be alert to three important points – or three changing proposals.

The first is the fact that there are innumerable problem-situations and solutions from the non school context - which results in transit by different areas of knowledge and are validated/shared by experience – which the mathematics we learn in the school context does not allow us to notice, maybe due to our tradition of always valuing one kind of mathematics – the mathematics built at the academy, in general, free of contexts.

The second, directly linked to the first, when we notice such problem-situations as rich situations in terms of mathematics teaching, the construction of a *bridge* between this set of (mathematical) ideas and that one systematized by the school is in danger due to inter-relations between thinking and emotion, thinking and traditions, thinking and religion, thinking and the myths that lead to unexpected situations because of the tendency of language to take different meanings. In fact, for this *bridge* to happen it is, a lot of times, necessary a translation between the speeches by careful attention to meanings, to representations and, a lot of times, to linguistic elements.

Third, if our objective with a research of this kind is to develop a teacher education curriculum in which we problematize questions/processes that emerge from the student's socio-cultural reality, we recognize that the foundation for a research and/or a mathematics teacher education to act in this direction requires an incursion in literature focused not only on Mathematics, like in Anthropology, Sociology, History, Psychology and, specially, in the research production about Teacher Education in the educational field.

And finally it was possible to notice that preparing mathematics teachers to the development of the student's concerns and "first knowledge" is not incompatible to orienting them to teach mathematics – on the contrary, this can be one of the aspects to be developed in the teaching process.

MATHEMATICS *FOR LIFE* OR MATHEMATICS *OF YOUR LIFE*: A STUDY OF THE RVCC PROCESS OF PORTUGAL

Maria Cecilia Fantinato

Universidade Federal Fluminense, Brazil

This text aims to present some results of a post-doctoral project, which sought to understand pedagogical practices in contexts of adult education in Portugal, in the area of Mathematics. The study was based on a theoretical framework that reconciles literature from the fields of Adult Education, Ethnomathematics and Experiential Learning. A qualitative and multi-sited research was conducted, following the dynamics of the adult education centers, the professionals who work with adults and particularly the formers of an area titled “Mathematics for Life”, which was part of the process of Recognition, Validation and Certification of Competences. The practice of the RVCC process proved to be challenging and complex, both to professionals and to adults involved.

INTRODUCTION

Throughout my journey as a researcher in the areas of Adult Education and Ethnomathematics, I have focused on some issues, such understanding the quantitative and spatial representations of a group of low educated adults (Fantinato, 2004), or how the ethnomathematical approach can contribute to teacher education. Among other subjects, I have investigated the extent to which contact with cultural diversity, which is characteristic of adult education, stimulates openness to unconventional forms of mathematical reasoning among teachers. I have studied as well, how adult Mathematics teachers create spaces of dialogue between different types of mathematical knowledge in the classroom (Fantinato, 2008). These issues were present during the achievement of my postdoctoral research¹, which sought to understand principles and practices of adult education both in Brazil and in Portugal, and in particular to grasp Mathematics teaching practices and their forms of interaction with students’ diverse mathematical knowledge and their construction processes.

This text aims to present some results of the development of this project, during the stage carried out in Europe. I have chosen here to perform an analysis, from the ethnomathematical perspective, of the Portuguese process of recognition, validation and certification of competences - named RVCC process - focusing on its contradictions and on the challenges faced by professionals of “Mathematics for Life” (ML) area.

THEORETICAL FRAMEWORK

From the moment of its entry into the European Community in 1986, politics of education and training of adults in Portugal have come under the influence of the

Lisbon Strategy² and its values of "lifelong learning". One of the consequences of seeking integration into European models was the creation of the *Centros Novas Oportunidades*³ (CNO), which from 2005 to May 2012, brought together the many activities related to adult education in Portugal, most of them located in school groups. The main activity performed in CNOs was the RVCC process, which was intended to assign a final school certification to adults.

The RVCC process is a practice on recognition of acquired experiential learning, and as such, according to Canário (2006), brings two ideas constituting its essential foundations: the notion that a person learns from the experience and the principle that one should not teach people what they already know. It assumes that "people are lifelong producers of their own knowledge, and that this knowledge driven from experiential learning processes, may be the subject of recognition, validation and certification⁴" (Cavaco, 2009a, p. 150). The RVCC process works on the principle of recognition of skills. This is a process that

is based on a set of methodological assumptions [such as Balance of Powers, (auto)biographical approach] that allow demonstration of competencies previously acquired by adults throughout life, in formal, non-formal and informal contexts, which unfolds in the construction of a Reflective Portfolio of Learning oriented to a Key Competencies Referential. (ANQ, 2007, p.15)

A competence approach involves recognizing and valuing the knowledge acquired, especially in informal and non-formal contexts, reflecting the life learning of adults, differing, thus, from approaches that focus on the acquisition of subject content in formal learning contexts. These are life skills that enable adults to "understand and participate in knowledge society, mobilizing through them the knowing, the being and the know how to solve problems that the changing current world confronts them constantly" (ANEFA, 2002, p. 9). In this perspective, in the RVCC process competencies appear "as emerging from the action, giving them a finalized, contextual and contingent character" (Canário, 2006, p. 41).

Experiential Education, one of the theoretical orientations that guide the practice of recognition of experiential acquired learning in Portugal (Canário, 2006), considers experiential learning as "a local use knowledge, that the individual shares with the other members of the community to which he belongs [...] comprises the dimensions of knowledge, know-how and know being (Cavaco, 2002, p.39).

The research line of Ethnomathematics (D'Ambrosio, 2001) has also addressed the issue of knowledge constructed within contexts of life, more specifically, of mathematical knowledge built by different cultures, namely "how social groups are aware of their needs and on what terms they use their local math to address them" (Moreira, 2009, p. 66). Ethnomathematics:

Has pioneered research and studies that seek to understand the different modes of youngsters and adults mathematical reasoning, that result from a cultural background

built predominantly in contexts of domestic and professional life, without excluding previous school experiences. (Fantinato & De Vargas, 2010, p. 37).

I consider that, despite some crossovers between this theoretical approach and Experiential education, Ethnomathematics can provide a differentiated analysis of some principles of the ML component of the RVCC process, as well as a new look at the (mathematical) experiential knowledge of adults to be certified.

RESEARCH CONTEXT AND METHODOLOGICAL PROCEDURES

Research carried out was of a qualitative nature, using the modified analytic induction approach (Bogdan & Biklen, 1994). The project was developed in several CNOs and therefore the investigation can be considered as multi-sited. I have carried out a descriptive study, with a concern for the meaning given by participants. Throughout the investigation I used different instruments for data collection: document analysis, participant observation and semi-structured interview. Analysis and data collection were developed alternately. Because this was a qualitative study, I considered my own transformations in the process as a way of defining the object of investigation.

In a first moment of investigation, I carried out an analysis of the official documents of the National Agency for Qualification of Portugal (ANQ), which provided theoretical and methodological policies and guidelines for adult education in this country, at the time research was conducted. Particularly, I studied the Referential of Key Competencies of Adult Education (ANEFA, 2002), for primary and secondary level, trying to locate where these documents addressed the area of Mathematics. Since I did not find in the document for the secondary level explicitly mathematics⁵, I focused on the analysis of one of the four areas of Referential for basic level, the one titled "Mathematics for Life". This document is structured into three skill levels, called "B1, B2 and B3, taking as reference the correspondence with the cycles of the Primary School, although they can not be identified with them" (ANEFA, 2002, p.11), and serves as a parameter to the RVCC process.

Fieldwork itself happened from November 2011 to March 2012, when I scoured several CNOs located in the metropolitan area of Lisbon and nearby municipalities. I watched practices and conducted interviews with directors, coordinators, and especially *formers* of "Mathematics for Life", using *snowball sampling technique*, one respondent indicating another, which indicated another, and so on, until I had enough information. Four of the Formers of ML selected for interview were graduated in Mathematics, and one had his graduation degree in Engineering. These professionals had all previous experience as Mathematics school teachers, and by the time data was collected, two of them, besides working with adults, were also teaching Mathematics to regular students. However, despite their experience as classroom teachers, in carrying out professional practices of RVCC process with adults, they would identify themselves as *formers*. The different designations are

consequence of different professional roles, while interacting with adults or with school children.

The interviews took place at informants' workplace, at a time that was convenient for both the interviewer and interviewees. Later they were transcribed and analyzed, based on the categories that emerged from the process. The analysis gave priority to challenges and contradictions of daily experience with RVCC process by professionals responsible for the area of mathematics. Therefore, this paper focuses on the interview data with ML Formers.

UNEARTHING THE PROCESS STEPS

The dynamics of the RVCC process comprises several steps. Upon arriving to CNOs, adults are received by technician for diagnosis and referral, which evaluates their ability to perform the RVCC process and indicates the level that should be integrated. After the RVCC professional has evaluated the adults in an individual interview, they go to next stage, when their work will be oriented by Formers from four different areas, one at a time, among them, "Mathematics for Life". The *decoding sessions* take place at this moment, whose main objective is:

to try to show people what they have, or can speak in terms of subjects, to meet, matters which make, mathematically speaking [...] shopping, budget management, administrating a house, or a division of a house, and all that that implies. Or something that people can make at work, and then can write about. And then try to make them realize that with these situations, they can get validate competencies in the four units that compose the Referential (Mariana⁶, ML former).

The initial work of the ML former is to show the adults what issues they might indicate in terms of their life experience and from a mathematical point of view, so they can later articulate in the written form their life story, where the situations described demonstrate competencies that can be validated according to the Referential "Mathematics for Life" (ANEFA, 2002). During the first decoding sessions, trainees have access to the Competencies Referential. One of the challenges of ML former is the adaptation of this official document text - written in formal language - into a form that is understandable to adults. Educators try to seek this challenge by elaborating tools for their work in the process. Mariana built a sheet entitled "What competencies from your daily life you can demonstrate?", which features more accessible and contextualized questions, elaborated consonants concepts that are at the Referential. One of the questions in this form asks if the adult usually relate the number of installments of a home, a car or an appliance with all the loans and the interest rates one will pay, and asked to describe life experiences that demonstrate this competence. Leandro, another ML former, when starting the decoding sessions, usually passes a movie that shows journalists interviewing fair dealers about their daily mathematical knowledge. He said it was a film "that dismantles everything," and that helps adults perceive that his role as former is

identical to the role of those journalists, who go identifying in fair dealers daily practices some mathematical contents: simple rule of three, series sequence, "contents that are taught here in the eleventh year" (Leandro).

The sessions of "Mathematics for Life" are developed in small groups of about ten people. Another former, Celina, believes that this group sharing favors the exchange of experiences, and so "they can catch a life example. One says one example, another remembers another, another remembers another, it generates a chain reaction" (Celina).

Throughout the sessions adults go on writing successive versions of their autobiography, which are evaluated by formers and returned to adults with their comments on the competencies achieved and on the ones which needs to be developed, until reaching a final version that proves the required competencies for validation in the area of ML. This written explanation and the making of a speech about the activities they perform day by day is one of the main difficulties of the RVCC process, especially for adults with little schooling, because "the ability to construct the discourse on action, namely the formalization of the action, is a skill that is developed and is perfected at school, which allows us to understand the difficulties that low educated adults have in this area " (Cavaco, 2009b, p. 763).

RECOGNITION, VALIDATION, CERTIFICATION: PROCESS ACTIONS AND CONTRADICTIONS

When they started working in CNOs, professionals involved in RVCC faced the challenge of developing a work that was entirely new to them and to which they were unprepared. Although some of our respondents have participated in 2008 in a formative action proposed by ANQ⁷, where some principles of this new methodology were transmitted, this training above all represented the learning of new terminologies and new roles (Fantinato & Moreira, 2012).

Likewise, for the professional in the field of Mathematics, there is a change of term that corresponds to a change in function, and Leandro makes explicit in his words:

In the area of RVCC I am a former. I am a mathematics teacher at school. Yes, because there are different terminologies. For example, in the RVCC one does not give lessons, there are sessions, it is not the teacher, it is the former, more from the perspective of guiding. And in the diurnal course it is the usual methodology: classes (...) Methodology is completely different. During diurnal course student learns, in nocturnal course, especially in RVCC, student already brings the knowledge, he will show the competencies he has. (Leandro)

Leandro's speech indicated that there was a difference between the teacher's work, who follows a school model - plans, teaches, evaluates - and the ML former, who "gives examples of things that adults will be able to look at their daily life" (João,

director of CNO). Former Fernanda also declared not being prepared for the process practice:

Usually I give lessons, students then show what they learned of what I taught. When I got here, they've brought their knowledge and I had to look at what they knew, what they already knew [...] (Fernanda)

Leaving therefore the acting as teachers to assume the role of formers, these professionals, to "ensure adequate performance must develop specific skills, rather distinct than those requested when they were exercising their functions as regular teachers" (Cavaco, 2009b, p. 700-701).

Despite not knowing Ethnomathematics, it is observed that ML formers, while developing the RVCC process, seem to be stimulated to look at the diversity of "ways of knowing and doing of the various cultures and an acknowledgment of how and why groups of individuals [...] perform their practices of a mathematical nature, such as counting, measuring, comparing, classifying" (D'Ambrosio, 2009, p. 19). When talking about their work, these professionals mentioned the everyday mathematics and valued adults own knowledge, built in their life experiences. They recognize, for example, that "the adult who comes from the rural area has very different apprenticeships than those learned by an adult that comes from the urban environment" (João).

However, although RVCC practice promotes "readiness for dialogue" (Freire, 1997) of the teacher to diverse mathematical knowledge, it carries an intrinsic contradiction. Recognition of the diversity of adult knowledge does not imply its validation, since it follows a single referential as standard. The formers, even recognizing mathematical competences of adults, could only validate those that were listed in the Referential. As says João: "We can only validate the competencies that are on the Referential, what you did in your life that can represent that competency. This is hard".

The story presented by former Rodrigo, describing his conversation with a man who raised birds, and who at first said he did not recognize the presence of Mathematics in his life history, shows some aspects of the complexity of the process:

"So you but if you raise birds, you do not have to buy rations, food for birds, what quantities do you buy? How much do you spend? Because if you make a table with such things, how much you spend per bird, quantities, and etc. All of this has to do with Math" [...] He understood. Then went home, and came up with things done. But what he wrote, that did not translate any special competence. However, after talking with him, I realized that the man used to build his your own cages of birds. He used to make the place where the birds were, then had to take measures, had to buy wood, had to go in search of prices, had to buy the network to put around. I told him: "This is where the competence is, when you take these measures, and do all those things, the competencies are there." That was when he realized what he had to do. So he came up to me with a concrete example of how

he had done there with the cages backyard. Because he had to buy the wood costing I don't know how much, took those measures, and so and so. So I could validate those competencies. Because before, I could not do it, even though he had such abilities [...]. (Rodrigo)

Rodrigo's report exemplifies the role of ML former, as a mediator between previous acquired knowledge and the competences listed in the Referential. But how to accomplish this if the Referential presents highly technical language, next to school mathematics? For example, how can a low educated adult identify in which situations of his life he can infer "laws of formation of numeric or geometric sequences, using mathematical symbols, namely designating expressions⁸"?

Another contradiction of RVCC process is the fact that it presupposes the use of the written mode of presenting the autobiography, which contrasts with the presence of mental calculation skills, from the so-called "oral mathematics" (Carraher, Carraher & Schliemann, 1988), common among low educated adults. This represents another challenge for ML formers. As Mariana says: "There is a phase where they say: 'Ah, but I do it in my head,' and I say, 'Yes, but what you do by heart, write, place, show, that it can be a proof' ". As for former Rodrigo, mental calculation usually reveals itself along with other calculations, and he realizes that "people who have this skill get the result sooner than others." However, despite recognizing this ability among adults, which indicates "some facility in mathematics," he warns: "I can not validate only because the person knows how to do good mental calculation."

The practices of recognition, validation and certification of acquired experiential learning among adults, involve therefore a great complexity, related to the act of valuing knowledge resulting from the action and to the search for establishments of links between them and theoretical knowledge. I agree with Cavaco, when she says that "theoretical knowledge and knowledge deriving from the action have different natures and irreducible differences, making it difficult and artificial any process that intends to merge or overlap them" (Cavaco, 2009a, p. 150).

Undoubtedly, "assessment is another element that contributes to this complexity in recognition devices of acquired experiential knowledge" (Cavaco, 2009b, p.766). Throughout RVCC process, adults are evaluated for their successive written autobiography. According to coordinator Leticia, this is a "dramatic" time, where professionals need to be careful how to address adults, because they are confronted with what they were not able, and can drop the process: "they leave, because they do not feel comfortable with someone who has more skills, they do not feel good about themselves. Because they were not able" (Leticia).

The adult going through the process receives from the CNO team several suggestions for improvement, until he reaches an autobiographical text that presents the competences needed to be validated and, thereby, can obtain the corresponding school certification. If needed, adults are referred for additional training, where

formers work more individually with each adult in their needs. Even so, at the end of all these stages school certification of the expected level is not always obtained, and there is the alternative of the adult receiving a partial certification, that is, only in some areas of RVCC.

MATHEMATICS *FOR LIFE* OR MATHEMATICS *OF YOUR LIFE*?

The proposal of "Mathematics for Life" Referential (ANEFA, 2002), used as a parameter to validate the mathematical competencies of adults who perform the RVCC process, presents some seemingly contradictory characteristics, which are a reflection of the inherent contradiction of validating knowledge built into everyday life by checking their equivalence to school mathematics knowledge. To what extent (mathematical) knowledge built in the diverse contexts of everyday life can be translated into a mathematical language seen as universal and unique? A discussion on bridging the gap between local knowledge and school knowledge, that is, transfer of knowledge from one context to another, has been in effect one of the critical points of the debate on the educational implications of the ethnomathematical approach (Pais, 2011). Power relations and values assigned to the different types of mathematical knowledge are present in this process of "translation".

The experience of the RVCC process is not immune to these contradictions. For adults with little education, to recognize that they built apprenticeships in contexts of life and that this learning can have be valued as a school certification, is certainly a challenge, which becomes even greater in the case of a socially valued area such as Mathematics. The contradiction of guidelines from RVCC process appears in the name of the area "Mathematics for Life". Is this a mathematics applied to everyday life, or recognition of the present mathematics in daily practices? Former Fernanda explains the little adequacy of this name, mentioning her professional experience with the process: "It seems that we are giving them the math and then people apply it. But that's not what we do here. Life, that already has mathematics, is that we seek".

NOTES

¹ Postdoctoral held in two phases, the first in Brazil between March and September 2011, in the Faculty of Education, Universidade de São Paulo (supervisor Maria do Carmo Domite), and the second in Portugal, between October 2011 and March 2012, at the Institute of Education, Universidade de Lisboa (supervisors João Pedro da Ponte and Darlinda Moreira), with a grant from Fundação para a Ciência e a Tecnologia (FCT).

² The Lisbon European Council (2000) set policies to boost the economy, end unemployment, stimulate competitiveness and reduce the differences in schooling and technology inclusion among adult populations of the member states of European Union.

³ After May 2012 the *Centros Novas Oportunidades* (New Opportunities Centers) came to be known as *Centros para a Qualificação e o Ensino Profissional* (Centers for Qualification and Vocational Education), and lost many of its functions of adult education and training.

⁴ Every translation from Portuguese in this paper will be our own..

⁵ This Referential covers three interdisciplinary areas; content area of mathematics can be found, implicitly, in the area titled Sociedade, Ciência e Tecnologia (Society, Science and Technology).

⁶ The names adopted herein are fictitious, in order to protect the identity of informants.

⁷ Training held in the Algarve, which lasted for three weekends.

⁸ Level B3 evidence criterion, from “Mathematics for Life” Referential (ANEFA, 2002, p. 24).

THE EMERGENCE OF AGENCY IN A MATHEMATICS CLASS WITH ROBOTS

Elsa Fernandes

University of Madeira; Research Group Education, Technology and Society, IE UL, Portugal

In this paper we will discuss and analyse students' participation in a mathematics class when using robots to think about the mathematical concepts. Our aim is to highlight the emergence of students' agency in the interplay with robots and discuss the role of agency in participation and in the learning of mathematics.

INTRODUCTION

Learning mathematics can be understood as participation in social practices (Lave e Wenger, 1991), where people get engaged in solving problems and making sense, use mathematical representations, concepts and methods (Boaler & Greeno, 2000). As such, analyzing students' participation in mathematics classes becomes important when we want to understand and discuss learning as a phenomenon emerging from participation in social practices. In this paper, we are not interested only with whether or not students participate but how they are given opportunities to participate and how they take advantage of them.

Both Situated Learning Theories and Critical Mathematics Education discuss the learning process as something in which the person must act in order to learn. Alrø and Skovsmose (2002), for instance, explore the idea of learning-as-action in which action can be associated with terms like aim, decision, plan, motive, purpose and intention. That is, "action presupposes both an involvement of the person and an openness of the situation" (p.43). On the other hand, school mathematics classes which allow students to engage in practices of negotiation and interpretation, using physical and discursive tools and resources, provide learning scenarios in which students participate by adapting to the constraints and agreements of it.

Through the project DROIDE II¹ – we have created learning scenarios in which robots are physical artefacts with which students think during school mathematics practices. Our aim is to understand how students produce meanings and develop learning of topics and mathematical concepts when robots are mediators' artefacts.

In this paper we will analyse students' participation in mathematics classes, amidst the scenarios created where robots had a central role, discussing the role of agency in the learning of mathematics.

ON AGENCY

An individual's agency refers to the way in which he or she acts, or refrains from acting, and the way in which her or his action contributes to the joint action of the group in which he or she is participating. (Gresalfi, Martin, Hand & Greeno, 2009, p.53).

According to our understanding, individual agency relates dialectically with structure, and it is a dynamic competence of human beings to act independently and to make choices (Andersson & Nóren, 2011). Agency is not born with the person.

Giddens (1984) argues that agency is the capability to make the difference and that it relates exclusively to humans. Artefacts are only “allocative resources that influence social systems only when incorporated in processes of structuration.” (p.33). Latour (1991) offers a concept of agency that is not restricted to human actors. He coined the term *actant* in order to allow the association of agency with humans. Doing this, he opens the space to conceive agency as something that can be allocated not only to humans. Indeed, if agency is the capability to make the difference then the machines also can exhibit forms of agency. In actor network theory, agency is not restricted to humans but is also attributed to technologies (Rose & Jones, 2005).

Material Agency

Pickering (1995) made a distinction between human agency and material agency. Humans are active and intentional beings. Human agency has an intentional and social structure and intentionality is what makes the difference between human and material agency. Physical artefacts are essential for the modern world. People manoeuvring in the field of material agency “capture, seduce, download, recruit, enrol, or materialize that agency, taming and domesticating it, putting it at [their] service, often in the accomplishment of tasks” (Pickering, 1995, p.6). Human agency is itself emergently reconfigured in its engagement with material agency.

There is no way that human and material agency can be disentangled. Or else, while agency and intentionality may not be properties of things, they are not properties of humans either: they are the properties of material engagement. (Malafouris, 2008, p. 22).

Pickering (1995) made a distinction, when he developed the terms conceptual and disciplinary agency, in his socio-historical analysis of a case of research in mathematics. Mathematicians “exercise conceptual agency when they engage in decision making, exploration, and strategizing” (p. 53). When they decide to use an established method, agency is turned over to the discipline. According to Pickering (1995) what generally happens in physics and mathematics is “a dance of agency” that combines the conceptual agency with the disciplinary agency, or the conceptual agency with the material agency.

Critical Agency

Alrø and Skovsmose (2002) presented the idea of critical learning of mathematics. This idea entangles the notion of agency. Although the word “agency” was absent in

Skovsmose's work until 2012, it has been implicitly present in expressions such as intentionality, action, reflection and choice used in his work (Anderson & Norén (2011).

Greer and Skovsmose (2012) think of *Critique* in terms of “critical agency” signifying that critique refers to both reflection and action. The concept of critical agency entangles the dialectic between reflection and action. And the genesis of critical agency lies on the ability and dispositions to imagine that things can be different (Skovsmose & Greer, 2012).

When we want to discuss the critical learning of mathematics, action appears as a fundamental notion and can be associated with expressions such as aim, decision, motive, and intention. This presupposes an engagement of the person. On this conception of learning, intention and action are strongly connected as well as in the notion of human agency.

Alrø and Skovsmose (2002), with the aim of discuss in dept the notion of critical learning of mathematics, also introduced expressions such as intention, reflection and critique. They tried to clarify the dialogic basis of critical learning (of mathematics) in terms of intention and reflection: “While intention refers to the involvement of persons, reflection refers to considerations carried out by persons” (p.157). To participate in a dialogue, in a way that promotes learning, presupposes engagement and this engagement can be characterized in terms of the notion of intention:

Intentions-in-learning are essential for the students' ownership of the learning process. [...] In order for the dialogue to continue, it is important that the intentions of the participants are continually modulated and adjusted to each other. (p. 157).

But students in the classroom have others intentions than those related with the learning of mathematics. They may have intentions of being noticed by the teacher or to sit next to their best friend, and the like. These are the underground intentions. But these intentions are intentions too and consequently they are part of the acts, but not of the learning acts (of the official classroom activity).

There are, according to Alrø and Skovsmose (2002), the resources of intentions. Intentions are formed based on experience, impressions, prejudices, preferences, etc. These resources of intentions are called dispositions. The disposition of the person is the raw material for their intentions and is seen as individual but also as a feature of the person's culture. When we think about learning-as-action, the notion of dispositions is used to describe the source of motives that students have to engage in the learning process.

“The student's dispositions for learning are thus indicative of the factual possibilities that the student holds for the school system and of the student's interpretation of these possibilities. Correspondingly, the student's dispositions make up a heavily structured

framing condition for intentions-in-learning. The students expose such intentions in patterns and according to their notions about learning and going to school.” (p. 160).

Peoples’ intentions reflect, to a large extent, their foreground or the foreground of a group of people to which they belong. Foreground can be understood as the way people interpret their possibilities given a certain political, cultural and economic context and their social position in it. Thus, the foreground refers to the person perspective (Skovsmose, 2005). As a result, the foreground of people should be considered when interpreting their actions. The background must also be taken into account. Both influence what a person might want as well as person’s possible actions. Both represent resources of intentions (including underground intentions).

METHODOLOGY

In this article we adopt a qualitative mode of research, because our aim is to develop an understanding of human systems. In this case the system composed by a technology-using teacher and his or her students and classroom (Savenye & Robinson, 2004).

To use Situated Learning Theories as a theoretical foundation implies some methodological assumptions such as assuming that investigating is to participate in a wide range of practices in which the investigation occurs (Matos & Santos, 2008). That was the positioning assumed by the researcher involved in the data collection. As a participant in the research, the researcher also learned. So, the participant observation was a central strategy and acquired the status of data collection methodology.

The data collection was made in two months of the school years 2010-2011. We chose to work with two classes of 7th grade students (ages between 13 and 15 years old) studying functions. There was an initial session, at Droide Lab in University of Madeira, where students had their first contact with the robots. A video cam was used, focused on a group. Four 90 minute classes were recorded (also with a video cam focusing in a group).

The analysis was made based on the video transcriptions and on the field notes taken by the researcher and teachers involved in data collection. The units of analysis included person, activity and the contexts where the activity took place.

We have been trying to find patterns of interaction, among students as well as among students and teachers, using Greeno’s (2011) ideas about students’ interactions because it allows us to explain students’ participation in school mathematics’ practices and to make visible the positioning students assume concerning agency and accountability (Fernandes, 2012). But we have also been trying to understand students’ intentions in order to discuss critical agency. On this paper the findings will focus on a particular case study of a student that will be referred as ‘He’.

A SCHOOL MATHEMATICAL PRACTICE WITH ROBOTS

During the initial session, students went to University of Madeira, to the DROIDE Laboratory, to assemble and program robots. When pupils assemble the robots, particularly when they ‘dress it’, they put so much of their living experiences and of themselves on the robots. There is a personification of the robot.

On the following day, back to school, they worked on a worksheet the ‘notion of a function’. The aim was for students to work with robots, oriented by the questions of the worksheet, and understand, learn and define the concept of function. It took two 90 minute classes. The worksheet had a closed and very scholar structure. The innovation was the inclusion of the robots to think about the mathematical concepts involved. Each group of students received a worksheet and, even before robots were distributed, the teacher asked them to read attentively the issues on the proposal.

The task consists in analysing two graphics depicting two robot trips. Firstly, students had to make a description of the robot trip having the starting point as a reference. The second question was about the robot’s programming in order to realize the trips, if possible. The graphics presented were the following:

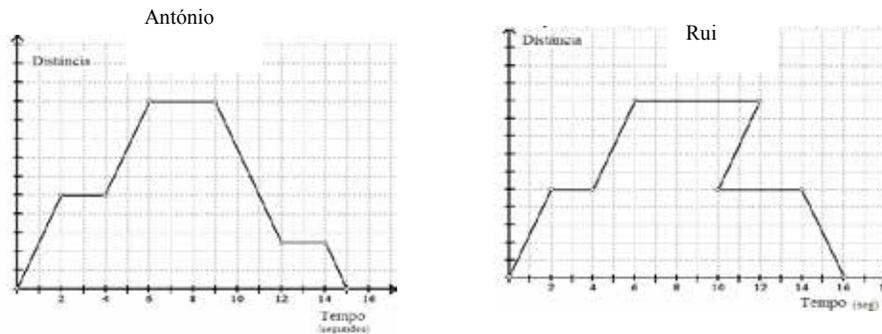

Figure1 – Graphics presented on the worksheet

The school mathematics practice analyzed can be characterized by the resolution of mathematical questions in groups, in which students had to discuss every task, to describe the processes that led them to results and finally students’ presentation of the results and conclusions to the rest of the class. The wider group discussion was mediated by the teacher.

‘He’ was one of the 10 boys that had failed the preceding year and during this school year only had a marginal participation in mathematics classes. Since the moment he began to work with the robots, ‘He’'s posture, in mathematics classes, changed. ‘He’ was the one handling the robot in the group, programming it and checking the programming results. It seems that robots made ‘He’ able of imagining that things can be different.

‘He’'s group read the graphic concerning António’s trip (on the left side) with few hesitations. After analysing António’s graphics and programming the robot to make

that trip, experimenting it on the floor and verifying if it is well done, they came back to the desktop and asked teacher's help.

He: In the second graphic we don't really have to do anything, right?

Teacher: Why do you say that? What do you mean by "don't have to do anything"?

He: We already analyzed Rui's graphic and we can't program it.

Teacher: And why can't you?

He: We can't because there's no command that allows us to make the robot go back in time.

Teacher: But where in the graphic do you see that the robot has to go back in time?

He: Right here teacher (He pointed the graphic to the 12s moment), at 12 second the robot was at a distance 10, but also at a distance of five, because the robot went back and time does not go back. It can't be at two places at the same time. We can't program it because it isn't possible.

'He' was very much convinced that this programming wasn't possible. Even so, he couldn't convince his colleagues that were not, at the time, able to see his point. After discussing his point of view with the teacher (may be with the intention of showing her what he can do with mathematics now) he left his colleagues to proceed with the task of programming the second trip even knowing it wasn't possible, as he pulled aside and started writing. After some time, the teacher went back to the group and asked if they already had reached to a conclusion. One of students in the group replied:

Pe: Yes we did. We can't program it. We only made it until here (pointing on the Robotics Invention System programming interface, to the path until the 12 second).

The inclusion of the robots motivated 'He', opened a space of factual possibilities that 'He' held and made him committed to the resolution of the working proposal. He convinced the teacher but not his colleagues. Probably due to the way other students saw 'He' in terms of mathematical knowledge. He was a student with marginal participation and maybe because of that his mathematical explanation wasn't accepted by the group. It was not supposed that 'He' was accountable to the solution of mathematical question due to his trajectory in mathematics classes along all the school year until robots arrive.

'He's' questions to the teacher were very useful for two reasons: (i) in order to include the teacher in the accountability system, as the person who could convince the others students of the group, once he wasn't been able to convince them (ii) in order 'He' shows to the teacher what he was mathematically capable of doing (accountable for). These are 'He's' underground intentions. After solving every other question of the worksheet, which included writing the condition needed to allow for

a correspondence to be a function, students had to comment on the following sentence "The correspondence presented by António is a function. Rui's correspondence isn't a function"

'He' again asked the teacher a question, for what he already seemed to have the answer, showing once again what they had been able to achieve making himself accountable to the idea.

He: Teacher, can we say that Rui's graphic isn't a function because there is one single time corresponding to two distances?

Teacher: And that's what can't happen for a trip to be possible?

He: Yes it is. For a trip to be possible, it can't be at the same time at two different places. Rui's robot at 10s is at the distance of 5 and 10.

'He' was the 'motor' of this group for the 'good' resolution of the mathematical question proposed, displaying his conceptual agency, that was emergently reconfigured in its engagement with material agency. Using the robots by which he showed great interest since the first session, seemed to be the starting handle to operate the change on 'He' participation on mathematics class. In this episode we can see some reflections of 'He', probably provoked by the introduction of the robots. He was able to explain why the correspondence was not a function in terms of the robots' functioning "[the robot] can't be at two places at the same time". The robot, associated to the notion of function, was part of the shared repertoire of this class. The students used that sentence every time they have to justify that a correspondence is a function and after they 'translated it' to the situation they had to solve.

Two classes after, students worked on the notion of "proportionality² as a function". The first question of the task was to compare the speed of two robots and to discuss if time and distance were in proportion. They have to program the robot to move forward for 1 second and then measure the distance covered by the robot; and then to do the same thing for 3 and 6 second. After that they have to calculate the quotient between distance and time and then to conclude about proportion. The group of 'He' has done for 1 second, and after doing for 3 seconds, 6 seconds, twice, 'He' said:

He.: It cannot be. The robot moved again 110 cm. I'll ask the teacher.

Fi.: I can't understand why you say it's not correct. We have already measured twice and it gives the same value and not 138cm as you want.

He.: You only have to do calculations. Do it!

Fi.: What calculations?

He.: 46 times 3...

Fi.: is 138.

He.: It is because of that that I say that it should be 138.

Pe.: Ah! Now I understand... we have to multiply the first value by the second

He.: Exactly. If in one second 'Tank' moved 46cm, times 3 is 138 e for 6 is 276... and this is not what we obtained...measuring.

In this episode we can see the difference of posture from the group colleagues to 'He'. 'He' was accountable to and accountable for by the colleagues. The different participation of 'He' on mathematics class gave him mathematical authority. Now colleagues listen and ask him to explain what he is saying.

[After that, teacher arrived to the group, listened all the students' complains about what is not going well, and said:

Teacher: Assuming that you measured correctly, try to think about reasons to justify the difference between what should be and what it really is.

In the students' discussion about the reasons for that, emerged justifications such as: the ground is not completely plan, robots' batteries had spent, braking time is different for different robots, etc.

It is interesting to see that students that had had a marginal participation now are able to reflect on mathematics. Robots brought to several students motives and disposition to engage in the learning process. This engagement made the difference on the kind of participation assumed by those students. 'He' and several other students, most of them 'disposable', in Skovsmose's (2005) sense, held that possibility from the school system.

During this work with robots, teachers were invited to organize a workshop to some classes of the school. We (researcher and teachers) decided to invite some students to do it for the colleagues. 'He' was one of the invited students. When we were in a meeting to prepare the workshop, 'He' asked:

He.: Teacher, is it possible to know for which classes we'll do the workshop?

Teacher: It's not important. There are colleagues from the school.

He.: But ... I would like to know if 8^o2 (the class he belong the preceding school year) will be...

Teacher: No. 8^o2 will not be.

On the following day 'He' did not come to the workshop.

On the following mathematics class teacher asked him why he didn't come to the workshop. First he said that the alarm clock didn't went off and then, after a pause of some seconds he added that he wasn't interested in teaching robots to school colleagues that he didn't know well. When researcher talks with him (informal interview) he explicitly recognizes that it will be interesting to teach the colleagues that 'know more than me ...because they are on the 8th grade'.

‘He’ seems to have the expectation of showing his colleagues of the preceding school year class, where he was not been successful, that now he is. This scenario did not occurred, so ‘He’ did not activated intentions to participate on the workshop and gave up. This intention of ‘He’ reflect his foreground. Analyzing his attitude without taking it into account can generate a conflict between teacher and ‘He’.

FINAL CONSIDERATIONS

The way pupils were involved in the construction of robots was a very important aspect of the process. Students personify the robots putting a lot of their experiences on it. The result of all this was that students felt ownership over the robots. This fact makes them deeply engage in practice and the results are visible in terms of participation and consequently of learning.

To introduce robots on this learning scenario made agency to emerge on students that usually have a marginal participation. These students acted on the field of material agency, brought by robots to the created scenarios, captured this agency and placed it in service of the task they have to carry out (Fernandes, 2012). Human agency was reconfigured in its engagement with material agency (Pickering, 1995). ‘He’'s work with robots changed his participation in mathematics class and also his group colleague's participation.

Some students, such as ‘He’, saw in robots the possibility to imagine that it was possible to be successful on mathematics class and they grabbed it. Thus, robots displayed, in students, intentionality to engage on the learning process and made them to reflect on the learning process.

Analysing students' participation without paying attention to their background and foreground can lead to narrow view of the learning of mathematics.

NOTES

1. The research reported in this communication was prepared within the project DROIDE II – Robots in Mathematics and Informatics Education funded by FCT under contract PTDC/CPE-CED/099850/2008.
2. After several tests we verified that the time that the robot needs to reach the standard velocity, as well as, the braking time, are negligible. So we can assume that, to the end of this question, time and distance covered vary in proportion.

MULTIMATHEMACY

Karen François* & Rik Pinxten**

*Center for Logic and Philosophy of Science, University Brussels (VUB), Belgium

** University of Ghent, Belgium

This paper starts from two statements based on a literature review. The first one concerns the learning process and states that learning is situated and socioculturally contextualized. Learning happens in the space of the background and the foreground of the learner in his or her particular environment of experience. This statement is based on the Vygotsky and the cultural psychology approach (Cole, 1996) and on the work of Vithal and Skovsmose (1997). The second statement concerns the drop out of schools. Based on the international comparative research on mathematical skills we claim that the drop out of school of many groups of children (OECD, 2010) has to do with the insufficient learning system at school that fail to fit with the daily background knowledge of the children.

INTRODUCTION

In Pinxten & François (2011) we introduced the concept of multimathemacy (after multiliteracy) to discuss the political agenda of ethnomathematics. We argued that multimathemacy should be the basis of the curriculum in order to guarantee optimal survival value for every learner. We described multimathemacy is an educational perspective that invites the teaching of different cultural insights on counting, proportional thinking, mapping or spatial organization in preschool knowledges. We argued that this view offers bridges between academic mathematics and cultural knowledge traditions for schooling. In this paper we will further elaborate on the theoretical framework and on the learning theories that support our statements on the concept of learning (mathematics) as a situated and socioculturally contextualized process.

Learning mathematics is a particular subset of learning. Hence, it is relevant to look at the learning theories, which are available so far. Since we focus on learning in /of different cultural groups or populations in this paper, we went looking for an inclusive theory of learning. That is to say, one that is sensitive to context, culture and social differences. This means that we hold, as an *a priori*, that learning is a process that happens not only in the brain or even in the organism of a single individual. Rather, we see it as a process of change in the individual in interaction with the social, cultural and environmental contexts. Looking at learning in this way we were driven almost necessarily to the sociocultural learning theories of Vygotsky and other neo-Vygotskian authors, lately synthesised in the cultural psychology theory, namely by Michael Cole. Learning is always ‘situated’ learning (Lave, 1988; Lave & Wenger, 1991), and through manipulation of the contexts of learning in teaching settings, the process of learning can be influenced substantially.

Secondly, and consistent with the first choice, we focus on the characteristics of all parties in the process, when devising a curriculum and learning strategies. That is to say, the curriculum developers (in this case, the mathematicians trained in Academic Mathematics), the teachers (basically of the same background) and the pupils have their own mental setups when entering the learning process in a mathematics classroom.

We take this seriously and investigate what the input of all of them amounts to. When developing a curriculum and teaching procedures we will take all of these into account.

The basic reason why we feel obliged to go along this track (apart from mere ideological preferences for this or that societal model) is the fact that the drop out in the schooling is consistent and at the same time rather specific. In the overview report of the OECD (2010) two of the key factors are described as “-continuing disparities in scholastic achievement between first and second generation immigrant students and their native peers; -lower *scholastic achievement* and graduation rates for indigenous populations in countries with long history of migration” (OECD, 2010, p. 14, italic in the original). Data from the PISA 2003 and 2006 (OECD, 2005; 2010) show that on average across all participating countries native students perform better in mathematics than first and second-generation immigrants (OECD, 2010, p. 24). This pattern is particularly troubling as it appears that native students perform better than the second-generation immigrants who are born and raised at the same country. At the same time – and part of the explanation of second-generation immigrants’ situation – figures indicate that a student coming from a low socioeconomic status is “twice as likely to be among the low achievers” (OECD, 2010, p. 25). Recent studies (Zhao, Valcke, Desoete, Zhu, Sang, and Verhaeghe, 2012) reveal that a large proportion of mathematics performance can be predicted from contextual variables, one of them being the link between the SES of parents and mathematics performance. Of the predictors of mathematics performance at age 10, the effect size of mother’s education level is higher than that of father’s education level. Mother’s educational level is also related to the mathematics score in primary education (Zhao et al., 2012). Zhao et al. (2012) assume that mother’s higher educational level implies that mother expects her children to take more responsibility at home and in relation to their thinking and learning.

Concerning indigenous students the challenges identified across all countries (having indigenous populations that pre-date the arrival of European settlers viz. Australia, Canada, New Zealand and the United States) are the following: “difficulty in accessing and receiving the level of early childhood education and care recommended; lower levels of literacy and scholastic achievement; lower rates of graduation; proportionally higher representation in vocational education and training streams than their non-indigenous peers; and lower rates of participation in tertiary education in many of these countries (OECD, 2010, p. 26).

This is some of the most important reasons why the executive board of the OECD states that educational systems have to become more effective and more equitable. These international research findings are confirmed by national research results, e.g. the Council of Australian Governments (COAG) states that indigenous people are the most educationally disadvantaged group within Australia. Their educational outcomes are substantially lower than non-indigenous students. For example, in 2006, 45,3% of the indigenous Australians had completed the 12th grade, compared to 86,3% for non-indigenous Australians (Howard, Cooke, Lowe, & Perry, 2011). If we know that Australians who have not completed the 12th grade are less likely to have the same opportunities as those who do, we can speak in terms of inequality and violation of human rights.

We want to understand what is going on, and our proposal is that the learner's perspective is not enough in the focus of mathematics educational programs so far. PISA research (OECD, 2005, p. 190) shows that high performance in mathematics education consistently links with high scores in reading and science knowledge. At the same time, low performance in school is uniform for a second group of the school population. The gap between both groups seems to consolidate or even widen, rather than narrow over the years. We interpret these results here as corroboration of our main thesis, namely that cultural and social differences between learners do count in education. That is to say, when pupils perform poorly in the dominant language of the mainstream culture in which they participate (which is more or less different from their home language) and in the dominant world view (for which the same can be said), then schooling which disregards in a general way these differences will presumably yield larger gaps between subjects of the dominant social and cultural groups (i.e., middle class white groups) and others. We want to understand what is going on, and our proposal is that the learner's perspective is not enough in the focus of educational programs so far. Here, we concentrate on mathematics education only, starting from a general focus on learning in the first place.

THE LEARNER'S PERSPECTIVE

The learner is not a mere receptive or passive party in our view. Hence, learning theories, which 'situate' the learner and the learning process in contexts will carry our attention, and we will disregard the other ones. In a very general sense, we follow Cole's (1996) synthesis in this respect.

In Vygotsky's (1934/1962) intriguing approach of almost a century ago, learning was first and foremost understood as a dialectical process between a learner and his or her environment. In other words, it was not identified merely with the processes inside the head of the learner or even at the edge of it. For example, in the very powerful stimulus – and response theory (behaviorism in its many versions) learning is studied as the result of the processing of (controllable) stimuli by means of the responses they trigger in an individual. Neither is it equated with a particular form of

adaptational action on the part of the individual in his or her biological maturation cycle (as was the case in Piaget's learning theory: Piaget, 1972). Vygotsky and his school broke away from these approaches and situated the learning processes plainly in the field of interaction between a learner and the physical, social (-historical) and cultural environment or set of contexts.

Such a focus has tremendous consequences for education. First of all, it entails that characteristics of both the learner and the environment matter in the curriculum and in the learning procedures. If the pupil is unable to grasp the point of the learning process, then failure will probably ensue. But if the context is too poor, too far removed from anything understood or recognized by the pupil or in any other way 'foreign' to the pupil's knowledge categories, then failure to learn will also be the result. In line with Bakhtin (1986), Bruner (1984) maintained that you always create or hear about a narrative in terms of your life experiences and background. Giving meaning and creating knowledge of the world is relative and it is dependent on the individual's past and present experiences.

Secondly, it then becomes important to look for types of matching between the student's mental setup and background knowledge and the challenges and possible inputs in the context. The latter could be hidden, openly offered, presented as triggers or otherwise entered in the interaction process with the learner. It is clear that learning procedures are in focus here.

Finally, evaluation of learning output stops being the assessment of the pupil's responses only. It clearly and equally involves the assessment if the success or failure to induce learning by the contexts of the pupil as recent research reveal that a large proportion of mathematics performance can be predicted from contextual variables (Zhao et al., 2012).

When we put the learner in the focus, it follows that we need to 'flesh out' the individual learner a bit more to go beyond the trivial. We side with a cognitive theory of the learner, claiming that some parts of the metaphorical 'black box' can be filled in a hypothetical, but nevertheless dependable way without losing scientific credibility.

In terms of mathematics education recent research in this area was done by Scandinavian colleagues in the research group of Skovsmose (Alrø, Ravn, & Valero, 2010). Skovsmose, who coined the concept of Critical Mathematics Education (CME) situates mathematics education within a broad social and political context. Indeed to Skovsmose mathematics teaching and learning could aim at developing democratic competencies. This is why CME is concerned with mathematics education for all –independent of color, gender and class. CME is concerned with the practical application of mathematics – being an advanced technological application or an everyday use. It is also concerned with the democratic setting of a classroom situation, with the life in the classroom, and with the critical voice of pupils. A

mathematics class has to be a space of learning where ideas are presented and negotiated. Indeed to Skovsmose and Borba (2004) CME is concerned with the development of critical citizenship.

In this social and political embedded learning process, any learner is a subject within historical, social and cultural contexts, from which he or she brings into the learning situation previously gathered concepts, problem solving strategies and learning procedures. These are summed up under the label of ‘preschool knowledge’. Obviously, the contents of this category are primarily defined by the worlds of experience of the child: the peer groups, the family, and the physical and sociocultural environment of the child. Hence, street children will differ in their preschool knowledge from Amazonian Indians, from city dwellers in Western Europe, from Aborigines and Torres Strait Islanders in Australia, or from peasant children in rural China.

A further sophistication introduces the distinction between ‘background knowledge’ and ‘foreground knowledge’. It was Vithal and Skovsmose (1997) who emphasized the concept of foreground – besides the notion of background. Where the background means what children bring to the classroom, foreground is to be understood as “[T]he set of opportunities that the learner’s social context makes accessible to the learner to perceive as his or her possibilities for the future” (Vithal & Skovsmose, 1997, p. 147). Skovsmose (2005) also emphasizes the political and cultural situation as an important aspect of the foreground, since they provide – or blocks – the opportunities for the learner. It makes the political nature of the learning process explicit because it has to do with the student’s possibilities in future life, not the objective possibilities as formulated by an external institution but the possibilities as the student perceives them.

The learner brings a ‘background of knowledge’ into the learning situation: he or she already appropriated knowledge, which is relevant for the issues or the problems presented in the school setting. For instance, each child has a mental map of the environment, which will allow to cover the distance between school and home cultures in a rather efficient and safe way. At the same time, the child has a ‘foreground of knowledge’, which is the set of extensions of the knowledge that is appropriated together with the competencies to enable further learning, like understanding the school culture, management of problem solving techniques regardless of concrete contexts, and so on are examples of this. The child is actively learning in a classroom while making use of this ‘mental setup’.

LEARNING AND CULTURE IN THE MATHEMATICS CLASSROOM

Every couple of years the OECD assesses the quality of education throughout the world. These researches yield regular reports (the PISA reports), which give an overview of the success and failure ratio of children in and through schooling in mathematics education. A recurring point in these reports is that (lower and higher)

middle class pupils have a high success rate, whereas lower social classes and minority groups are showing poor results (OECD, 2010).

Our hypothesis reads as follows: the common mathematics curriculum and teaching procedures start from the point of view that mathematicians (belonging to the group of so-called Academic Mathematics) define the school program in basic lines. The understanding seems to be that mathematics is what Academic Mathematics says it is. Obviously the immense sophistication of this type of knowledge and its proven worth in scientific and technological research feeds this status. The pupils then try to master that, equipped as they are with their particular sets of background of knowledge and foreground of knowledge. The systematic and clearly not decreasing failure in school mathematics of the groups mentioned, can hence only be blamed on the academic mathematics group who set out the rules of the curriculum.

When we take the stand that learning is in actual fact always situated learning and that the learner brings his or her background of knowledge and foreground of knowledge into the learning situation, we can draw the conclusion that the fact of disregarding the background of knowledge and the foreground of knowledge in the learners can explain why their performance is consistently poor. At the very least we can explain why more schooling does not automatically yield better results in mathematical education, especially for particular groups (as is shown in the PISA reports). But in order to do that, we have to take one more step.

Learners have a background of knowledge and a foreground of knowledge. But what about mathematicians, and their product of thought, i.e., Academic Mathematics? We propose the hypothesis that mathematical knowledge in Academic Mathematics has implicit categories, worldview notions, intuitions, and the conceptual frame, which can be argued to be compatible with or translatable into that of a particular group of learners to a larger or smaller extent. Concretely, we suggest to investigate whether the middle class western subject's background of knowledge and foreground of knowledge is more easily translatable, accessible, or more closely overlapping with the worldview and categorization of Academic Mathematics than is the case with North American Indians, or lower class local groups and immigrant groups in Western Europe.

What we do by forwarding this hypothesis is not denying the tremendous worth of Academic Mathematics as a way of thinking and as a formidable tool for science and technology. Neither do we fall prey to a simplistic relativism, denying the high level of sophistication of this discipline. Instead, we claim that Western Academic Mathematics, like any human product, has its roots and that in learning Academic Mathematics these roots may show their relevance.

The structure of the Indo-European languages distinguishes between verb and noun forms. With this distinction corresponds a differentiation between things/states and operations/processes in the conceptualization of the perceived reality. Intuitively,

mathematical thinking sophisticates these deep structural linguistic and cultural differentiations (Pinxten, van Dooren, & Harvey, 1983). Hence, the emphasis on geometric figures (with a thing-character) and their constitutive forms, on sets and their elements, on operations (of multiplication and so on) performed on entities (a number, a series, etc.). The point we want to make is that formal thinking elaborates the intuitive world view which is given in language and in folk knowledge (Atran, 1990). When investigating other cultural traditions we learn that Athapaskan and Cherokee languages, like Classic Chinese are ‘verb languages’. That is to say, the noun category is inexistent or at least not substantial, corresponding to a view on reality as basically a world of events (Whitehead, 1906).

Again, regardless of the great achievements of Academic Mathematics, it is our conviction that it will be important to take these preschool differences into account for mathematics education. The dropout rates (cf. the PISA reports; OECD, 2010) might well be better understood in the light of these differences in preschool competences, to be found in the learner’s background of knowledge. Following that line of reasoning, we must then conclude that it is likely that neglecting the background of knowledge of the child will yield lack of insights or more difficulties with the Academic Mathematics – inspired mathematics curriculum and learning procedures. Alternatively, we advocate to systematically involve the child’s background of knowledge and foreground of knowledge in the educational process. By necessity this means that mathematics education (and hence also introduction to Academic Mathematics concepts and theories) will have to take into account the different backgrounds of knowledge and foregrounds of knowledge of varying cultural traditions.

FINAL REMARKS

Learners always bring their background knowledge into the learning process. We proposed that Academic Mathematics is culturally embedded, that is to say, Academic Mathematics has its own (implicit) categories, worldviews and applications. The challenging question remains how to close and thus to overcome the gap between on the one hand the diverse Communities of the learners and on the other hand the communities of the learning institution (school cultures, curriculum, teacher, ...). In order for teachers to deal with the diversity of backgrounds of knowledge, they should have knowledge of these cultural backgrounds, traditions, languages, practices and mathematical practices the learner (can) bring into the learning context. Teachers should have an anthropological perspective on the learning processes, on the school culture, and on the diverse cultures the learners bring to school. That is why we propose to use anthropological studies in the learning process in general.

As an alternative to the monolithic approach to mathematics we can now pave the way for our option for multimathemacy. Multimathemacy is an educational perspective that invites the teaching of different cultural insights on counting,

proportional thinking, mapping or spatial organization in preschool and out of school knowledge and this view offers bridges between academic mathematics and cultural knowledge traditions for schooling.

IT IS A MATTER OF BLUENESS OR REDNESS: ADULTS' MATHEMATICS-CONTAINING COMPETENCES IN WORK

Maria C Johansson* & Lisa Björklund Boistrup**

*Malmö University, **Stockholm University, Sweden

In this paper, a social and critical perspective on mathematics education is operationalized through the concepts of habitus, field, and foreground. As part of an on-going project, we have made a tentative analysis of how reliance on colours in the field of workplaces can be seen as signs of mathematical aspects of a person's workplace competence. The analysis of this initial qualitative case study suggests that making this kind of mathematics explicit contributes to an understanding of what mathematics may "become" in work. Our assumption is that this point of departure, in the long run, can contribute to a deeper understanding of mathematics' function in workplaces, in society, and in school.

INTRODUCTION

Adults' mathematics containing-competences are in focus in a new project led by professor Tine Wedege, Malmö University. The purpose of the project is to describe, analyse and understand these competences – including social, ethnic and gender related aspects – in relation to demands made on students' qualifications in formal vocational education. One underlying aim for the project is to reverse the often assumed direction of knowledge distribution to be mainly from school *to* work to also include the process of school learning *from* work. Consequently, the name of the project is "Adults' Mathematics: In Work and for School." Taking part in one of the project's qualitative studies, we have conducted two out of twelve observations in workplaces within the sectors of nursing/caring and vehicles/transport. The observations will be followed by life history interviews, later in the project.

WORKPLACES AND MATHEMATICS

The fact that mathematics at work appears to be different from what is taught in schools is well described in the literature (e.g. FitzSimons 2012; Hoyles, Noss, Kent & Bakker, 2010; Wedege, 2000, 2004). In work, mathematics is often integrated in machines, technology, routines and competences (Wedege, 2004). Often adults show resistance towards mathematics. One example is given in Wedege (2000), who interviewed and observed people who referred to mathematics as something they didn't know or didn't use. This was in contrast to the fact that they told stories of, or participated in, activities where it was a straight-forward process for the researcher to construe them as containing mathematics. In contemporary workplaces, constantly evolving technical development and division of labour are changing the conditions of work. This could be seen as a widening gap between conception and execution of mathematics containing work tasks (Jablonka, 2003). The objective of this paper

is to explore the concepts of habitus, field, and foreground as tools for investigating mathematics-containing situations in work and how they are connected to the fields of workplace mathematics and school mathematics. The term mathematics-containing competences is used by Wedege (2000), and relates to the relation between everyday knowledge and school knowledge. In this paper the term is used as a broad interpretation of mathematics in order to understand differences between work and school. What is considered as mathematics in one field may not be viewed similarly in the other. Furthermore, we want to discuss the relation between the individual and the social and how different practices can be understood where mathematics is concerned. As Valero and Zevenbergen (2004) describe it:

... practice is social because it is historically constituted in complex systems of action and meaning in the intermesh of multiple contexts such as the classroom, school, the community, the nation and even the globalized world. (p. 2)

ANALYTICAL TOOLS: HABITUS, FIELD AND FOREGROUND

Our understanding of the concepts of habitus, field and foreground includes how they are related to each other and to mathematics in work and at school.

Habitus

When connecting individual experiences to structural and social factors a theory that takes both levels into account is required. One account of this view is presented in Salling Olesen (2008). He writes about how individual workers “carry their specific social history with them into the workplace, and they embody the experiences learned in the workplace in their subjectivity” (p. 123). In this paper we adopt Bourdieu’s (1991) concept of *habitus* to approach the dialectics between the individual and the social structure. This dialectics is built into the concept of habitus. It is conceptualised as a system of dispositions grounded in biographical experience, which is by its nature purely individual. Members of a certain class or group can, however, share ideas and habitus in the form of a class habitus but the essence of habitus is something unique for each individual (Bourdieu, 1991). In other words, habitus can carry both conscious and unconscious dispositions to act in the social world. Habitus is a complex system consisting of preferences and motives for individuals to act in the social world. An explanation of habitus, given by Bourdieu, is that of having a sense of how a given situation should be tackled. Then the individual has a “feel for the game” (Bourdieu, 1995).

Habitus and field

The above mentioned structures are described by Bourdieu (1991) as social fields and he argues that the socialized body with its habitus generally carries the same history as the social field where it is acting in establishing an infra-

conscious corporal awareness. In a certain field people are willing to play the game with the rules set by the field. A field has its tensions due to the battle between the newcomers trying to find a position in the field and the established actors who dominate the field (Bourdieu, 1991). Bourdieu (1989c, quoted in Grenfell & James, 1998) states:

the relation between habitus and field operates in two ways. On the one side, it is a relation of conditioning: the field structures the habitus, which is the product of the embodiment of immanent necessity of a field (or of a hierarchically intersecting sets of fields). On the other side, it is a relation of knowledge or cognitive construction: habitus contributes to constituting the field as a meaningful world, a world endowed with sense and with value, in which it is worth investing one's practice (p.16).

Two fields: school mathematics and workplace mathematics

Wedeg's (2000) examples of how one person can argue that s/he does not know mathematics, while simultaneously actively applying mathematics in work illuminates workplaces and schools as two different fields. In the preface to the Swedish translation of the book "Les règles de l'art: Genèse et structure du champ littéraire", Broady (cited in Bourdieu, 2000) explains how the concept of field can be understood, which is that social fields have similarities with physical force fields. However he warns that one should be careful when using the concept of field. A school, for example, can be seen as a field for teachers and staff members while it is not a field in the same sense for students who are passing by this field. We will return to this below, in the discussion. The following statements can be construed as differences in the rules of the game of mathematics, as a part of other rules set by the field. Wedeg (2000, p. 197) lists several differences between the fields of "task-driven" school mathematics and workplace mathematics. Table 1 highlights two of them. (See also FitzSimons, 2012.)

Work	School
There are often different solutions to a task. Accuracy is defined by the situation and the veracity can be negotiated.	There is only one correct solution, the accuracy is defined by the teacher and the veracity it not something that can be discussed.
Reality is the reason for using mathematical ideas and techniques. Solving tasks has practical implications	The task operates as a pretext for using mathematical ideas and techniques. Solving tasks has no practical consequences.

Table 1: Differences between the fields of school mathematics and workplace mathematics

Habitus and foreground

Skovsmose (2012) describes how the notion of foreground was first developed in 1994, and he elaborates on his earlier explanations. Drawing on Skovsmose,

we understand students' foregrounds as the opportunities society makes visible and possible for individuals. Skovsmose (2005) suggests that it is important not only to focus on students' backgrounds but also their foregrounds. "Foregrounds are not panoramic and coherent pictures of possibilities" (Skovsmose 2012, p. 2). Nevertheless, foregrounds have "objective" elements such as social, economic, political and cultural parameters. Still, foregrounds should not be understood as an objective affair. Instead, foreground is formed by the person's interpretations of the possibilities the circumstances provide. "In this sense the foreground becomes a complex mixture of subjective and external factors" (Skovsmose, 2012, p. 2). Foregrounds are dynamic rather than stable. Construing foregrounds should be seen as an on-going process and Skovsmose (2012) suggests that it is relevant to talk about *foregrounding* (as an action). Wedege (2011) suggests a local integration of Skovsmose's notion of foreground with Bourdieu's theory of habitus. When investigating the theoretical relevance for, and the advantages of, the integration of habitus and foreground, she concludes that they should be complementary because both frameworks are based on the idea of action and dispositions to act, and, furthermore, both are rooted in a critical perspective. As Alrø, Skovsmose, and Valero (2007) note:

Learning-as-action can only take place on the grounds of the person's *dispositions*, that is, on the person's readiness to find motives to engage in action. Dispositions can be seen as the constant interplay between a person's *background* and *foreground*. (p. 7, italics in original)

METHODS AND TRANSCRIPTS

The research design of this study is a multiple case study (Bryman, 2008), with comparative elements. In this paper, the comparison is related to previous research and our own experiences from school. Things taken for granted by those in the field could be noticed by an outsider and consequently made the object of attention. In this process, an important feature is reflexivity (Hammersly & Atkinson, 2007), and the assumption that researchers affect situations, while at the same time being affected in return. In the research design of the qualitative part of the project, the video-recordings described in this paper, are the first step of data-gathering and analysis. One way of interpreting a setting that is not ours can be to notice what is not the case, or what could have been the case in our own settings. In other words, to be attentive to hypothetical situations without letting go of the actual situation: "Doing critical research also means to explore what is not there and what is not actual. To research also what is not there and not actual means to investigate what could be" (Skovsmose & Borba, 2004, p. 210).

Earlier studies show that mathematical elements in workplace settings are subsumed into routines and are highly context-dependent. Moreover, the present mathematics is constituted through a variety of semiotic resources (e.g. written

texts, symbols, speech) including artefacts (e.g. tools). Here we draw on multimodal social semiotics (Van Leeuwen, 2005; see also Björklund Boistrup & Selander, 2009). This has consequences for our transcripts, which are made multimodally. In Table 2, we identify Time, Body (what people do including resources and artefacts), Speech (what people say and how they say it), and Gaze (where people look). The significance of including resources other than speech in the transcripts also has connections to habitus as an embodiment of the field (Bourdieu, 1995). The films are transcribed in the software Videograph.

A MATTER OF BLUENESS OR REDNESS: EXAMPLES OF ANALYSIS

Here we start by introducing a part of the transcribed observation from the garage.

The garage

The first transcript starts when a mechanic, “Anton”, has just finished a check-up of antifreeze/cooler by using a measuring device and comparing the value shown on the device with a value on a certain scale. Without letting his focus go from the work or the car he says: “So washer fluid is the next check-up to be done” (our translation). In the transcript, *A* stands for Anton and *R* for the researcher.

Time	Body	Speech	Gaze
14:19	A: Walking to water tap with bottle in hand	A: It is very concentrated so it has to be mixed with water. R: Okay	A: Looking at researcher
14:31	A: Pouring water into the bottle	R: How should it be mixed? What is the – how much water should there be, so to speak	A: Looking at the bottle
14:33	A: Stops pouring water and walks back to the car	A: I don't know exactly but it R: But how exact is it then, how precise is it? A: Well it is...	A: Looking at R
14:55	A: Pouring the mixed liquid into the tank in the car	A: It is the colour [inaudible] that is how exact it should be. But it ought to be quite blue anyway	A: Looking into the tank of washer fluid. Looking at R

Table 2: Transcript from the garage [selection]

The transcript from the garage shows that the mechanics Anton was going to refill the tank with washer fluid. What cannot be seen in the transcript is that the tank in the car contained a little wash fluid already. In order to complete the task, he had to estimate the volume required to fill the tank. He also had to be aware of which concentration the liquid should have, compared to the one in the tank. He used concentrated washer fluid that was to be diluted with water. For this purpose Anton had to estimate or measure both how much there was already

in the tank, how much concentrated washer fluid he needed to add, and how much water to add in order to get the proper concentration when he had filled the tank. He had been told by his boss that the concentration should be 50/50. As observed by Wedege (2000), accuracy in the workplace field is defined by the situation. This could mean that the blueness may need to be changed due to conditions such as outdoor temperature. In some way the blueness functioned as a security for him and he said: “It ought to be quite blue anyway,” by which he probably meant that rather a little bluer than running the risk of freezing washer fluid. This also corresponds to Wedege’s suggestion of tasks in the work place having practical implications. During another part of the observation, Anton answered a question about where he had learnt to estimate the volume of another liquid. After a little thinking he responded by talking about his early interest in cars and motor bikes. He didn’t learn it from school, however, he said. The competence seemed to be so well integrated into his habitus that he did not even think of himself as having learnt it, but rather as if he was born with it, or at least as being a natural part of his body and mind. In the terms of Bourdieu (1995), his socialized body with its habitus carried the same history as the field where it was embodied. He was actually so confident that he did not follow the advice from the boss to make a concentration of 50/50. Anton relied on his capacity of judging the blueness accurately as he relied on it when measuring the other liquid. Maybe his early interest in cars and motor bikes, and his competence, could be seen as a part of his foreground for choosing this kind of work.

The hospital

At another workplace, a semi-emergency unit at a hospital, we were invited to follow a nursing aide, Anita, in her work. During our observation she made a check-up on her patients. When the round was completed Anita went to a computer to put the values into the digital hospital record. While doing this she took a chart with colours from her pocket (Figure 1).

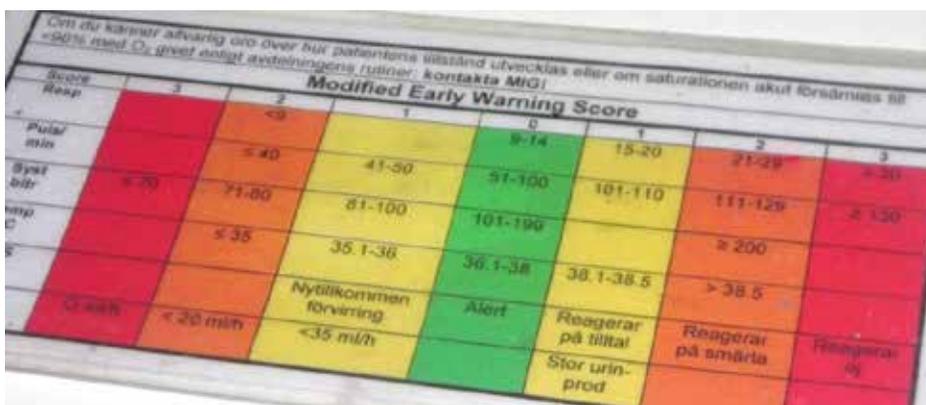

Figure 1. Chart with colours

The chart (Figure 1) was coloured outwards, from green in the middle (0), then yellow (1), orange (2), and, finally, red (3) at either end. In the green, middle column, the ranges of values were considered normal. Each column was given a

score, and a certain total score needed immediate attention from a doctor. The check-ups were done every fourth hour and included examinations like blood pressure, pulse/heart rate, temperature, volume of urine, and oxygen saturation. All the time, she had to change her priorities due to other more tasks that had to be taken care of. Therefore she kept the values from the patients in mind. When there was time she wrote them down on a piece of paper.

During our observation one patient needed a further check-up of the oxygen saturation. When the blood sample was taken by a doctor, Anita had to interrupt her work and go to a digital laboratory to get an analysis of the blood sample. After the sample was put into a measuring machine, she did not wait for the result, which would automatically be filled out in the patients' hospital record. She explained: "This will take one minute, but one minute is a long time so I will not wait for it." During the observation Anita was handling multiple tasks simultaneously. She also continuously compared the values given by the patients' supervising monitors and with questions to the patients or with taking the pulse manually. Although she was gathering numeric values they were surprisingly absent in her documentation. The values seemed to be a part of a bodily consciousness of the field and nothing worth mentioning. The expression "to have a feel for the game" (Bourdieu, 1995) could be said to be a relevant description of Anita's work. The nursing aides even had their own expression for this. They called it "the third eye", which meant just knowing what to do. Only once did she use values/figures explicitly; to encourage a patient whose values were much better than previously. For nursing aides like Anita, the critical feature was that the values should not enter the red sections of the chart.

Similarities and differences with regards to mathematics containing competences and the context

The observations were made in two very different settings. The second observation was in a clean, hygienic area, with a majority of women, mostly clad in white, taking care of humans. The first observation was in a more dirty area, with a majority of men, clad in blue, taking care of cars. The situations observed could be viewed as being very dissimilar, taking place within such different settings. Nevertheless, they have a commonality in that they rely on devices and colors, even using the colors as a security system. The mechanic relies on the blueness of his solution to determine the concentration of the washer fluid, and the nurse concentrates on her patients' values not getting into the red zones of the chart. One difference in the reliance on colours is that the mechanic's use of the degrees of blueness may not be easily communicated to others. Each mechanic has to make their own judgement of the blueness. In the case of the nursing aide, the well-defined colour system was presumably implemented to facilitate communication within different levels of organization, and thereby increase the security for patients. Workers in both case studies used

measurement in potentially critical situations, but there was an absence of explicit numbers which, it seemed, was replaced by a focus on colour.

DISCUSSION

We have made a tentative analysis of how reliance on colours could be seen as signs of mathematical aspects of a person's workplace competence. As analytical tools we have chosen the concepts of habitus and field from Bourdieu's theoretical framework combined with Skovsmose's notion of foreground. When the observed workers, in the next step, contribute their mathematical life histories, a more profound construal of habitus will be added to the analysis. We think that our chosen tools will then have greater application. We suggest that the tools can make visible individuals as agents construing their foregrounds and directing them towards certain fields. This may not be a straightforward affair. However, the individual's habitus and foreground, as analytical tools, can shed light on the possibilities for him/her to affect the rules of the field, and also its mathematics-containing activities.

As a possible consequence of what we have observed so far, vocational education needs to be careful when contextualising tasks. It should consider that the rules of our school field are embodied in our habitus and can easily be taken for granted. At the same time, school can be seen as an arena where students try to work towards their intended foregrounds. Some may already have experience from the field of work. A task like the washer fluid concentration could not be solved at all with school mathematics. The volume in the tank is unknown as well as the concentration. Therefore, the volume and the concentration to be added are also unknown. The only parameters known are that the final result is to be a full tank with a concentration of 50/50. The context that we as mathematics and/or vocational teachers may produce to inspire and help the students could instead make it more difficult. Students may need to decontextualize the task to compare it with the real world they know or in order make sense of the contextualisation and deal with the mathematics integrated in it. There may also be a gap between conception and execution in both fields, although noticing the colours in the workplace could be seen as a way of securing the execution. In a mathematics classroom there will most probably be no colours to rely on. From our experience it is not unusual that the mathematics, instead of being highlighted, is embedded in a language or a kind of mathematical 'conjuring' that is not familiar to all. For students with experience from the field of work, their understanding may be linked to the mathematical rules of that field, with its practical applications. Sometimes there may even be no practical implications in the workplace. The washer fluid could, for example, have been diluted in advance using more mathematical measurements. Yet, the social rules, formed by the structure of the field, and the agents in the field may be equally strong as the mathematics rules. As noted above, in school there is often only one correct solution and its veracity is not

open for discussion. However, in the case of the hospital observed, the accuracy could not be negotiated either. Yet, in a mathematics classroom, construing and constructing charts would most probably not be done under time pressure, while simultaneously handling other tasks. In a modern society, fields may to some extent be floating when new professions grow and individuals are mobile, and these may contribute to the changing conditions and rules in the fields of work. In this we see a challenge for schools to investigate the rules of their own field, and to understand the rules of workplace fields in order to make mathematical tasks accessible to different students. Our aim with the forthcoming research is to contribute to this understanding. Habitus and field, connected to foreground, could be useful as analytical tools for this purpose.

ACKNOWLEDGEMENTS

This paper is written as a part of to the research project “Adults’ mathematics: From work to school”, which is supported by the Swedish Research Council in 2011-2014. We thank Gail FitzSimons and Tine Wedege for constructive comments to an earlier version of the paper.

LOGIC, SOCIETY AND SCHOOL MATHEMATICS

David Kollosche

Universität Potsdam, Germany

An example of Aristotelian logic, which I show to be paradigmatic for Scholastic logic and school mathematics, is analysed for its social functions. This analysis builds upon a socio-historical interpretation of the meaning of early logic and shows its dialectic religious, epistemological and political dimensions: On the one side, logic can be used to appease, to emancipate and to amplify thought; on the other side, it might lead to fear, subjection and intellectual constraints. The combination of both allows logic and mathematics to become an instrument of power. Mathematics education, then, is the institution in which the acceptance of this instrument of power is cultivated.

AN EXAMPLE OF ARISTOTELIAN LOGIC

Research on the social functions of school mathematics tries to answer the question in which dimensions society and school mathematics interact. While Ole Skovsmose, Roland Fischer, Philip Ullmann and others have contributed in answering this question, many issues have not yet been addressed. This paper is a contribution to a deeper elaboration on the nature of mathematics and its impact on society. One of the main characteristics of mathematics is logic. This paper examines the social function of logic in the mathematics of German secondary education, using an example of Aristotelian logic. The discussion will address questions on a historico-cultural as well on an educational level: *Which social functions did logic serve in ancient Greece? What social functions does it serve in contemporary school mathematics?*

The Greek philosopher Aristotle is considered the founder of logic since he compiled, formalised and analysed rules for speaking and thinking in the 4th cent. BC. In philosophy, his *oeuvre* is a milestone. His logic processes the transitions in speaking and thinking which ancient Greek has gone through and which is expressed in the work of his predecessors, such as Anaximander, Parmenides, Socrates and Plato. But what had caused these transitions; which purposes does the new kind of thinking serve? The socio-cultural analysis of the four laws of thought which Scholasticism has identified in the work of Aristotle (e.g. Schopenhauer, 1813/1903, § 33) will provide answers for these questions. The four laws of thought are:

1. Law of identity. *Everything stays the same, nothing changes.* The principle of identity is tautological as long as it is read descriptive. Read prescriptive, i.e. as the rule to speak and think in a way in which everything stays the same, the principle of identity provides our speech and thought with concepts that are reliable in the sense that they do not change their nature with the speaker, the location or time. Already at the beginning of the 6th cent. BC, Anaximander of Miletus, probably a student of Thales, had argued for the existence of something “infinite”

which is “indestructible”, “deathless” and “imperishable” (Aristotle, trans. 1930, 203b). Half a century later, Parmenides seized the idea, described it with similar adjectives and called it *truth* (*aleteia*; Parmenides, trans. 2009, pp. 14–23).

2. Law of excluded middle. *Everything is or is not; there is no other way.* The law of excluded middle divides our statements into two categories, e.g. truth and the false, and leaves no other option.
3. Law of excluded contradiction. *Nothing is and is not at once.* The law of excluded contradiction demands a decision between the categories. Together with the law of excluded middle, it forces the statements of speech and thought into an antagonism introduced by Parmenides: the antagonism of being and not being, of true and false, leaving no room for a state in between or beyond the extremes.
4. Law of sufficient reason. *Everything but one thing has a reason and is defined by it.* Distancing himself from mythological thought, Anaximander claimed that everything but one thing has a reason which is its destiny (Anaximander, trans. 2007, p. 35). Therefore, he is often considered the founder of scientific thought. The law of sufficient reason is a method to decide over true and false on the one hand, and provides a scheme with which to order ideas on the other hand.

RELEVANCE OF THE EXAMPLE

The four laws of thought of Aristotle are relevant for philosophy, mathematics and contemporary school mathematics. The discussion of syllogisms constitutes the core of Aristotelian logic. It addresses the question which forms of conclusion are certain. Certainty here means that the truth of a statement can be shown with necessity and out of sufficient reasons. As the laws of thought are essential for the discussion of the syllogisms, they form an essential part of Aristotelian logic. Certainly, the logic of Aristotle was not uncontroversial among his contemporaries: it competed against the old myths and against alternative philosophical schools such as the school of the Sophists represented by Protagoras. However, it was most successful as it attracted most attention in Ancient and later philosophy.

Euclid’s *Elements*, the first systematic compilation of mathematical concepts, theorems and proofs, and *the* reference of mathematics for two millennia, are strongly influenced by Aristotelian logic (Wußing, 2009, p. 191). This influence does not only consist of proofing as the method for the validation of mathematical statements. Aristotelian logic also influences the whole architecture of Euclidian mathematics: Its concepts are defined as tight as possible to avoid any variations of meaning and to provide them with unalterable identities; as sharp as possible to allow a clear inclusion or exclusion of every phenomenon; and as connected as necessary to be able to verify the properties of the concept. Today, mathematics has the very same architecture. Alternatives, such as polyvalued logics, logics without the law of excluded middle and others exist, but they are hardly used in mainstream or even school mathematics. Thus, school mathematics is based on Aristotle’s logic:

- The concepts of contemporary school mathematics and their properties stay the same all through the curriculum. Usually, they are presented as universals which do not evolve or vary with culture or through history, leaving no room for an individual reading: Even and odd numbers, circles and so forth are its invariants.
- The concepts of contemporary school mathematics are structured in a way to either describe a phenomenon or not; they follow the antagonism of being and not being: A natural number is either even or odd; it cannot be both or something else. In fact, every classification follows this rationale: A straight line either shares points with a circle or not; and if so, then it shares either one point or two.
- The concepts of school mathematics refer back to their origin by which they are defined. Every super- and subordination, e.g. from the polygon down to the right-angled triangle, every implication, every transformation of terms and equations leans on the assumption that the truth of the new is already hidden in the original.

Although the relevance of the example of Aristotelian logic for the purpose of this paper has been illuminated, its social impact still has to be examined. The work of Klaus Heinrich, whose intention was to examine the “suppressed of philosophy” in its genesis (Heinrich, 1981, p. 10), provides a basis for a cultural analysis of early logic. He looks for radical changes in the thinking, feeling and activities of a society and asks for their reasons. His original perspective on Aristotelian logic is insightful as he succeeds in a fruitful combination of theory of science and cultural history. The following look at the birth of Ancient logic focuses the social circumstances that allowed Aristotelian logic to establish; it considers logic the intellectual manifestation of an experienced practice. What brings the thinkers of ancient Greece to cultivate that new form of thinking? Which were the social pitfalls and contradictions, the concerns, troubles and wishes that lead philosophers to logic?

LOGIC AND RELIGION

Before the birth of philosophy and science, only the myth offered explanations of the world, especially of its most alarming phenomena: the fatal threat of age and disaster. Hesiod’s *Theogony* and Homer’s epics describe the mythical world of gods who personify death, hunger, storms, floods, earthquakes, droughts and epidemics. These gods, and thus the phenomena they personify, were understandable as they were imagined as human-like creatures, who knew friends and foes, intrigues and murder. The strongest influence on the nature of gods was assumed to be their descent: It is regarded as an unalterable trait, as a fate that cannot be escaped as in the curse of the house of Atreus (Heinrich, 1981, p. 99). The myth allows for a comprehensive orientation in the world; it is an early philosophy of nature. However, this orientation was threatened as democracy developed. The open discussions on the market place, the agora, did not only address politics but also philosophy, ethics and religion. Thus, traditional convictions were called into question, leading to a confusion of world views (Vernant, 1962/1982, p. 52). Socrates was the incarnation of scrutiny and died

for it. The ongoing collapse of religious beliefs as well as political and economical structures led to a lack of orientation and security, and called for a new and possibly safer set of convictions.

However, Anaximander's disengagement from myth is only half-hearted. It is true that his world view goes without supernatural beings. But on the one hand, Anaximander sticks to the idea of the fateful power of descent as he claims that everything has a reason which is its destiny. This connection becomes clearer in the original word *archē*, which means not only reason or cause but also origin, descent and birth. On the other hand, Anaximander still believes in an ever-reliable existence, which he himself considers "divine" (Anaximander, trans. 2007, p. 37; Heinrich, 1981, pp. 60ff). Parmenides, in turn, presents his logic as a divine revelation. Calling the idea of the everlasting *truth*, he founds essentialist philosophy, which imagines a world of imperishable truths and dominates a large part of Antique philosophy (Vernant, 1962/1982, pp. 131f). In Heinrich's reading, the four laws of thought that had developed with Anaximander and Parmenides are an abstract derivative of the mythical religion – a world view that preserves the ideas of descent and the imperishable but avoids the debated existence of Hesiod's and Homer's gods. The spirituality of the laws of thoughts consists of the belief in the imperishable which opposes the threat of passing away and of the conviction that everything is connected and determined by ancestry. The law of identity is the imperative to belief in the imperishable. The laws of the excluded middle and excluded contradiction create the need for a decision between being and not being, between the true and the false. It is the mixtures and alternatives of being and not being, becoming and passing away, that are excluded. Therefore, Heinrich recognises early logic as a doctrine of salvation: "Do not be afraid', for there is an existence which is not affected by fate and death" (my translation; Heinrich, 1981, pp. 45f).

LOGIC AND KNOWLEDGE

Apart from the promise of salvation, the presented example of logic offers a paradigm to order and explain the phenomena of our world. Its rules are easy and familiar; they provide a supportive and socially accepted 'machinery of thought' which allows thinking to approach complex fields on well-concerted ways. This potent form of thinking is the answer to the confusion caused by the collapse of traditional religious, moral and political beliefs and it is the impetus of philosophy. An illustration of the latter is Plato's Socrates who, in the dialogue with Theaetetus, stated that "suffering from confusion shows that you are a philosopher, since confusion is the only beginning (*archē*) of philosophy" (Plato, trans. 1921, pp. 155f; incorporating the translation in Heinrich, 1981, p. 31).

The price for the extended range of thought is the limitation of the thinkable. It is a main point in the *Dialectic of Enlightenment* by Horkheimer & Adorno that logical thinking loses sight of everything that does not fit into the antagonism of being and

not being. Spinoza's logical ethics and the *Tractatus* of the young Wittgenstein, who wanted to trace language back to logic, show the limits of logical thought. Historical and cultural alternatives prove that logic in the form of the four laws presented is not the only form of fruitful thinking. Homer's epics, which count to the earliest records of ancient Greek writing, present meaning in analogies instead of logically ordered, in colourful images that connect the phenomena and emphasise commonalities. Even in the boom of early logic, Greek philosophy has critical schools such as the one of Heraclitus, who confronts the belief in the imperishable and true with the idea that everything is in flux and nothing persists, that "one cannot step twice into the same river" (Heraclitus, trans. 1979, p. 53). Today, many indigenous cultures understand and approach the world in a way which is based on the ideas of flux and mixtures instead of on the stasis of the unalterable and separated (Little Bear, 2002).

LOGIC AND POLITICS

Aristotelian logic also has a political dimension, which Xenophanes points at when he calls it a 'technique of reasonable speaking' (*logikē technē*): It is a tool for public speech, a tool for convincing and discrediting. Ancient Greek city states were usually governed by a democratically organised military aristocracy which represented a large part of the bourgeoisie. Politics was performed on the market place, where orators had to win majorities for their political campaigns. Politically powerful were those who performed best in convincing the people and discrediting the opponents (Vernant, 1962/1982, pp. 46–68). With his work, Aristotle wants to give directions for a convincing speech. He wants to show "what we must look for when refuting and establishing propositions" (Aristotle, trans. 2006, § 1). The question for truth and its origin, the rejection of the indefinite and unsteady, the exposure of inconsistencies, the installation of antagonistic options and the demand to decide are rhetoric weapons provided by philosophy. The teaching of such tools to the politically ambitious military aristocracy provided an income for many philosophers and explains their interest in logic. Thus, early logic constitutes a basis for democratic decision making. It provides socially accepted rules for argumentations in political discourses and helps to reduce more repressive forms of power. Nevertheless, even a democratically legitimated administration needs tools to control the population. Philosophy develops techniques which allow taking advantage of the logical laws of thought. As the acquisition of these techniques requires prosperity, logic has been an instrument of power for the aspiring middle class since its very beginning. As intended by Aristotle, the popular acceptance of the laws of thought subjects the masses to a form of speaking and thinking that they have nothing to set against.

THE DIALECTICS OF LOGIC

The cultural-historical analysis of the example of Aristotelian logic reveals its dialectic nature and allows for a comparison of the benefits and constraints it brings. On an epistemological level, it has already been pointed out that the laws of thoughts *ex-*

pand the range of thinking while *narrowing down* its focus. On a political level, early logic constitutes a *tool of power* which allows a less violent form of government but is *restricted* to one social class. Apart from that, the dialectics of logic become visible on a religious level: The belief in an imperishable truth might appease people who fear changes, especially the passing away. The emotionality with which Anaximander's infinite and Parmenides' truth is defended against any variation indicates a defence of this pacification. As Heinrich points out, even the *non* in Parmenides' "non being" (*mē einai*) translates with an undertone of menace (Heinrich, 1981, pp. 45f). Parmenides presents his logic explicitly as the salvation from an insane form of thinking – a form which "changes ways", which "considers being and not being the same and yet not the same" and which believes in "becoming and passing away". Parmenides' poem compares to a religious conversion using defamation and dictation: Those who think differently are said to be "double-headed", "helpless", "erratic", "drifting", "deaf" and "blind", "lost in confused wonder" and "unable to make decisions" (my translation; Parmenides, ed. 2009, pp. 17–23). The reader is told what to think and consider: to avoid the dissidents and follow logic.

However, the Frankfurt School points out that the belief in the unalterable only appeases some people while it frightens others: A world whose essence is invariant is a world that people cannot contribute to, that cannot be affected and must be endured. For Parmenides, humans are not the measure of all things (as Protagoras claimed to point out that everything is characterised by how we perceive and use it) but things *are by themselves*, beyond any human impact (Heinrich, 1981, pp. 32ff, 42). Consequently, the dead truths can only be approached in a quest for unveiling their dead and timeless mysteries. The dying Socrates believed in that when he told Phaedo that "the philosopher desires death" which is the ultimate "separation of soul and body" and frees the philosopher "from the dominion of bodily pleasures and of the senses, which are always perturbing his mental vision" and hindering him "to behold the light of truth" (Plato, trans. 1892, pp. 64–65). It is the paradox of essentialism that it forms an alliance with death to defend the passing away.

There is a touch of irony in the fact that logic cannot justify its basic laws in argumentation but has to build on myth and demand obedience as seen in the works discussed above. After his postulate of the law of excluded contradiction, i.e. that "it is impossible for anyone to suppose that the same thing is and is not", even Aristotle scolds: "Some, indeed, demand to have the law proved, but this is because they lack education; for it shows lack of education not to know of what we should require proof, and of what we should not" (Aristotle, trans. 1933, p. 1006).

Considering the actuality of the dialectics of logic, it has to be admitted that today such a pathetic statement concerning the laws of thought would hardly be expected. In Western society these laws are widely consolidated and accepted whereas in ancient Greek they had to be defended against alternatives. Right in the genesis of what came to be Aristotelian logic, in the time when the laws of thought had to fight for

their place in the world, the social background of logic comes to light. Therefore, ancient culture can tell us about disputes whose consequences we have learnt to accept without question. Indeed, it can hardly be claimed that the cultural-historical analysis of the example of Aristotelian logic does not affect our age: On the one hand, the exclusion of the changing, of alternatives and mixtures as well as the orientation on ancestry are integral parts of Aristotelian logic, regardless of the social circumstances of the time; even today, they open a field of possibilities for religious, epistemological and political use. On the other hand, the fear of passing away, decision making in democracy and the organisation and validation of knowledge are still challenging our culture (although they might appear less urgent due to the techniques we already have developed to deal with them).

Logic and mathematics have been enormously influential for philosophy and science as we know it today. In the age of Enlightenment, when science had to find its meaning and place in society, logic and the empirical method were the points of orientation and left a formative imprint on modern thought. René Descartes was a pioneer of this process. He was convinced of “the great superiority in certitude of Arithmetic and Geometry to other sciences” and argued that “in our search for the direct road towards truth we should busy ourselves with no object about which we cannot attain a certitude equal to that of the demonstrations of Arithmetic and Geometry” (Descartes, 1684/1990, pp. 224f). Mathematics is considered a prototype of science as it can be more logical than any other science: Its objects can be alienated from our world as far as necessary to fit the logical form and the validation of its assertions does not need any experiments but relies on logical argumentation alone. Mathematics has become modern not by turning towards empiricism but by petrifying its unique status. The foundational crisis of mathematics was connected to the critique on the idea of an unalterable truth. When the crisis was silenced by David Hilbert by negating all connections between mathematics and the world we live in, Hilbert installed mathematics as the science of pure structures: as a science that commits itself thoroughly to the order of logic (Hilbert, 1922).

LOGIC, MATHEMATICS EDUCATION AND SOCIETY

School mathematics is only a part of what is called ‘mathematics’ today – a part with a long tradition of specialised content and its presentation. As school mathematics builds on a long tradition and has little structural need for contact with contemporary academic research, it is not surprising that it hardly includes any new mathematics or any new philosophy of it. Especially the idea of ‘truth’ is more classical than modern, more Platonic than Constructivist. School mathematics excludes any contents that could threaten the classical idea of truth, e.g. non-Euclidean geometry, paradoxes of set theory or alternative logics. On the contrary, it adds only those parts of mathematics to its Euclidean core which approve the power of logic: Calculus and probability theory demonstrate how even the infinite and chance can be mastered by logic.

Experience shows that German students stop calling a task ‘mathematical’ when it no longer has a unique solution. Obviously, school mathematics follows the law of identity in allowing only one true and right answer, excluding any variation, individual interpretation and ambiguity. How school mathematics effects students can be traced in school books, e.g. in Brückner’s (2008) representative school book for the 7th grade of high school. In there, we do not only find an overwhelming dominance of tasks that allow for only one true and right answer and tasks that ask for the “truth content” of statements or for a decision between “true or false”, but also a task in which the reader is told that an algorithm “was applied wrongly”. The fact, that the authors provided this task with the emphatic title “Caution, mistake! Watch out!” demonstrates how uncommon it is that the mathematics school book provides something else than ‘the truth’. This taboo of the alterability of mathematics enables students to believe that school mathematics is about true and right answers and that, in general, every task that can be formulated mathematically has a distinct solution. Anything that could lead students to a different belief is excluded from the mathematics classroom. As school mathematics is the only mathematics students know, it prepares students to believe that mathematics is generally able to provide unique and unquestionable answers for any question. This turns mathematics into a tool of power with the help of which the public can be convinced of originally questionable decisions.

The same school book presents the following text without any further explanation, but with a sketch showing a circle and a line of each type (p. 142; my translation):

Lines and circle can have different locational relations.

Secant: a line that cuts a curve (g_1)

Tangent: a line that touches a curve (g_2)

Passant: a line that avoids a curve – the passing line (g_3)

Somebody not knowing these terms could rightly ask: *Can a tangent be a passant as it does not intersect but passes the circle undamaged? Can a secant be a tangent, i.e. can you cut without touching?* Only the reader familiar with the idea of classification could know that it is forbidden to place a line in more than one or in none of the three categories and that the definition quoted above is ‘meant like that’. Expecting the excluded middle and the excluded contradiction in the contents of mathematics is an *unspoken* prerequisite for its understanding. Thus, mathematics education does not only cultivate an unreflected and politically problematic idea of truth which gives power to those able to use mathematics; it also provides this power unequally. Those who understand the latent order of mathematics gain the possibility to perform well and become confident in the use of mathematics while those who do not understand its latent order are excluded from its power. Not talking about the logic architecture of mathematics leaves a large part of the students without any chance of understanding it and keeps the circle of mathematicians as exclusive as possible.

Although I presented only two examples for connections of school mathematics, logic and society, experiences from the classroom and students’ comments on mathe-

matics education (Jahnke, 2004; Motzer, 2008) indicate further connections, drawing even closer to the dialectics of logic presented before. On the one side, there are students who dedicate themselves to mathematics passionately, who understand and use its order, and who are able to explain and argue more convincingly than others. On the other side, there are students who are frightened by mathematics, who consider it lifeless and unapproachable, who – in spite of great efforts – do not understand its order, and who must accept the explanations of the teacher and capable students unchallenged. In an extreme case, we can speak about two different types of students: some who enjoy mathematics and logic and use it to order and present their knowledge persuasively, and others who – anxious and confused – distance themselves from mathematics and trust in the guidance of the mathematically educated. This mechanism separates a logically emancipated elite from its subjects. Particularly, this mechanism influences the students' relations to mathematics. It determines how mathematics is perceived and how people react to it. Research on mathematical world views shows that such a predisposition might indeed feature a view of mathematics as an inerrant decision-maker, the involvement in which is frightening and too demanding (Leder, Pehkonen, & Törner, 2002). In consequence of this mechanism, mathematics serves as an instrument of power which is trusted by the majority of people and whose rationale is no longer questioned. Mathematics education acts as an institution which unconsciously installs this instrument of power. This study shows that the social impact of mathematics education is not a matter of the style of teaching but connected to mathematics itself; for – since its very beginning – mathematics was the manifestation of a tool of power called 'logical thought'. The question on how to face this social impact of mathematics is open to debate.

DIVERSITY, DIALOGISM AND MATHEMATICS LEARNING: SOCIAL REPRESENTATIONS IN ACTION

Ricardo Machado & Margarida César

Investigação Educação e Desenvolvimento, Almada, Portugal &*

Universidade de Lisboa, Instituto de Educação, Lisboa, Portugal

Learning is a dialogical process in which diversity plays a major role. This research illuminates the connections between collaborative work, social representations and mathematics learning. We assumed an interpretative paradigm and developed an action-research project. The participants were eighth graders (N=21), a teacher/researcher and two other observers. Data was collected through an instrument to evaluate students' abilities and competencies, tasks inspired in projective techniques, questionnaires, observation, informal conversations and students' protocols. We did a narrative content analysis from which inductive categories emerged. Paula's life trajectory of participation is a paradigmatic example we discuss through the analysis of her social representations and her performances in some mathematics activities.

INTRODUCTION

Freire (2003) stated that education is a political act, based on social interactions and participation, or in the lack of possibilities to participate. Thus, it is dialectical and dialogical (Marková, 2005), as there are always conflicts that need to be addressed. However, according to dialogism, conflicts contribute to knowledge and progress. Education should celebrate and respect students' values and cultures, facilitating their participation in school activities, particularly through their (cultural and social) practices. How teachers interpret curricula and put them into practice, as well as the social interactions they promote while students are solving mathematics activities also play a major role in their performances and achievement (César, 2009, 2013). In order to express and respect each student's diversity, allowing them to have access to achievement, social interactions must contribute to the distribution of power, i.e., to students' empowerment (Apple, 1995). As Alrø, Skovsmose and Valero (2005), we assume diversity as a resource for learning as it brings into classes different experiences and perspectives related with knowledge, ways of thinking, solving strategies, abilities, and competencies. Diversity is connected to the participation in different cultures, and to the use of different symbolic resources, cultural tools and artefacts (Vygotsky, 1934/1962). Thus, in multicultural settings, being aware of the importance of culture, social interactions, and diversity is even more important, as they shape – and are shaped by – students' (mathematics) performances (César, 2009, 2013; Cobb & Hodge, 2007; Machado & César, 2012).

Some educational policy documents highlight the need of taking (cultural) diversity into account in order to promote equity and achievement in mathematics (NCTM; 2007). Learning meaningful mathematics and being able to internalise knowledge,

after attributing it a sense, is a way to develop some abilities and competencies, which are powerful to avoid exclusion, as they are needed in a society that is increasingly complex and technical. Intercultural and inclusive practices are essential to allow students who participate in socially undervalued cultures to become legitimate participants while developing mathematics activities, particularly in formal educational scenarios, like school (César, 2009, 2013; Lave & Wenger, 1991; Machado, 2008). In Portugal, a new construct coined by César (2013) has gained significance in mathematics education: students' life trajectory of participation, in and outside schools. The construct of trajectory stresses the time dimension in learning – and in life – as it includes past, present and future, i.e., direction, path. The trajectories are connected to participation, or the lack of opportunities to participate, i.e., the lack of power. However, learning is a lifelong process. Thus, these trajectories of participation are life trajectories. They begin when we are born and only end up when we die. For teenagers, school, family and their peer groups play a main role in their life trajectories of participation.

Students often experience feelings of rejection, frustration, and construct negative social representations (SR) about mathematics that shape their performances (Machado, 2008). Knowing SR is essential to promote students' access to mathematics achievement and to avoid school dropouts (Machado & César, 2012). The problem that originated this study was the existence of students' negative SR about mathematics and their impacts in their (under)achievement and in their school and social inclusion. The research questions we address are: (1) Which are these eighth graders' SR about mathematics at the beginning of the school year?; (2) Which changes do we observe in those SR during the school year?; and (3) What are the impacts of collaborative work on students' SR about mathematics, in their mathematics knowledge appropriation and in their mobilization and development of abilities and competencies?

THEORETICAL FRAMEWORK

SR are a dynamic, multi-faced and dialogic construct (Marková, 2005). They give us powerful insights about how the other interprets the contexts, scenarios and situations that s/he is experiencing. Thus, SR play an essential role in mathematics learning process, particularly in formal educational scenarios (Machado & César, 2012). SR are constructed since we begin interacting with other people and they are shaped by our life experiences but also by the *media* or the values of a particular culture. As many students construct negative SR about mathematics it is important to develop classroom practices that facilitate changing these negative SR into more positive ones. It means that teachers should create spaces and times that facilitate students' transitions between the different cultures in which they participate (César, 2009, 2013), like the school culture and their home culture(s), also facilitating students' mobilisation of abilities and competencies, particularly in mathematics classes.

Teachers should also reflect upon the importance of power relations (Apple, 1995) and they should distribute power among them, the students and other educational

agents (César, 2009). Similar to the appropriation of knowledge, the internalisation of empowerment mechanisms happens on the inter-individual plane and the intra-individual plane. Accordingly, César (2013) coined two new constructs: inter- and intra-empowerment mechanisms. She states that there are inter-empowerment mechanisms, used by those who have more power. Later, students are able to internalise them and they become intra-empowerment mechanisms. She illuminates the importance of these inter- and intra-empowerment mechanisms in students' mathematics performances and in their life trajectories of participation, particularly for those whose cultures are more distant from the school culture. Perret-Clermont (2004) designates as thinking spaces those where students can interact dialogically sharing their ways of thinking, solving strategies, doubts and fears. They are also assumed as a security and trust space and time, where students (inter)act as legitimate participants and power is distributed (Apple, 1995; César, 2009, 2013). This aspect is very important because if we want to develop equity among students (Cobb & Hodge, 2007), we need to allow them to assume their own voices, instead of keeping some of them silenced, namely in mathematics classes.

In multicultural settings collaborative work, particularly in dyads and small groups, plays an essential role (César, 2009, 2013; Machado, 2008; Tielman, den Brok, Bolhuis, & Vallejo, 2012). To develop collaborative practices one needs to negotiate a coherent didactic contract promoting autonomy, accountability, critical sense, respect for each other's cultures, and focusing on students' ways of acting and reacting. The teachers' practices change and teachers face much more challenges, as they have to work outside their comfort zones (Skovsmose, 2000). They should act as a mediator rather than someone who possesses all the knowledge. Then, they need to elaborate, adapt, and/or select tasks with different natures regarding students' characteristics, interests, and needs. Teachers should give working instructions that facilitate students' engagement in mathematics activities while working in their zone of proximal development (ZPD) (Vygotsky, 1934/1962) and respecting their own cultural mental tools (César, 2009, 2013). This also means reflecting upon the evaluation system and using diverse means of evaluation, conceiving this process as an auto-regulatory mechanism regarding meaningful learning.

METHOD

This study is part of a Master thesis developed within the *Interaction and Knowledge* (IK) project. The IK main aims were studying and promoting collaborative work in formal educational scenarios, and promoting a more inclusive, intercultural and high quality mathematics education (César, 2009). This project developed three research designs: (1) *quasi-experimental* studies; (2) action-research projects; and (3) case studies (for more details see César, 2009). We assumed an interpretative paradigm (Denzin, 2002) and developed an action-research project (Mason, 2002) at a very multicultural school near Lisbon whose region is affected by unemployment and poverty. The participants were the students (eighth graders, N=21), the teacher/researcher and two other observers. Students worked collaboratively during

the whole school year, mainly in dyads but also in small groups (e.g., during the project work, in Statistics or in Functions). Data was collected through questionnaires (Q) (beginning and end of the school year), tasks inspired in projective techniques (TIPT) (beginning of the 1st and 2nd terms; end of the 3rd term), an instrument to evaluate students' abilities and competencies (IACC) (first week), participant observation (written in the researchers' diary - D) and students' protocols (collected the whole school year). Such data was then treated and analysed through a narrative content analysis (Clandinin & Connelly, 1998), performed in a successive and in-depth way. Inductive categories emerged from this analysis (for more details see Machado, 2008). They allowed us to trace students' life trajectories of participation, in and outside school, as well as to illuminate the inter- and intra-empowerment mechanisms that facilitated students' mathematics learning (César, 2013).

RESULTS

According to the epistemological and pedagogical principles of the IK project the practices we developed included a different type of practices since the first week of the school year. Teachers did not teach any mathematics contents in that week. They used three instruments (TIPT 1, Q1, IACC) to gain access to a deeper knowledge about students' characteristics, interests, and needs. The TIPT 1 allows teachers to know students' SR about mathematics. The Q1 gives information regarding students' lives (about parents or other relatives, hobbies, future job, among other aspects), and their life trajectory of participation in school. The IACC allows knowing the abilities and competencies students are able to mobilise and the ones they need to develop. This information is very important for teachers. It allows students and teachers to participate in adequate practices (e.g., nature of the tasks and working instructions) regarding students' cultural diversity, i.e., respecting their own characteristics, avoiding deficit interpretations, assuming that learning and development are a lifelong process. Teachers' practices should contribute to promote students' knowledge and development, even when the educational system needs improvements. We assume that collaborative practices, based on dialogical interactions, also allow teachers to promote (academic) positive self-esteem and to avoid (subtle) ways of rejection of mathematics and forms of exclusion.

We are going to analyse a paradigmatic example (Paula, pseudonym) that illuminates other students' life trajectories of participation during that school year. She was 14 and lived in a low socio-economical area. She and her family were Portuguese but she had characteristics that put her away from the mainstream culture: she did not have a computer at home and did not spend time in social networks, she did not wear trademark clothes, and she did not have any sort of gadgets that were usual for many Portuguese teenagers. Still, she was similar to many other students in her school and she felt accepted by her peers. The expectations her family had towards schooling were low, as they did not believe a school diploma would provide for her living in the future. Thus, she did not put any effort or trust in school and in her performances, particularly in mathematics. She was polite, but did not engage in school activities.

Thus, she experienced subtle forms of social and school exclusion. Her socialisation among her peers included extra-school activities such as going to the cinema, to the shopping centre, to the esplanades, or to the gardens near her school. Thus, she had the same kind of life experiences as her classmates.

Paula was doubling the eighth grade. Her SR about mathematics was a very common one: a difficult and boring subject. As she reports: “It is the subject in which I have more difficulty and I think it’s less interesting” (Paula, Q1, September 19, 2006). She also added, “(...) [mathematics] is tiring” (Paula, Q1, September 19, 2006). This illuminates a strong rejection and a negative self-esteem regarding this subject probably shaped by her previous school experiences.

For me mathematics is a subject in which a lot of attention is needed and a teacher who knows how to explain it well and who doesn’t transform mathematics into something even more boring (*mais secante*) than it already is; and it is also a set of themes that include numbers. (Paula, TIPT 1, September 19, 2006)

She constructed a negative SR about mathematics because she associated it with a boring activity and something that needs a lot of attention. She also related mathematics to numbers. Another important feature of her answer is that she never describes mathematics as important for daily life or to get a better job, as stressed by many students (Machado, 2008) and by the *media*. This was probably shaped by the low importance of school in her life trajectory of participation and by the lack of intra-empowerment mechanisms. She participated in a culture with different life goals, ways of thinking about their future, and their role in the society. For her and her family, poor people only went to school because it was compulsory. Their lives were not going to be improved by school knowledge and studying many hours was a waste of time.

When we developed collaborative practices our aim was to support students’ (mathematics) knowledge appropriation and their mobilization and development of abilities and competencies. This was our way of avoiding exclusion, of promoting equity and inclusion. In order to achieve this we needed to promote inter-empowerment mechanisms to facilitate students’ access to achievement, particularly in a school system that was not tailored for them. Our commitment was precisely to avoid exclusion and to provide these students with a high quality education.

The majority of these students did not study in a regular basis outside school. One of the practices we developed to improve students’ study was our conception of the homework: (1) they received some homework to do once a week, always at the same weekday; (2) what counted for the evaluation was doing or not doing the homework; and (3) if they were not able to do it or to finish it they had to explain why that happened. At least once a term the homework needed the collaboration of family and/or friends in order to collect data needed to solve it. This was one of the inter-empowerment mechanisms we put into practice in order to promote an intercultural education, that valued family’s contributions to school learning. Different solving

The next task (see Figure 2) was connected with the previous one but also with some daily life situations. It includes two questions in which students: (1) have to calculate the area occupied by the four triangular faces in the figure; and (2) have to calculate the cost of ink cans knowing that 1 litre of ink costs 1,59 Euros and 2 litres of ink allow them painting 10m^2 . Paula and Carolina started to do the first question in which Paula took the leadership. They calculated the measures they needed.

Figure 2: Paula and Carolina solving strategy (October 26, 2006)

In the second part Paula did not know what she was meant to do. She was confused by so many data. Thus, Carolina took the leadership and explained Paula the solving strategy that she suggested. This was needed because the students knew that in the whole-class discussion, every student could be asked to explain the solving strategies of her/his dyad. When Carolina did the last step – to calculate how much was the cost – Paula interrupted her and said that she was doing a mistake, because in a store we do not buy 37,13 litres. We buy 37 litres or 38 litres (D, October 26, 2006). After Paula's comment, this dyad finished the second question. This episode illuminates that the role of the most competent peer, while working in their ZPD (Vygotsky, 1934/1962), may change during a mathematics school activity (Paula, Carolina, Paula). This is important if we want students to become more confident, autonomous, developing a positive self-esteem and some intra-empowerment mechanisms (César, 2013). It also illuminates that Paula was able to connect a daily life situation with the school mathematics, i.e., she was able to do what Abreu, Bishop and Presmeg (2002) called transitions between two contexts and cultures (home and school). This is particularly important for students whose home culture(s) is/are more distant from the school culture, and for those who value school knowledge less regarding their future.

At the end of school year, Paula and her colleagues answered to TIPT 3. While analysing Paula's drawing (see Figure 3), we observe that she changed her SR. Several aspects illuminate this change: (1) the teacher has a happy face and he is closer to the students than to the blackboard. Moreover, what the teacher is saying is understood by all the students; (2) there are not any chairs and tables, which illuminates the freedom of moves students connect to the autonomy collaborative work promotes; (3) the blackboard has a smiling face, i.e., it became a nice place where she felt secure and confident; and (4) the mathematics contents (Pythagoras theorem and special cases of multiplying binomials) are connected with two different experiences: (a) related to the Pythagoras theorem, was when she started to change

her SR about mathematics and started to engage in mathematics activities; and (b) it was the content she disliked the most and in which she experienced more difficulties (Paula, Q2, June 15, 2007). By then she already realised that it was better trying than not doing anything because otherwise her colleagues and her teacher could not do anything in order to facilitate her knowledge appropriation (D, June 15, 2007). For Paula, this was a very important step and corresponded to the internalisation of some inter-empowerment mechanisms, using them as intra-empowerment mechanisms in future situations.

Figure 3: Paula's drawing in TIPT 3 (June 15, 2007)

This illuminates the importance of teacher's ways of acting and reacting, and of the development of inter- and intra-empowerment mechanisms (César, 2013). These mechanisms allow students to become confident and to participate in mathematics activities, feeling that each one has a space and a time to be a legitimate participant (César, 2009, 2013; Lave & Wenger, 1991). The Portuguese educational system has no optional subjects until the 9th grade, and does not fit the needs of many students. Nevertheless, teachers' practices can make a difference and avoid exclusion.

She also chose to write. Her writing corroborates what we observe in her drawing. Paula stated very clearly that by then mathematics was real nice and funny.

In this term for me mathematics was super, mega, deep, huge, intensely fun... (Paula, TIPT 3, June 15, 2007).

During that school year, Paula had Level 2 (1st term) and Level 3 in the other two terms (Level 1 is the lowest and Level 5 is the highest mark; you fail if you get Levels 1 or 2). She was able to progress to the 9th grade without any negative marks. She stated that "The mathematics classes could be always like this... for next school year" (Paula, Q2, June 15, 2007), which illuminates the important role that collaborative work had in her life trajectory of participation, during that school year. It also illuminates that by then she realised that being at school and learning could be important for her future and to get a better job. However, above all she felt much more confident in her abilities and competencies, and she was able to mobilise them in many more contexts, scenarios and situations, as we observed and she also told us in several informal conversations.

FINAL REMARKS

Dealing with diversity is more challenging and meaningful if we assume it as vehicle for inclusion and learning, namely in mathematics. Teachers need to know students' SR about mathematics since the beginning of the school year to decide about the tasks and working instructions they will use in classes. Gathered with other information from the IACC, a questionnaire and the observation it shapes decisions about the first dyads. Collaborative work, in dyads and small groups, associated with a coherent didactic contract and working instructions can be used as a meditational tool to facilitate the change of students' SR. It also facilitates students' engagement in school activities, their mathematics knowledge appropriation and the mobilization and/or development of abilities and competencies, as it promotes dialogical social interactions between students, and also with their teacher. Developing practices that shape more intercultural and inclusive scenarios in which students have voice(s) and the power is distributed facilitates their legitimate participation in mathematics activities, promoting a high quality mathematics education. It also allows students to internalize inter-empowerment mechanisms and then using them as intra-empowerment mechanisms (César, 2013). Thus, their life trajectories of participation are also changed and include more possibilities of choice.

ACKNOWLEDGEMENTS

The *Interaction and Knowledge* project was partially supported by the Instituto de Inovação Educacional (IIE), medida SIQE 2 (project n.º 7/96) in 1996/97 and 1997/98, and by the Centro de Investigação em Educação da Faculdade de Ciências da Universidade de Lisboa (CIEFCUL) since 1996. Our gratitude goes to the teachers, students, other educational agents, and colleagues who participated in IK.

‘REGIME OF COMPETENCE’ IN A SCHOOL PRACTICE WITH ROBOTS

Sónia Martins

Louros Middle School, Portugal

This article analyses and discusses some topics that highlight the social nature of learning (Lave & Wenger, 1991). In particular it analyses how the ‘regime of competence’ (Wenger, 2008) is defined in a school practice, in which students work with robots. The learning scenario presented here followed a project work methodology and involved two primary school classes. The research reported in this paper follows a qualitative approach and participant observation was a central strategy in data collection. People in action constituted the unit of analysis. Relevant considerations about how competence is usually defined in the school context emerged from the discussion of the results.

INTRODUCTION

In the context of school, learning is often understood as an individual process that results from the act of teaching and in which it is best to disengage it from other students’ activities. Based on this assumption, classrooms are often organized as a place where students shall pay attention to the teacher and focus on ‘making’ exercises, while ignoring from the distractions of participation in the outside world. This model is inadequate when we take learning as a social phenomenon (e.g. Fernandes, 2004; Lave, 1996; Lave & Wenger, 1991; Santos, 2004; Wenger, 1998). Aspects of mathematics and mathematics education, largely ignored in the past, have gained a renewed interest within our scientific community in the last two decades. The classroom as a social context with different backgrounds, beliefs, agendas and expectations of its players has been a focus of much research in mathematics education (e.g., Atweh, Forgasz & Nebres, 2001; Boaler, 2000; Valero & Zevenbergen, 2004).

Lave’s studies (1996) of the acquisition of mathematical competence based on practices involving adults in workplace situations, specifically, within tailoring apprenticeships, led her to argue that cognition is located in particular forms of situated experience, not simply in mental contents. In the work that Lave developed together with Wenger (1991) it is clear that the focus moves away from cognition to a new approach that is related with learning concerns. Lave and Wenger (1991) clarify the relations that they consider essential between participation and learning: learning is a deepening process of participation in communities of practice.

By understanding a community of practice (Lave & Wenger, 1991) as a social learning system, Wenger (2010) locates learning in the relationship between the person and the world. This is a relation of participation where the social and the individual complement each other and where meaningful learning requires both

participation and reification to be in interplay. Over time, this interplay creates a social history of learning that gives rise to a set of criteria and expectations by which participants recognize membership. In other words, participants define what counts as ‘competence’. According to Wenger (2010) this competence includes being able (and allowed) to engage productively with others in the community and to use appropriately the repertoire of resources that the community has accumulated through its history of learning (p. 180).

Our aim in this paper is to discuss some ideas that enhance the social nature of learning by focusing on the ‘regime of competence’ (Wenger, 1998) of students from two primary school classes working together in a project work with robots [1].

EXPERIENCE AND COMPETENCE

Following Wenger (1998), the term participation describes the social experience of living in the world in terms of membership of social communities and active engagement in social enterprises. To participate is also to belong. It is both personal and social. It is a process that combines doing, talking, thinking and feeling. It involves the whole person including her/his body, mind, emotions and social relations. Engagement in social settings involves a dual process of making meaning, which results from the interplay between participation and reification (Wenger, 2010, p. 179). Wenger (1998) uses the word reification to refer to the process of giving form to our experience by producing objects that freeze this experience into “thingness” (p. 58). By reification, we create points of focus around which the negotiation of meaning is organized. Although participation and reification mean different things, we cannot conceive one without the other. They complement each other (Wenger, 2010). On the one hand we engage directly in activities, conversations, reflections and other forms of personal participation in social life and on the other hand we produce physical and conceptual artifacts such as words, tools, concepts, methods, stories, documents and others forms of reification that reflect our shared experience and around which we organize our participation. The interplay between participation and reification creates a social history of learning by which participants define a ‘regime of competence’ (Wenger, 1998).

Wenger (2010) defines a ‘regime of competence’ as a set of criteria and expectations by which the members of a community recognize membership. In this sense, communities are seen as social configurations in which their members experience competence and are recognized as competent (Wenger, 1998). Therefore, the term competence has no meaning, when disconnected from a particular practice. What is seen as competence is constructed and defined within the community. “It is by its very practice – not by other criteria – that a community establishes what is to be a competent participant, an outsider, or somewhere in between” (Wenger, 1998, p. 137). To be competent includes the understanding of what is important and what matters in the community, reflecting the accountability to the joint enterprise.

According to Wenger (1998) this competence is not merely the ability to perform certain actions, the possession of certain pieces of information, or the mastery of certain abstract skills. Competent membership presupposes three features: **Mutuality of engagement**: the ability to engage with other members and to respond to their actions in order to establish relationships in which this mutuality is the basis for an identity of participation. **Accountability to the enterprise**: the ability to understand the enterprise of a community of practice and take some responsibility for it and contribute effectively to its pursuit and to its on-going negotiation within the community. **Negotiability of the repertoire**: the ability to make use of the repertoire of the practice to engage in it. This requires enough participation in the history of the practice to recognize it in the elements of its repertoire and it requires both the capability and legitimacy to make this history newly meaningful.

The interplay between a ‘regime of competence’ and the experience of meaning allows learning by practice. According to Wenger (1998) there are moments when competence may drive experience and other moments in which the opposite occurs. In order to achieve the competence defined by the community, competence may drive experience when newcomers transform their experience until it fits within the regime. On the other hand, the members of an existing community also have a need to transform and increase their experience. However, new experiences may lead to the need to redefine the enterprise and require to add new elements to the repertoire of their practice. When one or more members have had some experience that currently falls outside of the ‘regime of competence’ of a community to which they belong, they may very well attempt to change the community’s regime so that it includes their experience. Thus, the meaning of their experiences is negotiated with the community of practice. They can invite others to participate in their experience and then seek to reify it for the others. If they have enough legitimacy as members, they will have an impact on the ‘regime of competence’ of the community and participate in the process of creating new knowledge. Learning can be thought of as a process of continuous interaction between experience and competence, “whichever of the two takes the lead in causing a realignment at any given moment” (Wenger, 1998, p. 139). A certain tension between experience and competence is what promotes learning.

METHODOLOGY

This paper takes *learning* as the phenomenon of study. The research sought to understand how the use of robots could contribute to the development of mathematical and other competencies, and to the appropriation of mathematics concepts by primary school students. To do this, a learning scenario was designed, which involved two primary school classes (2nd and 3rd grade, 24 and 16 students, respectively) from a school in Funchal – Madeira island – Portugal. In this learning scenario the children worked together with robots. In this section, we will describe

the learning scenario and the methodological options. This establishes a connection between the nature of the phenomenon under study and the theoretical background.

Learning Scenario

We conceptualize scenarios as “stories about people and their activities” (Carroll, 1999, p. 2). Scenarios have some characteristic elements, such as a context, a setting, the agents or actors and their goals. It includes a sequence of actions and events to be developed in order to achieve certain goals. These goals are changes to be accomplished by the actors in the circumstances of the scenario. The scenario’s narrative is fundamentally a description of people accomplishing tasks, pursuing goals and using technologies to achieve those goals. The learning scenario was constructed by the research team, the teachers from both classes and by their students. At the beginning, the research team presented, to both teachers, a draft of the learning scenario to be implemented. That initial draft was discussed and modified according to teachers’ and students’ ideas. In this process students had the opportunity to express their own options. These were very important for them and for the success of the project. Between the working sessions, teachers often contacted the researchers to convey students’ opinions and expectations. The learning scenario was developed in two stages: the first between May and June 2011 and the second between April and July 2012. The scenario’s activities followed a project work methodology.

In this project, students worked with two kinds of Lego robots: RCX and NXT. The programming environment is a very intuitive icon-based drag-and-drop programming language for both robots. It was designed for an easy introduction to programming. Students simply build up their program block by block by choosing program blocks that work with the motors and make the sensors react to inputs. In this way, they could create programs that range from simple to complex. Students and teachers had never worked with robots before.

Students worked in heterogeneous working groups with students from both classes. Teachers had to support students in their work. Researchers sought to support students and teachers and to take advantage of situations that could contribute to facilitating the emergence of mathematical concepts. Based on that intention, researchers assumed a questioning attitude towards students’ work in their practice with robots.

In the first part of the scenario’s implementation, students had to construct robots and define their physical and emotional features. Their creations would become characters in a play-story written by them all. After writing the story, students had to program their robots in order to perform their roles in the play. The initial goal was to accomplish those tasks in order to make the robots as characters on the play.

In the second part of the scenario’s implementation, students, teachers and researchers decided to produce a film. The written story was used as its storyline. Students established new tasks to produce the film and created teams to accomplish

those tasks. Each student chose in which team(s) he or she wanted to work. In this paper we will focus on the teams that decided to do the programming of the robots.

Methodological options

The nature of the research related in this article is qualitative and it was given particular relevance to the process and not to the product of the developed activities (Bogdan & Biklen, 2006).

Taking the phenomenon under study – learning – as connected to participation in specific practices, it became important not only ‘to observe’ but also ‘to participate’ in the activities in which students were involved. In fact, assuming a situated perspective of learning as a theoretical framework has certain methodological implications: Investigation is participation in the constellation of practices in which the research occurs (Matos & Santos, 2008). This was the position of the researchers involved in data collection. Participation was also learning. Thus, participant observation was a central strategy of data collection. The challenge was to maintain a genuine participation and to be able to reflect on it (Matos & Santos, 2008). In this research there was a close connection between the phenomenon under study and the theoretical framework. The unit of analysis in this research was constituted by people in action and it was analysed in the dialectic between the theoretical framework and the practices that were observed, experienced and reflected and that instantiate empirically the problem under study (Matos & Santos, 2008).

The study involved semi-structured interviews with some participants in order to clarify some aspects of the practice that raised doubts or were unclear when the data was analysed. The working sessions were video and audio recorded with a focus on students’ interactions. Not every phenomenon could possibly be recorded so researchers wrote down what occurred in the form of extensive field notes. Soon after, these notes were analysed in order to note patterns of behaviours, events and phenomena to be investigated in further observations.

WHAT DOES IT MEAN TO BE COMPETENT IN THIS PROJECT WITH ROBOTS?

A ‘regime of competence’ is constructed as a shared process of definition of a community’s joint enterprise (Wenger, 1998). In this study, the student’s joint enterprise was to write and implement a play-story in which robots were the characters (Martins & Fernandes, 2012). That joint enterprise allowed opportunities for students’ engagement across distinct forms and levels. In that process of engagement, the competencies of each member were jointly constructed. Students defined what was important for each one to know and they had to develop abilities to make a connection with what each one didn’t know. In the project work with robots students often needed to establish a division of tasks. That aspect contributed to the mutual recognition of competencies in the on-going practice. In that process students assumed responsibility for distinct aspects of the joint enterprise. The choices they

made were intrinsically linked to their individual preferences but were also in accordance with what was considered as important to pursue within the community's joint enterprise (Martins & Fernandes, 2012).

Some students were responsible for specific tasks within the practice. Once students agreed on what was important to do in order to accomplish a specific task, they jointly gave legitimacy to those students who were responsible for it. Students revealed an ability to understand the community's joint enterprise and to be responsible for it. This revealed their accountability. In this sense, we can argue that competences are neither merely individual nor abstractly communal. They implied a negotiated definition of what the community is about. What makes engagement possible is a matter of diversity and constant negotiation of meanings, reflecting the way participation occurs in on-going activities (Wenger, 1998). As we saw earlier, new tasks were jointly defined in order to be able to produce the film. In our analysis, we will focus on the tasks that were carried out by the programming teams. Those two teams (NXT team and RCX team) had to learn to program the robots in order to correspond to the remaining teams' solicitations when the shooting of the film began.

R and M were two students who worked in the RCX team. In the extract presented here, these students were working together on the same computer, although they had two computers at their disposal. They were trying to program the RCX robot, T-Rex [2]. These two students were initially disappointed because they were having some problems uploading the program to the robot. One of the researchers, Res, helped them to solve this problem. Throughout this process students' difficulties were discussed. The researcher noticed that the program they were trying to upload was very long and that the students were using the programming blocks without having the notion of the action that the robot would execute after programming. The researcher challenged them:

Res: I want you to program the robot in the computer. Don't ask him to do too many things.... Then you can write in a paper what the robot is going to do when you run the program.

Later, the researcher found that the students were programming on distinct computers and the programs were clearly 'shorter'. M continued programming the T-Rex and the other student, R, was programming another robot. The researcher asked M:

Res: So, can you tell me what the robot is going to do when you run the program?
[Student whispered:]

M: I can't talk now. I don't want that R hears what I'm saying.

Res: Why?

M: Because we are doing like this: I'm programming my robot and R is programming his robot. Then we are going outside. The programs will run and we have to discover the programming from each other's robots... looking to the robots.

The researcher continued observing. Afterwards, the two students went to the courtyard to test the programs they've made. In the courtyard the researcher realized that students began to identify the blocks they used in programming in the robots' actions.

This extract shows how students couldn't upload the program to the RCX brick at the beginning and how they were disappointed. Some mistakes were made in that moment and students experienced some conflicts, advances and retreats. However, all those components have proven to be learning opportunities. In the interactions between the students and the researcher, relations of mutuality were established, in which they jointly defined what was important to learn. To achieve the competence that was defined by the community, students transformed their experience of programming in order to fit within the 'regime of competence'. The researcher expected that students could achieve a better understanding of the program blocks that they used, when she challenged the students to write on paper the robot's actions. Both students revealed accountability and tried to develop this understanding about programming. However, instead of writing the actions of the robot on paper, they assumed that knowing how to program also meant recognizing the program blocks in the robot's actions. This was a big step in the learning of programming.

We will now analyse an episode with the other programming team. Seven students who were working on two computers constituted the NXT programming team. In the first session as a team, three students programmed Lama and Spider and the remaining students programmed two twin dogs. In the following session, the students had an additional computer available. The researcher suggested to swap the robots. All students agreed except H:

H: I was in the working group that built the robot Lama. In the previous session I was working in Lama's programming and I want to continue doing it. I don't want to program the other robots.

Res: But which is your team now?

H: NXT programming.

Res: So there is not a specific team responsible only for Lama's programming, right?

H: No it doesn't.

Res: If you have programmed the Lama and the Spider I think you now must change, for all of you have the opportunity to program all NXT robots.

H: Then I will not do anything.

The other groups worked on programming Spider and Lama and H returned to his group, which did not yet choose any robot. Later a student from H's group, A, asked:

A: Can we program one of the twin dogs?

Res: Of course. H said to me he didn't want to program a dog...

A: He doesn't want but we want to. We don't want to stay without doing anything.

After that, the researcher noticed that H still did not participate in programming the robot. This was very different from his behaviour in the past working sessions, in which he was always very involved in the activities. The researcher noticed that the students that were programming the Spider and the Lama were having some difficulties in doing it. She asked H:

Res: Can you help your colleagues with the Spider and Lama's programming? I think they're having some problems with that, but I can't help them at this moment. I really think that your team's colleagues are having some difficulties with the dog's programming too and they do need some help.

H: Can I?

Res: Of course. But don't program the robots alone, without teaching them. You have to find a way to make them understand how to program. I think you can do it.

After this moment H started to support all of the three programming NXT teams.

This episode demonstrates that H was not revealing mutuality in his engagement with the practice of programming in the beginning. What the researcher and his colleagues expected from him was not the same as what he considered important. That ambiguity ended up compromising his engagement in the on-going practice. After the researcher recognized H as competent to program any NXT robot he was committed to help other students with this task. The legitimacy that the researcher recognized in H was a turning point in H's participation in the practice of programming NXT robots. In fact, granting the newcomers legitimacy is important because they become aware of what a community regards as competent engagement (Wenger, 1998).

CONCLUDING REMARKS

Learning mathematics implies knowing mathematical concepts and using them to solve problems. When students were programming, several mathematical concepts connected with time and space have emerged, such as: positioning, orientation, duration, trajectories, direction and movement. However, this project work with robots gave students the opportunity to experiment with many other important aspects that we identify as being crucial to students' mathematics learning. These include developing and evaluating inferences, testing hypotheses and investigating conjectures, communicating coherently mathematical ideas and evaluating arguments and strategies of others.

In the school practice under analysis, mutuality was the basis of membership's recognition by the community and thus, the regime of competence was defined in relationships based on mutuality (micro-level). Those relationships were guided by the negotiation of meanings, by the constant division of tasks and by the accountability in achieving the goals that were jointly defined in the learning scenario. Students have done that and had that opportunity because teachers and researchers gave them legitimacy to do so. These aspects led to opportunities of alternative approaches to tasks and to opportunities to use different artifacts. These approaches and artifacts helped the community to define the competencies of participants, that is, the definition of the community's 'regime of competence'. The analysis shows how school practices with these features provide learning opportunities for all involved, in which the errors and conflicts are taken as natural and can be recovered as special situations for learning to occur.

In school practices of a more 'traditional' nature, competence is often conceptualized as being good in making/producing something and little emphasis is placed upon the process of doing and the relationships that have developed between people when they were doing it. As we have discussed, being competent is closely linked with what is recognized individually and collectively as competence in a particular practice, revealing the accountability within the joint enterprises. It implies not only being recognized as competent but also having legitimacy to participate meaningfully in the constant negotiation and definition of what we want to achieve.

What is defined as 'regime of competence' at the macro-level by the Portuguese Minister of Education is defined in a document named "competencies book". That document defines which competencies must be developed at school and what kind of experiences (e.g. projects) teachers must provide to their students in order to develop those competencies. The way teachers recontextualize this document to their practices is quite different for each one of them and in the most cases they conceptualize competence as being a good student, having good classifications in the exams and being good in following the school's norms. In this experience of working with robots the regime of competence defined in the micro-level matches the regime of competence defined in the macro-level and the conditions that promote that success was connected with the nature of the proposed tasks and the artifacts that allowed student's engagement and mathematical concepts emergence.

NOTES

1. The research reported in this communication was prepared within the project DROIDE II – Robots in Mathematics and Informatics Education funded by Fundação para a Ciência e Tecnologia under contract PTDC/CPE-CED/099850/2008.
2. T-Rex, Lama, Spider and two twin dogs are robots created by students that became characters in the play.

THE DIALOGICAL MATHEMATICAL ‘SELF’

Richard Newton & Guida de Abreu

Oxford Brookes University, UK

Mathematical identity is a growing area of contemporary research. This paper uses dialogical self theory to support a notion of mathematical identity as being made up of multiple positions. These positions make up the mathematical ‘self’. This paper focuses on a single case drawn from a wider study of parental mathematical identity. It demonstrates the application of dialogical self theory to show how mathematical experiences influences I-positions, how social and cultural factors shape social positions, and how the dialogical mathematical self can be seen to consist of multiple positions which vary both spatially and chronologically.

INTRODUCTION

A growing body of literature is beginning to look at how mathematical experiences are incorporated into, or reflected in, a person’s mathematical identity. For instance, studies have investigated mathematical identity in US classrooms (Boaler & Greeno, 2000; Esmonde, 2009), in parents of primary school children in the UK (Abreu & Cline, 2003; McMullen & Abreu, 2011), in both parents and children in the US (Esmonde et al., 2011), and on pupil and teacher identities in the UK (Crafter & Abreu, 2010) and Spain (Gorgorió & Prat, 2011).

From a sociocultural perspective Martin (2007, p.150) defined mathematical identity as:

...the dispositions and deeply held beliefs that individuals develop about their ability to participate and perform effectively in mathematical contexts and to use mathematics to change the conditions of their lives. A mathematics identity encompasses a person’s self-understandings and how they are seen by others in the context of doing mathematics

These generally incorporate notions of positioning and positionality that can be linked back to the work of Harre and van Langenhove (1991). This defines positions as a discursive mechanism through which “people locate themselves and others within an essentially moral space” (Harre & van Langenhove, 1991, p.396). In other words, in terms of mathematical identity, through dialogue people form positions for themselves regarding mathematics.

Much of the research on identity previously mentioned used notions of positioning. Advancements in psychological and educational research shown currently in dialogical self theory present an opportunity to take research involving positioning and mathematical identity further. This affords an opportunity to better comprehend parental mathematical identity. In doing so it may begin to enhance our understanding of how identity shapes parental involvement and activity, itself a key factor in mathematical attainment in UK primary school children (Duckworth, 2008).

THEORETICAL FRAMEWORK

Dialogical self theory provides a systematic approach to understanding identity through positioning of the ‘self’ via participation in sociocultural activity. It originated in the ideas of Hubert Hermans and builds upon the notion of ‘I’ and ‘self’ presented by the American philosopher and psychologist William James as well as the idea of polyphonic ‘voices’ within a personality provided by Russian literary critic Mikhail Bakhtin (Hermans, Kempen & van Loon, 1992).

When discussing his theory of the self, James distinguished between the self as object and the self as subject (Hermans et al., 1992). The self as object is characterised as ‘Me’ and the self as subject as ‘I’. ‘I’ is the self as knower, a sense of personal identity, whilst ‘Me’ is the self as known (Hermans, 2001) and ‘Mine’ is our mental ‘belongings’ (e.g. my daughter) (Hermans & Hermans-Konopka, 2010).

Through his analysis of Dostoevsky, Bakhtin developed the notion of the polyphonic novel (O’Sullivan-Lago & Abreu, 2010). Bakhtin argued that the characters in Dostoevsky’s work have separate, distinct voices. He termed this a polyphony of voices. It is through this mechanism that the novel is told, rather than a single voice of the author. Bakhtin applied this to the study of personality (Hermans et al., 1992). He suggested that dialogical processes involved the interaction of different voices (Hermans, 1996).

In dialogical self theory these two theoretical foundations are combined. The ‘self’ is narrative, and therefore temporal, and so evolves over time. It is evident in the stories we tell and the ways in which the past shapes the present ‘I’. It is also spatial in the sense that the ‘I’ shifts depending on the context we find ourselves in.

As with the research outlined earlier, dialogical self theory utilises Harre and van Langenhove’s (1991) concept of positionality. Indeed, positioning is central to the temporal and spatial nature of dialogical self theory (Raggatt, 2011). The self is made up of a variety of I-positions that alter as the self moves and evolves across time in different contexts. Hermans (2001) compares I-positions to characters in a story, each of which has a separate background that shapes its voice, producing a narrative, storied self. An example of an I-position might be ‘I as a student’ or ‘I as a father’. I-positions can easily support or conflict with each other.

Dialogical self theory is culturally embedded (Hermans & Hermans-Konopka, 2010). I-positions require dialogue and mediation. In this way dialogical self theory can be linked to the sociocultural theories of Vygotsky, Leont’ev and Wertsch (Hermans & Kempen, 1995). In dialogical intercourse in sociocultural contexts, we reflect on the labels given to us by others. These can become incorporated into the self as social positions (Raggatt, 2011).

As suggested earlier, research into mathematical identity is growing in popularity yet very little research has utilised dialogical self theory to look at mathematical identity using the notions of I-position and social positions.

METHODOLOGY

In order to investigate dialogical constructions of the ‘self’, twenty-four parents (16 mothers and 8 fathers), all of whom had children attending UK primary schools, took part in a semi-structured episodic interview with the first author. This approach, established by Flick (1997), asks respondents to produce opinions and narrative episodes linked to a series of pre-selected questions. Episodic interviewing is based upon the belief that narrative is a mechanism through which people understand and make sense of their experiences (Flick, 1997). Episodic interviews have been used previously to investigate processes of identity formation in mathematics (Crafter & Abreu, 2010) and in cultural contact zones of immigration (O’Sullivan-Lago & Abreu, 2010).

Interviews were conducted in the parent’s home, digitally recorded and then transcribed. The respondents produced a number of narratives and opinions that were then subjected to analysis. This analysis focused on studying narratives to ascertain the positions generated by the parents. The study of narratives to elicit positions has been widely used to study mathematical identity (e.g. Boaler & Greeno, 2000; Crafter & Abreu, 2010; Esmonde, 2009; Esmonde et al., 2010; Gorgorió & Prat, 2011).

The dialogical self analysis followed three stages by investigating I-positions, social positions and multiplicity. These were based upon the approaches taken from a number of different authors.

I-positions

O’Sullivan-Lago and Abreu (2010) studied I-positions in their work on identity in cultural contact zones. In their study, I-positions were identified through the coding of episodic interview transcripts. Using a similar approach in this study, codes were applied to segments of text where the interviewees positioned themselves whilst discussing experiences or opinions associated with mathematics and mathematical activity.

Transcripts were first open coded before being studied for patterns and commonalities. This resulted in the merging of some open codes into larger pattern or thematic codes.

In this stage of analysis coded segments for the ‘self’ generally, but not exclusively relied upon ‘I’ in the first person (I, we, me, us), for instance “*I like numbers. Alright, I like numbers, I like adding things up*” was coded as ‘I as enjoying mathematics’.

Social positions

The second stage of analysis addressed the role of the sociocultural environment on mathematical identity. This studied the ‘voices’ or social positions that could be seen in parental narratives.

This style of analysis followed the approach of Aveling and Gillespie (2008), which focused on the relationship between I-positions and the sociocultural environment.

Their coding of interview data was designed to discover the social origin of I-positions. It focused on reported speech and what they termed ‘echoes’, which are “utterances that are not attributed to others, but that nonetheless seem to have a distinct social origin beyond the speaker” (Aveling & Gillespie, 2008, p.6).

Following this approach, this stage of analysis began by open coding segments of data and then combining and refining codes through a recursive cycle. Here codes reflected actual specific voices and more generalised individuals. Codes could also be often connected to I-positions. For instance ‘I as good at mathematics’, an I-position, could be a general voice ‘I as more successful at mathematics than others’, or a more specific voice ‘I as more mathematically successful compared to my friends’.

Multiplicity and dialogical positioning in the mathematical ‘self’

Multiplicity within the mathematical ‘self’ was the subject of the final stage of analysis. It was ascertained through comparing the different positioning of the ‘self’ within individuals. This showed not only the number of positions but also the variety of similar and different ‘self’ identifications. Next, the positions within each individual were studied in terms of chronology to see whether positions remain fixed or shifted over time. Finally, by looking at the context in which they occurred, positions were compared spatially.

ANALYSIS

Because of the difficulty of presenting the wealth of data analysed in the project within this short paper, the analysis therefore focuses upon the results of a single parent within the sample. Ian was a father with two daughters, Megan in Year 4 (8-9 years old) and Louisa who attended reception (4-5 years old). Ian constructed fourteen positions related to mathematics and was broadly representative of the sample as a whole.

In first stage of analysis, focusing on I-positions related to mathematics and mathematical activity, Ian displayed twelve different I-positions as shown in Table 1. This shows Ian built a mathematical ‘self’ consisting of a range of I-positions associated with mathematical experiences, aptitudes and behaviours.

I-position
I as replicating my own upbringing
I as supporting a work ethic
I as a competent user of mathematics
I as confused by mathematics
I as good at mathematics
I as not good at mathematics
I as a novice and learning mathematically from my child
I as apprehensive of mathematics
I as enjoying mathematics
I as feeling supported by my parents
I as not interested in mathematics
I as regretful of mathematical activity

Table 1: Ian’s mathematically-related I-positions

For instance in Excerpt 1 Ian positions himself as ‘I as a competent user of mathematics’. Here the I-position is underlined and preceded by a number to specify its position in the text.

Excerpt 1: Ian - Interview	
Dialogue	I-position
Something, it keeps, (1) <u>I wasn’t brilliant at it at school but I’ve got a pretty good grasp of anything like that.</u>	(1) <u>I as a competent user of mathematics</u>

In the second stage of analysis, which investigated the social and cultural influences on positioning, Ian constructed two distinct social positions. These are shown in Table 2. These social positions suggest that Ian saw himself as similar to his daughter Megan in terms of mathematical ability and attitude, and that his views of mathematics reflected the society in which he grew up and lived.

Social positions
I as similar to my child
I as reflecting the influences of my social environment

Table 2: Ian’s mathematically-related social positions

A social position can be seen in the next example. Here I-positions are underlined and preceded by a number whilst the social position is presented in italic and preceded by a lower case roman numeral.

In Excerpt 2 Ian again constructs competent ability positions associated with mathematics and uses these when comparing himself to his daughter Megan. Here we see the links between I-positions and social positions. It also shows how Ian positions his daughter using his own experiences.

Excerpt 2: Ian - Interview		
Dialogue	I-position	Social position
I wouldn't say that it's her strongest subject really at school. (i) <i>She, she's very, very like I used to be at school I think. (1) <u>If I could be bothered to do it I'd do it and I'd be good at doing it.</u> (2) <u>If I couldn't be bothered to do it, I'd just wing it and get through it and be like that.</u></i>	(1) <u>I as good at mathematics</u> (2) <u>I as a competent user of mathematics</u>	(i) <i>I as similar to my child</i>

Excerpt 3 shows how the environment in which Ian lived influenced his attitude towards the importance of mathematics. It shows that he saw a value to mathematics in order to be successful in society. This can be labelled as a somewhat vague social position of 'I as reflecting the influences of my social environment'.

Excerpt 3: Ian - Interview	
Dialogue	I-position
<p>Researcher: Do you think it is important to be good at maths?</p> <p>Ian: Yeah definitely, (i) <i>You've got (pause) everyday life you use it and you are going and obviously it's a big thing in the structure of what you are going to do when you get older. It gets you certain jobs and things like that. You're always going to, you're always, it's the same as like English and things like that, you're always going to need it aren't you. And you're better off being good at it than bad at it.</i></p>	(i) <i>I as reflecting the influences of my social environment</i>

The third stage of analysis looked at multiplicity. The fourteen different mathematically-related positions exhibited by Ian hint at the multiplicity of positioning that is central in dialogical self theory. This polyphony of positions acts to construct a unique and complex mathematical ‘self’ for Ian. Multiplicity was a feature across the entire sample, as shown in the range of positions (6 to 26) and the mean number of positions (15).

The parents within the sample showed varying amounts of spatial and temporal shifts in positioning. It was noticeable that some parents presented a greater degree of stability over time and across contexts than others. Stability tended to increase in parents that were mathematically confident or who saw themselves as ‘good at maths’.

When studying Ian’s I-positions it is evident that many appear contradictory. For instance Ian positioned himself as ‘I as a competent user of mathematics’, ‘I as confused by mathematics’, ‘I as good at mathematics’ and ‘I as not good at mathematics’. As we see when comparing Excerpt 1 and Excerpt 4, Ian’s mathematical position changed depending on context and across time. In Excerpt 1, when discussing helping his daughter Megan with her homework, he positioned himself as a competent user of mathematics, even though he acknowledged that he “wasn’t brilliant at it at school”. When asked directly what he thought of mathematics, shown in Excerpt 4, Ian saw mathematics as a school activity that he was not good at and which filled him with apprehension and dread.

Excerpt 4: Ian – Interview	
Dialogue	I-position
<p>Researcher:</p> <p>What do you associate with the word mathematics?</p> <p>Ian:</p> <p>Probably Numbers, that’s probably the first thing that comes into your brain, numbers. (1) <u>I don’t know because I was rubbish at maths at school (laugh).</u> (2) <u>You probably think, “Oh god not maths again”.</u> Numbers, dread, homework <u>really.</u></p>	<p>(1) <u>I as not good at mathematics</u></p> <p>(2) <u>I as apprehensive of mathematics</u></p>

In a different context, shown in Excerpt 5, this time playing darts with his own father, Ian positioned himself as ‘I as good at mathematics’. This stems from an ability to quickly perform mental multiplication. A change in context and activity produced a

re-positioning towards mathematics. Again, he uses this to compare himself to his daughter.

Excerpt 5: Ian - Interview		
Dialogue	I-position	Social position
And I always say the same thing to her, because growing up when I was 9, 10, 11, 12 me and my dad used to play darts all the time. (1) <u>And I learnt all my numbers from playing darts, growing up with my dad. So anything that's multiplied into 16, treble this, treble that, double that, I got it straightaway.</u> (i) <i>And she's like that.</i>	(1) <u>I as good at mathematics</u>	(i) <i>I as similar to my child</i>

Excerpt 6 shows a change in positioning over time. Ian positioned himself first as enjoying mathematics at secondary school. This is opposite to the position he reconstructed of his primary-level education. Again uses this to support an identification of himself and his daughter.

Excerpt 6: Ian - Interview		
Dialogue	I-position	Social position
Err yeah, well (pause) (1) <u>probably more from secondary school really because I probably started getting it at secondary school</u> whereas sort of (i) <i>when I was sort of Megan's age I was probably exactly like she is.</i> (2) <u>As can't be bothered, don't matter.</u>	(1) <u>I as enjoying mathematics</u> (2) <u>I as not interested in mathematics</u>	(i) <i>I as similar to my child</i>

In the case of Ian, as with the whole sample of parents, it is possible to see chronological instability over time as remembered events and experiences lead to the creation of different mathematical I-positions. Similarly there is spatial instability as different activities result in different I-positions.

DISCUSSION AND CONCLUSION

The case presented in this paper is typical of the findings of this research project. It shows a highly complex mathematical 'self' that is made up of a series of different, and often contrasting, I-positions. These positions can also often be seen to reflect social positions emanating from the surrounding social and cultural environment. The

mathematical ‘self’ can also be seen to shift and alter depending on the mathematical context and also change across a lifetime.

The analysis also shows the potential for using dialogical self theory to better understand mathematical identity, linking a context-specific activity (mathematics) to a context-specific theory of identity (dialogical self theory). A limitation of this research is that it only focuses upon the identity of the parent and does not address the identity of the child. Through involving children in further research it should be possible to use dialogical self theory to better understand the mathematical ‘self’ of both parents and child. In turn this should allow greater understanding of the ways in which experiences shape identity, and identity shapes mathematical activity. This could reveal the extent to which the ‘self’ is shaped by the ‘other’. It could also study the degree to which a child’s mathematical identity reflects the identity a parent holds or constructs for their child. Understanding these kinds of elements is crucial if we are to support parental involvement in children’s mathematical development, a major contribution to mathematical attainment in the UK.

We take an experience of educational failure in school mathematics to illustrate the liberal capitalist ideology at work in educational institutions. This will be done by means of confronting the official discourse, which posits inclusion and equity as fundamental goals of mathematics education, with its actualization within a secondary school, whose student-intake can be labeled as marginalised or underprivileged. What normally runs well within the official discourse, when actualized in a specific practice, often encounters a series of obstacles that end up perverting the official intention. Usually research strives for identifying such obstacles under the imperative to eliminate them. This is assumed to ensure the full actualization of the official aims. However, we are instead interested in understanding these obstacles since they stand for the symptomatic points, which allow one to grasp the ideology manifest in current educational practices.

INTRODUCTION

International organisations (e.g. OECD), professional institutions (NCTM, 2000) and researchers (see e.g. Atweh et al, 2011; Herbel-Eisenmann et al, 2012; Gellert, Jablonka & Morgan, 2010, for very recent editions and conference proceedings) have been positing mathematics education as a key element for the development of a social just and equitable society. It is assumed that a quality mathematics education will allow people to become active participants in a world where mathematics formats many of the decisions that influence our lives. As a result, the main task of mathematics education research has been the development of teaching and learning strategies that can allow a meaningful mathematics for all. The fact that failure in school mathematics persists worldwide is seen by researchers as a contingent occurrence of a system that officially aims at equity and freedom (Pais, 2012; Pais, Fernandes, Matos & Alves, 2012). As such, researchers are often interested in describing successful experiences, showing how the obstacles to the learning of mathematics can be overcome, instead of analysing episodes of failure (Gutiérrez, 2010). This propensity to report successful experiences is supported by a broader ideology that Lacan (2008) characterized as *evolutionism*: the belief in a supreme Good, in a final goal of progress which guides its course from the very beginning. In the case of mathematics education, the supreme goal is “mathematics for all”, and research is set on eliminating the obstacles standing in the way of this goal (Lundin, 2012; Pais & Valero, 2012).

In this paper we present a study of educational failure. We settle our investigation in a secondary school that can be labeled as *marginalised* or *underprivileged*, and analyse two classroom episodes that led to students’ exclusion from learning

mathematics. If we followed the evolutionistic thesis, we were expected to formulate strategies to overcome the problems that led to students' failure. These could be formulated in terms of teacher education (e.g. a different way of interacting with the students), the curriculum (e.g. more challenging tasks), or the classroom organization (e.g. project or work group instead of blackboard centred and individual work). However, we will instead analyse this classroom episode *as it is*. This is because we are not interested in providing solutions for the problems of practice, but to pinpoint the ideological injunctions at work in the way teachers and students interact in the classroom. By analysing things as they are (instead of how they should be), we seek to make visible the incongruences between the official discourse and the life experiences of students and teachers.

We will focus our analysis in the way students decide to participate or not in the activities proposed by the teachers. The frame is set in a way that failure cannot be attributed to anything else than student's individual choice not to participate in the classroom activities. However, as we shall see, this is a false choice since participation in classroom activities also leads to failure. By analysing these cases, we are led to conclude that current educational practices in underprivileged mathematics classrooms initiate students into patterns of decisions not to participate.

THEORETICAL APPROACH

As a point of departure for our analysis we claim that schooling in current capitalist society *needs* failure as an integrative part of its economy (Baldino & Cabral, 2006; Bowles & Gintis, 1977; Pais, 2012). Failure in school mathematics is not an empirical phenomenon that can be solved through better research and the proper crew, but a necessary feature of existing schooling. As such, it becomes paramount to report not only experiences that tell stories of success on the local level, but also episodes that evince how failure is being built at the heart of an educational system that has inclusion and democracy as its self-legitimising principle.

As a way of conceptualizing educational failure, we find support in the work of Slavoj Žižek, who, in the last two decades, has been recovering the outdated notion of *ideology* as a crucial concept with which to understand the dynamics of our current capitalist society. Ideology operates in the discrepancy between the official discourse—which exalts the supreme goals of democracy, equity and inclusion—and its actualization into what Žižek (1997, p. 93) calls a life-world context. What, at the level of the enunciated content, runs smoothly—practically nobody within mathematics education research contests the supreme goal of mathematics for all—when actualized in a specific practice (in our case, school practice) often encounters a series of obstacles which ends up perverting its official intentions. This way, the motto “mathematics for all” functions as the necessary ideological double concealing the crude reality that - under the veil of meritocracy - mathematics is not for all.

Ideology simultaneously conceals its “motives” whilst making them actual and effective. It is in this sense that Žižek (1989, p. 34) says that ideology always appears in its sublated form, that is, its injunctions make effective what it “officially” conceals. When it is claimed that everyone should be provided with a meaningful mathematics education, this official claim conceals the obscenity of a school system that year after year throws thousands of people into the garbage bin that the school system itself erects. This happens under the official discourse of an inclusionary and democratic school. It is in this discrepancy between the official discourse and its (failed) actualization that ideology is made operational. Within the official discourse, what is *necessary* is the abstract motto of “mathematics for all”, all the exceptions to this rule (the ones who fail) being seen as contingencies. However, from the critical/dialectical discourse we are deploying here, what is *necessary* is precisely the existence of those who fail, the abstract proclamation being a purely contingent result of the frenetic activity of individuals (researchers, teachers, politicians) who believe in it. The antagonistic character of social reality – the crude reality that in order for some to succeed others have to fail – is the *necessary* real which needs to be concealed so that the illusion of social cohesion can be kept.

One of the ways of achieving the societal demand of mathematics for all is by implementing ability-streaming at the transition to secondary school. According to the official rhetoric, the stratification of streams shall allow the effective design of classes specifically for students with difficulties in mathematics (or more generally for students with difficulties with so-called abstract thinking). Apparently, students are confronted with the choice of participating or not in the official discourse, by means of active engagement in the classroom activities. However, as Žižek (2006, p. 348) puts it, “[t]his appearance of choice, however, should not deceive us: it is the mode of appearance of its very opposite: of the absence of any real choice with regard to the fundamental structure of society”. In our case, this appearance of choice to participate in classroom activities disavows the absence of any real choice regarding the possibilities these students have of pursuing a valuable education. The system initiates students to blame failure on their own choices in order to keep the appearance of a free and equal school system.

METHODOLOGICAL APPROACH

Mathematics education postulates equity as a crucial democratic value and as a final goal of schooling. This goal is understood to be achievable by some kind of evolutionary process that just demands *more* research and *more effective* research to overcome exclusion in mathematics education. Instances of exclusion are understood as dysfunctional within institutions that are supposed to promote inclusion. By locating our research in the critical research paradigm, and by focus on the *functionality* of exclusion within educational institutions, we seek to show how instances of exclusion are functional in 'keeping the system running'. This is, as pointed out by Popkewitz (2007), a fundamental task of a critical research:

To make the naturalness of the present as strange and contingent is a political strategy of change; to make visible the internments of the commonsense of schooling is to make them contestable (p. xv).

In this article, our problem consists in analysing the functional moments in the exclusion of students from mathematics classroom in a marginalised social environment.

Our critical investigation has been initiated by the discussion of already available data from the "Emergence of disparity" project, in which one of us is engaged [1]. Data-collection used videography, as this project had its main focus on the social interactions that discursively produce mathematical knowledge and consciousness. The focus was rather on the symbolic relations that were produced through interactions than on how interactants perceived this production. Extensive interview-material that systematically captures students' voices on their perception of their own social exclusion and educational marginalization is therefore not available.

However, what we are trying in this paper is to provide a *theoretical reading of a social reality* instead of a 'valid' reconstruction of individual motives and perceptions of this reality. This is in line with the critical orientation outlined above. Therefore, we used a key-incident-analysis (Kroon & Sturm, 2000) as a methodology to reconstruct case studies from the available videotaped material with the intention to explicate our theoretically driven reading of the data. Key-incidents are concrete incidents in the data that researchers deliberately chose to "make explicit a theoretical 'loading'" (Erickson, 1986, p. 108).

These key-incidents were selected from a data-set including videotapes of the first fourteen consecutive mathematics lessons in September 2009 at a low-streaming secondary school in Berlin, Germany. The students were in the seventh grade, in the age of twelve to fourteen. Before the summer holidays they have visited different primary schools and all have finished it with a recommendation to attend the lowest of three available ability-streams in secondary school. The school is settled in a neighbourhood that in the public discourse is often referred to as a ghetto. The students in the classroom are between the ages of twelve to fourteen. They can be considered as underprivileged given the social segregation that results from where they live, by their background as members of a cultural minority, by knowing the instructional language only as a second language learner, and by the institutional selectivity of the German streaming school system. Notwithstanding all these difficulties, the official discourse is one of inclusion and equity, with efforts being made by the school staff in order to make mathematics meaningful and valuable for the students.

ANALYSIS - TWO CASES OF RESISTANCE

In an exemplary report on the mathematics classroom under analysis, we (Straehler-Pohl & Gellert, 2011) have described the pedagogy enacted as one that

in order not to overcharge – infantilizes students and – in order to enable classroom management – objectifies students. [...] Learning in such mathematics classrooms adds to the underprivileged conditions that these learners face. (p. 198).

Classroom interactions are set up in a way that they hardly provide opportunities to acquire mathematical knowledge. Rather, students acquire a "consciousness of one's own ignorance" of mathematics (Straehler-Pohl, forthcoming, p. 19). Even though the cognitive demands set by the teachers were excessively low, students continuously failed on these demands and seemed to have no concerns demonstrating their failure. We concluded that most of the students did not fail because of an incapability of meeting the requirements set on them. Instead, they demonstrated an awareness of the fact that participation in this kind of mathematics education won't bring them back on the road towards participation in a meritocratic society. Failing on tasks can be seen as an integral part of the local classroom culture: For the students, it ensures that they demonstrate to their peers that they do not naively believe in the fallacy of the mathematics classroom. Simultaneously, students' failure on the tasks serves to reassure the teachers that they had been "right" in the excessively low choice of cognitive demands. Thus, taking the decision to participate in the classroom activities means to take part in the construction of one's own marginalisation. It implies not to make use of the opportunity to take a decision not to participate in a senseless and discriminating activity. The local classroom culture can thus be described as a *discourse of learning not to participate*. We will now provide two examples of students who chose to resist to this discourse of learning not to participate and report on the consequences it had for them.

The case of Melinda

Melinda's resistance is characterized by a total refusal of the teachers' authority (most of the times two teachers are present in class). In the beginning of the first math class in this new school, each of the students was required to complete the sentence, "I am feeling ____, because ____". Though just having had rare chances to get to know the second teacher, Melinda articulated the following: "I am feeling bad because today we have class with this teacher [pointing at the second teacher]". During the course of the mathematical activity (performing "887-339" at the blackboard), Melinda spent quite some time talking to Mariella, her classmate, in a foreign language, which was mostly ignored by the teacher, though two times the teacher spoke out an admonishment in a rather calm voice. When Mariella was demanded to finish the task at the blackboard, Melinda shouted at her: "what are you doing bitch?". Though understandable quite loud and clear, this interruption remained unsanctioned. However, a few minutes later, Melinda "collected" (word of the teacher) her third calmly spoken admonishment and was thrown out of the classroom for the rest of the day. The following day, math class took a similar course, resulting in Melinda being thrown out. The third day, Melinda did not appear anymore. She had been expelled

from school. As she was still in the age of compulsory education, she would have been directed towards another low-streaming school in the neighbourhood.

The teacher conceived Melissa's failure as her own personal choice. From teacher's and Melissa's classmates' perspective, she had the opportunity to choose to participate in the classroom activities, but refused to do so. But is this truly a choice of participation?

The case of Hatice

On the third day Hatice, who already was known as a truant to the teachers, appeared in class for the first time. In class, Hatice was quietly doing the calculations demanded of her by the work sheet (such as 9700-300). Hatice was among three students who succeeded in finishing their work sheets. The next time Hatice appeared in class, she completed three work sheets in twenty minutes including 186 simple multiplication exercises. The fourth sheet - that was given to Hatice "as a repetition" (words of the teacher) - claims on top of the page that, "it is now getting harder and harder", and concludes at the bottom that, "if you solve all the problems correctly, you are the king of computations". When Hatice came back to her seat and started filling in the solutions on the work sheet (see Fig. 1), the second teacher asked her to "read the instructions first". However, there were no instructions for the first 54 exercises. Ignoring Hatice's confusion, the teacher commanded, "read!". It was not before task no. 7, that there was an instruction. Hatice did not show up anymore during the following lessons.

Discussion of the two cases

It seems straightforward to read the case of Melinda as case of resistance, which is characterised by a clear and absolute stance of opposition. She makes very clear that she is not about to acknowledge the teachers' authority and thus is not about to participate in any of the activities imposed by the teacher. Instead she uses them to stage her resistance. For the teachers, entering a dialogue with Melinda would require taking a step up towards her and to give space to her voice. The teachers are not willing to do this, but still they also do not use their authority to react oppressively. They just rarely raise their voices and never shout, even though at times this would appear quite comprehensible. Admonishments were not characterised explicitly by threats of punishment, but by some sort of countdown

It is getting harder and harder - number range up to 10.000. Respect the transitions!

1. 4509 + 2 =	3490 + 20 =	8970 + 40 =
3804 + 7 =	7180 + 70 =	1990 + 50 =
7205 + 9 =	2570 + 90 =	5980 + 60 =
2. 3400 + 760 =	2780 + 45 =	3247 + 80 =
8900 + 480 =	1460 + 52 =	1199 + 20 =
7600 + 690 =	9690 + 69 =	7881 + 40 =
3. 2800 + 754 =	7997 + 4 =	5600 + 2800 =
6700 + 986 =	4995 + 9 =	4800 + 2400 =
8900 + 211 =	1999 + 8 =	1900 + 2700 =
4. 5000 - 50 =	3200 - 60 =	4200 - 400 =
8000 - 80 =	6100 - 90 =	7300 - 900 =
2000 - 10 =	9300 - 70 =	8100 - 600 =
5. 8000 - 8 =	5200 - 7 =	2482 - 6 =
2000 - 4 =	1700 - 4 =	8113 - 5 =
6000 - 5 =	9800 - 1 =	3685 - 9 =
6. 3200 - 23 =	8000 - 45 =	9010 - 40 =
4400 - 98 =	3000 - 21 =	6020 - 80 =
7900 - 11 =	5000 - 83 =	4030 - 60 =

7. Write all the exercises in the form of packages and compute them!

4000	4500	1740	2375	+	2	20	200
6000	5800	7690	9764	-	3	30	300

When you have solved all the tasks correctly - then you are the king of computations.

Fig. 1: Worksheet (translated)

leading towards physical exclusion from the class. The message is clear: Melinda's resistance is her own choice; she gets the opportunity to decide to participate in the classroom activity herself. Thus, Melinda is agentic in her own exclusion. Apparently, she took the opportunity to decide not to participate in the meaningless classroom activity, thus it seems as if she herself was responsible for the consequences: i.e. expulsion from the school.

The case of Hatice (when being present) is quite contrary. By apparently taking the decision to participate in the activity seriously and with dedication, she goes through it so fast, that the meaninglessness of the whole activity becomes visible for all those participating. When we read Hatice's behavior as a case of resistance, then we have to identify a different target than mere authority. Through her dedication, Hatice seems to be participating in a different activity than her classmates: It seems as if struggling with the work sheet is an integral part of the game that the teachers and the students are playing. Thus, just finishing it, as if it was no demand at all but just a practice of mechanical routines posits her outside the activity. Thus, Hatice also makes use of the opportunity to decide not to participate in the classroom activity. Hatice's resistance is thus not targeted at the superficial power-relations that guarantee the teachers' authority, but it is targeted at the underlying tacit rules of the game. It seems as if this does not remain unnoticed by the second teacher: instead of complimenting her for carrying out (correctly) three times as much calculations as her peers, she *invents* some illusive instructions to slow down Hatice. It seems as if the teacher signals her that she should rather participate in playing the game in the way her peers do. The message communicated to Hatice is that the way she participates is not considered to be legitimate. As a matter of course, Hatice's succeeding absenteeism is not taken as a challenge to question the organisation of classroom activities. Instead it is constructed as a matter of "truancy", as if it was a personal attribute.

DISCUSSION AND FINAL REMARKS

Apparently the "choice" that students face regarding school mathematics is one between participating in the classroom activities and refusal to participate. However, the argument of this paper shows that in certain mathematics classes, the choice is not an "individual" choice between participating and not participating, but between two modes of "non-participation". On the one hand, participating in classroom activities that contribute to an understanding of one's own ignorance of mathematics. This implies participating in one's own stigmatization and one's own exclusion from access to socially valued vocational and educational opportunities. On the other hand, the alternative is a straightforward non-participation by abandonment or exclusion from the school system. Regarding the first option, although the majority of students explicitly participate in the classroom activities, the narrow-mindedly mechanical and arbitrary activities guarantee that the outcomes of this learning will not provide students the right skills and knowledge to open up further educational or

vocational options. Thus, students' decisions to participate in classroom activities results in their non-participation in further education, in very much the same way as the direct decision not to participate. As such, the choice is a false choice, since in either ways students are paving the way of exclusion from a consensually valued form of life. At best, students can postpone the materialisation of an already determined exclusion.

We claim that this report reveals that we do risk a lot when we keep on considering educational failure as the unpleasant obstacle on the didactic road towards salvation. While the particular instances reported here make it easy to blame the teacher (and her pedagogical actions), we want to stress that it is not only the teacher, who *organizes* meaningless activities, but also the majority of students who actively *participate* in the *game of failure*, however demandless and meaningless the activities are. Together, the teachers and the students continue a system, where failure *is* a necessity and a predictable result of the process. An extensive interview with the teacher indicates that the reasons neither lie in the teacher's individual pedagogical ineptitude nor in a lack of professionalism; it is rather, the result of long years of experience in one and the same school that constantly and apparently inevitably produces failure. The reasons also neither lie in the students' cognitive inability nor in their bad behaviour; it is rather, a result of six years of school, showing them that *they are not the ones who profit from making use of their agency*. Thus, instead of choosing the path of resistance in claiming their right for a meaningful, demanding and empowering education, the students prefer to play the game of failure. Thus, the *necessity* of educational failure is a *result*, namely a result of the systematic organization of segregation for the supposed sake of the objects of segregation. To re-turn necessity into a contingency and thus, as a changeable educational phenomenon, we would need to deconstruct the naturalness of segregation.

A meritocratic legitimation of the school system presupposes that schools are places where equal students meet freely, and where some kind of “invisible hand” guarantees that the competition of individuals' egotisms works for the common good. What such an approach makes invisible is that such merit is possible only by the demerit of others, i.e., the notion of personal merit is only possible as long as others fail. This is the liberal capitalist ideology at work, by means of making individuals recognize their choices as their own, as free choices that they took – especially when these choices imply failure. Finally, a failed student is robbed of the ownership of all the work s/he produced: All the time he spent in school, is not his or her own, since he will not receive the diploma at the end of the year. However, without producing all this work, it would be impossible for him or her to keep living within the system [2]. Thus, it becomes an imperative that individuals must realise failure as the result of a wealth competition among equals, and repress the traumatic truth that they fail so that others can succeed. Schools need this subversive

supplement in order to retain their indispensable role in maintaining our democratic and inclusive society. In order for school to be the most important ideological apparatus, to function as a credit system (Vinner, 1997), it is not productive for it to be presented as an exclusionary institution. In order to perform well in the role of credit systems, schools need to be presented as inclusionary and emancipatory places, places where phenomena such as exclusion and failure are seen not as necessary parts of the same system which purports to be trying to abolish them, but as contingent problems, malfunctions of an otherwise good system.

NOTES

1. For more details, see Knipping, Reid, Gellert and Jablonka (2008).
2. We should note here that school represents one of several possible systems. It represents the dominant system within our society and the fact that school is compulsory for everyone ensures that no one remains unaffected by the dominance of this system.

MATHEMATICS FOR ALL AND THE PROMISE OF A BRIGHT FUTURE

Paola Valero

Aalborg University, Denmark

That “Mathematics is for all” is a recent statement in mathematics education research. Nowadays it is closely linked to the promise of social, economic and cultural development. It has become a commonsense statement positions mathematics education centrally in achieving a bright future. I examine the statement using an analytical strategy grounded on the cultural historical analysis of Michel Foucault and the examinations of the school curriculum as social epistemologies as presented by Thomas Popkewitz and collaborators. Three distinct but related elements allow me to examine the ideas on which “mathematics for all” emerged during the 1980’s. The elements point to the relation between the statement and the construction of exclusion for groups of students, particularly those of “low socioeconomic status”.

THE COMONSENSE OF “MATHEMATICS FOR ALL”

That people’s scientific and mathematical knowledge is important for the future well-being of society has become an idea that plagues commonsense. Parents, politicians, employers, teachers, and even children themselves have all learned the lesson well. Who would question the need for scientists, engineers and mathematicians for producing the great technological progress that has made the world reach this high point of advancement —and decay, as well? The idea that mathematics —as well as science— with all its applications in technology is the motor for achieving the promises of Modernity and that, therefore, their teaching and learning are central to the constitution of massive school systems is as old —or new— as the end of the 19th century. While towards the end of the 19th century those who had learned mathematics were struggling to find a place for its teaching in the classic curriculum of many European countries (Howson, 1974), now at the beginning of the 21st century the school curriculum without mathematic is unthinkable. Even more so, recent policies in various countries start over privileging mathematics at the expense of other subjects. The involvement of mathematicians with education was during most of the 20th century concerned with securing that an intellectual elite of highly competent youth would feed the production of mathematicians at universities. The issue was not a matter of quantity, but of quality (Jurdak, 2009): Enough but few would be educated in the finest form of human thinking. With the configuration of contemporary universities, those people would provide a highly valued knowledge to other disciplines in the pure sciences and the growing amount of applied scientific and engineering fields. They were the ones to

educate mathematics teachers. They were the ones to produce the highly desired and needed knowledge for the progress of society.

Nevertheless, the idea that mathematics should be for all—for each one and everybody, not only for all those who engaged with the study of mathematics—is an even more recent idea that is made intelligible at the end of the 20th century. The grid of conditions on which the statement of “mathematics for all” emerges is more complex than the natural evolution of education in an increasingly technological society or a response to the demands of the knowledge society. The statement is produced on the grounds of the advancement of mathematics education research as a field of scientific inquiry on the teaching and learning of mathematics and all its associated social and cultural phenomena. While until the 1970’s the beginning of systematic reflections about the teaching and learning of mathematics were focused on securing the excellence of those few who had an interest in the subject, the 1980’s started to be the time of the democratization of mathematics, of mathematics for all to empower all, and, more recently in the 2000’s, of mathematics for all to secure the national competitiveness in the global knowledge economies. Such formulated statement is an expression of a desire, of a normative vision that should guide policy proposals and, above all, research-based interventions to provide access to as many as possible to the important and valued knowledge. Such statement is however not an innocent declaration of good wishes for the future. The aim of this paper is to explore how at least three connected events during the 20th century set the ground on which it becomes possible for mathematics educators and now for the public in general to desire a “mathematics for all”.

For such exploration I start by locating my analytical strategy within the area of cultural studies of schooling and the curriculum and making available some of the main concepts in my theoretical toolbox to examine the school mathematics curriculum. I then deploy my tools on three elements which, I will argue, make part of the grid on which nowadays the statement “mathematics for all” can be thought. I conclude with some remarks on the usefulness of a cultural historical approach in the study of mathematics education.

ANALYTICAL STRATEGY: DECENTERING THE COMMONSENSE

The appropriation of the work of Michel Foucault in education has prolifically nurtured critical studies of schooling and the curriculum (e.g., Popkewitz & Brennan, 1998). In mathematics education it has been appropriated to think about the constitution of learners and teachers as subjects within the web of power of the institutional discourses of mathematics education practices (e.g., Walkerdine, 1988; Walshaw, 2004). Such studies have provided insightful interpretations of students’ and teachers’ identity formation in terms of their process of subjectivity in the practices of mathematics education. Walshaw (2004) claims that thinking mathematics teachers’ practices with the analytical strategies and concepts of

Foucault help her decentring the essentialist assumptions that other types of literature build around teachers' knowledge, beliefs or experiences as being the fundamental core of their identity as mathematics teachers. Although important in a quest for understanding the socio-political constitution of mathematics education practices, such approach that still focuses on some of the traditionally defined actors and elements of the classic didactic triad of mathematics education research is, from my view point, not enough to decentre the many essentialisms that the discourses of mathematics education have established.

Recent studies inspired by the work of Foucault deploy analytical strategies to explore the epistemological functioning of mathematics education discourses and their effects of truth in generating ways of thinking about mathematics education. Knijnik and collaborators (Duarte, 2009; Knijnik, 2012; Knijnik & Wanderer, 2010) have been not only examining ethnomathematics philosophically, but also providing cultural histories of statements that navigate as truths and have become the common sense of mathematics education. That “we need to bring reality to the classroom” as a pedagogical strategy, that “we need to use concrete materials for teaching”, or that “we have to promote mathematics for all” are not simply the accumulated knowledge that comes from applying research into the improvement of practice. Such statements epitomise culturally and historically inscribed forms of thinking about mathematics education. The work of Foucault and his strategies to perform a “social epistemology” (Popkewitz, 1991) of mathematics education as part of the school curriculum is an important move in order to:

“[...] place the objects constituted by the knowledge of schooling into historically formed patterns and power relations. Epistemology provides a context in which to consider the rules and standards by which knowledge about the world and “self” is formed. Epistemology also provides the means to investigate distinctions and categories that organize perceptions, ways of responding to the world, and the conceptions of “self.” Concurrently, social epistemology locates the objects constituted by the knowledge of schooling as historical practices through which power relations can be understood. Statements and words are not signs or signifiers that refer to and fix things, but social practices that generate action and participation.” (Popkewitz & Brennan, 1997, p. 293)

In other words, thinking mathematics education with Foucault in terms of making a social epistemology of mathematics education as part of the school curriculum allows us evidencing the way in which mathematics education and mathematics education research practices together and inseparably generate concepts, distinctions and categories that regulate the possibilities of thinking and being in/with mathematics as a privileged area of knowledge in the school curriculum.

It is important to my examination of the taken-as-truth statement that “mathematics education is for all” Foucault’s analysis of the involvement of fields of academic inquiry and knowledge in the production of the ordering of Modern life (Foucault, 1971), and of the organisation of different technologies of governmentalisation

(Foucault, 1997; Lemke, 2001). As I have argued elsewhere (Pais & Valero, 2012; Valero, 2008), understanding mathematics education as political enlarges the research gaze to notice and indeed focus on the way mathematics education research is implicated in producing and organizing what is conceivable as “mathematics education”. In my exploration in this paper I build on Popkewitz’ (Popkewitz, 2008) insights in how educational sciences have provided the tools for fabricating the cosmopolitan child through being a cornerstone of the planning of social life for the promise of a better and brighter future. In this paper I connect the statement of the need of a mathematics education for all for creating a brighter future with the way in which educational sciences in the 20th century have produced the elements for the reasoning making possible such statements.

One important effect of the school (mathematics) curriculum as a process of governmentalisation is its operation as mechanisms of classification of people. As technologies that embody the norms of reason and reinscribes them in populations and in individuals, the mathematics curriculum operates inclusions/exclusions. Popkewitz (2008) argues that any cultural thesis about the subjects of schooling effects abjections. Abjection is the way that exclusion is generated as the effect of defining the norm for inclusion and its hope for those who are not part of that norm. The statement “mathematics education is for all” functions as a discursive device that declares the necessity of making of success in mathematics learning the norm. While the statement apparently sounds as the expression of an intention of exclusion, it operates simultaneously the exclusion of those who do not comply with the norm (Popkewitz, 2004). The mathematics curriculum as a technology of the self effects in children’s mind, bodies and conduct the compliance with the norm, and thus operates inclusions and exclusions. This way of thinking brought me in my inquiry to focus on the doubleness of the words “mathematics for all”. If mathematics for all embeds those for whom learning mathematics is not possible, I looked at how, historically and in the formation of the social sciences and mathematics education research there were forms of identifying for whom learning mathematics is not possible.

This means that an examination of the statement that mathematics is for all as part of the logic of the curriculum as governmentality techniques invites to consider how the formulations of inclusion in relation to education and mathematics education identify those for who are not meant to be included and be successful in school mathematics. In other words, the emergence of mathematics for all as an important statement in in the current functioning of the mathematics curriculum emerges on the grounds of many children who had been abjected and for long time had been excluded from having a chance of success in school mathematics. Thus the examination of the statement of mathematics needs to be for all goes hand in hand with the examination of statements about those who do not succeed. In this case I will concentrate on the relationship between statements such as students with low socio-economic status do not succeed in mathematics and the statement of mathematics is for all.

My analytical strategy involves visiting a number of interconnected spaces that without any linear or strict logical connection, but rather with discursive resonance, map different aspects of the statement under examination. A rhizomatic analytical move (Deleuze & Guattari, 1987) of how this idea is made thinkable becomes a strategy. I also move in the connection of ideas in time and space. As mathematics education research is thought as an international field of inquiry, and probably because for many of its practitioners mathematics is still conceived as a universal activity, then as much as there are particular reinscriptions of these ideas in national or local contexts, at the same time there is a tendency to an abstract, internationalized discourse about what those ideas are and how they could be played out. In keeping my eye on the ideas that circulate across nations I try to make evident how a field of inquiry generates truths that seems to be transferable from place to place and from time to time, contributing in this way to the reification of mathematical ability as a human ability and right that equates with reason, and with that installs one unified logic of being.

EDUCATION, SCIENCE AND THE SOCIAL QUESTION

The social sciences and educational research can be considered as expert-based technologies for social planning. In the consolidation of Modernity and its cultural project in the 20th century, the new social sciences were seen as the secular rationality that, with its appeal to objective knowledge, should be the foundation for social engineering. The invention of statistical measurements in the social sciences generates constructs that help identifying the ills of society that science/education needed to rectify. This is an important element in how educational sciences address the differential access of different children to the school system. Constructs such as students' "socio-economic status" —later on expanded to school's and communities socio-economic status— emerged in the 1920's in a moment where the newly configured social sciences were addressing *The Social Question*, that is, the growing problems with crime, poverty, alcohol abuse, sexual abuse, school underachievement, etc., of the growing population in urban centers (Popkewitz, 2008) caused by immigration and the urbanization of many other types of populations. In Europe and in other societies, the association between the religious and normative grounds of educational thinking and the emergence of educational sciences made possible to articulate salvation narratives for facing the social problems for which education was a solution (Tröhler, 2011). How "the Social Question" was addressed in different countries in the turn between the 19th and the 20th century allows to see the different religious, political and economic rationalities behind making of education the motor of modern development (e.g., Tröhler, Popkewitz, & Labaree, 2011).

Despite particular inscriptions in space, there is a common thread in the way in which the social sciences were devising technologies to deal with difference from the values of a dominant class that at that time has already established itself as the norm

for measurement of all types of deviation. The “nurture–nature” debates —on whether it is the innate, genetic charge of an individual what is determinant in people’s “right” development, or whether it is what the environment makes available the determinant of one’s development— emerge hand in hand with the dilemma of how to govern a growing unfit population, and the pressures of democratization of education to tame the masses and make them productive, well trained work-force. Measurements of intelligence, measurements of achievement and measurements of socio-economic status were and still are technologies to provide the best match between individuals and educational and work possibilities. The double gesture of educational sciences of, on the one hand keeping a rhetoric for the importance of access to education, and on the other hand reifying difference by constructing them as a fact, inserts human beings in the calculations of power.

MATHEMATICS AND PROGRESS

The emergence of the connection between people’s mathematical qualifications and social progress can be traced to the end of the 19th century. During the second half of the 19th century, mathematics teachers in different countries struggled to make mathematics part of school the classic school curricula. Its place was relegated to vocational and military forms of education (See Howson, 1974 for the case in England). In the first number of the journal in 1899, Laisant and Fehr (1899), envisioned the important mission of the journal in contributing to the international, systematic and serious reflection on and study of mathematics education. They recognized the importance of the *preparation* of teaching staff, a group of “teachers deeply engaged with their mission, consecrated to it with all their devotion, instruction and intelligence” (p. 1, my translation). During the second industrialization, a time of tremendous scientific advancement, teachers had realized that *betterment* is always possible, no matter which pedagogical strategies teachers had used. The justification for the need for betterment was formulated as follows:

“The future of civilization depends greatly on the direction of mind that the new generations will receive in relation to science. Within the scientific education, the mathematical element occupies a dominant place. From the point of view of the pure sciences or from the point of view of the applications, the 20th century that is about to begin will place demands which nobody must or can avoid.” (Laisant & Fehr, (1899)

In the times of the Cold War, a similar argument emerged, however the justification was related to keeping the supremacy of the Capitalist West in front of the growing menace of the expansion of the Communist Soviet Union (Kilpatrick, 1997). Nowadays, professional associations argue that the low numbers of people in STEM fields can severely damage the competitiveness of developed nations in international, globalized markets (e.g., National Academies, 2007).

The narrative that connects progress, economic superiority, and development to citizen’s mathematical competence is made intelligible in the 20th century. The

consolidation of nation states and the full realization of the project of Modernity required forming particular types of subjects. The mathematics school curriculum in the 20th century embodied and made available cosmopolitan forms of reason, which build on the belief of science-based human reason having a universal, emancipatory capacity for changing the world and people. The ‘homeless mind’ (Berger, Berger, & Kellner, 1974 cited in Popkewitz, 2008, p. 29; Popkewitz, 2008) that school mathematics has operated is a type of individuality where the subject is set in relation “to transcendental categories that seem to have no particular historical location or author to establish a home” (Popkewitz, 2008, p. 30). In this way, subjects are inserted in a logic of quantification that makes possible the displacement of qualitative forms of knowing into a scientific rationality based on numbers and facts for the planning of society (Poovey, 1998). Thus, from the turn of the 19th century to our days the mathematics curriculum is an important technologies of the self that inserts subjects into the forms of thinking and acting needed for people to become the ideal cosmopolitan citizen.

MATHEMATICS FOR ALL IN RESEARCH

That high achievement in mathematics is a desired and growing demand *for all* citizens is a recent invention of mathematics education research. In the move between the years of reconstruction after the Second World War and the Cold War, where school curricula was modernized with focus on the subject areas for the purpose of securing qualified college students (Rudolph, 2002; Thompson, 1959), mathematics education in the decade of 1980s faced the new challenge of democratization and access. The “Mathematics Education and Society” session at ICME 5 in Adelaide is seen as the first formal session in an international mathematics education conference to have publicly raised the need to move beyond mathematical elitism towards inclusion of the growing diversity of students in school mathematics. The well-documented systematic lack of success of many students in school mathematics was posed as a problem that mathematics education research needed to pay attention to and take care of. Mathematics education researchers, the scientific experts in charge of understanding the teaching and learning of mathematics as well as of devising strategies to improve them, took gradually the task of providing the technologies to bring school mathematics to the people, and not only to the elite. The idea of succeeding in mathematics as an issue of equity was made intelligible in a historical grid of events at the end of the 20th century. The identification of mathematical achievement with the wealth of nations is a result, among others, of the growing series of reports that produced comparative information on educational achievement and development (e.g., Baker, Goesling, & LeTendre, 2002; Heyneman & Loxley, 1982). Such reports can be seen as performances of the comparative logic of Modernity that operates differential positioning, not only among individuals but also among nations, with respect to what is considered to be the desired and normal level of development and growth.

“Mathematics for all” can be seen as an effect of power that operates on subjects and nations alike to determine who are the individuals/nations who excel, while creating a narrative of inclusion for all those who, by the very same logic, are differentiated. As Popkewitz (2004) points, the rhetoric of inclusion in mathematics education embeds in itself the exclusion of those whose forms of being are distant from the norm.

BEYOND THE PROMISES OF A BRIGHT FUTURE

I argue that it is on the grounds of at least these three elements that the it is possible to examine the ways in which during the 20th century the statement “mathematics education is for all” came to enter the discourses of school mathematics. The mathematics curriculum as a technology of governmentalization installs the framework within which it is possible to think of school mathematics. Such ideas that organize populations as well as subjects work on the doubleness of a statement such as “mathematics for all”. While apparently declaring the necessity of inclusion, the statement draws clearly the boundaries for who are not part of the “all” included in the statement. In other words, mathematics for all implicitly states that mathematics is not for all, and that those for whom participation in school mathematics is not a possibility need redemption. The redemption and help should of course come from the successful application of the technologies devised by mathematics education research.

My analytical move allowed pointing to at least three rhizomatically connected nodes. First, the social sciences and educational sciences in particular have during the 20th century built statistical measurements that put forwards constructs such as “socio-economic status”. Such measurements identify and reify the people who do not fit with the norm. Second, the association of mathematics with the narrative of progress during the 20th century builds on the operation of the homeless mind citizen of Modernity. Third, mathematics education research brings together the fear for those who do not comply with the norm with the narrative of a bright future with mathematics. Mathematics education research and its statement on the need to make mathematics education fro all incorporates the excluded, the ones who have to be brought into the calculations of power. It redeems them by making low socio-economic students part of the didactical efforts of mathematics education.

I do not intend to say that being one of the persons who does not achieve as expected because of one’s differential position of socio-economic status is simply an unimportant “social construction”. My intention is to offer a way of denaturalizing the commonsense of a statement such as “mathematics is for all”. The denaturalization makes visible the network of historical, social and political connections on which the fact that differential students’ social and economic positioning is related to differential mathematical achievement.

SINGLE-SEX MATHEMATICS CLASSROOMS IN PUBLIC SCHOOLS: A CRITICAL ANALYSIS OF DISCURSIVE ACTIONS

S. Megan Che & William Bridges

Clemson University, USA

This poster will present the results of a critical discourse analysis of classroom lesson sessions from middle grades public mathematics classes. The teacher of interest for this particular poster session is responsible for coeducational, all girls, and all boys classes. The data for analysis derive from 10 instructional sessions for each of these class types, giving a total of 30 lesson session transcripts for analysis. The authors employ a critical theoretical frame, from a feminist perspective, to the discourse analysis. Findings indicate that, at a macro-level, the academic rigor of the learning environment is consistent across the three class types. However, momentary utterances by teacher and students indicate more nuanced differences in the socio-cultural classroom environment.

POSTER CONTENT

Study Context

The participating school of focus for this presentation is a public middle school with approximately 700 students in the southeastern U.S. More than half of the students at this middle school receive subsidies for meals, indicating a lower-than-median socio-economic status. In 2011, this school received ratings of Average on the Annual Report card; in 2012, however, the school was given a grade of A (the district as a whole received a grade of B). Thus, there are mixed indications about the academic ‘quality’ of this school. Single-sex classes in mathematics (among other academic subjects) have been an option at this school for several years. There are some 8th grade students at this school who have had single-sex classes in at least one academic subject for four years. This presentation focuses on one 6th grade mathematics teacher (male) who teaches coeducational, all girls, and all boys mathematics classes. The research focus for this study—a critical analysis of the discourses in this teacher’s classes—is part of a larger, federally funded project investigating classroom environments in single-sex mathematics and science public school settings.

Methodology

We are using critical discourse analysis, which “highlights the ways power relations work implicitly through language, demonstrating how language practices serve to reproduce and perpetuate power hierarchies and how language practices may be used for intervention and control” (Curran, 2008, p. 82). Within this critical classroom discourse analysis, we incorporate a thematic analysis (Lemke, 1990) as well as an analysis of discourse moves (Chapin, O’Connor, & Anderson, 2003; Krussel et al.,

2004). The thematic analysis reveals semantic relationships in classroom discourse, while an analysis of discourse moves focuses on actions teachers and students take to participate in or influence discourse.

Findings

This case study of one educator who teaches three different class types is part of a large research project involving several other teachers, students, and classes. The data were collected during the spring of the 2011-2012 academic year and thus are under analysis. We have collected more than 100 lesson sessions in addition to data related to student academic performance, student academic self-concept, and classroom academic rigor. The 30 lesson sessions from the teacher in this study are the first to undergo discourse analysis at the utterance level; we focus on this teacher because he is one of two mathematics teachers participating in this study who taught all three different classroom types. Though analyses are ongoing, preliminary indications point to the importance of this level of fine-grained analysis because of the ephemeral nature of momentary utterances; their transitory nature, however, masks the potential impact of such utterances on students' constructions of social norms (including gendered norms and academic norms). Discourse analysis is a way of capturing those fleeting moments in time that have potential for impact disproportionate to the quantity of time it takes to utter the statement.

POSTER STRUCTURE AND ORGANIZATION

The poster will be organized into three columns; transcript excerpts illustrating the emergent discursive themes will occupy the middle column. Illuminating excerpts will be included from all three class types (coeducational, all girls, and all boys). The first column of the poster will house the research statement, relevant scholarship, and methodology sections. Articulation of the discursive themes, a summary of the findings, and a discussion section will occupy the third column.

SOCIO-POLITICAL ISSUES IN THE CONTEXT OF DIFFERENT CONCEPTUALIZATIONS OF SUBJECTS

Reinhard Hochmuth

*Leuphana University Lüneberg & Centre for Higher Education in Mathematics,
Germany*

The explication of a socio-political dimension within issues related to mathematics education in school, university and research is crucial for a full understanding of subjective experiences by students, teachers and researchers. Different conceptualizations of subjectivity within society by Radford & Roth, Brown and Holzkamp are discussed and compared with respect to their inherent concretizations of specific societal assignments.

BACKGROUND

In a series of papers (Pais & Valero, 2011, 2012) claim that the political dimension is often neglected in the research on mathematics education. Furthermore they advocate the thesis that this is not only true for the so-called (quantitative and qualitative) “mainstream” in educational research but also for “critical approaches” following the paradigm of the cultural-historical school for example. This situation in research corresponds to the observation that socio-political issues typically do not play an important role in subjects’ reflections on individual experiences in the contexts of studying, teaching or researching, either. In (Pais & Valero, 2011), the authors argue that the disavowing of a political dimension “is precisely one of the strongest limitations for bringing equity and quality together.”

The poster was rooted in the conviction that the socio-political dimension does not only come up in the structure of schools and universities as “credit system”, “production of failure” or as the crucial ideological state apparatus in the reproduction of capitalism (Althusser, 2001). Beyond that, a socio-politically informed reading of school and university mathematics requires an adequate conceptualization of “subjects”. Categories are needed that allow in particular to analyze one’s own experience in the stream of life within a capitalistic society, its intertwined cognitive and emotional aspects like feelings of anxiety, anger or vague indispositions. The categories should enable subjects to relate themselves to the societal context such that its contradictions can be reflected, and that restricted actions which remain within a reproduction of those contradictions may potentially be overcome.

THE POSTER

The starting point of the poster was the observation that the understanding of the historical specificity of society and consequently that of subjectivity is debatable. The concrete goal was to work out differences in conceptualizing subjectivity between

the following three approaches taking into account their inherent concretizations of societal assignments:

- a) the cultural-historical approach *sensu* (Roth & Radford, 2011),
- b) the Lacanian approach *sensu* (Brown, 2008a, 2008b) and
- c) the subject-scientific approach *sensu* (Holzkamp-Osterkamp, 1991; Holzkamp, 1991).

In particular, from a) to c) an increasing conceptual abstractness of applied historic-specific societal categories could be observed and related consequences for the categories that allow to analyze subjective experiences in educational contexts were discussed. Details has to be presented elsewhere.

“IT DOES MAKE YOU FEEL A BIT HOPELESS”: PARENTS’ EXPERIENCES OF SUPPORTING THEIR CHILDREN’S SCHOOL MATHEMATICAL LEARNING AT HOME

Richard Newton & Guida de Abreu

Oxford Brookes University, UK

Parental support of children’s learning in mathematics has long been an aim of policy makers. However, a number of studies have suggested that factors exist which inhibit parents from playing an active role in their children’s mathematical education at home. Using a sociocultural perspective I report findings from a PhD project investigating how parents support their primary school children’s mathematics. Here we draw on narrative-episodic interviews undertaken with 24 parents of primary school-aged children. The parents were asked to recount their experiences of learning mathematics and of doing school mathematics with their children. This data was thematically analysed in order to develop an understanding of parents’ personal mathematical histories, their perceptions and representation of primary school mathematics, and their experiences of completing school work at home with their children. From this it became clear that the majority of parents in the sample faced a number of problems and impediments to supporting their children’s conceptual development in mathematics. Examples of these experiences, such as divergent understandings, curriculum changes and motivation are presented. It was also found that parents appeared to utilise a wide-range of strategies and approaches to overcoming these barriers. Illustrations of these strategies, for instance parental guidance and evaluating understanding are discussed. Dangerous

The content of this poster is displayed in discrete sections that:

- 1) Introduce the area of study, for example outlining the findings of Desforges and Abouchaar (2003) regarding the significance of parent-child interaction in academic outcomes for primary-aged children.
- 2) Highlight the four key research questions of the wider study, namely:
 - How do parents support children’s development of conceptual understanding of primary school mathematics?
 - What techniques and strategies to parents use to support their children’s mathematical development?
 - What barriers do parents face in supporting their children’s mathematical development?
 - In what ways do teachers and schools shape parental experiences and teaching practices?

- 3) Outline the characteristics of the study participants and the main method of data collection, namely episodic interviews (Flick, 2000).
- 4) Discuss the thematic analysis (Braun & Clarke, 2006) undertaken on parental interview transcripts.
- 5) Describe the key findings that emerged from the study concerning:
 - Parents' representations of mathematics
 - Parents' representations of parent-child school mathematical interaction at home
 - Parents' representation of communication with school shaping parental mathematical practices
- 6) Concludes by showing how the findings of this study link to contemporary research stressing the importance of parents' past experiences mediating their current activity (O'Toole & Abreu, 2005) and the different barriers parents face supporting their children (McMullen & Abreu, 2011).

INTRODUCTION TO THE PAPERS AND POSTERS OF WG11: COMPARATIVE STUDIES IN MATHEMATICS EDUCATION

Eva Jablonka (Sweden/UK)

Paul Andrews (UK/Sweden)

Richard Cabassut (France)

Christine Knipping (Germany)

Keywords: *Comparative curriculum analysis; validity of comparison; language and mathematics education; transition between school sectors; school-based teacher education; mathematics teacher beliefs; mathematics teacher guides; mathematical modelling; number sense; affect in mathematics education*

SUMMARY OF THE GROUP'S ACTIVITIES

The working group adopts an eclectic perspective on comparison, preferring to conceptualise it as a fundamental process of research rather than limit it to cross-cultural or cross-national forms. The twelve papers presented and discussed in the working group focused on both cross-cultural and cross-contextual similarities and differences across a wide range of aspects and levels of mathematics education. Moreover, the relatively small number of papers presented allowed for very full and professionally fruitful discussions of the issues they raised.

Group participants came from a range of institutions in Australia, Estonia, Finland, France, Germany, Sweden, the United Kingdom, the United States of America and Vietnam, while co-authors unable to be present represented institutions in Belgium, Chile, Latvia and Spain. The papers were arranged in five broad interlinked themes in order to facilitate discussion of the general issues of interest outlined in the call for papers. Indeed, all presentations provoked discussion of methodological and substantive relevance to comparative education research in general and to mathematics education research in particular. In the following summary, only presenters' names are given for papers that were multiply authored. A full list of papers and all authors is provided on the last page of this report.

Theme 1: Comparing curricula – goals and methodologies

Three papers were grouped under this theme:

A cross-national standards analysis: quadratic equations and functions (presenter: Melike Yigit, Purdue University, USA)

This paper compared four culturally different countries' – the Caribbean, China, Turkey and, as reflected in the Common Core State Standards for Mathematics, the USA - curricular presentations of quadratic equations and functions. Analyses, undertaken against three dimensions; content, mathematical reasoning and cognitive level, found much cross-cultural variation in systemic expectations.

Modelling in French and Spanish syllabus of secondary education (presenter: Richard Cabassut, IUFM, Strasbourg University, France),

This paper compared the curricular presentation of mathematical modelling in France and Spain. Drawing on the anthropological theory of didactics (ATD) it highlights well differences in the two systems' conceptualisation of modelling, not least with respect to its position as either explicit or implicit curriculum knowledge.

Analyzing mathematics curriculum materials in Sweden and Finland: developing an analytical tool (presenter: TuulaKoljonen, Mälardalen University, Sweden).

This paper compared teacher guides, as textbook support for teachers, from Sweden and Finland. Exploiting an analytical tool developed in science education, the study examined how and to what extent the guides could support teachers' professional learning. The results indicated considerable differences in the ways in which teacher guides are conceptualised and, therefore, prone to supporting teacher learning.

The issues emerging from the general discussion focussed on methodological questions of curriculum analysis and on levels of curriculum. Reviews of the role of teachers' guides (whether as support for a textbook or an official curriculum document) and of the level of autonomy of curriculum agents (textbook authors, schools, Head teachers) for each of the participants' countries provided interesting insights into the diversity of organisational forms and steering mechanisms. This diversity was acknowledged to be an important factor when choosing an appropriate methodology or level of analysis. Linked to this was the general issue of whether it is appropriate to use frameworks developed in one system for analysing data from another. It was noted, for example, that a framework exploiting verbs in curriculum documents, as placeholders for types of mathematical activity, would not work with documents in such activities are presented through nouns (such as *modélisation*, *Modellbildung*). Also, it is important to acknowledge that curriculum documents may vary considerably in length, not least because different cultures present such matters in varying ways, with different levels of specificity reflecting cultural communicative norms. Differences in level of detail also indicate the space left for autonomy of curriculum agents.

Theme 2: Characterising and comparing classroom instruction from three vantage points: 'neutral' observer, teacher practice and learners' experience

The development of foundational number sense in England and Hungary: a case study comparison (presenter: Paul Andrews, University of Cambridge, UK)

Drawing on framework derived from the literature, this paper compared how a case study teacher in each of England and Hungary addressed, when teaching a lesson on number sequences to grade one students, students' acquisition of foundational number sense. The analyses highlighted substantial differences in the opportunities the teachers incorporated into their everyday teaching activity.

School-based mathematics teacher education in Sweden and Finland: characterising mentor-prospective teacher discourse (presenter: Malin Knutsson, Örebro University, Sweden)

This paper compared how Finnish and Swedish school-based mentors and primary teacher education students undertake their roles in professional review meetings. The analyses indicate substantial differences in the ways that typical Swedish and Finnish teacher education discourses play out, with Swedish tending to focus more on the student teachers' learning, while the Finnish attended more to children's learning.

Comparing mathematical work at lower and secondary school from the students' perspective (presenter: Niclas Larson, Linköping University, Sweden)

Drawing on key concepts from the anthropological theory of didactics and Bernstein's theory of pedagogic discourse, this paper compared how students experience and perceive their mathematics education at lower and upper secondary school, and found substantial differences linked, in particular, to the *instructional* and *regulative* discourses of the two traditions of mathematics teaching.

An important issue raised in the discussion concerned the role of the researcher as a cultural insider: How is this managed when examining data from both culturally familiar and unfamiliar cultures? The importance of being aware of blind spots as well as of the danger of imposing categories and taxonomies that arise in one teaching culture onto another was recognised. Another issue raised, was the need to understand the power relations between participants during data collection, and of acknowledging culturally and micro-culturally constructed interpersonal relationships. Further, cultural authorship of theoretical frameworks was discussed, and openness towards the empirical field was seen as important.

Theme 3: Modes of constructing data, developing analytical categories and pursuing validity in comparative studies

The validity-comparability compromise in crosscultural studies in mathematics education (David Clarke, ICCR, University of Melbourne, Australia)

This theoretical paper argued that the use of general classificatory frameworks in cross-cultural research may not only misrepresent aspects of mathematical performance, school knowledge and classroom practice valued by the communities under scrutiny but sacrifice validity in the interest of comparability. Seven dilemmas are presented to highlight different ways in which these tensions may play out.

The problem of detecting genuine phenomena amid a sea of noisy data (presenter: Christine Knipping, University of Bremen, Germany)

This second theoretical paper argued that those engaged in qualitative comparative mathematics education research should acknowledge two key principles; that analyses should attend both to the explanation of phenomena rather than data and the common discourse necessary for any theoretical scientific discourse. These principles were illustrated by examples drawn from several well-known comparative studies.

Some ‘dilemmas’ in comparative studies were discussed in more depth, such as the advantages or disadvantages of exploiting too inclusive or too distinctive categories. As to the distinction between data and phenomena, participants agreed that the issue might be of greater complexity or more obvious in comparative studies than in other research. In this respect it was acknowledged that all data are, essentially, constructed and that data and phenomena codetermine each other; and that in cross-cultural research criteria for what constitute data must hold legitimately across settings.

Theme 4: Strategies and goals of comparing learners’ emotional and affective experiences

Comparing the structures of 3rd graders’ mathematics-related affect in Finland and Chile (presenter: Laura Tuohilampi, University of Helsinki, Finland)

This paper compared third grade students’ mathematics affect structures in Chile and Finland – a comparison new to the comparative field. Exploiting a survey instrument developed in Finland the study found both similarities and differences in the affect structures yielded by the students in the two countries, highlighting how cultures construct students’ affective responses to mathematics.

Boredom in mathematics classrooms from Germany, Hong Kong and the United States (Eva Jablonka, King’s College London, UK)

Drawing on interviews with students from six classrooms in each of Germany, HongKong and the United States, this paper explored students’ elaborations of the notion of boredom in relation to their classroom context, identifying substantial differences in the ways in which the concept is construed cross-culturally.

The dialectics between practice (e.g. classroom practice) and emotions arising from this practice was discussed, and different theoretical frameworks were acknowledged. The question as to what extent emotions can be seen as social constructs was discussed with reference to some examples, as for example ‘shame’. Further, it was discussed whether trying to explain students’ emotions as deriving from their general cultural context (rather than as deriving from the micro-culture of the mathematics classroom context) represents a form of cultural essentialism. As a consequence of the view that labelling emotional experiences in fact constructs what we call the emotion, a discussion about the role of predefined labels for emotions in questionnaires arose, as these might trigger a response that one thinks one has experienced it in the labelled way.

Theme 5: Modes and principles of using quantitative methods in comparative studies

Mathematics teachers’ beliefs in Estonia, Latvia and Finland (presenter: MarkkuHannula, University of Helsinki, Finland)

This paper, which exploited a multidimensional survey instrument, compared the mathematics- and mathematics teaching- related beliefs of Estonian, Latvian and Finnish teachers, with a key variable being the language of instruction employed in

teachers' schools. The analyses indicated both cross-national and cross-lingual differences in the ways that teachers' beliefs played out.

Re-examining the language supports for children's mathematical understanding: A comparative study between French and Vietnamese languages (presenter: HienThi Thu Nguyen, University of Pedagogy, HoChiMinh City, Vietnam)

This final paper, drawing on data from French-speaking Belgium and Vietnam, examined how the ways in which languages articulate numbers influence third grade children's mathematical understanding and performance. The analyses indicated that aspects of the Vietnamese language facilitated students' performance in some domains, when compared with French-speaking students, but not others.

It was noted that when imported instruments fail to be reliable in new contexts, this is an important research outcome. One approach to overcoming this problem would be to include open items to allow the voice in the new context to be heard. Further, examples were given of concepts exploited in studies that may have different salience or vocabulary in different cultures. For example, effective or efficient teaching is an acknowledgement of a local discourse. The relationship between qualitative and quantitative approaches to data gathering and analysis in comparative studies was another focus of the discussion. Questions raised included: How does one mode inform the other? How do they fit our objectives? What is the impact of cultural proximity (Finland and Sweden) or distance (Belgium and Viet Nam) on research design and expected outcomes? Another emerging issue concerned the sensitivity to cultural minorities in larger-scale studies: Are the cultural groups under scrutiny clearly defined?

A CROSS-NATIONAL STANDARDS ANALYSIS: QUADRATIC EQUATIONS AND FUNCTIONS

Tuyin An, Alexia Mintos, and Melike Yigit

Purdue University, West Lafayette, IN, USA

With the advent of the Common Core State Standards (CCSS), scholars are eager to understand its implications for their work. In this study we compare the characteristics of the CCSS for Mathematics (CCSSM) with other countries' mathematics curricula. In particular we investigated how quadratic equations and functions are introduced in the curriculum documents of four different countries: the Caribbean, China, Turkey, and the U.S. These were analyzed under three dimensions: content, mathematical reasoning, and cognitive level. The results show that all the standards introduce the foundational concepts of quadratic functions, but with varying procedural and conceptual expectations.

INTRODUCTION

The newly released *Common Core State Standards (CCSS)* have aroused wide interests in the field of education. As these standards state,

The standards are designed to be robust and relevant to the real world, reflecting the knowledge and skills that our young people need for success in college and careers. With American students fully prepared for the future, our communities will be best positioned to compete successfully in the global economy. (Common_Core State Standards Initiative [CCSSI], 2010)

Implementing these new standards has become a matter of concern for teachers, researchers, policy makers, students and parents. The standards also have implications for other countries, since international students and scholars are an increasing part of the post-secondary education population in the United States. As a group of international researchers studying mathematics education in the United States (we derive from the Caribbean, China, and Turkey), we set out to compare the *CCSSM* against the standards and teaching plans with which we are most familiar. We designed, therefore, a cross-national study to investigate the similarities and the differences of learning expectations for students among these four economically, socially, culturally, and geographically diverse countries. These countries also vary in terms of the structure and history of their educational systems, as well as the implementation of their intended curricula. However, the Caribbean, China, Turkey, and the U.S. all communicate, in various written forms, what and how students are expected to learn mathematics (these differences will be discussed subsequently); for simplicity we refer to these documents as *Written Learning Expectations for Mathematics (WLEMs)*.

In this study, we compare, in particular, the WLEMs related to quadratic equations and functions, irrespective of grade level. In so doing our goal is not to rank nations, but to

ascertain the strengths and weaknesses of different educational systems and provide a basis for improving the teaching and learning of mathematics (e.g., Cai, 2001; Porter & Gamoran, 2002; Robitaille & Travers, 1992).

BACKGROUND

Standards Analysis in Previous Studies

A few studies have focused on curriculum standards analysis; however, most of them only look at a single aspect of these standards, such as the coherence (e.g., Schmidt, Wang, & McKnight, 2005), format (e.g., Reys, Dingman, Nevels, & Teuscher, 2007), or content (e.g., Reys, 2006).

Schmidt et al.'s (2005) examination of the coherence of mathematics and science standards revealed that, compared to the six high-achieving countries in the *Trends in International Mathematics and Science Study* (TIMSS), each grade in the various U.S. national standards devoted instructional attention to many more topics and these topics stayed in the curriculum for more grades. Reys et al.'s (2007) report summarized the format of state-level curriculum standards and graduation requirements for high school mathematics. The result showed that states are varied with respect to required mathematics credit hours and courses for graduation. In work conducted by the Center for the Study of Mathematics Curriculum (CSMC), Reys (2006) reported results of comparing state-level K-8 mathematics curriculum-standards documents in three content strands: number and operation, algebra, and reasoning. The report highlighted how different topics within these strands were sequenced and emphasized across the different state documents.

Only one research study examined the multiple aspects of the standards: clarity, content, mathematical reasoning, and negative qualities (Raimi & Braden, 1998). Because this study aimed to critique the standards, not all the categories were suitable for international comparison.

Significance of Quadratic Equations and Functions

Solving quadratic equations is one of the most conceptually difficult topics in the secondary school mathematics curriculum (e.g., Vaiyavutjamai & Clements, 2006), and educators should be aware of these difficulties and be prepared to help students to confront these challenges. Even though quadratic equations play an important role in secondary school curriculum around the world, studies concerning teaching and learning quadratic equations are quite rare in algebra education research (Kieran, 2007; Vaiyavutjamai & Clements, 2006).

In addition, although quadratic functions are one of the most important concepts extending beyond linear functions in the secondary school mathematics curriculum, students have struggled to understand quadratic functions (Ellis & Grinstead, 2008). Students' struggles with quadratic functions are based on a few key areas, including inflexible connections between multiple representations; rigid views of graphs as whole

objects; incorrect interpretations of the role of parameters; and tendencies to incorrectly generalize from linear functions (Ellis & Grinstead, 2008). These findings indicate that educators should be aware that students must move flexibly and develop connections among different representations in order to establish a functional understanding.

METHODOLOGY

Theoretical Framework

The process of building a robust framework within which to perform a cross-national comparison led us to a three-dimensional framework: content, mathematical reasoning, and cognitive demand. For the content category we chose to follow the definition of content as “coverage,” and our analysis involved a comparison of the topics and concepts that each set of standards requires in relation to quadratic equations and functions.

The second dimension of the analytical framework is mathematical reasoning in relation to quadratic equations and functions. This part of our framework is based on the recommendations of NCTM’s (2009) Reasoning and Sense Making document. This document emphasises *Reasoned Solving* with algebraic symbols, which means that “problem solving with equations should include careful attention to increasingly difficult problems that span the border between arithmetic and algebra” (p.34). This ensures that students can see that algebra extends arithmetic reasoning and is a more powerful approach when solving more challenging problems alone.

In terms of functions, the document suggests three essential elements:

- *Using multiple representations of functions.* Representing functions in various ways, including tabular, graphic, symbolic (explicit and recursive), visual, and verbal; making decisions about which representations are most helpful in problem-solving circumstances; and moving among those representations.
- *Modeling by using families of functions.* Working to develop a reasonable mathematical model for a particular contextual situation by applying knowledge of the characteristic behaviours of different families of functions.
- *Analyzing the effects of parameters.* Using a general representation of a function in a given family (e.g., the vertex form of a quadratic, $f(x) = a(x - h)^2 + k$ to analyze the effects of varying coefficients or other parameters); converting between different forms of functions (e.g., the standard form of a quadratic and its factored form) according to the requirements of the problem-solving situation (e.g., finding the vertex of a quadratic or its zeros) (p. 37).

The third dimension, cognitive level, focuses on how students are expected to learn concepts, what they are expected to do in the process, and how they are to demonstrate their understanding. We chose to use the Bloom's Taxonomy, which is a classification of levels of learning objectives that educators set for students. It was initially proposed by a

committee of educational psychologists chaired by Benjamin Bloom in 1956. In this paper, we used a revised version of the taxonomy created by Anderson and Krathwohl (2001). Bloom's Taxonomy divided educational objectives into three "domains": *Cognitive*, *Affective*, and *Psychomotor*. Within these domains, learning at the higher levels depends on having attained prerequisite knowledge and skills at lower levels. In this study, we only attend to skills in the cognitive domain. There are six levels in the taxonomy, moving from the lowest order processes to the highest: (a) *knowledge*—Exhibit memory of previously-learned materials by recalling specifics and universals, methods and procedures, and patterns, structures, or settings; (b) *understand*—Understand facts and ideas by organizing, comparing, translating, interpreting, giving descriptions, and stating main ideas; (c) *apply*—Solve problems in new situations by applying acquired knowledge, facts, techniques, and rules in a different way; (d) *analyze*—Examine and break information into parts by identifying motives or causes. Make inferences and find evidence to support generalizations; (e) *evaluate*—Present and defend opinions by making judgments about information, validity of ideas, or quality of work based on a set of criteria; and (f) *create*—Create new product or point of view (Krathwohl, 2002). We also referenced a list of action words of the taxonomy categorized by other scholars (Center for University Teaching, Learning, and Assessment [CUTLA], n.d.).

Data Collection & Analysis

The quadratic functions and equations WLEMs from all the different countries in the study were collected for analysis, and the Turkish and Chinese WLEMs were translated by the members of the research team from these respective countries. Researchers who performed the translations used contextual clues and examples wherever possible to help maintain fidelity in the meanings of WLEMs.

For data analysis in the content dimension, team members recorded all the distinct topics and concepts related to quadratic equations and functions. For the mathematical reasoning dimension each country's WLEMs were coded for unique opportunities for mathematical reasoning according to the framework criteria. A narrative was compiled for each country and a cross-WLEM analysis was conducted. For the cognitive level dimension of the framework, we used Bloom's Taxonomy action verb analysis to code each WLEM into Bloom's categories. During the data analysis process, we wanted to make sure that the number of verbs that are used represented the actual number of tasks in each WLEM (a WLEM could include multiple tasks), and this rule was applied to all of the countries. To do this each WLEM was read in its entirety to determine the actions that students would be required to undertake (e.g. "Be able to plot the graph of a quadratic function, and know its properties by exploring the graph." (Chinese WLEMs, 2011, p. 21), has two verbs, which indicate two tasks were required) and each WLEM was coded based on the verbs that dictated its learning goals. Each set of WLEMs was coded by two members of the research team. Discrepancies were discussed and resolved by the team.

DATA INTRODUCTION

Caribbean WLEMs: The most recent Caribbean WLEMs document was written in 2008, created for 16 English speaking countries in the Caribbean region and is 47 pages long. It provides a rationale for the mathematics included, general and specific course objectives, a summary of how the syllabus is organized, and detailed descriptions of the exams that would be used to assess students (including the distribution of content to be covered and the details of the topics covered). The mathematical objectives listed in the WLEMs for quadratic functions list specific skills that students should acquire and gives a few example problems. In the general objectives, students are given esoteric mathematical expectations that are very broad. Some examples of the general learning expectations include: learning to treat algebra as a language and a way of communicating, appreciating the role of symbols and algebra techniques in problem solving, and being able to reason abstractly (*Caribbean Examination Council (CXC) syllabus, 2008*).

CCSSM: The *CCSSM* WLEMs is a 93 page document. It consists of two main sections: Standards for Mathematical Practice and Standards for Mathematical Content. In this study, we focus on the content section, which is organized by grades (K-8) and organized by content strand at the high school level (Number and Quantity, Algebra, Functions, Modeling, Geometry, and Statistics and Probability). It provides descriptions of what students should know and provides one or two example equations or problems where appropriate.

Chinese WLEMs: The *Full-time Compulsory Education Mathematics Curriculum Standards* (FCEMCS) was enacted by the Ministry of Education of the People's Republic of China, and published by Beijing Normal University Press in 2001. It is a 44 page document, which includes three stages: *stage one* (grades 1-3), *stage two* (grades 4-6), and *stage three* (grades 7-9); four areas of mathematics content: numbers and algebra, figures and geometry, statistics and probability, and integration and practice; and four types of objectives: knowledge and skills, mathematical thinking, problem solving, and emotion and attitudes. The latest edition of the *General High School Mathematics Curriculum Standards* (GHSMCS) was published by People's Education Press in 2011. This high school mathematics curriculum consists of two types of courses: compulsory and elective. The compulsory course contains five modules: *Math 1-5*. For the high school standards, we only focus on the module *Math 1*, which is a 5 pages long document and covers the WLEMs in relation to quadratic equations and functions

Turkish WLEMs: The high school mathematics curriculum (grades 9-12) has two main areas: mathematics and geometry. The mathematics curriculum is 364 pages long, and the geometry curriculum has 207 pages for grades 9 and 10, 127 pages for grade 11, and 176 pages for grade 12. In the WLEMs, every concept was designed according to four sub-sections: *subfields*, *gains*, *hints for the activity*, and *explanations*. These sub-sections indicate what students must learn about a concept by the end of instruction, examples

that are helpful for teachers to teach a concept, and explanations that are recommendations for teachers to use in their instructions. These standards are the requirements to be achieved by all students, and students must learn those standards in order to go a grade further.

FINDINGS

Content

In terms of content for quadratic functions and equations, the Caribbean WLEMs provided an introduction to basic principles, skills, and processes. Students are expected to be able to factor quadratic expressions, solve abstract quadratic equations and context specific ones in word problems, use symbols to denote quadratic functions, and be able to graph and interpret quadratic functions. Two optional specific objectives require that students find and understand the significance of the axis of symmetry and find the number of roots for a particular quadratic equation. The content range among *CCSSM*, Chinese and Turkish WLEMs are similar to those of the Caribbean, but there are also notable differences. For *CCSSM*, the content on quadratic functions requires that students solve quadratic equations using different methods, using multiple representations (graphical, tabular, and symbolic), comparing and evaluating the characteristics of quadratic functions with other families of functions; and modelling real or natural patterns with quadratic functions and also problem-solving by using quadratic functions in realistic contexts. *CCSSM* also emphasizes the relationship between different types of functions. The Chinese and Turkish WLEMs also include fundamental properties of quadratic equations and functions (e.g., zero roots and extreme values) and basic problem solving means (e.g., graphing, factoring, and completing the square). Additionally, there are some minor differences: Chinese WLEMs are more specific on the properties of functions (e.g., direction of the opening, monotonicity, domain and range, and even/odd functions) whereas Turkish WLEMs also embed their mathematical content in specific examples and have made problem solving a foundational part of the WLEMs.

Mathematical Reasoning

Reasoned solving of equations. The Caribbean WLEMs clearly require students to be able to solve quadratic equations and solve a pair of equations when one of them is a non-linear equation. The *CCSSM* high school algebra standards require students to create quadratic functions that describe numbers and relationships, to solve quadratic equations in one variable, and to understand solving equations as a process of reasoning. Both *CCSSM* and Chinese WLEMs emphasize the connection between equations and functions; that equations can be solved by using graphs of the corresponding functions. The Turkish WLEMs emphasize the connections between the roots and coefficients of quadratic equations.

Using multiple representations of functions. The Caribbean and Turkish WLEMs have similar requirements with regard to the form of representations. They both expect students to use graphical, symbolic, and tabular representations while the use of technology is not mentioned. The *CCSSM* are the only WLEMs among the four countries that mention verbal representation. They also state that students should be able to graph functions both by hand and with technology. The Chinese *WLEMs* emphasize plotting graphs of quadratic functions and suggest using technology, such as the calculator, to analyze the graph and to find the solution of the corresponding equation.

Modelling by using families of functions. There is no explicit mention of modelling with quadratic functions in the Caribbean WLEMs, with the exception of the general objective that students should “appreciate the usefulness of concepts in relations, functions and graphs to solve real-world problems” (*CXC*, 2008 p. 24). The *CCSSM* has a set of modelling WLEMs embedded in other WLEMs that appear throughout the entire high school section. For example, there is an emphasis on modelling skills in the domain of building functions, which requires the ability to describe a relationship between two quantities in a contextual situation (F-BF). The Chinese WLEMs not only require a deep understanding of the concept of modelling through various examples, but also the ability to represent functions in an appropriate form (e.g. graph, table, and equation) in a real world context. The Turkish WLEMs do not have specific standards on modelling. They provide many examples, but in these examples, the model is usually given.

Analyzing the effects of parameters. The Caribbean and Chinese WLEMs include understanding and using the form $f(x) = a(x - h)^2 + k$, although this is optional for Caribbean students. All the *WLEMs* require a general representation of the quadratic function except for the *CCSSM*. However, the *CCSSM* mentions using various equivalent forms. Uniquely, it requires students to represent the quadratic equation and its solution in the form of complex numbers $a \pm bi$ for real a and b . The Turkish WLEMs emphasizes the use of $f(x) = ax^2 + bx + c$. All the WLEMs emphasize the study of the properties of functions through graphs (e.g., finding the zeros, symmetry, intercepts and extreme values) while they have slightly different emphases on problem solving methods. The Caribbean WLEMs focus on analyzing the graph, with symbolic approach being optional; the *CCSSM* focus on factoring and completing the square; the Chinese WLEMs suggest various methods, including factoring and completing the square, root-formula, and dichotomy (by using the calculator); the Turkish standards do not have specific requirements for problem solving methods.

	Knowledge	Understand	Apply	Analyze	Evaluate	Create	Total
--	------------------	-------------------	--------------	----------------	-----------------	---------------	--------------

CCSSM	0	5 extent, interpret, estimate, observe	14 choose, complete the square, factor, graph, solve, write, show, sketch, relate, calculate, determine, combine	0	1 properties	0	20

Chinese	7 Know	7 determine, know, obtain, represent, understand, learn	11 apply, draw, examine, find, plot, represent, solve, use	2 experience	1 investigate	0	28
Turkish	1 Identify	1 Identify	11 calculate, find, show, sketch, write	0	0	1 organize	14

Table 1: Action Words for Bloom's Taxonomy in Cross National Comparisons
Cognitive Level (Bloom's Taxonomy)

With respect to cognitive level, we analyzed 45 WLEMs of quadratic equations and functions across all the countries and found 72 tasks (Table 1). The results show that Bloom's *apply* category is most common across all the WLEMs; 46 tasks were identified in this category. In the Caribbean WLEMs all action words alluded to the *apply* category. The *CCSSM* has 14 such tasks, the Chinese WLEMs has 11, as does the Turkish. We also found some distinctive characteristics among the WLEMs. As indicated above, the Caribbean WLEMs has only one category of action words, *apply*. The *CCSSM* has none of the categories: *knowledge*, *analyze* or *create*. The Chinese WLEMs includes all categories except for *create*; being the only standards to address the *analyze* level. Additionally, the Chinese WLEMs emphasizes the foundations of *knowledge* and *understanding*. Turkish WLEMs do not have any action words at the *analyze* or *evaluate* levels but are the only WLEMs to include the *create* level.

DISCUSSION

One of the limitations of this study was the different representations of learning objectives used in the different WLEMs of the project countries. While there were similar content coverage goals, what was expected of students, how the content

emerged, and the role of the teacher in deciding when the content was to be taught varied across WLEMs. Also, several issues emerged during the coding of WLEMs translated from Turkish and Chinese that led us to infer that some of the original intent of the WLEMs was lost in translation. Besides identifying action verbs using Bloom's taxonomy we also had to read the each WLEM completely to determine whether the verb was categorized correctly or if the verb needed to be placed into a different Bloom's level depending on the requirements from the WLEMs. In the categorization, there is also the possibility that the same verbs in different WLEMs might imply different actions, and one action in different WLEMs might be represented by multiple verbs. Therefore, the precision of our results might be limited by the translation of WLEMs. In addition, the conclusions that we can make about these four different *WLEMs* are only with regard to quadratic functions and equations. Further studies would be needed to make larger comparisons regarding all of the content taught in high school mathematics.

We believe our study may facilitate discussion between mathematics education colleagues internationally. Particularly, since the *CCSSM* is newly released, we hope that the similarities and differences identified above will help US-based mathematics educators and teachers, not only understand the *CCSSM* more fully but implement it more effectively. Of course, no WLEMs gives a complete picture of the curricular opportunities for students to learn about quadratic equations and functions; they cannot predict the quality of instruction or the level of achievement that students experience in their post-secondary careers. However, we can conclude that the learning expectations for these concepts are comparable across the four countries and are also diverse in many aspects.

THE DEVELOPMENT OF FOUNDATIONAL NUMBER SENSE IN ENGLAND AND HUNGARY: A CASE STUDY COMPARISON

Jenni Back, Judy Sayers and Paul Andrews

University of Cambridge, University of Northampton, National Centre for Excellence in the Teaching of Mathematics, England

Foundational number sense - being able to operate flexibly with number and quantity - is a predictor of later mathematical achievement. In this paper, drawing on lessons on number sequences to grade 1 children, we examine how two teachers, one English and one Hungarian, construed locally as effective, created opportunities for children to develop foundational number sense. The Hungarian teacher, in ways typical of that country's mathematics teaching tradition, offered frequent and coherent opportunities for students to develop foundational number sense. The English teacher, working in a tradition whereby interactive technology increasingly mediates classroom discourse, offered few and less coherent opportunities, masked by the teacher's frequent attention to display features of the technology.

INTRODUCTION

Described as a “traditional emphasis in early childhood classrooms” (Casey et al 2004: 169), the quality of young children’s number sense is a key predictor of later mathematical success, both in the short (Aunio and Niemivirta, 2010) and the longer term (Aunola et al, 2004). Consequently, particularly as number sense deficits tend to lead to later difficulties (Jordan et al., 2007), the development of children’s number sense “is considered internationally to be an important ingredient in mathematics teaching and learning” (Yang and Li 2008: 443). Importantly, without appropriate intervention children who start school with limited number sense are likely to remain low achievers throughout their schooling (Aubrey et al., 2006).

Defining foundational number sense

Our understanding of number sense is that it comprises two related but distinct concepts that the literature typically conflates. The first, which we label foundational number sense (FNS), concerns the number-related understandings children develop during the early years of formal instruction. The second, which we have labelled applied number sense, draws on the first and concerns the number-related understanding necessary for people to be mathematically competent and functionally effective in society. In this paper, while remaining mindful of the latter, we focus on the former.

For the purpose of this paper we define FNS as the ability to operate flexibly with number and quantity. It develops over time “as a result of exploring numbers, visualizing them in a variety of contexts, and relating them in ways that are not

limited by traditional algorithms” (Sood and Jitendra, 2007, p. 146). It comprises, so our understanding of the literature informs us, several elements, among which are:

Awareness of the relationship between number and quantity (Berch, 2005; Clarke and Shinn, 2004; Van de Rijt et al., 1999; Griffin, 2004).

Understanding of number symbols, vocabulary and meaning (Clarke and Shinn, 2004; Van de Rijt et al., 1999; Malofeeva et al. 2004; Yang and Li, 2008).

Systematic counting, including notions of ordinality and cardinality (Gersten et al., 2005; Griffin, 2004; Malofeeva et al. 2004).

Awareness of magnitude and comparisons between different magnitudes (Gersten et al., 2005; Griffin, 2004; Ivrendi, 2011; Jordan et al., 2007; Malofeeva et al. 2004).

An understanding of different representations of number (Ivrendi, 2011; Jordan et al., 2007; Yang and Li, 2008),

Competence with simple arithmetical operations (Berch, 2005; Ivrendi, 2011; Yang and Li, 2008).

An awareness of number patterns including recognising missing numbers (Berch, 2005; Clarke and Shinn, 2004; Jordan et al., 2007).

In this paper, as an introduction to comparative research in the field, we examine the question, what opportunities do two teachers, in different cultural contexts and considered locally as effective, create for their students to acquire FNS?

DATA COLLECTION AND ANALYSIS

In addressing our question, we compare excerpts from two lessons taught to grade one children in England and Hungary. The lessons from which they were drawn were each part of a wider collection of videotaped lessons gathered independently of each other. The English lesson derived from the second author’s PhD case study examination of primary mathematics teachers’ enactment of whole class teaching. The Hungarian lesson derived from a study of exemplary Hungarian primary mathematics teaching undertaken by the third author to inform curriculum development activities in England. Both teachers were construed against local criteria as effective in the manner of the Mathematics Education Traditions of Europe project (Andrews, 2007). Thus, the two data sets were not only serendipitously available but also appropriate for comparative analysis. Both teachers, with microphones, were video-recorded in ways that would optimise the capture of their actions and utterances. Both data sets entailed repeated observations of a small number of case study teachers over a period of several months in order to ensure a sense of the typical lesson. The Hungarian lessons were supported by a home-based English-speaking colleague providing a contemporary translation augmented by the first author’s sufficient understanding of Hungarian to be able to follow much of the discourse of a mathematics classroom. In other words, while the two sets were collected independently, they were gathered in similar ways and amenable to similar

analyses. The excerpts analysed here were based on the teaching of number sequences. This topic was chosen because, among the various FNS-related components, it was the only one addressed explicitly in both sets of lessons. Moreover, our belief was that number sequences would provide more opportunities for the incidental teaching (Radwan, 2005) of the other FNS components. With respect to analysis each excerpt was viewed simultaneously and repeatedly by all three researchers. This led to our seeing not only that each excerpt comprised three distinct phases, which frame our analyses, but also which components of foundational number sense were addressed, both implicitly and explicitly.

RESULTS: THE ENGLISH EXCERPT

This excerpt derives from a lesson taught to 6 and 7 year olds on number sequences and patterns. It began with the teacher, Sarah, reminding her children about previous work on sequences, how odd and even numbers create an alternating pattern in the number system, and informing them that today they would be looking at some more sequences and number patterns. The 5 x 10 grid below was displayed on the interactive white board – a resource typical of English classrooms - with the cells containing the first six even numbers shaded. Sarah asked if anyone could explain the pattern. One child responded by saying that they all end in 0, 2, 4, 6 or 8, after which Sarah commented that they are all even. Next she asked about the column patterns and, after a suggestion that the numbers in each column end in the same digit, Sarah accepted the suggestion that the column pattern goes odd even odd. At this point, exploiting the whiteboard's software, she displayed the odd columns in one colour and the even in another.

1	2	3	4	5	6	7	8	9	10
11	12	13	14	15	16	17	18	19	20
21	22	33	24	25	26	27	28	29	30
31	32	43	34	45	36	37	38	39	40
41	42	53	44	55	46	47	48	49	50

Commentary: In these first few minutes several FNS categories appeared to have been addressed. For example, Sarah's explicit emphases seemed very much geared towards inducting her children into an awareness of number patterns alongside a clear expectation that children recognise number symbols and vocabulary.

Next, Sarah put up another 5 x 10 grid but with no coloured cells. Beneath the grid was the following:

1, 4, 7, 10, 13, __, __

She asked how other numbers in the sequence could be found and invited her class to look at the number grid. Having evoked no responses Sarah tapped, in turn, each of the five numbers to change the colour of their cells and create the image below. At this point she commented that the grid looked different from that of the previous

problem and asked *have I done it wrong?* Different students offered, tentatively, both negative and positive responses, which went without comment.

1	2	3	4	5	6	7	8	9	10
11	12	13	14	15	16	17	18	19	20
21	22	33	24	25	26	27	28	29	30
31	32	43	34	45	36	37	38	39	40
41	42	53	44	55	46	47	48	49	50

Next, Luke raised his hand and the following ensued:

- Sarah Luke?
- Luke Sixteen
- Sarah Why sixteen?
- Luke Because you're adding on three
- Sarah Because it's adding on three isn't it (she taps the cell to change the colour)...
What's going to be the next one? Isla?
- Isla Nineteen
- Sarah What's going to be the next one? Ian?
- Ian Twenty-two
- Sarah Twenty-two (she taps the cell). And the next one? (more hands go up this
time) Rachel?
- Rachel Twenty-five

Commentary: In the above is evidence of different aspects of FNS. The four students were clearly extending the sequence given them. Also, the assertion that they were adding on three indicated an engagement with simple arithmetical operations and, of course, they were still being made aware of the relationship between symbols, their vocabulary and meaning. By now the grid looked as below.

1	2	3	4	5	6	7	8	9	10
11	12	13	14	15	16	17	18	19	20
21	22	33	24	25	26	27	28	29	30
31	32	43	34	45	36	37	38	39	40
41	42	53	44	55	46	47	48	49	50

- Sarah Twenty-five (she clicks on the cell, which becomes red) Can anybody see
any colour patterns coming out of this?
- Boy It looks like a bit like stairs!
- Sarah Rosie? (Rosie says something inaudible so Sarah walks to the middle of the
room to hear what Rosie says)

Sarah Yes, they're going diagonally aren't they. Yes when we extended this pattern we started to see that. There's a diagonal pattern made by the squares coloured in. Now, if Rosie's right then this one's (she taps 34, which turns red) going to be in our sequence. I'm going to fill it in and then count on three each time. One, two, three (she taps 28, which change it to red). One, two, three (she taps on 31). One, two... (she points to 34, which is already red, and faces the class)

Children Threeee (a few children shout out)

Commentary: In this closing episode Sarah appeared to be encouraging systematic counting from an ordinal perspective as well as further opportunities for children to recognise number symbols, vocabulary and meaning. Thus, over the whole excerpt, Sarah seemed to have addressed four of the seven FNS categories.

RESULTS: THE HUNGARIAN EXCERPT

This excerpt was taken from a sequence of lessons focused on children's coming to know and work with integers to 20. The lesson began with Klara, having written on the board prior to the start of the lesson, the configuration shown below.

—	—	—	—	—	—	—	—	—
3	7	6	10	—	—	—	—	—
				—	—	—	—	—

Having been invited to do so, the class read out the numbers in unison as Klara pointed to each in turn. Next, moving from left to right, she invited volunteers to explain how each number could be derived from the one preceding it. Students volunteered that the first operation was add four, followed by subtract one and add four. With each offering Klara wrote the operation underneath, as shown below, before inviting predictions as to what operation would be expected next. Eventually, after several contributions, the table was completed.

—	—	—	—	—	—	—	—	—
3	7	6	10	—	—	—	—	—
	+4	-1	+4					

Commentary: During this period it seems to us that Klara had encouraged several aspects of FNS. Firstly, an introduction during which children were invited to recognise and read the numbers on the board was focused on the recognition of number symbols and their vocabulary. Secondly, in the ways in which successive numbers were identified, Klara was addressing simple arithmetical operations. Thirdly, the episode was explicitly focused on an understanding of number patterns.

Next, Klara produced some cards, each of which had a letter written on it. She announced that she was going to ask questions, the answer to each would be one of the numbers in the sequence. Each correct answer would yield a letter to spell a word

that would tell the class where it would be going in the story of this particular day. The following reflects the first minute of next five minutes of discourse.

- Klara So my first statement is... please look only at the numbers on the board... I am thinking of the largest one-digit number. Balasz?
- Balasz Six (Pupils protest)
- Klara Look at the sequence again, and please correct yourself.
- Balasz Seven
- Klara Look at the number line... Ferenc?
- Ferenc Nine
- Klara That's right. So I will give you a reward for the nine (Klara placed a card with the letter \acute{I} on the board above the number nine). The next number I am thinking of... You mustn't look behind you (Referring to a picture on the back wall) is the value of the black stick in our collection. Perszi?
- Perszi Eight (Pupils protest)
- Klara (to Perszi) Look around, the others don't agree with you... Mara?
- Mara Seven
- Klara Let's see who's correct. (They all look at the back wall, where they can see the members of the Cuisenaire rod collection and their values)
- All (In chorus) Mara was correct (at which point Klara placed a card with the letter \acute{A} above the seven).

The lesson continued with Klara asking a different form of question for each number in the sequence. These included statements like, a number two smaller than nine, the largest two digit number, the smallest one digit number, a number whose digits add up to 4, and so on. In each case at least one child was involved in publicly responding to the questions posed. Eventually, as shown in figure 4, the following emerged with only the number ten left without its corresponding letter.

B	\acute{A}	B	—	\acute{I}	N	H	\acute{A}	Z
3	7	6	10	9	13	12	16	15
+4	-1	+4	-1	+4	-1	+4	-1	

Commentary: In this phase several FNS categories were addressed. The largest one-digit number discussion encouraged not only recognition of number symbols, their vocabulary and meaning but also awareness and comparison of magnitude. In considering a Cuisenaire rod, Klara addressed not only an understanding of different representations of number but also an awareness of the relationship between numbers and quantities. In fact, every statement seemed to address an element of FNS. For example, a number two smaller than nine is a different representation of seven. Similarly, several statements involved simple arithmetical operations.

Having identified all the letters bar the one linked to ten Klara passed responsibility to her students and invited them to offer statements appropriate to that number. This led to the following:

Mara: It is the bigger neighbour of the number 9.

Ildikó: It is the smallest 2-digit number.

Csaba: It is the smaller neighbour of the number 11.

Gabor: The sum of its digits is 1.

Judit: Even number.

Klara: Have we got anything else?

Zsolt: It is the sum of the 1 and 9.

Klara: Yes, the sum of the 1 and 9... and who knows the letter in my hand?

All: Sz (the juxtaposition of s and z in this manner is, in Hungarian, an alphabetic letter with a sound similar to the s in sun)

Klara: Yes, and where are we going today?

All: Bábszínház. (Puppet theatre)

Commentary: In this final episode was further evidence of Klara's promotion of FNS. For example, both understanding of different representations of number and recognition of number symbols, their vocabulary and meaning was, we believe, implicit in all contributions. Simple arithmetic could be seen in Gabor's statements that the sum of ten's digits is one and Zsolt's suggestion that ten is the sum of one and nine. Awareness of number patterns was implicit in Judit's even number suggestion, while awareness of magnitude was implicit in Mara's bigger neighbour of nine and Eva's smaller neighbour of eleven.

DISCUSSION

In this paper we have attempted to show how opportunities for students to acquire FNS played out in two culturally different classrooms. Apart from explicit focus of the excerpts – number sequences - neither teacher appeared to focus explicitly on the development of FNS. However, through an analysis of such snapshots we can examine the extent to which the development of foundational number sense is an

integral, albeit implicit, component of children's early school experiences of mathematics. Moreover, since both teachers were construed locally as effective, such snapshots may offer insight into how teachers, in different cultural contexts, have been conditioned - by their experiences as learners of mathematics, their professional training and subsequent career opportunities - to address such issues.

The analyses above, summarised in table 1, indicate both similarities and differences in the ways in which foundational number sense was addressed. In respect of similarities both teachers addressed several categories, with Klara addressing six of the seven categories and Sarah four. Both encouraged, throughout their respective excerpts, students' recognition of number symbols, vocabulary and meaning. Both encouraged the awareness of number patterns and missing numbers and both exploited simple arithmetical operations. In respect of differences Klara addressed three categories, the relationship between numbers and quantities, comparisons of magnitude and different representations of number that Sarah did not, while Sarah was seen to address systematic counting when Klara did not.

	Sarah's episodes			Klara's episodes		
Relationships between numbers and quantities					X	
Number symbols, vocabulary and meaning	X	X	X	X	X	X
Systematic counting			X			
Comparisons of magnitude					X	X
Different representations of number					X	X
Simple arithmetical operations			X	X	X	
Number patterns and missing numbers	X	X		X	X	

Table 1: the distribution of the categories across the excerpts' episodes

However, while it is clear that both teachers encouraged various aspects of FNS as part of the incidental learning of their lessons it seems to us that Klara's was a more didactically complex encouragement than Sarah's. Put crudely, Klara addressed, on average, four categories of foundational number sense per episode while Sarah addressed barely two. Klara encouraged mathematical reasoning, while Sarah seemed to subordinate such reasoning to an examination of the coloured patterns on the interactive whiteboard. This latter expectation, it seems to us, appeared not only a distraction from children's learning of mathematics but indicative of a more general problem for teachers working in technology enhanced classrooms (Muir-Herzig, 2004; Wang and Reeves, 2003). Moreover, if number sense develops gradually as a result of exploring and visualizing numbers in different contexts (Sood and Jitendra, 2007) then Klara's practice seems more likely to succeed than Sarah's.

Interestingly, both teachers' practices find some resonance with earlier studies of mathematics teaching in the two countries, albeit at the level of the upper primary

classroom rather than the lower primary. Andrews (2009) found Hungarian teachers exhibiting didactical sophistication in their encouragement of cognitively demanding but coherent learning outcomes. The same study found English teachers exhibiting relatively unsophisticated didactical practices in their promotion of substantially more modest and less coherent goals. That is both Klara's and Sarah's practices appeared commensurate with that of their compatriot colleagues working in later phases of schooling. Thus, the limited evidence of this study indicates that teachers working in the first years of schooling, teachers defined locally as effective, behave in ways similar to their compatriots and that the Hungarian tradition seems more likely to facilitate a secure FNS than the English. That being said, clearly more research in this particular field is necessary if we are to understand more fully how teachers induct their learners into this essential mathematical prerequisite.

MODELLING IN THE FRENCH AND SPANISH SYLLABUS FOR SECONDARY EDUCATION

Richard Cabassut⁽¹⁾ and Irene Ferrando⁽²⁾

(1) IUMF – Strasbourg University, LDAR – Paris 7 University, France

(2) Dpto. de Didáctica de las Matemáticas – Universitat de València, España

In this paper we present the exploratory phase of an ongoing comparative study on the teaching of modelling in France and Spain. The study aims to describe the place of modelling in the curricula. In this exploratory phase we will use some tools of the Anthropological Theory of the Didactic (ATD). We will discuss the rationale, theoretical framework and methods of this study. Then we will determine if modelling is designated to be taught in France and Spain. We will try to give some conditions that could explain the place of modelling in the syllabus. We will formulate propositions for the next step of this research.

RATIONALE, THEORETICAL FRAMEWORK AND METHOD

Blum and Ferri (2009) point out that “mathematical modelling (the process of translating between the real world and mathematics in both directions) is one of the topics in mathematics education that has been discussed and propagated most intensely during the last few decades. In classroom practice all over the world, however, modelling still has a far less prominent role than is desirable”(p.45). For us (as in Cabassut, 2009) a modelling cycle is the process of solving a real world problem by translating it into a mathematical one (called model of the real world problem), then solving this mathematical problem before translating the mathematical solution back into solution of the real world problem, and validating this solution.

In the previous quotation of Blum and Ferri (and in the whole article) we note the gap between the importance of modelling in mathematics education research and the impact of modelling in classrooms. With this in mind, we compare here the role of modelling in French and Spanish curricula. To compare the teaching of modelling between France and Spain we will use some tools of the Anthropological Theory of Didactic (ATD) described in (Bosch & al., 2006) that points out the important role of institutions in teaching. In modelling, we can refer to everyday life or to sciences, from which the real world problem comes, and to mathematical knowledge from which the mathematical problem comes. How is the transposition of these two references undertaken in the teaching institution? Is modelling designated to be taught in France and in Spain?

We present the exploratory part of our on-going work. We concentrate initially on the question: in the curriculum, is modelling designated to be taught? This question will be answered in the second section. In further research we aim to see if modelling is taught, for this aim we will need to analyse textbooks, resources, interviews teachers, etc. Our study is limited to the secondary school curriculum because a similar study

about primary school was previously made between France and Germany by Cabassut and Wagner (2011).

In the third part of this paper we will try to justify the conclusion of the second part using the levels of determination proposed by ATD.Dorier (2010) gives a description of each level:

“Chevallard takes into account the level of the Pedagogy, i.e. the general teaching principles included in the description of the curriculum of an institution. Then the level of School, takes into account how the general curriculum is structured, the division into disciplines, the time allocated to each, the fact that teachers are mono- or pluri-disciplinary, etc. The next level deals with Society, that is to say, the institutional organisation of the educational system in a country or a region, the most general level of the curriculum, etc. The highest level has to do with Civilisation, it takes into account variations between different cultures, like western versus eastern culture” (p.12).

Each level could help to explain the place of modelling in the syllabus.

To analyse the different curricula we refer to the official texts produced by the corresponding ministries of education of both countries and select those sentences where some words semantically related to modelling appear. From these collected citations we try to answer the question: is modelling designated to be taught? In order to analyze levels of determination, we will use the same method but we will enlarge the reading to more general text, as European Parliament recommendations, PISA results, etc.

We have chosen a bi-national research team because “the comparative method seems to be a major tool in clinical questioning, making it possible to break with the apparent naturality of observations in each country, which encourages the constitution of multinational teams of research” (Cabassut, 2007 p.2431).

IS MODELLING DESIGNATED TO BE TAUGHT?

The French secondary school

In France, secondary school lasts from grade 6 (11 to 12 years old) to grade 12 (17 to 18 years old) and, in contrast with primary school, mathematics teachers are subject specialists. Secondary school is organised in two parts. There is a common school from grade 6 to grade 9, *collège*, with the same curriculum throughout France. After this schools are differentiated (vocational, technical or general, *lycée*). We will consider the curriculum of both the *collège* and the *lycée*. The contents of the first year of *lycée* (corresponding to grade 10) are common for all students. In the final two years (grades 11 and 12), students choose between literary, scientific or economic branches. Compulsory education ends at age 16, corresponding to end of grade 10 for pupils who have never repeated a school year. France is a centralised country and the same official texts edited by the Ministry of National Education (MEN) describe the curriculum and are applied everywhere. There are two kinds of official texts. The first describes the content to be taught for every year of the

curriculum and is found in the newspaper of the Ministry of Education (Bulletin Officiel de l'Éducation Nationale [BOEN]). The second presents resources or advice produced by the MEN. For mathematics these texts are often produced under the responsibility of the body of General Inspectors of Mathematics (Inspection Générale de Mathématiques) that monitors mathematics teaching everywhere in France. The present curriculum was introduced in the *collège* from 2006 to 2009 and in the *lycée* from 2010 to 2012.

Curriculum of general education (from grade 6 to grade 10)

In France, the common base of knowledge and skills (BOEN, 2006) considers that

“the main elements of mathematics are acquired and exercised primarily by problem solving, especially from realistic situations. [...]. On leaving compulsory school, the student must be able to apply the principles and processes basic math in everyday life, in his private life as in his work. [...]. The student must be able [...] to model so elementary, to understand the link between natural phenomena and mathematical language which applies to it and helps to describe it.” (p.6-9).

The introduction to the *collège* syllabus asserts that

“through problem solving, modelling of some situations and progressive learning of the demonstration, students learn little by little what a real mathematical activity is: to identify and to formulate a problem, to conjecture a result by experimenting on examples, to build an argumentation, to check the results by assessing their relevance for the studied problem, to communicate on a research, to give form to a solution” (BOEN, 2008, p.9).

For problem solving, the relations with everyday life or other subjects, and particularly sciences, are mentioned. After this introduction the mathematical content of the syllabus is described by mathematical domains: data organization and functions, numbers and computing, geometry, magnitudes and measures, and later analysis, statistic and probability, algorithmic, arithmetic...

For grade 10 the objective “is to train students in the scientific process in all its forms to enable them to model and to engage in research activities [...], to make a critical analysis of a result, of a process [...], to communicate in written and oral form” (BOEN, 2009, p.1). In the detail of the content of different mathematical domains we find references to modelling and models. For example, regarding problems related to first degree equations, the syllabus recommends that “each time the different stages of work have to be identified: setting equation, solving the equation and interpreting the results” (p.29), which is a reference to a kind of modelling cycle.

Scientific branch (grades 11 and 12)

This branch develops scientific education in grades 11 and 12. Moreover, in grade 12 pupils have to choose one speciality among earth and life sciences, physics and chemistry, or mathematics, with a supplementary syllabus. The introduction to the mathematics syllabus of the scientific branch specifies that “activities [...] should lead students to: search, experiment, model, [...] explain a process, communicate

results in a write and oral form” (BOEN, 2010a, p.1). Different mathematical domains such as analysis, probability and geometry, refer to modelling and models (for example: “Diffusion model of Ehrenfest: N particles are distributed in two containers, and at each instant, a randomly selected particle exchange container” (BOEN, 2011a, p.18). We have also found nine explicit connections to the science syllabi. For example, in relation to sine and cosine was “progressive sinusoidal waves, mechanical oscillator” (p.6) or, in relation to probabilistic independence was “heredity, genetics, genetic risk” (p.12). We think that such relations with the science syllabi encourage students to understand how mathematics is used to model science. In the mathematics specialism syllabus of the final year, the study of the situations considered in the context of this course leads to a modelling work and places students in a position to undertake research.

Economic and literary branches (grades 11 and 12)

For students following the literary branch mathematics is optional, although, as with the scientific branch, those pupils who choose to apply mathematics have to be trained “to develop the following skills: to implement independent research; to conduct reasoning; to have a critical attitude towards their results; to communicate in writing and orally [...] to experiment and to model” (BOEN, 2010b, September 30, p.1). Different mathematical domains (algebra, analysis, statistics and probability, geometry) allude to modelling and models. In the economic branch curriculum, particularly in the last grade, we find, as expected, some explicit references to modelling. In this branch “teaching is based on problem solving. [...] The study of such situations leads to modelling work, and places students in a position to research”. Examples of these problems are given, including “workflow, simple problems of graph partitioning under constraints: the traveling salesman problem management, road or air traffic, scheduling sports tournaments... modelling of inter-industry trade (Leontief matrices)” (BOEN, 2011b, p.10).

The Spanish secondary school

In order to study the teaching of mathematical modelling in secondary education in Spain, we focus on the official syllabus from the Ministry of Education. Spain is divided into 18 autonomous regions; each of these regions also has an official syllabus of secondary studies. Each regional syllabus must be framed within the national one, which is why, for this work, we centre our attention on the syllabus published by the Ministry of Education at Boletín Oficial del Estado (BOE).

The structure of secondary education in Spain is regulated by Education Law (BOE, 2006, p.17158-17207). It comprises two stages: compulsory secondary education (from grade 7 to 10) and high school (grades 11 and 12) from which, after passing a test, students can access university. In contrast with primary education (grades 1 to 6), secondary teachers are subject specialists, with each subject taught by a different teacher. To analyse the content of every stage, we will focus on the study of the

syllabi which regulate both the compulsory secondary (BOE, 2007, p.31680-31828) and the non-compulsory high school (BOE, 2008, p.27492-27608).

Curriculum of compulsory secondary education (grades 7 to 10)

All curricula refer to eight core competences or essential skills that students must reach across all subjects. These are communication skills, mathematical competence, competence in the knowledge and interaction with the physical world, information processing and digital competence, social and civic competence, cultural and artistic competence, learning to learn competence and autonomy and personal initiative.

In the introduction to the section on mathematics it is mentioned that, historically, mathematics “has been used by scientists of all times to build models of reality” (BOE, 2007, p. 31789). The objective is that students, at the end of compulsory secondary education, should “be able to use [mathematics] to think critically about the different realities and problems in today's world” (BOE, 2007, p. 31789). To achieve this objective, they recommend that the content is presented in a problem-solving context. Thus, problem solving stands as the cornerstone on which to work the mathematical content of the curriculum. In this introduction we find some explicit references to modelling, particularly in the domain of geometry “learning of geometry should provide continued opportunities for [...] modelling” (BOE, 2007, p. 31790), and also in the domain of relationships between variables from tables and graphs (analysis function) through which “students are intended to be able to distinguish the characteristics of certain types of functions in order to model real situations” (BOE, 2007, p. 31790). Finally, the syllabus offers methodological guidelines focused on mathematics as a discipline. For example, they recommend working on open situations as this allows students with higher levels of cognitive development to be able to “conceptualize progressively contents in order to ask questions about what is sought” (BOE, 2007, p. 31803), while these open situations can also serve to support and reinforce students with difficulties.

Spanish high school (grades 11 and 12, from 16 to 18 years old) comprises two years of study divided in three branches: literary, scientific and artistic. Mathematics is only compulsory for scientific students during their first year. Below we discuss aspects of the mathematics offered to students in the science and literary tracks; students in the artistic high school do not have to study mathematics.

In its introduction to the content for science-oriented students, the syllabus specifies that mathematics “gives rise to the necessity to solve practical problems [...] and [mathematics] are supported by their ability to [...] model real situations” (BOE, 2008, p.27574). Among the seven general objectives of mathematics for scientific students, no explicit reference to modelling appears. However, the need to “use scientific research strategies and skills specific to mathematics [...] for general research and explore new situations and phenomena” (BOE, 2008, p.27575) is stressed.

During the first year of high school, mathematics (Matemáticas I) is divided into four domains: algebra (and arithmetic), geometry, analysis and probability (and statistics).

The only explicit reference to modelling appears in the domain of analysis, where pupils must be “able to model situations and phenomena with known graphics” (BOE 2008, p.27575). In its section on evaluation the syllabus asserts that pupils should be able to “solve problems drawn from social reality and nature involving the use of equations and inequalities, and must interpret the results” (BOE, 2008, p.27576).

During the second year of high school, we find no mention of inquiry based learning, problem solving or modelling in the mathematics content. However the evaluation criteria suggest that teachers should “intend that students manage information drawn from various sources and use available technologies [...] model situations, [...] extract information, make interpretations [...] and process mathematic data” (BOE, 2008, p.27577).

For students of the **Literary branch** mathematics is not compulsory, although in the syllabus for Mathematics Applied to Social Sciences it is emphasized that it should be worked from a practical point of view rather than from a mechanical point of view, going “beyond the mechanical resolution of exercises that requires only the immediate application of a formula” (BOE, 2008, p.27606). In order to understand the use of mathematics “activities arising should encourage the possibility of applying mathematical tools to analyse social phenomena particularly relevant, such as cultural diversity, health, consumption, coeducation, peaceful coexistence and respect for the environment” (BOE, 2008, p.27605). In the two years of high school, mathematics (as applied to social sciences) is subdivided into three domains: algebra, analysis and statistics (and probability). Regarding the domain of algebra, in the evaluation criteria we found that pupils must “use appropriate techniques to solve real problems giving an interpretation of the expected solutions” (BOE 2008, p.27606). In general, teachers of mathematics have to show students how to “deal with real life problems, organizing and codifying information, developing hypotheses, selecting strategies and using both the tools and modes of argumentation of mathematics to face new situations effectively” (BOE, 2008, p.27606).

ANSWER TO THE QUESTION AND DISCUSSION

In the French secondary curriculum the reference to modelling is frequent throughout: it is always related to problem solving either inside pure mathematics or in relation to other subjects, particularly sciences and technology. This means that it is not clear if modelling is always referenced to a real world. For example, geometry, where optimisation problems are mentioned, can be considered as a pure mathematical world. That is, modelling in this context could be construed as operating within a mathematical world. We note clearly the reference to a kind of modelling cycle involving the three steps of setting an equation, solving the equation and interpreting the results (BOEN, 2008 p.14). All the mathematical domains are involved in modelling, and specially probability. The competences are mentioned often in a general context because most of these competences are related to general and transversal competences, like to be able to communicate, to be critical, to reason, to argue... For all these reasons **we can conclude that in the curriculum modelling**

is designated to be taught, in all branches of general secondary education. The differences between branches are related to the mathematical level and the nature of the problems (scientific, economic or social) in which it occurs.

In the secondary Spanish curriculum, particularly in the mathematics syllabus of compulsory education we find some reference to modelling, most of which are in the domains of geometry and analysis. We think that the references to modelling that appear in the introduction to the scientific branch can increase inquiry based learning, however it is quite revealing that, in the final year before university we find no mention of modelling. We think the reason may be the following: at this level, the syllabus contains many new topics (matrix algebra, integration and limits) and preparation (often mechanical) for the final examinations for university applications prevents any kind of innovation in the classroom. In the syllabus of Mathematics applied to Social Sciences (literary branch) we find, as expected, several references to the relationship between mathematics and reality. So, we conclude that indeed modelling is **designated to be taught**. However, these official texts give no explicit guidance on how to work mathematics through modelling. They merely recommend that the subject should be worked through problem-based learning (problem must be taken from everyday life). Unlike France, in Spain any teaching resources are published by the Ministry of Education. Possibly further research may well lead us to resources published at the level of the regional government.

Discussion

In contrast with Germany, where modelling is one of the seven core competences of the secondary mathematics curriculum, in neither France nor Spain is modelling so explicitly defined. Official texts discuss modelling both explicitly and implicitly but it is not always clear if students are expected to apply a given model or construct a model in order to solve a problem. However in the French texts is mention of the part of the modelling cycle where the model is built. Indeed, there are several resources from the French Ministry in which can be found classroom tasks where models have to be built, like for example in probability (MEN, 2008). We have also noticed that it is difficult to compare the French and Spanish syllabi, since these are written in different contexts. For these reasons, we will study now why modelling is designated to be taught.

LEVELS OF DETERMINATION

At the level of civilisation and society, in France, the common base of knowledge and skills (BOEN, 2006) refers explicitly to PISA and to European parliament recommendations. In the text of the latest Spanish education law we find also explicit reference to both the Organization for Economic Co-operation and Development (OECD) and the European Union (BOE, 2006, p. 17160).

At the level of school we remark that in both France and Spain secondary mathematics teachers are subject specialists, which could make it more difficult for them to teach themes linked to other subjects.

In France, over the last few years, new curriculum structures have encouraged schools to integrate different subjects. For example, in grade 10, there is now an optional course on scientific methods and practices (BOEN, 2010c, p.1), which entails one and a half hour per week in students' time-tables. It allows them to explore different areas of mathematics, physics and chemistry, life sciences and earth and engineering sciences. Also, during grade 11, students of the scientific branch have to undertake a supervised project, called TPE (BOEN 2011c). Over eighteen weeks, small groups of students work collectively on a project, using various resources, on a subject chosen by them that connects two topics (as, for example: How can we use satellite images to refine forecasted monsoons? Modification of food is it progress?). TPE bring into play at least two disciplines, including one which is essential to the students' orientation. The realisation of the project is supervised by teachers of the relevant disciplines with two hours per week in the students' timetable. Assessment considers all aspects of the students' contributions, including written and oral presentations, and is part of the final mark for entering university. Clearly, modelling activities with an open building of the model are easier in this kind of structure (themes of convergence, exploration teaching, TPE) than in a one subject lesson. In the Spanish programme, such opportunities are not found. Some regional university institutes (called IREM) take charge of in-service training of mathematics teachers or offer resources, in relation to modelling. Starting in 2012, a network of science houses is developing in France in order to offer in-service training for the teachers and could offer training on modelling or on inquiry based approach. In Spain the problem is that the training of secondary school teachers in didactics is poor (García et al., 2007). In view of these observations, it is understandable that, still, the majority of Spanish secondary school teachers find working in accordance with the official syllabus guidelines difficult. To get a broader view of the resources available for teaching modelling it would be desirable to extend our research to the study of textbooks. In any case it seems clear that, compared to France, Spain is far from incorporating modelling into its mathematic classrooms.

At the level of pedagogy, in France, the *college* syllabus proposes a common introduction for all scientific subjects and defines (BOEN, 2008, p.5) different *themes of convergence* to be worked together by different subjects and supports a common inquiry based approach that fits well with modelling activities. The Spanish education system insists in the connection between all subjects (all the competences have to be developed in all the disciplines). Obviously, modelling activities promote the acquisition of these eight competences. Moreover, the official text of the curriculum claims that “the teaching methodology must be communicative, active and participatory”, fostering cooperative work and “highlighting the relationships between subjects and its relationship to reality” (BOE, 2007, p.31682). In the definition of the eight core competences, we realize that these make sense when teachers propose to work on real situations (near to daily reality of students). Indeed, we can conclude that both programmes are based in a pedagogy that could promote the use of modelling as a teaching tool.

At the level of the mathematical domains, in France, resources in numbers, geometry, magnitude, data-organisation and specially in statistics and probability, mention explicitly modelling and propose activities for the class. In Spain there are no national resources like in France. In particular, probability seems a domain underused for modelling in comparison with France.

At the level of mathematical themes and subjects, in France and also in Spain, it is difficult, from official texts, to find a clear link with modelling. We have to investigate resources like textbooks in a next study. Textbooks, in both France and Spain, are non-official resources designating what is to be taught and, when they are used by teachers and students, showing what has been taught.

CONCLUSIONS AND OPEN QUESTIONS

The comparative method shows phenomena in one country (like for example official resources for the teachers in France) absent in the other. The method shows also that the same condition (for example modelling designated to be taught) can produce different consequences because other levels of determination play different roles depending on the country. That is, the comparative method, in fact, helps us to understand more deeply the, not so obvious, conditions of one country in contrast with another. Further research would be able to examine how modelling is taught and learned, and specially the role of non-official resources - like textbooks.

NOTES

I. Ferrando acknowledges the support of the Ministerio de Economía y Competitividad (Spain) for the research project EDU2012-35638.

THE VALIDITY-COMPARABILITY COMPROMISE IN CROSS-CULTURAL STUDIES IN MATHEMATICS EDUCATION

David Clarke

University of Melbourne, Australia

The pursuit of commensurability in international comparative research by imposing general classificatory frameworks can misrepresent valued performances, school knowledge and classroom practice as these are actually conceived by each community and sacrifice validity in the interest of comparability. The “validity-comparability compromise” is proposed as a theoretical concern with significant implications for international cross-cultural research in mathematics education. The paper uses current international research to illustrate various aspects of the issue and its consequences for the manner in which international research is conducted and its results interpreted. The effects are extensive and constitute essential contingencies on international comparative research in mathematics education.

Key words: International Research, Mathematics Education, Comparability, Validity

INTRODUCTION

This paper identifies key considerations affecting the conduct and utility of international comparative research. Central to the design of such research studies are the dual imperatives of validity and comparability. Unfortunately, as will be illustrated, these imperatives are inevitably in tension. This paper identifies, illustrates and discusses these tensions, utilising very specific examples from current international comparative research. It is argued here that any value that might be derived from international comparisons of curricula or classroom practice is critically contingent on how the research design addresses the dual priorities of validity and comparability. It is further argued that since these priorities act against each other, researchers undertaking international comparative research must find a satisfactory balance between these competing obligations.

Perhaps only the drive to categorise is more fundamental than our inclination to compare (cf. Lakoff, 1987). Indeed, the two activities are intrinsically entwined since the act of comparison involves the recognition of the distinctive attributes of the objects being compared, and these attributes represent a form of categorisation. It is a key premise throughout this paper that comparisons are undertaken between constructed representations, whose structure and attributes are reflective as much of the value system of the researcher as of the objects being represented for the purposes of comparison. That these constructions are encrypted in language and effected socially aligns the paper's theoretical orientation with socio-cultural theorists prioritising the role of language as mediating experience and action (Vygotsky (1978) being the obvious example). In this paper, commensurability is interpreted as the right to compare (cf. Stengers, 2011). And it is our central assertion that this right to compare cannot be assumed, but is contingent on our capacity to legitimise both the

act of comparison and the categories through which this act is performed. The need for such legitimisation has been raised for international comparisons of student achievement, but less frequently and less carefully for the cross-cultural comparison of curricula and classrooms. Some examples are cited in this paper of cross-cultural comparisons of limited legitimacy (eg participation or lesson structure) or legitimate comparisons framed at levels of granularity such as to limit or remove explanatory capacity (eg between-desks-instruction or student classroom talk). In each example, I have attempted to suggest how to maximise both the validity and the explanatory power of the categorisation schemes employed for purposes of comparison.

Critical in the legitimisation of these acts of comparison are the validity of the categories we employ and of the act of comparison itself. Much of the focus in this paper is on cultural validity, which is interpreted (with Säljö, 1991) as a key determinant of practice in the international settings we aspire to compare. Research designs, especially data generation and categorisation processes, can misrepresent or conceal cultural idiosyncrasies in the interest of facilitating comparison.

This paper considers this validity-comparability compromise in relation to both curriculum and classroom practice research. Curricular comparisons raise issues related to the structure of school knowledge and the aspirational character of valued performances. Comparisons of classroom practice foreground the performative realisation of school knowledge and introduce the teacher as curricular agent (among other roles), modelling, orchestrating, facilitating and promoting performances aligned with the educational traditions of the enfolding culture. Any cross-cultural comparative analysis faces the challenge of honouring the separate cultural contexts, while employing an analytical frame that affords reasonable comparison.

The paper utilises seven “dilemmas” to reveal some of the contingencies under which international comparative research might be undertaken. The issues raised by each dilemma are not mutually exclusive sets. Specific empirical examples from current international research provide the vehicle by which the entailments of each dilemma can be explored to identify areas of cross-cultural research requiring critical examination.

COMPARABILITY AND VALIDITY IN CROSS-CULTURAL STUDIES

In an international comparative study, any evaluative aspect is reflective of the cultural authorship of the study.

Culture is thus what allows us to perceive the world as meaningful and coherent and at the same time it operates as a constraint on our understandings and activities.(Säljö, 1991, p. 180).

In seeking to make comparison between the practices of classrooms situated in different cultures, the most obvious comparator constructs become problematic.

Dilemma 1: Cultural-specificity of cross-cultural codes

Use of culturally-specific categories for cross-cultural coding (eg participation, mathematics).

In the Chinese adaptation of the research design for the Middle School Mathematics and Institutional Setting of Teaching (MIST) project, the decision was made not to use the Instructional Quality Assessment (IQA) (Silver & Stein, 1996), but instead to develop a local instrument for the evaluation of mathematics classroom instruction. The reason for the rejection of the IQA instrument for use in Chinese school settings reflected the embeddedness, within the instrument, of particular values characteristic of the cultural setting and educational philosophy of the authoring culture (USA). For example, for the measurement of students' participation in classroom instruction, new criteria are needed that accommodate the larger class size and norms of social interaction of the Chinese mathematics classroom. Figure 1 shows the criteria for evaluating the level of student participation in teacher-facilitated discussion in mathematics classes.

A. Participation

Was there widespread participation in teacher-facilitated discussion?

4	Over 50% of the students participated consistently throughout the discussion.
3	25 to 50% of the students participated consistently in the discussion OR over 50% of the students participated minimally.
2	25 to 50% of the students participated minimally in the discussion (that is, they contributed only once.)
1	Less than 25% of the students participated in the discussion.
N/A	Reason:

Figure 1. Participation criteria from the *Instructional Quality Assessment (IQA)* instrument (Silver & Stein, 2003).

In countries such as China and Korea, teachers in both primary and secondary schools make extensive use of elicited student choral response as a key instructional strategy (Clarke, 2010). In the lessons analysed from one Shanghai classroom, a large number of choral responses (~ 80) were used in each lesson. In the analysis of a classroom in Tokyo, there were a similar number of individual student public statements, but no evidence of choral response. Applying the IQA participation criteria (Figure 1), the regularity and frequency of the use of choral responses would characterise this classroom as participatory at a level comparable with the classroom in Tokyo. Yet the students in the Tokyo classroom participate primarily through individual contributions rather than choral response and the type of teacher-facilitated discussion and the nature of student participation in that discussion in the two

classrooms are sufficiently different to make their comparability with respect to participation highly questionable. The cultural authorship of research instruments and their cross-site legitimacy has implications for both data generation and interpretation and must be accommodated carefully through revision or replacement, or through reconception of the nature of the comparison being undertaken.

While Dilemma 1 arises through the misapplication of a culturally-authored categorisation scheme, Dilemma 2 arises from the need to categorise at a level of granularity sufficiently large as to accommodate (mask or gloss over) more fine-grained differences between the objects of comparison. The difficulty here arises not because the category scheme is culturally-specific, but because the objects to be categorised are sufficiently disparate or varied at one level of granularity as to defy comparison, but able to be included in a more inclusive (less discriminating) categorisation scheme that then supports the act of comparison, but disengages the act of comparison from the more fine-grained descriptions that could explain the origins of identified differences.

Dilemma 2: Inclusive vs Distinctive

Use of inclusive categories to maximise applicability across cultures, thereby sacrificing distinctive (and potentially explanatory) detail (eg. mathematical thinking, lesson structure).

In a recent study undertaken by the author and his colleagues, we compared the ways in which mathematics curricula are framed in Australia, China, Finland and Israel. We sought to identify the similarities and differences in the organisation of mathematics curricula in the four countries in terms of their aims, content areas and performance expectations. In particular, we investigated the ways in which “mathematical thinking” was framed through curricular statements.

The key documents analysed in this study were: the Victorian Essential Learning Standards (VELS), the Chinese Mathematics Curriculum Standards (CMCS), the Finnish National Core Curriculum (FNCC) and the Mathematics Curriculum (Israel) (MCI). The four curricula are structurally quite different and prioritise different performance types. The excerpts below capture some of these qualitative differences.

See mathematical connections and be able to apply mathematical concepts, skills and processes in posing and solving mathematical problems (VELS).

[Translation] Obtain important mathematics knowledge that is essential for functioning in society and further development (including mathematical facts and experience in participating in mathematics activities) and basic mathematical thinking skills as well as essential skills of application (CMCS).

The task of instruction in mathematics is to offer opportunities for the development of mathematical thinking, and for the learning of mathematical concepts and the most widely used problem-solving methods (FNCC).

[Translation] Mathematics is not only a collection of calculated algorithmic operations that serve an applied purpose but also a subject with its own structure that includes unique thinking and investigation methods. The goal of the curriculum is to generate a change in the way that students view the subject (MCI).

Any attempt to characterise the relative emphasis given to particular types of valued performance at different grade levels can only be undertaken if a common classificatory framework can be imposed on all curricula. But such a general framework must not be allowed to mask the significant emphasis given to Geometry in grades 7 to 9 in China, or to “Communicating” in grades 3 to 5 in Finland, or the idiosyncratic prioritizing in grades 7 to 9 in Israel of “the evolution of phenomena from the perspective of mathematics.” The danger is that the commensurability demands of such comparisons conceal major conceptual differences in the curricular expression of categories of school knowledge. For example, it can be argued that the curricula in Australia, China, Finland and Israel are similar in that they advocate the development of “mathematical thinking” but this conceals important differences in the nature of the mathematical thinking that each curriculum seeks to promote. The act of developing more inclusive categories by combining more fine-grained culturally-specific categories in order to enable cross cultural comparisons runs the risk of distorting the knowledge categories we seek to compare. In cross-cultural research the imposition of an “external” classification scheme for the purposes of achieving comparability can sacrifice validity by concealing diversities reflecting cultural characteristics and by creating artificial distinctions. Comparability is achieved through processes of typification and omission, and each has the potential to misrepresent the setting.

Dilemma 3: Evaluative Criteria

Use of culturally-specific *criteria* for cross-cultural *evaluation* of instructional quality (eg. Student spoken mathematics).

Where research is specifically constructed to be evaluative, the question arises as to the legitimate application of criteria developed in one culture to the practices of another culture. The use of evaluative criteria posits an ideal of effective practice that should be substantiated by reference to research. Problems arise when the research on which a criterion is based is itself culturally-specific.

For example, despite the emphatic advocacy in Western educational literature, classrooms in China and Korea have historically not made use of student-student spoken mathematics as a pedagogical tool. In research undertaken by Clarke, Xu and Wan (2010), classrooms were identified in which student spoken mathematics was

purposefully promoted in public but not in private interactions (eg Shanghai classroom 1), in both public and private interactions (eg Melbourne 1) and in neither public nor private interactions (eg Seoul 1). Each of these classrooms models a distinctive pedagogy with respect to student spoken mathematics.

If the occurrence of student-spoken mathematics is identified with quality instruction, then the instructional practice of the classroom in Seoul would be judged to be deficient. The classrooms in Shanghai and Melbourne differed significantly in the extent to which private student-student interactions were encouraged, but the teachers in both classrooms prioritized student facility with spoken mathematics. In the Shanghai classroom, promotion of this capability was developed solely through public discourse, whereas in the Melbourne classroom, private student-student mathematical speech was an essential pedagogical tool. Interestingly, in post-lesson interviews, the students from Melbourne and Shanghai showed comparable fluency in their use of the language of mathematics, while students from the classrooms in Seoul showed little evidence of such a capacity. The comparability issue here is whether it is legitimate to undertake evaluative comparison of frequency and sophistication of student spoken mathematics in Melbourne, Shanghai and Seoul, if the operative pedagogy in the Seoul classrooms does not actually value student facility in spoken mathematics as a learning outcome and therefore cannot be presented legitimately as having “failed” to develop this capacity in the students. Evaluative judgments of instructional quality made in the context of international comparative research must justify the model of accomplished practice implicit in the criteria employed and provide evidence of the cross-cultural legitimacy of these criteria.

Dilemma 4: Form vs Function

Confusion between form and function, where an activity coded on the basis of common form is employed in differently situated classrooms to serve quite different functions (eg kikan-shido or between-desks-instruction).

Kikan-shido (a Japanese term meaning “between-desks-instruction”) has a *form* that is immediately recognisable in most countries around the world. In kikan-shido the teacher walks around the classroom, while the students work independently, in pairs or in small groups. Although kikan-shido is immediately recognisable to most educators by its form, it is employed in classrooms around the world to realise very different functions. A teacher undertaking kikan-shido in Australia, will do so with very different purposes in mind from those pursued by a teacher in Hong Kong, or, for example, a teacher in Japan. In reporting the frequency of occurrence of an activity such as kikan-shido for the purposes of comparative analysis, the researcher conflates activities that are similar in form but which may be employed in differently-situated classrooms for quite distinct functions. Such conflation can create an impression of similarity although differences in practice are actually quite profound (for more detail, see Clarke, Emanuelsson, Jablonka & Mok, 2006). The distinction

between Dilemma 4 and those preceding it, derives from the combination of the legitimate equivalence of form (between-desks-instruction) across cultural sites, and the disparity of function (rather than of yet more fine-grained form) that exists at the same level of granularity between sites (rather than between different levels of granularity across all sites).

Dilemma 5: Linguistic Preclusion

Misrepresentation resulting from cultural or linguistic preclusion (eg Japanese classrooms as underplaying intellectual ownership).

The analysis of social interaction in one culture using expectations encrypted in classificatory schemes that reflect the linguistic norms of another culture can misrepresent the practices being studied. This can occur because characteristics of social interaction privileged in the researcher's analytical frame may not be expressible within the linguistic conventions of the observed setting. For example, the Japanese value implicit communication that requires speaker and listener to supply the context without explicit utterances and cues. This tendency is typically found in leaving sentences unfinished. As a consequence, in Japanese discourse, agency or action are often hidden and left ambiguous. In English, when introducing a definition, the teacher might employ a do-verb: "We define". In a Japanese mathematics classroom, the teacher often introduces a definition in the intransitive sense (*SouNatteIru* = "as it is" or "something manifests itself") as if it is beyond one's concern. Such differences in the location of agency, embedded in language use, pose challenges for interpretive analysis and categorisation of classroom dialogue.

Dilemma 6: Omission

Misrepresentation by omission, where the authoring culture of the researcher lacks an appropriate term or construct for the activity being observed (eg. Pudian).

The Sapir-Whorf hypothesis suggests that our lived experience is mediated significantly by our capacity to name and categorise our world.

We see and hear . . . very largely as we do because the language habits of our community predispose certain choices of interpretation (Sapir, 1949).

Marton and Tsui (2004) suggest that "the categories . . . not only express the social structure but also create the need for people to conform to the behavior associated with these categories" (p. 28). Our interactions with classroom settings, whether as learner, teacher or researcher, are mediated by our capacity to name what we see and experience. Speakers of one language have access to terms, and therefore perceptive possibilities, that may not be available to speakers of another language. For example, in the Chinese pedagogy "Qifa Shi" (Cao, Clarke, & Xu, 2010), the activity "Pudian"

is a key element. Pudian can take various forms: Connection, Transition, Contextualising, but its function is to help students develop a conceptual, associative bridge between their existing knowledge and the new content. There is no simple equivalent to Pudian in English, although teacher education programs delivered in most English-speaking countries would certainly encourage the sort of connections that Pudian is intended to facilitate. Many such pedagogical terms have been collected in a variety of languages (Clarke, 2010), describing classroom activities central to the pedagogy of one community but unnamed and frequently absent from the pedagogies of other communities. It follows that an unnamed activity will be absent from any catalogue of desirable teacher actions and consequently denied specific promotion in any program of mathematics teacher education. It is also likely that such activities will go unrecognised in reports of cross-cultural international research, where the authoring culture of the research report lacks the particular term.

Dilemma 7: Disconnection

Misrepresentation through disconnection, where activities that derive their local meaning from their connectedness are separated for independent study (eg. teaching and learning (cfobuchenie), public and private speech).

Whether we look to the Japanese “gakushu-shido”, the Dutch “leren” or the Russian “obuchenie”, we find that some communities have acknowledged the interdependence of instruction and learning by encompassing both activities within the one process and, most significantly, within the one word. In English, we dichotomise classroom practice into Teaching or Learning. One demonstration of the consequences of the inappropriate disconnection of actions that should be seen as fundamentally connected is evident in the comparison of two published translations involving Vygotsky’s use of the term “obuchenie” (discussed in Clarke, 2001).

From this point of view, *instruction* cannot be identified as development, but properly organized *instruction* will result in the child's intellectual development, will bring into being an entire series of such developmental processes, which were not at all possible without *instruction* (Vygotsky, as quoted in Hedegaard, 1990, p. 350).

From this point of view, *learning* is not development; however, properly organized *learning* results in mental development and sets in motion a variety of developmental processes that would be impossible apart from *learning* (Vygotsky, 1978, p. 90).

The analogous disconnection of public and private speech in classrooms, and of speaking and listening (Clarke, 2006) has the same effect of misrepresenting activities that may be fundamentally interrelated (not just conceptually but also functionally connected) in their enactment in particular classroom settings.

CONCLUSIONS

The pursuit of commensurability in international comparative research by imposing general classificatory frameworks can misrepresent valued performances, school knowledge and classroom practice as these are actually conceived by each community and sacrifice validity in the interest of comparability. In this paper, the “validity-comparability compromise” has been proposed as a theoretical concern that has significant implications for international comparative research. The identified dilemmas offer different perspectives and illustrate some of the consequences of ignoring this central concern. Some dilemmas are not specific to cross-cultural comparative contexts (eg inclusive vs distinctive - Dilemma 2), but should be considered any time difficulties caused by diversity at the intended level of comparison can be avoided by undertaking the comparison at a larger (more inclusive) level of granularity, sacrificing distinctive (and potentially explanatory) detail in the interests of legitimate comparison. Other dilemmas are a direct consequence of the idiosyncrasies of culture and language (eg Linguistic Preclusion or Omission – Dilemmas 5 and 6). The examples also illustrate the steps that can be taken to improve the legitimacy of the intended comparison. Partnerships with those being compared can minimise misrepresentation, but the necessity of the compromise is inescapable. The interpretation and application of international comparative research is critically contingent on researchers’ capacity to address those “dilemmas” pertinent to their particular design. As they have been framed in this paper, the dilemmas relate to methodological concerns. However, each dilemma can also serve as an interrogatory instrument: a tool directing the researcher’s attention to salient characteristics that, while presenting impediments to comparison, simultaneously provide insight into nuances of meaning and practice. This paper is intended to fuel a wider engagement in the critical interrogation of international comparison as a socio-material knowledge practice.

MATHEMATICS TEACHERS' BELIEFS IN ESTONIA, LATVIA AND FINLAND

Markku S. Hannula¹, Madis Lepik², Anita Pipere³, and Laura Tuohilampi¹

¹University of Helsinki, ²Tallinn University, and ³Daugavpils University

The article presents results from a cross-cultural comparison of mathematics teachers' beliefs. We report how nationality and language in Estonian, Latvian and Finnish schools shape mathematics teachers' beliefs, the schools' microcultures and the relations between teachers' beliefs and their schools' microcultures. Results indicate cultural differences in school microcultures and teachers' beliefs as well as in how these variables are related to each other.

INTRODUCTION

Research on teacher beliefs has been motivated by the assumption that teacher beliefs largely determine the reality of teaching in classrooms. However, such naïve views have been challenged by case studies indicating inconsistencies between teacher's beliefs and practice suggesting that more emphasis should be paid to contextual factors. In this article we suggest an overall theoretical frame for the role of culture, school microculture, and teacher beliefs in the formation of actual classroom practices. Moreover, we present results of a cross-cultural survey of mathematics teacher belief structures in Estonia, Latvia, and Finland and how these beliefs are influenced by school microculture.

Teacher beliefs

Teaching in schools is orchestrated by teachers. They interpret policies and curricula and implement them in classrooms. Based on this perspective, there has been extensive research on teachers' beliefs, which reflect their priorities for the practices of mathematics classrooms and play a significant role in shaping teachers' instructional behaviour (Thompson, 1992; Schoenfeld, 1998). However, there remains considerable debate about the definition and characteristics of beliefs (see, Furinghetti & Pehkonen, 2002). In this study beliefs are construed broadly as those conceptions, views and personal ideologies that shape teaching practice. Beliefs research in mathematics education has focussed on how teachers view the nature of mathematics, its learning and teaching, and teaching in general (Dionne, 1984; Ernest, 1991; Liljedahl, Rösken, & Rolka, 2007).

Contextual influences on beliefs

The manifestation of teacher's beliefs in practice is influenced by the context: pedagogical traditions in the country, school culture, social background of the students, etc. This makes the relationship between teachers' beliefs and their teaching practice complex; research often reports inconsistencies between teachers' beliefs and their actions (Cooney, 1985; Skott, 2009). There are two levels of contextual factors. The overall cultural milieu includes not only

curriculum and other educational policy, but also unofficial aspects of the culture, which impact the values of education and teacher-student relationships. Such influences do not always follow the national borders as religion, and language may be more relevant determinants. An individual teacher must largely take these for granted and just adjust to them.

Another level of context is the local microculture in the school, which is reflected in the school rules and norms and in the way teachers collaborate. The teacher is an important actor of this microculture and may influence its development over time. The importance of school microculture has been found repeatedly in intervention studies. For example, in an evaluation of one large professional development program within mathematics education (Bobis, Clarke, Clarke et al., 2005), the aspects that were considered most effective were the practical resources and activities, the assessment process, the influence of significant people, classroom support, and the opportunity to share ideas. On the other hand, significant barriers to teachers' implementation of the program were time, resources, class management and information overload. Almost all of these can be influenced locally.

So far, few studies have compared teacher beliefs across countries (e.g., Andrews, 2007; Andrews & Hatch, 2000; Felbrich, Kaiser & Schmotz, 2012). The TALIS survey explored conditions of teaching and learning in 24 OECD countries (OECD, 2009). Loogma, Ruus, Talts and Poom-Valickis (2009) constructed two factors for different teacher beliefs: 1) traditional beliefs and 2) constructivist beliefs. Their analysis showed that in some countries teachers tended to choose one view over the other while in other countries there was a strong positive correlation between these two perspectives.

Teacher beliefs and cultural influences in Estonia, Latvia and Finland

Since regaining their independences in 1991, Estonia and Latvia have undergone many changes affecting their educational systems. While natural sciences and mathematics were emphasised in the Soviet curriculum, the focus has shifted towards other topics. Also the attractiveness of the teacher profession has fallen considerably.

In Estonia, there was also a concern among mathematics education researchers that teaching was too much based on drill and practice-methods (Lepik, 2005). Yet, TALIS found Estonia to be one of the countries with strongest support for constructivist teaching beliefs (Loogma et al., 2009). Although Estonian teachers believed more in a constructivist way of teaching they did not directly contrast this view with the direct transmission of knowledge, and could therefore believe in the combination of these two views.

Latvian teachers have been found to be more oriented towards constructivism than teachers in the USA (Ravitz, Becker, & Wong, 2000; Šapkova, 2011). Whilst both primary and secondary teachers supported constructivist ideas, primary teachers

reported more implementation of constructivism in their classrooms than secondary teachers (Pipere, 2005). A recent study (Austers, Golubeva, & Strode, 2007) shows that teachers in Latvia, irrespective of the language of instruction, stage of education and school subject, report symptoms of burnout syndrome. Right-wing authoritarianism was found to be above the median, especially in Russian-speaking schools and primary schools, alongside below median levels of social dominance orientation; a positive belief found among teachers from Latvian-speaking schools. In 2006 and 2008 new standards in basic and secondary education were introduced in Latvia. These reforms, as well as the ESF project “Elaboration of the Content of Learning and Teacher Further Education in the Subjects of Natural Sciences, Mathematics and Technologies” (2008-2013), changed the philosophy of the Latvian education towards constructivism. Yet, despite these new standards the mathematics performance of Latvian students in international studies has not improved and is below the OECD average (Shapkova, 2012).

In Finland, the fall of the Soviet Union was one reason for a serious economic crisis. Although this influenced also the educational system, the national policy emphasised mathematics and sciences. A national LUMA-project (1996-2002) was set up to enhance the learning of mathematics and sciences (Ahtee, Lavonen, Parviainen, & Pehkonen, 2007). The national ethos of the time was inspired by the rise of Nokia, generating a vision of Finland as a high-tech economy. As a surprise for Finns, Finland achieved the highest score in PISA 2000 and continued to do well in the following measures. However, Finland was also characterised by less favourable affect (OECD-PISA, 2004).

Research questions

Based on the review of the literature, we consider cultural factors to be relevant for teachers’ beliefs. In addition to country (Finland, Estonia and Latvia), we expect the language of instruction (national and Russian) to be relevant in Estonia and Latvia. Moreover, we acknowledge the importance of local school microcultures. Whereas nationality and language are considered to be two independent variables, we see the local micro-culture of the school to be interrelated with teacher’s beliefs. Firstly, we acknowledge that the teacher has significant influence on the formation of that microculture. Secondly, our measure of school microculture is based on the self-report of the teacher, thus indicating as much the teacher’s personal interpretation of that culture as the local culture per se (Figure 1).

In this paper we explore the following research questions: 1) How do the variables of country and language of instruction mediate school microculture and teacher beliefs?) 2) What kinds of relationships can be found between school microculture and teacher beliefs?

Figure 1: The theoretical framework for the study

METHODOLOGY

Participants

The data were collected from 815 7-9th grade mathematics teachers in Estonia (N=333), Latvia (N=390), and Finland (N=92). Subsamples of teachers who teach in Russian speaking schools were collected in Estonia (N= 99) and Latvia (N = 96). Data collection was completed in late 2010 and early 2011. The age of the Estonian teachers ranged from 25 to 77 (M=47), the age of the Latvian teachers ranged from 25 to 66 years (M=46), and the age of the Finnish teachers ranged from 25 to 61 years (M=42).

Instrument

A seven-module questionnaire was devised to explore teachers' beliefs. In this paper, we shall analyse and report on three modules: (1) teachers' overall job satisfaction; (2) their general beliefs on teaching and learning; and (3) their beliefs on mathematics teaching and learning. Teachers responded to each item using a 5-point Likert-scale. The first part of the instrument was designed as an indicator of teachers' overall job satisfaction. As many of the items relate to administrative support and teacher collaboration, we consider it a relevant indicator for school microculture. The dimension comprised items for a factor "collaboration and recognition", for example "In our school, staff members are recognized for a job well done". Teachers' general beliefs on teaching and learning were measured using items typical for constructivist (or non-constructivist) philosophies of teaching, for example, "Teachers should direct students in a way that allows them to make their own discoveries" or "Effective/good teachers demonstrate the correct way to solve a problem".

The module measuring teachers' beliefs on mathematics teaching and learning was constructed using 26 Likert statements from Pehkonen and Lepmann (1994). Sample items for the different dimensions are: "Pupils should have an opportunity to independently develop their mathematical understanding and knowledge" (Process), "In a mathematics lesson, there should be more emphasis on the practicing phase than on the introductory and explanatory phase" (Toolbox); "Working with exact proof forms is an essential objective of mathematics teaching" (Proofs). The theoretical background, development and structure of the questionnaire are described more thoroughly in a previous paper (Lepik & Pipere, 2011).

Analysis

In order to reduce data into fewer, but more reliable variables, the different modules of the questionnaire were subjected to principal component analysis with

varimax rotation. We removed several variables due to low communality or multiple loadings. In order to determine the number of factors we used different methods, such as scree-test, “eigenvalue greater than 1” rule, and parallel analysis. Several solutions with different numbers of factors were tested. The criteria to select the factors were reliable and allowed easy interpretation of the factors.

Based on the factor analyses, we computed the following sum variables. School micro-culture: Collaboration and recognition ($\alpha=.696$; 5 items); General teaching beliefs: Constructivist approach ($\alpha=.730$; 12 items), Traditional approach ($\alpha=.577$; 4 items); Mathematics teaching beliefs: Process ($\alpha=.732$; 9 items), Toolbox ($\alpha=.677$; 6 items), Proofs ($\alpha=.592$; 4 items).

We examined the possible differences of three countries (Finland, Estonia and Latvia) using Kruskal-Wallis test, and language groups in Latvia and Estonia (national language and Russian) using Mann-Whitney tests for each pairwise comparison. In order to analyse the relationships between teacher beliefs and school microculture, we calculated the Pearson correlations for each subsample.

RESULTS

Cultural differences by countries (Table 1), determined by Kruskal-Wallis tests, were statistically significant for all examined sum variables ($p<.001$). The results show significantly higher scores for teachers from Estonia in all sum variables compared with the teachers from Finland ($p<.001$). With respect to differences between the teachers from Latvia and Finland, with the exception of the Toolbox aspect, teachers from Latvia reported significantly higher scores for all other sum variables (Traditional beliefs $p<0.05$; other variables $p<.001$). The most disparate comparison of scores turned out between Estonia and Latvia, where teachers from Latvia reported stronger emphasis on Collaboration and recognition ($p<.05$), and Constructivist beliefs ($p<.05$), while teachers in Estonia scored significantly higher in Traditional beliefs ($p<.01$), Toolbox aspect ($p<.001$) and Proof aspect ($p<.01$). The Process aspect of mathematics teaching did not show any significant differences between teachers from Estonia and Latvia.

Both in Estonia and Latvia those teaching in Russian reported higher Collaboration and recognition ($p<.005$ in Estonia, $p<.05$ in Latvia) and Proof aspect ($p<.001$ in Estonia and Latvia). Estonian teachers from Russian speaking schools reported higher agreement with Constructivist beliefs ($p<.05$) and Process aspect in mathematics teaching ($p<.01$) than teachers from Estonian speaking schools. Comparing the four language groups from Estonia and Latvia with Finish speaking teachers from Finland, it appears that for all sum variables teachers from Finland scored significantly lower (range of p from $p<.001$ to $p<.05$), except for the non-significant difference between Latvian speaking teachers from Latvia and Finnish teachers for Toolbox aspect.

Group		Collaboration & recognition	Constructivism	Traditionalism	Process aspect	Toolbox aspect	Proof aspect
By country	EST	3.81	4.13	3.39	4.18	3.49	3.43
	LAT	3.92	4.19	3.22	4.17	3.27	3.29
	FIN	3.60	3.96	3.02	3.92	3.16	2.92
By language	ER	3.97	4.20	3.37	4.31	3.51	3.79
	EE	3.75	4.10	3.39	4.13	3.48	3.30
	LR	4.05	4.18	3.26	4.24	3.35	3.53
	LL	3.88	4.20	3.21	4.14	3.25	3.21

Table 1: Means for examined sum variables according to variables of country and language. EST = Estonia, LAT = Latvia, FIN = Finland, LR = Latvia-Russian; LL = Latvia-Latvian; ER = Estonia-Russian; EE = Estonia-Estonian.

The largest similarity was found between Russian speaking teachers from Latvia and Estonia, where Russian speaking teachers from Estonia reported higher scores only for Toolbox ($p < .05$) and Proof aspects ($p < .01$). No difference was found between Latvian speaking teachers and Russian speaking teachers from Estonia for Collaboration and recognition, Constructivist or Traditional beliefs, while the latter was in larger agreement with Process ($p < .01$), Toolbox ($p < .01$) and Proof aspect ($p < .001$) of mathematics teaching.

Significant differences were observed between Latvian and Estonian speaking teachers: Latvian speaking teachers were higher in Collaboration ($p < .05$) and Constructivist beliefs ($p < .01$) while Estonian speaking teachers were higher in Traditional ($p < .01$) beliefs and Toolbox aspect ($p < .001$). Russian speaking Latvian teachers and Estonian speaking teachers showed quite disparate results: the latter scored lower for Collaboration ($p < .001$), Process ($p < .05$) and Proof aspect ($p < .05$), while their scores for the Toolbox aspect ($p < .05$) were higher.

Pearson correlations confirmed some expected results, but also revealed some unexpected results (Table 2). We found a strong correlation between the constructivist view of teaching and process view of mathematics teaching in all groups. A similar strong correlation was found between traditional view of teaching and toolbox view of mathematics teaching.

	Constructivism	Traditionalism	Process Aspects	Toolbox Aspects	Proof Aspects

Toolbox FF					.061

Table 2: Pearson correlations between collaboration, general teaching beliefs and mathematics teaching beliefs. LR = Latvia-Russian; LL = Latvia-Latvian; ER = Estonia-Russian; EE = Estonia-Estonian; FF = Finland-Finnish.

Moreover, there was interesting variation regarding how collaboration was related to teaching beliefs in different groups. For example, only for Latvian groups and Estonian speaking Estonian teachers' collaboration had a positive correlation with constructivist teaching beliefs and process view of mathematics teaching.

Additionally, only in Finland, the emphasis on proofs had no positive correlation with the process aspect and toolbox aspect of mathematics.

DISCUSSION AND CONCLUSIONS

Teachers' beliefs reflect the way that teaching and learning is conceptualized in different countries. Cross-cultural differences in teachers' beliefs provide important information regarding teachers' inclination to different teaching approaches. The TIMSS and PISA studies have shown that the mathematical attainment of Finnish, Latvian and Estonian pupils are different. Therefore, it would be relevant to assume also that teachers' beliefs would somehow differ in these countries. The country comparison indicates that Latvian teachers emphasize the constructivist teaching beliefs most, while Estonians were the strongest supporters for the traditional beliefs. On the overall level, Finland agreed the least with both of these approaches. We found that all countries and language groups had a similar pattern of higher emphasis for constructivism over traditional general teaching beliefs and for Process approach over Toolbox and Proof approaches for mathematics teaching. We also identified differences within Estonia and Latvia according to the language of teaching, Russian speaking teachers putting more emphasis on proofs.

The results indicate that mathematics teachers' overall teaching beliefs are related to their view of mathematics teaching. Those who believe more strongly in constructivist ideas tend to emphasize the process aspect of mathematics more. On the other hand, those who hold a more traditionalist view of teaching tend to emphasize the toolbox aspect of mathematics in their teaching. Yet, it is important to notice that there was no negative correlation either between constructivism and toolbox-approach or between traditionalism and process-approach. The school microculture – as reflected in teacher perception of collaboration and recognition – seems to have a clear relation with constructivist practices in both Latvian subsamples and in Estonian speaking sample from Estonia but not in the other groups. Such findings are bewildering and ask for further analysis of the data.

ACKNOWLEDGEMENTS

We thank Kirsti Kislenko's for her assistance with analysis. The study was supported by the European Social Fund Programme Eduko (grant no. 1.2.0302.09-0004).

ANALYZING MATHEMATICS CURRICULUM MATERIALS IN SWEDEN AND FINLAND: DEVELOPING AN ANALYTICAL TOOL

Kirsti Hemmi, Tuula Koljonen, Lena Hoelgaard, Linda Ahl, and Andreas Ryve
Mälardalen University, Sweden

This paper aims to contribute to two interrelated areas. Firstly, it adds new insights into the variation of curriculum materials within and between two countries, Sweden and Finland, with respect to their potential to contribute to various kinds of teacher learning. Secondly, it aims to build on and develop an analytical tool for analyzing curriculum materials. To accomplish these aims we explored two teacher's guides from each country, applying a tool derived from the context of science education. The analysis reveals substantial differences between all four texts concerning the categories in the analytical tool. We suggest how the analytical tool could be developed to more deeply explore its potential for supporting qualitatively varied teacher learning.

Key words: analytical tool, comparative study, curriculum materials, mathematics teacher's guides, teacher learning

INTRODUCTION

Curriculum materials such as commercially produced textbooks and teacher's guides have a strong presence in mathematics education in large parts of the world. These materials are typically a major resource for teachers' planning and practice (Stein et al., 2007; Jablonka & Johansson 2010). One of the tasks of curriculum materials is to bring different discourses together (Jaworski, 2009). On the one hand, there is an academic conceptualization from which the intended curriculum derives and, on the other hand, the socio-cultural settings where teaching and learning occur: the enacted curriculum. Writers of curriculum materials may therefore interpret the intended curriculum and adjust to the socio-cultural settings to function as a bridge between the two different discourses. From this perspective, curricular materials serve as an important tool for teachers in both enabling and constraining their thoughts and actions (Stein et al., 2007). Further, curriculum materials are not only important resources for teachers in designing teaching (Stylianides, 2007), but also for teacher learning (Doerr & Chandler-Olcott, 2009). For instance, Remillard (2000) and Davis and Krajcik (2005) emphasize that curriculum materials could productively contribute to teachers' professional development if they encompass an elaborated attention to the process of enacting the curriculum. Therefore, potentially, well-designed curriculum materials could create opportunities for teacher learning.

There exists no role model for how to design such materials, since teachers' use of, and learning from, curriculum materials are related to their experience, knowledge and the particular classroom situation. This study aims to contribute to the knowledge about teacher's guides and their potential for various kinds of teacher learning in two

neighbouring countries with quite similar school systems but different teaching styles: Sweden and Finland. One rationale for undertaking a comparative approach is that through a process of investigating similarities and differences in various countries' curricular materials we reveal some taken-for-granted and hidden aspects (cf., e.g., Andrews, 2010) of teachers' work in classrooms. Such findings, we believe, could contribute to the international research discourse on aspects of curriculum materials and their influence on teaching and teacher learning.

Teachers in Finland use the textbook and teacher's guides extensively (Joutsenlahti & Vainionpää, 2010). There are indications that many Finnish teachers are satisfied with the way their teacher's guides are built, and that they consider them to be very helpful in differentiating their teaching (Heinonen, 2005). Further, Finnish teachers state that the guides provide help and ideas for new ways to teach and simultaneously ensure that the children learn what they are supposed to learn according to the state curriculum (L. Pehkonen, 2004). Swedish teachers also use the textbook to a very large extent, but seldom use teacher's guides (Jablonka & Johansson, 2010). Teachers in Finnish classrooms often lead whole-class instructions whereby all pupils are engaged in the same mathematical area (e.g., E. Pehkonen et al., 2007). In Sweden, on the contrary, it is common to conduct teaching as "speed individualization" and as personalized teaching (e.g., Jablonka & Johansson, 2010) where pupils work, in the same classroom, with different mathematical areas. Due to these differences, it is interesting to compare the curriculum materials used in the two countries. In this paper, we aim to answer to the following questions: *What similarities and differences in curriculum materials exist within and between two countries, Sweden and Finland, with respect to their potential to contribute to various kinds of teacher learning? How is it possible to develop and amend an analytical tool for examining the potential for teacher learning in curriculum materials?*

TEACHER LEARNING AND ARTEFACTS

There are numerous ways of conceptualizing teacher knowledge and teacher learning (e.g., Rowland & Ruthven, 2011). However, instead of digging into these theories and frameworks, we regard teacher learning as a process of social participation in communities of practice according to Wenger (1998), and we understand the artefact of the curriculum material as a resource used in teachers' professional practice. In line with Brown (2009) we emphasize that teachers and curriculum materials participate together in a collaborative relationship, whereby teachers are viewed as active agents in developing and constructing the planned and enacted curriculum. Both teachers and curriculum materials have a role in mediating the relationship, which is shaped by historical, social and cultural factors. This implies that the results of this study could be seen as one piece in the building of an understanding of how curriculum materials, teacher learning, teacher education, culture, etc. are related to, and constitute, each other. Brown (2009) also reflects upon different resources and how they can lead to different opportunities for teachers' and students' learning. We want to stress that a teacher's guide can only hold the potential for teacher learning in

practice, and that teachers in the schools form a heterogeneous group with respect to their developing identities, competences and professionalism.

METHODOLOGY

Context

This paper presents one of several studies connected to two larger research programs. The first program is a comparative project examining similarities and differences between mathematics education in Sweden and Finland (e.g., Ryve, Hemmi & Börjesson, 2011). The second concerns a design research project carried out within and together with one municipality in Sweden, within which Finnish curricular materials (translated into Swedish) are tested by some teachers. Both Sweden and Finland have a nine-year comprehensive school that begins at the age of seven, is free of charge, and involves no tracking. Teachers in both countries are free to choose what curricular materials they want to use; since the beginning of the 1980s in Finland and 1991 in Sweden, there is no state control over curricular materials (E. Pehkonen et al., 2007; Jablonka & Johansson, 2010).

The analytical tool

Wenger's (1998) theory of learning is very general; hence we need to ascribe meaning to the artefacts used in the teachers' practice (cf. Hemmi, 2010), in our case teacher's guides in school mathematics teaching practice. For this purpose we apply the analytic tool of Davis & Krajcik (2005), which focuses on opportunities for teacher learning within the practice of science teaching, as a starting point for approaching our data. With regard to conducted research in mathematics education, we modified it to fit our purpose (Table 1).

Categories	Categories for data analysis
1a) General knowledge of students' ideas and strategies	Describes why students might hold particular ideas about mathematical concepts and exemplifies common strategies among students.
1b) Suggestions for how to encounter students' ideas and strategies	Gives suggestions for how to deal with/encounter various ideas and strategies of students and how to enhance their learning and prevent future difficulties.
2) Concepts and facts	Describes concepts and facts within mathematics such as history, field of application, derivations, methods, proofs, correct terminology.
3) Progression and connections	Shows the mathematics progression throughout the school years as well as connections between mathematical topics; for example, explains the future development of methods and concepts.
4) Connecting theory	Supports the teacher's actions in practice beyond the

and practice	curricular materials by connecting theory and practice. Exposes the central ideas in national curriculum and research results for promoting teachers' autonomy.
5) Design of teaching	Supports the teacher's ability to act in practice by suggestions with respect to the design and enactment of lessons, tasks, formative assessment, individualization of teaching, homework, etc.

Table 1: Five categories for data analysis

Data and data analysis

Our selection of teacher's guides was based on two criteria: that they represent curricular materials commonly used in the respective countries and that they represent both older and newer curricular materials. In this paper we focus on four different teacher's guides for first-grade mathematics. As publishers do not give access to sales figures, we based our choice on commonly used curricular materials based on our own experiences as teachers and researchers.

The four teacher's guides we investigate are:

- *FIN 1: Laskutaito* (1999), a Finnish teacher's guide still used in Finnish schools,
- *FIN 2: Min Matematik* (2004), a Swedish translation of a Finnish teacher's guide, *Tuhattaituri*, for use in the Swedish-speaking part of Finland,
- *SWE 1: Matte Direkt Safari* (2011), a Swedish teacher's guide that has been on the market for several years, and
- *SWE 2: Matte Eldorado* (2011), a Swedish teacher's guide that has been on the market only a few years.

Four researchers conducted the analyses together. Two of the researchers are of Finnish ancestry, and examined the teacher's guide that was not translated into Swedish. We first discussed the categories in Table 1 in relation to the empirical data. Then, each member of the research group took special responsibility for one teacher's guide and investigated the extent and qualities of the topics connected to each category. This process was followed by a collective analysis of our findings in relation to the data as a way of checking each other's analysis.

RESULTS

We found substantial variation concerning the presence of the topics connected to the first four categories. Either they occurred regularly in connection to most mathematical areas (++), sporadically with only some sentences (+), or were totally missing (-); see Table 2.

	FIN 1	FIN 2	SWE 1	SWE 2
1a) General knowledge of students' ideas and strategies	++	-	-	+
1b) Suggestions for how to encounter students' ideas and strategies	++	-	-	+
2) Concepts and facts	+	++	-	+
3) Progress and mathematical connections	+	+	-	+
4) Connecting theory and practice	++	-	-	+

Table 2: Occurrence of the topics connected to categories 1-4. ++ occurred regularly, + occurred sporadically, - were absent.

In *Laskutaito* (FIN 1), topics connected to all four categories were identified. This suggests that it supports teachers in acting beyond the curricular materials by connecting theory and research with practice on two pages at the beginning of every chapter (Category 4). These pages present the overall goals as well as how children may think, and what activities a teacher can do to prevent misunderstandings and promote learning (Category 1). For example, it could be a description of prerequisites for learning in geometry according to research, and suggestions for how teachers could work with the ability of spatial perception.

“7. **Visual memory.** Visual memory can be trained, for example, using the traditional KIM games, whereby 10-20 objects are placed on the table and the children get to see them for a short period of time. When the children then close their eyes, the game leader removes an object and mixes the order of the remaining objects. The children then try to remember which item is missing...” (Laskutaito, 1999, p. 124-125).

Min Matematik (FIN 2) is the only teacher's guide that describes concepts and facts regularly (Category 2). The facts deal with, for example, definitions and correct terminology but also the historical background of, for instance, our number system.

“**Facts.** $3+1$, for example, is an expression. An expression can also consist of a single number or a symbol (for example, a). $4=4$ is an equality. An equality that contains one or several unknowns is called an equation.” (Min matematik, 2004, p. 27).

Sometimes, in connection to the mathematical facts, there is information about progression (Category 3). For example, when presenting the correct terms involving subtraction it also states that “*in this textbook the concepts of addition and subtraction are used with the pupils in this phase but the terms sum and difference are taught later*”. Hence, under these sub-headings the guide combines facts with progression, but progression appears more sporadically. Topics belonging to the categories 1a, 1b and 4 are lacking. For example, no references to research are made.

In *Safari* (SWE 1), no topics were found that could be connected to these four categories.

Matte Eldorado (SWE 2) deals with all the categories, but not regularly. There is some information at the beginning of the guide about number sense and arithmetic, with descriptions of possible difficulties and ineffective strategies children can use and how to prevent and encounter them (Category 1a & 1b), but this does not appear regularly in connection to new areas. There is a matrix at the beginning of the guide displaying how the textbook and the goals for the students are connected to the goals in the curricula. Every goal is also described in the text (Category 4). Yet, no connections to research are made. The matrix also gives the teacher an overview of the progression from school year 1 to 3 (Category 3). In the ordinary text, topics connected to this category (progression and mathematical connections) occur sporadically. Topics dealing with mathematical knowledge (Category 2) occur only a few times.

All but *Min matematik* (FIN 2) include a general presentation at the beginning of the guide with an explanation of why one should engage pupils with the activities presented in the guide. In *Safari* (SWE 1) this part is very short, and in *Matte Eldorado* (SWE 2) it is extensive. This could possibly be added as an additional category in the analysis tool, as we can see differences in the guides concerning the underlying assumptions about teaching and learning, something to focus on in further studies.

Design of teaching

As to Category 5, dealing with topics more directly connected to the design of the lessons, we found several aspects important to dig more deeply into. It could involve, for example, support for how teachers could differentiate their teaching; what materials they could use to concretize learning, engagement in problem-solving and playing games; and how they could assess students' knowledge of mathematics. We found considerable differences between the guides concerning the structure of these aspects; something that, we hypothesize, may influence teacher learning in practice.

Laskutaito (FIN1) is structured around learning outcomes for pupils. The guide also focuses on lesson plans, but leaves a great deal of room for the teacher to design activities suitable to various students in the classroom as there is no suggestion for a particular lesson plan. The guide is based on the pages of the textbook. Sub-headings *Ideas for how to teach/deal with the current object*, *Mental arithmetic*, *Practice and games/plays*, *including challenges for quick and "talented" pupils*, and *Problem-solving* reappear in the section for each lesson. The guide aims to hold the pupils together but offers them partly different activities, and also suggests a small number of tasks connected to every lesson as homework for the pupils. Concerning assessment, there is a short test after every chapter. Ideas for problem-solving are offered in every lesson.

Min Matematik (FIN2) is structured around learning outcomes for students. The guide focuses on lesson plans, and each session is described on four pages. All the sub-headings (*Discussion about a picture*, *Mental arithmetic*, *Suggestion for a lesson*

plan, On the board, A story, Problem-solving, Tips (for example games), Extra, Facts and The following lesson) reappear in the same order and in the same place on these four pages. The guide suggests a lesson plan with various activities in which the class is held together and where differentiation is organized by extra tasks and problems within the same area. It suggests a small number of tasks connected to every lesson as homework for the students. Concerning assessment, there is a short test after every chapter. Ideas for problem-solving are offered in every lesson.

Matte Direkt Safari (SWE1) is structured around the student textbook, and is not structured according to certain time periods, for example a lesson. Each page in the guide includes information about what “*students learn from the pages*”, sometimes how they should work with the pages in the textbook or with some extra pages from the teacher’s guide (for example, what hands-on material they need). On a few occasions there are suggestions for other activities. At the end of each chapter there is a page with ideas for collective activities, like games and outdoor activities. No ideas are offered for differentiation of teaching until the students have finished all the pages in a chapter and received a diagnosis according to which of two paths they can choose. There are suggestions for homework three times in every chapter. No instructions or ideas for problem-solving can be found in the guide.

Matte Eldorado (SWE2) is structured around learning outcomes for students. The guide is not structured in relation to a particular time period, for example a lesson, but is based on the pages of the textbook. The sub-headings *Aim* (with some suggestions for activities supporting learning), *Simplify*, *Challenge*, *Observe*, *Material* and *Go on working* reappear in the same order, but not in all units. Under the sub-headings *Simplify* and *Challenge* are ideas for how to differentiate the teaching regularly. Ideas for collective activities, for example games, are presented at the beginning of the book. Considerations regarding assessment take a dominant place at the beginning of the guide, where different ways of observing pupils’ learning are presented. There is one pre-test at the beginning of the school year and one test after each semester. The sub-heading *Observe* aims to help the teacher observe student behaviour during the lessons. There are suggestions for homework on some occasions. General aspects of problem-solving are dealt with at the beginning of the book, while more specific aspects of problem-solving occur at the end of each chapter. The character of the problems seems to be quite different from that in the Finnish guides. For example, they are always placed in an everyday context.

CONCLUSION AND DISCUSSION

The analyses revealed significant differences between the four teacher’s guides both within and between the countries. Two of the guides (FIN1, SWE2) deal with topics connected to all the five categories, and can hence be regarded as resources for potential teacher learning in practice concerning aspects of encountering pupils’ ideas in a productive manner, confronting the teacher with mathematical ideas and concepts connected to the mathematical topics in the classroom, and making visible the demands of the practice concerning the curricular goals. Only one of the guides

(FIN1) offers resources for teachers' access to the practice of mathematics education research. The older Swedish material distinguishes itself from the other three in that topics connected to these categories were not dealt with.

Concerning Category 5 (Design of teaching), we found the following similarities between the Finnish materials that distinguish them from the Swedish ones: Both focus on lesson plans and offer ideas for teaching, mental arithmetic, differentiating, problem-solving, games and homework in connection to *every lesson*. This is not the case with the Swedish materials, which leave more space for the teacher to decide the units they will use in their teaching. This difference could be connected to differences in teachers' work in practice, which in Finland (e.g., E. Pehkonen et al., 2007) often means leading whole-class instructions whereby all pupils are engaged in the same mathematical area or mathematical problem (Franke, Kazemi & Battey, 2007) whereas in Sweden it involves communicating with individual students and pupils working in the same classroom but often with different mathematical areas (e.g., Jablonka & Johansson, 2010). Our analysis shows that three of the four guides emphasize aims and goals in the curricular program, which is interesting in relation to our study of the role of the aims and goals of lessons in school-based teacher education in Sweden and Finland (Bergwall et al., 2012). The older Swedish teacher's guide, *Matte Direkt Safari* (SWE1), represents material that is extremely dependent on the pupils' textbook and, hence, may have some special impact on teacher autonomy. The Finnish guides offer superfluous ideas for various kinds of activities for each lesson, supporting designs of different kinds of resources for students' learning. On the other hand, there is not much room for teachers to work thematically or spontaneously starting from students' ideas if they try to strictly follow the chains in the teacher's guides in their work.

In regard to the first four categories, the tool worked well in its current design. Based on our data analysis, we could add a category containing topics concerning how the textbook authors motivate their choices concerning the progress, structure and different activities. Teacher learning is situated within the practice of studying textbooks and teachers' guides, discussing the materials with other teachers, planning and evaluating the teaching as well as working with the students in the classroom. The professional skill of designing lessons for unpacking mathematical ideas is a kind of participation in practices. The fifth category appeared to embrace a broader qualitative dimension of potential for teacher learning that we should focus on more in further studies. Teachers have various experiences and identities (cf. Wenger, 1998; Brown 2009) and they have also been active agents in developing their own classroom practices. From this perspective, we are eager to extend this study by data analysis of both collaborative discussions between teachers in planning lessons using the teacher's guides as well as classroom teaching in teachers' daily practice.

BOREDOM IN MATHEMATICS CLASSROOMS FROM GERMANY, HONG KONG AND THE UNITED STATES

Eva Jablonka

King's College London, UK

Based on interviews with students from altogether six classrooms in Germany, Hong Kong and the United States, the paper explores students' elaborations of the notion of boredom in relation to their classroom context.

INTRODUCTION

When watching videos from altogether 60 lessons in the countries/regions mentioned in the title, I observed in all classrooms at times some students sprawling on their desks or leaning back with their eyes half-closed, seemingly unlinked to the place and time of their experience, others heavily sighing, drumming their fingers on the desk, or playing around with their pens. Are these cross-cultural expressions of boredom?

BACKGROUND

There seems to be a range of more or less existential experiences in different cultures, summarised in English by the notion of boredom. In the languages relevant for this investigation, these have different connotations. The German *Langeweile* appears first in a dictionary from 1796 (Adelung, 1796), and is described as experiencing with listlessness a long (*lange*) “empty” while (*Weile*) when one is not busy with anything. The Online Etymology Dictionary (“Bore”, 2012) finds the use of “bore” in the sense of “be tiresome or dull” in 1768. The word is traced back to variants of the German *bohren* (to drill), the meaning of “bored” being possibly a figurative extension of “to move forward slowly and persistently”, as a boring tool does. According to Vadanovich et al. (2011), the Chinese phrases for boredom refer to “having nothing to do” and to “not being of interest”.

Taken up by individual psychology, these experiences became classified as an emotion or mood, including elements of discomfort or even resentment. Paradoxically, various constructs describe the emotion of boredom as a lack of other emotions, as if emotions would fade away towards zero and then continue on the same dimension with negative values, e.g. as *lack of* interest and satisfaction (e.g. Smith, 1981; Bourgeois, 2001). Further, boredom has been essentialised as a trait called “boredom proneness” or “boredom susceptibility”, for which scaled tests have been developed that are used for measuring students' or workers' dispositions for getting bored. Country differences in such measures have been found and elaborated by common sense cultural explanations, for example by Vadanovich et al. (2011). Autochthonous and philosophical terms for experiences summarised in English by the notion of boredom, here intermingle with moral or essentialist interpretations of behaviour. In a psychological study, focussing on an operational definition and its technicality, Sparfeldt et al. (2009) developed a mathematics-related “boredom-scale” and related their results to other mental states (intelligence, self-concept and interest)

as well as to achievement, for all of which they found negative correlations with their scale amongst German students in grade four.

“Boredom”, or whatever has been translated into this notion, is a category also frequently used by students and researchers in mathematics education internationally. For example, Brown et al. (2008) found that lack of enjoyment and perception of the subject as boring is, amongst higher attaining students in the UK, a common reason for not choosing post-compulsory mathematics at age 16. Amongst Norwegian first year upper secondary students (grade 9), Kislenko (2009) found half of the students claiming that mathematics is boring, but also students stating that mathematics is interesting and boring at the same time. Measures of experiences of students’ boredom have also been used in TIMSS. The students’ questionnaire includes a question, where they can choose one out of four valences of agreement to the statement “Math(s) [in 1995]/ mathematics [in 1999 and 2007] is boring” (TIMSS context questionnaires, 1995, 1999, 2007). As to cultural differences, Li (2002) derives a model of the ideal Chinese student (a person with *Hao-Xue-Xin*, “heart and mind for wanting to learn”) from interview data with high achieving college students, where the strategy to force themselves to persist when faced with boredom is an important feature of the “behavioral ideal”. Li (p. 260) explains:

Like any learners from any cultures, Chinese students too encounter the problem of boredom. Consistent with research findings on achievement motivation in the West ... it is also no easy obstacle for Chinese students ... a stronger measure is called for to counter the severe demotivating effect of uninteresting content: Force oneself to persist.

By basing this model on empirical data and a Chinese folk term, Li’s construction shows how the projected image of a culture itself is a production of that culture.

Instead, the study reported here takes mathematics classrooms as “small cultures” (Holliday, 1999). This is to overcome the assumption of a hierarchical relation between a country’s (or a group of countries’) culture, and a school classroom’s (or any other institutions’) culture. Holliday sees the “onion-skin-relationship” model that sees small (sub)cultures as subordinate to and contained within large cultures, as a form of cultural essentialism, as it amounts to explaining differences in smaller units as stemming from the larger culture surrounding the inner layers. Activities in a mathematics classroom could as well amount to the production of cultures that cross the borders of classrooms and countries. Consequently, it is of interest whether there is cohesion in relation to attributes of classroom practice. Students’ motivations for engaging with mathematics for the same six classrooms as in this paper have been reported elsewhere (Jablonka, 2005). Here the focus is on the range of experiences linked to “boredom”: *Is there any cohesion visible in the students’ engagement and related feelings, expressed as “boredom”, that is related to classroom micro-culture?*

Data and method

The investigation draws on student interviews from the Learner’s Perspective Study (LPS) (e.g. Clarke et al., 2006), which were conducted in the form of video-

stimulated recall interviews. The table below summarises some features of the selected classrooms. Some of the interviews were conducted with groups; hence the discrepancy between the number of interviews and interviewees. The selection of the two (out of three) classrooms videotaped in the LPS is based on maximising differences between classrooms from the same country in terms of student achievement. The rationale for selection of the classrooms in the LPS was based on selecting experienced and competent teachers according to local criteria.

Class	Achievement	Cultural composition	Students interviewed	Number of interviews	Class Size
G1	Average-high	Homogen.	22	11	27
G3	Low-average	Heterogen.	10	8	12
HK1	High- average	Homogen.	19	19	35
HK3	High	Homogen.	18	18	39
US1	Low	Heterogen.	20	20	29
US2	High	Heterogen.	20	20	33
			109	96	

Table 1: Features of the classes and number of students interviewed

Although the interviews had as their main goal the elicitation of students' interpretations of classroom events, a number of issues emerged that centred around students' feelings. In addition, all interviews contained an explicit question about whether they liked mathematics (lessons), but the notion of "boredom" was not used by the researchers. In the interview transcripts, all episodes where students talked about feelings and use the notion of "boredom" were identified. Names used in this paper are pseudonyms.

OUTCOMES

In total, 30 students explicitly used the notion of boredom, both, "positively", in saying that mathematics lessons were not boring, or for describing experiences of boredom in the lessons video-taped in the study, or in mathematics lessons in general. The summaries and quotes below display a wide range of experiences.

Germany, G1:

Five students from this class talk about boredom in the interviews.

Gabriel compares mathematics lessons with history lessons and states that mathematics is less boring, which he links to the subject and the teacher. Similarly, Stefan states that there are worse subjects, which are more boring.

Martin in general likes mathematics and links boredom to review, and to a lack of challenge in general; he names some high achieving classmates who are also likely to experience boredom:

Martin: Well for Philip here ...it's also boring sometimes...because he's generally very good in school ...in all the subjects ...yeah and for Lisa ...

Albert likes mathematics, but says that it sometimes becomes boring and then he does not pay attention. He explains:

Albert: Only when the questions you've already done a month earlier and are still being repeated all the time; that's really boring then, when you can already do them perfectly ... and - and it's fun, when there's something new.

Fred is generally not fond of mathematics, stating he likes other school subjects if he gets good marks; he names specific activities that he finds boring:

Fred: Sometimes it is a bit boring a bit ... as a matter of fact, so, with all that numbers, if you then solve only algebraic terms for the whole lesson, well then you are not very keen on it anymore for the next lesson.

As less boring he mentions geometry and contextualised problems.

Germany, G3:

From this class, four students use the notion of boredom in the interviews.

Jeannine says she generally likes mathematics and links her experience of boredom to the specific topic of percentages. She expands:

Jeannine: Erm, yes then there are simply some people for whom the lessons are too boring. Well, I find the lessons quite boring myself sometimes. Well, if you did not at least have something to gabble about, so if I would not gabble now, I believe, I would always fall asleep.

Later in the interview, she also says that gabbling leads to not listening, which in turn leads to not understanding, which leads to boredom. She also says that experiencing boredom is partly related to the teacher.

Mona says she actually likes mathematics when she feels she understands. She gets bored if she feels she does not grasp a method:

Mona: Don't know, somehow I didn't get anything at all, whatever I said was wrong, and then I got bored. Okay, if I understand something then I actually like it. [...] I was bored because I didn't get it, and then I automatically switched off.

Later she explains why school in general can be fun:

Mona: Sometimes it is fun, well if there wasn't any school we all wouldn't have met, after all, this is how you should look at it.

Jasara, when asked whether she likes mathematics, says laughing, "it's a bit tricky". She talks about being bored during the lesson and explains how her lack of engagement was linked to an upcoming test in another subject:

Jasara: I was only bored. [...] Then I preferred to write and doodle. Actually, I, we had an English test after the lesson well now. Sat an English test and I mean, if Math had been added I think I would have muffed the English test.

Peer does not really dislike mathematics; for him the subject is “mediocre, yes it is not really my favourite subject”. He elaborates:

Peer: Yes, that wasn't boring because Selin sat next to me ... this was a little bit funny but now during the lessons mostly because somehow I am on my own now (...) [...] And don't get anything Mrs. Md. is doing at the front on the blackboard, then it is going to be boring.

Hong Kong, HK1

Eight students in the interviews refer to what has been translated into the English terms ‘boredom’, ‘boring’ or ‘bored’.

Polly, like two students from G1, says she likes mathematics and compares mathematics lessons with other subjects:

Polly: No. It is just mathematics lessons uh- no, because in other lessons such as Chinese and Chinese history I do not need to use the brain, no, only listening to Miss talking- so it is boring. [...] But I can think in mathematics lessons, so it is not- no, so it is not boring.

Michael talks about the choice of the social base for the communication and the hierarchy between teacher and students, and explains:

Michael: This is because we have to sit in this kind of environment- this particular environment is very boring. Although I am interested in mathematics, I will not like this every- every day.

Int: What do you think it should be?

Michael: I don't know, more freedom. [...] If you sit where you like, you will be more interested to have the lesson. [...] I think that this is better because there is a gap between the teacher and us. With a gap, we cannot ask so happily- cannot ask so easily. Asking our classmates can be very natural and easy and learn- I think we can learn faster

Nina states she cannot say whether she has positive or negative feelings in relation to mathematics. When comparing the lesson they have just had with others, she “quite liked it” because it was not boring, while there are some other more boring lessons.

Osbert says whether he likes mathematics depends on the topic, indicating that he enjoys things that are “difficult” less. He likes equations, but did not like cosine. He compares mathematics lessons in general with other lessons:

Osbert: Mathematics lessons... It's not as boring as other lessons [...] He teaches us something. For the other lessons, the teachers talk about...the texts. But he teaches us, math. [...] He teaches us what to do and we're thinking at the same time. We merely listen in other lessons.

Similarly, Paul compares mathematics with Chinese or Chinese history lessons, and mentions humour as a reason for engagement:

Paul: It's more interesting. It's not as boring as Chinese, which requires you to memorize things. Mr. Ng. will say something funny. In Chinese History

lessons, the teacher only talks about the facts and asks you to do homework, but Mr. Ng will not. He draws the graphs with us and tells us some jokes.

Even though Patrick is not very fond of the current topic and finds the “graphical method [for solving a system of linear equations] troublesome”, he states:

Patrick: Why do I like having math lessons? It’s not so boring...you can use your brains, and...talk a little, because he allows you to have discussions at least.

Ruth mentions a lack of variation in lesson structure, and also states that releasing the seriousness could foster engagement. Further, she talks about a “sense of achievement” as important for enjoying a subject.

Ruth: Feeling? Mm... We must listen to the teacher, or we won’t understand. And...it was a bit boring. He teaches in the same way every day. I think...we would be happier if he [the teacher] is not so stern.

Asked whether she likes mathematics, she says:

Ruth: Do I like mathematics? Mathematics...I like the arts subjects better, like Chinese. I’m good at arts subjects... when I was small they gave me...a sense of achievement, which couldn’t be obtained from mathematics.

Rose generally does not dislike mathematics lessons, but states that they can be boring sometimes:

Rose: Yes. Sometimes, I find it’s boring to solve problems again and again.

Further, she states preferences for some topics over others. She likes “drawing graphs”, but finds (algebraic) calculations “confusing”.

Hong Kong, HK3

Seven students explicitly refer to what has been translated into “boredom”.

Janet likes the lessons, and in comparing them with the ones they had earlier she finds them “less boring”. She links this experience to the atmosphere and says she likes that it is more “crowded” and also states:

Janet: It seems to have more freedom in this lesson.

Jane also refers to the environment and says:

Jane: Okay, too quiet is not good, it will be boring if it is too quiet.

Further, she appreciates that there is some space for relaxing between phases of work:

Jane: I can daydream when he is teaching us. So I work on the questions when we have to, can’t daydream while working on the questions.

Gordon gives as a reason for enjoying the mathematic lesson they just had that he “did not feel bored”.

Jessica says she generally does not like mathematics very much and refers to a sense of repetitiveness:

Jessica: A bit boring, just keep on doing exercises. I don’t really like it very much, nothing but just keep calculating and calculating, just calculating.

Joyce likes mathematics, as she moved from a feeling of difficulty to a feeling of being at ease with it. She compares the lessons with those she had earlier:

Joyce: The teacher teaches quite well, he is better than the last one, who just did the problems on his own [...] after finishing doing it, was teaching a couple of questions, then asking us to do the exercises, after that he jumped to the next chapter. Very boring.

June says she does not like mathematics very much as she got low scores in primary school, which made her “a bit afraid of it.” Yet she “quite” enjoys the lessons, but also says, “It’s boring sometimes”.

James, when asked whether he likes mathematics, states it is “just average”, but there are not any aspects he dislikes. He also compares mathematics with other subjects:

James: Mathematics is just fifty-fifty, but not very boring, because you can have something to do, because in IS [Integrated Science] lessons, we don’t even have to make a move, just keep watching the teacher just...

United States, US1

There are two students from this class who elaborate on boredom.

Esperanza likes mathematics, but sometimes, she says, she gets bored, and then she is “day dreaming”. This she links to a lack of competitive atmosphere, as it happens “when they don’t have a quiz”. The quizzes she appreciates because she likes to have good grades. She also compares mathematics with other subjects (science and history), which she does not like, stating that she does not like to “read”.

Fred says that mathematics used to be his favourite subject, but, “It’s gotten a little bit harder, over- over the years”. Now he just wants to learn, while being less excited about it. Seeing himself in the video, he says:

Fred: [laughs] It was too boring. I’m sitting- I was sitting there, trying to keep myself awake, (oh my lord) I’m sitting there [pretends to sleep]/

He links this experience to the fact that the lesson was about reviewing a test. He elaborates on a strategy of reduced attentiveness:

Fred: Because I was paying attention enough to get the facts, but I wasn’t exactly paying attention, if you know what I mean.

United States, US2

In the interviews with students from this class, four mention boredom.

Shannon does not explicitly dislike mathematics, but she talks about her preference for the “old” class she has been in, where she never felt “bored”. She associates boredom with “having nothing to do”. By this she refers to phases after having finished group work tasks earlier than other groups:

Shannon: Alright, now I think it’s ... I’m thinking it’s kind of this, kind of boring. And so I- I just ... have nothing to do so I’m just kinda sitting there.

Brenda talks about her preference for “hands-on things”, which she enjoys and which help her learning through making her engaged:

Brenda: It helps me learn a lot. Like, when I actually- like with the lesson when we were measuring things, that really helped me understand because it was hands-on, rather than reading from the textbook, which is really boring.

Amy says she does enjoy mathematics, but not very much and not always. Of the things she finds boring, she does not think she dislikes them at the same time. She does like “graphing things”, but neither fractions nor equations, and adds:

Amy: I mean I'm- it's not like I don't like it, I just think it's kind of boring. So it's not like, oh I hate math, I just real- kind of boring.

Angie never really liked mathematics because, “it's usually hard for me”. But she enjoys when she gets engaged, which for her is related to having conversations:

Angie: At the same time while we're doing work, we can actually talk about stuff that happened in the day and stuff like that. [...] Um, it just gets me more involved in it. I mean like when I'm bored and I don't even really want to be doing something, then it's like, oh okay, I'm just going to do this.

She links her general engagement to her daily mood, but also compares mathematics with other subjects, which she likes more (history, computer applications):

Angie: Like if I'm tired and I'm not really in the mood for anything, I don't want-like any classes, but if I'm in a good mood, I like every class.

DISCUSSION

The experiences reported by these students cover a wide range of elaborations on feelings related to classroom practice. A few named specific “troublesome” or “confusing” topics they find boring, (Fred G1, Jeannine G3, Patrick HK1, Rose HK1). In contrast, Osbert (HK1) finds “difficult” topics less boring. Boredom is also elaborated as the feeling of already knowing a topic (Martin G1, Albert G1, Fred US1), but also related to “not getting it” (Jeannine G3, Mona G3, Per G3). Ruth (HK1) elaborates this by saying that she needs to experience “a sense of achievement”. Jasara (G3) explains her deliberate choice for non-attentiveness. A couple of students see their lessons as less boring than in other subjects, as they “use the brain” or “think”, in contrast to just listening (Polly HK1, Osbert HK1, James HK3). Some expand on their lack of feeling to have control over the communication, or on the possibilities for talking to each other (Michael HK1, Joyce HK3, Angie US2). Other atmospheric dimensions that are appreciated as helpful in overcoming boredom, include background noise and a “crowded” environment, as well as the releasing effect of jokes and humour (Paul HK1, Ruth HK1). While Jane (HK3) appreciates having time for “day dreaming”, Shannon (US2) finds idle time boring. A sense of monotony and repetitiveness was also mentioned as causing boredom (Ruth HK1, Rose HK1, Jessica HK3). Brenda (US2) appreciates hands-on activity for overcoming boredom, and Esperanza (US1) competitive situations. Further, tiredness was mentioned by some in their elaborations of boredom.

Altogether, “boredom” was not a very common notion for describing their experiences, much less common indeed than reported in some of the studies cited above. This is perhaps due to the fact that here the students came up with the notion themselves, instead of answering a questionnaire where “boredom” is already included. Some of the experiences from the Hong Kong students can be interpreted as linked to lesson structure and social base of the communication in the classrooms, which appeared more varied in the other cases (as can be seen from the videos). Further, the notion of “thinking” or “using the brain” (as compared to only listening and learning by heart), was only mentioned by students from Hong Kong when they compared mathematics with other subjects. Other experiences might perhaps be related to the lower achievement of the students in Germany in G3 (“not getting it”). For the students from the German and US classrooms, the teaching practice in other subjects tends to be less boring (with the exception of one US1 student). Obviously, “hands-on activities” and other specific features of classroom practice can only be mentioned when they are used.

From these observations it becomes clear that these students’ perceptions of boredom in mathematics do not stand alone, but have to be ‘calibrated’ against their general experiences at school, as they often talk about other subjects. Further, some associate boredom only with specific topics, activities or events in the lessons. This challenges the use of the notion in international quantitative studies. Given the considerable variation of what is perceived as boring (or not) within each class, it seems to be disproportionate to link the students’ experiences to a wider culture of learning habits, as for example claimed by Hess and Azuma (1991), or by Li (2002) cited above. The cultural essentialism implied in the “onion-skin-relationship” model of culture adopted in such explanations, in addition to the questionable labels used for describing the wider culture (such as “East” and “West”), renders such explanations largely unproductive. Studies in other contexts have also attempted to link students’ disengagement to specific features of mathematics classroom practice. For example, Nardi and Steward (2003), in their analysis of interviews and lesson observation data from secondary mathematics classrooms in England, identified issues of pupils’ concern similar to some of those mentioned by the students from this study.

Further, this investigation is a reminder of the importance of including affective outcomes and emotional co-productions of mathematics learning as an important part of studying mathematics learning processes at school. The elaborations of boredom given by the students indeed suggest that framing the interpretation of cognition and emotion in social contexts is a fruitful endeavour and can help to overcome a view of emotions situated in isolated minds, through employing frameworks that recognise that emotional experiences are situated, subconscious and embodied, as for example suggested by Drodge and Reid (2000) or Walshaw and Brown (2012).

THE PROBLEM OF DETECTING GENUINE PHENOMENA AMID A SEA OF NOISY DATA

Christine Knipping, Eva Müller-Hill

University of Bremen, University of Cologne

In our paper we consider two principles that are essential for research and, in particular, for qualitative comparative work in mathematics education. First, we consider the explanation of phenomena rather than data as fundamentally important in educational research. Second, we discuss a holistic conception of human knowledge, suggested by Sellars, emphasising the role of common discourse for any theoretical scientific discourse. We relate our discussion to a number of comparative studies in mathematics education, as well as to conceptual modelling, a trans-disciplinary methodological framework that follows and reflects an interactive process in the transition from data to phenomena.

Keywords: Comparative Studies, Philosophy, Methodology, Data, Phenomena

INTRODUCTION

Comparative research in mathematics education, especially qualitative comparative research, is relatively new (see ZDM 2002 Vol. 34,6). One reason for this may be due to the origins of mathematics education in psychology. The first comparative studies were quantitative, as in the First International Mathematics Study (FIMS) (Husén, 1967), and compared results rather than processes. As it has developed, and mathematics education has embraced more sociological and anthropological approaches, more qualitative comparative research has been done, but compared to psychological methods in mathematics education it is often less accepted and understood. Indeed, as Kaiser (2002) observes in her introduction to the special ZDM issue on *Comparative Studies in Mathematics Education*: “it seems that... qualitative strategies are still not well considered” (p. 240).

In this paper we seek to provide a clearer foundation for qualitative comparative research in order to increase its acceptance by the wider mathematics education community. We focus on two principles: the emphasis on phenomena rather than data and the incorporation of stakeholder views. In respect of the first, and acknowledging that qualitative work in the social sciences is typically focused on phenomena, we argue that a more conscious attention to phenomena could increase the recognition of qualitative comparative research methods in mathematics education. The second aspect is the recognition of the perspectives of the stakeholders, e.g., students, future teachers, in-service teachers, and administrators. Qualitative research is more likely than quantitative research to take such perspectives into account, but the relationship between these perspectives and results arrived at by scientific analyses is rarely described clearly. By drawing on Sellars’ idea of a “stereoscopic” view we provide a way to describe this relationship, which we feel would make qualitative comparative research methods more compelling.

Compared to qualitative comparative research methods in social science and anthropology, comparative research is less theorised in mathematics education. Anthropology and the social sciences developed a strong theoretical basis for their methodology through their longer history. The challenge is to explain the value of qualitative comparative research methods to mathematics education without having this long history to draw on. The methods can be copied, but the theoretical basis cannot, because its origins are different. Instead of recapitulating the hundred year history of comparative methods in anthropology, we suggest in this paper to go more directly from principles derived from the philosophy of science. We consider especially emphasis on phenomena rather than data, and incorporating stakeholder views into research. Throughout we draw on comparative research studies in mathematics education to provide examples of the two principles in practice. These include Knipping (2003), a qualitative small scale comparison of proof teaching in France and Germany; the Learner's Perspective Study (Clarke, Keitel & Shimizu, 2006; Clarke, Emanuelsson, Jablonka, and Mok, 2006); and the TIMSS Video Study (Stigler & Hiebert, 1999).

THE DATA-PHENOMENA DISTINCTION

The data-phenomena distinction was posed and discussed for the general case of empirical science by Woodward and Bogen in the 1980s. Since then, it has shaped debates in general theory of science. According to Woodward and Bogen, scientific theories are not about data. In particular, it is not data that are explained by mature scientific theories, but phenomena.

Underlying the distinction between data and phenomenon is the idea that the sophisticated investigator does not proceed by attempting to explain his data, which typically will reflect the presence of a great deal of noise. Rather, the sophisticated investigator first subjects his data to a great deal of analysis and processing, or alters his experimental design or detection technique, all in an effort to separate out the phenomenon of interest from extraneous background factors. [...] Figuring out what one should even try to explain—what the phenomena are in a given domain of inquiry—and what is mere noise is, as we shall see, an important aspect of scientific investigation, especially in relatively immature areas of inquiry like the social sciences. (Woodward, 1989, p. 397)

Data are characterized as the results of idiosyncratic, local measurement processes:

As a rough approximation, data are what registers on a measurement or recording device in a form which is accessible to the human perceptual system, and to public inspection. [...] They typically are of no theoretical interest except insofar as they constitute evidence for the existence of phenomena (Woodward, 1989, p. 393 f.).

In contrast, phenomena are:

relatively stable and general features of the world which are potential objects of explanation and prediction by general theory (Woodward, 1989, p. 393 f.).

Though the examination of data serves both as a source of discovery and as evidence of the existence of phenomena, phenomena themselves are “not observable in any interesting sense of that term.” (Woodward & Bogen, 1988, p. 305 f.)

Examples for data in physics and empirical psychology are patterns of discharge in electronic particle detectors and records of reaction times and error rates in various psychological experiments.

In Knipping (2003) the data includes photographs and transcripts of audio tapes made in French and German 8th grade classrooms during lessons on the proof of the Pythagorean theorem.

Examples for phenomena in physics, chemistry, empirical psychology and sociology are “gravitational radiation, Brownian motion, capacity limitations and recency effects in short term memory, and the proportionately higher rate of technical innovation among middle-sized firms in moderately concentrated industries” (Woodward, 1989, p. 393 f.).

An example of a phenomenon in Knipping (2003) is that “proofs” in the German classrooms observed follow a leitmotif that can be characterized as “anschauendes Deuten” (a visual contemplative approach), whereas the French classrooms observed follow a discursive leitmotif, where explicit verbal descriptions are essential. These phenomena only became transparent through comparison of the proving processes in the different classrooms and particularly by rigorous argumentation analyses of the proving processes (see Knipping, 2008, for a description of this process). The fine argumentation analyses of the talk in the class and the written texts on the blackboards were necessary to reveal these phenomena, which were at first, without comparisons, not directly observable in the data.

As a practical and methodological consequence of a clear conceptual distinction between data and phenomena, a large amount of research effort has to be spent to face the resulting problem of detecting a genuine phenomenon rather than some artefact of the experimental setting [1]:

The problem of detecting a phenomenon is the problem of detecting a signal in this sea of noise [that is: in data], of identifying a relatively stable and invariant pattern of some simplicity and generality with recurrent features—a pattern which is not just an artifact of the particular detection techniques we employ or the local environment in which we operate. (Woodward, 1989, p. 397)

For example, many attempts have been made to explain the phenomenon of the shift in performance of Finnish students on international assessments from average performance prior to 1999 to leading the European countries in recent assessments. However, this phenomenon may simply be an artifact of the methods used to compare mathematics achievement in different countries. Finland’s recent scores are on PISA surveys, while the older scores are on TIMSS. “It may be the case that Finnish educators chose to participate after 1999 in a test oriented to the kind of mathematics curriculum they had been training new teachers to implement” (Stotsky,

2012, p. 299). In other words, the phenomenon of increasing scores is an artifact of the change in testing.

Criteria for evaluating comparative studies in mathematics education are and should be diverse, related to the research questions and aims of these studies, and the theoretical perspectives and paradigms they are committed to. For example Clarke et al. (2012) suggest multi-theoretic approaches “highlighting the dangers of the circular amplification of those constructs predetermined by the choice of theory”. We suggest that the philosophical principle presented here may contribute to the selection of appropriate criteria for scientific adequacy in qualitative comparative research methods. To put it in a nutshell, the data-phenomena distinction may form a basis for finding appropriate qualitative counterparts to the criteria of objectivity and reliability used in quantitative approaches. We now turn to Sellars's stereoscopic view, which has potential to serve as a foundation for an adequate specification of the concept of validity in qualitative comparative research methods.

THEORETICAL SCIENTIFIC DISCOURSE AND SOPHISTICATED COMMON SENSE

So far, the data-phenomena-distinction may have helped to highlight that “detecting a signal in this sea of noise [that is: in data], of identifying a relatively stable and invariant pattern” (ibid., p. 397) is essential. But how can this be done? We suggest that a holistic view, as outlined in the following, is particularly promising for comparative approaches in mathematics education.

In the philosophy of language and general epistemology, so-called holistic conceptions of human knowledge (prominently argued by outstanding philosophers such as, W.V.O. Quine, Wilfrid Sellars, or Donald Davidson, and taken up and developed further by, e.g., Robert Brandom) have strongly influenced current views of the development of and relation between common, every-day discourse and knowledge on the one hand and theoretical scientific discourse and knowledge on the other. We consider such an approach as important as it can help to identify phenomena by including the perspectives of the involved participants, teachers and students in mathematics education.

As a first step, Sellars calls for scientific theories to connect to pre-scientific and everyday constructions and interpretations of the observable physical world and to take into consideration the complicated inner logic of everyday circumstances.

I suggested that the most fruitful way of approaching the problem of integrating theoretical science with the framework of sophisticated common sense into one comprehensive synoptic vision is to view it not as a piecemeal task—e.g. first a fitting together of the common sense conception of physical objects with that of theoretical physics, and then, as a separate venture, a fitting together of the common sense conception of man with that of theoretical psychology—but rather a matter of articulating two whole ways of seeing the sum of things, two images of man-in-the-world and attempting to bring them together in a “stereoscopic” view. (Sellars, 1963b, p. 19)

However, the stereoscopic view is itself still part of the scientific and not the common image of the world. A stereoscope allows a viewer to see a three dimensional scene by looking at two dimensional images taken from different perspectives through a suitable frame. Sellars' intent is for research to be done in such a way that the differing perspectives offered by different theoretical ways of seeing be presented in such a way that a researcher sees a single true-to-lived-experience representation of the world.

As a second step, Sellars addresses the question when such a scientific image is "complete". This is not the case when the "common man" has understood and taken over the whole scientific image itself. The Sellarian concept of completing the scientific image is rather functional with regard to the "common man": He shall be able to relate the circumstances and purposes of his actions to the general statements of the scientific theories.

Thus, to complete the scientific image, we need to enrich it not with more ways of saying what is the case, but with the language of community and individual intentions, so that by construing the actions we intend to do and the circumstances in which we intend to do them in scientific terms, we directly relate the world as conceived by scientific theory to our purposes, and make it our world and no longer an alien appendage to the world in which we are living. (Sellars, 1963b, p. 40)

The Learner's Perspective Study attempts to provide such a stereoscopic view through "complementarity" (Clarke, Keitel, & Shimizu, 2006).

Complementarity is fundamental to the approach adopted in the Learner's Perspective Study. This applies to complementarity of participants' accounts, where both the students and the teacher are offered the opportunity to provide retrospective reconstructive accounts of classroom events, through video- stimulated post-lesson interviews. It also applies to the complementarity of the accounts provided by members of the research team, where different researchers analyse a common body of data using different theoretical frameworks. (pp. 4-5)

A second element in the Learner's Perspective Study that supports a stereoscopic view is the bringing together of insiders' perspectives with the more typical outsider perspectives. This is especially the case in Clarke, Keitel & Shimizu (2006) where the authors describe their own school systems and cultures, supported by data including the voices of teachers and students in the classrooms studied in their countries. This is done in the framework provided by the overall study, however, so the authors are presenting their perspective with awareness of the differences that exist internationally.

Contrasting approaches to phenomena are evident when the TIMSS Video Study (Stigler & Hiebert, 1999) is compared with the Learner's Perspective Study. Both sought to compare characteristics of teaching in different countries. In the TIMSS Video study the phenomenon of national teacher scripts for mathematics education was assumed and data was collected in order to study this phenomenon more closely. Because the phenomenon was assumed to occur everywhere, it was not necessary to

collect data in multiple locations in each country. An outsider perspective was taken, in order to reveal culturally ingrained characteristics of teaching that are invisible (due to their familiarity) to insiders.

In contrast, in the Learner's Perspective Study the Hong Kong team (for example) started off by asking whether a Chinese teacher script of mathematics education actually exists (Mok, 2006). Multiple lessons were recorded, in two Chinese cities and in the classrooms of six teachers. Both outsider and insider perspectives were sought and both the teacher and the students' actions in the classroom were recorded (Clarke, Emanuelsson, Jablonka, and Mok, 2006). Data was collected not to study a presupposed phenomenon, but rather to understand teaching "based on the perspective of relevant stakeholders such as teachers and students" (Mok, 2006, p. 133).

In the Learner's Perspective Study participants were asked explicitly for their views to bring in the common sense perspective. In contrast, Knipping (2003) observed the participants in their everyday activity of teaching and learning, and their comments on their own activity were later juxtaposed with the results of the scientific analysis to provide a stereoscopic view.

The focus of Knipping's research was classroom proving processes. In order to reconstruct the rationale of mathematical proving practice of teachers and students in the classroom she needed both a view grounded in classroom practices as well as a rigorous analysis of classroom argumentations. Formal mathematical logic cannot capture the rationale of proving practice, as arguments that are produced during proving processes in the mathematics classroom follow their own peculiar rationale.

As a method Knipping (2008) proposes a three stage process: reconstructing the sequencing and meaning of classroom talk; analyzing arguments and argumentation structures; and finally comparing these argumentation structures and revealing their rationale through an interplay between the structures and the reconstructed classroom talk.

As a first stage the reconstruction of the common sense meaning of proof in classroom talk is essential. Interpretative methods are used to reveal what teachers and students say and mean, when they produce arguments and proofs in conversation.

Second, the arguments and argumentation structures are analyzed to provide the scientific view. This involves two moves, first analyzing local arguments on the basis of Toulmin's functional model of argumentation, and second analyzing the global argumentation structure of the proving process.

Comparing argumentation analyses of classroom proving processes in different contexts provided a stereoscopic view. It allowed not only the reconstruction of different leitmotifs of proving processes in classrooms, but also made the perspectives of the participating teachers on proving visible. These two-dimensional images come together into a three dimensional view of the proving processes in the classrooms. In this three dimensional view phenomena stand out and become more accessible to further study.

For example, teachers had communicated to their students during the proving process what they considered to be important, but this was at first not noticed in the data analyses. Only when the phenomena were described in form of leitmotifs, were these statements recognized and their significance acknowledged. One German teacher tried to encourage her students during the proving process as follows:

Teacher: Mmh. We don't know yet what exactly to write in the middle. But, you know, what I really like about your answer is that you looked for squares, you could somehow find the area of. But we don't know exactly the lengths of the sides of the inner square. b^2 would be a square, that is here somewhere.

Maren: Mmh.

Teacher: ... that does not work so well. Maybe you can find something else. Sarah, don't write, don't write, just think, just look. We can write this down later. Jan.

In a French classroom, the teacher guided her students' proving in this way:

Thierry : DCH and BCG.

Teacher: # are ..

Thierry : DCH are complementary.

Teacher: Yes. (9 sec.) And then, are complementary, did you write that? Yes? So?

Stephanie: You write that C, so the angle C is equal to 180 minus

Teacher: You have to say first that HC, why 180?

Stephanie: 180, because it's straight.

Teacher: Well, you have to say it at least, eh? We have not said it yet. We have said it, but we have not written it down. In a proof we have to write everything that we said, so, next line, so HCG equals 180 degrees.

The statements "Sarah, don't write, don't write, just think, just look. We can write this down later" and "We have said it, but we have not written it down. In a proof we have to write everything that we said" were part of the data all along, but once the phenomena of the leitmotifs was recognized in the scientific analysis, such comments could be recognized as also describing the phenomena, providing the "sophisticated common sense" framework for them. Comparing both the argumentation structures and the actual classroom talk provided "two whole ways of seeing the sum of things."

In the Learner's Perspective Study and in Knipping's research we have examples of comparative mathematics education research in which an attempt was made to investigate both phenomena that were identified by insiders in the community, and also phenomena identified by outside researchers, but which were described in ways that made them visible to the wider community as a whole.

There are other approaches that may address this challenge in comparative empirical research in mathematics education. We conclude with some suggestions in this direction.

THOUGHTS TO THE FUTURE

In this paper we have discussed two principles we consider as essential for research in general, and for comparative work in mathematics education in particular. First, we emphasised the essential distinction between data and phenomena. Second, we discussed the issue and relation of common discourse and scientific discourse and why a ‘stereoscopic’ view is necessary to overcome unintended shortcomings of educational comparative research. We have referred to ideas from the philosophy of science and discussed how these ideas make a valuable and significant contribution to comparative research in mathematics education. More can be learnt from the works cited and generally from philosophy, and particularly from philosophically motivated socio-empirical studies in the context of mathematics.

Müller-Hill (2011), for example, has studied formalisability in proving practices in mathematical research. She finds that proving practices vary in a significant way in the different subfields of mathematical research, e.g. mathematical logic, algebra, geometry, applied mathematics. In a comparative approach, interviewing mathematicians as experts in these different fields, she investigates to what extent formalisability really plays a fundamental epistemic role, as is often presumed by general epistemology, in these subfields. Her socio-empirical study was based on an approach, called ‘conceptual modelling’, developed by Löwe & Müller (Löwe & Müller, 2011; see also Löwe, Müller & Müller-Hill, 2010). Conceptual modelling is a trans-disciplinary methodological framework that follows and reflects an interactive process in the transition from data to phenomena. The sophistication in this approach cannot be discussed in detail here. We only want to point out that looking more closely at, and reflecting more carefully on, the conceptualisation and application of the transition from data to phenomena, is vital. It is of particular interest for research in general and for comparative research in mathematics education in particular. This is especially important in respect to differences in quantitative approaches compared to qualitative approaches, and a possible mix of these methods. There is much more potential in the work of philosophy of science and particularly the works we have cited than we can discuss here.

Also the distinction of common discourse and scientific discourse is reflected in Müller-Hill’s research and the work of her colleagues. She makes a distinction of ‘armchair’ epistemology of mathematics, related to normative philosophers’ discourse about epistemic aspects of mathematical practice, and the discourse of mathematical practice, related to mathematicians’ discourse about their work. Conceptual modelling proved to be particularly helpful to investigate the issue of formalisation not just as a philosophical or logical issue, by not only interviewing practicing mathematicians, but also combining and reflecting on these perspectives to provide a ‘stereoscopic’ view of the issue.

NOTES

1. In (Woodward, 1989, p. 453), the following example is given:

The authors of a recent study (Kamien and Schwartz 1982) devote approximately half of their book to arguing that the relationship [a relatively higher rate of technical innovation in moderately concentrated industries] is indeed real—that it has the characteristics of a phenomenon and is not an artifact of various statistical and measurement assumptions they employ. They investigate the relationship by regressing various measures of technical innovation on various measures of firm size and market concentration, the underlying assumptions about functional form being supplied by economic theory. They show that the relationship is relatively robust under different assumptions about how to measure these quantities and that it is fairly constant and stable across different industries. It is only in the second half of their book that the authors turn their attention to what they call ‘theoretical explanation’.

SCHOOL-BASED MATHEMATICS TEACHER EDUCATION IN SWEDEN AND FINLAND: CHARACTERIZING MENTOR-PROSPECTIVE TEACHER DISCOURSE

Malin Knutsson^{a,b}, Kirsti Hemmi^a, Andreas Bergwall^{a,b} & Andreas Ryve^{a,c}

^aMälardalen University, ^bÖrebro University, ^cUmeå University

Despite many similarities between the neighbouring countries Sweden and Finland, prior studies indicate that conceptualizations and discourses about school-based teacher education are very different. In this paper we add to this picture of differences, and contribute to the research discourse about school-based teacher education, by identifying and characterizing aspects of mathematics teaching made relevant in review meetings between mentors and prospective primary teachers. While the Swedish discourse typically focuses on the students' individual work with textbooks, connections to everyday experiences and teaching as individual supervision, the Finnish discourse emphasizes lesson aims, learning and progression in mathematics through formative assessment and differentiation according to pupils' abilities.

Keywords: Comparative study; Finland, school-based teacher education, Sweden.

INTRODUCTION

To become, and develop as, a mathematics teacher can be seen as a lifelong socialization process, initiated in school and teacher training and continued throughout one's entire professional life. There are many different aspects of this process worth studying, and multiple ways of describing and conceptualizing it (Adler, Ball, Krainer, Lin, & Novotna, 2005). Through this process the teacher should, for instance, develop necessary knowledge in and about mathematics, a number of competencies and teaching skills, as well as a productive teacher identity within a teacher community. A substantial number of studies have engaged in these areas (see, e.g., Jaworski & Gellert, 2003; Rowland & Ruthven, 2011; Rowland, Turner, Thwaites, & Huckstep, 2009; Sowder, 2007).

Whatever perspective one adopts, it seems reasonable to assume that university-based teacher education alone cannot provide teachers with the very specialized and complex competencies needed for productively teaching mathematics and acting as a mathematics teacher. Such competencies must be continually developed through years of critical reflection over one's own teaching practice (e.g., Adler & Davis, 2006). However, research indicates that if deliberately designed, such a critical attitude towards teaching can be fostered in teacher training programs (Rowland & Ruthven, 2011; Rowland, et al., 2009). School-based parts of pre-service teacher education may have a crucial role to play when it comes to creating opportunities for the prospective teachers (PTs) to experience and reflect upon the complexities of mathematics teaching together with mentors (Jaworski & Watson, 1994). Ideally, in such situations, qualified and experienced teachers serve as important guides in

socializing the PTs into ways of becoming, and thinking like, a critically reflective teacher (Hegender, 2010; Jaworski & Gellert, 2003). Although school-based teacher education (SBTE) in mathematics has been suggested as an important instance for developing as a teacher (e.g., Frykholm, 1999), the opportunities created for developing competencies in teaching mathematics within this practice cannot be taken for granted. For instance, while several studies (e.g., Ebby, 2000; Krzywacki-Vainio & Hannula, 2008) show that PTs regard the SBTE as the most important element of their education, “too often school experiences, particularly student teaching, are disconnected from university-based components of teacher preparation” (Sowder, 2007, p. 202).

In understanding more about SBTE and the opportunities created for PTs to develop as competent mathematics teachers in such practices, we find the cases of Sweden and Finland of interest to study. Despite many similarities between Sweden and Finland concerning the school system, prior studies indicate that conceptualizations and discourses about SBTE in the countries are very different (Ryve, Hemmi, & Börjesson, 2011) and we are beginning to collect evidence that there are substantial differences between the countries concerning curriculum materials (Hemmi, Koljonen, Hoelgaard, Ahl, & Ryve, 2012) and classroom teaching (Andrews, Ryve, & Hemmi, 2012; Hemmi & Ryve, 2012). In this paper we are particularly interested in characterizing the discourse, where discourse is defined as a recurrent way of communicating (Ryve, 2011), between mentors and prospective primary school teachers (PTs) after classroom lessons in which PTs have taught. We aim at characterizing such meetings by engaging in the research question: *Which kinds of aspects of teaching practice are made relevant in the discourses and how are phenomena related to mathematics teaching construed?*

METHODOLOGY

This paper is situated within the principle that language use can be seen not only as a reflection of reality but also as a tool for constituting reality (e.g., Sfard, 2008; Säljö, 2000). Data were collected in the form of audio-recordings from ten review meetings between mentors and PTs in Sweden and six in Finland. The meetings took place immediately after a mathematics lesson that a researcher had attended and made field notes of or videotaped. The researcher was also present at the meeting, but took a passive role. Common for all PTs is that they are attending their second (of four) period of SBTE. In our Finnish cases the prospective teachers conduct their SBTE in pairs and hence are two prospective teachers present in the review meetings from Finland. During the Swedish meetings no university lecturer was present, and this relates to fact that during the whole eight-week SBTE period no university lecturer visited the PTs. In contrast, in Finland, university lecturers were present, and took an active role, during two of the analysed meetings. Further, in the Finnish cases the SBTE is conducted at a university practice school where mentors have several hours per week for developing their mentoring. In Sweden the SBTE is organised in ordinary schools where teachers have limited time for mentoring. This means that the

review meetings had different conditions and this reflects a structural difference between the two countries.

In this paper we present the initial analysis of four meetings that we have transcribed so far from each country and this will guide us when analysing the rest of the data. The analysis uses an iterative approach going through several cycles. We used NVivo as a facilitating tool, and all four authors contributed to interpretations of the data. The Swedish transcripts were first analysed by two research team members and the Finnish transcripts were analysed by the Finnish speaking member of the team. We had no explicit categories when we conducted the first analysis but we were searching for aspects made relevant.

We checked each other's analysis and agreed on the following categories that we had derived from the data: *Lesson aims, Learning and progression in mathematics, Differentiation and individualization, Mathematics and its connections to everyday experiences, Assessment, Classroom management, Mathematics textbooks and Resource constraints.*

We decided also to attempt to describe how the role of the teacher, pupil, mentor and PT is conceptualized in the discourses. We then analysed the data once more using all the categories and finally, compared the categories in both countries. When we are referring to the Swedish and Finnish discourses we are only expressing the characteristics of the discussions we have analysed and do not attempt to generalize cross-national differences.

RESULTS

The results section is structured in such a way that all recurrent themes of aspects made relevant within the union of Swedish and Finnish discourse are presented in order to make the comparison of the discourses of the countries transparent. (SWE M1) refers to a Swedish mentor in Group 1 and (FIN PT12) refers to PT one in the second group in Finland. A university lecturer in mathematics education is represented by U.

Lesson aims

The Finnish discourse is typically anchored in relation to the written lesson plans and the PTs' teaching. For example, the mentors point out the importance of making the aims of the lesson clear to the children by writing a proper headline on the board. Lesson aims also become relevant in relation to issues about pupils' mathematical knowledge and progression as well as the assessment of pupils. Hence, the aims of the lessons are both made relevant and explicit through the lesson plans and stressed as important to make explicit for the pupils in the classroom.

The Swedish discourse contains no explicit statements about formal learning goals for the lessons, or about the outcome in relation to such goals. On a few occasions, these two matters are implicitly included through questions such as "*What was your*

intention that they [the pupils] would get from this lesson?” (SWE M:2) and “Did you feel that the children were following you? Did they understand?” (SWE M:3).

Learning and progression in mathematics

The issue given most relevance in the Finnish discourse is how to develop pupils’ knowledge and progress in mathematics. The following conversation, from G1 in Finland, is an illustrative example:

M1: Why have we done the divisions of numbers so eagerly?

PT11: Well, if one masters them, they help children even in basic addition, especially when they go to the ten transitions, so they know when they have, say 4+7, how much you need to add to seven to get ten and how much is left.

M1: Yes [...] and now the next work is to teach them how to use them. They’re two distinct matters, using them comes when we pass ten.

The connection between formative assessment and ideas for progress is exemplified by a university lecturer, who says *“for example, as a formative test let them write all the divisions of number 9. If one finds this kind of problem-solving strategy, it’s easier to remember and check what’s missing”* (FIN U2) and then continues *“I wonder if the strategy could be opened, like if we use the nine balls and then move the magnet ruler to make the strategy visible”* (FIN U2).

In the Swedish discourse, issues of learning are typically discussed on a general level, often emphasizing reasoning and interaction: *“[I]t’s the journey, they actually learn from the reasoning”* (SWE M4), *“it’s very good learning [...] when they teach, and learn from, each other”* (SWE M4), *“you could see the difference all the time, that they’re advancing conceptually and how much they understand and can begin to reason a little more”* (SWE M4). This last statement is, in principle, the only statement in the Swedish discourse related to the progression of pupils’ mathematical learning. There are no statements about pupils’ development of mathematical proficiencies other than that of reasoning. When the mentors and PTs discuss forthcoming lessons, there are few statements about how the pupils’ knowledge could be deepened. More common are statements such as *“it’s important to go back and do more work on liter and deciliter [...] they need to repeat, over and over again, in order to cement it”* (SWE M2).

Differentiation and individualization

In the Finnish discourse individualization and differentiation of the teaching was present in all four discussions, with respect to both how to organize the classroom teaching in order to meet the needs of different pupils (*“You’ve now learnt to handle a class with two grades and think about two groups all the time and you’ve managed it well. Therefore you’ve already learnt to differentiate the teaching according to two groups. I haven’t demanded that you think so much about the individualization within the groups, only a few aspects of handling pupils working at different speeds”* (FIN

M1)), and how to develop mathematical tasks during the lessons in order to present challenges to all pupils (*“One group of pupils understands immediately, okay this kind of task, and writes it mathematically at once, whereas others need more time, and they should have the right to go on with their thinking process for a longer time”* (FIN PT11)). We conclude that aspects of how to plan and adjust the classroom teaching to ensure that each pupil receives appropriate mathematical challenges is very typical of the Finnish discourse. In the Swedish discourse, the issue of how to arrange the classroom teaching in relation to the pupils’ diverse pre-knowledge and interests is not made relevant. However, the importance of helping/teaching the pupils in one-to-one situations is stressed. Supporting pupils who have difficulties was mentioned once, when a mentor referred to special education teachers and their responsibility for this.

Mathematics and its connections to everyday experiences

One of the most specific features of the Swedish discourse is the emphasis on the importance of connecting mathematics to everyday experiences. Such everyday experiences are typically not formalized into mathematics, but are seen as mathematical activities in themselves. For instance, one of the mentors states that *“mathematics [...] is loads of everyday experiences”* (SWE M2). Therefore, everyday experiences are typically put forward as relevant in themselves, not for deepening mathematical concepts or ways of reasoning. The situation in the Finnish discourse is different; only once is a connection to everyday life mentioned, in the context of feedback from the mentor to the student: *“And I think that was a really good example you gave [before the lesson] but it didn’t appear during the lesson, talking about something like there are no people within a radius of a hundred kilometers or five kilometers, but you forgot it, that would’ve been a good example about where we can use the concept of radius”* (FIN M4).

Assessment

Assessment is another dominant theme in the Finnish discourse. It mostly concerns formative assessment connected to learning and progression in mathematics, as shown above, but also concerns the principles of giving pupils their grades in mathematics, and the difficulties in working with assessment are acknowledged in the discourse. When discussing pupils with wrong answers in their homework, one mentor states that *“one has to react with some questions and try to sort out whether the pupil is way off track, and this is difficult for the teacher”* (FIN M4). Another typical example regarding formative assessment is the following: *“Yes, the goal of the lesson was to draw a circle according to the given rules and internalizing the concept of a circle. I’m sure they learned to use the compasses by doing it, but I wonder how it is with their ability to draw according to the rules since you gave them a lot of freedom. So we could now think about giving quite strict rules and checking whether they can draw a circle with, for example, a diameter of 6cm or a radius of 3cm, and then it’s easy to see who has succeeded and why somebody hasn’t succeeded in doing it”* (FIN M4).

The mentors also pose questions about student learning so the prospective teachers have to be aware of how the pupils progress: *“Yes, but otherwise everyone’s done the tens table right (in a test) and Silja and Aapo are the only ones who aren’t ready with the twos table...”* (FIN PT1).

Assessment is only briefly touched upon in the Swedish meetings, when mentors ask the PTs whether they think the pupils understood the content of the lesson, but they do not give explicit suggestions for how one might get this information. The mentors and PTs discuss the importance of meeting the pupils’ one to one, or having time to watch them work in smaller groups, in order to get a grip on what parts of the content they understand as well as how they understand them.

Classroom management

The aspect given the most relevance in the Swedish discourse is organizational issues regarding pupils and artefacts. How the pupils should be grouped (*“When I was thinking about it in retrospect, maybe one should’ve separated Anna and Jennie so that Eric, Maria and John could’ve been with one of them”* (SWE PT4)), where the books should be stored, the importance of being clear when writing on the board or pointing to exercises, which measuring spoons to use and the length of the teacher’s introduction (*“and when they have to sit for so long and listen [...] then it’ll be tiresome to sit and concentrate”* (SWE M3)) are examples of such issues. This finding of the heavy focus on organizational issues harmonizes with the recent study by Hegender (2010) about mentor-PT discussions during SBTE in Sweden.

Classroom management, like the use of manipulatives and ICT, is also clearly present in the Finnish discussions connected to, for example, formative assessment and disciplinary issues: *“It was good that you solved the problem of who the head of the group is so quickly, so that everybody could start working in time”* (FIN M4). One university lecturer states that if the group is intense and impulsive one could let pupils explain as a way of handling the group: *“When a classmate is saying something the others are trying to listen”* (FIN U3). Another example of managing the class is the following comment about how to start a lesson: *“You wait until you have all the children’s attention, all the children are looking at you, they’re ready, there’s no use saying something before that”* (FIN M4).

The mentors typically also suggest ways to organize the teaching in a way that makes pupils’ learning visible and allows them all to be active in engaging with tasks: *“Yes, and again the pupils can have the number cards on their desks as the number area isn’t so big when solving equations in their head, so that all the pupils at once can show what number we can put in the square so that you don’t need to say ‘raise your hands’, but here also the teacher gets immediate feedback about who’s way off”* (FIN U3).

Mathematics textbooks

Mathematics textbooks are referred to three times in the Finnish discussions, and all these references explicitly deal with the treatment of the specific topics: investigation of divisions (*“Tuhattaituri [the name of the textbook] uses exactly this model where one moves the vertical line when investigating divisions”* (FIN U2)); the notion of a product and the value of a product (*“But the textbooks are like this, it’s not only in our textbook but also the others that I’ve studied, but if we think back to year x, the beginning of my teaching carrier, there they were already separated [product and the value of the product]”* (FIN M1)); and the use of the number line (*“[...] as even some researchers say, this book series uses the number line too much, is it true and whom does it suit, I don’t know”* (FIN U2)).

In the Swedish discourse the textbook is more prominent. They do not discuss specific topics in more than one episode; instead, the pupils’ use of the mathematics textbook is either mentioned as the main part of the lesson or seen as a goal of the lesson that the pupils can work individually in the textbook. After one lesson when the pupils have worked in the mathematics textbook for practically the whole lesson, one mentor says *“Well it was a very ordinary lesson as many of them are”* (SWE M1). *“[T]he book is something they should be able to work in on their own”* (SWE M3) is a statement from another mentor, who later in the discussion says that *“if one were certain they understood and then started with the book [...] one could do a demonstration and then they could work on their own”* (SWE M3).

Resource constraints

Issues about constraints regarding both the time to plan lessons and the length of lessons are brought up several times in all four Swedish meetings. One mentor refers to changes in teachers’ working conditions: *“This dilemma that we’re struggling with right now, [...], when I started working as a teacher, I had plenty of time to, sort of, plan lessons, to really think through what I wanted to do, I made my own material and such. But now that time doesn’t exist”* (SWE M1). Especially the PTs express that they do not have time to do all they want: *“I’d planned to do that at the end, but we didn’t have the time”* (SWE PT2). The same PT mentions that the lesson in consideration would have been impossible to realize if he had been the only teacher in the classroom: *“I wouldn’t have been able to carry this out on my own”* (SWE PT2). The mentor continues: *“No, and that’s why we have a special education teacher”* (SWE M2). Hence, an implicit assumption is that productive teaching is more or less impossible to conduct without several teachers present in the classroom.

Resource constraints are made relevant much more seldom, and in a different way, in the Finnish discourse. The mentors and PTs do not focus on time constraints as a problem but instead on how to cope with them. Aspects of the importance of the teacher staying calm are emphasized, as is the importance of not transmitting the feeling of stress to the pupils: *“If the teacher herself has a hurried feeling this is easily transmitted to the children”* (FIN M4). They also discuss issues concerning the

teachers' responsibility to adjust the plans for the next lesson by considering issues that could not be handled during the current lesson: *"As a teacher one should hold the threads in one's hands and think that I'm going to sort this out then and how we can repair this next time, it shouldn't be the pupils' responsibility if the use of the time during the lesson hasn't worked as the teacher had planned"* (FIN PT21).

CONCLUSION AND DISCUSSION

The results indicate that there are rather substantial differences between the discourses of the Finnish and Swedish groups. We cannot generalize the results from the present study to the two countries, but they add to the growing body of knowledge obtained from the previous studies. We could further compare the discourses by introducing preliminary results of how the teacher's and students' respective roles are conceptualized as well as discussing aspects of specificity and structure of the discourse. As described above, the teacher's practice within the Swedish discourse is conceptualized in terms of a "supervisor" who should primarily engage in one-on-one discussions with pupils. This finding is in line with findings in Hemmi & Ryve (2012), in which Swedish mathematics teacher educators typically portray classroom teaching as a teacher-talking-with-one-student phenomenon. In contrast, the Finnish discourse puts much more emphasis on whole-class teaching and the teacher acting in whole-class situations.

In the Swedish discourse the pupils are described several times as resources, in teaching and gaining understanding from each other: *"It's very good learning [...] when they teach, and learn from, each other"* (SWE M4). One thing that is mentioned as an obstacle to pupils' understanding is their level of maturity, which seems to take precedence over the teaching. An example of this is: *"Well, you also have to realize that they're not that big yet, they don't have it, it's not close to them"* (SWE M4). In the Finnish discourse the teachers' responsibility of students' learning and students' behaviour is stressed in different ways.

Another typical recurrent pattern in the discourses is that Finnish mentors and PTs are rather specific in talking about mathematics, pupils' learning, goals of the lessons, etc. Our analysis of the Swedish discourse suggests that the statements, suggestions and reflections upon the classroom practice are formulated rather generally. This aspect is also related to a fourth characteristic we noticed: the Swedish classroom teaching as well as review meetings are loosely structured, with few explicit frameworks or plans for how to act. For instance, as indicated above, lesson plans are typically not produced or made relevant within the discourse as a way to structure the review meetings. In contrast, the Finnish context is structured through, for instance, lesson plans, visits from university lecturers, and explicit discussions of the lesson goals. Possible explanations for these differences could be the different position of the mentors in the system. Our initial analysis has not revealed differences between the characteristics of the feed-back discussions conducted by the mentors (class teachers) on the one hand and the university lecturers on the other hand in the Finnish context. A deeper analysis of the whole data could inform us whether the presence of

the university lecturer seems to have a positive effect on the qualities of the review discussions and in that case how. It would also be interesting to analyze who raises the recurring themes and what this says about the relationship between the participants.

This paper should be seen as a contribution to the research on SBTE and especially on ways of characterizing the discourse of university lecturers, mentors and PTs (cf. Jaworski & Gellert, 2003; Sowder, 2007). The analysis of four meetings from Sweden and Finland shows some similarities, but also many differences. Basically, teaching mathematics seems to be conceptualized in two distinct ways, and in future studies we aim to both complement the study by analysing more data and deepen the analysis by contextualizing the results within a broader frame of similarities and differences between the two countries regarding aspects such as classroom teaching, teacher education, the role of school in society, and cultural patterns. We believe that such an approach could add to the research discourse on the role of SBTE in educating PTs in mathematics, assistance teacher educators in making informed choices about SBTE, as well as deepen the understanding of pupils' learning of mathematics in Sweden and Finland.

COMPARING MATHEMATICAL WORK AT LOWER AND UPPERSECONDARY SCHOOL FROM THE STUDENTS' PERSPECTIVE

Niclas Larson and Christer Bergsten

Linköping University

As part of a comparative study between how students experience and perceive their mathematics education at lower and upper secondary school, a classroom episode is analysed from a theoretical approach combining key concepts from the anthropological theory of didactics and Bernstein's theory of pedagogic discourse. The findings are discussed with reference to the usefulness of the theoretical approach.

Key words: mathematical knowledge, transition, praxeology, recognition rules

INTRODUCTION

In addition to the general relevance of increased knowledge about similarities and differences between mathematics education at the compulsory and non-compulsory school levels, low pass rates on the national tests on the first mathematics course during the first year at upper secondary school in Sweden have been reported, especially on vocationally oriented study programmes (Skolverket, 2012). It is therefore of interest to compare students' experiences of their mathematics studies during this transition process. Differences between lower and upper secondary school mathematics that students can meet may be related to curriculum issues, differences in styles and focus of teaching or textbooks, kinds of examination tasks and evaluation criteria, pace and work load. However, this paper sets its main focus on how to identify and describe possible differences in the classroom teaching that may (partly) account for transition problems.

Knowledge in mathematics can refer to different things, such as technical skills in solving tasks by using a certain method, the ability to justify why a method works or to prove mathematical theorems. A common psychological approach for addressing these issues draws on the distinction between procedural and conceptual knowledge. However, to *compare* the character of the mathematical knowledge as it is being practised within the two different institutions (lower and upper secondary school in Sweden), including criteria for what counts as an accepted knowledge production by the institution, an approach that also takes institutional factors into account is needed. One such tool is provided by the anthropological theory of didactics, ATD (see e.g. Bosch & Gascón, 2006), within which the notion *praxeology* (or mathematical organisation) addresses different aspects of the mathematical content in for example a school context activity. More general structural issues regarding the distribution of knowledge in pedagogical contexts are described by Bernstein (2000), where some of the key concepts of his theory such as *classification* and *framing* of knowledge, and *recognition* and *realisation* rules, can be used as analytical tools when researching what possibilities the students have to succeed in the mathematics classroom. In this

paper, the use of these theoretical tools for investigating the transition will be discussed and illustrated by preliminary empirical data from grade 9 and first year of upper secondary school. We thus address the question about how and to what extent a combination of these two theoretical approaches will support the comparison of how students might experience differences in their mathematics studies between the end of lower and the beginning of upper secondary school.

BACKGROUND

In Sweden, children begin at the age of seven in the nine years compulsory school. Almost all students proceed to upper secondary school, which is non-compulsory and consists of 18 different national programmes, theoretically as well as vocationally oriented. The students apply for upper secondary school during the last semester of grade 9 in compulsory school. One of the required qualifications for a national programme is to have passed in mathematics in grade 9. In the core school subjects, such as mathematics, national tests are compulsory in order to set a common national standard. Results from May 2011 show that 19 % of the students in grade 9 did not pass the national test in mathematics (Skolverket, 2012). However the national tests are consultative and only 6 % finally did not pass in mathematics in grade 9.

There are three versions of the first mathematics course in upper secondary school. Course 1a is studied mainly in vocationally oriented study programmes, course 1b e.g. in the social science programme and course 1c e.g. in the science programme. To acquire a general eligibility for university studies a student has to follow the study programmes including courses 1b or 1c. Results from May 2012 show that around 35 % of the students did not pass the national test for the first mathematics course. Of these, for course 1a 48 % of around 25 000 students did not pass the national test, for course 1b 30 % of around 30 000 students and for course 1c 9 % of around 7 000 students (Skolverket, 2012). Since all those students passed in mathematics in grade 9 (although not necessarily on the national test), these results point to a concern about the transition from lower to upper secondary school mathematics.

The different levels of the Swedish school system are regulated by national curricula, including syllabuses describing ‘core content’ and ‘knowledge requirements’ (Skolverket, 2011a, 2011b). While core content is naturally expanded in the first mathematics course in upper secondary school compared to grade 9 in compulsory school, the formulations of the main goals for the subject do not differ considerably between the two school sectors, both emphasising conceptual and procedural proficiency, problem solving and modelling skills, and mathematical reasoning and communication ability. Classroom practice, though, is not regulated in the steering documents and can differ between groups, teachers, schools and school sectors. To understand how the students experience their mathematics studies during the transition stage, it is therefore necessary to investigate potential differences in classroom practices with analytical tools that are flexible enough to make a comparison of these practices possible.

STUDIES OF TRANSITIONS

Most of the existing research on transitions between school-sectors deals with other levels than the transition from lower to upper secondary school. At this level, most studies have focused on less domain specific issues such as identities and motivation (in relation to mathematics, see for example Midgley, Feldlaufer, & Eccles, 1989). However, some studies focus on differences related to the teaching at the two school levels. With a focus on the character of the mathematical work in classrooms, Sdrolas and Triandafillidis (2008) investigate the transition from primary to secondary school geometry in Greece using a semiotic approach, concluding that students' continued construction of mathematically more developed signs may not be supported by the teaching they receive. They observe an increase in logical rigour in secondary school that does not build on children's primary school experiences. In addition, a "rushed move /.../ towards the production of a general law" is seen in teaching at both school levels, with a negative influence both on students' participation and on the "clearness of a mathematical idea" (ibid., p. 167). In Norway, Nilsen's (2012) study employs a semiotic perspective to compare the teaching and learning of linear functions at lower and upper secondary school, concluding that a lack of flexibility in the mathematical teaching, tasks and tests was impeding students' transition towards a more abstract notion of gradient at upper secondary level. The same author also investigated differences and similarities in teachers' beliefs about mathematics teaching at the two school levels (Nilsen, 2009). It was found that teachers at the lower secondary level put more emphasis on "reaching the individual student" (p. 2502), while upper secondary teachers focus more on good explanations and mathematical techniques for students' individual work on tasks.

Research on the transition from upper secondary to university level mathematics has focused on several of its aspects, including differences regarding the content and character of mathematics at the two levels of education. In the Swedish context, Brandell, Hemmi and Thunberg (2008) point to problems created by a gap in topics covered, as well as a change towards a more theoretical mathematical discourse, while Stadler (2009) characterises the transition in terms of how students refer to the different available resources. In an on-going project it has been shown that students' recognition of what counts as the promoted institutionalised mathematics is related to their achievement levels (Jablonka, Ashjari, & Bergsten, 2012). In their study Bernstein's concepts 'classification' and 'recognition rules' have been used to study changes in institutionalised mathematical discourse during students' transition between two levels of education.

THEORETICAL APPROACH

Previous research on transitions has pointed out several features within the receiving institution that seem to be "new" in relation to the students' experiences of mathematics education from the institution they are leaving. These relate to an increase in logical rigour and a more theoretical discourse combined with an increased pace, new mathematical content and work with more advanced mathematical signs, and a

teacher focus more on subject matter explanations than “reaching the individual”. In order to account for what students experience as different (and possibly problematic) in the passage from lower to upper secondary mathematics education, an analytical tool is needed that makes it possible to analyse the mathematical work at both institutions in a way that makes it open for comparison. Semiotic analyses of the treatment of specific mathematical concepts or ad-hoc comparisons of mathematical content covered will then need to be complemented with a more holistic analysis of the type of mathematical work and knowledge criteria that students experience in the classroom (cf. Nilsen, 2009). This will require a tool that can describe structures in the mathematical work that are *general* across institutions and relevant enough to capture those potential differences that transition research has pointed at, as well as others that have not yet been observed, and *flexible* enough to be applied to both institutions which are steered by different curriculums and different teaching traditions. This would suggest the use of a theory in the sense of Jablonka and Bergsten (2010), with the potential to describe relations between categories and account for aspects not yet observed.

A potential such tool is found within the anthropological theory of didactics, ATD, with its theoretical construct *mathematical organisation* or *praxeology* (e.g. Bosch & Gascón, 2006). By locating the praxeological analysis in relation to different *levels of co-determination* (ibid.), curriculum and teaching traditions can be adhered to. However, while the praxeological analysis accounts for the organisation of the mathematical knowledge in the classroom but not for the overall organisation and structure of the classroom work, we also suggest to employ some notions from Bernstein (2000) to be able to analyse differences and similarities along that dimension at the two school levels, which can be captured by ‘classification’ and ‘framing’. These two theoretical approaches are compatible as they both consider institutional dimensions and share the same intellectual roots (cf. Bergsten, Jablonka, & Klisinska, 2010).

In this paper the theoretical construct ‘praxeology’, a key concept in ATD, will thus be employed to characterise the mathematical work in an activity such as a mathematics lesson: what types of tasks are given to the students and what techniques are used to solve these tasks (the praxis part of the praxeology, or the ‘know-how’), what kind of arguments are used to justify the use of these techniques, and what theoretical background these justifications are based on (the logos part of the praxeology or the ‘know-why’). For the study, it is of interest to investigate to which degree there is a difference in the character of the praxeologies, for example in terms of balance and links between the praxis and logos levels, developed in lower and upper secondary school mathematics. To account for constraints on classroom work coming from outside the classroom, such as curriculum, pedagogy and teaching traditions, the ATD employs the theoretical construct ‘levels of co-determination’. The ATD is a general theory in the sense of Jablonka and Bergsten (2010) and has

been applied in different subjects and school levels (see e.g. Bosch & Gascón, 2006) pointing to inconsistencies and constraints in educational contexts.

Also Bernstein's theory of pedagogic discourse (e.g. Bernstein, 2000) is such a general theory that has been applied in different cultural contexts, and it is here used for comparing the level of explicitness of the knowledge criteria for the students: are there differences in the strength of the *framing of the knowledge criteria* in the two institutions (ibid.)? There may also be differences with respect to the framing of the selection (e.g. who selects the tasks to work on), sequencing and pace, as well as the balance between *instructional* and *regulative* discourse (ibid.), where the balance between these two constituent parts of the pedagogic discourse is expected to change during the transition towards a stronger dominance of instructional discourse. Furthermore, how do students differentiate between what the mathematically relevant aspects of the tasks are and what is less relevant, such as specific context issues? This dimension of comparison may be described in terms of *classification* (ibid.).

Similarities and differences between the two school levels may concern what aspects of mathematical work are emphasised in the mathematics classroom teaching. For example, is solving the task enough or is the student also required to explain why and how a method is working? A comparison of this issue will be possible by way of a praxeological analysis combined with a focus on the framing of the classroom work. Furthermore, knowledge of mathematics includes the ability to communicate about the subject, according to the syllabus. One aspect of communication is writing down the solution of a task. To be able to do this in a way that is legitimate within the institution, the student must know what is expected from him/her, that is, has to be in possession of *recognition* and *realisation rules* (ibid.). The character of the praxeologies, framing of the knowledge criteria and possession of recognition and realisation rules are factors that likely influence students' experiences of mathematics at their respective school level.

AN EMPIRICAL STUDY

The study as a whole will contain analyses of curriculum documents, observations of mathematics lessons at the two school levels, interviews with students and a questionnaire survey. In this paper the main focus will be on the comparison of the classroom work at the two school levels. For this purpose, two mathematics classes were video and audio recorded during three consecutive lessons at two different occasions during the last semester of grade 9. Some of these students volunteered for follow up interviews and most of these students were revisited in their mathematics classes in the first semester of upper secondary school. Thus, three classes in the first year of upper secondary school, following the mathematics courses 1a, 1b, and 1c, respectively, were also video and audio recorded in a similar way as the grade 9 recordings, along with follow up student interviews.

For the purpose of illustrating how the theoretical approach suggested may support the analysis of empirical data that can be used to study the transition process in focus,

an episode from a mathematics lesson in one classroom in grade 9 will be discussed and compared to preliminary observations in a mathematics class from upper secondary school. The teacher-student communication selected in the grade 9 classroom took place when the class was repeating the content of the course before the national test. The lesson pattern is typical for Swedish mathematics lessons, at lower as well as upper secondary level: a main part consists of individual work, where the students solve tasks from the textbook; the teacher walks around in the classroom helping the students, who raise their hands to call for help; teaching in front of the class is done mainly at the beginning of the lesson and for a relatively short time (Skolverket, 2003).

A teacher-student dialogue

A student has asked the teacher for help. The task is to calculate the cost of 0,9 kg shrimps, when the price is 95 SEK per kg. The student has written $95 \cdot 0,9$ in the notebook but does not know whether she should use the calculator or do the calculation by hand. The dialogue in focus here is about how to calculate $95 \cdot 0,9$ without a calculator. The teacher writes a standard algorithm and starts calculating:

- 1 Teacher: Nine times five is forty-five and nine times nine is eighty-one, eighty-five [$81 + 4$], which give eight five five, and then one decimal [writes a decimal sign between the fives]
- 2 Student: How do you know that? [that it will be *one* decimal]
- 3 Teacher: I was going to make another suggestion, but this might answer your question. If you take nine times ninety-five
- 4 Student: Mm [agreement]
- 5 Teacher: it will be eight hundred fifty-five.
- 6 Student: Mm
- 7 Teacher: But you shouldn't take nine [with emphasis] times ninety-five, but zero point nine [with emphasis].
- 8 Student: Yes
- 9 Teacher: And because zero point nine is ten times less than nine
- 10 Student: Mm
- 11 Teacher: it means that if we answer like this [855], the answer will be ten times too large.
- 12 Student: Mm
- 13 Teacher: Yes

Here the teacher switches between describing techniques and providing justifications. In line 1 the teacher explicitly performs an algorithmic technique for multiplication that the student does not seem to question apart from the last expression, the claim “and one decimal”, for which the student asks for a ground (line 2). As a response, the teacher then in line 3 starts to present an idea of how to explain the position of the decimal sign. The argumentation from line 5 through lines 7, 9 and 11 is used by the teacher to justify the claim made in line 1, where the warrant is implicitly included in a reasoning about powers of ten, again including calculations.

It is the student who raises the question (line 2) about *how* you know that it will be one decimal, though it seems (from line 3) that the teacher had prepared to warrant his claim some way. This question of justification can be either a question about the technique required to find the number of decimals or an explanation about *why* you can come to that conclusion. Due to the other very short contributions from the student, it is likely to conclude that the question *how* was about ‘how to do it’ rather than to understand. However, the teacher’s immediate answer to the question was to provide a rational explanation. In the continued dialogue the same pattern goes on. The teacher provides another justification (warrant) of why the product contains one decimal. When the student (later) raises a question about how to do when the numbers have many digits and decimals, the teacher employs a backing strategy providing a rule that can be used. As this rule is again a technique given without ground, he uses estimation to assure that the answer is correct, employing the qualifier ‘reasonable’. This pattern is typical for the dialogues during the three lessons. One of the students asks for help and the teacher gives an explanation including explanations both of how to do it and why it works. The student’s responses are mainly short, but sometimes s/he asks another question about *how* to solve the problem. In the excerpt the teacher’s explanations are intra-mathematical. However, in other discussions he uses models or metaphors when switching between technique and justification, e.g. ‘common economy’ when explaining addition or subtraction of positive and negative numbers. He also mentions sign rules as techniques to help doing the calculations.

The excerpts show that both mathematical techniques and reasoning at the level of justification are frequent in the dialogues between students and the teacher. The teacher’s explanations often contain different ways of attacking the problem, as well as types of justifications suggested, thus providing a base for a more general praxeology to be developed (cf. Barbé, Bosch, Espinoza, & Gascón, 2005, pp. 237-238). This strategy may also promote the students to get a broader view of the subject mathematics than ‘just finding an answer’. However, the students’ contributions to the mathematical discussions are mostly short, containing very few questions or conclusions about explanations and do not show signs of engagement in the justification of the mathematical techniques. Hence it is not possible, from these data, to know to what extent the students are aware of the teacher’s endeavours of explaining more than just the technique to find the answer to the task. From a more detailed look into what types of tasks and techniques are used, including those appearing in the examination tests and described in the textbook with justifications offered there, it will be possible to describe the character of the praxeology developed in the lessons (cf. Barbé et al., 2005). The mathematical knowledge in focus during the individual discussions between the teacher and the students was strongly classified, though in some explanations metaphors from outside mathematics were used.

Framing of the criteria

Explicit discussions about knowledge criteria, in the sense of what is expected when you write down a solution to a task, are rare during the three lessons. There is one

episode from the beginning of the first lesson when the teacher informs that they will get copies of national tests from earlier years, along with solutions, for practicing: "... and then we will go through them with solutions so you will think of that you not just write answers or what is important to include in a solution". That is the single part where this is clearly mentioned. There is also one question from a student about if you just should write down the answer after you have completed a calculation by hand. It is not clear whether this question really is about how to present a solution or if it just aims to check if the task is completed. In summary, explicit information about how appropriate solutions should look like is not frequently offered during the lessons to support students' development of recognition rules for what counts as legitimate knowledge in this mathematics classroom.

The teaching observed in the three lessons does only to a very small extent explicitly discuss the knowledge criteria with the whole class, thus not providing many opportunities for the students to develop appropriate recognition rules. This is then possible only in the individual discussions with the teacher or with other students. The data presented above point to a rather weak framing of the knowledge criteria also in such situations. Otherwise there is neither discussion of what is important in mathematics nor discussions about students' solutions of tasks or standards for written solutions. However, that does not exclude that recognition rules are developed when students work with tasks in relation to solved examples in the textbook, or when they get their result, perhaps with their teachers' comments, on written exams.

Some preliminary observations from the upper secondary classroom

Preliminary analyses from the upper secondary school classroom observations show that there are significant differences between the three classrooms visited. In the class studying course 1a, the praxeology is constituted mainly by the 'know-how'. The teacher's explanations are short and mainly inform the students exactly how to solve a task. In the course 1b class there are more explicit arguments why a certain technique works and the framing of the knowledge criteria is visible. In the third class, studying course 1c, there is more teaching from the front, in some lessons up to 30 minutes. Questions from the students are rare, even when they work individually, but when someone asks a question, the teacher's answer includes both an appropriate technique and its justification. There is generally a strong classification of the mathematical knowledge in these classrooms but answers in student interviews indicate an increasing use of mathematics in other school subjects as compared to grade 9.

In the data from the grade 9 classroom presented, a weak framing of the knowledge criteria was found, indicating that students may develop only weak recognition rules. The preliminary data from the upper secondary school classrooms suggest a more visible pedagogy in the more theoretical courses.

DISCUSSION

Differences between the two school levels that may account for transition problems, or challenges, may be searched at different levels of co-determination. As the general

goals and knowledge requirements for the mathematics studies as formulated in the national curriculums are found to be not very different, and the mathematics lessons generally structured by an overall similar pattern, a conceptual framework has been suggested for analysing differences in the organisation of the disseminated mathematical knowledge and the criteria (and their explicitness) for legitimate knowledge productions from the students at the two school levels. By the focus on general characteristics of the organisation of mathematical knowledge in terms of its technical and theoretical levels, and the framing through the teaching practice, it has the potential to detect critical differences, between the two school levels, in the character of the mathematics taught, including the knowledge criteria and their explicitness for the students, as well as differences in pacing and selection and sequencing of the content. The preliminary data indicate such differences as well as differences with respect to the balance between *instructional* and *regulative* discourse as predicted, but this also seems to differentiate *between* the programmes at upper secondary school.

It was also a preliminary assumption behind the study that school mathematics in compulsory school is more “mixed up” with for example everyday contexts than the mathematics in upper secondary school, thus pointing to the relevance of employing Bernstein’s notion of classification. The relation between mathematics and other school subjects is also an issue of concern here. Some observations could be done on this dimension already in the preliminary data reported here.

From the rather small empirical basis reported above, it has been possible to characterise the mathematical work in the classroom in terms of the praxeology that seems to be developing, as well as issues related to the classification and framing of the pedagogic discourse, and thus establish links between the empirical data and the key descriptive terms from the theoretical framework suggested. When analysing empirical data from sequences of mathematics lessons at different occasions and in different classrooms at both school levels, the framework has the potential to support the kind of qualitative comparison aimed at here. For the purpose of the overall transition study, students’ experiences of the mathematics taught at the two school levels will be investigated, complemented by theory guided analyses of transcripts from student interviews, curriculum documents, textbooks, and examination tests (such as the national tests). By this theory based approach for comparing two different educational contexts, we hope to avoid projecting categories developed within one context on the other which would run the risk of missing out on some critical differences. However, the approach can only work by remaining sensitive to the dialectic between the theoretical and the empirical (cf. Bernstein, 2000, p. 135).

RE-EXAMINING THE LANGUAGE SUPPORTS FOR CHILDREN'S MATHEMATICAL UNDERSTANDING: A COMPARATIVE STUDY BETWEEN FRENCH AND VIETNAMESE LANGUAGE

HienThi Thu Nguyen^{a,b}, Jacques Grégoire^b

^aUniversity of Pedagogy HoChiMinh City, Vietnam

^bCatholic University of Louvain, Belgium

The aim of the present study was to re-examine the influence of language characteristics on mathematical understanding and performance. Third grade French-speaking Belgian and Vietnamese students participated in the study. In Vietnamese, the number-name system has particular characteristics, which indicate explicitly the zero's position (e.g, 2004 is said "two thousand zero hundred remainder four"). Language had an impact only on the number-name related task and did not affect the tasks involving manipulation of symbols. The relative influence of language, the use of tasks in comparatives studies and the different numerical experiences of children are discussed.

Keywords: language support, cross-national comparisons, syntactic zero, transcoding, relativity language

INTRODUCTION

Even though the Arabic number and its mathematical structure are used worldwide, Arabic code(e.g., 45) cannot be used by itself. It is required to be transcoded in a language to be used, to attribute a meaning to those symbols, which are called a verbal-number (e.g., forty five). Therefore, even if the code is used worldwide, this unavoidable transcoding process is going to induce significant differences on its treatment by each individual, depending on their language and cultural context.

Previous cross-national studies showed that due to a more transparent verbal name system, differences in performances and errors in a verbal-Arabic transcoding task were found (Seron&Fayol, 1994; Lochy, Delazer, Domahs, Zoppoth, &Seron, 2004; Nguyen &Grégoire, 2013). The more efficient way of naming numbers in Asian languages is also an important explanation for the differences favoring Asian children in previous studies between Asian and Western children in certain mathematics skills such as abstract counting(Miller, Smith, Zhu & Zhang, 1995; Miller & Stigler, 1987), mental addition (Geary, Bow-Thomas, Fan & Siegler, 1993; Geary et al., 1996), understanding of the canonical base-10 system and place value understanding (Miura, Okamoto, Kim, Steere&Fayol, 1993). The effect of language differences has also supported the Chinese children to surpass their English and American counterparts in embedded-ten cardinal understanding (Ho & Fuson, 1998) and in the acquisition and

use of ordinal numbers corresponding to their ordinal names (Miller, Major, Shu & Zhang, 2000).

Like other verbal systems of numbers in East Asia, the Vietnamese language possesses a transparent name-number system, in particular the name-number for the teens. The number designation from eleven to nineteen is done with an addition relationship (e.g., eleven is pronounced “ten one”). However, the Vietnamese language has peculiarities when the digit in the tens or hundreds position is a zero. This is not found in other Asian languages like Chinese, Korean or Japanese. Vietnamese uses the word "zero" as a lexical primitive in the number construction. For example, the Arabic number 3024 is named “three thousand zero hundred two ten four”. This zero is not masked in its verbal form like in other languages. There is however an exception when the zero is in the tens place where it is replaced by the word "remainder". For example, the Arabic number 309 is named "three hundred remainder nine". We can understand the word "remainder" as the rest of the division of 309 by 100. Therefore, for the Arabic number 2009, it is said in Vietnamese "two thousand zero hundred remainder nine".

Depending on the position of a zero in a number, two types of zero were distinguished (Granà, Lochy, Girellid, Seron, & Semenza, 2003). The first type is the lexical zero, as in numbers “520”, which is semantically represented. The second type is the syntactic zero as in numbers “508” or “7014”, which is a production of syntax. The syntactic zero is inserted into the number by application of a rule to indicate a missing value in a position.

According to the characteristic of the Vietnamese language and to the linguistic relativity, the syntactic zero may be easier to manipulate in Vietnamese than in other languages. In our previous study (Nguyen & Grégoire, 2013) we examined the impact of language differences related to the syntactic zero on a verbal-Arabic transcoding task in Vietnamese and French. Results from this study also highly showed the advancement of Vietnamese children in comparison with Belgian children (French-speaking Community). However, the mathematical program in Vietnam is more developed on the large numbers topic than in Belgium. As our task comprised many large numbers, the difference between the two countries may be highly due to variation between the two countries’ mathematical programs.

Previous studies emphasized the role of languages in the understanding of mathematics and in the performance on mathematics tasks but notice here that there is also a limitation of this influence. Nunes (1992) had demonstrated that the developed number name system can restructure mental activity and not involve other basic abilities such as memory and logical reasoning. Results from Miller and Stigler’s (1987) work showed that even if Chinese children were better than US children in abstract counting, there is no difference between the two groups in counting objects. In addition, the difference between children in cross-cultural studies really appears in tasks directly related to language. The Chinese children were more advanced than U.S children in abstract counting but they did not differ in object

counting and problem solving, which is more symbol related (Miller, Smith, Zhu & Zhang, 1995). The limitation of language influence on the cognitive representation of number is also remarked in the cross-cultural study of Saxton and Towse (1998). In this study the researchers suggested that the difference between performances of English-speaking and Japanese-speaking children was mainly due to the task instructions.

From the perspective of limitation concerns of language influence on mathematical understanding and performance, Vietnamese children may not differ from others in the case of a task indirectly involving a name-number. To better understand the influence of language, tasks specifically related to the syntactic zero were built, not only verbal-Arabic transcoding tasks as in the previous study. Four tasks assessing the competence in comparison, understanding of positional digit in the number, verbal-Arabic number transcoding and analog-numerical-representation into Arabic code transcoding were administered in the present study. In the analog-Arabic transcoding task, the children are asked to produce the Arabic number from a number represented with cubes (e.g., a big cube represents a hundred and a small cube represents ten etc.). Therefore, the children in both countries have the same input code and the support from transparent denomination of the syntactic zero is here masked for Vietnamese children. Having the analog-Arabic transcoding task at the same time with a verbal-Arabic transcoding task allowed us to determine more specific effects of language on the interpretation and performance of children. The tasks in the present study comprised only four digits numbers to avoid the variation of the mathematical programs between the two countries Vietnam and Belgium (French-speaking Community).

We investigated whether the numerical language characteristic involving a zero has also an effect on the tasks involving the manipulation of symbols. Children at grade 3 from the two countries Vietnam and Belgium (French-speaking Community) performed four tasks: understanding of digit value (Comparison), understanding of positional digit in the number (Digit Identification), verbal-Arabic number transcoding and analog-Arabic number transcoding. It was expected that in this examination of transcoding from verbal into Arabic number, Vietnamese children should have higher performances than Belgian children because of the Vietnamese linguistics' support. But this support would disappear on the other tasks such as comparison, number digit identification or analog- Arabic number transcoding.

METHOD

Two groups of children participated in this research. In Belgium, we assessed 56 children of Grade 3 (26 girls and 40 boys; mean age 106 months). In Vietnam, we assessed 92 children of Grade 3 (51 girls and 41 boys; mean age 105 months). The children were randomly selected. The study took place in the second half of the school year.

Four Paper-and-pencil tasks were constructed with twenty four items for each task. The test was performed collectively in the classroom. Children worked individually without time pressure. The average time to achieve each task was between five and fifteen minutes.

The Comparison task consisted of 24 pairs of natural numbers. Half of the items included two digits equal to zero (e.g. 4500 vs.4050) and the other half consisted of items with one digit equal to zero (e.g.6302 vs.6032). Both numbers of each pair had the same digits and the same thousand. They only varied in the position of the digits, which had the form $\overline{a0bc}$ vs. $\overline{ab0c}$ or $\overline{ab0c}$ vs. $\overline{abc0}$.

The Verbal-Arabic Transcoding task asked participants to write the natural numbers from a verbal form into an Arabic number. There were two categories. The Syntactic Zero Verbal Transcoding category was used for numbers containing a syntactic zero (e.g.3604). Numbers without zero, such as 2146, were used in the Non Syntactic Zero Verbal Transcoding category.

The Digit Identification task included none to two digits of zero (e.g. 2146; 3064 and 2006). Children were asked to circle the digit indicating the tens and the hundreds. There are two categories. The category Zero Digit Identification comprised the numbers with the digit needed to be circled equal to zero (e.g. “Circle the digit indicating the tens in the number 4205”). The category Non Zero Digit Identification comprised the numbers with the digit needed to be circled different from zero (e.g. the number 3264).

In the Analog-Arabic number Transcoding task, children were asked to produce the Arabic number from a number represented with cubes (e.g., a big cube represents a thousand and a small square represents a unit etc.). The same 24 items of the Verbal-Arabic Transcoding task were used for the Analog-Arabic Transcoding task. Notice that item order was changed in the two tasks. The Syntactic Zero Analog Transcoding category was used for numbers containing a syntactic zero (e.g.3604). Numbers without zero, such as 2146, were used in the Non Syntactic Zero Analog Transcoding category.

RESULTS

Overall

Two-way repeated measures analysis of variance (ANOVA) was conducted on the correct response rates with the Category (Comparison, Transcoding Verbal-Arabic, Digit Identification and Transcoding Analog-Arabic) as the within subjects factor and the Country (Belgium and Vietnam) as a between subjects factor. The main effect of Country was significant, $F(1,156)=7.15$, $p=0.008$, partial $\eta^2 = 0.44$, which means that the scores of Belgian children were higher than those of Vietnamese. The main effect of Category was also significant, $F(3,468) = 21.01$, $p<0.001$, partial $\eta^2 = 0.119$ implies that performances differed across tasks. The interaction between Category and Country was also significant, $F(3,468) = 6.85$, $p<0.001$, partial $\eta^2 = 0.042$ which

means that the achievement across category differed according to the country. To understand this difference more precisely, we made four one-way ANOVA with «Country» as a between-subject variable, separately for each category.

On the category Comparison and Transcoding Analog-Arabic, there are significant differences between Belgian and Vietnamese children, $F(1,156)=9.78, p=0.02$ and $F(1,156)=18.8, p<0.001$ respectively for task Comparison and Transcoding Analog-Arabic. The scores of Belgian children were higher than of the Vietnamese in these tasks. Only on the category Transcoding Verbal-Arabic, however, the scores of Vietnamese children were slightly higher than the Belgian but there is no significant difference between them ($p>0.05$). Also, on the task Digit Identification, children in the two countries did not differ ($p>0.05$). The findings are consistent with our hypothesis that the influence of different mathematical languages changed according to the tasks which were associated with language in different ways.

Table 1: Mean rates and standard deviations of correct responses (in percent) in each category by country

Category	Belgium		Vietnam	
	M	SD	M	SD
Comparison	97.0	8.6	89.2	18.9
Digit Identification	77.9	29.8	71.5	41.8
Transcoding Verbal-Arabic	84.5	26.6	90.4	18.6
Transcoding Analog-Arabic	84.9	26.7	65.1	29.5

The impact of zero in the digit identification task

To investigate the impact of zero in the task Digit Identification, the correct response rates in two categories named Zero Digit Identification and Non Zero Digit Identification were compared. Two-way repeated ANOVA was conducted with the Zero Identification (Zero Digit Identification and Non Zero Digit Identification) as a within-subjects factor and the Country (Belgium and Vietnam) as a between subjects factor. The main effect of Country was not significant, $p<0.05$. The main effect of Zero in the Digit Identification task was significant, $F(1,156) = 18.9, p<0.001$, which means the children had more difficulties in identifying the digit of a number when this digit was equal to zero. The interaction between Zero Identification and Country was also significant, $F(1,156) = 9.25, p<0.05$, which means that the effect of zero differed according to the country.

To understand this interaction more precisely, two-way repeated ANOVA was conducted, separately for each country. The effect of Zero in digit identification was emphasized more for Belgian children than for Vietnamese. In fact, this effect was significant for Belgian children, $F(1,65) = 15.3, p<0.001$, meaning that the presence

of a syntactic zero leads to lower scores for Belgian children, but it was not significant for Vietnamese children, $F(1,91) = 1.64$, $p > 0.05$.

Table 2: Mean rates and standard deviations of correct responses (in percent) in the category Digit Identification

Category	Belgium		Vietnam	
	M	SD	M	SD
Zero Digit Identification	69.7	40.5	70.0	43.6
Non Zero Digit Identification	86.1	26.6	72.9	42.7

The impact of zero on the task Transcoding Verbal-Arabic

Table 3: Mean rates of correct responses (in percent) depending on the type of zero in the category Transcoding

Category	Belgium		Vietnam	
	Syntactic Zero	Non Syntactic Zero	Syntactic Zero	Non Syntactic Zero
Verbal-Arabic	85.3	82.0	89.2	93.8
Analog-Arabic	83.2	89.9	57.4	88.2

Two-way repeated ANOVA was conducted with the Category (Syntactic Zero Transcoding Verbal and Non Syntactic Zero Transcoding Verbal) as a within-subjects factor and the Country (Belgium and Vietnam) as a between subjects factor. The main effect of Country was not significant, $F(1,156)=5.3$, $p > 0.05$, partial $n=0.033$. The main effect of Category in the task Transcoding Verbal-Arabic did not differ significantly $F(1,156)=0.25$, $p > 0.05$, partial $n=0.002$. But the interaction between Category and Country was significant, $F(1,156)=7.4$, $p < 0.05$, partial $n=0.045$, which means that the effect of syntactic zero differed according to the country.

To understand the impact of the syntactic zero more precisely, two-way repeated ANOVA was conducted, separately for each country. The results confirmed that the impact of syntactic zero was not significant for Belgian groups, $F(1,65)=2.41$, $p > 0.05$, partial $n=0.036$ but it was significant for Vietnamese, $F(1,91)= 5.7$, $p < 0.05$, partial $n=0.059$ which means the Verbal-Arabic transcoding with a number containing a syntactic zero is more difficult than without a syntactic zero.

The impact of zero on the task Transcoding Analog-Arabic

Two-way repeated ANOVA was conducted with the Category (Syntactic Zero and Non Syntactic Zero) as a within-subjects factor and the Country (Belgium and Vietnam) as a between subjects factor. The main effect of Country differed significantly, $F(1,156)=13.06$, $p<0.001$, partial $\eta^2=0.077$, which showed that the performances of Belgian children were higher than of the Vietnamese. The main effect of Category in the task Transcoding Analog-Arabic differed significantly $F(1,156)= 44.77$, $p <0.001$, partial $\eta^2=0.223$, indicating that the category Syntactic Zero Transcoding Analog provided less correct responses than the category Non Syntactic Zero. The interaction between Category and Country was also significant, $F(1,156) = 18.65$, $p<0.001$, partial $\eta^2=0.107$.

To understand the impact of the syntactic zero more precisely, two-way repeated ANOVA was conducted, separately for each country. The results confirmed the impact of the syntactic zero was significant for both countries, $F(1, 65) =4.86$, $p<0.05$, partial $\eta^2 = 0.07$ and $F(1,91)= 53.38$, $p<0.001$, partial $\eta^2= 0.37$ respectively for Belgian and Vietnamese samples. The impact of the syntactic zero was more highlighted with Vietnamese children than with Belgian.

DISCUSSION

In the current study, the superior performances of Vietnamese children in a verbal-Arabic number transcoding task over Belgian children, even when this task comprised only numbers of 4 digits, was consistent as reported by our previous study (Nguyen & Grégoire, 2013) related to an effective number-name system of the Vietnamese language compared to the French. In addition, regarding the results of Vietnamese children in the Digit Identification task, we observed a large variation between them ($M=71.5$, $SD=41.8$) and the performances across the Zero Digit Identification and Non Zero Digit Identification were similar. If the Vietnamese children had low performances in this task, they failed to grasp the basics of the positional number system. For Belgians, on the one hand the impact of zero was significant on the Digit Identification task and on the other hand the variation between children was smaller than for Vietnamese. In addition, performances of Belgian children were also higher in other tasks involving the Arabic number production such as analog-Arabic number Transcoding. This suggests that Belgian children's difficulty with this task is only slightly due to a general failure of mastery of positional number and rather more to a specific misunderstanding of zero. Even if Belgian children surpassed Vietnamese in this task, they were more affected by the impact of zero than Vietnamese. Vietnamese children may be able to better detect the role of zero, occupied by a position in the number. It can be explained by the support of a greater transparency in Vietnamese number denomination, where the zero's position is explicit. This result also confirmed the previous studies concerning supports of language characteristics on mathematical performances.

The linguisticrelativity hypothesis was well examined by many studies of Muira and colleagues. Looking at the impact of languages closely, Saxton and Towse (1998) replicated a study of Muira with some subtle changes in task instructions. Results suggested that the impact of languages on the cognitive representation of a number was less direct than previously suggested and that the numerical experience played an important role. Recall that in our previous study (Nguyen &Grégoire, 2013), in the verbal-Arabic number transcoding task with numbers from 3 to 6 digits, Vietnamese children at grade 3 were more advanced than Belgians, particularly with large numbers such as 5 and 6 digits. This difference corresponds to the Vietnamese experience of large numbers in school and daily life. Even if only 4 digit numbers were used in this study to avoid the dissimilarity of experience between the two samples, Vietnamese children’s performances were always higher than of their counterparts. However, in the Analog-Arabic number Transcoding task, a large gap between Vietnamese and Belgians was observed, which means Belgians surpassed Vietnamese children. One explanation is due to the manipulation experience with analog-representation numbers of Belgian children. In fact, in Vietnam, this number code is rarely used in textbooks and also for mathematical activities in school. These results showed the limitation of language influences on the less related name-number tasks and emphasised the numerical experience in cross-national performance differences.

It can be questioned what kind of task can measure the impact of languages on mathematical understanding and performances. As Saxton and Twose (1998) had pointed out, the task used by Muira and al. (1994) to attest the support of languages didnot measure this impact directly. In fact, the matching numbers task to evaluate the place-value understanding in this study rather involved analog code (the cubes used to represent units and tens) which connect indirectly with language (Dehaene, 1992). Results from work of Miller etal. (1995) also supported the perspective of language influence limitation regarding these kinds of tasks. Chinese children were better than U.S children in abstract counting but they did not differ in object counting or mathematical problem solving, which revolved more on the relation and manipulation of symbols. Therefore, choosing tasks in order to measure correctly the impact of language in cross-national studies must be done carefully.

The results supported our hypothesis. On the one hand, support of language characteristics was also demonstrated with the superior performances of Vietnamese children in the verbal-number transcoding task. On the other hand, this support was not direct and showed its limitation when the introduced task was less related with the number-name. In the task related to Arabic numbers and semantic representations (analog code) of numbers, the effect of language did not appear. Other factors like mathematical experience and differences in approach to mathematics teaching might be a plausible explanation for the differences between the two countries, which favoured Belgian children. The utilisation of varied tasks was useful to underscore the strong effect of different competences related with numerical language. In

particular, it also showed how the performances of children in each country changed due to the relation with number-name on the corresponding tasks. It provided a fuller view about the mathematical understanding and performances in cross-cultural studies. It will be worth, in further researches, to re-examine the appropriateness of tasks which were used in previous studies that concern testing the influence of language on mathematical performances.

COMPARING THE STRUCTURES OF 3RD GRADERS' MATHEMATICS-RELATED AFFECT IN CHILE AND FINLAND

Laura Tuohilampi¹, Markku S. Hannula¹, Valentina Giaconi², Anu Laine, and Liisa Näveri

¹University of Helsinki, ²University of Chile

Affective factors are a significant indicator of the quality of learning. However, cultural differences in affective factors have not been studied comprehensively. In this report we will present Chilean and Finnish 3rd graders' affective structures regarding mathematics. We identified both similarities and differences between the structures in these two countries. The study contributes to our knowledge of cultural comparison of affect research by extending the comparisons to the Latin American – Nordic axis.

INTRODUCTION

In affect research it is widely claimed that affective factors regarding mathematics play a significant role when learning mathematics (for reviews, see Op 't Eynde, De Corte, & Verschaffel, 2002; Leder, 2006; Hannula, 2011). However, international comparative studies have shown that students from one country have different affective relations with mathematics from those elsewhere (Lee, 2009; Pehkonen, 1995). More importantly, the relations between affective variables and achievement also seem to have culturally specific characteristics (Lee, 2009). To date, some cultural features in affective structures have been acknowledged. However, the focus has mostly been on examining the distinction between Western and Eastern cultures, and not Latin American and Nordic cultures.

In this article we study the affective structures of students in Chile and Finland in order to identify both similarities and differences. In so doing, the study contributes comparative to research in comparative education by examining countries representative of both Latin American (Chile) and Nordic (Finland) cultures. In addition to the cultures being different, the countries also differ in how their students have been performed in international assessments of mathematics, such as in PISA and TIMSS (OECD, 2010; Mullis et al., 2000). Our focus is on young pupils (9-year old), so we will also learn about the possibilities of measuring affective aspects by a questionnaire with respect to pupils as young as that. By doing the study, we aim to go deeper in understanding the cultural features that influence the affective side of learning.

THEORETICAL BACKGROUND

Mathematics related affect has been conceptualized in a variety of ways, for example as attitudes, beliefs, emotions, motivation, values and identity. Important dimensions of different theoretical approaches are 1) the distinction between state- and trait-type constructs, 2) distinctions between social (group level), psychological (individual level) or physiological (biological level) theories of affect, and 3) distinctions

between cognitive, emotional and motivational aspects of affect (Hannula, 2011; 2012).

In this article, we look at the relatively stable affective traits of individuals. We are interested in the influence of social factors in the formation of affective traits, but we do not theorize affect as a social construct. More specifically, we are interested in the structure that the cognitive, motivational and emotional traits are forming.

The cognitive dimension - beliefs

In this article, we define the cognitive dimension of affective traits as “mental representations to which it makes sense to attribute a truth value” (Hannula, 2011, p. 43). This is very similar to Goldin’s (2002) and Op ’t Eynde and others’ (2002) definition of beliefs. Argued by Op ’t Eynde and others (2002), beliefs become from what is “first told”. This means that if they perceive no contradiction with given information, (whether true or false), students tend to accept it as true. Only when contradictions appear do students have reason to evaluate their former beliefs, as well as given information in the light of former beliefs.

Students’ mathematics-related beliefs can be structured into beliefs about mathematics as a subject, beliefs about mathematics teaching and learning, beliefs about the self, and beliefs about the social context (e.g., Pehkonen, 1995, Op ’t Eynde et al, 2002). Regarding beliefs, we will in this study concentrate on the first and the third aspect, beliefs about mathematics as a subject (difficulty of mathematics) and beliefs about the self (self-efficacy). Both aspects, i.e. self-efficacy beliefs and beliefs about difficulty of mathematics can be construed as mental representations that an individual can cognitively evaluate: a truth value or a justification can be attributed at least by the person him/herself.

Emotional dimension - liking

Here, we define the emotional dimension of mathematics-related affective traits, as “typical emotional reactions to typical situations in the mathematics classroom” (Hannula, 2011, p. 45). To be more exact, the definition refers to how the stable emotive trait is revealed during the lessons: the students have their own typical ways of reacting to the situations that emerge based on their long-term emotional traits. Hence, we are not discussing here the fleeting emotional states that occur, for example, during problem solving.

In mathematics education research, mathematics anxiety is a special case of an emotional trait that has been studied extensively (for a meta-analysis, see Hembree, 1990). Another emotional trait that has been studied comprehensively is liking of mathematics (for a meta-analysis, see Ma & Kishor, 1997). In this study, we are interested in the latter, i.e. the enjoyment students derive from doing mathematics. Many studies show that teenagers tend to not find pleasure in doing mathematics (McLeod, 1992; Metsämuuronen, 2010), whereas primary students have more positive emotions (Tuohilampi, Hannula & Varas, accepted).

Motivational dimension

Motivation research has several theoretical approaches and its use of terminology is sometimes confusing (Murphy & Alexander, 2000). Motivation reflects personal preferences and explains choices and, unlike the cognitive dimension, it is not possible to attribute truth to motives, because they are volitional (e.g. Op 't Eynde et al., 2002). The trait aspect of motivation is related to the overall values the person attributes to mathematics and to the general motivational orientations for learning. In this study, we are interested in students' mastery goal orientation, which is one dimension of their achievement goal orientation (Pintrich & Schunk, 2002).

The structure of affect in Chile and Finland

Although it is generally assumed that there is a relationship between mathematics-related motivation, beliefs, and emotions, the theories of their relationships are fairly recent (Op 't Eynde, De Corte, & Verschaffel, 2006). In this study, we consider the affective structure to include a cognitive dimension, an emotional dimension, and a motivational dimension, each influencing the affective structure as a whole. In addition, we are interested in students' effort in mathematics. These dimensions are of interest, because we think that self-efficacy beliefs (cognitive dimension) influence how students attempt to work with mathematics; goal orientations (motivational dimension) imply students' initiative in mathematics; emotions frame how students experience working with mathematics; and effort shows their resilience in working with mathematics.

Affective structures have been found to be culturally dependent (e.g. Lee, 2009). In Finland, for example, the structures constitute separable dimensions within older (15-year) students (Lee, 2009). Despite being among the most successful on PISA, Finnish students were also characterised by less favourable results on affective measures. Finnish students lack interest and enjoyment in mathematics, they have below average self-efficacy, and low levels of control strategies. On a more positive note, levels of anxiety were low. The study also revealed that gender differences favouring males in affect were larger in Finland than in OECD on average. (OECD, 2004)

With respect to the affect towards mathematics in Chile, positive affective dimensions are connected to good achievement. Also, a study that used TIMSS data and a survey about students' affect showed that the following dimensions exist among Chilean 8th graders: *liking mathematics*, *importance of mathematics*, *difficulty of doing mathematics* and *importance of luck and talent in doing mathematics*. Also there were found that Chilean students have an inflated self-perception of their mathematical competence and that students who perceived that mathematics is difficult have lower scores in TIMSS. (Ramírez 2005)

METHOD

Affective traits are typically measured by questionnaires. This is an economic, fairly simple method that is familiar to many students, and is particularly appropriate for measuring established, fairly resilient aspect of examinees' views (trait aspect)

(Leder, 2006). With respect to affective structures, questionnaires, wherein students report their views in relation to different items, enable the collection of data appropriate for statistical analysis in general and correlations in particular.

The data used in this study were gathered during an on-going research study aiming to improve mathematics learning in Chile and Finland. In Chile, the number of participants was 459, and in Finland 466, giving a total of 925 participants. Data were collected during the academic year 2010-2011: February-March 2011 in Chile and September-October 2010 in Finland. The Chilean school year begins half a year later than it does in Finland, so the research phase, despite such apparent difference in date, was undertaken at the same time in the respective school years.

By means of a survey, 3rd grade students were asked their views on effort, competence, enjoyment, difficulty, confidence and mastery goal orientations with respect to mathematics. The instrument has a long history of gradual development. It is a shortened and simplified version of the instrument used in Hannula and Laakso (2011), which was based on a number of earlier instruments: The Patterns of Adaptive Learning Study (PALS) (Midgley, Maehr, Huda, et al., 2000); The view of mathematics indicator (Rösken, Hannula & Pehkonen, 2011); The Fennema-Sherman mathematics attitude scales (Fennema & Sherman, 1976).

The results in Hannula & Laakso (2011) suggested that the reliability of the instrument might have been compromised in their younger population of 10 year olds because of the relatively demanding language of the questionnaire items. Therefore, we carefully modified the language to make items easier to comprehend. Moreover, we reduced the number of response options from the original 5 to 3. Some of the items were presented as a direct claim (e.g. "I have done well in mathematics"), while some consisted of an indirect claim (e.g. "I am not very good in mathematics"). The items that had an inverse content were recoded to share the same direction with directly stated items.

Analysis

To find out the structure of students' mathematics-related affect, we did both exploratory and theory-driven factor analyses. The structure, as well as the similarities and differences between the structures in the two countries were inferred comparing different types of factor solutions.

The initial factor analyses were undertaken separately with both data sets (Chilean and Finnish) using the criterion of all the eigenvalues being greater than 1. This is an explorative approach to factor analyses, as the number of the factors is not predetermined. After that, we forced the number of factors according to the theory underlying instrument construction (Hannula & Laakso, 2011).

Statistical criteria were used to support decisions concerning the number of factors, as well as to justify that the explored solutions were appropriate. We tested the following assumptions (see e.g. Leech, Barret & Morgan 2008): The determinant of the correlation matrix should be more than 0,0001: if this value is close to zero, there are considerable amount of collinearity; if zero, the solution is impossible. The

Kaiser-Meyer-Olkin (KMO) measure should be greater than 0.70, and it is inadequate if less than 0.50. The Bartlett test should be significant ($p < 0.05$). The analysis itself was made using principal component analysis with Varimax (orthogonal) rotation.

RESULTS

The structure in Chile

Regarding Chilean students, the non-predetermined solution comprised seven dimensions. The dimensions were *negative self-beliefs in mathematics* (inverse items from competence), *easiness and fun* (1 item from competence, 1 item from EoM), *determination* (MGO + confidence), *effort, displeasure* (inverse items from EoM + inverse items from DoM), *confidence*, and *enjoying calculations* (1 item from EoM). Within the Chilean data, the statistical criteria were satisfied: $\det = 0,005 < 0,0001$; $KMO = 0,801 > 0,70$; $p = 0.00 < 0,05$. These five factors accounted for 54% of variance.

The scree plot suggested a 5-factor solution which produced dimensions that could be easily interpreted. These were *determination* (MGO + confidence), *willingness* (effort + 1 item from competence + direct items from EoM + direct item from DoM), *displeasure* (inverse items from EoM + inverse items from DoM), *competence* (inverse items from competence + inverse item from effort), and *confidence*. This structure is presented below (Table 1), so that it can be compared both with the theory-driven solution and with the 3-dimensional solution from Finnish students. In Chile, there are also dimensions concerning negative perspectives related to mathematics. Further, the structure seems to be more unclear within Chilean students, which was also seen in the reliabilities that were lower regarding Chilean data (see Tuohilampi & al, accepted). Within this predetermined solution, the five factors explained 46% of variance.

The structure in Finland

When the number of factors was not predetermined, the solution for Finnish 3rd grade students consisted of five dimensions that complied with instrument construction. The dimensions were *competence*, *enjoyment of mathematics* (EoM), *mastery goal orientations* (MGO), *effort*, and *confidence*. However, the theory-based dimension *difficulty of mathematics* (DoM) was lost: all the items of that scale loaded on the same dimension as the items of competence. Within Finnish data, the statistical criteria were satisfied, though not thoroughly: $\det = 0,00005 < 0,0001$ (still, $\det \neq 0$, see method part for interpretation); $KMO = 0,895 > 0,70$; $p = 0.00 < 0,05$. These five factors accounted for 56% of variance.

After the initial solution, we forced a three dimensional solution as suggested by the scree plot. Again, all dimensions were easily labelled. The dimensions were *capability* (competence + DoM + confidence), *enjoyment of mathematics* (EoM + MGO), and *investment* (MGO + effort + confidence). As this solution did not follow the original theorization, it is reported below (Table 1). In this solution, the motivational dimensions effort and MGO (investment) were united. However, all the items of MGO had correlations also to EoM. Confidence did not build up an own

dimension. Its items had correlations with competence and with investment. The relation between confidence and competence could be expected as many of these items originate from the same scale (Fennema & Sherman, 1976). Within the predetermined solution, the three factors accounted for 47% of variance.

Comparison

Among Finnish students, enjoyment was connected to mastery goal orientations. Chilean students' emotions were divided: different types of emotions built up separate dimensions. In both countries, mastery goal orientations were connected to confidence. In the Finnish population effort was connected to confidence and mastery goal orientation. In Chile, effort was connected to emotions and easiness. This suggests that in Finland students' effort for learning mathematics is more independent of their feelings than in Chile. Yet, this may not be a positive thing: if Finnish students go on trying and making an effort in spite of feeling no enjoyment, the two belief clusters (emotions and behavior) might become thoroughly distinct. This may in the future turn up to be a barrier for a change, as the change in beliefs needs an open and irritating conflict (Chapman, 2002). The conflict is not likely, if the clusters are too distinct or if the student has constructed explanations for the conflict (e.g. emotions are not important, enjoyment does not belong to school context, making effort does not give satisfaction).

Within Finnish students, the emotions, confidence, and mastery goal orientations were in interaction. Further, in Finnish students' structure, confidence was connected to competence. Thus, poor achievement (low feeling of competence) is likely to decrease confidence and/or vice versa: low confidence is likely to decrease effort, resilience and thus achievement. Whatever the causation, it is possible that once the confidence decreases, emotions become more negative, and this influences mastery goal orientations, effort, and eventually achievement. In Chile, effort connected to enjoyment. What is more, there was also negative dimension of beliefs connected to emotions and perceived difficulty of mathematics. The Chilean students' connection between effort and enjoyment may be protective with respect to that pattern: effort is an attribute to behavior, so if the Chilean students avoid making much effort when not feeling pleasure, they might avoid facing frustration caused by forced attempts with disappointing consequences.

Items	Finnish students' structure			Chilean students' structure				
	Capability	Enjoyment	Investment	Determination	Willingness	Displeasure	Competence	Confidence
Effort: hard working			,454		,604			

Effort: preparing carefully for exams			,591		,693		
Effort: much working			,579		,630		
Effort: working too little (recoded)			,430		,323		,487
Competence: not that good (recoded)	,738						,743
Competence: have done it well	,677				,461		
Competence: not the type who can (recoded)	,718						,615
Competence: weakest subject (recoded)	,601						,657
Enjoyment of Mathematics (EoM): enjoy pondering		,669			,414		
EoM: pleasant to calculate		,756			,263		
EoM: has been something of a core (recoded)		,542				,628	
EoM: boring to study (recoded)		,762				,543	
EoM: mechanical and boring subject (recoded)		,677				,677	
Difficulty of Mathematics (DoM): easy	,729				,425		,537
DoM: laborious (recoded)	,538					,627	
DoM: difficult (recoded)	,704					,531	
Confidence: can get good grade	,634						,597
Confidence: can succeed	,353		,497				,531
Confidence: would handle more difficult	,533		,324	,536			,407
Confidence: confident that can learn	,365		,498	,409			,479
Mastery Goal Orientation (MGO) item 2		,468	,482	,501			
MGO item 7		,387	,500	,685			
MGO item 10		,471	,571	,493			
MGO item 12		,382	,472	,680			
MGO item 25		,421	,614	,606			

Table 1. Factors in Finland and Chile in the solution suggested by the scree test.

DISCUSSION

This study suggests that 9-year old students' affective structures might consist of different types of connections in the two countries. Further examinations need to be done with respect to verifying the structures, as well as to further elaborate the interaction and hierarchy within the belief structures. More specifically, we noticed that in the Chilean, but not in the Finnish, population the inversely and directly formulated items tended to load on different factors. This suggests that questionnaires may be sensitive to the linguistic or cultural context. In future analyses we intend to explore this phenomenon further.

Chilean pupils had lower reliabilities and are noticed to be lower in their reading skills (OECD, 2010). Thus the quantitative results may be less well justified regarding Chilean students than Finnish. All in all, this study suggests that 9-year old students' belief structures might consist of different types of dimensions and connections in the two countries, and in Chilean culture, the view of affect might be more complex than what has been measured in most studies (see e.g. Chamberlin, 2010).

In an earlier study, Pehkonen (1995) noticed that the cultural differences between the countries in mathematics related beliefs can be larger than the variation within the countries. In our study we observed variation in the structure of affect which, in our opinion, is much more fundamental difference between countries. However, to know about the differences is not enough; we also have to understand the meaning of the beliefs in different countries and cultures.

NOTES

1. This research project is funded by Chilean CONICYT and the Academy of Finland (project #135556).

INTRODUCTION TO THE PAPERS AND POSTERS OF WG12: HISTORY IN MATHEMATICS EDUCATION

Uffe Thomas Jankvist, Kathy Clark, Snezana Lawrence, Jan van Maanen

Keywords: History of mathematics; Whig history; interdisciplinarity; early childhood; primary, secondary and tertiary education; teacher education; theoretical frameworks and constructs.

ABOUT THE WG ON HISTORY IN MATHEMATICS EDUCATION

2013 was the third time that the history working group was part of the CERME program. This time the group had about twenty participants, presenting twelve papers and three posters. The educational scope of the contributions ranges from the use of history in kindergarten over primary and secondary school, upper secondary school, tertiary level, and teacher education. In addition to this, the group also has studies on the history of mathematics education as long as they have relevance for mathematical practices of today, as seen from the main themes in the call for papers:

1. Theoretical, conceptual and/or methodological frameworks for including history in mathematics education;
2. Relationships between (frameworks for and empirical studies on) history in mathematics education and theories and frameworks in other parts of mathematics education;
3. The role of history of mathematics at primary, secondary, and tertiary level, both from the cognitive and affective points of view;
4. The role of history of mathematics in pre- and in-service teacher education, from cognitive, pedagogical, and/or affective points of view;
5. Possible parallelism between the historical development and the cognitive development of mathematical ideas;
6. Ways of integrating original sources in classrooms, and their educational effects, preferably with conclusions based on classroom experiments;
7. Surveys on the existing uses of history in curricula, textbooks, and/or classrooms in primary, secondary, and tertiary levels;
8. Design and/or assessment of teaching/learning materials on the history of mathematics;
9. The possible role of history of mathematics/mathematical practices in relation to more general problems and issues in mathematics education and mathematics education research.

THEMES AND QUESTIONS DISCUSSED DURING THE WG SESSIONS

The presentation of papers and following group discussions were ordered according to five general themes deemed important for history *in* and *of* mathematics education:

- i. Interdisciplinarity
- ii. Theoretical frameworks in history *of* mathematics education
- iii. History in pre high school mathematics education
- iv. History in high school mathematics education
- v. History of mathematics in teacher education and design

In the following, we list the questions which initiated and/or formed the subgroup discussions of the five themes.

Theme I: Interdisciplinarity

- What is true interdisciplinarity? (e.g., the principles, techniques, frameworks, etc. from one discipline that are used to gain new insights within another discipline.)
- How do we ‘measure’ the level of interdisciplinarity obtained in a given context?
- To what extent does *interdisciplinarity* (need to) go hand in hand with *cooperation between researchers*?
- What is a good example of interdisciplinary research; and what is a non-example?
- Do we consider a study about mathematics education as interdisciplinary (i.e., between mathematics and the social sciences)?

Theme II: Theoretical frameworks in history *of* mathematics education

- What is the difference between *story* and *history*?
- What theoretical frameworks are available already?
- To what extent does history of mathematics education require the study of primary sources?

Theme III: History in pre high school mathematics education

- What are the special challenges when using history in primary school, kindergarten, etc.?
- How do we stay *true* to history, i.e., non-Whig, when applying history of mathematics at pre high school levels? (Briefly, ‘Whig’ history may be explained as an interpretation of the past through the eyes of the present.)

- How do we determine the effect of history, as opposed to the use of physical materials/resources or other interventions (e.g., drama, poetry, posters, and presentations)?

Theme IV: History in high school mathematics education

- How far can you ‘push’ the use of primary sources when using history of mathematics at high school level? What are techniques for doing so?
- If one of the aims of using history of mathematics at high school level is to develop students’ mathematical awareness (beliefs, images, etc.) about mathematics as a (scientific) discipline, what is then the best way(s) to describe or maybe even ‘measure’ such development?
- How do we appreciate the principle of ‘authentic practice’ (i.e. to have the students act as if they were a 17th century surveyor, or a Roman treasurer?)
- What role can history in mathematics education play in building new mathematical concepts with the students? Are there other specific domains in which history in mathematics education was useful, or can be useful?

Theme V: History of mathematics in teacher education

- In the UK there is an increasing public opinion that the universities should get out of teacher training, and that the teachers should be employed by schools where they will train on the job. If this is the case, what role would or could academic research in the history of mathematics have in teacher training?
- What is the role (from a policy/institutional point of view) of history of mathematics in teacher/mathematics teacher education?
- What lessons can we learn about the engagement of teachers with the history of mathematics and their professional progression for the teacher training?
- What part of cultural/historical/heritage implications does the history of mathematics have in teacher training?

SELECTED OUTCOME OF THE GROUP DISCUSSIONS

In the final session, every subgroup gave a report of its discussion of the five themes and the related questions. Providing a full account of all these subgroup discussions is beyond the possible scope of this introductory report, but in order to illustrate what went on in the WG we shall focus on a few of the themes and questions by drawing in viewpoints and arguments on these from all subgroup reports.

The first is theme II. The reason for including this as one of the general themes has to do with our experiences of sometimes receiving manuscripts, e.g., when reviewing for journals, that seem to report more of a story related to mathematics education, than to conduct an actual historical research study. We are delighted to report that this was not the case of the participants of WG12, which was also reflected by the discussions. For example, there was a consensus about *story* being something

narrative, whereas *history*, although it may contain narratives (or stories), is structured by theoretical frameworks, the purpose of which includes being able to see benefits or limitations, to communicate results, and to enable the researchers to organize and present findings, assertions, etc. As examples of such frameworks, the participants point to for example constructs from history research, e.g., those of more externalistic historiography of studying factors crucial to the development of institutions, etc. But in the light of bullet 9, frameworks from mathematics education research of course also play an important role in creating a scene for pointing at possible consequences for modern day practice. As to the role of primary sources, all consider these practically a necessity for conducting history of mathematics education. But one important aspect regarding this is that primary sources in this context can be of various different kinds, including written documents, oral records, textbooks, conference proceedings, etc. This is different from when discussing, for example, theme IV, where the reference to primary sources usually refers to original mathematical texts.

The use of history at high school level (theme IV) is something that has been extensively discussed within the context of using history in mathematics education, not least because students at this level to some degree can be successfully exposed to original sources, even if it is still a challenging task for them. But what about using history in pre high school education, such as primary school, kindergarten, and other early childhood education contexts? An actual reading of original texts at this level is often far beyond reach. The participants point to the fact that in practice when using history at younger age levels there is a need for compromise, also in order to make the mathematics itself more accessible to the children. In particular with very young children there may be the need for narratives in the form of telling stories of mathematics, rather than confronting them with the actual history of mathematics. But as one of the subgroups state in their report: “You have to tell stories, but the knowledge of history enables you to tell *true* stories.” To the question of why one would even bother to go to all the efforts of bringing in history of mathematics to younger aged pupils, another subgroup refers to the discussion of providing *context* in the teaching of mathematics stating that lack of context can have a negative influence on learning and that “history provides that context” which is often needed and welcome.

The above naturally links in with theme V, illustrating that sound knowledge of history of mathematics can act as a valuable resource for teacher practice. But equally important is that history of mathematics has a role to play in mathematics teachers’ professional development – something which was illustrated through a few empirical studies already in the late 1970s and early 1980s. Nevertheless, the frequency with which we come across examples from practice of using history of mathematics in mathematics teacher training is still fairly low. Why is this so? It is an open question. But it is clear that it is related to the matter, as one subgroup mentions, of showing teachers, mathematics educators, curriculum designers, and politicians the benefits

and potential of using history of mathematics in mathematics education. How to possibly, and partly, do so is addressed next.

A PERMEATING QUESTION OF FRAMEWORKS AND CONSTRUCTS

One topic or question which permeated many of the other discussions and to which we found ourselves returning again and again, is that of which frameworks, theories, or theoretical constructs from mathematics education research may apply best to the various uses of history of mathematics in the teaching and learning of mathematics. The challenge of conducting studies within the scope of WG12 is to find a balance between the three fields: that of the *history of mathematics*, *mathematics*, and *mathematics education (research)*. This requires knowledge of all three disciplines, often making such studies a relatively demanding task to undertake. For ‘outsiders’, e.g., math educators who are not as familiar with the history of mathematics, we need to be able to provide convincing arguments for wanting to resort to history in the teaching and learning of mathematics. A sensible way of doing so is to argue by means of theoretical constructs from mathematics education research and to rely on suitable mathematics education frameworks for analyzing data, presenting and discussing results, etc. For ‘insiders’, who are familiar with history of mathematics, it is important not to be unintentionally anachronistic (or ‘Whig’) when including history in the teaching and learning of mathematics. From an educational point of view, this is important if having as a goal to foster historical awareness with students. From a research community point of view, it is important if we want to maintain our integrity and strengthen the connections with the research historians of mathematics.

EVALUATION AND ASPECTS TO CONSIDER FOR THE NEXT WG

In accordance with decisions made at CERME-7, more time was allocated to poster presenters during the WG sessions of CERME-8. More precisely poster presenters gave short presentations of their posters in the WG *before* they presented their posters in general. This initiative seemed to function well, and we plan to repeat it again. As always, the history group at CERME works to maintain very close connections to the HPM group, not least within the leading team. As new initiatives for CERME-9, we have in mind to broaden the ‘bullets’ in the call for papers to also encompass studies related to epistemology of mathematics in relation to mathematics education and the use of philosophy of mathematics in the teaching and learning of mathematics.

TEACHING MODULES IN HISTORY OF MATHEMATICS TO ENHANCE YOUNG CHILDREN'S NUMBER SENSE

Mustafa Alpaslan

Ziřan Güner

Ahi Evran University, Turkey

Bülent Ecevit University, Turkey

This study aims to investigate potential effects of two teaching modules in history of mathematics in order to develop number sense in young children aged 5. We reanimated two historical artifacts as using tally marks and pebbles for counting activities within symbolic play context. Data were obtained by anecdotal records of the implementation of the modules at the fall of 2012-2013 academic year. Data analysis was made through Dunphy's framework for number sense in young children. Findings revealed that the modules could contribute to various aspects of number sense. We finalized with a discussion about the findings and implications for further research on using history of mathematics with younger children.

INTRODUCTION AND THEORETICAL FRAMEWORK

Number is one of the main concepts for primary mathematical reasoning in young children. They exhibit different kinds of behaviours and skills as a sign of their development in number sense. According to Charlesworth, Lind and Fleege (2003), children are able to relate number of objects by counting, to compare number of objects, and to master benchmarks as five and ten. Children aged between six and eight can make one-to-one correspondence, meaningfully count, and notice cardinal and ordinal numbers in a set of objects (National Council of Teachers of Mathematics [NCTM], 2000). The most basic skill may be rational counting, which requires mastering one-to-one correspondence, arranging names of numbers in exact sequence, being able to continue counting from a predetermined number, and perceiving total amount of objects in a set (Reys, Lindquist, Lambdin, Smith, & Suydam, 2001). Four year olds are initially able to transfer knowledge of rote counting into skills of rational counting (Charlesworth et al., 2003). Another issue is that children should be aware of numbers within verbal and written communication as a part of social life in community (Tolchinsky, 2003). Indeed, it is possible for them to initiate and improve number sense through daily life experiences (Dunphy, 2006b) such as pulling on one glove for each hand before starting to play snowball. Such experiences should be supported by parents and early childhood practitioners since communication with relatively intellectual people builds on children's learning (Vygotsky, 1978).

In Turkey, young children enrol in primary school at six years old. Thus, early childhood education given before this age seems to be crucial for developing number sense so as to meaningfully learn mathematics concepts in primary school. For this purpose, relevant objectives are set in Turkish pre-school curriculum (Ministry of National Education [MoNE], 2012) as to count objects given in a set, to rhythmically

count on and back, to determine ordinal numbers in a set, to group objects in benchmarks such as five, and to make one-to-one correspondence between objects. Numbers up to 20 can be used in classroom activities. The curriculum also emphasizes concepts of equity and numerical superiority/inferiority regarding number sense. Though the curriculum sets a variety of objectives, developing number sense in young children does not seem to be an easy and straightforward task. For instance, children are likely to get confused about meaning of cardinal and ordinal numbers of toys in a set (Cooke, 2005). They might have difficulties in one-to-one correspondence such as counting up to seven objects in right order by simultaneously touching some of them more than once (Charlesworth et al., 2003).

It is generally presumed that adventure of mathematics was initiated by different groups of human beings with separating *one* and *many* to get control of their environment for survival and to have a better quality of life. (Boyer & Merzbach, 1991; Burton, 2006). Such needs make them to keep records of concrete objects in daily life. The records connote concepts of number and equity, which was a common abstract property of concrete objects, through one-to-one correspondence (Boyer & Merzbach, 1991). Necessity of numbering plenty of objects makes ancient humans to group these objects in various representations in order to easily count and recognize the product (Boyer & Merzbach, 1991). According to Burton (2006), using *tally marks* and *pebbles* are two of such artifacts around 30.000 B.C. The oldest tally marks are found in today's Czech Republic as 55 parallel line segments drawn on a wolf's bone in groups of five (Cooke, 2005). Pebbles indicate small stones that were round and smooth in shape.

There is an expectation for the re-emergence of certain obstacles and difficulties encountered in the evolution of mathematics while learning mathematics (Jankvist, 2009). We can take advantage of sources in history of mathematics for the aim of preventing problems that might occur in understanding mathematical concepts (Sfard, 1994). In history, human ancestors initiated mathematics by manipulating concrete materials rather than a direct usage of abstract number symbols. It is possible to find an agreement between ancient humans and present-day young children in respect of being mentally ready for learning number concept. It is our opinion that if young children, who are at the beginning of their mathematical account, are instructed through early historical artifacts that used materials as alternative and simple kinds of representation while dealing with numbers, they might overcome possible obstacles/difficulties hindering number sense acquisition. Moreover, history of mathematics can be employed for keeping motivation and engagement high, revealing the human and cultural face of the subject through storytelling and pictures with young children (for details, see Tzanakis & Arcavi, 2000). In order to investigate our claim that historical teaching modules might enhance young children's number sense achievement, we set the following two research questions:

- To what extent do the historical teaching modules have potential effects for developing number sense in young children aged 5?
- In what particular sense do the historical teaching modules have potential effects for developing number sense in young children aged 5?

In an effort to include history of mathematics in mathematics education, there are mainly three different ways: (1) *illumination approaches* in which historical factual information was presented as supplementary to routine mathematics classes, (2) *modules approaches* requiring mathematics instruction through specific cases based on history, and (3) *history-based approaches* meant mathematics courses wholly built on historical perspectives (Jankvist, 2009). In this study, the *modules approaches* kind is adopted since we focus on the process of young children's number sense acquisition through historical materials within two class periods. It may also be characterized as Tzanakis and Arcavi's (2000) *historical package* in which a mathematical topic from the curriculum of interest is taught by means of historical materials in a relatively short period of time.

METHOD

Design of the Study

In this study, we aim at making an in-depth analysis of the learning process in the historical modules. We carefully observed this process occurring within a natural setting, and took anecdotal records. Hence; it can be characterized as an observational case study (Bogdan & Biklen, 1998).

Participants

The study was conducted in a pre-school classroom in Ankara, Turkey. The participants consisted of 12 children (five females and seven males) who were aged 5 years. The children would enrol in primary school in the next academic year.

The children had some background knowledge of numbers which was gained during the pre-school education. They were expected to have the abovementioned knowledge and skills that were defined by MoNE (2012).

The Historical Teaching Modules

The two modules were based on different stories made up by the researchers to enable the children engage in the two historical artifacts including tally marks and pebbles. The modules were implemented in a classroom environment where children could feel comfortable. One of the researchers showed pictures related to the stories and guided the children while working on the tasks. The other fluently read the stories and dramatized certain parts in them. Both of the stories included words and/or phrases such as *centuries ago*, *in very old times*, *times when technology was not invented* to emphasize that the events occurred in past times. As for the teacher, she was in the classroom as a non-participant observer during the implementation of

the modules. The modules were conducted in one class hour (30 minutes) within two consecutive weeks. In the following paragraphs, we explained how the modules were conducted.

The first module was named as “Retired Island”. Black and white pictures about the story (referred to old times), wooden sticks, coloured papers and crayons (to draw tally marks) were used as concrete teaching materials. The children were gathered around a table to easily see the pictures and to record the amount of wooden sticks on their papers. Before getting started, transition questions such as “Have you ever gone to sea?” and “Have you ever seen an island?” were asked to prepare the children to the content of the story. After taking the answers, a world map was shown to tell where the story happened. Some other pictures of a ship, storm in sea, a retired island, Captain Jack, a bag on beach, timbers, and a boat were showed hand in hand with the story. After the story was read, it was explained that the children should help Captain Jack so as to count the number of timbers for constructing his boat to escape the island. Additionally, it was stated that the captain determined to record this work in his diary. The children were asked for how to count the timbers (seven wooden sticks). They were invited to draw tally marks on their paper for recording the number of wooden sticks in the meantime. After this task, it was announced that the boat sunk due to the lack of timbers. The number of wooden sticks was increased to 10. A discussion was created about how to notice the higher number of timbers in the record this time, and the children were guided to feel need of grouping the tally marks.

“A Shepherd in Kuka Tribe” was the name of the second module. Materials employed in this module were black and white pictures about the story, sheep pictures and pebbles. The children sit in a half circle position on floor to provide interactivity. At the beginning, they were asked some transition questions such as “Have you ever seen a forest?” After sharing their experiences, a world map was put on floor to show where the story occurred at this time. During the story, some other related pictures as rain forest, a mountain, sheep, a house and a shepherd were also shown. When it finished, the children were invited to help the shepherd so as to count and record his sheep. They were initially asked for how to count and shared their ideas. After that, nine sheep pictures and pebbles were separately placed on floor. The children were expected to count and record the number of the sheep using their own ideas. They also invited to group the sheep and corresponding pebbles in different ways.

Finally, the children were asked some open-ended questions related to the objectives of two modules.

Data Collection and Analysis

In order to collect data, ethical approval document was provided from Research Center for Applied Ethics in Middle East Technical University in Ankara. The pre-

school administration gave permission for conducting the study with one group of five year olds after being informed about ethical considerations.

Data were collected through anecdotal records of the implementation of two modules at fall semester of 2012-2013 academic year. Anecdotal records were taken for the children's observed behaviour and speech during the implementation.

Data analysis was made considering Dunphy's (2006a) four aspects for young children's number sense, which she introduces in her comprehensive dissertation. She sets a framework regarding number sense in young children who were around five year olds. The framework has four aspects as *pleasure and interest in number*, *understandings of the purposes of number*, *ability to think quantitatively*, and *awareness/understanding of numerals*. Children's *pleasure and interest in number* is their disposition towards practices regarding numbers such as being motivated for games that can be played with numbers. *Understandings of the purposes of number* refers to having some idea about the reasons behind humans' need for numbers, for instance, being interested in why numerals written on home telephone. As for *ability to think quantitatively*, it addresses "to count, subitize, and estimate, and to relate numbers to each other" (Dunphy, 2006b, p. 58) which can be exemplified with proficiently utilizing concrete models for counting. Lastly, *awareness/understanding of numerals* denotes knowing language of numbers (i.e., symbols corresponding to numbers). For example, children should notice numerals written in an elevator for going upstairs home. This framework can be employed for both describing young children's existing number sense and revealing their relevant learning in progress (Dunphy, 2006b).

FINDINGS

From this preliminary study, we explored findings addressing certain aspects of Dunphy's framework to a certain extent. They were delineated in the subsequent subtitles and summarized with respect to aspects, themes, related behaviours and sample quotes (in which R means 'researchers' and C is 'children') in Table 1 as Appendix.

Positive Influence on the Pleasure and Interest in Number

It was remarkable that the children were quite interested in the historical modules. Both of the stories supported by black and white pictures seemed to take their attention and kept them silent. It can be asserted that storytelling made them mentally ready for the actual tasks. The stories, which gained inspiration from needs for counting and keeping records in history, made them engage in the tasks. In addition, concrete materials as pictures, tally marks, wooden sticks, pebbles, and sheep cards also aroused an interest by visualizing the number related tasks.

In the first module, the children loudly counted the wooden sticks one by one and drew corresponding tally marks at the same time. It is possible to state that being

actively involved in drawing tally marks by a hands-on experience kept their interest alive in performing the task. At the end, the children were asked for what they liked and/or disliked in the module. It was observed that they were impatient to answer the questions. Eleven children noted that they liked and particularly underlined *drawing tally marks, seeing pictures, counting, and saving Captain Jack*. One of them expressed that she did not agree because of studying on the desk and she added that *play* was the favourable part within this module.

Saying that we had another story in the second module made the children be silent. One of them explicitly stated his wonder. Such behaviours might be a result of their positive experiences in the first module. They were also concerned with pebbles, which were not yet used in the previous activities, and appeared to be impatient about using them. After the story ended, there was a pretty chaos among the children for doing the task with sheep and pebbles. This time all of the children pointed out that they liked the module and then highlighted the following activities and elements: *using stones, seeing pictures, sheep, story, putting pebbles for each sheep, asking questions*.

Conscious Understandings of the Purposes of Number

In both of the modules, we aimed to contribute the children's understanding related to purposes of numbers through stressing that we as human beings need numbers. The related discussions followed each of the modules. The children concentrated on the need for numbers both in general and in conjunction with the modules' context. They emphasized the underlying reasons for mathematics in daily life activities and technological developments together with those who use mathematics in that manner. In these discussions, it was remarkable that the children included *building ships* to the common answers such as *making inventions*. Among those doing mathematics, they added *students* and *workmen*, which possibly referred *them as helpers* and *Captain Jack and the shepherd* respectively. Herein, we distinguished that the children believed to make a worthwhile task and they felt some self-efficacy in mathematics. The modules may show an idea that mathematics is for everyone and everyone can do/study mathematics.

Potential for Fostering Quantitative Thinking Abilities

We intended to stimulate the children's perceptions about one-to-one correspondence, equity, cardinality, ordering and grouping through using concrete historical materials.

The children successfully matched seven wooden sticks one by one with tally marks in the first module. They drew the tallies in parallel with counting up to seven. When we increased the number of the wooden sticks to 10, we guided the children to group the sticks and asked for the possible reasons behind grouping. They presented the corresponding arguments such as "To make them five." and "To separate them."

They finally decided to group the 10 sticks in three and considered the last one as the rest.

The second module actually proposed to provide an opportunity for articulating the identical mathematical notions of the first. This time it is possible to state that the children did somewhat illuminated mathematics. The mathematical work was more meaningful because they seemed to thoughtfully recall the ideas of one-to-one correspondence, equity, ordering and grouping. To illustrate, when we asked what to do if the shepherd has many sheep (by showing nine), some of them suggested to bring the half to his house. Then they immediately did not find this idea to be feasible and asked as “Shall we divide?” This question brought them to the idea of grouping at the end. We dug this elegant idea and questioned how it was possible to group the nine sheep of the shepherd, they replied as “We drew a line at the centre [addressing the first module]. We may group in five?” After noticing that there was an asymmetry with putting five pebbles in a linear order and four pebbles under that order, they changed their mind as: “In three!” Regarding this new arrangement, they forwarded that the regularity came from the multiplication of three by itself.

DISCUSSION AND IMPLICATIONS

This study indicates that teaching modules in history of mathematics have some potential to assist development of young children’s number sense under the three aspects identified by Dunphy (2006a) as *pleasure and interest in number*, *understandings about the purposes of the number*, and *ability to think quantitatively*. Regarding the first, telling stories, showing old pictures and using concrete materials linked with the two historical artifacts seemed to make their attention alive. Smestad and Clark (2012) also points out that using history of mathematics can arouse interest and mathematical thinking in younger children through storytelling and multiple representations. Herein, we believe that history inspires educational designers to make up meaningful authentic stories that our antecedents has experienced in the paths of mathematical knowledge. What is more, the children may be attracted by simple but original historical materials that have never used before in their classes. As for the second, the children’s explanation for the need of mathematics in daily life might be caused by the content of the two stories stressing the uses of mathematics. In the third, concrete historical materials may make the children’s learning more meaningful in the same manner that children at early ages need to learn by concrete, visual and hands-on experiences (Hohmann & Weikart, 1995). Furthermore, probing questions derived from the necessary skills (e.g., one-to-one correspondence) in the historical artifacts could have catalysed the children’s quantitative thinking based on the idea that reflections of thinking with concrete materials helps quantitative thinking and understanding (NCTM, 1989). Lastly, recording the results through the historical materials appeared to enable them not to get confused during this thinking process. The modules did not seem to influence *awareness/understanding of*

numerals since they did aim to study mathematics verbally rather than to enhance the children's recognition with abstract number symbols.

The teaching modules could be characterized as practical in terms of the concrete materials used and the time spent. Conducting the modules required materials which were easy to find and cheap. The modules also took reasonable time in terms of implementation which was an issue of concern in the field of using history of mathematics in mathematics education (Tzanakis & Arcavi, 2000). In other words, the stories inspired by the historical artifacts did not appear to steal from the children's learning about numbers. On the contrary, they seemed to mentally warm up the children to learning about numbers and endured their motivation during this process.

According to Carraher and Schliemann (2007), early years are critical and important for young children to gain number sense due to the fact that it took long time. In this sense, early childhood practitioners as implementers of early years' mathematics should be trained on how to use history of mathematics as an alternative way for developing similar mathematical understandings in young children. Accordingly, further research should be made on how the history could be an inspiration for developing similar teaching practices.

NOTES

1. We would like to specially acknowledge reviews of Uffe T. Jankvist, Kathleen Clark and Tinne H. Kjeldsen in improving the quality of this paper.
2. Thanks to leaders, co-leaders and all members of Working Group 12 for their constructive critiques and feedbacks to advance the paper.

STUDENTS' VIEWS ABOUT ACTIVITIES FOR HISTORY OF MATHEMATICS INCLUDED IN MATHEMATICS CURRICULUM

Semiha Betül BAYAM

Mathematics Teacher, Republic of Turkey Ministry of National Education

The mathematics curriculum proposed by The Ministry of National Education, was re-organized within the scope of the study in the experimental group and famous mathematicians and historical anecdotes that played a role in discovery or development of the attainment were given to students (aged 12) as performance projects. The teaching periods of 8 attainments were supported with 24 mathematicians and historical anecdotes during 4 weeks. In the study students' opinions were asked, the qualitative data were obtained via semi-structured interview form and descriptively analysed. Students expressed a positive opinion about the contribution of the method used to affective and cognitive dimensions.

INTRODUCTION

Content and topics in mathematics textbooks are usually without historical background. Through this kind of mathematics education intended for only right answers in the exams, it is imposible to devolop the mathematical thought. In this aspect, my intention is not to teach the history of mathematics, but to study how we can use historical material in the attainments for meaningful mathematics education. There is no use of history of mathematics in attainment of mathematics curricula in Turkey (TTBK, 2009). In this study attainments were supported by history of mathematics.

In addition to enjoyable examples from the history of mathematics and solving problems in several ways suggested by mathematicians in different periods, biographies of ancient and modern mathematicians motivate pupils (Gulikers & Blom, 2001; Furinghetti & Radford, 2008). However, the motivation of teachers is important and a historical approach to mathematics enables the attitude of teachers to develop (Kin Ho, 2008). History is a prerequisite for comprehensive mathematics education (Haverhals & Roscoe, 2010). In this context, I believe that there is a need to raise interest in mathematics and awareness of importance of mathematics for science by using history of mathematics.

MATERIALS AND METHOD

The working group included 24 sixth grade students, (12 female, 12 male), from a rural school in the village of bolu, Turkey in the 2011-2012 academic year. All students were 12 years old. There was one mathematics teacher at the school. The school, where the researcher teaches, was determined as the research school. Thirteen of 24 students were interviewed. The interviews were recorded. The duration of interviews varied from 5 to 8 minutes and they took place over one week.

While preparing interview questions, the factors of attitude test applied for preliminary test and postliminary test were used (Nazlıççek & Ertkin, 2002). In line with factors of this test, an interview protocol was designed. The four interview questions were:

- What are the negative things in the class in which the history of mathematics has been used and in the presentation of performance projects? What are the different and good things in the issues mentioned above?
- Do you think that using the history of mathematics in the class and you presenting this as a performance project had an effect on your learning mathematics or your understanding of mathematics better?
- It is required to think of mathematics class of the last year. Did you like the mathematics class? Why? Have the activities about the history of mathematics been helpful for your liking mathematics? How?
- Do you think mathematics class is difficult or easy? Has the history of mathematics made the class easier or difficult? Why?

Pilot application of interview questions was carried out with four of the seventh grade students who had a similar application about history of mathematics in the past academic year. According to feedback after the pilot application, interview questions were modified.

In Turkey there are five learning areas in primary school mathematics curriculum, which are number, geometry, algebra, probability, and measurement. This study covers eight attainments (i.e. objectives) in the learning areas of algebra, numbers, geometry and probability (TTKB, 2009).

The educational environment based upon these concepts was designed under the leadership of the researcher by giving students of working group performance projects about historical development of thema. In line with the practice, the curriculum suggested by The Ministry of National Education was reorganized with the history of mathematics. Appendix-1 shows a part of the reorganized curriculum.

The performance projects were presented by students as a song and a poem written for a famous mathematician, a drama about discovery or invention of an attainment performed in the classroom, and a poster with information about historical development of the subject or mathematician. The contents of the performance projects were evaluated with a rubric developed by the researcher. Reinforcement practices were made under the guidance of the researcher within the remaining time allocated for the attainment.

The research participant group had four-hour mathematics lessons, which were divided in half on two different days during the week, for four weeks total. In the first hour of the lesson, three students presented their performance projects for an attainment and the researcher evaluated them with the rubric. In the second hour of the lesson, the problematic situation of the attainment was pointed out and the mathematicians' reasons developing or contributing to the subject mentioned in the

attainment were discussed. On the second day, the same practice was made and six performance projects were introduced to class during each week and 24 performance projects about history of mathematics were introduced to class during the four-week practice.

The students were encouraged to benefit from different resources appropriate for their level and a mini-library consisting of mathematics and history of mathematics books was built and made available. Two of the students' presentations are explained below as examples.

Firstly, a student, who made a presentation about Ali Kuscü in relation to the attainment of "Makes a prediction based on data.", introduced a model explaining the construction of a simple astrolabe to his/her classmates. An instruction explaining the construction of a simple astrolabe was given out. The predictions and deductions, which Ali Kuscü made about sky by using the astrolabe, were discussed. After the presentations about Ulugh Beg and Omar Khayyam, a drama including the characters of Ali Kuscü, Ulugh Beg and Omar Khayyam was performed by students studying the same attainment.

Secondly, the term "to construct" was used during the introduction of mathematical objects. Before dealing with the attainments in the geometry learning area, it was thought that geometry needed to be constructed and it was decided that one of the performance projects was the birth of geometry. In the drama performed by students, one student represented the Nile River and the Egyptian people, who experienced flooded lands, determined the boundaries by asking priests for help and after ebbing they redetermined the boundaries with measuring instruments. After these experiences, students' views were asked.

Here, a semi-structured interview method was used in order to examine in-depth views of students about using history of mathematics in mathematics education. The purpose of the interview technique is to find out the feelings, views, and beliefs of an individual about the study (Çepni, 2010). Semi-structured interview integrates fixed alternative questioning into looking in depth in the related area (Büyüköztürk et al., 2010).

The data of the study were descriptively analysed. Hence, in the descriptive analysis, the views of individuals interviewed or observed are frequently quoted in order to reflect their views dramatically. The objective of the analysis is to present findings to readers in an organized and interpreted way (Yıldırım & Şimşek, 2001).

The recorded interviews were transcribed. Each student's responses were separately examined. Data were generally categorized according to the responses. After reviewing the categories, sub-categories, which would cover all data, were determined. Some of the categories, which would cover the codes, were combined. Sub-categories covering one another or substituting for an other, were combined by taking the expert opinion. All participant responses, which they gave to the same

questions, were included in the analysis. Therefore, there is a difference between frequency and the number of participants (Çepni, 2010).

FINDINGS

Student views about history of mathematics themed lessons in affective dimension

The perceptive dimension of student views was examined according to their positive and negative. Eighty (95%) out of 84 answers in the emotional dimension were positive and four (5%) were negative nature. It can be said that the history of mathematics themed activities effect students positively in an emotional dimension because positive answers were more frequent than negative answers. Detailed themes of positive answers about the method used are given in Table 1.

Table 1: Positive student views about history of mathematics themed lessons

	Frequency	Percentage
To like learning about mathematicians' lives	11	14
To be a centre of attraction	1	1
To make models of inventions about attainment	7	9
To like using poem, song and drama	25	31
To learn by having fun	9	11
To think it will benefit future	1	1
To like mathematics more	9	11
To be curious	3	4
To be influenced by a mathematician's life/ to aspire to it	6	8
To participate actively in the learning process	5	6
To overcome the fear of mathematics	3	4
Total	80	100

Student Medine underlined that her mathematics awareness of the external world developed with the activities.

Student Medine: Math is also related to play and poems. It spices. Nature is based on math.

Students Eren and Semiha said that they enjoyed at the lessons.

Student Eren: Lessons are really comical and fun.

Student Semiha: We performed several plays and at the same time covered several subjects. I had a lot of fun.

When positive student responses are taken into consideration, it can be said that they liked using the forms of poem, song, and drama in history of mathematics-themed lessons. The students had knowledge of previous studies on the attainment and enjoyed the experience in the mathematics lesson.

The other frequency in the emotional dimension is “to like learning about mathematicians’ lives” with 11 responses (14%). If this dimension is thought to be the second important sub-category, it can be said that the deficiency of mathematical acculturation was filled. Student responses support this finding. Students Seda and Emre expressed their views about the subject as follows:

Student Seda: While doing projects, we are learning mathematicians’ lives. I like this much more. After learning about their lives, I liked math more. I enjoyed learning about their lives. I think we should do many more things about history of mathematics. We should learn about their lives.

Student Emre: We are learning about a mathematician’s life. We are learning how difficult it was in finding their math theories and we have fun while learning these things.

When student answers and the corresponding their percentages were examined, it can be said that students learning how to discover the subject in the attainment and who contributed to the development of this subject with the play-like activities provided positive student views about mathematics by exceeding the traditional mathematics. These findings are parallel with student views in the study which Lit, Siu and Wong (2001) conducted with a similar experimental subject. Students in that study stated that, they liked the lessons which were entertaining, different, not boring and made understanding easier. In the same direction, students in the study about re-invention of geometry, which Gulikers and Blom (2001) conducted, emphasized that they felt more competent in mathematics and said that they overcame their fear of mathematics and learned while having fun.

When student views and their percentages within the sub-category were taken into consideration, it can be said that students liked mathematics more with the history of mathematics activities and that they overcame their fear of mathematics. The students expressing no negative opinion about this finding reinforced this notion. Similarly, Kin Ho (2008) collected student views about lessons where history of mathematics was covered. Positive feelings were reported, such as belief, interest, trust, and determination in students’ views.

There were four negative student responses about history of mathematics themed activities. Two (50%) out of the four responses said that performance projects of the history of mathematics activities were difficult. However, the students said that they had difficulty while preparing the project but after some time they succeeded.

One (25%) of the students' negative responses stated that s/he did not like the presentations of his/her friends.

Student views about history of mathematics themed lessons in the cognitive dimension

The cognitive dimension of student views were analysed under two themes that were the effects of history of mathematics themed lessons on learning and the difference of the method used. The effects of the method used on mathematics learning were analysed in Table 2. Nineteen student responses (38%) showed that the students understood mathematics better and learned it better with the history of mathematics themed activities. Student Semiha expressed that her perceived success for mathematics increased.

Student Semiha: This year my math lessons are better than the ones in the last year and I increased my grades. I tried to practice some stuffs by learning about mathematicians' lives. I started to chew on my lessons more.

Table 2: The effects of history of mathematics themed lessons on mathematics learnings

	Frequency	Percentage
To provide foreknowledge	4	8
To learn/understand better	19	38
To learn about mathematicians' lives	9	18
It did not have any effect on my learning	1	2
The lessons got easier	16	32
The lessons got tougher	1	2
Total	50	100

As seen in Table 2, another important dimension of this sub-category is that the lesson was thought to be easier by the student with the activities including history of mathematics. 16 students (32%) gave this answer. Student Medine and Mahmut expressed their feelings in this regard.

Student Medine: The lesson got easier when historical figures were included.

Student Mahmut: The lesson was not tough because I understood better.

When student answers and their percentages were taken into consideration, it can be said that history of mathematics themed lessons increased the ratio of students' understanding of lessons. Also, students said that history of mathematics made lessons easier by enabling better understanding of mathematics and providing foreknowledge about a lesson can be evaluated as a functionality of the method.

These findings correspond to the study of Haverhals and Roscoe (2010). Who anticipated that the students' academic success would increase because they faced the problem in person by saying that the method they used was the heart of problem-solving.

Another sub-category of the cognitive dimension is the different aspects of history of mathematics themed lessons. While 4 (45%) out of 9 students said that they found the method used different and thought the use of poem, song and drama was different, 3 (33%) out of 9 students underlined that knowing how the attainment was discovered did not look familiar to them.

Student Hakan: We were learning different things. For example, I masqueraded as sheep. I performed in Tuba's play. A wolf came in. When she came home in the evening, she realized it. In the morning of the next day she understood it by notching and found numbers.

It is clear that a different method used in the mathematics lessons got the attention of students and aroused interest in them. In the same way, Taşkın, Yıldız, and Arslan (2010) took postgraduate students' views on their class entitled "Historical Development of Mathematical Concepts." Participants said that history of mathematics would get the attention of students and enable the subjects to be learned in a meaningful way.

DISCUSSION AND IMPLEMENTATIONS

The students who said that they enjoyed participating actively in the process of learning also mentioned that they overcame their fear of mathematics. Students making active presentations was important for student participation while the history of mathematics was introduced to the class in relation to the attainment.

The biggest reason not to teach or use history of mathematics, in lessons which is often propounded by teachers, is the lack of time to do so. This study is important because it shows that history of mathematics can be introduced to student by being included in major learning areas in primary school mathematics curriculum.

As a result, history of mathematics should be included in mathematics learning environments, especially if it is a goal to develop students' mathematical points of view.

Appendix1: Organized Mathematics Curriculum Based On History of Mathematics

ARITHMETIC TEXTBOOKS AND 19TH CENTURY VALUES

Kristín Bjarnadóttir

University of Iceland, School of Education

In this paper two nineteenth century Icelandic arithmetic textbooks are investigated, both written according to the late medieval tradition of libri di abbaco, practical textbooks. The authors were influenced by the German Protestant tradition that arithmetic was to serve ethics education, as well as by the Enlightenment. Above all, their goal was for the autonomy of Iceland from Denmark. Their textbooks served the purpose of teaching young people wise allocation of their resources with the overall goal of individual as well as national prosperity and financial independence.

INTRODUCTION

Iceland was a pre-industrial society at the beginning of nineteenth century. At its close it had become modernized in the sense that towns and villages had been formed, a few bridges been built and school legislation was about to be enacted. Two substantial arithmetic textbooks, written in Icelandic, were published during the century. The purpose of this paper is to determine the role of the textbooks in the development of the society, more definitely phrased:

How did the two textbooks relate to the struggle for Iceland's autonomy from Denmark in the nineteenth century, and which values did the authors deem to serve that purpose?

The research method is historical; exploration of the historical background of the Icelandic society by reference to papers by distinguished scholars, and examination and interpretation of the textbooks themselves. Some research has been done recently, e.g. by Bjarnadóttir (2010; 2012), where the textbooks in concern were situated in the Icelandic heritage of arithmetic textbooks, while in this paper it focussed on the specific aspect of ethics education.

ARITHMETIC TEXTBOOKS

The structure of arithmetic textbooks fell early into a specific pattern, while authors have had some freedom on pedagogical ordering of the material; to present mathematics in context and to develop natural curiosity. Early textbooks were not written for use in institutionalized school systems and the presence of a teacher was not assumed (Howson 1995).

Libri d'abbaco

During the twelfth through the fifteenth centuries, algorithms, based on al-Khwarizmi's arithmetic, appeared in great numbers and in a diversity of languages other than Latin. There are numerous Italian *libri d'abbaco*, arithmetic textbooks written by teachers who spoke the ordinary language of the marketplace. The books typically contained an introduction to the Hindu-Arabic numeration and the

accompanying arithmetic operations, in addition to mathematical techniques for business use (Swetz, 1992; Tropfke, 1980).

The protestant reform

The general approach of the Protestant Reform in the early 1500s was to literate the population. Martin Luther's collaborator, Philipp Melanchthon, was particularly keen on nurturing mathematics education. For him, knowledge existed primarily for the service of moral and religious education and he praised mathematics for its ethical role. Most textbooks were written in the vernacular with self instruction in mind while the mercantile community was the main target group (Grosse, 1901).

NINETEENTH CENTURY ICELAND

In the early 19th century, Iceland was essentially a pre-industrial society. The population numbered only 47,000, almost exclusively rural. Reykjavík was becoming the centre of government and a capital town. The number of inhabitants in Reykjavík was 307 in 1801. There were no schools apart from one Latin School which was a theological seminary as well until 1847.

The Icelandic Enlightenment movement, originating in Denmark where in turn it was largely derived from Protestant Germany, had made considerable efforts in publishing educational material by the 1780s. Calamities: volcanic eruptions and earthquakes, followed by bankruptcies of official agencies, caused by Danish participations in the Napoleonic wars, reduced its impact. Two substantial arithmetic textbooks were published in the 1780s, one of them by Stephensen (Stefánsson, 1785), the main Enlightenment champion. Manuscripts were also dispersed from person to person. Reading and knowledge of Christianity were required for confirmation from 1743 upon the responsibilities of the homes, while legislative act, adding writing and arithmetic, was first issued in 1880. Textbooks of the 1800s were therefore not aimed at children, but young people.

By the end of the century, two lower secondary schools offering general education, primary schools in the largest towns, and a handful of schools for prospective farmers, housewives and seamen, had been spontaneously established. Legislation on state support did not exist as yet except for the Latin School and one lower secondary school. Pupils had to have private tuition in Latin prior to admission to the Latin School and both schools required living in student residences, demanding expenses which limited attendance. The Latin School pupils were sons of officials and farmers (Karlsson, 2000), the state lower secondary school pupils were mainly sons of farmers (*Skýrsla um Gagnfræða Skólann á Möðruvöllum*, 1881–1905), but in its parallel private town school, a few girls were registered (*Skýrsla um Alþýðu- og gagnfræðaskólann í Flensborg*, 1883–). The number of pupils in each cohort in the three schools was 40–50 in 1880, or about 3% of the population (*Hagskinna*, 1997).

THE AUTHORS AND DISTRIBUTION OF THEIR TEXTBOOKS

The two nineteenth century arithmetic textbooks describe the current society and propagate ideas of how to make the most of it. Both of their authors later became Members of Parliament; Jón Guðmundsson (1807–1875) during 1859–67 and Eiríkur Briem (1846–1929) in 1881–91 and 1901–1914. They did not serve concurrently at Parliament but both were avid supporters of Jón Sigurðsson (1811-1879), the leader of a movement for autonomy from Denmark, Member of Parliament 1844–1879.

As young men, Guðmundsson was a secretary of Reykjavík Town Magistrate in 1832–1836 while Sigurðsson was the Bishop’s Secretary in 1830–1833, a post that Briem served in 1867–73. In the small community of Reykjavík, young men working as assistants to the highest authorities became knowledgeable about matters and men. The single most important matter all through the period from the 1830s was raising Iceland to autonomy. Sigurðsson, the leader, wrote papers about his vision for schools: primary schools, schools for seamen and farmers, and gymnasia by the Prussian model, free trade and financial independence of Iceland. Guðmundsson supported Sigurðsson duly in his newspaper and Briem gave a comprehensive overview of Sigurðsson’s work in his obituary of 42 pages (Briem, 1880b). The main issues in the Parliament during Guðmundsson’s terms were financial claims related to the autonomy from Denmark (Laxness, 1960). In spite of Sigurðsson’s hard work, by 1874, when Icelanders were granted their own Constitution under which the Parliament became a legislative body with own budget, there was hardly any piece of road in the country, no bridged rivers, no transport on sea along the coast and only little transport to other countries (Bárðarson, 1930).

The technological changes that had taken place in the neighbouring countries had only reached Iceland to a limited extent by the turn of the 20th century. Education for the common people was much slower to emerge in Iceland than e.g. in Denmark, and there were relatively fewer towns than in most other European countries. This may be seen as a favourable set of conditions for the reception of ‘enlightened’ ideas (I. Sigurðsson, 2010). Both Guðmundsson and Briem were influenced by Stephensen’s textbook, and his writings about national economy (Bjarnadóttir, 2012).

Jón Guðmundsson

In later life Jón Guðmundsson became best known as newspaper editor supporting J. Sigurðsson. Due to bad health and poverty, Guðmundsson had become 25 year old when he completed the Latin School. Serving as overseer of the King’s properties in South-East Iceland, he wrote an arithmetic textbook. *Reikningslist, einkum handa leikmönnum / Arithmetic Art mainly for laymen*, published in 1841, well before he became known for his participation in the struggle for Iceland’s autonomy from Denmark. The content of the book is traditional, but its characteristics are his sincere advice to young people on avoiding squandering on luxuries like coffee, sugar and spirits. It was only printed once and used one year only at the Latin School. Other

schools had not yet been established. No sources have been found on its use, but as the only available printed textbook for 28 years, it is not unlikely that some number of farmers' sons who had no choice of schools, tried to learn from it.

Eiríkur Briem

The Reverend Eiríkur Briem (1846–1929) became a professor of theology at the Theological Seminary, later University of Iceland, established in 1911. He was also the guardian of the first bank, The National Bank of Iceland, established in 1886, and was entrusted to a number of tasks concerning Iceland's economy in the early 1900 (Bárðarson, 1931). Briem did most of his secondary schooling and the Theological Seminary education staying at home, teaching his siblings. Home education was therefore natural to him. He was only 23 years old and had not yet been ordained when he published his arithmetic textbook, *Reikningsbók*, in 1869 which was expanded into two volumes in 1880. The first volume was republished ten times until 1911 and the second one four times, thus being the main reference book in arithmetic for half a century. It was used for teaching at both lower secondary schools (*Skýrsla um gagnfræðaskólann á Möðruvöllum*, 1880–1905, *Skýrsla um Alþýðu- og gagnfræðaskólann í Flensborg*, 1883–) and the first one at the Latin School (*Skýrsla um hinn lærða skóla í Reykjavík*, 1875–1983). When primary schools became more common from the 1860s, it was recommended as a handbook for teachers.

THE CONTENTS OF THE ARITHMETIC TEXTBOOKS

Table 1 provides a list of the typical content of the *libri d'abbaco* (Van Egmond, 1980) with columns for comparison to the contents of the two arithmetic textbooks: *Reikningslist* (J. Guðmundsson, 1841), and *Reikningsbók* (E. Briem, 1869; 1880).

	J. G.	E. B.
1. Arithmetic:		
Numeration: the four arithmetic operations, applied successively to whole numbers, fractions and the compound quantities of monies, weights and measures	X	X
Tables: multiplication tables for numbers and monetary units, tables of squares and lists of the parts of monetary units	X	X
2. Business problems:		
Finding the price or amount of goods, usually by the Rule of Three	X	X
Currency exchange, and conversion of units of measurement	X	X
Problems relevant to bartering	X	X
Partnership – dividing profits between members of partnership	X	X

Interest and discount – distinguished between simple interest and compound interest, computed by percentages	X	X
Equation of payments – a series of loans combined for repayment on a single date		
Alligation – metals of varying purities combined in a mixture		X
3. Recreational problems; often including algebraic questions		X
4. Geometrical problems		X
5. Methodological section		
Rule of Three or the “golden rule”	X	X
Rule of the false position, rule of the double false position		
Algebra, solution by an unknowns and equations		X
6. Miscellaneous – number theory, tariffs, calendars, etc.		X

Table 1: Comparison of Guðmundsson’s and Briem’s textbooks to the *libri d’abbaco*

The content of Guðmundsson’s *Arithmetic Art* was confined to the above list, while Briem’s *Arithmetic*, in the first edition of its second part, contained more advanced material, such as logarithms for quick backwards computations of compound interests. The fact that the sections of algebra, equations and logarithms were excluded in later editions of the book, witnesses the fact that the general public, who were the readers of the book, did not require it and may not have wanted to spend money on unnecessary information. Books had to be kept at minimal price.

Both authors mention foreign textbooks, e.g. by the Dane Georg F. Ursin, which both may have studied at the Latin School. However, the contexts of their books do in both cases concern the Icelandic farming society and its economic issues.

THE MESSAGES OF THE TEXTBOOKS

The two textbooks describe similar societies, the old farming society of rural inhabitation. The farmers went together with their tenants and servants to the fishing grounds in the spring fishing season. They allocated the revenues of their farming and fishing and dealt with the merchants, mainly by bartering where no money was present, although prices had been calculated in terms of money since 1776 (Karlsson, 2000, p. 244). The farmer deposited his products: wool, meat, fat, fish, knitting and weaving products, and feathers. Against this he drew on his account what he needed. The society was to large extent built up as self-sufficient, and the necessary goods were often confined to grain, such as rye, oats, etc. In addition there were luxurious goods, such as sugar, coffee and spirits. The farmer was also to pay his taxes and various official payments. An important part was the support of paupers and invalids, which expenses had to be computed to a certain degree of exactness.

Each category of arithmetic: the four arithmetic operations by simple numbers, composite numbers (with monetary or measuring units) and fractions; the Rule of Three, simple and inverse; percentages and interests; was followed by six to ten verbal problems by Guðmundsson. The majority concern the above transactions by the merchant, clearing up death estates and heritage, etc. In most categories one meets one or two problems containing advice on sensible allocations of resources.

Briem's textbook contained many more problems and their solutions were generally left to the reader except the very first ones in each section, which served as examples. Problems containing advice and warnings were located in the latter part of the 1869 edition in the sections of percentages. In the 1880 edition the content had been split into two volumes and the ethical advice was exclusively contained in the second volume along with the inverse Rule of Three, percentages and interests. Several recurring themes of the two textbooks are recited below.

Avoid borrowing

Both authors warned seriously against borrowing. An example tells of a man who borrowed money for two years by accepting an obligation of 100 kronas which only gave him 70 kronas. Furthermore, he had to pay 4% rent p.a. In fact he had to pay $27\frac{1}{7}\%$ p.a. (Guðmundsson, 1841, p, 241). Usury was clearly not invented in the 21st century. The author added a comment following this and another similar example:

These 2 examples exhibit how unscrupulous some people are by utilizing others' hardship, and how these in trouble, often out of distress and sometimes out of ignorance, submit to high rents (Guðmundsson, 1841, p. 243).

In Briem's opinion, it was not appropriate to borrow for anything that did not provide revenue (Bárðarson, 1931):

A farmer borrowed autumn-wool by the end of March against paying it back by the end of June by the same amount of spring-wool; now the price of the autumn-wool was 22 shillings, but of the spring-wool 36 shillings; how much did he have to pay in percentages p.a.? Answer: $254\frac{6}{11}\%$ p.a. (Briem, 1869, p. 131).

The farmers had to ensure enough wool for their family and servants to spin for knitting and weaving in the late-winter and early spring before the bustle of lamb-births, shearing and hay-making; the old farming cycle in a nutshell. Therefore, the farmer had two options; either to keep his people idle for several months or to borrow wool at high price. The latter was a better option as the home-made products would increase the value of the wool considerably.

Improve farming and avoid spending on luxurious goods

Briem was much occupied with teaching the youth how to make the most of traditional farming and avoid spending. The extended version of 1880 contained:

A farmer calculated that his household spent 100 kronas on coffee a year. How much is that for twenty years if he could have had 5% revenue of the 100 kronas by allocating

them to improve the land and increase his livestock? Answer: 3306.60 kronas (Briem, 1880, p. 37).

Briem knew how sensitive his countrymen were to taxes and gathered that taxes on luxury spending were the most justifiable. In 1889 when the Budget was unusually difficult after periods of pack-ice, stopping fishing, causing famine and emigration to America, Briem suggested in Parliament an extra tax on coffee and sugar as luxury (Bárðarson, 1931). This suggestion echoes his textbook example nine years earlier.

Guðmundsson (1841, p. 215) told about a coffee-gulper who used to drink five cups of coffee a day. He bought coffee-beans that he thought would last for a year. After twelve weeks he realized it would only last 40 weeks. The task was to find how long the portion would last if three cups a day were consumed and six cups on Sundays. Briem (1869, p. 107) repeated the task for a whole farm where the master directed how much his servants may drink a day.

Guðmundsson also told a long story of two brothers. Both had been working as free workers for salary, including food and working clothes. This was a novelty. Before, all people had to belong to a farm, either as family or servants. The elder brother had earned more, but spent his salary on spirits, coffee, clothes, knick-knacks, etc. and had less left of his year-salary than his younger brother.

The consumption of coffee seems to have worried many responsible citizens in the 19th century. The import of coffee increased from practically nothing in 1820 to 44 tons in 1840 and to 218 tons in 1866 or fivefold (*Hagskinna*, 1997). The same applied to sugar. A contemporary source (NN1, 1849) expressed concerns that even people in the smallest cottages had to drink strong coffee, up to twice or thrice a day. The farmer could not direct his servants to work, and his servants could not work, until they had had their coffee. Seafarers had to wait for coffee however the weather and other conditions were. In another article in the same issue (NN2, 1849), the writer understood well that many a good farmer was shocked to learn how much of the farm's resources was spent on coffee and its auxiliaries; the grinder, the kettle, the cups, the sweets and the cream, in addition to the firewood- and time-consumption. Coffee consumption was also discussed in the parliament (*Alþingistiðindi*, 1871).

It is by no means unique in history to resist coffee consumption. In the after-WWII period, German economy was ruined. People were urged to drink beer rather than the imported coffee which had high import duties into the 1970s.

Wise allocations and investments

Briem gave an example demonstrating that a tenant who owned 300 kronas was better off by improving and evening out a rented land for the amount in order to be able to feed more cows than else. The other option was to rent the amount to another person by 4% interest p.a. The result was that the tenant would make a profit of nearly 400 kronas exceeding the interest (Briem, 1880, pp. 33–35). This example is

not found in the 1869 edition of the textbook where compound interests were also introduced. Briem, as a parish minister during 1873–1880, did similarly himself. He had swamps drained on the farm belonging to his parish church, and set up irrigation on the land on his own cost. However, he was well off after his seven years parish service (Bárðarson, 1931). Depositing money in a bank was still unusual. The first bank was only established in 1886 where Briem himself was involved.

Spirits

Both authors present a number of exercises involving spirits. People mixed the spirit with water, sometimes to lower the price (Briem, 1880, p. 2) but often to gain more profit. Guðmundsson (1841, pp. 228–230) tells a long story of a shady dealer buying spirit in Reykjavík to sell in rural areas and making (too) much profit. Another example concerns a worker in Reykjavík who consumed half a pot of spirit each day from the age of thirty to his death at sixty. The expenditure was gigantic, which must have been the intention to demonstrate (Guðmundsson, 1841, p. 40). Briem was also concerned about alcohol consumption:

In 1866, 33,029 pots of wine were imported to Iceland which was 2.2% more than the year before; how much was that? (Briem, 1869, p. 125).

In 1866 the number of households in Iceland was about 9,400, and official numbers for import of spirits were 511,700 litres and other alcoholic beverages 88,200 litres (*Hagskinna*, 1997). This means that 54 litres of spirits were consumed on average in each household and 9 litres of other alcoholic beverages. These numbers dropped suddenly in 1873 after an ordinance 1872 regarding a duty on spirits (Árnason, 1988). The duty was still raised in 1875 and 1879, reflected in drops in the import quantities. They rose again, but never to the levels from before 1873. The 1872 ordinance was issued in the period between the Parliament services of Guðmundsson and Briem but was duly supported by Sigurðsson, also for morality reasons (*Alþingistiðindi*, 1871).

Health issues and social problems in connections with alcohol were not mentioned in the arithmetic textbooks, only the waste of money. However, alcohol consumption was considered a growing social problem when a branch of IOGT, the International Organization of Good Templars, was established in 1884 (Karlsson, 2009).

SUMMARY AND CONCLUSIONS

Guðmundsson and Briem both belonged to the typical landless educated elite who had themselves to be economically thinking and thrifty. According to Enlightenment ideas they believed that education would “enlighten” people to allocate their resources wisely. Their textbooks belong to the *abbacus* tradition of practical textbooks as is clearly seen from Table 1. Furthermore, the authors, both theologically educated, were faithful to the protestant tradition in including ethic education in their arithmetic textbooks. They warned people against spending money

on luxurious goods, such as coffee, sugar and spirits, for their own financial prosperity but also for the society's. The homes were expected to consume their own products as was the society as a whole. Sources witness that Briem practiced in his own life and in Parliament what he preached in his textbook. Less is known about Guðmundsson. His biography author was more concerned with his activities towards autonomy from Denmark. This was certainly the overall goal of all these men; Sigurðsson, the leader, Guðmundsson and Briem, and for that the population had to be educated and capable of allocating their own personal resources in a wise manner. The conclusion is therefore that the two textbooks by Guðmundsson (1841) and Briem (1869; 1880) were important channels for conveying ideas that the authors gathered would lead Iceland and Icelanders to prosperity and financial independence.

“I WAS AMAZED AT HOW MANY REFUSED TO GIVE UP”: DESCRIBING ONE TEACHER’S FIRST EXPERIENCE WITH INCLUDING HISTORY

Kathleen M. Clark, Lisa G. Phillips

Florida State University, Florida State University Schools

In the following narrative we share the perspectives from our two different roles in thinking about history of mathematics in mathematics education. The first author’s perspective provides insight into how a university professor thinks about her graduate students’ learning with regard to incorporating history of mathematics in teaching. The second author’s perspective presents the reality of the classroom teacher making a first attempt at both studying history of mathematics and incorporating history in teaching mathematics.

INTRODUCTION

In this paper we present simultaneous accounts from two different perspectives about promoting the inclusion of history of mathematics in teaching secondary school mathematics in the United States. The first author’s account is from the perspective of university professor, teaching a graduate-level history of mathematics course for teachers and prospective teachers. The second author’s account is from the perspective of a secondary mathematics teacher, who took the graduate-level history of mathematics course in summer 2012 and subsequently pursued ways to incorporate history of mathematics in her teaching.

Thus, this paper is less about presenting a formal research study (i.e., with the expected literature review, research question(s), methodology, data collection and analysis, and assertions and conclusions) and more about describing the experience of a classroom teacher’s efforts to include history of mathematics in her teaching. In the field of history of mathematics in mathematics education there are several examples of theoretical and empirical contributions, discussing a variety of issues ranging from ideal ways to implement a history of mathematics course for prospective teachers (Clark, 2008; Charalambous, Panaoura, & Phillippou, 2010) to studies on students’ experiences with learning mathematics using original source material (Jankvist, 2010). However, there remains a gap in the available literature that provides insight into how and why secondary mathematics teachers include history of mathematics in teaching (or, elementary teachers teaching mathematics, for that matter) [1].

Avital (1997) stated that “[m]athematics is by nature a cumulative subject; most of what was created millennia ago – both content and processes – is still valid today. Exposing students to some of this development has the potential to enliven the subject and to humanize it for them” (p. 3). Moreover, Avital claimed that, “[i]f we want to change the present situation we have to do it through the teachers” (p. 3). Consequently, when working with mathematics teachers with the goal of determining

when, how, and why to incorporate history of mathematics in teaching, it is a worthwhile task to examine the different claims for each.

RELEVANT BACKGROUND

In summer 2012 five prospective mathematics teachers [2] and one classroom teacher completed a course on using history in teaching mathematics (or, “Using History” course). The course was taught as a hybrid, in which the course met one evening per week for six weeks and as an asynchronous online course for the remaining six weeks of a 12-week semester. The course was also designed to contain two parts. Each of the six graduate students possessed a different mathematics background and knowing this, the course was designed so that the first eight weeks focused on studying several mathematical topics from an historical perspective. Then, the remainder of the course was devoted to pedagogical concerns and the ways in which history of mathematics can or should be incorporated in teaching mathematics. Table 1 displays the schedule of topics of the course.

Week Number	Topics
1	Overview of research skills and the foundations of early mathematics
2	Content Focus: Cultural and historical development of mathematics; number systems; development of the complex number system
3 – 8	Content Foci: Solving polynomial equations, Geometry, Advanced mathematics topics, Calculus
9 – 12	Pedagogical Foci: Using original sources, Emphasizing historical problems, Cultural- and ethnomathematics

Table 1: “Using History in Teaching Mathematics” course schedule of topics.

The primary intent of the course was to provide future and current teachers with resources, strategies (e.g., aspects of the “hows” per Jankvist, 2009), and reasons for including history of mathematics as part of their practice in teaching mathematics (i.e., the “whys” per Jankvist, 2009). In particular, there were two key course products that prompted students in the course to plan for the role of history in their future teaching. The first, weekly contributions to asynchronous discussion board prompts, allowed the students enrolled in the course to share ideas prompted by weekly assignments, which included mathematical tasks, original source readings, and articles from the field of history in mathematics education.

The second product was the capstone assignment for the course, for which students were required to create a historical lesson for a mathematical concept or topic that they would potentially teach in their future teaching assignment. For the historical lesson, students were directed to include historical information and historical problems or processes. The reason for the requirement to include both anecdotal and mathematical aspects in the lesson was to eliminate the possibility of creating a

purely “history as interesting story” (Clark, 2011) lesson, that would most likely not have the potential to engage pupils in learning mathematical content.

THE NARRATIVE

Kathleen’s Perspective.

During the course it was clear to me that Lisa was thinking about how history of mathematics could enhance her instruction in ways that the other students could not. This was, of course, primarily due to the fact that Lisa was the only classroom teacher taking the course. In addition to having taught for many years, Lisa was experiencing what many teachers often describe as “hitting a wall” – or becoming somewhat disenchanted with the way they have always taught particular topics or courses. As Lisa explained, she “didn’t want to get burned out”, and she wanted to include authentic problems to engage students.

In this section, I share two important aspects of my interactions with the students in the course. First, I present examples of Lisa’s contributions to the online course discussion board. The sample posts are helpful in revealing Lisa’s disposition towards to role of history in teaching. Secondly, I briefly describe the historical lessons that the students produced for their capstone assignment, with particular attention to Lisa’s historical lesson.

Discussion Board Contributions.

During the seventh week of the course, students were asked to select one of the topics of focus [3] and to share on the discussion board why they would be most excited to teach the topic using history. Furthermore, students were asked to consider the explicit use of historical problems (or, applications). That is, the students were challenged to consider using history for more than just the exciting stories, anecdotes, or biographies. In response to the discussion board assignment, Lisa stated:

Trigonometry is usually introduced after the lessons on right triangles. After working on the historical aspect of trigonometry, I think it would have more meaning if the lesson could be taught after the circle concepts. With the circle concepts (especially chord relations) fresh in the students’ minds and providing real-world problems from the ancient world, I think trigonometry will make more sense to the students. They may actually have fun with the concept. I do need to do more investigating as to the types of astronomy-based problems to give the class to solve. I am looking forward to building on this lesson and to compare the type of learning from previous years of introducing trigonometry as just ratios in a right triangle. (Discussion Board, Week 7)

Later in the course, Lisa responded to a discussion board prompt that asked for students to express how some of the course readings helped them to think about the possibilities, benefits, and obstacles to using history in teaching:

Avital’s article contained many wonderful ideas that I have been looking for; that these ideas will help me use history in the classroom is a bonus. These days the focus [in teaching] is on reading and rightly so. We also need the same push to work on students’

ability to think. If the answer does not come quickly, so many students shut down. I have even heard of instances where teachers become frustrated and make the work easier, but making it harder for the student to develop their thinking skills. In the article, Avital mentioned that we should educate students to conjecture “It cannot be done” and then try to prove this conjecture. The problems he presented as examples make this “doable”. An example was asking eleven-year-olds to obtain the sum 45 by adding 8 numbers taken from the set 1, 3, 4, 7, and 11. (This is very doable and the students would love the challenge.) (Discussion Board, Week 9)

Finally, Lisa contemplated a specific way to incorporate history of mathematics in teaching (e.g., Jankvist’s “hows”) toward the end of the course. In her reflection about Jankvist and Kjeldsen’s article in *Science & Education* (2011), she observed:

What drew me to the article was [Jankvist’s] teaching module. We have been talking about bringing history to the classroom as more than an additive. We need to give it substance and [for it to] have meaning. Many times it has been suggested that if the students ‘witnessed’ the struggles of the men and women as they toiled through the beginnings of mathematical concepts, then the students would find more meaning in their learning of the same concepts. I have been wrestling with the idea of how to incorporate history of mathematics in the classroom in order to share these struggles with the students. I feel Jankvist’s module is a good start. I like the questionnaire that was given to the students before the study. I always wonder what students really thought of math and their ideas of where the subject came from. How did math come about or did it just appear? Many of the historical developments seem to have had some controversy associated with the people involved. The discussions seem to bring the students into the controversy with the debates with one another. All students have an opinion and I feel even the quiet, struggling student will gain insight to the human side of the mathematics. (Discussion Board, Week 11)

Lisa shared a valuable perspective for research in the field of history of mathematics in mathematics education. In particular, Lisa sought out the “Using History” course because she was interested in finding and implementing new strategies to meet the needs of her students, as well as to prevent her own burn-out from teaching mathematics as she always had. Secondly, she was able to read, analyze, and apply ideas that she read about during the course to her particular experience as a veteran classroom teacher. Finally, Lisa used her new learning about history of mathematics, different approaches for incorporating history in teaching mathematics, and reasons why history may contribute to student learning to create her historical lesson in the course.

Historical Lessons.

The six “Using History” students each produced an extensive historical lesson as the capstone assignment for the course. A brief description of the lessons is provided in Table 2.

Student	Lesson Topic	Grade Level	Details
Lisa	Pythagorean Theorem	High School	4 activities; different cultures included; base-60 calculations; proofs
Student 2	Probability	Middle School	1 one-hour lesson; original readings; questions on the readings; mathematical problems
Student 3	Multiplication Strategies	Elementary	3 multiplication methods from three cultures; open-ended questions; mathematical problems
Student 4	Volume of a Sphere	High School	3 methods from three cultures
Student 5	Method of False Position	Middle School	Primarily a description of Fibonacci’s application of the method; only two historical problems (out of seven questions)
Student 6	Conic Sections	High School	No history included

Table 2: Brief description of historical lessons.

Four of the six “Using History” students designed lessons that met the required elements of the capstone assignment (Lisa and Students 2, 3, and 4). It was apparent from Lisa’s historical lesson that she was an experienced teacher; her lesson was organized with four delineated activities. Each activity represented part of an overall progression to engage pupils with the mathematics of several ancient cultures, ranging from different numeration systems to an example of measurement (e.g., the Pythagorean Theorem). The other students’ lessons differed from Lisa’s in this key regard. In particular, the other historical lessons contained one main activity, with several aspects (cultural background, historical readings, mathematical tasks) included in the activity.

Lisa's Perspective.

In this section Lisa shares her perspective, both as a classroom teacher and as a graduate student enrolled in the course on using history in teaching mathematics. In the following, then, the first person “I” is used by Lisa.

I have been teaching mathematics at the secondary level for the past 18 years. I enjoy mathematics and would always look for real world applications in the form of activities to make mathematics exciting for the students. In my reflections over the past few years, it seems as though the students are becoming more disconnected from mathematics. In this “quick fix” world, students are looking for formulas to solve all the problems. Consequently, I wanted to find something that would broaden the students’ understanding of mathematics as well as give them a whole new perspective of the subject.

As part of my search to find content and strategies to include in my teaching, I met with Kathleen to discuss course offerings at the Florida State University. She told me about her “Using History” class and I immediately thought this could be the answer to my dilemma. I always believed my understanding of mathematical concepts would be enhanced if I knew about the origins of the concepts. And, more importantly, I hoped that it would do the same for my students.

The course proved to be fascinating. The courses I teach range from middle school mathematics to honors-level geometry. As I studied the required course readings, my thoughts were always focused on how I could use the material in the classroom. I found many ideas in the course text (*Math Through the Ages: A Gentle History for Teachers and Others*), as well as the assigned journal articles. For example, Avital (1997) suggested introducing open problems to develop critical thinking and problem solving. Meavilla and Flores (2007) presented an interesting activity of analyzing problems as they were given in their original language. One of my concerns has been students’ poor problem-solving skills. Thus, the ideas suggested by Avital and Meavilla and Flores caught my attention as a potential strategy to help students develop this important life skill.

I also found the lives of mathematicians fascinating and feel students would enjoy learning the stories behind the individuals responsible for mathematical ideas. Additionally, I feel that my students could possibly relate to the struggles these great thinkers faced. It would be interesting to hear my students’ opinions of what particular mathematicians dealt with in their lives. My thoughts during the “Using History” course were to make plans for when to introduce these interesting activities throughout the year. During the summer, I had other (though unexpected) encounters with the history of mathematics. At one conference I attended one of the lesson plans presented involved Eratosthenes’ measurement of the Earth. A brief history was given and an outdoor activity for participants followed. This lesson provided proof that introducing history into lesson plans does not take the huge commitment of time that many teachers fear.

Since completing the “Using History” course, I must admit that I have been slow to introduce history into the classroom. My lessons for the academic year began with integers and measurement and this presented the perfect opportunity to introduce the many number systems of the ancient world. I began my 7th grade classes with the different numeration systems of the ancient Egyptians, Babylonians, and Romans. I expanded on the Roman Numerals by mentioning that it is believed that it was motivated by the human hand. The numbers 1 through 4 were the fingers and the numeral for 5, “V”, was the hand, which showed how the thumb formed a “V”. In class, we discussed what it would have been like working with other groups from different parts of the world, with each having their own number system.

Later in the academic year I spent a class period in my two Geometry Honors classes working on proofs of the Pythagorean Theorem. After distributing the handout with various proofs, I let the students be to see if they could come up with the proofs. As we worked together on deciphering the directions, the students became excited about setting up the problems. One student even jumped up in the air when he figured out a proof, and he quickly asked for another. In fact, other students asked to try another. I was amazed at how many refused to give up and say the usual ‘I don't get it’.

The greatest challenge in planning lessons informed by history of mathematics, however, deals with the resources available. Thus far, as I develop lessons and activities, I started small and as I continue to work on the plans, the ideas continue to evolve into many sub-phases. My slow start with introducing history as part of my lessons is due in large part to my lack of confidence with the many sources that available. For example, I read several interesting articles and books to learn about a number of mathematicians and found enough discrepancies to make me hesitant about the reliability of the information that I would use with students.

This, however, will not deter me from developing more lesson plans that draw upon the history of mathematics. For example, as a result of the class discussion on ancient number systems, I believe it will be fun for them to perform operations within each of the different number systems and I will design a lesson on this topic. In the lesson, I want students to compare the different number systems to each other, as well as to the way in which we perform operations in our base-ten numeration system. Although my efforts to include history in my lessons may appear to be a slow start, I do not plan on letting history go by the wayside.

Kathleen's Additional Response.

As a final orientation for the reader, the narrative returns to Kathleen's first person perspective.

Lisa's reflections brought three important issues to my attention. When Lisa first shared with me the lesson on Eratosthenes' measurement of the Earth that was presented at a professional in-service meeting for classroom teachers, I missed a valuable opportunity to share published examples of this activity with Lisa. Indeed, seeing a lesson plan that used history of mathematics – in the context of the in-service

meeting – was an important cue for Lisa regarding the viability of incorporating history in her mathematics teaching. However, taking the time to share further examples with Lisa, particularly from resources that she would have valued (especially given her desire for more scholarly resources resulting from her experience during the “Using History” course), would have contributed to the ongoing discussion in which we were (are) engaged. For example, sharing lessons on the topic found in the *Historical Modules for the Teaching and Learning of Mathematics* (Katz & Michalowicz, 2005) or the excerpt on the story of the ancient history of Earth measurement (Führer, 1991) would have, taken together, emphasized Lisa’s idea that there are important stories to be shared with students and the mathematical content.

Reflecting on the story presented by Führer (1991) prompts another reaction to Lisa’s perspective. As Lisa shared in her narrative – as well as many times during our meetings together – she felt overwhelmed by the number of resources that she perceived as providing different historical information. Führer stated the exact situation that Lisa found herself in: “[Most mathematics teachers] would be quite ready to include historical aspects in their lessons, provided someone would help them to overcome their feelings of precariousness concerning the uncertainty of history and the methodological problems of teaching it seriously” (p. 24). Though I tried to alleviate Lisa’s “feelings of precariousness”, her perceptions remained. Quite possibly, however, her strong feelings were tied to the need to please me, as her university course instructor. As a result, in my future work with Lisa I will be sure to emphasize Führer’s exact sentiment that, “It cannot be the job of the mathematics teacher to idolize the standards of historical science. The teacher must not lie, but should free herself from the heavy burden of exactness” (p. 24).

Finally, Lisa’s revelation that she discussed the origin of the Roman numeral “V” as it related to the angle formed by the thumb and index finger of a human hand reminded me that the work to incorporate history in teaching mathematics must – at least from its initial stages – be a true collaboration among classroom teachers who want to provide an historical perspective for their students and mentors (e.g., math historians, mathematics educators, history of mathematics course instructors). With respect to the example about the origin of the Roman numeral “V”, Lisa and I could have worked together while she planned for including this story (and subsequent discussion with her students). Then, when confronted with a possibly too convenient explanation about the possible origin of “V”, we could have searched sources together to investigate alternative explanations. For example, Menninger (1969) discussed the development of the Roman numerals I, V, and X from notches cut into tally marks: “At the very beginning, the Roman numerals observed the basic and simple laws of ordering and grouping, like the notches in tally sticks” (p. 241). Furthermore, V may have resulted from a half-symbol (the “V” formed from half of the “X” symbol). [4]

NEXT STEPS

I argue that the inclusion of history of mathematics in meaningful ways (i.e., addressing both content and affective dimensions for learning mathematics) may most successfully come to fruition in classrooms when sought after by teachers who are “looking for another approach” or are fearful of becoming “burned out”. In our joint narrative Lisa and I described first, her initial journey to investigate how to incorporate history in her teaching – and her first steps to do so. Lisa’s desire to seek formal instruction on how to do so marked the beginning of her journey. From my perspective – that of a mentor of sorts and fellow traveller – introducing teachers to the tools that they can use to plan for incorporating history in teaching mathematics is essential. In the case of Lisa, studying and working with a variety of resources presented tangible ways for her to begin to change her practice, but this also presented a challenge for her. Our continued collaboration will include discussing Lisa’s lessons as she develops them, with attention to appropriate resources.

Our initial collaboration prompts important considerations for future research. Indeed, I have not had access to classroom teachers interested in using history of mathematics in their teaching in a long while. I have renewed interest to investigate the following with Lisa – and hopefully others:

- (1) How do mathematics teachers select historical stories to use with their students?
- (2) In what ways do teachers envision that historical stories will promote or support the learning of mathematics content?
- (3) What are the most effective resources available for teachers to use to incorporate history of mathematics in teaching, in their current classroom context?
- (4) What resources are needed to promote or support teachers’ further use of history of mathematics in teaching, and how can academic historians of mathematics contribute to the construction of these resources?

NOTES

1. In this paper I use “elementary” to refer to pupils aged 5 to 11 years and “secondary” to refer to pupils aged 12 to 18 years.
2. These five students were enrolled in a master’s (graduate) program designed to gain certification to teach secondary mathematics.
3. Topics for week 7 included early number theory, trigonometry, probability, the concept of infinity, or set theory.
4. The first author is grateful to Jan van Maanen for his suggestions on how to improve the original draft of this paper.

THE USE OF ORIGINAL SOURCES AND ITS POSSIBLE RELATION TO THE RECRUITMENT PROBLEM

Uffe Thomas Jankvist

Roskilde University [1]

Based on a study about using original texts with Danish upper secondary students, the paper addresses the possible outcome of such an approach in regard to the so-called recruitment problem to the mathematical sciences. 24 students were exposed to questionnaire questions and 16 of these to follow-up interviews, which form the basis for both a small quantitative analysis and a qualitative elaboration of this.

Keywords: Original sources; recruitment problem; view of mathematics; HAPh.

INTRODUCTION

Usually when discussion falls on the use of original sources in mathematics education focus is on the teaching and learning of mathematical in-issues such as abstract mathematical concepts, mathematical ideas and notions, theorems, proofs, etc. (e.g. Jahnke et al., 2000). And it is true that original sources indeed have a lot to offer in this respect – for recent empirical examples, see Clark (2012); Glaubitz (2011); Kjeldsen & Blomhøj (2012). But as occasionally suggested, a use of original sources may have *more* and quite *different* things to offer our educational systems as well. In fact, a use of original sources may be a way of dealing with more general problems such as: *recruitment* of students to the mathematical sciences; *transition* of students between educational levels, in particular between upper secondary level and university; *retention* of students once they have entered the mathematical sciences at university level; and the dimension of *interdisciplinarity* often appearing somewhat artificial to students when implemented in a classroom situation. In this paper, I shall address the first of these, i.e. the recruitment problem – for an elaboration of the three other possible roles of original sources, see Jankvist (preprint) – and I shall do so by relating to empirically collected data from upper secondary students, in order to both strengthen and unfold the claimed role of original sources in relation to this educational problem.

HAPH-MODULES AND ORIGINAL SOURCES

From February 2010 to May 2012, I followed a Danish upper secondary class of 26 students who through two teaching modules were exposed to extensive readings of original sources. An overall purpose of the modules were to introduce the students to aspects of history, application, and philosophy – abbreviated *HAPh* – of mathematics and to do this simultaneously in one module relying on original sources (for more

detailed description, see Jankvist, In press). In the first HAPh-module, implemented in April-May 2010, the students read Danish translations of the following three texts [2]:

- LEONHARD EULER, 1736: *Solutio problematis ad geometriam situs pertinentis*
- EDSGER W. DIJKSTRA, 1959: *A Note on Two Problems in Connexion with Graphs*
- DAVID HILBERT, 1900: *Mathematische Probleme – Vortrag, gehalten auf dem internationalen Mathematiker-Kongreß zu Paris 1900* (the introduction)

The overall theme of this module was mathematical problems, as addressed by Hilbert in his introduction to the 1900 lecture. To make Hilbert's quite general observations a bit more concrete, the students first were to read the two other texts, each of which addresses a mathematical problem. Euler's paper from 1736 addresses the Königsberg bridge problem: how to take a stroll through Königsberg crossing each of its 7 bridges once and only once – today this paper is considered the beginning of mathematical graph theory. With the dawn of the computer era two centuries later, graph theory (and discrete mathematics in general) found new applications. Dijkstra's algorithm from 1959 solves the problem of finding shortest path in a connected and weighted graph – today it finds its use in almost every Internet application that has to do with shortest distance, fastest distance or lowest cost. Furthermore, Dijkstra also discusses a method for finding minimum spanning trees, a problem relevant for the building of computers at the time, and since then used in telephone wiring, etc. (see also Jankvist, 2011).

The second HAPh-module was implemented in September-October 2012, and here the students read Danish translations of the following three texts:

- GEORGE BOOLE, 1854: *An Investigation of the Laws of Thought on which are founded the Mathematical Theories of Logic and Probabilities* (chapters II and III)
- CLAUDE E. SHANNON, 1938: *A Symbolic Analysis of Relay and Switching Circuits* (first parts)
- RICHARD W. HAMMING, 1980: *The Unreasonable Effectiveness of Mathematics*

The title of Hamming's paper made up the theme for this module. Hamming discusses 'the unreasonable effectiveness of mathematics' from the viewpoint of engineering (and computer science) asking why it may be that so comparatively simple mathematics suffices to predict so much, this making up the 'unreasonable' aspect. To provide the students with a possible concrete example of this, they were first introduced to Boole's idea of a two-value algebra – and the context in which this was conceived by Boole in 1854, namely that of trying to describe language (and thought) from a logical point of view. Next, the students were to study a later – to some degree contemporary – application of Boolean algebra by Shannon from 1938. By relying on a set of postulates from the now further developed Boolean algebra ($0 \cdot 0 = 0$; $1 + 1 = 1$; $1 + 0 = 0 + 1 = 1$; $0 \cdot 1 = 1 \cdot 0 = 0$; $0 + 0 = 0$; and $1 \cdot 1 = 1$) and by interpreting these in terms of circuits, Shannon is able to deduce a number of theorems which can be used to

simplify electric circuits and thus the building of such considerably (see also Jankvist, 2012a).

EMPIRICAL SETUP

As part of the empirical setup the students were exposed to a series of questionnaires and follow-up interviews during the 2-year period in which I followed them (for specific details, see Jankvist, 2012b). In order to get an indication of the possible effect of the modules and the students' readings of original sources in relation to the recruitment problem, their final questionnaire of March 2012 included the following set of questions:

1. Have the two modules provided you with a different view of what mathematics is; how it comes into being; and what it is used for? If yes, explain how and in what sense. If no, then why not?
2. Did the two modules encourage you to study or in any way concern yourself with mathematics (and/or natural science) after upper secondary school? If yes, how and why? If no, why not?
3. Whether you answered 'yes' or 'no' to the above question (2), do you then consider the two modules to have provided you with a more *enlightened basis* on which to either select or deselect mathematics (and/or natural science) to be part of your future education? If yes, how? If no, why not?

Question 1 above of course concerns the students' beliefs about mathematics as a scientific discipline, which was one of the main objectives of the overall study (Jankvist, 2012b), but which is also relevant for the following reason: Often when students either select or deselect mathematical sciences as part of their higher education, they may in fact be basing their choices on 'incorrect' assumptions. In the panel on empirical research at HPM2012, David Pengelley referred to this problématique as "reality vs. fantasy" [3]. This phrase has to do with students – including upper secondary ones – not having an (accurate) idea of what mathematics is about when practiced as a scientific discipline at the tertiary levels, e.g. by pure and applied mathematicians at universities. As found in Jankvist (2009), upper secondary students' answers to the question of what professional mathematicians do typically range from having no clue at all to believing that they perform some kind of 'clean-up job' consisting in finding 'errors' in already existing formulas and proofs, more efficient ways of calculating already known quantities, etc. Often such views has to do with their belief of mathematics as something a priori given; static and rigid – a belief of course not unrelated to textbooks' usual presentation of mathematical topics. Only very few students seem to believe it possible that mathematicians can come up with actual *new* mathematics. Therefore the students know neither what they accept to study if they choose to engage with the mathematical sciences, nor what they reject to study if they do not. The claim, which I am of course trying to make, is that a study of original sources may provide students with a truer image of mathematics as a scientific

discipline, both pure and applied, because history in general and original sources in particular show mathematics-in-the-making as opposed to mathematics-as-an-end-product (Siu & Siu, 1979), i.e. the usual textbook presentation. Question 3 addresses this aspect by asking the students if they think that the modules enabled them to make their choice on a more enlightened basis. Question 2 is a more straight forward question asking if the modules in any way encouraged the students to pursue a study of the mathematical sciences – or to put it on the edge; if the study of original sources ‘attracts’ or ‘rejects’ in terms of recruitment.

I shall split my analysis of the students’ answers into two parts: one in which I perform a small scale quantitative analysis of the students’ questionnaire answers; and another in which I try to elaborate and deepen this by drawing on the follow-up interviews with the students.

QUANTITATIVE DATA AND RESULTS

Out of the 27 students, 24 answered the final questionnaire. Of these 24 students, 16 were exposed to follow-up interviews. The possible answer combinations of the students are given in table 1. The reason for distinguishing between students who were exposed to interviews and students who were not is that sometimes students would change their answer during interviews. In particular to question 3 (Q3) some students would alter their original answer, since apparently the phrasing in the questionnaire was not entirely clear to all of them. Any such changes are taken into account in the column ‘Quest.+Int.’.

Combination			Quest. + Int.	Quest. only	Total
<i>Q1</i>	<i>Q2</i>	<i>Q3</i>	<i>16 students:</i>	<i>8 students:</i>	<i>24 students:</i>
Yes	Yes	Yes	6	0	6
Yes	No	Yes	7	1	8
No	No	Yes	2	0	2
Yes	Yes	No	0	1	1
Yes	No	No	1	5	6
No	No	No	0	1	1

Table 1: Number of student answers according to occurring combinations [4].

A first observation based on table 1 is that a total of 21 students (88%) agreed to the HAPh-modules having provided them with a different view of what mathematics is, how it has come into being, and what it is used for (Q1). 7 students (29%) agree to the

HAPh-modules having encouraged them to study mathematics or natural science as part of their future studies. Out of these 7 students, 4 already had decided to pursue a higher education related to the mathematical sciences, but the remaining 3 may be characterized as possible ‘win over’ students. Regarding question 3 (Q3), a total of 16 students (67%) agree to the HAPh-modules having provided them a better foundation to either select or deselect mathematics and/or natural science to be part of their future education. Taking into account that the 15 of these were the ones exposed to follow-up interviews and that 4 of these actually altered their answer during the interview after having been explained the meaning of question 3 more clearly, it is reasonable to assume that the total number could have been considerably higher had all 24 students been exposed to follow-up interviews [5]. The observation that the majority of these students actually answers ‘Yes’ to question 1 (5+1 students) only supports this further, since the majority of the interviewed students who answered ‘Yes’ to question 3 also answered ‘Yes’ to question 1. I shall return to this observation in the final discussion.

SELECTED QUALITATIVE DATA

In order to deepen some of the reported findings, I shall display a selection of students’ answers from questionnaire and follow-up interviews in order to illustrate students’ rationale behind their answers as well as possible changes in these [6].

Christopher, who represents the ‘Yes-Yes-Yes’ combination in questionnaire as well as interview, replied to question 1 that the modules provided him with “a different way of seeing things, that it [mathematics] isn’t only calculations with numbers”. When asked to elaborate in the interview, he replied:

Well, you can say that what gave me some [insight] was all this philosophy, which lies behind, but also the way in which it has evolved... that it has evolved in order to describe a certain thing; for example that Boole used it to describe one thing, and then Shannon saw, okay, I apply it for this other thing and then develop it according to that. This connection; that it is two completely different things they are working with and they then can use the same [mathematics]... that this mathematics can be applied in so many different contexts. (Christopher, March 29th, 2012)

Regarding question 2, Christopher was already set on studying something related to the mathematical sciences, but he stated in his questionnaire answer that “the modules definitely did not reduce this desire”. Also Christopher stated that he simply had been “thinking more” while working with the original texts during the modules, than he usually did when working with the textbook in his regular classes.

Another example of a ‘Yes-Yes-Yes’ student is Katharine, who provides the following answers. Question 1: “Yes, since here connections are made between problem, solution, and practice, so that we in the end can exploit it. Then you get the ‘whole ride’ which makes it easier to understand.” Question 2: “Yes, because it wakes you up! And you then want to find out how other things were created also.” Question 3:

“Yes, because they [the modules] have provided me with an insight in what mathematics at a higher level can do.” When asked, immediately after the second HAPh-module, about reading original sources, Katharine said:

I like the original [texts] better. You kind of get inside the head of those people and think, well that’s how they... Because, if there is another one [a secondary source] trying to interpret it, then I feel that they can’t really figure out the original, so they take it to a lower level. Whereas I feel that you are challenged more when reading the original [text]. You get to sense how he [the author] has structured it, how he has thought, and so. Of course, it is okay to have the small explanations afterwards on what is meant with this and that... So you see, okay, that was a quick summery, and I understood that. Then you feel that you have won something, because you understand his [the author’s] intention, how he carried it through, and so on. That was incredibly exciting. You felt that you got to know them a little more personally and how they expressed themselves using mathematics, explained [things], and so. Also, it gave you ideas on how to express yourself mathematically, in your hand-in tasks etc. I found that very exciting. (Katharine, November 3rd, 2011)

To illustrate the ‘Yes-Yes-No’ combination and the change of this into ‘Yes-Yes-Yes’, we shall look at an extract from the interview the student Tobey:

Tobey: Yes, they [the original texts] gave me an understanding of how you need to think completely different. [...] It has been quite an instructive experience in that regard; kind of an *aha*-experience once you began thinking about it in relation to all the [questionnaire] questions afterwards.

Interviewer: Besides you being surprised due the two modules, did they have any other impact on you?

Tobey: What they impacted is that I now may consider, well not to study mathematics directly, but to study something where you use mathematics to more than what you use it for in physics... Because it is a deeper discipline than what you usually think it to be, with just formulas, plus, and minus. [...] There’s more to it. It can be applied to several things, at least in relation to these... It would be cool to look at those problems which have been posed, but which have no solution yet... It would be cool to be involved in finding the solution to just a single one of them. It would be completely awesome.

Interviewer: But then you answer [‘No’ in question 3] here... What I might have hoped is that regardless of you wanting to study math or not, then the modules might have provided you guys with a more... well, done that you could either select or deselect on a more enlightened basis?

Tobey: But it has! I mean, after these [questionnaire] questions my answer has definitely changed, because yes, they can do that. (Tobey, March 29th, 2012)

As Tobey, the student Nikita also expressed being more open to possibly pursue a study related to mathematical sciences after the modules than she had been prior to the HAPh-modules:

I do think that I have got more of a reason to select it, than I had in the beginning [of upper secondary school], because we've seen several different aspects of it [mathematics] due to these modules. If I had only been working with the textbook and so, my answer would definitely have been 'No', I believe... because it's very monotonous and much of the same, whereas with the two modules we've had the opportunity to think differently and view things through different lenses and... Yeah, see the interrelations in a more comprehensive way than we usually get things presented. So, personally I've discovered that there is much more to mathematics than what it says in the textbook. [...] I think it surprised me that someone actually has been sitting and working with these things, and then arrived at this. Because before I've only thought about mathematics as something just being there, and us as just having these and these things which we could make use of. I've never given it a thought that someone had sat down and worked on it and arrived at something to be used in certain contexts... I've never thought about it like that, only in the way that it's in the textbooks and that's just the way it's given. (Nikita, March 29th, 2012)

In both questionnaire and interview, Nikita is quite clear on answering 'Yes' to question 3, almost as if this is implicit to her due to her answer to question 1. Due to Nikita's positive change from questionnaire to interview regarding question 2, she is counted as a 'Yes-Yes-Yes' student in table 1. Regarding her encounter with original sources, Nikita had on a previous occasion expressed herself positive regarding this:

... not only did you have to understand what it was about, you also had like the language of it, and it has been a different way of thinking compared to the mathematics we are usually taught, where we have this formula and it works like this, this, and this. Here you got all the background knowledge, and how he arrived at it, etc. For me, I personally think that I get much more interested, when I see it all, than if I'm only told that now we are studying vectors and we must learn how to dot these vectors and then we must be able to calculate a length, right. That's all very good, but what am I to use it for? Whereas, when you know about the background, the development up till today, that I think was exciting. (Nikita, November 3rd, 2011)

As a representative of the 'Yes-No-Yes' combination we shall take a look at an extract from the interview with the student Liza, who is also quite settled on her positive answer to question 3:

Interviewer: Let us take *you*: You are not interested in studying mathematics?

Liza: No.

Interviewer: No. And after you've followed these modules, do you then feel that you know what you say 'No' to, to a higher degree than if you had not been through the modules?

Liza: For sure, I do.

Interviewer: You do?

Liza: Definitely, yes. I would never have thought mathematics at the university to be about things such as Euler...

Interviewer: As [Euler's] graph theory?

Liza: Graph theory! Or I might have thought, okay, there is something related to graphs. But graph theory, no. So yes, it certainly did provide me with a more enlightened basis. (Liza, May 22nd, 2012)

Another student representing the 'Yes-No-Yes' combination is Salma, who give the following three questionnaire answers. Question 1: "Yes. It has shown me how mathematics develops, and at the same time how mathematicians work with mathematics. And that mathematics is its own language." Question 2: "No, I must admit that it hasn't. I do find it [mathematics] quite interesting, but there are things which excite me more." Question 3: "I have never considered studying mathematics. But if I had, then it would have been nice with these modules, since I feel that you will know much better what you agree to study."

A third representative of the 'Yes-No-Yes' combination is Sophia, who explains her encounter with original sources in mathematics as follows:

Regarding the modules, even though it has been a little dry from time to time, I do think that it has been nice to get the historical [dimension], to read the original texts, and do it the way they did, the people who developed things. [...] ... in order to get it at a slower pace... to try and figure out 'what the fuck is going on here?' That is, instead of just sitting and doing exercises, which you do in school. To try something completely different, something which might be more similar to what they [the originators] actually did. (Sophia, March 27th, 2012)

DISCUSSION AND RESULTS

Both Tobey and Nikita are representatives of the previously mentioned potential 'win over' students to the mathematical sciences as a consequence of their studies with the original texts in the HAPh-modules. For both of them it seems quite clear that this 'encouragement' to possibly pursue mathematics further is due to the effect of the original texts on their view of mathematics. Nikita gives as reasons the interrelations between different parts of mathematics which the texts reveal, the fact that mathematics has come into being by the hands of human beings, and not least the different way of working when studying an original source as opposed to the regular textbook. Tobey stresses the dimension of creativity in research mathematics and refers enthusiastically to the posed but yet unsolved problems in mathematics (with an implicit reference to the text by Hilbert). Also, Katharine was an example of a 'win over' student, since she prior to the second HAPh-module had no intentions of possibly pursuing the mathematical sciences. Regarding the four other students who gave positive answers to question 2 (table 1), the thing to notice is that the modules –

and the reading of original sources – did not diminish their desire to pursue the mathematical sciences. As illustrated by the quotes of Christopher and Katharine, it may have even enhanced it.

Although the above suggests that a use of original sources may have as an outcome that some students can be encouraged to study the mathematical sciences, the more important finding of the study is that in relation to question 3. Namely, that 2/3 of the students agree to the modules having enabled them to either select or deselect future studies involving mathematics and/or natural science on a more enlightened basis. For the majority of these students this appears to be directly related to the original texts having provided them with a different view of mathematics as a discipline (Jankvist, 2012a). Of course, that a use of original sources can change students' view of mathematics is not a new finding. Still, the present study confirms it once again. What is new in this respect, however, is that this study, although small in scale, suggests a direct connection between a students' positive answer to question 1 (Q1) and a positive answer to question 3 (Q3) [7]. Hence, the more important finding of this study is not necessarily that a use of original sources may 'win' some students over to the mathematical sciences, but that the students who are 'won over' are done so on a more enlightened basis. (Equally important is of course that the students who deselect the mathematical sciences also do so on a more enlightened basis.)

This again has a direct relation to the problem of retention, as mentioned in the introduction. Because if the students who enter the mathematical sciences at tertiary level have a more realistic image of the discipline which they are about to study, then surely one would expect a higher degree of retention among such students.

NOTES

1. The present work has – as part of the STAR-project – been supported by the *European Social Fund* through grant no. ESFK-09-0024. The development of the two HAPh-modules was supported by the *Danish Agency for Science, Technology and Innovation*.
2. The precise references to the original sources may be found in the teaching modules, which are available as texts no. 486 and no. 487 at: <http://milne.ruc.dk/ImfufaTekster/>
3. The panel on "Empirical research on history in mathematics education: current and future challenges for our field" at HPM2012 in Deajeon organized by Uffe Thomas Jankvist along with panellists David Pengelley, Yi-Wen Su, and Masami Isoda.
4. No answers of the combinations 'No-Yes-Yes' and 'No-Yes-No' occurred.
5. As in any other interview situation, there is always the possibility that the interviewee is trying to please the interviewer by answering what (s)he thinks the interviewer wants. The way of trying to avoid this here was to invite the students to elaborate on their answer to question 3, and when doing so some students would realize more clearly the meaning of the question and change their answer from 'No' to 'Yes'.
6. All student quotes have been translated from Danish.
7. If we follow through with this, we may assume that the 6 'Quest. only' students who answered 'Yes' to Q1 but 'No' to Q3, might have altered their answers had they been explained the question more thoroughly in an interview session. Taking the 2 'Quest. + Int.' students who answered 'No' to Q1 but 'Yes' to Q3 as a source of error, we would get 20 out of 24 (83%) instead of 16 out of 24 (67%). But this is of course to some degree speculation.

HISTORY OF MATHEMATICS AS AN INSPIRATION FOR EDUCATIONAL DESIGN

Rainer Kaenders, Ladislav Kvasz, Ysette Weiss-Pidstrygach

University of Cologne, Charles University in Prague, University of Mainz

Use of historical and cultural perspectives in education supports the development of mathematical concepts which are thus not as usually based on logical relations. They allow embracing new individual contexts of experience as well as methods of science and humanities. The use of models of historical development and the need of understanding of phenomena that foster or block learning challenges teachers as well as learners. It will be shown at the hand of concrete and relevant examples how historically, culturally and socially inspired problems can encourage an alternative approach to well-known mathematical concepts and deepen understanding.

INTRODUCTION

The employment of historical examples can enrich mathematical teaching in various ways. From the viewpoint of a historian, problems of inadequate methodology and a lack of contextual understanding might easily occur when historical material is used in the classroom. In this paper we do not put stress on the professional handling of historical material. We would like rather to consider the use of historical material as a source of inspiration in educational design and as a diagnostic mean.

In the first part we discuss different approaches to the employment of historical content at the hand of existing forms of presentation of historical material in teaching. Hereby we pay attention to the representation of the historical material and its potential to initiate in the class room a discussion of the socio-cultural aspects connected to mathematical topics. The second part will exemplify the relations of various models of historical development and will make related positions in learning theories explicit. This constitutes the basis for the conceptual understanding of historical aspects by means of mathematical awareness in the third part. Here we are guided by examples from mathematics textbooks and examples from the education of pre-service mathematics teachers for grammar school.

FORMS OF EMPLOYMENT OF HISTORICAL CONTENTS IN TEACHING

The use of historical material in educational design has a long tradition. For instance Walther Lietzmann gave in 1921 a lecture course on recreational mathematics at the University in Göttingen and emphasized the important role of social and cultural aspects as well as the potential of historical contexts for the design of mathematics instruction. He encouraged the publication of corresponding materials with direct use for teaching. Although Lietzmann gave in (Lietzmann 1922) extensive references, the discussion of the authenticity of the presentation of historical content (Fried 2001) was not a predominant issue. In Lietzmann's book impulses to reflect about mathematics and incentives to deal with mathematical problems are given by means

of varied, witty and curious comments. In contrast to the approach of a historian, where the existence and under-standing of later mathematics is assumed, and is even part of the background, Lietzmann's approach does not involve an understanding of modern mathematics. Historical contents and examples are used to make other points of view accessible to the reader, to free her from thinking routines by the use of metaphors, unexpected representations, and confrontations in order to enhance a deeper understanding and ludic handling of mathematical objects.

There are various models of historically oriented mathematics teaching developed by historically interested mathematics educators (see Fauvel & Van Maanen 2000, Jankvist 2009), however, for Lietzmann history of mathematics is a source of inspiration for storytelling. In most current mathematics textbooks we can find some historical content. The presentation forms range from historical anecdotes to excerpts from historical documents (Kronfellner in (Kronfellner 1998) gives an overview of commonly used forms of historical content in the classroom). These materials are usually designed as insets or appendices that fit in the textbook design. They are additions to the canonical representations in the given textbook. The related omissions and circumlocutions thus easily lead to erroneous ideas about the historical development of mathematical ideas. In developing a socio-cultural context of the historical material the teacher should be aware of adjustments that have possibly been made.

Many textbook examples of historical inserts in mathematics textbooks show the effort to bring authenticity with learning and reading habits in line. The language and symbolism used correspond only to a small extent with those in the original historical sources. The presentations often build on the student's presumed skills and routines. The student is more likely to reproduce logical steps in the modern style than that she is stimulated to think in the framework of the historical context.

In the design of learning environments based on historical sources the deliberate inclusion of national diversity in language and culture that can be found in the classroom can often be rewarding. An example would be the inclusion of original texts. Another practical link between the mathematical content and Islamic culture is shown in (Moyon 2011), by attributing geometric problems of area decomposition to inheritance rules in the form of rules for splitting acreage.

Admittedly, a playful handling of historical events, oriented at imagination, transfer and variation is in danger of losing its historical authenticity but it can stimulate a much broader mathematical activity. Everyday knowledge and intuitive ideas can contribute amenable to different perspectives. When you want to understand historical hypotheses related to the constellations of celestial bodies (Jahnke and Wambach 2011), unwanted references to reality and modern general knowledge can interfere with the unbiased view. The latter interference can be avoided by an initial settlement of the problem in a fantasy world. The necessary alienation of everyday experience of space and time can be generated playfully by the transition into

computer games, science fiction and fantasy-inspired worlds. The resulting relationships between socio-cultural and extracurricular mathematical approaches allow diverse developments. Versions of the transmission of mathematical problems in other worlds (in the literature there are many examples, e.g. Jules Verne, Kurd Laßwitz, Ian Stewart, Stanisław Lem, Terry Pratchett), and social relations in the world of mathematical objects (Isaac Asimov, Edwin A. Abbott) allow direct involvement of dramaturgic tools to deal with interaction of cultural and historical mathematical and scientific phenomena. Taking together these and many other examples, we can see a wide variety of possible inspiration from historical material in the mathematics classroom.

HISTORICAL PERSPECTIVES ON MATHEMATICAL DEVELOPMENT AND CONCEPT DEVELOPMENT IN MATHEMATICS EDUCATION

The references and school examples listed in the first section show that historical materials in textbooks usually occur as a reference to historical sources or as an illustration by means of a historical record of the mathematical concepts, objects, methods, or mathematicians just treated in the class. History here is strongly identified with the existence of historical sources, usually without paying attention to the historical source itself. This may partly be due to the fact that the use of historical sources for general goals of mathematics education, such as to experience mathematics as a living, evolving science or to create access to the cultural heritage, are difficult to interpret in such a general formulation. Thus the tool is turned easily into the goal and the historical work is reduced to mere reference to the existence of historical sources. The indeterminacy inherent in the historical approach can be ignored because there is the simple control feature *availability of the historical source*. The exciting and very challenging task of designing a learning environment based on the historical source cited in the textbook by introducing historical contexts rich with potential for socio-cultural, mathematical and scientific development lies in the hands of the teacher. How can, however, a short section of a historical text be turned into a mathematical development and what can actually be understood under mathematical development?

In designing such learning environment the question of the underlying concept of a scientific theory, the choice of the general philosophy and of the appropriate developmental model plays a crucial role: is the historical progress based on endogenous and exogenous factors; is it based on the activities of some eminent personalities, or are there rather economic, political and social factors that contribute to the development of this subject? Is it necessary, for an appropriate understanding of the development of mathematics, to turn to methods such as source-analysis and source-interpretation, ethno-mathematical approaches or other perspectives?

For a historian in the choice of the developmental model the scientific criteria are in the foreground. When contextualizing a historical fragment, the distinction between perspectives on history as a tool and as a goal and further differentiation of these

categories as introduced by Jankvist (2009) seems natural and fruitful. In the development of learning environments by means of historical sources the entertaining potential can also play a role. Whiggish or present-centered representations (for this distinction and for a discussion of their unscientific nature see (Wilson et al 1988)) can still inspire genetic instruction or, as the first part exemplified, by means of relocating the actions, personalizing circumstances, and introducing other ways of alienation we can trigger a change of perspective leading to deeper understanding. The mathematics educator, not bound by the norms of scientific rigor of the historian, is open to other developmental models and many more possibilities of the use of historical sources in developing teaching environments.

In a class, the concern is less on the development of mathematics as such as on the development of specific mathematical notions and concepts.

For the development of mathematical concepts in the classroom an important role is played by the implicit phase in which a mathematical concept is not systematized, defined or referred to, which phase is for the historian hard to grasp and not often studied. As appropriate structures or regularities at this stage, however, often appear in the form of a problem solving method or a representation not really anchored within the context of the language of mathematics, the implicit phase can be helpful in instructional design in motivating a definition or in helping to formulate a problem aimed at introducing a concept.

From a historical perspective, there are helpful approaches to extend intension-extension of the conceptual dynamics, such as in Hans Wubings model by *ostension* (Scholz 2010). The presentation of the development of Euler's formula, as Imre Lakatos in (Lakatos 1976) has reconstructed it, is oriented before all on the development of mathematics as a language. This developmental model may be whiggish for a historian. However, it makes important issues of epistemological debates of the last century accessible to a class discussion and it makes tangible the otherwise hardly conveyable idea that even the meanings of mathematical concepts are negotiated. For the long-term conceptual development in the classroom it is worth to think about what historical or other socio-cultural developmental models reflect the dynamics described in Figure 1. Even for local ordering and linking of concepts in school mathematics it is useful to deal with regularities in the development of mathematical language and with regularities in the development and formalization of mathematical methods from a historical perspective (Kvasz 2008).

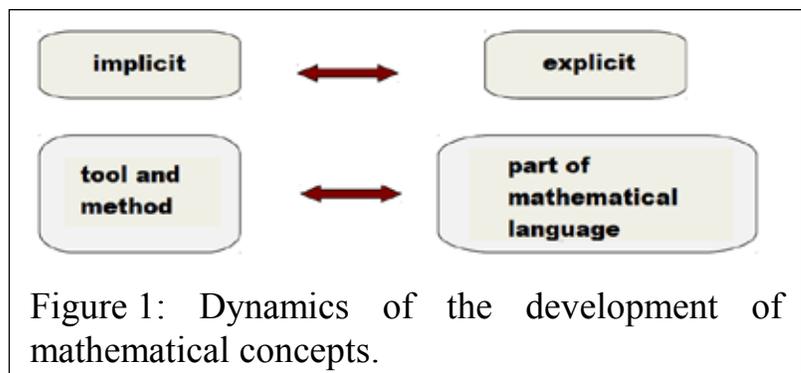

Figure 1: Dynamics of the development of mathematical concepts.

DESIGNING LEARNING ENVIRONMENTS BY THE AID OF HISTORICAL PERSPECTIVES AND MATHEMATICAL AWARENESS

The development of mathematical concepts in the classroom is based on omissions, substitutions, rearrangement distortions, misrepresentations and other customizations transformations of relevant historical processes. On the other hand, there is not the one historical process of a concepts development but many aspects and perspectives under which one can see development as already discussed in the previous chapter.

The following example (Figure 2) shows that historical jackets of mathematical problems do not necessarily initiate a change in routine approaches or standard solutions. In teacher training seminars the solutions students had for this text book problem were hardly related to elementary or historical approaches.

These solutions, with only minor variations occurred in multiple (parallel) seminars on mathematics education. The tasks were part of a seminar presentation prepared by students on real numbers. The student's answer was to express half the length of the edges of half a regular n -gon by the sine of the angle π/n . They expressed their calculation using the calculator and multiplied this length by $n/2$ also with a calculator. The presentation of the solution consisted of giving symbolic expressions. The irrationality of the terms of the sequence, which approximate π was not noticed because the computer automatically rounded. Reflections on the convergence of the sequence and the transition from geometric objects (lines) to arithmetic sequences, i.e. sequences of numbers were not made.

Approximation of π

The determination of the number π was in the history of mathematics an important task. Various processes have been developed. One method is to approximate a semicircular arc of radius 1 by a line of equal chords.

a) Calculate π for approximately three equal sections. Evaluate the results.

b) Develop a process that allows you to find a better approximation of π .

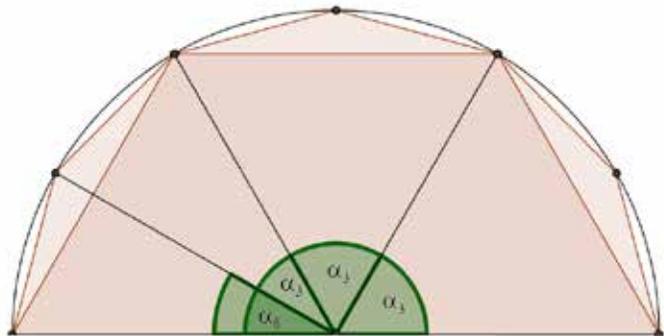

Figure 2: Example of an exercise in historical jacket.

Despite the historical jacket and the instruction for a direct calculation, the students calculated the solution with calculator using the sine function even for half a hexagon – although the three equilateral triangles give the approximation of π by 3 accurately. If you want to combine the cognitive process with the historical one, the reason for the superficial solution can be seen as a lack of *experimental* and *intuitive* awareness (see Kaenders and Kvasz 2011). The easy change between the geometric and arithmetic representation was based less likely to automation or a deeper understanding of the limit, but on the lack of experience with pathologies. The latter historically led to the necessity of the precise formulation of the limit concept. The two examples in Figure 3 (Lietzmann 1949) above do not represent this historical development of a precise formulation of a geometric limit. However, they show that they are necessary and can therefore lead to doubts about the solution and give rise to rethink the solution.

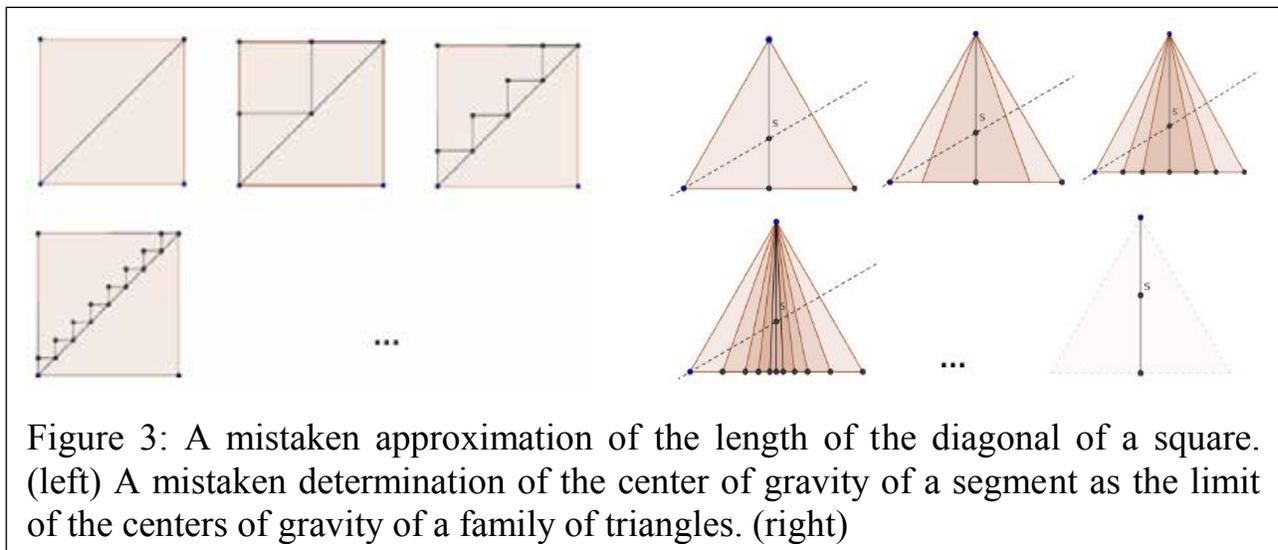

Figure 3: A mistaken approximation of the length of the diagonal of a square. (left) A mistaken determination of the center of gravity of a segment as the limit of the centers of gravity of a family of triangles. (right)

Simplifications of the long historical development of the concept of limit in the classroom are of course essential. Omission of pathologies in this example could be seen in relation to the historical development as an aggravating, trivializing simplification rather than a support to conceptual understanding.

The next example relates to a change in the usual representation of the solution of systems of equations. Given a system of linear equations with two equations and two unknowns, such as:

$$2x + 2y = 3$$

$$-5x + 2y = 2.$$

The approach proposed by the math textbook begins with the algebraic solution of the system: by equivalent transformations, the two equations can be converted into two equations, from which the solution $x = 1/7$, $y = 19/14$ can directly be read of. The corresponding geometrical solution process is started with the visualization of a given system of equations. Here, the linear equations can be brought into a form from which the transition *equation* \leftrightarrow *geometric object* is routine operation.

Since this has been trained in the context of drawing graphs of linear functions, it is a common textbook exercise to find the equation of the form $y = mx + b$, when the line in a coordinate system is graphically given. Just examples of the form $x = b$ cannot be selected. In the next step, the transition between the expression $y = mx + b$, and the function graph is automatized. The visualization of the algebraic method or the "geometric solving" of the system of equations is now to determine the two function expressions corresponding to the initial equations, to draw the graph and read of the coordinates of their intersection.

The use of the concepts linear function, with slope and intercept, the ability to draw straight lines and the associated determination of the intersection of two graphs of functions by reading of the value of a function at a point are required as appropriate skills. The concept of equivalence transformations – in this case to determine the nicest representatives $x = x_0$, $y = y_0$ from the set of all pairs of linear equations with the solution set $\{(x_0, y_0)\}$ is not evident in the described approach: in the geometric representation of the equivalent transformations in each step the two lines preserve the intersection of the lines. Since the straight line $x = x_0$ is not common in the understanding of function graphs, the geometric representation of the algebraic solution method is reduced to the visualization of the given lines, and reading of the intersection. The described way of visualizing the equations, graphs is probably chosen also because the understanding of analytical geometry of curves in the plane, especially of lines is not developed.

The concept illustrated in Figure 4 of equivalent transformations and conservation laws, which is essential for the solving of systems of algebraic equation of higher order, and appropriate geometric representations by hyperplanes cannot be generalized by the transition to function graphs and values of a function at a point.

The language used in the example shows above all a lack of contextual awareness. Instead of a change of representation a visualization of an equation is performed. From this we can conclude a lack of logical awareness, too, i.e. the role of systems of equations in an adequate development of theory is ignored. When we orient ourselves in the historical process, then the later and in a different context developed representation of functions as graphs of functions in Cartesian coordinate systems is rather misleading here – the Cartesian coordinates go back to René Descartes (1637)

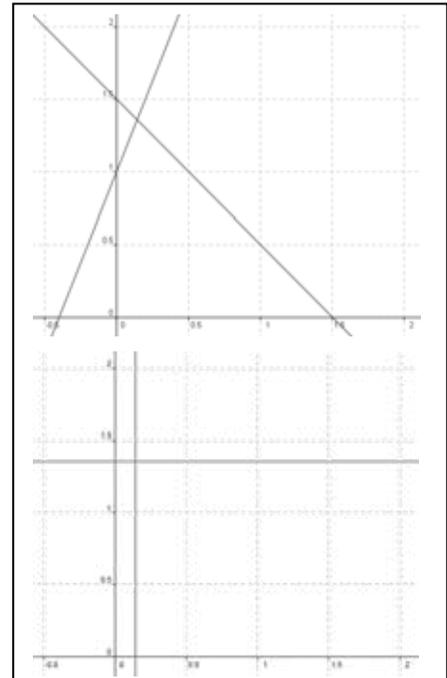

Figure 4: Visualizing of equivalent systems of equations:

$$\left| \begin{array}{l} 2x + 2y = 3 \\ -5x + 2y = 2 \end{array} \right| \Leftrightarrow \left| \begin{array}{l} x = 1/7 \\ y = 19/14 \end{array} \right|$$

The lower situation does not exist in the language of school books.

and the concept of a coordinate change to Christiaan Huygens (1656). One could denote the misplaced use and the transfer of concepts that are developed in other contexts as *ahistorical implant*.

Another example deals with the currently conventional introduction of integral calculus, where three different aspects of the integral are introduced simultaneously:

- Integral as oriented area,
- Integration as anti-derivative,
- Integration as a way to determine a function from a given function of change.

One aim of this introduction is the motivation and direct introduction of the fundamental theorem of differential and integral calculus. To allow a direct connection between calculation of area and the determination of a function from the function of change, the change function is replaced by a step function, and thus the oriented area under the curve is replaced by the area of rectangles. The original functions are monotone, the determination of the step function is carried out graphically by estimating the areas of respective triangles. The replacement of the function by a step function aims at simplicity of calculation, but does not fit into the framework of the developed mathematical language of calculus: The geometric transition from secant to tangent with slope or the notion of actual speed would suggest an approximation with piecewise linear (rather than piecewise constant) functions. A historical insert of the parabolic segment method of Archimedes would show that it is a technically challenging problem and so, it could motivate the need for the later introduced Riemann sums.

The language used shows *experimental* and *intuitive* awareness. Upon further conceptual and technical development of the concept of the integral taken simplifications can nevertheless lead to motivation and understanding of issues and the development of logical and theoretical awareness counteract. The summary described the technically difficult problem of the definition of the Riemann integral, and of conceptual understanding of the relationship between differential and integral calculus will not do justice to the complexity of the task, so you might call the representation as a caring shortening.

A well-known transformation of historical contexts is what Freudenthal formulated as a criticism to the New Math movement (*anti-didactic*) *inversion*, which even today often determines the representation of higher mathematics at the University:

“... the final result of the developmental process is chosen as the starting point for the logical structure in order to finish deductively at the start of the development. This genetic-logical inversion expresses itself as a didactical – or rather antididactical – inversion.”
Hans Freudenthal, 1991, Chapter 11, S. 305.

In this kind of concept development the focus is on the long-term development of *logical* and *theoretical* awareness. The inclusion of an implicit history of the

development of a concept and the *ostension* of a notion would lead to a more balanced mathematical awareness that also includes *intuitive* awareness.

And finally, we introduce the well-known parable of Achilles and the tortoise by Zeno of Elea (495 - 430 BC.) Still today it is treated in many math textbooks. Unfortunately the Zenon paradox causes rarely the expected confusion or amazement. That may be partly due to the role of the problem as an application to the convergence of geometric series, which might inhibit a direct confrontation with the verbal formulation of the paradox.

It was interesting to observe that the arguments in the teaching seminar consisted in the verbal recapitulation of the steps. However, to find own formulations and phrases related to the initial formulation of the Zenon paradox were a problem to our teacher-students. Paradoxes force a change of perspective, re-orientation and provoke cognitive conflicts. One way to achieve this would be by the following possible question of Thomson (1954): Suppose a referee actuated whenever Achilles catches up to the new position of the turtle, the switch on a lamp. If the lamp is switched on or off when Achilles overtakes the tortoise? Also indirectly present ideas, such as the overall presence and familiarity with real numbers and their completeness, separate the students from the original and the paradoxical phenomena. The neglect of such indirectly involved factors when considering historical episodes can be called *cultural alienation*.

For the analysis of the concept development of the textbook examples, it was helpful to further investigate, identify and name the changes made to the historical development of concepts (e.g., reductions, simplifications, omissions, ...). To draw attention to several emerging problems in the integration of historical content, we have introduced these following terms: *(ahistorical) implant*, *(caring) abridging*, *(trivializing) simplification*, *(anti-didactic) inversion* and *(cultural) alienation*. For the previous investigation of handling and development of concepts in teaching at the hand of concrete textbook examples and the description of possible problems of precise formulation, of conceptualization and transfer the perspective of mathematical awareness was useful. Based on an analysis of the mathematical language, we examined two aspects: First, what qualities of mathematical awareness do not occur in the language and symbolism and second, by which evolution of the subject could these qualities of mathematical awareness be developed.

THE HISTORY OF 5TH POSTULATE: LINKING MATHEMATICS WITH OTHER DISCIPLINES THROUGH DRAMA TECHNIQUES

Panagiota Kotarinou, Charoula Stathopoulou

University of Thessaly

We present the design and implementation of a cross-curriculum project concerning the history of 5th postulate that was carried out among 11th grade students in a public school in Athens. We used History of mathematics as a unifying framework for an interdisciplinary curriculum through 'Drama in Education' techniques. Drama in education contributed to a creative way for the students to reflect on broader learning issues (emotional, cognitive, social and political) mostly because of Drama experiential dimension. Students' active involvement through this framework helped the students to conceive both mathematics and other disciplines knowledge in a meaningful context and made them realize that mathematics is a cultural and social construction; a component of our world.

INTRODUCTION: HISTORY OF MATHEMATICS AND INTERDISCIPLINARITY

Specialization in education is a modern phenomenon, which results in viewing present day school mathematics as completely separate from other subjects of the curriculum. Meanwhile, school administration and timetabling of classes also often work against efforts to make links between subjects (Grugnetti and Rogers, 2000: pp.52) making mathematics teaching ineffective (Anice, 2005).

This finding leads to the reassessment of the content and way of teaching mathematics. Interdisciplinarity is suggested as a way of "injecting" meaning to mathematics. This rationalization process is associated with personal experiences and the collective engagement in an activity. Interdisciplinarity is perceived as a complex process which, in the context of teaching design, requires the detection of each child's personal rational experience and the cooperation in groups based on common interests in complex matters (Kalavasis, 2008: pp. 24).

Interdisciplinary methods strive to create connections between traditionally discrete disciplines such as mathematics, the sciences, social studies or history, and English language arts (Coffey, 2011). During interdisciplinary teaching, educators apply methods and the language of more than one academic discipline to examine a theme, issue, question, problem, topic, or experience, enabling students to see the links between various subjects and consequently to see the knowledge in a unified way, making their school experience more compatible with their real life. The objective of interdisciplinary teaching can be orientated towards content, method, competence and ways of thinking,

as well as to the characteristic forms of subject- parallel and comprehensive-orientation (Bechmann, 2009: pp.32).

Throughout the literature we encounter different kinds of interdisciplinarity. In Jantsch's (1972) five level taxonomy of disciplinarity the three middle ones that may be considered as 'true' types of interdisciplinarity are: *pluridisciplinarity*, when various disciplines, usually at the same hierarchical level, cooperate without coordination about a common theme, *crossdisciplinarity*, when the axiomatics of one discipline are imposed for support upon other disciplines and *interdisciplinarity (proper)* when there is coordination in all involved disciplines by a higher level concept (Jankvist, 2011).

Research has shown that interdisciplinary and cross-curricular teaching can increase students' motivation for learning as well as their level of engagement and thus provide conditions for effective learning (Thaiss, 1986). Barton and Smith (2000) explain that interdisciplinary units enable teachers to use classroom time more efficiently and address content in depth, while giving students the opportunity to see the relationship between content areas and engage in authentic tasks. '*Interdisciplinarity is increasingly viewed as a necessary ingredient in the training of future oriented 21st century disciplines that rely on both analytic and synthetic abilities across disciplines*' (Shriraman, 2009: v).

The History of mathematics provides a suitable framework both for integrating varied disciplinary areas of curriculum, as well as for helping students with their understanding both of mathematics and other subjects. Keeping in mind that the history of mathematics as the history of ideas is strictly linked to the history of human beings, we have to analyse the cultural, political, social, economic contexts in which ideas arose (Grugneti and Rogers, 2000). Interdisciplinarity through history of mathematics can reveal this wider aspect of mathematics as a cultural activity; as a human activity both done within individual cultures and also standing outside any particular one.

This integration of history is not confined to traditional teaching delivery methods, but can often be achieved through a variety of media such as doing projects, watching films, constructing models, researching history in libraries, devising dramatic presentations, surfing the www, which add to the resources available for learner and teacher (Nagaoka, 2000).

In this paper, based on our research results, we claim that the use of 'Drama in Education' in Mathematics teaching motivate students to reflect on broader learning issues (emotional, cognitive, social, and political) mostly because of Drama experiential dimension.

HISTORY OF MATHEMATICS AND 'DRAMA IN EDUCATION'

Drama in Education is (DIE) is a form of theatrical art in which the child while creating and playing roles, projects himself into fictional characters and situations, exploring and expressing his ideas with his body and his voice (Alkistis 2000: pp.78). It is a highly structured pedagogical procedure utilizing specific rituals and techniques of dramatic art which grants us, through the creation of an imaginary world, the context for teaching a notion, an idea, a fact, a solution of a problem as well as the potential of cultivating personal and social skills. It constitutes a dynamic and creative tool for the teaching of different subjects of the syllabus through collective and experiential activities (Andersen, 2004), putting children in the position of the actor (experience), audience (critical ability), author (meaning) and director (form) (Neelands 2008). DIE combines a) form and content b) action and reflection c) logic and imagination d) thought and emotion and e) body and soul.

Regarding the teaching and learning of mathematics, the research of the influence of introducing drama in the teaching process, limited in primary and junior high school, is very encouraging in students' understanding and retention of mathematical notions (Saab, 1987, Omniewski, 1999, Fleming et al., 2004, Duatepe, 2004) and in creating positive impact in their attitudes towards mathematics (Duatepe, 2004). Specific techniques such as the 'as-if' approach can create the context for teaching a concept, an idea or an event and offer opportunities for exploring mathematics in a variety of historical, social, political and cultural contexts (Kotarinou et al., 2010, Ponza 2000b, Pennington and Faux, 1999).

THE RESEARCH METHODS AND CONTEXT

Empirical data for this paper arose from our research on exploring the dynamics of Drama in Education Techniques in teaching Geometry in high upper school. This paper discusses the following research question: does and in which way interdisciplinarity through history of mathematics in a DIE setting affect students' learning as well as their epistemological beliefs about mathematics?

The setting: the research was carried out in a group of 26 (11th-grade students) from different directions of studies in the 2nd High School of Ilion (Athens, 2010-11) during four months.

The method: we designed and implemented an interdisciplinary didactical intervention, a teaching experiment (Chronaki, 2008). The teaching experiment concerned the teaching, through Drama in Education techniques, the axiomatization of Euclidean and Non-Euclidean Geometries as well as the history of Euclides' fifth postulate. The question of judging the effectiveness of integrating historical resources into mathematics teaching may not be susceptible to the research techniques of the quantitative experimental scientist. It is better handled through qualitative research paradigms such as those developed by anthropologists (Fauvel & van Maanen, 2000, pp. xvii).

Exploitation of ethnographic research techniques (observation-interviews) helped us gathering research data. All students' presentations were videotaped and analyzed regarding the proper use of mathematical notions in their dialogues, while some episodes of students' group work were audio recorded and analyzed regarding the role of Drama as a mediating tool for the negotiation of meaning and the development of understanding.

The interdisciplinary project 'The history of 5th postulate. From Euclid till non-Euclidean geometries': Within this paper we present the unit of the teaching experiment which concerned the history of the fifth postulate as one of the five set by Euclid and it being challenged as an independent one by mathematicians of classical Islam and by the West mathematicians of the 19th century, until its replacement following its refusal by Bolyai, Lobatscevski and Riemann.

The researcher in teaching role carried out the project in 18 teaching periods, in Geometry, History, Literature, Greek Language, and Ancient Greek Language class. The three main points of the interdisciplinary project were: the mathematics per se, the Mathematicians and the historical, cultural political, social, economic contexts in which these mathematical notions arose. Our teaching aims were: a) the students acquainting with the axiomatization of Euclidean Geometry b) the students perceiving the role of the postulates in the axiomatic foundation of a science c) through the errors of different proofs of the fifth postulate, the students to acquaint with the various equivalent with the 5th request propositions that characterize Euclidean Geometry d) students perceiving that Mathematics is constructed through its development located in various specific historical, geographical, cultural and social contexts.

The project consisted of the following units-steps:

1. *Euclid's Elements and the axiomatization of Euclidean Geometry (6h):* The relation between Euclid's axiomatic foundation of Geometry and Aristotle's 'Logic' was studied as well as the definitions, the Postulates and Common Notions from the Book I of Euclid's 'Elements'. Knowing from Thomaidis and Tzanakis, (2010) research, that the study of original texts in the classroom creates a new didactical environment in which students actively participate in the classroom discourse and exhibit a positive attitude towards the subject, which never happens in conventional geometry teaching, we gave students, in Ancient Greek language class, excerpts from Euclid's original texts and requested them to read and translate the text. In Geometry class, students in groups were asked to answer questions concerning the mathematics of the text, after having studied some relevant excerpts of the book 'The Historical Roots of Elementary Mathematics' by Bunt Jones and Bedient (1976). Then students prepared and had performances concerning the postulates, the common notions and some definitions of Euclid axiomatic foundation of geometry, using drama techniques as 'role-playing', 'reportage', 'alter-

ego', 'interview'. We must notice here that in this unit students for the first time came into contact with Euclid's own form of the fifth postulate.

2. *Euclid and the historical, cultural and political frame of his era (4h)*: The purpose of including elements of the history of mathematics has to do with showing the students that mathematics is dependent on time and space, culture and society, that mathematics is not 'God given' and that humans play an essential role in the development of it (Jankvist, 2009:2734). For this reason, in order the students to know the historical context in which Euclid's Elements were written, a digital presentation was held by the researcher in History class, concerning Alexandria in the Hellenistic period, while excerpts from the book "The Parrot's Theorem" were read concerning the history of this era, as well as the reasons for the blossoming of Mathematics in this historic period and area. Knowing that Dramatization is an important tool in the repertoire of a teacher for humanising and contextualising the development of mathematical concepts (Hitchcock 1996a; 1996b; Ponza, 2000a, 200b), the chapter 'Euclid's conceit' from J. P. Luminet book 'Euclid's bar', presenting the mathematician Euclid and his era, was read expressively by some students in Literature class, while some scenes of the same chapter concerning differences in thought between Pythagorians and Euclid, as well as historical anecdotes about Euclid were dramatized.

3. *'History in shadow': the controversy of Euclid's Fifth postulate till 18th century (5h)*: There is a common belief held by many, teachers and students alike, about the static nature of mathematical concepts (Jahnke, 2000). The history of Euclid's Fifth postulate provides the potential to undermine this entrenched perception. In mathematics class the unsuccessful efforts of Arabs mathematicians Thabit ibn Qurrah, Al-Haytham, Omar Khayyam and Nasir al-Din al-Tusi as well as Saccheri and Lambert to prove the famous Euclid's fifth postulate were presented, while equivalent to the 5th postulate propositions were presented to interpret the mistakes made in these efforts. In history class the development and the reasons of development of Mathematics in the Islamic world, from the 8th to the 13th century AD, were discussed. For this reason, a short extract from the book "The Parrot's Theorem" of Denis Guedj (pp. 269-272), which refers to the "House of Wisdom" in Baghdad and its role in the collection and translation of the work of the ancient Greeks, was read. A combination of 'Shadow Theatre' and 'role playing' was used for presenting all these unsuccessful efforts as well as the mistakes made at the proofs.

4. *János Bolyai, Lobachevsky, Riemann, the founders-creators of non Euclidean geometries (3h)*: As the biographical allusions serve the purpose of humanizing concepts (Ponza, 2000a) students, in Greek language class, studied the biographies of the two latter mathematicians from Bell's book 'Men of Mathematic's' as well as quotes from letters from Gauss to F. Bolyai and between father and son Bolyai. Different Drama

techniques as ‘Letters’, ‘Portrait’, ‘Role on the wall’, ‘Conscience alley’, ‘Conflicting advice’ were used for presenting their work and some snaps shots of their lives.

Integrating history of mathematics invites us to place the development of mathematics in the scientific and technological context of a particular time and in the history of ideas and societies (Jahnke, 2000). Hence, we emphasized that many times dominant philosophical stances during a historical era act as obstacles to the challenge and the overcome of assumptions in mathematics, as well as to the publication and widespread acceptance of new mathematical theories. An example lies in our case of concern, the controversy of the uniqueness of Euclidean Geometry. Within this context we mentioned the example of Immanuel Kant, the dominant philosophical physiognomy of the century that preceded the discovery of non-Euclidean geometry, whose ideas about space and geometry acted as an obstacle on the acceptance of non-Euclidean geometry. Some attribute the non-publication of Gauss's ideas on non-Euclidean geometry just in his unwillingness to conflict with Kant (Davis, 2007: pp. 133). In this unit

RESULTS AND DISCUSSION

Analysis of the dialogues in students’ Drama performances suggests that students conceived the mathematical notions that they had been assigned to present, integrating them correctly in their dialogues. As Ponza (2000a) refers: *‘This method of teaching is not just intuitive. When students write or dance or perform mathematics they work out, they analyze, organize and solve’*.

The students’ answers in the interviews, two months after the end of teaching experiment, indicate that students themselves believed that through Drama based instruction they learned better and easier.

-(A) The way we presented, using theater, it isn’t that we just sat up and said it, we had to prepare it, and this required to have understood it.

-(I) in the way we did all these, I think that one learns more easily. What we learned (through this procedure) wasn’t designed for learning by heart or to show to the teacher that we really learned that. I think it was easier to learn in this way and to retain this knowledge in our mind.

-(G.) Well. Until now, geometry was completely indifferent to me, and still is, if they teach it the way they do. Because to learn something by heart it is not nice, while if there is a story it is a little more interesting, while if you do a sketch it is nicer and it becomes a more interesting lesson. Because you learn more this way.

What was the main effect of Drama in students’ learning? In this teaching experiment, due to students’ responses, it was Drama that motivated all students’ active participation in the teaching experiment.

-(S.) If we have done all the tasks except the presentations, we would have been bored to death.

- (N.) *Without drama, I don't think that anyone would be interested (in the project).*
- (V.) *It was completely different than just writing stuff, from comprehending something yourself and trying to pass it to others. It was very nice.*

How did interdisciplinarity affect students?

• ***In unifying knowledge:*** Interdisciplinarity enabled students to see the links between various subjects and consequently to see the knowledge in a unified way.

-(St.) *It was something very different, something not expected and we had to wait till this grade of high school to be able to do something similar, a similar activity that is related with something different from the syllabus. Indeed the specific issue that connects Mathematics with different disciplines as Ancient Greek, History, was very interesting. It was interesting because we talked about Euclid but not only about the postulates and the various theorems, but we talked about the historical and cultural context that prevailed in Alexandria at that time.*

-(J.) *This was interesting and we had not done something like this before. I think this did History, which I do not like, more interesting because I learned about mathematicians and I like this more.*

• ***In students' beliefs about Mathematics' historical and cultural context:*** Students experienced a diachronic evolution of geometry and its interaction with the historical, the scientific, and the cultural evolution, as well as with social, economic and political conditions of each era. The introduction of mathematics history into the course curriculum attracted the attention of pupils, since it was the first time that they had such an experience. Students welcomed the activities related to the history of geometry, which linked the science back to the specific historical, political and economic context within it developed

-(Char.) *It was nice that we learned about this era, while in the ordinary lesson we didn't learn anything about this, it was just triangles, squares.*

From students interviews it appeared that there were students who linked the development of mathematics with the economic development of the region in which it was developed.

-(St.) *We realised that in order for the science to be evolved, there needs to be evolution in all other areas first, starting with financial areas and then cultural ones'.*

• ***In students' beliefs about Mathematics as a human creation:*** From the follow-up answers in the interviews concerning students' beliefs about the evolution and development of mathematics, it seems that students believe that mathematics is timeless and superhuman and ahistorical.

-(A) *The historical connection of mathematics is very important. Mathematics seemed like having come from heaven. We had just been told the 1 and 2 and the numbers and the calculations, all ended there. The historical connection of mathematics is very important, as*

it is its historical evolution as well as that of Geometry.

- (V.) Previously, I thought that the knowledge of mathematics came from God, from heaven. I couldn't be in the process of thinking that someone thought of it.

Through the efforts of proving Euclid's fifth postulate and through the mathematicians' biographies, students perceived mathematics as a historically evolving human creation and also realized that other cultures also, have contributed to what is defined as Western mathematics.

- (Tz.) It was nice, because if you only see the result it is boring. You must learn a little bit of what has happened in the past; who created it, so it was nicer, I learned more things.

- (Th.)...We saw how theorems and postulates have been created and it was interesting, because it is difficult to understand them if you see them in their final form.

Students met for the first time the struggle of many mathematicians that has not been crowned with success. They emphasized the continuous and strenuous effort that was made by the mathematicians of the wider Islamic world and later by Renaissance mathematicians, to prove the fifth postulate.

-(Tz) In the beginning I said, well, as they don't find it, why don't they stop? Yet they have been trying and trying. They liked all these too much.

We asked students to tell us their thoughts from their acquaintance with the biographies of Bolyai, Lobachevsky and Riemann. Students in their responses highlight the dedication of all these people in mathematics and the perseverance in their objectives.

- (Mar.) ...I saw that these people in a great part of their lives were dealing with mathematics and they had set a target, trying to reach it. It was very interesting, all this effort to prove something, really interesting.

CONCLUSIONS

Our research offers considerable evidence of the effectiveness of History of Mathematics in linking mathematics with other school disciplines. History of Mathematics became an open door towards interdisciplinary work and consequently towards a wide range of possibilities for all subjects. Students had the opportunity in language class to write texts, which included mathematical discourse, while in History class for the first time they experienced mathematics as a cultural treat. This interdisciplinary approach was the key role for the historical and social context in which mathematical concepts were created to be illustrated and provided students the opportunity to modify their epistemological conceptions about mathematics. Likewise, cultural construction and the contribution of different cultures in the creation of mathematics were showcased. Drama provided students the incentive to work while through drama techniques students were able to experience all these dimensions of mathematics, not only mentally but emotionally and physically.

THE POWER OF MATHEMATICS EDUCATION IN THE 18TH CENTURY

Jenneke Krüger

Flisme, University of Utrecht, Netherlands

In the Dutch Republic in the 18th century mathematics was considered very important for many professions. However there were hardly any national or regional educational institutes which provided mathematics education. Three orphanages in different towns received a large inheritance under condition that they provided education for technical and artistic professions. The Foundations which were established had a curriculum in which mathematics was the main subject. The influence of several curriculum components and some external curriculum factors are recognisable in documents and archival data. This is illustrated by the history of one student.

THE FUNDATIE VAN RENSWOUDE

During the 18th century in the Dutch Republic mathematics was considered very important for professions such as navigation, architecture, the technical weapons, shipbuilding, water management and also fine arts (Van Maanen, 2006). However there was a serious shortage of mathematically trained professionals. The main reason for this was the absence of national or regional institutions which offered mathematics education (Beckers, 2005; Boekholt & Booy, 1987). The example of the Dutch Engineering School at Leiden University in the 17th century (Krüger, 2010) had resulted in lectures in Dutch language on fortification, navigation and architecture at a few institutes for higher education. But they occurred only intermittently and were not for those on a low income. Professional education was mainly left to individuals, the quality varied and the fees could be high. The Dutch adopted a religious form of Enlightenment; they believed in progress through mathematics and science, which also revealed God's work. Many saw the value of education, also for poor people; initiatives of wealthy individuals, of learned societies and of local government became more common in the Dutch Republic during the 18th century (Dodde, 1991; Roberts, 2010, Smid, 1997). An early example of such an initiative is the legacy of Maria Duyst van Voorhout, baroness of Renswoude: in 1754 three orphanages, in Utrecht, Delft and The Hague, each inherited about 500 000 Dutch guilders (HUA 771, inv. 3). The main condition was that the money should be used to select talented orphan boys, at least 15 years old and teach them separately from the other orphans in:

Mathematics, Drawing or Painting Art, Sculpture or Stone Cutting, practices in building dykes to protect our Country against floods or similar Liberal Arts....

It seems that Mathematics was meant as a profession, but also as the main subject taught: all the professions mentioned used mathematics in some way. One of the other conditions was that the capital should be administered by an independent

administrator and that there should be some alignment between the three Foundations (HUA 771, inv. 1). As a result, in 1756 three Foundations were established, each called *Fundatie van Renswoude* (in full: Foundation of the Baroness of Renswoude), with communal rules, the General Regulations (HUA 771, inv. 5). The archives of the Foundation in Utrecht are well preserved, they provide much information about the intended and implemented curriculum. A question one may ask is:

Which factors and which actors influenced the curriculum of this Foundation?

The main subject in all three Foundations was mathematics or rather mathematical sciences. When one analyses the available information on the curriculum many curriculum components, which are distinguished in present day research, are recognisable. In this paper I will discuss some of these components, but also some other factors which were of notable influence on the curriculum of the Foundation in Utrecht. This will be illustrated by the history of one of their students, Dirk Kuijper.

CURRICULUM RESEARCH

A useful model to describe curriculum and its components is the spiderweb model used by Van den Akker (2003). Characteristics of the spiderweb model, which has ten components, are the visibility and influence of these components in the intended and/or implemented curriculum and the interconnections between the various components. If one component changes this effects some or all of the others and each component may be influenced by others (fig. 1). In this paper I add the component Alignment, as this is mentioned explicitly in all documents of the intended curriculum. For instance, the regents

Fig. 1: Spiderweb model

of the three Foundations were to discuss with each other the state of affairs and progress in the three institutes at least once a year. These meetings promoted the wish to find a mathematics teacher of similar quality as the one in Delft. Also within the Foundation teachers and housefather had to inform each other of the students requirements and behaviour (HUA 771, inv. 5, inv.8).

There are other factors which are influential, but a major difference with the curriculum components mentioned is the mainly one-way direction of this influence. They could be named ‘external factors’. Finance and transition are the examples mentioned here. Transition refers to the preparation of students for the next stage of their life, after completing the curriculum. See table 1 for an overview of curriculum components and external factors.

<i>Rationale</i>	Why are they learning?
<i>Aims & Objectives</i>	Toward which goals are they learning?

<i>Content</i>	What are they learning?
<i>Learning activities</i>	Through which activities are they learning?
<i>Teacher role</i>	In which way does the teacher facilitate the learning?
<i>Learning materials</i>	With what materials are they learning?
<i>Grouping</i>	With which students are they learning?
<i>Location</i>	Where are they learning?
<i>Time</i>	When and for how long are they learning?
<i>Assessment</i>	How far has their learning progressed?
<i>Alignment</i>	Is the learning coherent with the larger curriculum?
External factors	
<i>Finance</i>	Which financial means are available to facilitate learning?
<i>Transition</i>	In which way is the start of students in the next stage facilitated?

Table 1: Components and external factors of the curriculum, based on Van den Akker (2003)

The influence of these curriculum components) and external factors are to some extent illustrated by the history of student Dirk Kuijper.

DIRK KUIJPER (1766 – 1830) AND THE *FUNDATIE VAN RENSWOUDE*^[1]

Fig. 2 Dirk Kuijper

Dirk came into the care of the town orphanage on 3 May 1769, when he was about three years old. Thirty years earlier, his prospects would have been rather bleak. However, since 1756 the Foundation, of which the big house was situated next to the orphanage, offered a better opportunity to talented boys. In 1756, only some of the boys of the right age (15 – 18 years old) could read a little and none could do arithmetic. So the regents had appointed a carefully chosen teacher to teach the eligible boys reading, writing and arithmetic. This was the preparatory school and in 1773 Dirk was one of the 22 boys in the preparatory school, with ages ranging from 5 – 15 years old (HUA 771, inv. 37). Of this group 10 boys would in the following years be admitted into the Foundation.

The mathematics instructor (mathematics teacher) of the Foundation, Laurens Praalder, was the main teacher and also the supervisor of the Foundation school. He visited the preparatory school at least once a week to watch progress and to discuss with the teacher the potential of each boy. Once a year the regents asked his advice on which boys should do an admission exam to assess if they qualified for entrance into the Foundation. On 28 April 1779 Dirk was one of the boys who was allowed to take the exam, which consisted mainly of arithmetic. On 11 June 1779 the board of regents admitted Dirk, 13 years old and one other boy, who was 12 at the time. The average age on admission was 15 years.

Mathematical education

The education process in the Foundation was structured into three phases. During the first phase, which lasted about two years, teaching would be in small groups and the program was the same for all the students. After about two years, depending on the progress of the individual student, a profession would be chosen. In most cases the student would start in a part time apprenticeship with a work master, while continuing theory lessons in the Foundation in the evenings and during some afternoons. The third and last phase would usually consist of a fulltime apprenticeship, preferably in some other part of the country or abroad. During the first two years Dirk

Fig. 3 Large lecture room

would have about 32 hours of lessons per week, of which at least 20 were taught by the mathematics teacher. Drawing lessons, by the drawing master, took eight hours and the remaining hours were spent on writing, French language and religion. Outside teaching hours there was homework to do, mathematical exercises, drawings to finish, etc. Lessons took place in the large lecture room (fig. 3), homework was made in the dining room, under supervision. In both rooms books and writing materials were available; the mathematics teacher also liked to do practical exercises with the students, preferably based on measurements in the environment (Krüger, 2012). In spring 1781 Dirk had been nearly two years in the Foundation; he had made sufficient progress to choose a profession and start an apprenticeship. His first choice was instrument maker, however as at that time there was no suitable instrument maker in Utrecht willing to take on an apprentice, Dirk became a student of the mathematics instructor. During the following years Laurens Praalder taught him several mathematical subjects as a general preparation for technical professions.

In February 1785, Dirk had studied the following mathematical subjects: arithmetic (whole, rational, irrational and decimal numbers, calculating roots and powers of numbers), geometry (Euclid I – VI, XI and XII), algebra (including linear and second degree equations and series), the theory and practice of surveying (including trigonometry and the use of logarithms), civil and military architecture, mechanics and geography.

The importance of social and cultural education

Mathematical subjects were very important, but not sufficient to succeed. Dirk also learnt to draw, both technical and artistic drawing, French language and how to write properly. Students would need these skills in most of the professions for which the Foundation provided education. They also needed the skills to maintain a position on a middle class level of society. So like all students Dirk learnt proper table manners, how to read a newspaper, how to behave in company and similar skills.

Specialisation

In the course of 1784 Laurens Praalder suggested that Dirk might become an army engineer, a very unusual choice for the Foundation in Utrecht at that time. Perhaps the fact that the Director-General of the Fortifications, Carel Diederik Du Moulin, some of the regents and the secretary-administrator of the Foundation all were members of the Provincial Utrecht Society (PUG), had something to do with this new possibility of career choice for the students. PUG, a scientific Society, was established in 1773 by Laurens Praalder and J.van Haeften and attracted a good number of members (Van Haeften, 1781). Du Moulin was very much in favour of mathematical instruction for officers in the army. On 1 December 1784 the regents decided that Praalder should contact Du Moulin to enquire if he would be willing to take on a student of the Foundation. Du Moulin quite liked the idea and after an exchange of some letters on what was expected of Dirk he was sent on his way to the Grebbe on 12 February 1785. He had with him with a warm coat, field maps, a suitcase with the necessary clothes and linen, a good quality surveyor's chain, a surveyor's level and an astrolabe. Dirk was to write every eight days to report on the spending of the extra pocket money he received and on his whereabouts.

Apprenticeship and politics

During 1785 Dirk worked as an apprentice-engineer for the army. Some of his letters are kept in the archives; he wrote on the work he was doing and where he was staying. He wrote to the regents in general, to regent Nes, and later on also to mr. Van Voorst, the secretary-administrator from 1788 – 1802 (HUA 771, inv. 38; van Lier, 1954).

Towards the end of Dirk's first year, in September 1785, his supervisor, a major Kupfer, wrote a letter to the regents in which he was very positive; he mentioned Dirk's diligence, good behaviour and skills. The major proposed to employ Dirk in the army, in that way he could earn some income as well. The regents decided to decline this offer. The Foundation was responsible for her students until they could earn an income which allowed them to be independent and they considered Dirk too young to be left on his own. So on 28 December 1785 Dirk was back in the Foundation home, the army had its winter stop. That winter Dirk continued to study theory of military engineering. In the spring of 1786 Dirk worked under guidance of captain Ulrich Huguenin, who also appreciated Dirk very much and who in the years to follow would be important for his career. Huguenin had studied mathematics while in the army and had also taught mathematics at a private school for artillery officers. Like Du Moulin he considered knowledge of mathematical sciences very important. Dirk started to learn German during that year, on his own request. Possibly Huguenin had advised him on this to enable him to study the German military literature. Huguenin was in the artillery, so this meant for Dirk a change from military engineering to artillery. He also proposed to let Dirk enrol in the army. Unfortunately for Dirk, the political situation had changed; in October 1786 the patriots had come to power in Utrecht. As a consequence the regents of the Foundation were either patriots

or neutral, as most Orangist regents were replaced by patriots. The army in principle supported the Orangists, so the regents could not allow a student of the Foundation to fight in the army against their patriotic comrades. Dirk was not allowed to continue with his work for the artillery, he remained in the Foundation; during 1787 he supervised defence works and enlarged a map of Utrecht, on order of regent Eyck, an active and popular patriot. In September 1787 the Prussian troops intervened, the Patriots lost power and a number of them, like regent Eyck, went into exile for some years. Most patriotic regents were replaced by Orangists, so a military career became again a possibility for Dirk. In December 1787 regent Kien told the meeting that he recently had met captain Huguenin who had expressed his regrets that Dirk Kuijper had not returned into the army. The regents decided at once to invite Huguenin for a dinner and to tell Dirk about the good opinion captain Huguenin had expressed. Soon after it was decided that Dirk should train as an artilleryist, but in accordance with the regulations he remained a student of the Foundation for the time being. That meant that the Foundation paid for most of his cost of living and study.

The start of a career

On 27 February 1788 Dirk left for The Hague. As was common in the army he moved around frequently and was often short of money, as life in these army towns was expensive. Early in March he wrote, that he hoped to be accepted as a cadet-bombardier on 25 March, and that he had bought a German textbook, which had been advised by captain Huguenin (fig. 4). Being a cadet-bombardier meant that he earned a little bit of money, about 40% of the amount he needed for board and living. From then on his career went well. In 1788, possibly under pressure of the political

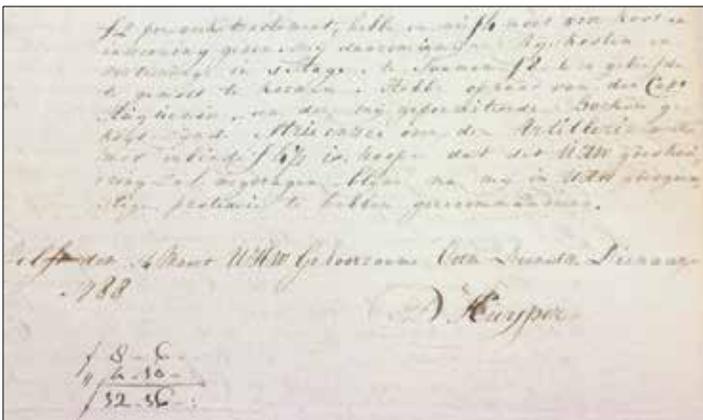

Fig. 4 Letter by Dirk Kuijper, 14-3-1788

situation, the stadtholder finally agreed to establish three Artillery Schools. In May 1789 when Dirk was in Breda, with Huguenin, he was promoted to lieutenant-to-be. Soon afterwards Dirk also became a junior teacher at the new Artillery School in Breda, with Huguenin as Director. He still had to study hard to be able to fulfil the demands of his teaching position. The Foundation received another bill, of a German bookseller. In August 1790 he became lieutenant and was appointed tutor at the Artillery School, which enabled him to become independent. He was dismissed with honour from the Foundation and in December 1790 married a wealthy orphaned young lady, ms Stuerman, from Baarle Nassau. In 1795 he became director of the Artillery School in Groningen. In that position he admitted and taught some students of the Foundation in his school.

the stadtholder finally agreed to establish three Artillery Schools. In May 1789 when Dirk was in Breda, with Huguenin, he was promoted to lieutenant-to-be. Soon afterwards Dirk also became a junior teacher at the new Artillery School in Breda, with Huguenin as Director. He still had to study hard to be able to fulfil the demands of his teaching position. The Foundation received another bill, of

Learning materials

Learning materials were considered very important by teachers and regents. They consisted of student's notes, many books, tools and instruments, such as surveying tools, compasses, drawing utensils and gauging rods. Laurens Praalder wrote his own teaching texts to use during the first and part of the second phase (Krüger, 2012). The students made extensive notes, during the first phase they may have used the available books during homework time. In phase two and three they needed more specialized books for their future profession. On average ca. 3,6% of the yearly expenditure was spent on learning materials (Table 4).

Information about the books Dirk possessed come from an inventory Dirk made in January 1787, from his letters and from the invoices of the booksellers (HUA 771, inv. 38, inv. 90, inv. 103, inv. 129, inv. 130).

On 24 January 1787 Dirk possessed some mathematics books all students used, on algebra and *Euclid* in the edition of P. Warus. For surveying he had *Werkdadige Meetkunst* by J. Morgenster & J. Knoop, a leading book on trigonometry and surveying (Van Maanen, 2006), which was used by many, but not all of the students. Also on his list were five books on military architecture; one in the style of the Dutch military architect Menno van Coehoorn, which used mainly geometry; one in the style of the French military architect Sebastian le Pretre de Vauban, published in 1784, in which book algebra was combined with geometry. These books represented different points of view on military architecture and also different mathematical approaches. He possessed a French grammar and a German-Dutch dictionary. During 1786 and 1787 the regents bought three books of B.F. de Belidor (*Sciences des ingenieur, Le bombardier françois* and *Nouveau cours de mathématique à l'usage de l'artillerie*). This suggests that Dirk's command of French was at least sufficient to study from these more specialised books. In 1788 Dirk bought *Anfangsgründe der Artillerie*, by K.A. Struensee (fig. 4). In 1789 in Breda he purchased *Magazin für Ingenieur und Artilleristen*, 11 volumes, by A. Böhm; *Lehrbegriff der gesamten Mathematik*, 8 volumes, by W.J.G. Karsten and *Mémoires d'artillerie : contenant L'artillerie nouvelle* by H.O. Scheel.

So from 1787 on he used more specialised military literature, which was written in French or German. But he also bought the eight volumes of a general mathematics publication in German. This extensive work by Karsten is still available in print.

Finance ^[2]

Finance is rarely a topic in research on mathematics curricula. However, the financial means available were very important in the 18th century, as they are today. The amount of money at the start of the Foundation was a factor which permitted the building of a home suitable for physical care and for education. The financial situation also made possible to engage good quality teachers who were well-paid. At least as important was financial management, which in Utrecht became more professional from about 1771. From 1772 – 1809 on average the yearly income and

expenditure of the Foundation were in balance, both slightly more than *f* 15000 (HUA 771, inv. 89 – 92). In 1810 the income was severely reduced, due to French regulations (Table 3).

	1772 – 1809, average	1810
Income	<i>f</i> 15909	<i>f</i> 6938
Expenditure	<i>f</i> 15378	<i>f</i> 11660

Table 3 Average income and expenditure of the *Fundatie van Renswoude* in Utrecht.

Between 1772 and 1787 there are sufficient data to estimate the relative expenditure of some entries and their range (HUA 771, inv. 89, 90). See table 4.

	Average of total	minimum	maximum
Household and clothing	30,6 %	<i>f</i> 4011	<i>f</i> 5506
Salaries	24,9 %	<i>f</i> 3686	<i>f</i> 4202
Work masters	6,5 %	<i>f</i> 250	<i>f</i> 1705
Learning materials	3,6 %	<i>f</i> 226	<i>f</i> 1076
Pocket money etc.	2,7 %	<i>f</i> 188	<i>f</i> 806
Gift at dismissal	4,7 %	<i>f</i> 54	<i>f</i> 2695
Students abroad	4,1 %	<i>f</i> 0	<i>f</i> 2494

Table 4 Yearly expenditure 1772 - 1787

During this period costs of household and clothing were on average 30,6% of the total expenditure; salaries of teachers and personnel were on average nearly 25% of total expenditure. The salary of the mathematics teacher was by far the highest, *f*1500. The costs of work masters fluctuated, but over the years the relative cost increased, from about 1,5% to about 10% of the total expenditure. Learning materials included paper, writing utensils, books and some instruments, the cost fluctuated, but there is no trend visible. A student, who became independent and thus was dismissed, usually received equipment and money to assist him in the start of his career. The remainder of the expenditure, ca. 22% of total cost, was for maintenance of the building, interest, administration, costs of meetings, etc.

Dirk Kuijper on average paid *f* 5 per week for board and lodging. He received some income from the army: about *f* 2:10 per week. The additional funding by the Foundation also was *f* 2:10 each week. The Foundation also paid for travelling costs, books and clothes. In January 1789, when he got promoted and had to make extra costs, he received an additional *f* 250. On his promotion to lieutenant and his appointment as a tutor at the Artillery School, in August 1790, his salary became *f* 49 every six weeks, which was sufficient to become independent. He was dismissed

from the Foundation on his own request and received *f* 350 as the remainder of his dismissal gift.

DISCUSSION

In the curriculum of the *Fundatie van Renswoude* in Utrecht the components and external factors, mentioned in table 1, are clearly recognisable, perhaps with the exception of grouping. In Utrecht, but also in Delft, the selected boys were cared for and educated in a location close by but separate from the orphanage. As a result it became possible to give these students not only a sound mathematical education, but also a social and cultural education, thus facilitating the transition to their future profession and position in society. This is illustrated by the history of Dirk Kuijper. He would very probably have remained a labourer all his life if the Foundation had not only offered him the opportunity to learn mathematics quite well, but also to learn languages and social skills. While he was a student of Laurens Praalder he was taught surveying theory and practice, military architecture and mechanics. This made a career as an engineer in the army a possibility, but water management, surveyor or mathematics teacher would have been equally possible (Krüger, 2012). Very important was the financial support of Dirk by the Foundation. So it was not only the mathematics which was fundamental for Dirk's career, the financial support was essential as well, as was to some extent the broader curriculum.

Important actors in the implementation of this curriculum were clearly the mathematics teacher, the regents and in this particular case also C.D. Huguenin. Not all regents had the same importance, i.e. regent Eyck, regent Kien and regent Nes seem to have been more involved than others, as was mr. Van Voorst, the administrator. Though it must be kept in mind that in archives only traces of what really happened, are to be found. In a way the students could be seen as actors influencing the implementation of the curriculum as well. Dirk himself asked permission to study German and so later on he could ask for and study from the relevant specialised publications.

In the 17th century the Dutch Engineering School at Leiden University had similar, but more restricted aims as the *Fundatie van Renswoude* (Krüger 2010). In 1863 a new type of secondary school was introduced, with mathematics and science as important subjects. Its aims were general education as preparation for the higher positions in industry and commerce and preparation for the Polytechnic School and the Military Academy. Most of the curriculum components and external factors are recognisable in these curricula as well. In all three cases mathematics is important and mathematics has to be applicable, but from the only subject in the 17th century it became one of 16 subjects in the 19th century. Comparison of the three curricula will show which factors are consistently important and in which way actors influence the success of a curriculum.

NOTES

1. Sources: Hua 771, inv. 11, inv. 12 (resolutions of meetings of regents), Langenbach (1991), unless otherwise stated.

2. A guilder (*f*) was 20 pennies, so *f*2:10 is two guilders and 10 pennies, or two and a half guilders.

EVALUATION AND DESIGN OF MATHEMATICS CURRICULA: LESSONS FROM THREE HISTORICAL CASES

Jenneke Krüger & Jan van Maanen

Freudenthal Institute, Utrecht

Our central question is: Which factors and actors influence the content of mathematics curricula? In answering this historical question we also hope to provide inspiration and references for those involved in curriculum design and evaluation. We will base our answer on historical data from three mathematics curricula from the 17th, 18th and 19th century:

1. *The curriculum of the Dutch Engineering School established in Leiden in 1600.*
2. *The 1756 curriculum for Utrecht orphans, funded from a huge legacy.*
3. *The curriculum of the HBS schools, established by the Dutch government in 1863.*

We test whether the theoretical framework of current curriculum research also applies to these historical case, and sketch a comparative perspective.

HISTORICAL RESEARCH AS A BACKGROUND FOR CURRICULUM DESIGN

We became interested in historical decisions to define or renew the mathematical curriculum because of current and ongoing discussions about this issue in the Netherlands. In discussions and plans the arguments are always shortsighted. They refer to the actual situation and to the needs for the future. Never, or at least not often, crucial episodes in the past enter the scene. Yet, historical research has a valuable set of characteristics which makes it interesting for the curriculum evaluator and designer: the historical process is completed, and therefore it is possible to study the process and at the same time its outcome; also the current observer is not involved herself or himself in the discussions of the past, which makes an unbiased approach easier; and finally the current curriculum in any country in the world is a historical construct. Therefore we expect that historical research will produce results that are important not only for historians but also for curriculum specialists.

A first and superficial analysis reveals that personal preferences of influential individuals play an important role in curriculum development, next to arguments about societal needs. This first analysis brought us to our central research question

Which are the factors and actors that influence to a high degree the content of mathematics curricula?

and in order to structure the research we subdivide this question into the following three:

- Which motivations and whose ideals are influential on the content of the formal curriculum?
- Which factors and which people determine the interpretation of the formal curriculum and its implementation?
- Which factors and which people are important for successful implementation of a curriculum?

Method

First we select three cases of new mathematics curricula in the Netherlands, which were designed in three subsequent centuries (17th-19th). For each case the listed questions will be investigated. We will analyse the data and also make a comparison between the cases. The projected outcome is a historical description, and also a list of conditions, which are important for successful curriculum design and development. Comparison of these conditions with recent curriculum design theory and with developments in mathematics education should result in criteria which are decisive for successful mathematics curricula today. We refer to curriculum studies such as (Goodlad, Klein & Tye, 1979) and (Van den Akker, 2003), and ‘borrow’ their terminology, especially the following division in stages (or ‘domains’):

- the intended curriculum, the ideal of persons who initiated the curriculum and the translation of the ideal into the formal curriculum;
- the implemented curriculum, interpretation and implementation of the formal curriculum, by teachers and through teaching materials;
- the attained curriculum, success (or lack of success) in relation to the students.

The selected historical cases are:

1. The Leiden Engineering School, established in 1600 and affiliated to Leiden University, also known as *Duytsche Mathematique*, shows the first known example in the Netherlands of a formal curriculum. The school flourished until ca. 1665.
2. The three Foundations of Renswoude, founded in 1756, offered professional education to talented orphans. Mathematics was the main subject, at least during the first two years of their education. The focus is on the Foundation in Utrecht, operational since 1761 and still existing today, although with different goals.
3. In 1863, the Dutch government established the **Hogere Burgerschool (HBS)**, a secondary school for children of citizens who would not enter university, but who were to take up higher technical or administrative positions in society or enter the Polytechnic School in Delft, the present Technical University of Delft.

For each period the data will be presented and analysed separately. They will be combined and compared in the final section, which also presents our conclusions.

THREE HISTORICAL CASES OF CURRICULUM DEVELOPMENT

The curriculum of the Leiden Engineering School (Stevin and Van Schooten)

Leiden had a university since 1575, the first one in what in 1588 would be the Republic of the Seven United Netherlands, a federal state in which the House of Orange played a crucial role. Since 1568 the Dutch were at war with the Spanish king Philip II. The war, combined with strong economic development, led to the need for a type of professional that was not yet existing, the military and civil engineer. Therefore, in 1600, the Dutch leader Prince Maurits of Orange decided to connect to Leiden University an Engineering School called *Duytsche Mathematique*. Its name points at two central characteristics of the curriculum: it was taught in vernacular, i.e. Dutch, and mathematics was the main subject.

The formal description of the curriculum, written by Simon Stevin at the request of Prince Maurits, is still available. The elaboration and implementation by one of the first teachers, Frans van Schooten Sr, is amply documented, as well as the interpretation of Stevin himself in in part 1 and 2 of his *Mathematical Memoirs* (Wisconstighe Ghedachtnissen, 1605-1608).

Prince Maurits asked his former fellow student and later private mathematics tutor Simon Stevin to write an ‘instruction’ for the teaching at the *Duytsche Mathematique*. This 3 page manuscript, dated 9 January 1600 and signed by Maurits, is preserved in the archives of Leiden University library. It was published in (Molhuysen 1913, annex 338, 389*-391*) and in a five page pamphlet (published by Jan Paedts Jacobsz, Leiden 1600). Stevin’s instruction is truly the intended curriculum, as the excerpt in Figure 1 shows:

Arithmetic: the four operation in whole numbers, rational numbers and decimal numbers, also the rule of three in those three types of numbers

Surveying on paper, that is calculating area with the use of decimal numbers

Measuring a circle, parts of a circle and area, ... learning to subdivide rectilinear figures and curvilinear figures into several parts, such as triangles or other figures, to check calculations

Measurements on paper of dykes and works to learn how many ... feet the works contain.

Fieldwork, learning how to use tools properly.

Mapping on paper what is measured in the field and the reverse, from a map setting out stakes in the field

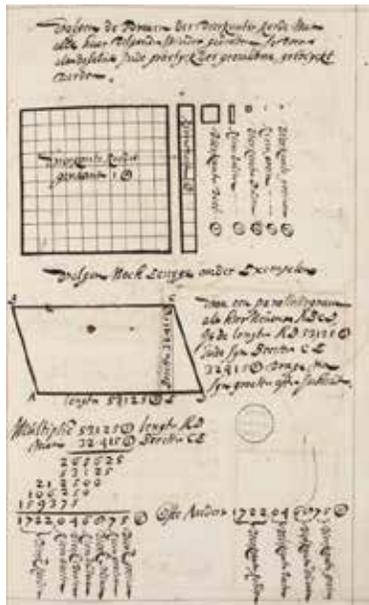

Fortification, learning the names of the parts from wooden or earth models. They will learn to make maps of towns. They will draw on paper the perimeter of fort or towns with four, five or more bastions and stake them out in the field.

Figure 1: excerpt from Stevin’s ‘Instruction’

The emphasis on practical geometry is striking. Practical geometry also involves the calculation of perimeter, area and volume, so arithmetic is part of the programme, but subjects as the area of circle sectors and measurements on conic sections are not “since engineers will only rarely hit upon these”. Note that in the field of arithmetic Stevin prescribes “decimal numbers”, which he had introduced himself in his *Thiende* (1585). The teaching of Van Schooten, who was one of the first to use decimal numbers, contributed to their introduction. Stevin also indicates that topics are to be taught both theoretically (“on paper”) and in practice (“actual surveying in the field”), which is important since ruler, compass and right angle, useful for work on paper, are to be replaced by the typical tools for fieldwork. Students were expected to spend the summer months to service the army in helping with the fortification works. There is even advice how the theoretical course of arithmetic and geometry should be taught: every lesson to be split in half an hour group instruction and half an hour tutorial in which questions of individual students are answered.

An implemented curriculum soon followed. Stevin’s own *Mathematical Memoirs* from the years 1605 to 1608 (Stevin, 1608) can be considered as such. Yet, it is quite unlikely that this expensive folio-size book was used directly in teaching. Moreover Stevin’s instruction of 1600 is well recognizable in the texts that Van Schooten used in his teaching at the Duytsche Mathematique, and therefore we take these documents, which are mainly in manuscript form, as an account of the implementations in actual teaching. Van Schooten succeeded the two first teachers of the school, Van Merwen and Van Ceulen. Both were appointed at the 10 January 1600 meeting of the Board of Leiden University in which the school was erected and Stevin’s instruction was registered. They both served until 1610, the year of their death. By then Van Schooten had already assisted Van Ceulen in the fieldwork.

It took many deliberations and even some petitions by students until in 1615 Frans van Schooten (1581/2-1645) was appointed successor to Van Merwen and Van Ceulen. A series of manuscripts, kept in the university libraries of Leiden and Groningen, indicate how Van Schooten interpreted Stevin’s instruction. A comprehensive description with detailed sources, is to be found in (Krüger, 2010). The central source that informs us about Van Schooten’s teaching is the Leiden manuscript *BPL* 1013, 256 leaves in folio, which bears the title “Mathematische Wercken door F. van Schooten” (... works by ...). The manuscript can be dated c.1622; for a discussion of the evidence and further physical properties of the manuscript, see (Van Maanen, 1987). *BPL* 1013 discusses arithmetic (extraction of roots, decimal numbers, calculation of area), geometry (definitions and axioms, propositions (Euclid), constructions), surveying (measuring distances in accessible lands and calculations), use of trigonometric tables (measuring in inaccessible lands, making maps, measuring heights (or depths), also measurements without use of tables, c.f. Figure 4), solids (calculations on all kind of shapes and materials, calculating content) and fortification (definitions, plans and calculations).

The structure of *BPL* 1013 is clear: each topic starts with an introduction. Van Schooten defines the new concepts (cf. Figure 2, the start of the practice of surveying; also interesting on this page is the use of decimal numbers; it shows the decimal comma as well as circled integer, Stevin's 1585 notation). The introduction is followed by a carefully chosen set of worked problems, in rising order of difficulty. Van Schooten designed these problems in an almost industrial manner. At least the section where he shows how to measure distances and heights contains drawings of landscapes prepared by an artist, before he himself drew the specific configuration of the problem. Some of the landscapes remained empty because Van Schooten had run out of problems (cf. Figures 3 and 4).

The curriculum of the Utrecht branch of the Foundation of Renswoude

The case that comes up now is a curriculum by private initiative, although eventually three institutes in three different Dutch cities were involved. The wish to establish a mathematical curriculum was a last wish: it was expressed in the last will of a very wealthy woman, Maria Duyst van Voorhout, baroness of Renswoude (1662–1754). The will, signed in 1749 and executed from 1756 onwards, allotted to orphanages in

Delft, The Hague and Utrecht each half a million guilders. These huge sums should afford the orphanages to

... select some of the most talented and suitable boys, at least 15 years old, to set them apart from the orphanage in order to teach them Mathematics, Drawing or Painting Art, Sculpture or Stone Cutting, practices in building dykes to protect our Country against floods or similar Liberal Arts....” [Utrecht Municipal Archive: *HUA* 771, inv. 1)]

And so it happened, with some variation between the three independent but cooperating institutes, which all three were called after their founding mother “Fundatie van Renswoude” (foundation being the common name for an institution, funded by a legacy). The focus in this article will be on the branch in Utrecht. Its mathematics curriculum was described in (Krüger, 2012). In a remarkable way the structure and progress through time of the Utrecht institution parallels the curriculum models of Goodlad et al. and Van den Akker, summarized above.

First, the last will of the Baroness van Renswoude made a concise and precise statement about her aims: promising orphan boys should receive an education in technical or artistic professions, which would respond to the needs of the nation. Mathematics was the first “practice” that the boys should learn. This concise visionary statement can be considered as the intended curriculum. It was elaborated into a formal curriculum by the executors of the testament in cooperation with the regents of the three orphanages. Together they composed an on 17 May 1756 signed “General Regulations”, a document that specified how the visionary statement would materialize. The Regulations describe a variety of aspects: the learning environment and structure of the course, the professions for which it should cater, the subjects to be taught (reading, writing, arithmetic, drawing, principles of mathematics and if necessary French and English language), the accountability of the professionals involved (governors, teachers and Foundation personnel), assessment of the students and also a consultation procedure between the three branches of the Foundation.

The implementation in the Utrecht branch required some strong measures. Up to 1756 few boys mastered reading, writing and arithmetic, so a schoolmaster was appointed to raise the entrance level of the boys. The Utrecht orphanage was so crowded that it had no room for further teaching activities, so a new spacious Foundation house was constructed. In 1761, an “Instruction” for the mathematics teacher was agreed upon. As to the mathematical topics the Instruction was brief: “General mathematics, Military and Civilian Architecture, Surveying, Etc.” The interpretation was left to the mathematics teacher (the “mathematician”). More detail was attached to the procedures of admission and examination (students were to be examined twice a year in the presence of the regents). The mathematician also had to advise on the future profession of a student. In this sense, the intended curriculum focused more on organizational aspects of learning than on its cognitive aspects.

The Utrecht regents made a lucky choice with their appointment of Laurens Praalder. Praalder (1711-1793) was a mathematical practitioner, versatile and widely respected.

He had no academic background, started his teaching career in a region where navigation and building dykes were central topics. In 1751 he was appointed at the Rotterdam Naval School, and in 1761 called to the Foundation. Praalder brought the implemented curriculum, which was still a draft, into practice. He taught at Utrecht until 1792, so for more than 30 years. He had a broad and practical view on the subjects and teaching methods, integrating mathematical theory with physical experiments and practical work with his students, especially in surveying. The duty in finding proper professions for his students was with Praalder in the good hands; he was linked in an extensive and varied network, where he established many useful apprenticeships for his students.

The Instruction had a rather general statement about the topics to be taught. So Praalder faced both the duty and the freedom of choice. He adopted the drafted structure of a course in three phases. Phase 1, which lasted two years and had two examinations per year, was devoted to theory and practical exercises in mathematics, drawing, French language and religion. In Phase 2 Praalder continued the theory but also shifted towards the preparation of the apprenticeship. Phase 3 was the actual internship, often out of town; some students even went abroad. The Foundation paid attention (and money) to providing the students with proper textbooks, which Praalder used next to his own extensive collection of notes; when he retired in 1792, 19 notebooks on a variety of subjects were copied for the sake of his successor.

From 1761 - 1810 the average number of students was 11.5, with a maximum of 15. Their average age was 15. They entered at an age between 12 and 18 and studied and lived within the Foundation for 8.2 years (an average again). A total of 71 boys were admitted, 52 of them completed their studies and started a professional career. Some succeeded well, e.g. as governmental officials, and in general the conclusion is that the Foundation provided education which made a seamless connection with a professional career. The programme was designed as such, and it was effective.

Secondary education for children of citizens, the HBS in the 19th century

In the Netherlands during the first half of the 19th century, secondary education continued to be a matter of private initiative. However booming industry and commerce required a nationally regulated educational system which would cater for subjects such as mathematics and science, languages and economics. Both the Royal Academy for Civil Engineers in Delft and the Royal Military Academy in Breda struggled with students who entered with insufficient knowledge of mathematics and science. The growing middle-class repeatedly proclaimed that it wanted better education possibilities for their children. After several unsuccessful attempts, the liberal statesman J.R. Thorbecke (1798 –1872), who also promoted and formulated the 1848 revision of the constitution, managed in 1863 to introduce the law on secondary education (WMO, 1863). The WMO 1863 distinguished several types of school. A really new school type was the Hogere Burgerschool (higher secondary school for citizens) or HBS. It was modelled after the Prussian Realschule. As a consequence of WMO 1863, for the first time in Dutch history the government

established and paid a limited number of exemplary national HBS and partly financed a number of HBS established by local councils.

The WMO 1863 defined two types of HBS, a three year school and a five year school. We focus here on the HBS with five year course. Its objectives were to provide general education with science and mathematics as important subjects for sons of the middle class and to provide admission to Delft Polytechnic School. Students with an HBS certificate were exempted of the first exam of the Polytechnic School. The school programme was ambitious, with 18 subjects: mathematics, mechanics and technology, physics, chemistry, natural history, cosmography, Dutch, English, French and German, geography, history, political science, two economic subjects, technical and artistic drawing, writing, and physical exercise. All subjects apart from writing and physical exercise were assessed in a regional final exam. As Latin was not a subject taught in the HBS, the HBS certificate did not give admission to university. Knowledge of Latin remained a condition for university admission.

Only for mathematics the syllabus was prescribed. In his “Explanatory Memorandum”, Thorbecke mentioned the topics he deemed suitable for the HBS: (1) arithmetic (continuing where primary school had finished), (2) algebra, including quadratic equations, arithmetic and geometric series and Newton’s binomial theorem, (3) plane and solid geometry, (4) trigonometry and goniometry and (5) descriptive geometry up to curved surfaces. This rather full programme was indeed assessed in the final exams, as is shown in the report on examinations of 1887. The mathematics programme of the Polytechnic School consisted of: higher algebra, spherical trigonometry, analytic geometry, descriptive geometry and applications, differential and integral calculus, surveying and geodesy. Thus the mathematics programmes of HBS and of the Polytechnic School fitted together, at least on paper.

At least two other people were influential in the preparation of the legislation. P.L. Rijke (1812–1899), physics professor at Leiden University, advised on the programme for the HBS and wrote a first draft of the law of 1863. He was in favour of experimental physics; Thorbecke, however, favoured a more mathematical physics programme. D.J. Steyn Parvé (1825–1883) taught mathematics at the Athenaeum in Maastricht and published his ideas on mathematics education in the Netherlands in 1850. Some of his ideas on the role of mathematics were very similar to those Thorbecke expressed in his Explanatory Memorandum. From 1858 until 1863 Steyn Parvé worked at the Ministry, where he was a close co-operator of Thorbecke. In June 1863 he was appointed Inspector of secondary education; the Inspectors were very active in supervising and guiding the schools for secondary education.

The HBS with five year course soon became very popular. Quite a number of students who passed their final exams took a course in Latin and gained entrance to university. Four of the five Dutch Nobel laureates received their education at a HBS. The fifth, Van der Waals, who was born in 1837, taught physics at a HBS. The WMO 1863 stated that teachers at the HBS needed a university degree or equivalent. Although there were worries about a possible lack of qualified teachers, the existence

of these schools offered employment opportunities for graduates and so encouraged enrolment in a university programme for mathematics and science.

Our collection of data on the design and implementation of the HBS curriculum continues. The influence of supervision (national inspectors and local committees), of regional certificate exams, of the Polytechnic School and possibly the Royal Military Academy and of the financial aspects will receive further research.

A COMBINED AND COMPARATIVE PERSPECTIVE AND CONCLUSIONS

When we compare our findings for the three cases, we see them in this perspective:

- current curriculum theory, as described in the **Method** section, applies well to all three cases. In all cases there was a single person (Prince Maurits, the Baroness of Renswoude, Thorbecke), who translated a societal need into a visionary intended curriculum and who took care of funding. Co-workers took care of the further elaboration of the curriculum. Maurits' vision was materialized by Stevin and Van Schooten, the Renswoude testament turned into a regulation thanks to the regents of the Foundation, and Rijke and Steyn Parvé assisted Thorbecke in specifying and introducing his ideas about mathematics under the new WMO law.
- current emphasis in practical curriculum development differs considerably from the historic cases. In the 19th century the interest in detailed mathematical content is observed already, but in the two earlier curricula there is more emphasis on the societal context of the students. The Renswoude testament went very far in this.
- the attained curriculum is strongly depending on the quality and energy of the teacher. For the HBS case our data should first be analyzed, but the result in the two earlier cases is the merit of inspired teachers (Van Schooten, Praalder)
- in all cases assessment is a crucial part of the whole set-up. For the Duytsche Mathematique we have not paid much attention to the surveyors examinations, but these played an important role in the admission to official functions. In the case of the Foundation the examination system was strict. The regents attended the examinations, which implied that it was at the same time a quality check for the teacher. The HBS directly started with common certificate examinations for each region; here the inspection enters the scene, acting on behalf of the government.

There is clear evidence that vision towards society prevailed in the stage of the intended curriculum, that funding, a good team and trust was crucial in the stage of the implementation, and that the curricula attained results thanks to sound teaching, care for examination and coherence. We intend to be more specific and more operational at a later stage of our research, so that we can turn the above comparative observations into recommendations for the curriculum designer and evaluator.

MAKING SENSE OF NEWTON'S MATHEMATICS

Snezana Lawrence

Bath Spa University, Bath, England

*This paper describes a project conducted by the author, developed at the Bath Spa University in England, and which included teachers in training and their pupils, working alongside each other in order to make sense of Newton's mathematics. It drew on the original sources: "Newton's Mathematical Wastebook", albeit in its electronic format. The two main aims of the project were to engage teachers and pupils in a joint research enterprise, and improve on teachers' subject knowledge by asking them to prepare resources based on Newton's original work for their sessions with secondary pupils. The project described here was part of the educational remit of the **Newton Project** website aiming to put all Newton's work (and interpretations related to it) on-line.*

BACKGROUND TO THE PROJECT

The outreach for the *Newton Project*ⁱ consisted of engaging thirty one student teachers, attending the PGCE Secondary Mathematics course at the Bath Spa University, and thirty five pupils with whom the teachers worked (of varying ages, 13 to 18 year olds) from two mathematics departments in two Bath Schools.

The benefits of the work with the original sources from the history of mathematics have been explained at length in various publications in the past twenty years, most notably in Laubenbacher & Pengelley (1996). We particularly mention this publication, as it was the description of the excitement of learning that we wanted to initiate in our teacher students:

As with any unmediated learning experience, a special excitement comes from reading a first-hand account of a new discovery. Original texts can also enrich understanding of the roles played by cultural and mathematical surroundings in the invention of new mathematics. Through an appropriate selection and ordering of sources, students can appreciate immediate and long-term advances in the clarity, elegance, and sophistication of concepts, techniques, and notation, seeing progress impeded by fettered thinking or old paradigms until a major breakthrough helps usher in a new era. No other method shows so clearly the evolution of mathematical rigor and abstraction.ⁱⁱ

As one of the issues in teacher education, identified by the author in previous studies,ⁱⁱⁱ is the lack of subject knowledge and interest in learning more about the mathematical content, this approach seemed worthy of at least an experiment, and certainly worthy as an attempt to bring Newton's mathematics closer to school teachers and pupils.

The main aim of the project was therefore to engage both teachers and pupils to read original sources in the search for deeper understanding of mathematical concepts taught at secondary level.^{iv} Whilst the mathematics which is being taught and practiced

now is quite different to that which Newton knew and developed, a correlation was established between the two through attempts to read diagrams, equations and Newton's explanations of his thought processes in the development of calculus. As we shall see at the end of this paper, teachers reported that the understanding of some of the most fundamental concepts of A-level mathematics became deeper and meaningful to both pupils and teachers as a consequence of their engagement in the project, and the teachers were able to prepare and extract enriched pedagogical material as examples for their pupils.

Teachers were divided into five working groups, investigating the:

1. General history of calculus
2. Introduction to the study of mechanical curves and the tangent problems
3. Development of Binomial Theorem
4. The development of the Fundamental Theorem of calculus
5. The spread of Newtonian science in Europe.

The teachers worked on 'deciphering' Newton's original manuscripts (given in electronic format) and preparing extracts of these to present to the secondary pupils. They all looked at the possible links between their topic and the topics from the A-level syllabus.

EXPECTATIONS IN THE PROJECT AND TEACHER TRAINING

'Making sense of Newton's Mathematics' was an experimental project – it tried to establish how and if, the novice teachers and their students make more sense of mathematical concepts through the learning process by having access to original works of mathematics. The expectation was not for all teachers to make use of all the resources available to them, nor to be able to explain each and every concept mentioned in Newton's *Mathematical Wastebook*, a notebook Newton kept whilst studying mathematics from the late 1664 to 1665.¹ We wanted, and asked teacher students, to make a correlation between what is being taught at A level (pre-undergraduate mathematics course in UK, 16-18 year olds) and what we expect our pupils to understand, with what Newton and his contemporaries really discovered and worked on.

Teachers were therefore asked to manage their workload in such a way that they familiarised themselves with all available resources, and produced one good explanation and/or resource for one concept they wanted to understand better themselves, for teaching during their practice in schools.

¹ For further details about this notebook and its electronic copy see the webpage *Wastebook* at the University of Cambridge <http://cudl.lib.cam.ac.uk/view/MS-ADD-04004/>.

Mathematics teachers sometimes expect their pupils to take things for granted as not all mathematics can be explained by what is already known to them.^v There is also a noted disparity between what actually students understand and what they think they understand (and the same goes for teachers).^{vi}

Even if the question of the subject knowledge (including the historical account of the development of a concept) was not an issue with teacher trainees, there is also the issue of the lack of time to explain the whole development of a concept, and there is not often enough time to explain why exactly something works as it does in mathematics as the lesson time is limited, and the syllabus to be covered is usually substantial.

In the last several paragraphs therefore, we have introduced many issues relating to the subject knowledge (or the lack of it) in teacher students. In order to avoid vagueness, let us summarise some of the findings from the studies described at length elsewhere^{vii}:

- a) Teachers generally have poor level of subject knowledge (of those mathematical topics that are prescribed by the National Curriculum in Britain) at the beginning of their Teacher Training course,
- b) Teachers have very poor, if non-existent, knowledge of the historical mathematics (apart from the incidental and the anecdotal)
- c) Teachers have no, or very vague, knowledge of the benefits of understanding mathematical content in the context in which the concept taught was invented

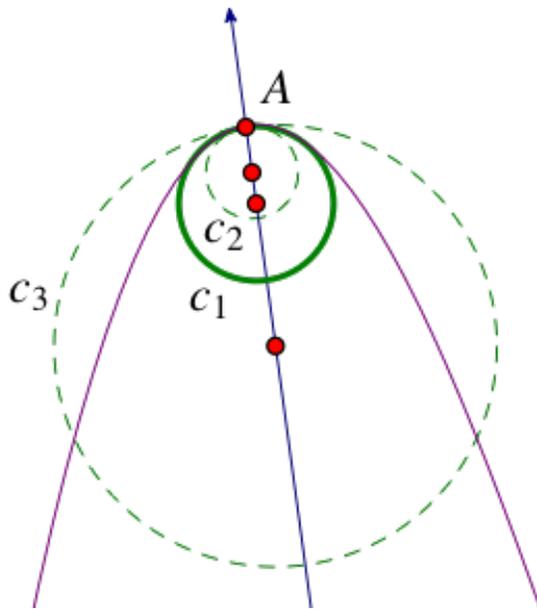

Another recent study by the author^{viii} also concluded that teachers are, at this time of their professional development, exploring the ways which support their exploration and discovery of mathematical concepts in a way that offers new insights, allowing them deeper understanding of the mathematics. Teachers also seem very keen at the beginning of their teaching career to undertake intense study in this area, i.e. the history of mathematics.^{ix}

Having these findings in mind, and the principle of ‘reorientation’ as described by Furinghetti (Furinghetti, 2007), the project aimed to link student teachers’ learning of mathematics from the original sources and compare it with mathematics of the modern/current syllabus. The reason was to get teachers to both pay attention to the development of subject knowledge, and re-position themselves in terms of the pedagogy related to it. The latter (the repositioning) would be achieved through greater understanding of both the concept in question, its historical development, and in trying to overcome the difficulty in trying to explain the concept from two different perspectives (the concept as originally developed, and the concept as presented in the modern-day syllabus).

HOW NEWTON'S APPLE HIT THE GROUND

Majority of the pre-university syllabus in mathematics in England is based on the study of calculus (and most of other topics appearing can also be linked to Newton's work).^x The study of curves however is devoted, almost entirely, to the study of quadratics and cubics, albeit without any attempt to consider them in the wider scheme of things either in terms of their classification or as part of wider classification of curves.^{xi} For example the study of conics is now redundant in the English pre-university mathematics curriculum, so the study of parabola is entirely based on its algebraic analysis and does not mention that this too is a conic section curve.

It was considered that some historical insight into the study of curves by Newton, his persistent attempts to 'resolve problems by motion'^{xii}, and his study of the curves as described in the writings of Descartes and van Schooten (1615-1660) as well as their description of dynamic generation of curves, was crucial to his later work on fluxions and subsequently his formulation of calculus. To this end, an introduction to the work

of van Schooten and Descartes was deemed useful. Newton built his work on, as we already said, Descartes among others. In his study of tangents, Newton looked at finding not only the one circle which touches a given curve at a given point, but to finding the 'best fit' curve – the one which would most closely approximate the curve at the given point. His work on this concept is described in *Epistola Posterior* 1676 and can be seen on the diagram in Fig. 1. The three circles there all touch the curve at A , but only $c1$ is the one which fits the curvature of the curve at point A .

Figure 1: Newton's work on approximating the curve at the given point; see *Epistola Posterior*, 1676.

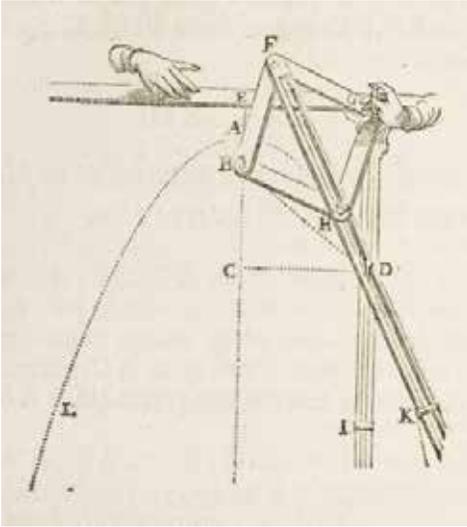

Figure 2: Newton manuscript 4004: Mathematical Wastebook - p.14. Cambridge University Library.

Newton uses the infinitesimal quantities to find the slope of a tangent to a curve at a given point, and calls these *fluxions*. At this point the link between the study of the curves and in particular their 'dynamic qualities' or description became apparent and the teacher students were encouraged to consider the following:

- What is the difference between geometry of Euclid and the mechanical or dynamic study of curves?
- How do we find the gradient of a straight line? How do we apply this to differentiation?
- What are Newton's fluxions?

Further, inspired by looking at Newton's study of dynamic description of curves which

he learnt of by studying van Schooten's work (as per the illustrations in Fig. 2 & 3) the student teachers created a number 'mechanical devices' both from cardboard and in the virtual world, by using dynamic geometry software.

METHODOLOGY – GATHERING DATA

All the teachers were aware that the project would assess the suitability of the approach to both learning mathematics and teacher training. All teachers were part of the collaborative teaching cycle: they did research, lesson planning, teaching and evaluation in groups of five and six, and were then given a task to complete a reflection on the way they worked in researching the original sources, trying to make sense of it and structure it for the discussions and lessons with their pupils, and the teaching sessions. They

Figure 3: van Schooten's construction of the parabola, 1646.

evaluated how their pupils learnt mathematics by doing informal interviews with pupils and incorporated these findings into their reflections. The author of the paper was present during the discussions and guided teacher students in their work, but there was no detailed analysis done of the lesson plans (apart from group discussions) or of research materials during the project.

Whilst small in scope, the project was used as a basis to evaluate possible outcomes and applications of the *Newton Project* in education, in particular in teacher training and the use of original sources that *Newton Project* offers in electronic format on its website, in the classroom.

Teachers were asked to reflect upon the project immediately after the completion of the teaching sequence, i.e. within a week.

TEACHER STUDENTS' ASSESSMENT OF THEIR DEVELOPMENT

Whilst the teachers originally commented on the amount of time they were going to spend learning what they thought they already knew, in their reflections (anonymous)

they commented on the usefulness of the exercise. Some of their conclusions are given below:

1. After the Newton Project I feel I understand the area well and can now explain it to others. The link between Newton and Binomial theorem was interesting and I did not know such a link existed before this project... I found that this helped put things into context and improve my understanding.
2. In the whole I believe this project has been a fantastic learning curve, as it consolidated skills I was strong at and strengthened those I was weak at. My research skills, for one, are an area that I lack in. My groups topic was, *The History of Calculus*, having such a topic forced me to do research allowing me to develop a skill I otherwise wouldn't have.
3. This was not only a learning curve for the pupils, but also for me.
4. The 'deconstruction' process was absolutely pivotal in creating process and breaking down the 'lesson' into manageable chunks for the students... So the 'deconstruction' process' was important for both students and teachers.

Some of the benefits the students therefore themselves identified:

- Working from original sources may lead to learning about the links between the topics teachers did not know of before, therefore enlarging their understanding of both the topics they teach, and the interrelationship between mathematical discoveries
- The research skills were improved – a necessary skill for a teacher, but one which is rarely put to the test in teacher training
- The deconstruction process on the topic is integral to the teaching, and the opportunities were all the more available when the teachers had to engage themselves with the learning process.

The assessment of the views of students was overwhelmingly positive; it remains to be seen in further analysis, and in a more detailed study, how this type of work can be modelled as a common practice in teacher education.

CONCLUSION

Whilst the evaluations of the project are purely qualitative, out of thirty one teacher students only one had a negative comment in their evaluation. This related to the fact that the student teachers are already under a lot of pressure to complete various tasks; learning about the origin of calculus this student did not deem necessary when preparing to teach it. Because the evaluations were anonymous, it is impossible to say anything about the progress of this student in the latter part of the course.

The structure of the project allowed for not only pupils in schools and teacher students to learn some new facts about mathematics, but also teacher mentors and the author of

the project and the paper, learnt about some new connections between the topics, as well as the resources which they will be able to use in the future. The learning therefore occurred at all levels, promoting the model of learning in mathematics whereby the history of mathematics offers a field through which the professional learning landscape is being developed for teachers at the same time as the mathematical knowledge is being developed for their pupils.^{xiii}

Out of all the outcomes, the most unexpected one was perhaps an occasion during which a student was able to help the teachers by translating the original text from Latin, thereby contributing directly to the teachers' understanding of the mathematical content. In this context, 'making sense' meant learning of teachers and students side by side, in a very literal way.

^cCMAT – Centro de Matemática, Universidade do Minho [1]

This paper reports a mathematics experiment conducted in a Portuguese secondary school, with 11th and 12th grades pupils (pre-university). We have used original historical sources for teaching the mathematical concept of tangent line to a curve as well as its connection with the concept of derivative. Emphasis will be given to the conception of the designed module, to the analysis of the pupils' answers and to the pupils' final outcomes. We will infer both benefits and disadvantages of using such activities into the teaching of mathematics.

Keywords: Tangent line; derivative; historical sources; history of mathematics; mathematics education.

INTRODUCTION

The use of history of mathematics in mathematics teaching is increasingly advocated by experts in mathematics, history of mathematics and mathematics education. Many reasons have been presented to justify why it is advantageous to use history of mathematics in mathematics teaching, within those we emphasise the humanization of mathematics, the motivational tool, the dynamical vision of mathematics and its evolution and/or the support for development of an internal image of mathematical concepts (Fauvel&Maanen, 2000; Jankvist, 2009).

Nevertheless some disadvantages have also been identified (Siu, 2006, p. 268-269) and on these we may highlight the time consuming problem, the pupils' concerns about the benefits of this use and the lack of teacher training.

In Portugal we may speak, at least theoretically, of a tradition in the use of history of mathematics in mathematics teaching, which dates back to 1772 when a Faculty of Mathematics was created at the newly reformed University of Coimbra (Mota & Ralha, 2011).

According to this long lasting tradition we have developed an experiment, as part of our PhD research on the historical evolution of the concept of tangent line and its teaching, which aimed at examining the use of original historical sources in teaching mathematical concepts.

THE TEACHING OF THE CONCEPT OF TANGENT LINE

The concept of tangent line to a curve is a concept that becomes familiar to most pupils during their compulsory education but, as Vinner showed (1991, p. 65-81), the pupils' concept definition and concept image of tangent line are not usually the same

and this does not allow learners to correctly work with the concept. To avoid this situation, Tall (1990, p. 58) defended that students should face enriching learning experiences to help them construct concept images that are as close as possible to the concept definition.

As Tzanakis & Thomaidis (2011, p.1654-1655) showed history of mathematics can be used in mathematics teaching to, among others, uncover/unveil concepts, as a bridge between mathematics and other disciplines, to get insights into concepts by looking from a different point of view and to compare old and modern. Within our experiment we have tried to achieve such goals by using original sources. Our guidelines were: the works of Euclid, Archimedes and Apollonius, the work of Roberval, Descartes, Fermat, Newton and Leibniz, as well as the notion presented by the Portuguese mathematician José Anastácio da Cunha in the 18th century.

The concept of tangent line in the Portuguese curriculum and textbooks

In Portugal, on one hand, the curriculum for mathematics advocates explicitly (in every grade) the use of the history of mathematics. On the other hand, for our concept of tangent line to a curve we find it approached in the relationship between the derivative of a function at a given point and the slope of the tangent line to the graph of the function at that point. We may, for example, read [2]:

The use of historical examples or references to the evolution of mathematical concepts will help pupils to appreciate the contribution of mathematics to Humanity problem understanding and problem solving. Some suggested situations: polynomials according to Pedro Nunes, history of differential calculus, history of complex numbers. (Departamento Ensino Secundário, 2001, p. 20)

Curriculum directives are, as expected, vague but, in Portugal, most textbooks and teachers follow only the so called “illumination approaches” (Jankvist, 2009, p. 245-246). In our opinion, Portuguese textbooks [3] aim at informative purposes more than formative ones, illustrated with the use of mathematicians pictures and very scarce references (sometimes even misleading) to the work of these mathematicians. Therefore such historical facts may often become more distracting than informative.

Methodology and data collection

Our experiment took place in two different moments with different approaches and was conditioned by the school executive board directives: we were asked to use the fewest possible classes and we were not given permission to the collection of images or for pupils’ interviews. Thus, data collection was carried out exclusively from the pupils’ written answers as well as our field notes but we believe that our results are still valid. In fact, having developed the experience in usual classroom environment we believe that we have gotten more genuine reviews and reactions from pupils.

In a first phase, involving an 11th grade class of twenty-one pupils, we have used “the modules approach” (Jankvist, 2009, p. 246) with a “historical package” that had the duration of three-class periods of ninety minutes each. This choice was due to the fact

that we wanted to focus on a small topic, with strong ties to the curriculum, and we had limited class periods available.

Table 1: Structure of the historical package.

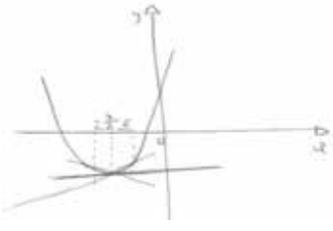

Author	Original Source used [4]	Question/task presented to pupils
Euclid	<i>Elements III</i> , Definition 2 (Heath, 1956, p. 1) and <i>Elements III</i> , 16 (corollary) (Heath, 1956, p. 39)	<ol style="list-style-type: none"> 1. Is this definition suitable to all curves? Justify. 2. Present a method to draw the tangent line to a circle at a given point.
Archimedes	<i>On Spirals</i> , Definition 1 (Heath, 2002, p. 165)	Is Euclid's definition suitable for Archimedes' spiral? In case of a negative answer present an alternative definition for a tangent line to a curve.
Roberval	<i>Observationes sur la composition des mouvements et sur le moyen de trouver les tangentes de lignes courbes</i> (Roberval, 1736, p. 22-23) <i>Traité des indivisibles</i> (Roberval, 1736, p. 209-212)	<ol style="list-style-type: none"> 1. Use Roberval's method to draw the tangent line to a cycloid at a given point. Make a small report about the taken steps and justify it with transcriptions from the original text. 2. Using the concepts presented by Roberval and your knowledge in the theory of movement establish connections between the concepts of movement, velocity and tangent line.
Fermat	<i>Methodus ad Disquirendam Maximam et Minimam</i> (Fermat, 1891, p. 121)	<ol style="list-style-type: none"> 1. Using Fermat's method, determine the extremes of a 2nd degree polynomial function. 2. What is, geometrically, the interpretation of Fermat's method?
Leibniz	<i>Nova Methodus pro Maximis et Minimis, Itemque Tangentibus, qua nec Fractas nec Irrationales Quantitates Moratur, et Singulare pro illi Calculi Genus</i> (Leibniz, 1684/1983, p. 5-7)	<ol style="list-style-type: none"> 1. Using an image of the differential triangle, establish a relationship between the slope of a tangent line to a curve at a given point and the function derivative at that point. 2. Establish a relationship between function monotony and the sign of the derivative. 3. Using the established relationship present a method to determine the extreme of a function.

Both authors and tasks were chosen to represent different approaches to the concept of tangent line as well as its relation with other concepts, namely the Greek “touch without cut” approach, the relationship with physics and, in particular, with movement, the limit position of the secant approach and the relationship with the concept of derivative.

Our pupils worked in five small heterogeneous groups but their answers, in the different groups, were quite similar. Hereby we present the most relevant data:

Table 2: Data collection of the module-based approaches.

Question/task	Collected Data
Euclid 1	<p>All groups answered “no” and presented a graphic of a curve where the tangent line at a point cuts the curve at another point to justify their answer (below we present two examples of pupils’ answers).</p> 
Euclid 2	<p>All groups presented a correct method to draw a tangent line to a circle, for example:</p> <ul style="list-style-type: none"> - Trace the radius through the given point; - Construct the perpendicular line to the radius through the given point.
Archimedes	<p>All groups answered “no” and presented an alternative definition. Bellow we present two examples of pupils’ answers:</p> <p>Example 1: <i>Tangent line to a curve is a straight line that cuts the curve in only one point of the curve near the considered point.</i></p> <p>Example 2: <i>A straight line is tangent to a curve if it touches the curve without cutting it at that point.</i></p> <p>In fact, all the presented definitions had as common idea the fact that the tangent line touches the curve at the contact point and no other in a neighbourhood.</p>
Roberval	<p>The pupils presented many difficulties in the implementation of the proposed tasks, despite the examples presented in the ‘historical package’. They just managed to perform the task after a few explanations of the teacher, mainly one related to the description of curves through movement.</p>
Fermat 1	<p>All groups, after some discussion and despite presenting some doubts about the method, were able to follow the method’s directives and correctly determine the minimum of the function $f(x) = x^2 + 3x + 2$.</p>
Fermat 2	<p>Only one group was able to present the geometrical interpretation of Fermat’s method, which was the following:</p>

	 <p style="text-align: center;"><i>The tangent line is horizontal.</i></p> <p>To allow all pupils to fully understand the method, the teacher had to thoroughly explain it.</p>
Leibniz	<p>All groups recognized, by using similarity of triangles, that the slope of the tangent line at a given point is the derivative of the function at that point.</p> <p>All groups establish the correct relationship between the function monotony and the sign of the derivative and used that relationship to present a method that allowed the determination of extremes of a function.</p>

The second phase of the experiment took place almost one year later and involved pupils of the 12th grade, ten of them (group A) that had participated in the first part of the experiment and twelve (group B) that were participating for the first time in the experiment. In this phase, it was used “the history-based approaches” (Jankvist, 2009, p. 246-247) by confronting the pupils with different definitions of the concept of tangent line and propositions about this concept, presented in a historical order, that were discussed and analysed with the pupils aiming at achieving a clearer and more complete concept image and concept definition of tangent line. We have chosen to work with the same mathematicians used in the first phase of the experiment, adding a new one: the Portuguese mathematician José Anastácio da Cunha (1744-1787) aiming at dealing with yet a different point of view on the concept alongside with a national/cultural component. The definitions/propositions analyzed are the following:

Table 3: Structure of the history-based approaches.

Author	Definition / Proposition
Euclid	<i>Elements III</i> , Definition 2: A straight line is said to touch a circle which, meeting the circle and being produced, does not cut the circle. (Heath, 1956, p. 1)
Archimedes	<i>On spirals</i> , 13: If a straight line touch the spiral, it will touch it in one point only. (Heath, 2002, p. 167)
Roberval	<i>Observationes sur la composition des mouvements et sur le moyen de trouve les touschans de lignes curves</i> , Axiom or Invention Principle: The direction of the movement of one point which describes a curve is the tangent line of the curve at the position that the point occupies. (Roberval, 1736, p. 22)

Fermat [5]	Tangent line is the limit position of the secant when the two points of the curve tend to meet. (Eves, 1992, p. 391)
Leibniz	<i>Nova Methodus pro Maximis et Minimis, Itemque Tangentibus, qua nec Fractas nec Irrationales Quantitates Moratur, et Singulare pro illi Calculi Genus</i> : drawing the tangent line is to draw the straight line that joins two points on the curve that are distant from each other an infinitely small distance, or the side of a polygon of infinite angles that we consider equivalent to the curve. (Leibniz, 1684/1983, p. 7)
José Anastácio da Cunha	<i>Princípios Matemáticos II</i> , Definition III: If the sides of an angle meet at the vertex such as it is not possible to draw two straight lines between them it is said that the sides of the angle are tangent to each other. (Cunha, 1790, p. 13)

First the pupils were asked to write their comments and opinions on the definition validity, evolution and/or applicability and afterwards to debate their writings in the class. The most receptive and participative pupils were the ones who took part in the first phase of the experiment and almost all comments, in the class debate, were lead by those pupils. Hereby we present the most relevant data:

Table 4: Data collection of the history-based approaches.

Author	Comments (group A)	Comments (group B)	Comments (class debate)
Euclid	This definition is not valid for all curves.	This definition is correct and is the one generally used.	Group A tried to convince group B that this definition shouldn't be used today since it is not valid for all curves by using examples of curves where the tangent line cuts the curve.
Archimedes	Reference to the uniqueness of the tangency point that is not valid if the curve is a straight line.	Accepted that this property is valid for all curves.	Group A presented their example to group B.
Roberval	Pupils were able to establish, even though with some difficulties, the	Pupils weren't able to understand the relationship between the presented	An explanation on the part of the teacher was necessary in order to make the relationship between mathematics and

	connection with physics.	definition and their concept image of tangent line.	physics evident to all pupils.
Fermat	Recognized this as the generally used definition of tangent line.	Established a relationship with the concept of derivate.	The two groups' approaches were considered complementary.
Leibniz	Pupils referred to the last part of the definition as having no connection with the rest and so it is unnecessary.	Established a relationship with the concept of derivate.	Recognized the similarity with the treatment given by Fermat and discarded the last part of the definition.
José Anastácio da Cunha	Stated the difficulty of the definition and weren't able to understand the connection of the definition with the geometrical treatment of the functions they are used to do.		The teacher explained the presented definition, presenting Anastácio da Cunha's use of the definition.

In the end pupils were asked to present their own definition of a tangent line to a curve and they have chosen the definition referred as Fermat's.

CONCLUSIONS

The use of original sources to teach the concept of tangent line has proved to be not only important for us to realize many positive aspects, but also to identify some obstacles to overcome.

The first major difficulty was faced when constructing the historical package. The choice of the sources to be used, the translation of the original sources into Portuguese that have raised problems of terminology and notation, and the choice of the questions/tasks made the construction of the module to be time-consuming and scientifically intense. It is only possible to develop this type of work if the teacher has some teaching experience and a profound knowledge of the concept/subject to teach together with historical interest and practice. We are sure that we might never develop such competence if it was not for our own process of finding, disclosing and intense debate on many details on the studied sources. This calls our attention to the need of introducing/consolidating history of mathematics in teachers' training as well as the need of a real collaborative work among colleagues that are mathematics teachers, to share materials, experiences, ideas that will make less time-consuming the preparation of this sort of activities.

During the three-class periods where the history package was used, it was hard to get the commitment and stimulate pupils' interest in this type of activity. The first

arguments used by the pupils were that mathematics is not history, they do not attend history classes anymore and that they do not like history. Pupils were not, at all, aware of the importance of the historical development of mathematics for understanding mathematics itself, so they discard this sort of activities even before they begin working with them. To overcome this pupils' arguments/attitude history of mathematics might be introduced into mathematics teaching early and often and history classes and mathematics classes might even become, in some aspects, coordinated disciplines.

After the first refusal and the beginning of the task, pupils faced the complexity of the presented texts. The texts had been previously prepared by ourselves but, even so, since Portuguese pupils are not used to read mathematical texts, it was difficult for them to understand the presented historical material. This barrier might only be overcome if pupils are more often faced with reading and analysing mathematical texts. In fact, if we decide to use this historical package again, it might be necessary to prepare its application, by presenting earlier to pupils small excerpts of original sources so that students gradually become familiar with that sort of texts.

Pupils also presented difficulties with the establishment of connections between mathematics and physics. Although Portuguese mathematics curriculum explicitly defends the interdisciplinarity of mathematics and physics, that is rarely a fact in teaching practices. This experiment shows us that a true collaborative work between the teachers of the two disciplines is necessary, for example, for pupils to realise the importance of mathematics to explain physic phenomena.

Another difficulty was related to the purpose of the task. In Portugal, history of mathematics is not a topic evaluated in final examinations, so pupils of these levels (prior to being selected for universities) tend to discard anything that will not be part of national examinations and to concentrate only in "model questions" which might prepare them to the final exam. Pupils showed only interest in the questions concerning to Leibniz's work, since it seemed to them that this might be useful for their exam preparation and they were not able to see any more immediate advantages in any other part of the work.

After using the historical package with the pupils we realised that some changes are necessary. The first one is the awareness that it is necessary more time for pupils to fulfil the tasks presented. We also noticed that it is necessary to introduce more information concerning Roberval or Fermat's method for pupils can perform the tasks and understand it. The use of secondary sources (such as the work of Eves concerning Fermat's definition of a tangent line or the differential triangle, in the Leibniz method) may seem awkward but justified by the need of additional information that would help pupils fully understand the original sources.

The real advantages for pupils with the use of original sources came to be fully acknowledged by them in the second year of the experiment. When asked to comment the definitions/propositions presented, the pupils who took part in the first

phase of the experiment were the most receptive and participative ones. They also presented less doubts and less difficulties. This shows that, even though they had some initial concerns, the work made in the previous year developed the inwardness of concepts that gave them the knowledge to perform easily the 2nd phase tasks. At the end it was clear to all participants that the pupils involved in the two years of the experiment had a more solid formation than the others, showing the utility of this sort of tasks to develop a profound and more complete knowledge of the concept. When faced with counterintuitive examples such as the tangent line to a straight line or the tangent line to a curve at an inflection point, pupils showed little difficulty and did not present the problems that are often reported (Vinner, 1991; Tall, 1990) concerning to the concept of tangent line.

It is our conviction that the contact with the historical evolution of the concept allowed our pupils to fully understand it: they internalized the concept, they constructed clearer concept images, they achieved a correct concept definition in their minds. They even performed better in their final examinations.

NOTES

1. This research was financed by FEDER Funds through "Programa Operacional Factores de Competitividade COMPETE" and by Portuguese Funds through FCT - "Fundação para a Ciência e a Tecnologia", within the project PEst-C/MAT/UI0013/2011.
2. All translations into English were made by the authors.
3. We have analyzed the textbooks *Matemática A 12º*, *Novo Espaço 12* and *Xeqmat 12* which are the most used in the country.
4. All texts were translated into Portuguese by the authors.
5. Although Fermat does not present a definition of tangent line in his work he has presented a method from which Eves has composed the definition used in our experiment.

THE DEVELOPMENT OF PLACE VALUE CONCEPTS TO SIXTH GRADE STUDENTS VIA THE STUDY OF THE CHINESE ABACUS

Vasiliki Tsiapou, Konstantinos Nikolantonakis

Elementary School Teacher, University of Western Macedonia

The paper presents part of the findings of a study that intended to use the history of mathematics for the development of place value concepts with 18 sixth grade Greek students. In the given pre-tests students faced difficulties in solving place value tasks, such as regrouping quantities and multi-digit subtractions. Also, they vaguely explained the carried number, a notion which is structurally associated with calculations. We held an instructive intervention via a historical calculating tool, the Chinese abacus. In the post-tests students improved their scores and they often put forward expressions influenced by the abacus investigation. To a smaller extent we attempted to highlight the historical dimension of the subject.

INTRODUCTION

Studies have shown that many students are not aware of the structure of the numbers. A great difficulty is in developing an understanding of multi digit numbers. Students need to understand not only how numbers are partitioned according to the base-10 structure, but also how these values interrelate (Fuson, 1990). Resnick (1983b) used the term ‘multiple partitioning’ to describe the ability to partition numbers in non-standard ways, e.g., 34 can be decomposed into 2 Tens and 14 Units. This ability is essential for competence in calculations and many types of errors that studies have been observed in subtraction (Fuson, 1990; Lemonides, 1994) are due to the students’ difficulty to acquire this competence. As a consequence, they cannot interpret the carried number, a concept structurally associated with calculations (Poisard, 2005b).

In this paper we focus on the difficulties that the students of the present study faced in the above concepts and the way that we tried to address these difficulties with the use of the history of mathematics. Initially, we present the reasons that historical instruments may positively contribute to mathematics education. Then we describe the didactical use of the historical instrument that we used in the intervention, the Chinese abacus. Afterwards we present an overview of the intervention: the objectives, the design with the use of history, and an example of a didactical session. Then, a brief quantitative and a more detailed qualitative analysis of the results follow. Finally, we discuss the findings and further research issues.

THE ROLE OF THE HISTORY OF MATHEMATICS IN THE CLASSROOM

Researchers have long thought about whether mathematical education can be improved through incorporating ideas and elements from the history of mathematics. Tzanakis and Arcavi (2000) offered a list of arguments and Jankvist (2009) distinguished these arguments between using “history-as-a-goal” (learning of the

development and evolution of mathematics) and using “history-as-a-tool” (learning mathematical concepts). Jankvist also classified the approaches in which history can be used. One of these is the ‘modules approach’. Modules are instructional units suitable for the use of history as a cognitive tool, since extra time is required to study more in-depth mathematical concepts, and as a goal. (Jankvist, 2009). Among the possible ways that modules can be implemented using history as a ‘tool’ as well as a ‘goal’, is through the use of historical instruments since they can illustrate mathematical concepts in an empirical basis. They are considered as non-standard media, unlike blackboards and books, that can also affect students emotionally (van Maanen, 2000). Students explore them as historical sources for arithmetic, algebra, or geometry and they may also enable students to acquire awareness of the cultural dimension of mathematics (Bartolini Bussi, 2000).

Chinese abacus: A historical calculating instrument

The Chinese abacus is comprised of vertical rods with same sized beads sliding on them. The beads are separated by a horizontal bar into a set of two beads (value 5) above and a set of five beads (value 1) below. The rate of the unit from right to left is in base ten. To represent a number e.g. 5,031,902 (figure 1) beads of the upper or/and the lower group are pushed towards the bar, otherwise zero is represented.

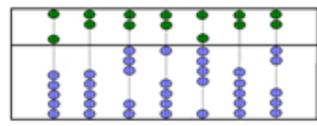

Figure 1: Representation of numbers on Chinese abacus

Many characteristics of our number system are illustrated by the abacus (Spitzer, 1942). Unlike Dienes’ blocks the semi-abstract structure of the abacus becomes apparent as the same sized beads and their position-dependent value has direct reference to digit numbers. The function of zero is represented, as a place-holder. Furthermore, it may illustrate the idea of collection, since amounts become evident in terms of place value. Finally, the notion of carried number emerges. Poisard (2005b) argued the fact that we can write up to fifteen units in each column and make exchanges with the hand reinforces the understanding of the carried number in operations. From the definition of the carried number (Poisard, 2005b) highlighted its relation to the functionality of the decimal system to allow quick calculations: “the carried number allows managing the change of the place value; it carries out a transfer of the numbers between the ranks” (p. 78).

Based on the studies about students’ difficulties and the possible positive contribution of the history of mathematics via the Chinese abacus in place value understanding, the present study set the following objectives:

1. To study whether sixth grade students recognize the structure of our number system when handling numbers.

2. To study how they verbally explain the carried number and how they use it in written calculations.
3. To study to what extent an instructive intervention with the Chinese abacus would help students handle possible difficulties and misconceptions.
4. To highlight the historical context of the abacus and enrich teaching with a variety of approaches where students are actively involved.

In the present study we adopted Poisard's (2005b) proposal for the didactical use of the Chinese abacus; we used all the beads in order to record up to 15 units, unlike the standard technique where one of the upper beads (value five) is not used at all. This allowed us to add new elements in the present study, such as the use of regrouping activities as essential knowledge (Resnick, 1983b) before implementing the written algorithms of addition and subtraction.

RESEARCH METHODS

The study took place in an elementary school in Thessaloniki during the school year 2010-2011. The participants were 18 twelve-year-old students (9 girls and 9 boys). The criterion was that the students would be able to participate once a week during the hours when their school program was to work on a two-hour project. Four students had a very weak cognitive background and eight students often relied on procedural rules due to partial conceptual understanding.

For the first two objectives two questionnaires (pre-tests) were administered in November. **Questionnaire A** consisted of six closed-type questions and one that required a written explanation (Appendix II, p.10). After the intervention similar questions were administered as post-test. The questions were created with the following in mind: (a) the literature about students' difficulties (b) the Greek mathematics curriculum so as to ascertain that they constitute important and prerequisite knowledge in the beginning of grade 6, and (c) the feasibility of teaching via the abacus. For integers the questions concerned: named place value, expanded form, regrouping, rounding, subtraction, and multiplication. For decimals: transforming from verbal to digit form, number pattern, addition, and subtraction. Two of the questions that are subjected in the present analysis concern exchanges between classes: sub question 3b, which concerned regrouping and comparing quantities, and sub question 7a, which dealt with subtraction with carried number. In order to study how students perceive the concept of carried number used in the subtraction tasks, we administered **Questionnaire B**. It consisted of Poisard's (2005b, p.101) four open questions. The same questions were given as post-test. Here we present student responses to the question: *what is a carried number?*

The design of the intervention with the use of the History of Mathematics

For the other three objectives we implemented a five-month instructive intervention. It was inspired by modules approach (Jankvist, 2009). We designed a didactical sequence for the teaching of mathematical concepts that was allocated in sections (integers, decimals, and operations). For every session a teaching plan was elaborated

including procedure, forms of work, media and material. The outcomes were recorded and several sessions were videotaped as feedback for the researchers. The introductory and closing activities aimed at using history mainly as a goal.

Initially, the arguments mentioned below are aimed at exploring why history would support the learning and raise the cultural dimension of mathematics. They were based on Tzanakis's & Arcavi's (2000) arguments and were grouped under Jankvist's (2009) categorization. We have included a third category placing pedagogical arguments in an attempt to emotionally motivate as well as develop critical thinking. Thus, students are expected to:

A. History as tool

1. develop understanding by exploring mathematical concepts empirically
2. recognise the validity of non-formal approaches of the past

B. History as a goal

1. become aware that different people or in different periods developed various forms of representations
2. perceive that mathematics were influenced by social and cultural factors

C. Pedagogical arguments: motivate emotionally, develop critical thinking and/or metacognitive abilities

Some examples of the interrelation between the activities chosen and the arguments for such a choice are presented below. (The arguments are in parentheses). Introductory and closing activities: Presentations about number systems of the antiquity: Roman, Babylonian, Greek, Mayan (B1, C); students create numbers and discuss the effectiveness of the systems (A2, B1, C). Presentation about the ancestor of the abacus, the counting rods (B1); form rod numerals and compare with the modern representation (A1, A2, C). Information about the abacus (B2); compare the two forms (abacus and rods): advantages/disadvantages similarities/differences (B1). After the intervention students presented their work to an audience in the role of the teacher (C); they elaborate on information about the cultural context of the abacus that led to prevail over the counting rods (B2, C) for a multicultural event. Main part: Students investigated place value with handmade abaci, web applications (A1, A2, C; Appendix I, p.10) and worksheets designed by the researchers (A2, C); they analysed the abacus's representations/procedures and corresponded with the formal one (A1, A2); contests between groups (A1, C).

The implementation of the intervention through an example of a session

The example is based on Poisard's (2005b) proposal for subtracting on an abacus with carried number. The method mainly taught to Greek schools and other European educational systems is the 'parallel additions', which uses the relation $a-b = (a+10^x) - (b+10^x)$. The other method, the 'internal transfers', is taught in second grade as an

introductory method so it is rarely used over the years. It allows exchanges between classes and is the only that can be implemented on abacus when using all beads.

Previous knowledge on abacus: decompose quantities; perform subtractions without trading. Procedure: The teacher forms the minuend of the subtraction $933-51$ on the abacus. The number 1 can be subtracted immediately by removing one unit bead (figure 2, step 1) but in the tens column the regrouping process must be put forward. A student removes a one-bead from the hundreds and replaces it with two five-beads in the tens (figure 2, step 2). Having a total 13 on the tens he/she removes one five-bead and gets the result (figure 3, step 3). The student is encouraged to explain in terms of place value: *I decompose 1 hundred to 10 tens and then subtract 5 tens.*

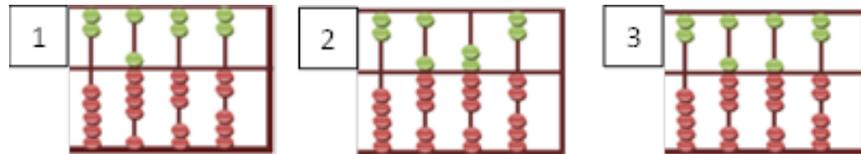

Figure 2: Example of the subtraction method ‘internal transfers’ on abacus

Observation from the teaching: A student solved the subtraction $4,005-8$ initially on the blackboard. She transferred a 1 thousands’ unit directly to the units’ position; she subtracted and found 3,007. We also observed this error (Fuson, 1990; Lemonides, 1999) in some answers of the pre-test. When prompted to use the abacus, the student correctly implemented the decomposition process and explained it in terms of place value. Our discussion then revolved around the two results, so that the student reflected on her incorrect thought when she solved on the blackboard. One of the reasons that she did not make a mistake on the abacus – apart from the intervention’s influence – is possibly the visual-kinetic advantage of the tool; the space that occupies the intermediate columns may act as a deterrent for the eye to arbitrarily surpass them. Also, since we use the hand to remove one upper class unit bead, the fingers are merely guided to the next column in order to replace it with 10 equivalent lower units. The role of the teacher was crucial at this point to link the semi-abstract with the abstract technique, and at the same time to emphasize the common underlined mathematical theory.

DATA ANALYSIS AND RESULTS

Questionnaire A: The total score of Questionnaire A was 100. The t-tests showed a statistically significant difference between the two measurements of students’ scores ($t= 5.243$, $df = 17$, $p < 0.001$), with a pre-test mean of 50.5 and a post-test mean of 78.2. For the questions 3 and 7, the t-tests showed a statistically significant difference between the means of the two measurements: Question 3 ($t=6.172$, $df=17$, $p<0.001$) pre-test: mean 4.67, standard deviation 5; post-test: mean 12.9, standard deviation 3.5. Question 7 ($t= 2.807$, $df = 17$, $p < 0.05$) pre-test: mean 17.1, standard deviation 11.2; post-test: mean 22.6, standard deviation 9.0. The qualitative analysis that follows concerns the sub questions 3b and 7a. It aims to find if the scores’

improvement is connected with better understanding through the investigation of the abacus. For question 3b we studied students' written explanations.

Sub question 3b, Pre-test: 'Compare 8 hundreds 2 tens 1 unit ___ 7 hundreds 11 tens 16 units using the sign of inequality/equality. Explain the way you have thought'.
Post-test: 'Compare 6 hundreds 3 tens 3 units ___ 6 hundreds 14 tens 13 units using the sign of inequality/equality. Explain the way you have thought'.

Types of reasoning	Pre-test	Post-test
correct	4	16
incorrect	8	
insufficient/no explain	6	2

Table 1: Reasoning analysis for answers to sub question 3b

Four students on the pre-test (table 1) gave correct justifications, while on the post-test the majority of them were correct. Examples of students' written explanations on the pre- and post-tests follow. The abbreviations used are H=Hundreds, T=Tens, and U=Units.

Correct reasoning: $1T=1H$ and $1T$. Also $16U=1T$ and $6U$. So we have $700+110+16=826$.
Incorrect reasoning: They saw individual numbers on both sides: *The second is bigger than the first in two numbers.* They isolated digits and arbitrarily formed a number: *826 less than 71,116.* They compared the hundred's class, possibly recalling a vague knowledge of upper classes: *The first number has 1H more so it is bigger because hundreds matter.*
Insufficient reasoning: *Because 7hundreds 11tens 16units is bigger.*

Post-test: A figurative explanation appears (figure 5). By circling and using arrows, students were depicting the abacus process of composing ten units to a higher class.

6 Εκατοντάδες 4 Δεκάδες και 3 Μονάδες < 6 Εκατοντάδες 14 Δεκάδες και 13 Μονάδες
 Το δεύτερο είναι μεγαλύτερο.

Figure 3: Sub question 3b – Example of regrouping at the post-test

Translation: *Seven hundred and fifty three is bigger*

A more detailed response: *I get 10 from 14 T and make 1 H. The H now are 7. Then we have 13 U. I take 10 U and do another 1 T. The number is 753 greater than 643.*

Sub question 7a, Pre-test: Solve the subtraction 70,005-9 in vertical form. **Post-test:** Solve the subtraction 40,006-9 in vertical form.

	carried number not noted	parallel additions	Totals
Answers	10	6	16
Success	4	5	9

Table 2: Management of the carried number on the pre-test (sub question 7a)

Two students did not answer this question. From table 2 we observe that half students succeeded. The visible method was ‘parallel additions’, since the rest of the students did not note the carried number. The types of errors are categorised in table 3.

Question: 70,005-7	carried number not noted		use of carried number	
<u>Types of errors</u>	N	Examples	N	Examples
Carried number	5	60,008 70,010 81,098,		
Copying numbers	1	7,005-7		
Number facts			1	69,997

Table 3: Types of errors on the pre-test (sub question 7a)

The main type of errors (table 3) seemed to be the management of the carried number. For example, in the result ‘60,008’, though the carried number is not noted, the error is the transfer of 1 thousand to the units’ position.

Sub question 7a, Post-test: Almost all students succeeded and the number of students who did not use the carried number decreased because of the use of the new method that requires the notation of the carried number (table 4).

	carried number not noted	parallel additions	internal transfers	Totals
Answers	4	7	7	18
Success	3	6	7	16

Table 4: Management of the carried number on the post-test (sub question 7a)

The method ‘internal transfers’ appears and along with ‘parallel additions’ was applied successfully (table 4). The method ‘parallel additions’ was applied mainly by students who had successfully applied it during the pre-test, while the method ‘internal transfers’ was given by those who had not be able to handle the carried number correctly.

$$\begin{array}{r}
 40.006 - 9 \\
 \hline
 39.997
 \end{array}$$

Figure 4: The method ‘internal transfers’ as implemented on the post-test**Questionnaire B: ‘What is a carried number?’**

Explanations	N
find/use/ something in calculations	9
Example with addition	5
I don't know/remember; I cannot describe it	4

Explanations	N
When the number exceeds 10	1

Table 5: The interpretation of the carried number (Pre-test)

Explanations with the use of an example	N	Verbal explanations	N
Composing e.g. 10 hundreds = 1 thousand	6	Ten units of a position move to the next position as one unit	3
Decomposing e.g. 1 hundred = 10 tens	1	Number we keep aside/use in operations for transfer	2
Composing/decomposing	1	Borrowing from a number	1
		A format of tens, hundreds, etc., for transfer	2
		Convert a number of ten and over to another format	1

Table 6: The interpretation of the carried number (Post-test)

The explanations with the use of an example differ between the two tests (table 5 & 6). At the pre-test students just performed an addition while in the post-test they put forward composing and decomposing examples. Verbal explanations at the pre-test seemed meaningless. Only in one answer we detected an attempt of mathematical explanation; *when the number exceeds 10*. At the post-test we can still observe a difficulty to explain but most students used the idea of exchanging (e.g., ‘transfer’, ‘convert the format’). One is specific: *10 units move to the next class as 1 unit*; others mix the knowledge before and after the intervention: *a number we keep for transfer*.

DISCUSSION

The results of the pre-tests showed that most students did not have a profound understanding of the numbers’ structure; almost all could not recognise the numbers behind a non-standard partitioning (Fuson, 1990; Resnick, 1983) and half failed to solve a four-digit subtraction across zeros, a task that other studies have shown is difficult (Fuson, 1990). In addition, they could not interpret the notion of carried number (Poisard, 2005b) considering it as an aid in operations but more of a vague nature. At the post-test, almost all displayed a better conceptual understanding. Using schematic representations and place value explanations influenced by the abacus’ activities, they successfully regrouped non-standard representations to standard numbers. As for the subtraction task, the students that had unsuccessfully managed the carried number in the pre-test, they implemented successfully the abacus’ method ‘internal transfers’, which requires the reverse process of decomposing numbers. In agreement with Poisard (2005b) the method has the advantage of illustrating the properties of our number system when they have not been adequately understood. The regrouping activities on the abacus and their connection to the algorithms of addition and subtraction changed students’ perspective about the concept of the carried number. They explained it as an exchange between classes, either verbally denoted or through an example.

Despite the limitations of the study, such as the small sample and the lack of relevant experiential studies about the Chinese abacus, except Poisard's (2005b), the authors believe that the reasons for using the history of mathematics were accomplished in a quite satisfactory way. By elaborating on place value concepts via the abacus, students developed understanding on an empirical basis (literally with their hands). By analysing processes with the historical tool, students appreciated that mathematics of the past also lead to results that have logical completeness. In general, Bartolini Bussi's (2000) argument was verified that in the tactile experience offered by the ancient instruments one may find the foundations of mathematical activity.

During the intervention we recognised the crucial role of the teacher in the teaching/learning process. Students may learn to calculate correctly with the tool, but without conceptual understanding. Also, as the example from the didactical session showed, they may achieve understanding place value concepts when calculating with the tool but they continue to misapply the written calculations because they do not connect the two processes. That is why teachers should encourage students to gain insight into the relation between the tool and the concept that it represents (Uttal, Scudder, & Deloache, 1999), otherwise its semiotic function will not be transparent.

As further research we suggest the study of the Chinese abacus with younger students for the teaching of simpler concepts (Zhou & Peverly, 2005). In addition, it would be innovative the production of material involving the history of mathematics in the primary education with the cooperation of university departments and classroom teachers.

APPENDICES

APPENDIX I

Abacus for demonstration

Student's abacus

Web application

APPENDIX II

Questionnaire A-Post-Test

1 Write the place value of the digit "2" of the number 27,257,275

2. Write the number 4,018,379 in the expanded form as in the colored example

$$(4x \text{ _____}) + (0x \text{ _____}) + (1x \text{ _____}) + (8x \text{ _____}) + (3x \text{ _____}) + (7x \text{ 10 _____}) + (9x \text{ _____})$$

3. Compare the numbers using the signs >, <, =. Explain written the way you have thought

- A. 4 Tens and 3 Units ___ 3 Tens and 13 Units
- B. 6 Hundreds 4 Tens and 3 Units ___ 6 Hundreds 14 Tens and 13 Units

4. Round the number 5,283

a.	To the nearest ten	
b.	To the nearest hundred	
c.	To the nearest thousand	

5. Write the following decimal numbers with digits

a.	Eight tenths	
b.	Forty six hundredths	
c.	Seven thousandths	
d.	Twelve tenths	

6. Fill in the gaps using the sequence of numbers

0.2	0.5	0.8		
-----	-----	-----	--	--

7. Perform the operations in vertical form:

$$40,006 - 9 \qquad 5.4 + 3.46 \qquad 21 - 3.56 \qquad 623 \times 82$$

CALCULUS AND APPLICATIONS – LEARNING FROM HISTORY IN TEACHER EDUCATION

Regina D. Moeller, Peter Collignon

University of Erfurt, Germany

The current scientific body of calculus may appear as if its development were carried out on a linear path without many optional possibilities which appeared along the historical processes. Under a historical perspective stressing the conditions of its genesis many decisions were made along the way. This contribution emphasizes the importance of generating an awareness of the unfolding character of the history of calculus when addressing student teachers. The aim is an enhanced teaching process of the body of analysis with its pure and applied parts.

TOWARDS AN AWARENESS OF HISTORICAL DEVELOPMENT

Modern calculus textbooks are characterized by an axiomatic representation and often offer physical applications. The main concepts are the real numbers, the notion of a function and the notion of a limit. All are presented by a certain way of formalization: definitions, theorems, proofs, added by a few examples illustrating the propositions. This representation of the body of calculus was developed during the first half of the last century and is still regarded as “modern” and constitutes the result of a long historical non-linear development with discontinuations.

From a “postmodern” point of view questions arise and the necessity for a broader perspective: Are there alternative ways that calculus could have taken? Why did the idea of Archimedes concerning “exhaustions” not lead to a first draft of the Riemannian integral? Why were the steps which Newton, Euler and Weierstrass took, in fact, a dynamical idea of the limit, the notion of a function, the epsilon-delta-concept, widely accepted? Under what circumstances the infinitesimal numbers of Leibniz or the non-standard-analysis would have become more important? In how far do computers influence the way we practice and interpret calculus and its applications? Already the process of answering these questions helps deepening the understanding of the development of calculus.

EDUCATIONAL ASPECTS FOR STUDENT TEACHERS

Within the context of teacher training students should receive a deepened insight in the process of mathematics and develop an appropriate concept of science by considering historical circumstances. Infinitesimal calculus is both – a branch of pure mathematics

as well as a tool in applied mathematics, and it often happens that its use lacks critical reflection. This situation provides a favorable opportunity to discuss the diversity of doing research – within and through mathematics.

Taking account of the different aspects of pure and applied mathematics, calculus shows an odd ambivalence. On the university level lectures of calculus are usually considered to be a part of pure mathematics. On the other hand it embodies strong connections to numerical mathematics. Additionally, the methods of infinitesimal calculus play more and more a decisive role in mathematical modelling. Besides well-known modelling procedures in “exact” sciences such as physics, contemporary modelling is increasingly concerned with other initially non-mathematical scientific issues such as economy or social sciences. These subjects deal with quantities that are not originally discrete in every case. This raises the question of whether infinitesimal concepts are a suitable tool for describing the “reality” in those subject areas. There are different possible answers that depend on the perspective and the targets under investigation and the perception of science. Future teachers need to develop an awareness of the genesis of calculus since it will enable them to teach the sense of it in class.

WAY OF REPRESENTING – THE POSTER

In the center of the poster two timelines represent the history of calculus and the actual representation in textbooks. It also displays the important correlations of the topic predominantly in the form of a concept map and includes several text passages giving guidelines and showing some of student’s elaborations and (mis-)conceptions. Based on the well-known didactical triangle an extended scheme shows the connections to teaching-relevant aspects of history. Proposals concerning teacher education are included.

IDEAS ABOUT MODERN MATHEMATICS AND TEACHER TRAINEES AT LICEU NORMAL DE PEDRO NUNES (1957-1971)

Teresa Maria Monteiro

Instituto Politécnico de Beja

*This poster presents a longitudinal analysis of the texts published in *Palestra* magazine by mathematics teachers, not teacher trainees^[1]. In our study we divided in four categories the ideas that were advocated by this magazine: Mathematics and programs; Geometry teaching and axiomatics; Modern algebra and algebraic structures; Teacher training and math didactics. We see a convergence of views on the need for the introduction of modern algebra in programs and math classes; the moderate interest in the geometry axiomatization among pupils; and a paradigm shift in teaching methods, which call for student participation in the learning process and also for the teacher continuing education. **Key-words:** Portuguese mathematics education history, Teacher trainees, Modern mathematics.*

It is important to investigate the history of school subjects (Chervel, 1990). The international movement of Modern Mathematics was felt in Portugal in 1950s and 60s and introduced a change in contents and methods in the teaching of this discipline (Matos, 2006), to which the teacher training had to respond.

We are interested knowing a little better what ideas about modern mathematics and mathematics education circulated at Pedro Nunes Normal Secondary School (*Liceu*). With this objective, we focused on *Palestra* magazine, which was founded by Dias Agudo, methodologist and dean of the *Liceu*. The magazine was subsidized by the Portuguese State. The first number was published in January 1958 and the last one was number 42, published in 1973, which excluded mathematics sections. The last one with a mathematics section was number 41, published in 1972.

The chronological scope of this study is limited by the reopening of the training programs in this *Liceu* in October 1956 (which had been suspended in 1947) and the beginning of José Veiga Simão's mandate, who sets in motion a new reform of the Portuguese educational system. This was preceded by a new training model in 1969, which led to the teacher training reduction from 2 to 1 year.

In our study we divided in four categories the ideas that were advocated by the magazine^[2]: Mathematics and programs (Calado, 1958; Dantas, 1958; Leote, 1958 and 1964; Silva, 1959); Geometry teaching and axiomatics (Leote, 1958 and 1964; Paulo, 1959 and 1962); Modern algebra and algebraic structures (Calado, 1958; Leote, 1958; Paulo, 1963); Teacher training and mathematic didactics (Calado, 1958; Dantas, 1958; Leote, 1958 and 1964). Leote (1958) argued that teachers should "enjoy and encourage" (p. 37) the creative activity that students possess. He further sustains that the teacher must be an investigator and shouldn't think that concepts that he himself took years to learn are obvious to pupils. Leote and Dantas argued that the heuristic

method, although desirable, does not respond to all educational needs. A real difficulty that those teachers were faced with was the overcrowding in classes, which had 42 students. For Dantas (1958) a problem resided in the "limited time to teach [...]. The pace of discovery is very slow" (p. 99). Dantas cites the conclusions of the Congress of Mathematics Education held in Salvador da Bahia from 4 to 7 September 1955: "All [the methods] are good as long as the teacher leads the student to participate rather than to observe." (p. 101). Calado (1958) warned about the need to "review the scientific recruitment and preparation of teachers of secondary education" (p. 91) in the light of new concepts and language which are intrinsic to modern mathematics. Addressing the Minister of National Education, Pinto Leite, who was present at the *Liceu*, Calado requested that in the Secondary Schools with teacher training "there should be beginners' courses or seminars on Algebra of the Logic, on the Foundations of mathematics and on Modern Algebra carried out by renowned teachers "(p. 102). Calado argued that these courses should be compulsory for the trainees of the mathematics group and disseminated to all teachers of Mathematics and Physics of secondary education. A response to this desire came to pass with the lessons of Silva (1959).

In our study, we came to the conclusion that there was an upgrading of knowledge and of the presented proposals, just like in the rest of Europe and the United States. With respect to teacher training, though not discordant, the authors refer to different facets of this issue: Gonçalves Calado, Silva Paulo and Sebastião e Silva contribute to scientific education; Furtado Leote and Martha Dantas reflect about the teaching of mathematics. In the *Liceu*, the presence of leading figures of the ministry of education and of the Portuguese State was frequent, including the Republic's President Almirante Américo Tomás, who visited the *Liceu* in 1959 and 1966. Between 1957 and 1971 we found 50 mathematics teacher trainees in this school and, possibly, they heard these words.

NOTES

1. For teacher trainees you have another work (Matos & Monteiro, 2012).
2. Calado: 1958, *Palestra*, 1, 89-105; Dantas: 1958, *Palestra*, 3, 97-103; Leote: 1958, *Palestra*, 1, 37-48; Leote: 1964, *Palestra*, 21, 110-123; Paulo: 1959, *Palestra*, 5, 97-106; Paulo: 1962, *Palestra*, 13, 78-88; Paulo: 1963, *Palestra*, 17, 29-44; Silva: 1959, *Palestra*, 6, Separata 1-66.

*This paper studies the presentation of the Cartesian coordinate system in Euler's *Introductio in Analysin Infinitorum* and in Lacroix's *Traité du calcul différentiel et du calcul intégral* and *Traité Élémentaire de Trigonométrie Rectiligne et Sphérique*, et d'Application de l'Algèbre a la Géométrie, searching for what components made possible its systematization, and bearing in mind students' difficulties.*

INTRODUCTION

It is a well known fact that students have difficulties with understanding and dealing with the representation of functions in the Cartesian coordinate system (CCS). This didactic problematics has led us to determine “which texts must be sought out in history and what questions we should address to them” (Puig, 2011, p. 29). The texts chosen are Euler's *Introductio in Analysin Infinitorum* (1748), and its French translation from 1796-1797, and Lacroix's *Traité du calcul différentiel et du calcul intégral* (1797) and *Traité Élémentaire de Trigonométrie Rectiligne et Sphérique, et d'application de l'Algèbre a la Géométrie* (1797).

REASONS TO CHOOSE THE TEXTS

The reasons to choose Euler's *Introductio* and Lacroix's textbooks are, first, that we wanted to study texts from the moment in history when the present way of representing functions in Cartesian coordinates was being constituted, and from the moment when it was being incorporated as a teaching topic in textbooks. Next, the main reason to choose Euler's *Introductio* is that it is one of the first books to deal with Cartesian coordinates in a systematic way. Lacroix's textbooks have been chosen because 1) they elementarize mathematics in order to teach it (Schubring, 1987), 2) they deal specifically with Cartesian coordinates in a progressive way, and 3) they had a big impact in the teaching of mathematics, not only in France, but also in Spain. Lacroix's *Traité Élémentaire de Trigonométrie Rectiligne et Sphérique, et d'application de l'Algèbre a la Géométrie* was translated into Spanish, as part of the *Curso completo elemental de matemáticas*, a Spanish translation of Lacroix's textbooks. This translation was widely used because it was established as an official textbook by King Fernando VII's law-ranking decree of 1824, whose Article 42 states “in all these

¹ This is a result of a research program funded by the Ministerio de Ciencia e Innovación (EDU2009-10599) and Ministerio de Economía y Competitividad (EDU2012-35638) of Spain.

Chairs [referring to the Chairs of Mathematics and Sciences in Universities], lessons will last one hour and a half in the morning, and one hour in the evening; being used as textbook the Pure Mathematics by Mr. Lacroix translated by Rebollo”. As far as we have found, the Spanish translation *Tratado elemental de trigonometría rectilínea y de la aplicación del álgebra a la geometría* was published eight times, the 8th edition being from 1846. We have used the Spanish 6th edition of 1820 (Lacroix, 1820), and the original French 4th edition (Lacroix, 1807). No Spanish translation of Lacroix’s *Traité de calcul* was published. We have used the original French first edition (Lacroix, 1797).

COMPONENTS OF THE CONSTITUTION OF CCS

As a result of our study, we state that the main components that make possible the systematization of Cartesian coordinates as presented in these texts are:

1. The endowment of negative quantities with meaning both in algebra and geometry, and the setting of a fixed origin (of coordinates).
2. The constitution of the concept of abscissa.
3. The movement from the notion of applicata (a segment raised at the end of the abscissa) to the ordinate concept (a distance measured in the ordinate axis).
4. The movement from coordinates as segments to coordinates as distances, and the consequent movement to coordinates as numbers.
- 5 The establishment of absolute coordinate axes, i. e., axes not specific to the curve.

A study of student difficulties in the light of these components is in progress.

INTRODUCTION TO THE PAPERS AND POSTERS OF WG13: EARLY YEARS MATHEMATICS

Maria G. Bartolini Bussi, Ingvald Erfjord, Esther Levenson, and Cecile Ouvrier-Bufferet

Keywords: *Children play; counting; curriculum; digital tools; family; geometrical shapes; kindergarten and primary school; measurement; relational thinking; teachers' role*

The working group on Early Years Mathematics was established at CERME 6 in Lyon, in 2009. The aim of this working group was, and continues to be, the sharing of scholarly research related to mathematics education concerning children aged 3-8. This age group spans preschool through the early grades of primary school, and takes into consideration that in different countries children begin primary school at different ages.

Since that first meeting in 2009, there has been increased appreciation for the need to provide young children with a rich environment where they can explore mathematical ideas and relationships and increased recognition of the need to explicitly promote young children's mathematical knowledge. There has also been an increased appreciation for the need to explore, investigate, and research different aspects of early childhood mathematics. This was reflected in the working group of 2013 where we saw an increase in the number of presentations (19 papers and one poster were presented) as well as an increase in the number of participants (34 participants from 10 different countries). Table 1 presents an overview of the presentations and participants according to nationality.

Country	Number of papers	Number of posters	Number of Participants
Canada	1		1
China	1		1
France	1		2
Germany	6		12
Greece	1		1
Israel	2		1
Italy	4	1	7
Norway	1		3
Sweden	2		5
Turkey	-		1
TOTAL	19	1	34

During the current conference, there was a growing interest in exploring cultural differences among the various cultures and more of an emphasis on researching mathematics education before the beginning of primary school. In the following sections we offer a brief review of the papers presented at the conference.

The interest in cultural differences was sparked by two papers, one from China (Sun) and one from Italy (Ramploud & Di Paola). Within the mathematical context of addition and subtraction, these papers explored task design in the different countries, different epistemologies, pedagogies, and beliefs related to cognitive processes. Different cultures also have different approaches towards early childhood education. This was apparent when discussing two papers related to the concept of measurement. The paper from Germany (Zöllner & Benz) explored children's ways of comparing lengths indirectly when given a variety of tools and explicit directions to compare the lengths. On the other hand, the paper from Sweden (Lembrer) explored how different concepts related to measurement arise as children engage in a map drawing activity.

Many of the papers focused on specific mathematical content. As mentioned above, addition and subtraction and measurement were the focus of four papers (Sun; Ramploud & Di Paola; Zöllner & Benz; Lembrer). Four papers focused on geometrical shapes (Acar-Bayraktar; Bezold & Ladel; Maier & Benz; Tabach, Tirosh, Tasmir, Levenson & Barkai). The geometry studies were based on various theoretical frameworks, and explored learning and teaching geometry in different situations such as classifying, defining, reasoning, describing, explaining, and working on properties. The studies also utilized different materials such as drawn representations of figures as well as concrete objects. Four papers related to counting and enumeration (Bartolini-Bussi; Guidoni, Mellone & Minichini; Ouvrier-Bufferet; Sinclair & Sedaghatjou). These papers described very different ways of promoting children's knowledge of these skills, including the use of narratives and storytelling (Guidoni, Mellone & Minichini), the use of concrete materials and lists (Ouvrier-Bufferet), and the use of digital technology (Sinclair & Sedaghatjou). Another paper described promoting prospective primary teachers' knowledge of counting and enumeration through semiotic mediation and the use of a giant abacus (Bartolini-Bussi).

In addition to specific mathematical content, mathematical processes such as reasoning, generalization, and explanations may also be encouraged during the early years. This was the focus of two papers (Levenson & Barkai; Vighi). The paper from Israel (Levenson & Barkai) theorized about the functions of explanations during mathematical activities while the paper and poster from Italy (Vighi; Vighi & Aschieri) showed how even young children in kindergarten are capable of reaching general conclusions when engaging in a mathematical puzzle.

Finally, one paper (Jung & Vogel) addressed the issue of coding children's mathematical activities while they are involved in situations of play and exploration, revealing the existence of preferred mathematical domains for particular children during the process of problem solving.

One of the new areas of research which arose during the CERME 8 conference was that of Information and Communication Technology (ICT) and how it can be integrated into early years mathematics. Once again, cultural differences were noted. In Sweden (Lange & Meaney), a study was conducted which explored the mathematics which may be hidden in popular games played on the iPad. A paper from Canada (Sinclair & Sedaghatjou) presented a study related to specifically designing a game for promoting young children's knowledge of number concepts. A third paper (Hundeland, Erfjord & Carlsen) explored the roles of the teacher when employing ICT related mathematics activities. A fourth paper (Bezold & Ladel) analyses how ICT can support the mathematical learning processes, focusing on exploration and discovery of mathematical relations. This new area of research led to additional research questions, such as the difference between engaging children with concrete versus virtual manipulatives.

Besides the paper described above (Hundeland, Erfjord & Carlsen) which investigated the teacher's roles when integrating ICT with mathematics learning, two other papers focused on early childhood teachers. One paper (Bartolini-Bussi) described a program for developing preschool teachers' mathematics knowledge while a second paper (Kröger, Schuler, Kramer & Wittmann) explored the beliefs of kindergarten and primary school teachers related to mathematics teaching and learning. However, teachers are not the only ones which may influence children's mathematical learning. Two studies (Acar-Bayraktar; Tiedemann) focused on the possible roles of the family in supporting mathematics learning during the early years.

The obvious common thread which runs throughout all the papers described above is the desire to improve mathematics learning for young children. That being said, as can be seen from the diversity of papers described above, there are many aspects to consider and many avenues yet to explore. At the last session of the conference, a questionnaire developed by the group leaders, was passed out to participants. The questionnaire included the following four questions: (1) Have you participated in the past in this working group? (2) If so, have you noticed a change? (3) Do you have specific questions? (4) What have you learned? In general, 20 participants had participated in this working group in the past and some of the changes they noticed were in the way the group was organized, pairing papers together for a fruitful discussion, having reactors to each paper, and allowing time for small group discussions. Other issues which arose either as questions or as new ideas

learned during the conference, related to the different cultural perspectives, to the practice and acceptance of different research models, and the issue of ICT. For several participants, this was their first time taking part in this group. We hope to see additional participants join this working group at the next CERME in 2015.

THE SECOND DISCERNMENT INTO THE INTERACTIONAL NICHE IN THE DEVELOPMENT OF MATHEMATICAL THINKING (NMT) IN THE FAMILIAL CONTEXT

Ergi Acar Bayraktar

Johann Wolfgang Goethe-University, Department of Mathematics Education

As a reflection of mathematics education on developmental psychology and cognitive development, Götz Krummheuer created the concept of the “interactional niche in the development of mathematical thinking (NMT)” as a new theoretical framework in the mathematics education. This theoretical framework has been adapted as a developmental niche in the familial context (NMT-Family). Through an empirical study in familial play situations more details of the NMT are investigated. In this paper it will be stepped into the second discernment into the NMT-Family through the study erStMaL-FaSt.

1. INTRODUCTION

The IDeA (Center for Research on Individual Development and Adaptive Education of Children at Risk) is a research centre, which investigates extensively the development of children at risk and the processes of individual learning. This research centre is constituted by the German Institute for International Educational Research (DIPF) and Goethe Universität Frankfurt. The financial support provided by the Ministry of Higher Education, Research and the Arts from the state of Hessen. [1]

One of research project of IDeA Center is a Project erStMaL (early Steps in Mathematics Learning), which investigates the mathematical development of children with regard to their migration background. It is designed as a longitudinal study to follow children from the age of three, until the third year of primary school from a socio-constructivist perspective. While the first survey period contains only kindergarten children, the second survey period contains the same children in primary school ages (see also Acar Bayraktar et al. 2011).

In the scope of the project erStMaL, a family study is performed, which is designed as a longitudinal study and named as erStMaL- FaSt (early Steps in Mathematics Learning-Family Study). The study deals with the impact of the familial socialization on the mathematics learning and due to the following three criteria, 8 participants are chosen from the project erStMaL. The criteria are the ethnic background (German or German/Turkish), the duration of the formal education of the parents and the sibling situation within the families (see Acar Bayraktar and Krummheuer 2011, Acar Bayraktar 2012). Data collection comprises of recorded videos and their transcripts. Once in a year, an appointment is arranged with each family. This leads step by step to a collection of data from each child. In each appointment the erStMaL child is

video-recorded together with members of the family while they are playing in different settings.

For the family study two mathematical domains are chosen: Geometry and Measurement. Four play situations are conceived, due to these two mathematical domains. The members of the family are supposed to choose at least 2 games out of 4 and to perform them. For participation of all families, instruction manuals of each play are made both in German and Turkish, which can be spoken freely by families during play situations. The game materials are provided and put at the disposal of the family in the recording room. Currently, the new play situations are set up for the third observation phase in September.

In this paper it will be stepped into the second discernment into the NMT-Family.

2. THEORETICAL BASIS

“The play, for the child and for the adult alike, is a way of using mind, or better yet, an attitude toward the use of mind”(Bruner 1983, p. 69).

erStMaL-FaSt enables families freely to play with their children. During each play situation with maintenance of father/mother/sibling the child explores something about the issued mathematical domain. This accompaniment of family provides to the child some “learning offerings” and interactive negotiation about the mathematical play. During the interaction of such various mathematical learning situations, there occur different emerging forms of participation and support.

For the comparison among the various mathematical learning situations and for the longitudinal analyses, the concept of the “interactional niche in the development of mathematical thinking” (NMT) will be used, which has been constituted by Krummheuer (2011a, 2011b). He explains NMT as in follow:

The concept of the “interactional niche in the development of mathematical thinking” (NMT), consists of the provided “learning offerings” of a group or society, which are specific to their culture and will be categorized as aspects of “allocation”, and of the situationally emerging performance occurring in the process of meaning negotiation, which will be subsumed under the aspect of the “situation” (Krummheuer 2012).

NMT- Family is a *subconcept* of NMT and offers the advantage of more close analyzes and comparisons between familial mathematical learning occasions in early childhood and primary school ages.

In view of the design of FaSt, three components of NMT-Family are shown and then their details given below:

NMT-Family	component: content	component: cooperation	component: pedagogy and education
aspect of	mathematical	Play as a	developmental theories od

allocation	domains: Geometry and Measurement	familial arrangements for cooperation	mathematics education and proposals of activeness for parents on this theoretical basis
aspect of situation	interactive negotiation of the rules of play and the content	leeway of participation	folk theories of mathematics education, everyday routines in mathematics education; MLSS

Content: In the practice of erStMaL-FaSt, children and their families are confronted with mathematical play situations, which are – as mentioned - either in mathematical domain “Geometry” or in mathematical domain “Measurement”. The play situations in erStMaL-FaSt are designed to offer the families opportunities for interactive negotiations. From the situational perspective, in these play situations, processes of negotiation emerge, in which the rules of play and/or mathematical topics might be chosen as themes.

Cooperation: The process of cooperation between the adult and child provides the opportunity to refine their thinking and to make their performance more effective. Depending on this cooperation, a different leeway of participation comes forward. Krummheuer meant Leeway as a colloquial meaning of “room for freedom of action” (Krummheuer 2012).

“Leeway of participation” („Partizipationsspielraum“, Brandt 2004) is one of the interactionistic approaches, by which a child explores his/her cultural environment while co-constructing it. “Leeway” is taken here in the colloquial meaning of “room for freedom of action”. So, this is a concept belonging to the situational aspect. Brandt (2004) explains that the participants interactively accomplish different margins of leeways of participation that are conducive or restrictive to the mathematical development of a child. (see also Krummheuer 2011c; 2012). Alongside of contents, the children are involved in the social settings in the play situations, which are variously structured as in child-parents interaction and/or child-sibling interaction. These social settings need to be accomplished in the process of interaction.

Pedagogy and Education: Developmental theories and theories of mathematics education describe and delineate learning paths for the children’s mathematical growth from which point of view. With the respect to the folk pedagogy, the participating adults and children become situationally active and operant in the concrete interaction. The cognitive development of each individual is constitutively bound to the participation of these individuals in a variety of social interactions. During these interactions and participations in the mathematical discourses, there occurs a “support system”, which is proposed as a concept for the learning of mathematics and called “Mathematics Learning Support System” (MLSS) , with respect of Bruner’s concept of a Language Acquisition Support System (LASS)

(Bruner 1986, p. 77; see also Acar Bayraktar and Krummheuer 2011, Krummheuer 2011b, Tiedemann 2010).

In the patterns and routines of interactions between child and families, MLSS occurs in different ways. In the mathematical competitions of play situations in FaSt, adults maintain the play, in which, possibly, emerges a support system. During these play situations they impart *their knowledge* by giving for example explanation to the statements during the negotiation of meaning. Not only through “the right given instructions” but also through “the wrong given instructions” by families, there occur some different types of support. Through the negotiation of the given instructions, children and parents lay out new interpretations, which support the development of the child either in a positive or a negative way (see Acar Bayraktar and Krummheuer 2011, Acar Bayraktar 2012).

With the respect to all these three components, it will be introduced one chosen scene as an example to show how the spatial abilities (spatial thinking) in the interactional niche in a familial context emerge.

3. A PLAY: BUILDING 02

The mathematical play “Building 02” refers to geometry and spatial thinking. The family is supposed to build three-dimensional version of the picture with wooden bricks, which all are in the same size and weight. Supposedly, they perform the relations between two- and three-dimensional representations. The player chooses one card from the deck and builds a wooden corpus from the image on the card. In the play, cards are placed on the table face down. Each card has a difficulty level ranging from 1 to 4. The cards with the number 1 are the easiest. The cards with the number 4 are the hardest, whose transitions between the various blocks are fluid and are purposed more complicated.

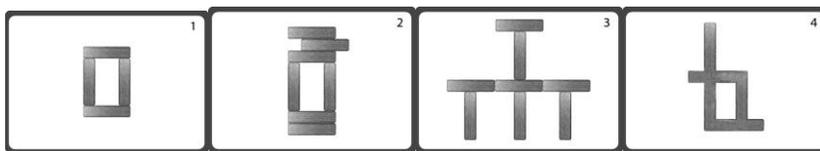

Fig 1. The game cards in different levels

An Example: Family Ak

The required information about Family Ak is in the following table:

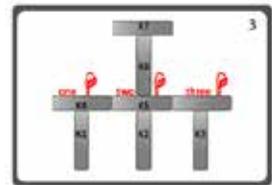

Aleyna	6;9 years old	Single Child	German, Turkish rudimental
Father	Studied 15 years	Higher Education	German, Turkish rudimental
Mother	Studied 12 years	Higher Education	German, Turkish rudimental

Fig 2. Information about Family Ak

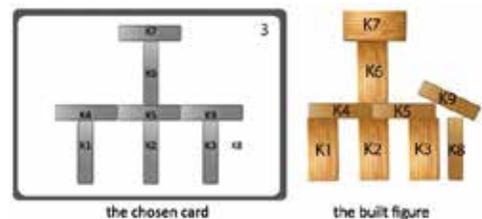

reaction can be interpreted, that she calls her attention to the block, which actually has to be laid next to the K5 on the right side on the card, in the built figure and hereby she gives her a chance to think about her oversight. Then she tells her daughter, that there are only two blocks on “it”. Probably the pronoun “it” refers to the structure, which consists of K1, K2, K3. Hereby she might try to open a discussion that could foster her daughter to think about her oversight. Likely to make easier Aleyna’s task, her mother gives her a clue, that how many blocks on which structure should be put. But then her father punctuates and warns her mother about, to be quiet and not to interfere herself to their play. After the both commentaries made by her parents, Aleyna gives a response, which is not clear enough to determine if she gives it to her mother’s commentary or her father’s. But as a consequence, she does not accept the critics and tells that the built corpus is correct.

After Aleyna’s denial, her mother proposes her to look the built figure carefully.

Then her father tries to call her attention to her oversight (?) on the card. By showing with his index finger, he counts the interjacent blocks on the card. This reaction of him could be interpreted as he is influenced by his wife’s struggle to show Aleyna her oversight. Hence, he may try to show and make it

clear how the structure actually has to be built. As a confirmation of the father’s explanation, the mother tells her that the built figure is not correct without the third block, which has to be laid next to K5. The mother calls her, probably to get a response from Aleyna. Aleyna tends to respond her mother and probably tries to rectify her own oversight. But the father cut her off and says that she lost the turn. Hence, he takes the card away and tells that his turn begins. Presumably, he does not have enough perseverance to explain to Aleyna what her oversight is and how she can rectify it. Against her father’s reaction, she takes the card furiously from him and puts K8 vertically near K3. Possibly she does not loose the game. It also could be that she very much involved in the correction of her initial construction and would like to continue regardless what game they are playing. Then the father reacts as if she is in the contravention of the play rules by working over the built figure. Without saying anything, Aleyna goes on constructing the figure and puts K9 diagonally on K8 and K5 (see picture in below).

As response, the father gainsays her action and tells her smilingly that the built corpus is not the same with the figure on the card. This could be as a

interpreted as the smirk of the winner of the game or as a cordial attempt to mitigate the tension in the dispute. Aleyna lays K9 back on the table as if she abandons insisting, that the built figure is correct and she did not loose her turn. At the end of Aleyna’s turn, the father says that his turn is up and removes blocks of the built corpus in the box. Obviously this is the end of Aleyna’s turn.

4. CONCLUSION

As a summary, , a developmental niche for Aleyna emerges slightly in the chosen play situation, although there are an oversight of Aleyna and deficient information by father. While her father cuts out that she did wrong and lose the turn, her mother tries to give some hints and to call her attention to her oversight. With both emotional motivations, encouragement by her mother and declining reaction by the father, Aleyna realizes her oversight and tries to work on it again. In spite of her endeavour her father insists, that she doesn't build the corpus correctly and thus loses her turn. However this reaction of her father works on Aleyna and urges her to continue improving her construction. Actually and finally she does not come up with the correct solution but her activities give reason to assume that her competencies in spatial structuring and visual discrimination are enhanced.

She sets the different faces of blocks in the figure, and also she cannot coconstruct the built figure. According to the National Research Council Committee on Early Childhood (National Research Council 2009, pp. 186), the children at age 4 can identify the faces of 3-D shapes to 2-D shapes, can match faces of congruent 2-D shapes and can represent 2-D and 3-D relationships with objects. Furthermore at 5 years old they can build complex structures from pictured models. Considering these statements, it could be assumed that Aleyna's spatial thinking is not developed enough to think about parts and to relate them to the whole. But after constructing the figure with oversight, realizing and trying it to coconstruct, are the indicators to perceive Aleyna's developmental niche. Both together, encouragement by her mother and disapproval by her father, directs and provides her to see "mistakes" and to struggle getting at the "truth".

According to this analysis the three components of an interactional developmental niche in familial context can be structured as in follow:

Component "Content": Block Building provides a view of children's initial abilities to compose 3-D objects. In the chosen play, four goals are pursued: Spatial structuring, operating shapes and figures, static balance between blocks, identifying the faces of 3-D shapes to 2-D shapes. By National Research Council is also reported that 5-years-old children can understand and can replicate the perspectives of different viewers. These competencies reflect an initial development of thinking at the relating parts and wholes level (National Research Council 2009, p.191). Aleyna realizes the spatial relations between 2-D and 3-D objects. She can relate some parts with the whole. So, as an allocation aspect occurs the spatial structuring and operating with shapes during the play. As a situational aspect, Aleyna negotiates with her father and mother. In this trial structure, there emerges a negotiation about the built figure. But neither her mother or her father assists her to explore how the figure actually has to be and what she overlooks on the built figure, there occurs a *consensus*, that Aleyna built the figure incorrectly.

Component “cooperation”: The play situation is changeable, but directed by father. While he plays with his daughter, the mother does not refrain herself from interfering in their play and giving help to her daughter. Thus she plays such a role as a contributor in their play.

While her mother encourages Aleyna seeing her oversight, she also gives her a chance to an exploration and discussion on it. This means that she opens up a leeway of participation for Aleyna. While her father disapproves her, he also motivates her to struggle getting her due. So, the parents together in their seemingly uncoordinated moves open up a leeway of participation for Aleyna. On the other side, because the father always tries to end up her turn and brings no more discussion about the built figure, he limits the leeway of participation for Aleyna. Thus in all, father and mother together co-construct a leeway of participation in this play situation.

Component “pedagogy and education”: The chosen play situation refers to the spatial structuring in geometry. In the chosen scene, by the organizing and setting objects, the graphical- and spatial-development of Aleyna are slightly assisted. While she is called attention to her oversight and is motivated co-constructing the built figure, she is not directly assisted, how this figure actually has to be. One can conjecture that the parents follow a rather constructivistic idea of helping and educating.

NMT Family Ak Building 02	component: content	component: cooperation	component: pedagogy and education
aspect of allocation	Geometry, Spatial structuring, operating shapes and figures, static balance between blocks, identifying the faces of 3-D shapes to 2-D shapes.	Playing with father, and Mother as a contributor	Theory of the development of spatial skills and spatial structuring
aspect of situation	negotiation between father, mother and Aleyna about the built figure; <i>consensus</i>	Different leeways of participation offered by the parents	Emotional motivation from parents provides Aleyna to explore her oversights and to endeavour coconstructing the built figure.

“The play under the control of the player gives to the child his first and most crucial opportunity to have the courage to think, to talk, and perhaps even to be himself” (Bruner 1983, p. 69).

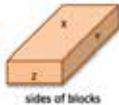

In the chosen example, with mother's encouragement and father's disapproval, Aleyna realize her oversight and tries to resolve it. Although there occurs an "antagonisms" between Aleyna and her father, she can interpret her deficiency. This is an over careful learning progress, in which the interactional developmental niche slightly occurs for Aleyna. Clements and Samara reports that spatial processing in young children is not qualitatively different from that of older children or adults, but children with the age produce progressively more elaborate constructions (2007, p. 512). Hence, It will be really exciting to go on augmenting the examples of Aleyna, and to find out how NMT-Family functions work on Aleyna's spatial development in her familial context.

5. NOTES

BAMBINI CHE CONTANO: A LONG TERM PROGRAM FOR PRESCHOOL TEACHERS DEVELOPMENT

Maria G. Bartolini Bussi

Università di Modena e Reggio Emilia (Italy)

This paper aims at reporting about a five years program for preschool teachers development, with the author as a teacher educator, on appointment of the city council of Modena. The project has involved every year about 25 teachers. In this paper the political background and the structure of the program are reported together with some outcomes concerning the materials for teacher development, the activities realized in schools by the teachers and the construction of a community of inquiry involving teachers, teacher educators, pedagogists and policy makers.

INTRODUCTION

Modena is a city of about 190.000 inhabitants in the region Emilia-Romagna. In Italy compulsory education starts at 6 (first grade of primary school) but there is an ancient sensitivity to the organization of public school institutions for children aged 0 – 6, especially in some regions, like Emilia-Romagna. After the Second World War, parents, educators and politicians of this region united their efforts to provide child care for young children. Originally inspired by the need of women to return to the work force, this education system has been developed in different places (e.g. Reggio Emilia, Modena, Bologna) with programs that have caught the attention of early childhood educators worldwide. In order to fill the social gap between peasant, working and middle classes (*cognitive democracy*) the civil society agreed to start high quality schooling as early as possible, as 6 years old children might have already experienced the devastating effects of social inequalities. In Reggio Emilia, Loris Malaguzzi developed the so-called Reggio approach, well known all over the world (<http://www.reggiochildren.it/?lang=en>), while in Modena, Sergio Neri developed a parallel approach, with similar formats for teacher development and similar involvement of parents and the civil society. The differences between the two approaches may be very roughly outlined focusing on different curricular choices for children aged 0-6, with a major focus on *enculturation* in Modena and on the so called “*hundred languages of children*” in Reggio Emilia.

I have worked in both programs, for a short time on appointment of Reggio Emilia city council and for a longer time on appointment of Modena city council. The latter collaboration was started in the eighties, when Sergio Neri was in charge of the pedagogical coordination of the municipal preschools, and was resumed in 2007 after a ten years interruption. An outcome of the first phase collaboration was the preparation of the field of experience *Lo spazio, l'ordine, la misura*, i. e. early year mathematics, of the *Orientamenti* (1991, the national suggested curriculum for preschools: <http://www.edscuola.it/archivio/norme/programmi/materna.html>). This contribution concerns the second phase of collaboration, started in 2007.

THE PROGRAM FOR TEACHER DEVELOPMENT

As preschool is not compulsory in Italy, in the case of this program, the educational policy has to be distinguished into two parts: the national one; the local one.

The political choices at the national level

In 2007 a major effort was started by the Ministry of Education to design anew the standards (*Indicazioni*) for students aged 3-14, thus involving also the level of preschools (covered by *Orientamenti* from 1991). General educators called up the complete responsibility for the new document for the age 3-6, without consulting experts of specific subjects (contrasting the choices made in the early 90s), and decreased the reference to the adult culture as a curriculum organizer and increased the freedom and responsibility of children themselves in defining the direction of their learning. The six fields of experience of the *Orientamenti* were reduced to five, with the merging of mathematics and science in only one field of experience (*la conoscenza del mondo*, i. e. world knowledge). In the fifth field of experience words like numbers and counting totally disappeared, as considered too much oriented to mathematics in the adult sense. The draft document of *Indicazioni* was officially issued in July 2007 to raise comments from schools. The part of the *Indicazioni* for children aged 3-6 was quickly put in the shade, as comments from schools were not positive at all. In 2012 a new version of *Indicazioni* has been issued for students aged 3-14. In this case, although the number of fields of experience for preschools has not been restored to six, the weight of early years mathematics has been increased distinguishing in the fifth field of experience two subfields, concerning mathematical and scientific experience.

http://hubmiur.pubblica.istruzione.it/web/istruzione/prot7734_12) **The political choices at the local level (Modena)**

In 2007, when I started the second phase of collaboration with the Modena city council, preschool (and especially the presence, if any, of early years mathematics) was in the heart of the debate at the national level, as learned societies had strongly criticized the choices made by general educators. To design anew a program for preschool teacher development it was necessary, first, to agree on the intended curriculum for schools. Officially, the 1991 *Orientamenti* have not been abrogated as the new *Indicazioni* were still only a draft to be discussed by schools. The local authority for instruction, Adriana Querzè, a very intelligent and open-minded policy maker, agreed that, for mathematics education, *Orientamenti* (1991) still represented the framework of the municipal preschools in Modena as a model of enculturation, updating the original text to meet the needs of schools in the new millennium. Hence the political choice was to focus on early years mathematics (especially on numbers and space) to be tested in the large laboratory of the 22 municipal preschools.

The local organization

Every year, eight different projects are offered for teacher development by Modena city council: Italian language, Mathematics, Science, Art, Music, English, Orienteering and Philosophy for children. Enrolment in one project is compulsory for each teacher of the 22 municipal preschools and included in their working hours. Local teachers from governmental, private or religious preschools are welcome to (yet not forced to attend) the meetings. Also prospective preschool teachers from the Faculty of Education are welcome, as a part of their compulsory schedule for practicum. The system of Modena municipal preschools and the programs for teacher development are coordinated by a team of pedagogists (education committee). For the Mathematics project, two pedagogists have been involved in sequence: Maria Teresa Corradini (2007/2011) and Mariavittoria Vecchi (2011/now). I am the only permanent mathematics teacher educator with some other invited teacher educators for specific meetings. In 2010 a new member was appointed by the city council to join the small steering committee: Susanna Stanzani, a former teacher, expert in multimedia documentation; for nearly two years, she has part time taken care of the collection of materials from schools and authored the multimedia report on behalf of the city council.

For each project, every year the pedagogist specifies, in cooperation with teacher educators, the focus of the yearly project, the timetable and the contents of each meeting and the way of documenting school activities. She is in charge also of special meetings at schools to discuss with small groups of teachers problems found during school activities. In this sense, she represents a bridge between teacher educators and teachers. Her feeling of teachers' attitude is precious to detect whether there are problems or needs in the implementation of activities.

At the beginning of every school year a group of teachers is appointed (about one per school) for each project. Teachers are encouraged to be permanent members of the projects, but, for Mathematics project, in the period 2007-2012 there was a large fluctuation, because of different reasons (teachers' retirement; teachers' moving to other schools; new teachers entering municipal preschools and so on). This fluctuation represents a problem as every year it is necessary to welcome newcomers and to organize meetings so that they feel comfortable and ready to work. Now (2012) expert teachers are expected to take part as tutors in the small group sessions (third meeting, see below).

The general structure of five half day meetings with the group of about 25 teachers is shared by all projects. All the meetings but the third involve teachers, teacher educators and pedagogists.

First meeting (October): welcome to newcomers, summary of the past experiences and launch of the year activities (adult education and examples from classrooms)

Second meeting (November): continuation; design of some activities for different students' age (3, 4 or 5 years old);

Third meeting (January: small groups of teachers with pedagogist and expert teachers, in schools): 2-3 sessions for discussion on the ongoing activity (problems, needs, criticisms, new ideas);

Fourth meeting (February): discussion about the issues of the third meeting;

Fifth meeting (May): presentation and discussion of some activities realized in the schools; small exhibition of materials from schools.

If necessary, additional meetings with the pedagogist or the teacher educators are agreed with groups of teachers to meet specific needs.

Occasionally each project presents to the large group of teachers (about 160) of municipal preschools the outcomes of the project. The Mathematics project, called Counting and Measuring at the beginning, and later *Bambini che contano* (Counting Children), presented the partial outcomes in September 2010, after a three years activity, with speeches by the teacher educator, the pedagogist and a group of teachers. The multimedia report of the project will be published on-line at the beginning of 2013 at the website of the documentation centre for education of the town council of Modena (<http://istruzione.comune.modena.it/memo/>)

The outcomes of a complex long term program of teacher development concerns different issues. The general effectiveness is measured by changes in teachers' beliefs and school activities. They both have been focused in the program, the former with teachers' interviews and the latter with the documentation of school activities.

THE REPORT *BAMBINI CHE CONTANO* (COUNTING CHILDREN)

The multimedia report is divided into several parts and organized into three frames: <http://memoesperienze.comune.modena.it/bambini/index.htm>. The first part (introduction) is accessible from the left frame and concerns the intended program from a political perspective (video interview with Adriana Querzè), from a pedagogical perspective (interview with Mariavittoria Vecchi) and from the mathematics educator perspective (interview with Maria G. Bartolini Bussi). In the same introduction video interviews with teachers focus the links between theory (as perceived in the meetings with teacher educators) and practice (the school realization) and the changes, if any, in their system of beliefs about early years mathematics.

The main frame contains a rich repertoire of activities realized in the schools, with teachers' design and report. For each activity, there is a collection of commented children's protocols (drawings, transcripts of individual interviews, transcripts of either small group or large group discussion, video clips, and so on). School activities are divided into four parts, each structured in different chapters: Hands and finger counting; Slavonic abacus; Everyday mathematics; Numbers in space. The main frame has been designed to be independent from the other parts of the multimedia report. It is targeted to laymen (as long as they are interested in education) and may be used, for instance, to present school activities to parents and members of the civil society.

The right frame links to a rich collection of materials for teacher development, that put at disposal of teachers printable texts, videos, annotated and translated references usually available only to researchers in specialized literature, a glossary and a short presentation of each quoted author.

The reference to scientific literature in teacher development has been discussed and agreed by the teacher educator, the pedagogist and the policy maker. This choice cannot be taken for granted: in most cases in Italy teacher development is likened to teacher training with exemplary activities to be repeated in schools. The long term feature of this program allowed maintaining a high quality offer, to work at a slow pace, involving teachers as protagonists of the innovation and treating them like professionals of culture and education rather than like imitators of recipes.

THEORETICAL FRAMEWORK

To approach the issue of counting and measuring some foci were agreed with the pedagogists and teachers at the beginning and reconsidered every year (in the first meeting). The approach drew on the firm belief that mankind came to construct mathematics as a cultural object, producing *artefacts* which embody mathematical meanings and processes, although the emergence of meanings for users cannot be realized without specific activities (Meira, 1998). Hence we focused:

- The function of some selected cultural artefacts, developed by mankind.
- The teacher's role as cultural mediator in the enculturation process.

The theoretical framework for analyzing and designing the teacher's role in the classroom process was slowly reconstructed with teachers after the framework of semiotic mediation (Bartolini Bussi & Mariotti, 2008), that had already been validated from primary school on. In this paper I only report the main ideas from the perspective of the teacher's role.

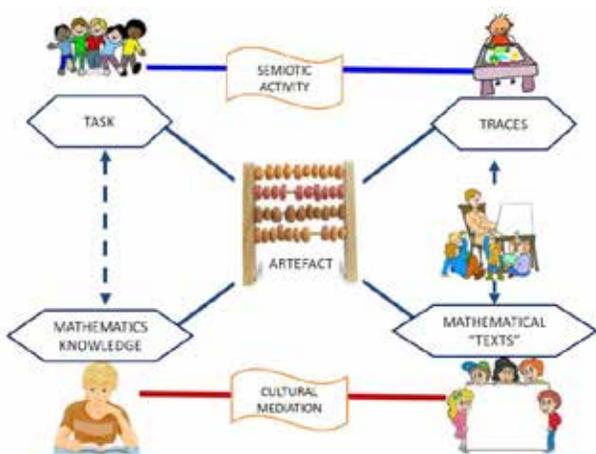

Figure 1: Semiotic mediation

The teacher is in charge of two main processes: the design of activities; the functioning of activities. In the former the teacher makes sound choices about the artefacts to be used, the tasks to be proposed, the pieces of mathematics knowledge at stake, according to the curricular choices. In the latter, the teacher exploits, monitors and manages the children's observable processes (semiotic traces), to decide how to interact with

children and what and how to fix in the individual and group memory.

Some cultural artefacts were considered by the group as paradigmatic at the beginning (others were added later taking into account teachers' suggestions). A giant

Slavonic abacus (especially for children aged 4 and 5, see fig. 2) was chosen at the beginning as paradigmatic by the whole group (see below).

Mathematics knowledge at stake was shared exploiting the research studies on counting and measuring processes. This choice was strongly biased by the initial choice to give value to numbers, counting and measuring; later a focus on space too was introduced.

Exemplary tasks were collaboratively designed by the whole group during the meetings. Others were creatively designed by teachers during school activities. Tasks were intended for individuals, for small groups or for large groups.

The design process is encapsulated by the left triangle of the fig. 1. The other parts of the scheme concern the functioning in the classroom. When children are given a task they start a rich and complex semiotic activity, producing traces (gestures, drawings, oral descriptions and so on). The teacher's job is first to collect all these traces (observing and listening to children), to analyze them and to organize a path for their development towards mathematical "texts" that can be put in relationship with the pieces of mathematics knowledge into play.

EXAMPLE: THE GIANT SLAVONIC ABACUS

The artefact

At the beginning of the second year of activity (2008/09) all the municipal preschools were given a giant Slavonic abacus. Teachers themselves had designed it with forty beads because this number meets the most common needs of school activity (e.g. counting children in the roll, counting the days per month in the calendar). The large size fosters large body gestures (even steps) to move the beads. Intentionally, schools received a dismantled abacus, as most teachers agreed that the very assembling could have been an important part of the exploration of the artefact.

Figure 2: The giant Slavonic abacus

The mathematics knowledge at stake

The "embodied" mathematical meanings were analyzed in the meetings:

Partition, to separate counted beads from beads to be counted;

One-to-one correspondence, between beads and numerals;

Cardinality, given by the last pronounced numeral;

Sequence of early numerals, to be practiced in counting.

Place value (early approach), as beads are divided in tens.

THE SYSTEM OF TASKS FOR THE SLAVONIC ABACUS

A system of suitable tasks was collaboratively produced in the meetings, drawing on the same methodology of projects for primary and secondary school (Bartolini Bussi & Mariotti, 2008; Bartolini Bussi, 2009; Bartolini Bussi et al., 2011). The aim is to foster children's productions of different voices to allow the teacher to organize a *polyphony of voices*, which, according to the theoretical framework of semiotic mediation, nurtures the individual construction of mathematical meanings during classroom discussions. In this way the same artefact is looked at from different perspective. Some tasks tested with 4 or 5 years old children follow. Teachers have arranged these tasks (or similar ones) according to their educational planning.

Task 1: The first impact

Tasks are different if the abacus is assembled (A) or if it is dismantled (B): *A) What is it? Have you seen it before? What's its name? B) What have I carried today? What do you see? Do you know objects with many beads?* Such tasks, to be used in either small or large group discussion, aim at evoking earlier experiences and involving children. At the end the name may be introduced (in Italian *pallottoliere* – abacus has the same root as *pallina* – bead). This tasks foster the emergence of a *narrator* voice. An individual drawing of the materials is in the fig. 3 (A).

Task 2: The structure of the artefact

How is it made? What do we need to build another one? How to give instruction to build another one? Such task, to be used in either small or large group discussion, aims at identifying the components and naming them in a correct way and at describing the spatial relationships between them. They foster the emergence of a *constructor* voice. After discussion, individual drawing tasks are given: *draw our abacus*. The previous verbal analysis of the structure of the artefact fosters the production of very detailed drawings, with, for instance, the right number of beads and the realistic representation of legs and other parts (fig. 3, B and C).

Task 3: The use of the artefact

The task is functional to the context where the artefact is used. For instance it may be used to keep the score in skittles or to count the present children during the call. It may be given in small or large groups. *How do you use it to keep the score? How do you use it during the call?* This task fosters the emergence of the *user* voice.

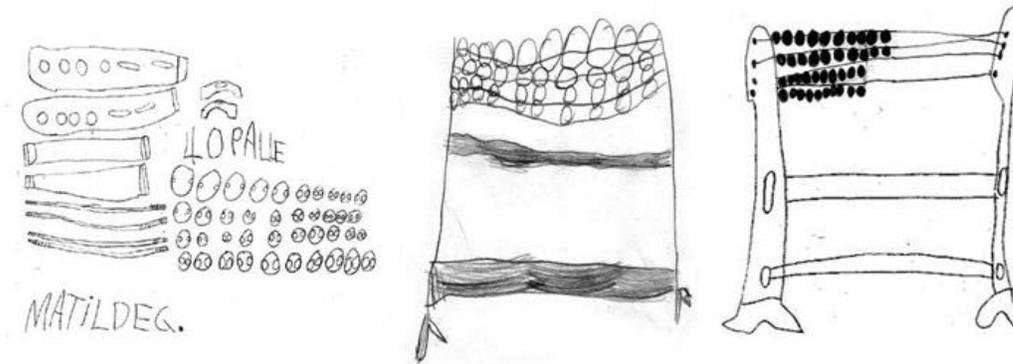

Figure 3: Drawings of materials (A) and of assembled abaci (B,C)

Task 4: The justification for use

In this case too the task is connected with the context. Children are asked to explain *Why does it work to keep the score?* and similar. This is a very difficult task, that fosters the emergence of the *theoretician* voice, to explain what mathematical meaning or process makes us sure that the functioning is effective. This task may be given indirectly, showing a puppet that makes mistakes and encouraging children to comment and to correct it, if they do not agree, explaining why.

Task 5: New problems

These last tasks were not designed in advance but emerged together with creative solutions in classroom activities. For instance, in a classroom, children proposed to use the Slavonic abacus to plan the preparation of tables for lunch. They suggested registering on the abacus the number of children for each table on a different line. When they realized that the tables to be set were 5, they told that there were not lines enough and decided to create a new line on the floor, lining up 10 small cubes and moving them accordingly. These self posed tasks foster the emergence of *problem poser and solver* voice.

THEORY AND PRACTICE

The system of tasks for the giant Slavonic abacus may be usefully referred to literature on mathematics education.

The emergence of the *narrator* voice in the task 1 is related to *devolution* (Brousseau, 1998) as it fosters the personal involvement of children in the tasks. The emergence of the *constructor* voice in task 2 is related to Rabardel *instrumentation* (1995) as it concerns the component of the artefact as an object. The emergence of the *user* voice in task 3 is related to Rabardel *instrumentalization* (1995), as it fosters the emergence of individual *utilization schemes*. The emergence of the *theoretician* voice in task 4 is related to mathematical meanings, hence consistent with the Vygotskian approach through semiotic mediation (Bartolini Bussi & Mariotti, 2008). The emergence of *problem poser and solver* voice in task 5 shows that, in spite of the teacher's cultural guidance, children creative ideas have space to be developed. However, it is better to

say that, in this program, those tasks were not exercises of application of that literature, but rather *experiments developed, interpreted, analyzed and generalized, in collaboration between teacher educators, teachers and pedagogists in a dialogic way, exploiting the literature.*

In each task, *explanation* is in the background. There are, however, different kinds of explanation s(Levenson & Barkai, 2013), which are related to the different voices: a narrative explanation (task 1); a communicative explanation (task 2); an argumentative explanation (task 3) that develops into a proving explanation (task4).

CLOSING REMARKS

The protagonists in the recorded interviews show that an inquiry community (Jaworski, 2005) has been constructed with shared values, beliefs and competences.

Adriana Querzè (policy maker): “We have played with the title “Counting children” as our children count with hands, with artefacts, with abaci, with situations, but, above all, count as they can exercise their rights of citizenship. Knowledge makes up citizenship as it allows reading and understanding reality. In the case of math and science, it allows constructing skills in analyzing and arguing, hence, in a broad sense, in communicating one’s own point of view. We believe that it can be done also with young children, who are “citizens in the age of development”, yet “citizens” to all purposes.[...] Parents can understand from this documentation what their children do in school, also for learning, strictly speaking. [...] We believe that teacher education and development must be high quality [...] and we want to dispel the myth that teaching young children is easier.[...] The “good” mathematics questions, the tasks, are not very different in preschools and university. Yet to look for answers to good questions with 3 years old children is much more difficult, hence requires a deep knowledge of mathematics and of methodology”.

Mariavittoria Vecchi (pedagogist): “It is necessary to join disciplinary, methodological and didactical competences together with relational competences. On the one hand teacher education and development cannot be reduced to practice and, on the other hand, a purely theoretical knowledge, with no elaboration on the job, is fruitless. Teachers’ practices need to be deeply analyzed together with the theoretical models. It is necessary to give teachers high quality cultural tools, to enhance their planning autonomy, to make them keen on what they are doing and to construct a community of inquiry where the voices of mathematicians, teachers and pedagogists dialogue with each other”.

Marina (teacher): “I feel more competent in mathematics and more expert in the organization of school activities”.

Laura (teacher): “The child is the centre of this mathematical experience. The teacher has to come along with child in this experience”.

Rosa (teacher): “Meetings are very important for our professional development as we bring there our experience with children and discuss with each other”.

Cinzia (teacher): “Children do mathematics in a spontaneous way. The most important thing is to raise that at the level of consciousness [...]. This program is very demanding, but I am enthusiastic. It’s up to us to transpose knowledge to practice”.

The above short excerpts from the multimedia report show that the program *Bambini che contano* is the offshoot of a synergetic effort of teacher educators, pedagogists, policy makers and teachers. Each of them has played a specific role and collaborated to construct an inquiry community where to develop their existing knowledge and beliefs system (Kreiner, 2011).

NARRATIVE CONTEXT AND PARADIGMATIC TOOLS:

A TALE FOR COUNTING

Paolo Guidoni*, Maria Mellone** and Ciro Minichini*

*Dipartimento di Scienze Fisiche, **Dipartimento di Matematica e Applicazioni

Università degli Studi di Napoli Federico II

We present a design study about the use of narration to frame a work on counting in a first grade class. We propose to use the ideas of ‘narrative’ and ‘paradigmatic’ ways of thinking (Bruner, 1986) in order to design, manage and analyse the development of children’s experience. In this specific experience the role of logical tools is played by the criteria used to carry on the count process, conceived as coordination of two different semiotic activities.

INTRODUCTION

Stories and storytelling continue to arise interest of practitioners in different research fields, from psychologists and anthropologists that characterize this kind of activities as crucial in human cognitive and cultural development, to educators recognizing their value in order to pursue educational goals for specific disciplines: “*The value of the story to teaching is precisely its power to engage the students’ emotions and also, connectedly, their imaginations in the material of the curriculum*” (Liljedhal and Zazkis, 2009, p. 3). Actually, stories can provide controlled contexts for experimenting parts of the complexity of life and for creating meaning in our lives and environments (Green, 2004). In this sense telling a story is a way of creating meaning also for mathematical structures: in a story context we can offer pupils an authentic experience of modelling by leading and supporting them in recognizing the mathematical structures as embedded in facts and embodied in human ways of managing them. Our research group has been working on this idea for several years, with the aim of recognizing some features of narratives – and of the way of using storytelling – which can enable mathematical meanings to emerge among the several ones intertwined in a narrative context.

In this paper we present a particular design research (Cobb et al., 2003) built upon the theoretical perspective of the paradigmatic and narrative ways of thinking pointed out by Bruner (1986). We used this frame in order to actually design a teaching-learning trajectory using storytelling with first grade children, with the aim to explore children’s counting strategies and suitable didactical mediations to make their mathematical skills develop. In particular we aim at exploring opportunities (in terms of capacities of designing settings and interpreting the correlated dynamics) provided by a driving-conjecture about counting as *focusing of attention*.

THEORETICAL FRAMEWORK

As many scholars have been pointing out in the last years, a mathematics classroom practice exclusively built on standardized word problems and routine exercises does

not educate students to a genuine mathematical modelling disposition (see for example Verschaffel et al., 2000). One of the hypotheses put forward claims that the verisimilitude and likelihood that something told could be true and real in same coherent “world” (even though it could be not true and real at all) have been very often neglected in the stories used to do mathematics at school (see for example the narrative ruptures in the word problem texts detected by Zan (2011)). On the contrary storytelling can – by means of its verisimilitude – represent a special experience of teaching and learning also in a mathematics classroom (see for example Lilledhal and Zazkis (2009)), precisely for its power to evoke situations (even though completely fantastic) in which children can project themselves according to their previous experience and own sensitiveness. Indeed telling a story, as well as proposing a “story problem”, entails a triggering process of the children’s natural interest for human actions and interactions (Donaldson, 1978).

According to Bruner what makes a narrated tale really interesting for people is its “violation of canonicity”, that is a situation that a listener feels as unusual with respect to the expectations determined by the contextual background (Bruner, 1990). The problem of restoration of canonicity is crucial in the development of the tale and we think that it can be used in an education perspective as an occasion to introduce or to build new cultural tools. In particular, Bruner (1986) points out two complementary ways of thinking: the narrative one arranged as an open space of possibilities that frames the temporal sequence of events and the choices taken time after time; and the paradigmatic one linked with the formal constraints (logical, algebraic, physical and so on), which rules the space of possibilities opened by the tale. On the mathematics education level we assume that within a story the violation of canonicity can be used to introduce or build paradigmatic mathematical tools in order to establish again the scripts of the narrative space. For this goal we also recognize the need to let children directly experience the actions described in the narration. In this view dramatization – as acted narrative – represents a natural step to be explored, along with the development of the story (for another example at kindergarten level see Mellone et al., 2012). Outside of the dramatization – and while it develops – the children, supported by adults, can explore how to overcome the breaches in canonicity building the paradigmatic tools that are useful to solve the tricky situations.

The design study we are going to outline here is placed in the trend focused in the use of stories in order to build new mathematical tools and meanings: in particular, it concerns a work around the counting process. Regarding the paradigmatic aspects of counting we refer first to Gelman & Gallistel (1978) who describe the counting process through five principles: the One-one Principle, the Stable-order Principle, the Cardinal Principle, the Abstraction Principle, the Order-irrelevance Principle. Such principles have the merit of carefully describing the counting process giving, at the same time, instruments to detect the difficulties that children meet during this activity. But, nowadays the new insights coming from neurosciences (see for example

Piazza (2010)) show that the counting process is, beside being an external phenomenon, an active mental process of either recognizing a naturally discretized aspect of reality, or imposing a more or less rhythmical discretization of continuous magnitudes. In both cases the core of such a process is a (perceptual and) internal gesture of *focusing of attention*, in the sense that what we count is always a “closed” internal action-of-individuation, variously correlated to others (from utterance to external doing). This conjecture becomes useful mainly when we want to study the counting of events developing along time. In this situation, one of the problems that needs to be firstly faced is that of deciding what are the rules to proceed into the count, that means understanding “what we count when we count”. This metacognitive activity can be supported by a semiotic activity (in a vygotskian sense) by expressing, and in this way stabilizing, the external events in correspondence of which we can add one to the count: in other words, using paradigmatic tools to lead the focusing of attention.

Our hypothesis is that this aspect of the semiotic activity linked with counting is different from – and needs to be coordinated with – the ones described by Gelman and Gallistel, which mainly deal with the use of labels (“numeros” for them). In other words, in counting events children need at first to recognize the discrete events corresponding to “add one to the count” and then to coordinate this recognition with the use of labels (as described in Gelman and Gallistel’s principles).

THE DESIGN STUDY

The research has been carried out in two primary school classes. The research team is composed by the class teachers and by some researchers. Two researchers play an active role in the ordinary educational work, spending about two hours a week in each class throughout the whole school year. The research is still going on, following the class through years. In this work we only account a part of the path developed in one of the involved classes, when it was at first grade. This specific part lasted two months at the beginning of the school year (that is seven working sessions of two hours each). Our research work can be defined as a design experiment (Cobb et al., 2003) for its ecologic and engineering features in exploring the opportunities that the conjecture of counting as focusing of attention can offer in planning and managing long term educational paths framed in a narration context. The classes also dealt with number issues in several other ways, working in the daily activities with the teachers. Nevertheless the teachers’ work and our design research were closely intertwined and reciprocally supported.

We believe the goals of mathematics education should include letting children experience rich activities that, in the case of counting, mean also involving them in purposeful activities of counting events. Having this in mind we built an ad hoc narrative frame, encompassing an element bringing about a breach in canonicity and letting children give themselves up the story development and directly act (as characters) in dramatized forms of the tale. We aim at leading children in building their own (geometrical and numerical) semiotic tools and use them in order to enable a restoration of canonicity and a consequent development of the story. In particular,

in order to support the children into the coordination of the two semiotic activities linked with counting, we propose to lead them to move to a representation level, where *both* the events and the objects to be counted are represented with certain mobile marker objects (in the case of counting objects the markers should be different from the objects). In the analysis we will develop in the following paragraph, we underline the moment when we “went out” of the tale and the way we worked on the coordination of the two semiotic activities described in the previous paragraph. Our data consist in researchers’ and teachers’ observations, in excerpts from classroom discussions and children’s representations.

Lastly, we would like to highlight the choice we made to put problems that were difficult enough in order to be hardly handled without the use of suitable tools (as marks or signs) and, at the same time, accessible and comprehensible enough in order to let the children recognize them as manageable. In our case, a difficulty was related to the presence of several rhythmical processes to be simultaneously controlled; another difficulty concerned the fact that the number of times (or the number of things each time) to be counted, though small enough, exceeded the limits related to the *subitizing* (for a review on this issues, see (Dehaene, 1997)).

THE DEVELOPMENT OF THE TALE

Temujin has been taken captive and is compelled to serve a sentence: he has been tied to a grindstone and forced to go round and round, in order to hull rice. Every morning Temujin is woken up by two beats of a gong, struck by a guard, and begins its job. He has to stop at the evening, when the guard beats the gong one time. Each time Temujin completes a turn around the grindstone, four rice grains are hulled and cumulatively collected in a holder. Several ‘accountants’ have the task of counting the number of turns accomplished by Temujin and the number of days of work, in order to report them to an inspector.

In this phase, as in the following ones, the action presented in a narrative form is also contextually dramatized by the children, so that they have to deal with the necessity of orienting their actions, leading to a certain development of the story. A child played the role of Temujin (fig.1); two children played the role of the grindstone, having autonomously to decide when the rice grains should be dropped in the holder (fig.3 and fig.4); a researcher played the role of the guard (actually signalling the end of a day every time Temujin completes two turns, but this was not made explicit with the

children); some children had to count the number of turns completed by Temujin (fig.5); other blindfolded children had to count the number of the days spent (fig.2). The dramatization has been repeated many times and each child has played several roles in order

to let children became familiar with the canonicity of the situation. Each dramatized sequence lasted about six “story days” (twelve child’s turns) and, at the end of each sequence, a sharing was held in order to check if the counting worked.

The design of the story has been driven by the conjecture according to which counting is basically an oscillation between recognizing and imposing a rhythm, meant as complementary aspects of an intentional and aware addressing of attention and action. The considered situation is characterized by different rhythms: Temujin has to comply with the rhythm marked by the gong; the rice dispensers have to decide the right moment when they have to drop the rice grains and – at the same time – they have to warrant the right number (four) of dropped grains at each turn; the accountants have to establish how to record number of turns or days they counted. We intended to support children to try and orient themselves among these different rhythmical structures, by mean of discussions devoted to collectively treat each issue.

Initially we observed the counting strategies children adopted. In this phase we distinguished three kinds of attitudes:

1) Some children count properly. They recognize the occurrence of a repeated structure, distinguishing the base elements: two beats plus one beat of gong; four rice grains. These children are able to express the operative procedure they follow in order to rhythmically modulate the action

Elena: Maya shouldn't add four grains if Alyce has already dropped them [Maya and Alyce played the role of the grindstone], because Temujin didn't do two turns! [...]

Ilario [a counter of the days]: I add one after two beats, he after one beat [turned to another counter of the days]. It's the same! We always count the days, only I count the mornings and he counts the evenings.

Here Ilario evidently recognizes there are alternative criteria for deciding when one has to proceed in the counting.

2) Other children tendentially singsong, in the sense that they count throughout the whole development of an action (i.e. during a whole day or a whole turn), even if they understand there are moments when the counting has to be stopped, for example during the night, when one sleeps. The conduct of these children is coherently commented by the first ones:

Stefano: Gianluca [a counter of the days who singsongs] is counting the minutes or the seconds, not the days.

Alyce: The seconds, not the days! [...]

Camilla: Ornella [a counter of the turns who singsongs] isn't counting the turns! She's counting the steps!

3) In an intermediate position there are children that struggle to keep counting properly. These children understand the constraints to be complied with in order to proceed with counting, but they apparently make a great effort to avoid the singsong, or to avoid counting two times the same base elements. It is interesting to highlight Lucio's conduct. As a blindfolded counter of days, he counted "one" in

correspondence of morning beats and “two” in the correspondence of the evening one, while he tried to avoid this mistake:

Lucio: One... two... oh no, wait!

With the exclamation “wait!” aimed at himself, Lucio brings out the fact that counting is actually an oriented activity, which implies effort. An analogous situation concerns those children who play the role of parts of the grindstone. Maya’s case seems to be emblematic. At the beginning Maya had difficulties in playing alone the role of grain dispenser; then she completely relied on Alyce, who helped Maya and suggested her when dropping the grains. In the meantime Maya tried to autonomously move, oscillating among three facts: the peremptory indications by Alyce, the continuous wheeling around of Antonio (who played the role of Temujin) and her attempt to coordinate herself with them and to autonomously decide when dropping the rice grains.

In a second phase, we provided the counters with some objects, as bottle tops and seashells, to be used as markers during the counting. Nevertheless, the introduction of these supports did not change the scenario. In fact, the use of markers seems to be not particularly useful – at least for little quantities – for those that are already able to count properly, as highlighted by these comments

Eleonora: I count in my head!

Lars: I make it like this [counting on his fingers] and I make it well!

At the same time those who had difficulties in controlling the several rhythmical scans appear to be even more confused by the invitation to use the markers. At this point we considered opportune for the group to move outside from the temporally ordered narration and from its heuristic dramatization, in order to build the atemporal paradigmatic prostheses, the explicative tools aimed at establishing rules and controlling procedures in counting. This is a crucial point in the development of our intervention. Our tale comprises several activities, which can be effectively managed through some kind of (mathematical) formalisation. Now, the activity aimed at formalising does not belong to the narrative. It rather needs for another setting, other actions and other discourses, in order to build the tools used for explaining and controlling what happens at the narrative level. Therefore children are continuously invited to go back and forth between the dramatized narration and the paradigmatic level, in alternating and complementary phases. So we transferred into the gymnasium to work on structuring the space, in order to be able to determine when a child completes a turn. The children formed a circle and were invited to discuss about the movement of some classmates, who had the task of completing a turn around that same circle. The discussion was aimed at settling criteria for understanding when a child completes a turn. At the end, the group agreed on the advisability to mark out a line on the floor, in order to recognize the end of a complete turn. We made the same for what concerned the counting of the days spent. In this case the group should have dealt with a structuring of the temporal events: the discussion focussed on the

distribution of beats of gong in a day and on the different ways to recognize the passing of the time, following some suggestions given by those who count properly.

After this activity, we came back to the narrative context, providing children with markers that were used by most of them. Therefore objects were used in order to record the number of turns and days, as well as signs were used to decide ‘what’ had to counted: the crossing of a line, the sound of two close beats, the sound of a separate beat, a special sequence of sounds (two close beats plus a separate one). It seems interesting to recognize the usefulness of support given from the practice of proper counting together: being supported by others, children that have difficulties can find time and ways of coordinating words and gestures with what they perceive, distinguishing the events to be counted and being able to record all of them, without getting confused in the complexity of those operations.

Subsequently, a second part of the story was told.

Suddenly an inspector arrives, with the task of verifying whereas Temujin has served the sentence. The inspector declares Temujin will be released when he will have worked for no less than 7 days (and no one more) and will have completed 16 turns. The accountants are so consulted in order to decide about the Temujin’s destiny. But different groups of accountants express contrasting opinions about the possibility of setting Temujin free. Therefore the inspector gets initially angry. At the end he will accept other conditions, but he will ask for a written document, which certifies the actual Temujin’s work.

The new situation is clearly designed so that the condition put by the inspector is incoherent with the constraints of Temujin’s activity: for those who count days, he may be free; for those who count turns, he may not. This is the point where we introduce in the tale a studied violation of canonicity. A character with a normative role (the inspector) provides a criterion to decide if the prisoner can be set free or not. According to canonical expectations, the given condition should be granted or not, so that one should be able to decide about the release of Temujin. In our case, the contradictory judgements of the accountants, and the consequent impossibility of deciding, put the group at an impasse. This doubtful situation needs explanations and strategies to allow a plausible development of the tale. At this point the paradigmatic mode, the arithmetic in our case, is committed to explain the rifts in the narration (Bruner, 1990). Through the necessity of settling this matter, we aimed at making explicit (at least at a certain level) the multiplicative structure, which is always intertwined to the counting operation (characterized by the ratio of two turns per day, which was left hidden during the whole development of the activity). At the same time, we aimed at raising the necessity of producing a representation of what had happened in order to encompass the several rhythms that had characterized the considered processes.

Meanwhile, one looks for plausible solutions to the missing satisfaction of the conditions necessary to set the prisoner free. Anyway, no child observed that the inspector’s conditions couldn’t be fulfilled together: this suggests that the ratio,

which correlates number of turns and number of days, is not well understood by pupils even if it is clearly “smelled”: here we move in a zone of proximal development (Vygotsky, 1934). In fact, when we ask to dramatize again the situation, children begin to identify the correlations among the several rhythms as a crux, even if they do not have a symbolic system which enables them to highlight the inner contradiction of the inspector’s request

Elena: You finish the day too soon! You should let him do more turns! [talking with the researcher that beats the gong]

Researcher: I only beat when the night comes.

Elena: We can change both the things. Day and night longer and Temujin faster.

Lucio: Or we could say to the inspector Temujin worked for seven days and did sixteen turns!

Elena: We can’t say he did sixteen turns! We can’t cheat! The inspector will realize it!

Lucio: How does he realize it?

Elena: If he counts the grains, he realizes it!

We are at a moment when the children try to identify the crucial ratio between turns and days, but they are not able to make it explicit. We decide to intervene, simplifying the situation and addressing the work toward a clarifying semiotic activity: the inspector negotiates his request, asking Temujin to work for 8 days doing 16 turns. In return for the prisoner’s freedom, the inspector asks for a written document, which certifies the exact number of days of work, completed turns and hulled grains. Children work in little groups on drafting several documents using mobile markers. This activity is carried out under adult’s supervision, gradually helping to organize the groups work. The adults support and partially address the activities, fostering the circulation of ideas among groups, asking for explanations, giving suggestions. At the first, we attempted to share ways of representing days, turns and grains:

Eleonora: We can make two circles, which are the two beats.

Stefano: But I counted a day each three beats.

Eleonora: But I don’t find it good, so.

Researcher: What do you mean about making a white circle, as a sun, in order to represent a day?

All children agree.

This short excerpt represents an attempt of coordinating the two semiotic activities of focussing of attention and labelling. In fact during the first phase of the path the adult mediation led the semiotic activity related to identifying events that corresponds to add one to the counting. Now one has to coordinate this semiotic activity with that

described by Gelman and Gallistel (1978). By means of the use of shared markers (white circle for the days, macaroni for the turns, pumpkin seeds for the rice grains) the groups build several documents, actually several ways of giving form to the rhythmical structures and to their mutual correlations (see for example fig. 6, fig. 7, fig. 8, fig. 9). The produced representations are shared and read together (fig.9), in order to test their comprehensibility and coherence (fig.11). In some cases the particular rhythmical disposition of the markers on the sheet, as well as their spatial relationships, enable to highlight the more “difficult” relations which were not yet made explicit, as the number of hulled grains per day, or the number of turns per day. A final discussion (fig.9) aims at selecting the “best” document for the inspector (or at producing a shared new one).

Camilla: According to me, one better understands our one [fig.8], because it really says what happened. [She points out the first column of the array] There is the day, then he has made a turn, so the grindstone has dropped four grains, then another turn and other grains.

Elena: Oh yes, but our one [fig.10] is more orderly. The sun, then two turns, then the grains.

We would like to emphasize the different features of the strategies adopted in these two representations, according to their authors’ comments that had the opportunity to emerge due to the use of mobile markers. On the one hand, Camilla is interested in producing a representation faithfully keeping the temporal development of the narrated and dramatized action. On the other hand, the introduction of markers as meaningful signs led Elena’s group to reconsider and reorganise signs according to their meaning, in a semiotic activity that actually presents a fruitful ground for the

further dealing, in a significant way, with the roots of the multiplicative structure and its dimensional issues.

CONCLUSION

Our design study showed the relevance of encompassing the possibility of getting out from the tale, in order to build mathematical tools. This became a methodological assumption during our work and could be suggested as a central element in designing activities where math education is carried out through a storytelling. For example children that presented difficulties in counting the events, such as turns and days, didn’t seem to take advantage of using mobile markers during the dramatization. Rather children benefited by discussions aimed at establishing semiotic rules, which helped them to focus their attention, such as marking out a line on the floor in order to recognize the end of a complete turn, or focusing on the sequence of beats in order to recognize the end of a day. This supports our assumption that the *focusing of attention* plays a central cognitive role in the counting practice and suggests

introducing quantity markers only after activities devoted to clarify what one has to control in counting. After the second part of the tale, the use of mobile objects and the work with their arrangements actually supported the children in the difficult task of catching and precisely expressing the several simultaneous rhythmical processes in the story, enabling children to progressively appropriate of role and meaning of conventional representations. In fact the following step was dealing –within the frame of the same story – with the base-ten representation (Guidoni et al., 2011).

USE OF DIGITAL TOOLS IN MATHEMATICAL LEARNING ACTIVITIES IN THE KINDERGARTEN: TEACHERS' APPROACHES

Per Sigurd Hundeland, Ingvald Erfjord and Martin Carlsen

University of Agder (UiA), Kristiansand, Norway

In this paper we study how kindergarten teachers used digital tools in mathematical learning activities in the kindergarten context. With digital tools we mean mathematical software for computers and ICT applications for digital white boards, mathematical games and memory games. Within this context we study the various approaches the kindergarten teachers took when orchestrating mathematical learning activities. Through analyses of these mathematical learning activities, we find that the kindergarten teachers took three different approaches in their orchestration, the assistant approach, the mediator approach, and the teacher approach. These approaches all carry qualities and potentials for children's learning of mathematics, but in different ways.

INTRODUCTION

The Norwegian kindergarten is regarded by OECD (2006) as situated within a social pedagogy tradition, i.e. an educational institution where core enterprises are upbringing, care, play, and learning. A new curriculum for kindergarten was launched in 2006 in which mathematics was comprised for the first time as a separate subject area (Ministry of Education and Research, 2006b). Additionally, policy documents as regards implementation of information and communication technology (ICT) in the kindergarten were made (Ministry of Education and Research, 2006a). However, the combination of mathematics and the use of ICT has been more or less left for the kindergarten teachers to elaborate and implement in learning activities.

With this as a background we initiated a project called ICT Supported Learning of Mathematics in Kindergarten. In this project we aimed at collaborating with kindergarten teachers to gain insights into children's mathematical learning processes when interacting with digital tools. We argue in accordance with Plowman and Stephen (2003) and Sarama and Clements (2004) that research is needed to identify the mathematics learning potentials of digital tools. Hennessy (2011) explored interaction possibilities when using interactive whiteboards (IWB) in teaching. She came up with affordances such as the multimodal nature of interaction possible and the opportunities for direct manipulation of objects.

In this study we are particularly interested in analysing the ways the kindergarten teachers use these digital tools and how they interact with the children in their orchestration of mathematical learning activities. For the present study we have formulated the following research question: *What characterises kindergarten*

teachers' approaches when using digital tools in mathematical learning activities? This question is interesting to pursue due to the fact that there is an insufficient amount of literature in this area of research.

THEORETICAL FRAMEWORK

In this study we adopt a sociocultural perspective on learning and development, a theoretical stance originating in the work of Vygotsky (1986) and further developed by socioculturalists such as Rogoff (1990) and Wertsch (1998). Two main concepts within this perspective are indubitably the notions *mediation* and *tool*.

Mediated action through the use of tools

In mediated action humans use several tools. Language, both oral, written, and body language, plays a fundamental role in mathematical learning activities (Goldin-Meadow, 2009; Roth, 2001). In order to communicate and interact, both adults and children use various kinds of language to collaborate, discuss, and make sense.

Relevant for the study reported here is the use of digital tools, i.e. in our case mathematical software engaged with by the children through their use of computers and IWBs. Following a sociocultural perspective, use of digital tools mediates mathematical ideas and concepts. Thus, learning becomes a process of mastering these tools and performing in appropriate ways when engaging with the applications, since “our mastery of such tools is a critical element of what we know” (Säljö, 2010, p. 62). By using digital tools in their orchestration of mathematical learning activities, the kindergarten teachers seek to mediate mathematical ideas and concepts for the children to make sense of. The kindergarten teachers' use of digital tools in mathematical learning activities thus establishes opportunities for the children to appropriate mathematical concepts, ideas, and actions.

Orchestration of mathematical activities

As already mentioned several times we view the kindergarten teachers' actions and communication through the metaphor of *orchestration*. Following Kennewell (2001), we see orchestration as managing “the visual cues, the prompts, the questions, the instructions, the demonstrations, the collaborations, the tools, the information sources available, and so forth... (p. 106). The notion of orchestration is thus used to describe what kindergarten teachers do when hosting mathematical learning activities using digital tools.

When considering teachers' orchestration of digital tools for the benefit of learning mathematics, researchers have pinpointed many aspects. Goos, Galbraith, Renshaw and Geiger (2003) studied teachers' orchestration of calculator use in mathematics teaching. They observed clear differences in the orchestration and argue for the importance of directing students to explore the tasks, use the digital tools to discuss the solutions of tasks, teachers' ability to hold back information and stimulate collaboration and discussion among students.

Mathematics teachers' activities when using technological tools in the classroom is discussed by Monaghan (2004). He argues that to integrate technology in mathematics teaching is a complex undertaking, and teachers experience multifaceted processes when integrating the use of digital tools in their teaching. Moreover, Monaghan argues that the use of technology, computers and calculators, plays a vital role with respect to the social interactions between teacher(s) and student(s). In referring to the research literature, Monaghan argues that there has been a change of emphasis in describing teachers using technology and their role. The term 'facilitator' is used as a metaphor for teachers' roles within a radical constructivist paradigm. Contrastingly, the term 'mediator' is used as a metaphor for teachers' roles within a social constructivist paradigm. This term is used about teachers who play "an active part in the students' learning" (p. 329) through social interactions.

Similar arguments have also been advocated by Zbiek, Heid, Blume, and Dick (2007). These authors coin two roles mathematics teacher take when implementing technology in teaching, called Technical Assistant (The teacher assists the students with software and hardware difficulties) and Counselor (The teacher is familiar with the mathematical ideas and concept addressed in applications and supports the students upon request). The former role is described in a similar way as Monaghan's (2004) term facilitator, while the role labeled Counselor might share similarities with Monaghan's term mediator.

The study of Zbiek et al (2007) identifies teachers' roles when interacting with students at school. As will be seen later in the paper our identified approaches taken by kindergarten teachers differ from the labels coined by Zbiek et al. From the analysed data we needed to divide the Counselor role of these authors in two, the Mediator approach and the Teacher approach, since these approaches more distinctively address the studied kindergarten teachers' interaction with the digital tools and the children.

METHODS

In our project we collaborated with three kindergartens called Bee Pre-school centre, Swan Pre-school centre, and Frog Pre-school centre. As methods of data collections in the project we used video data of 12 sessions where kindergarten teachers orchestrated mathematical learning activities by the use of digital tools. Video recordings of the 12 sessions, each of approximately 30 minutes of duration, were complemented by observations and field notes. From initial analysis of these sessions and our general discussions regarding our experience within the project, a hypothesis emerged concerning the kindergarten teachers' approaches to the use of digital tools. Secondly, based on our reasoning, we returned to the video data and looked at some sessions more in depth. Guiding our analysis was the communication between adult and children and to what extent they engaged with mathematics. From this process, we were able to characterise three approaches the kindergarten teachers used. Thirdly, we returned to the data in order to identify episodes which illustrate these three approaches. The three excerpts chosen are meant to illustrate these three

approaches. Conversations with the kindergarten teachers, meetings in kindergartens and a workshop at the University were also arranged. However, data from these events are not particularly used in the study presented here.

ANALYSIS AND RESULTS

The data we present comprises video data from three kindergarten teachers, one from each of the three kindergartens. In the excerpts below the kindergarten teachers used digital tools covering applications with mathematical elements such as counting, comparing sets, measurements, and shapes. We have identified three different approaches the kindergarten teachers took, the Assistant approach, the Mediator approach, and the Teacher approach. After describing these approaches, examples of adult-child interaction will be analysed to justify the identification of the three approaches as well as point to what these approaches encompass.

The Assistant approach (AST)

When the kindergarten teachers take an Assistant approach to their orchestration we characterise what they do as assisting the children with minor issues such as starting and running the software; they organise the activity so that one or two children interact with the digital tools at a time, they point at places where to touch the screen or keyboard, i.e. keystrokes, to answer software inherent questions and tasks. In one of the sessions we videotaped, the kindergarten teacher made small remarks regarding where to press the various buttons at the IWB to navigate and choose different games to play. The kindergarten teacher led the session, by pointing at what children should do to engage with the ICT application and by asking the children whether they wanted to play another game.

The Mediator approach (MED)

The second approach that we have identified is the approach called Mediator. When the kindergarten teachers took the Mediator approach they orchestrated the mathematical activity by being more active in interpreting the digital tools the children engaged with. The Mediator approach is further characterised by the kindergarten teachers reading text within the applications, and they supported the children in interpreting the screen. The teachers helped the children to become aware of crucial elements and aware of parts of the screen. Taking this approach it is the applications which determine the interaction.

The Teacher approach (TEA)

The third approach the kindergarten teachers took when orchestrating mathematical learning activities involving interaction with digital tools, we have called the Teacher approach. This approach is characterised by the kindergarten teachers' use of questions and comments with respect to the children's interaction with the applications. When taking the teacher approach, the kindergarten teacher actively chooses what applications for the children to engage with and monitors the pace of

children's interaction with the digital tools. Taking this approach it is adults who determine the interaction.

The case of Ann

In this excerpt one child is engaged with an IWB in a mathematical learning activity with the use of a digital tool involving numerals and counting (implicitly). The application was designed for the kindergarten age group and it was called "Labbe Langøre" [1]. Three children were present. Sound is included in the digital tool, giving the child instructions of what to do at various places and stages within this short excerpt. In this application numerals are shown on a poster. Four trees are also shown, each of them having a numeral posted on them. The child is supposed to identify similar numerals.

Ann (AST): Your turn [Judy walks towards the IWB and up on a bench] Do you want me to move that bench?

Judy: Yes

Ann (AST): Then you can press the START button [Judy chooses an application called 'Memory']

Ann (TEA): Can you choose 'the Mathematical Cat'? [Judy chooses that application, and she presses the correct numeral. Two snakes emerge on the screen]

Ann (MED): Press the cat and see what happens [When pressing the cat, the software confirms whether the answer is correct or incorrect]

[Judy does that and the cat confirms that she is right. Then a new task shows up]

Ann (TEA): Can you count them [the animals] when they appear?

[The numeral 5 is shown on the poster, and Judy presses the numeral 5 on one of the trees. Five frogs emerge and Judy points at one after another while Ann counts loudly]

Ann (MED): One, two, three, four, five

The orchestration could be described by the kindergarten teacher having responsibility for hosting the session. From the excerpt it is evident that Ann is shifting between all three approaches. Ann serves the children by managing the computer and the software, assisting Judy in her interactions with the applications. The digital tool took care of much of the necessary information the child was in need of since oral sound was included in the applications. The Mediator approach was thus not so often needed in this case. Ann seems to adapt her interventions, comments and questions with respect to both the child in action and the actual application the child interacts with. Ann also took the Teacher approach in her goal-directed instruction of Judy to choose the mathematical application and Ann addressed the mathematics implicitly present in the application.

The case of Egil

In the following the kindergarten teacher ran an application on an IWB from the software named “Salaby” [2]. The application concerned the clock – the attention was on the relationship between written time slots such as 11:00, the hour hand and the minute hand. In this particular episode, all the minute hands were fixed at 12. The application presented twelve different clocks which represented twelve different time slots. The written time slots should be dragged and dropped to the corresponding clock symbol. Egil starts the application in front of 15 children and one other adult. Egil shifts between different approaches during the excerpt.

Egil (MED): Herman, try one o'clock. [After some hesitation, the child points at the clock symbol that represents one o'clock.]

Egil (TEA): How did you see that this was one o'clock?

First, Egil supported Herman in interpreting the application and Egil continued with a question which requested an argument. This may indicate that Egil wanted to promote a learning goal beyond just interacting with the application. Additionally, an important part of the mediation is to describe what is visible at the screen:

Egil (MED): The hour hand points at one and the big minute hand points straight up. It points straight up in every clock here: Twelve, twelve,, twelve [He points at every clock on the screen, one after another until he has pointed at all twelve clocks]

Egil (MED): But, on which of this clocks does the hour hand point at eleven? Raise your hand if you believe that you know the answer.

Apparently, the mediation approach changes suddenly when Egil asked the question that give us association to a normal classroom conversation. However, the content of the question draws attention to the meaning of the application. In order to respond correctly, the children have to identify the correct clock symbol. We claim that this question is part of Egil's mediation approach.

There is a blurred border between the Mediation approach and the Assistant approach. The Mediation approach is linked to the message the software brings and the Assistant approach is linked to the physical and organising part of the software. For example, Egil selected what child who was supposed to use the software, and he adjusted the children's behaviour and made them focus at the screen. Use of IWB gave the children challenges related to the touch technology within the screen. A typical Assistant approach that we observed was when the adults helped the children with the drag-and-drop functionality.

The case of Unni

In the observed lessons at Bee Pre-school centre, the children were organised in groups of two children and one adult sharing a portable computer. Below two episodes are presented with one adult, Unni, and one child, Trine, aged 5 years. The

software used is again “Salaby” [2]. In the application at stake here, cars are supposed to be elevated into different numbered garages (numbered 2, 4, 6, 8, 10 and 1, 3, 5, 7, 9 respectively on each side from bottom to top of the garage). In order to drive a car into correct garage, first an addition task such as $2 + 3$ is supposed to be solved. Then the user needs to correspond that sum with the correct symbol, 5.

In the episode below, Trine started by choosing the car to the right where the task is $5 + 5$. She was able to move the car into the elevator and then the episode below appears. Unni showed the numbers with her fingers ($5 + 5$) and Trine was able to respond orally with correct answer and to recognize how ten is written. This we consider as evidence that K3 after a brief mediator comment adopted a Teacher approach helping the child to understand why the car should be placed in garage number 10.

Unni (MED): Now you have to wait a little bit. Where is it supposed to be parked?

Trine: There (Trine points to the car with her finger, appears to be in doubt).

Unni (TEA): Yes, where will you park the car? How many fingers do I have on my hand (Unni shows her left hand to Trine)?

Trine: Five

Unni (TEA): Yes, and then you add 5. How many fingers will that be?

Trine: Ten

Unni (TEA): How does number ten look?

Trine: (Trine points to the correct numbered garage 10).

An indicator of Unni’s concern and judgment for the mathematics at stake is also visible in an episode occurring immediately before the one displayed above. Unni seemed to be reluctant to Trine’s choice to park the car on the right and suggests she chooses the car on the left. We believe this suggestion from Unni came based on a judgment that Trine rather should start with an easier task to solve. However, Trine decided to keep her choice and Unni then accepts this and adapted her support.

Unni (MED): Which car do you want to park?

Trine: (Trine points to the car on the right hand side where the task is $5+5$)

Unni (TEA): Maybe you rather take the other one (Unni appears to think that the other car with the task $2 + 3$ might be a more suitable task for Trine).

Trine: (Trine still points to $5+5$)

Unni (TEA): You want that one. Which number will that be? $5+5$, how much is that?

Trine: (Trine drives the car into the elevator)

These two episodes were brief and the time spent from Unni was to engage in mathematics with the children. We argue that episodes presented illustrate a typical pattern in Unni's approach to orchestration of the sessions. Unni spent most of her time taking a Teacher approach. Unni uses many questions indicating that she adapts what mathematical challenges the children should deal with. We also found a few utterances where Unni explains the technical actions with the tool taking a Mediator approach.

DISCUSSION

In this study we have seen that the kindergarten teachers orchestrate children's engagement with the digital tools differently. We agree with Monaghan (2004) and Zbiek et al. (2007), that it is a complex endeavor to implement the use of digital tools in mathematical learning activities. We have identified three different approaches the kindergarten teachers took when orchestrating the activities and interacting with the children. This is not to say that other approaches were not taken, but the three identified approaches were the most dominant ones. We have identified these approaches and called them an Assistant approach, a Mediator approach, and a Teacher approach. The approach called Mediator has several similarities with what Zbiek et al. label Counselor. Our description of the Assistant approach shares similarities with what Zbiek et al. call 'Technical Assistant' and what Monaghan labels 'facilitator'. However, what we call the Mediator approach differs slightly from what in the research literature has been labelled mediator role taken by teachers (Monaghan, 2004). We interpret that mediator role as encompassing a broader perspective than how we use the label mediator approach in our study. The way Monaghan (2004) refers the use of the term we interpret as comprising both what we call Mediator approach and Teacher approach. Our use of the Mediator approach is more in line with what Zbiek et al. (2007) call Counselor role. These discrepancies might be due to the fact that Zbiek et al. studied mathematics teachers at school level. We have, on the contrary, studied teachers at kindergarten level. By taking the Mediator approach, the kindergarten teachers become a bridge between the digital tool on the one side and the children on the other side. The kindergarten teachers support the children in order for them to make sense of the digital tools and for them to know what to do at various places when interacting with the applications. Thus, the kindergarten teachers mediate what the applications are about and come up with questions that make the children pay attention to relevant elements within the tools.

When taking the teacher approach, the kindergarten teachers purposefully decide for the children what digital tools to engage with. This approach initiates mathematical reasoning amongst the children, since the comments and the questions request predictions and justifications on behalf of the children. Thus, the kindergarten teachers utilise the digital tools to mediate mathematical ideas and address mathematical learning goals.

We argue that all three approaches to orchestrating mathematical learning activities in the kindergarten carry qualities and potentials when it comes to the children's

opportunities for appropriating mathematical tools and actions. By taking these three different approaches the kindergarten teachers adapt to the situations and contribute with their support as the children and the situations request. With respect to the sequentiality of the interaction, the different approaches are needed to a differing degree. Typically, within the initial phase of interacting with the digital tools the Assistant approach is often needed in order to keep the activity going. However, when children are engaging actively with the mathematics within the digital tools, the Mediator approach is needed to support the children's sense making of the digital tools. Eventually, the Teacher approach carries affordances as regards the children's mathematical learning opportunities. The applications are used to serve mathematical learning goals formulated by the adults.

The main difference between the Mediator approach and the Teacher approach is that when using the Teacher approach, the adult focuses particularly on the mathematics implicitly present within the applications to serve pre-formulated mathematical learning goals. Thus, when taking the Teacher approach the kindergarten teachers are seen to orchestrate the children's mathematical learning process.

From our analyses it is also relevant to discuss the quality of the digital applications the kindergarten teachers used in terms of the mathematics learning opportunities created and whether the applications became utilised as tools, in a sociocultural parlance, for mathematics learning. The quality of the applications used, we argue, cannot exclusively be judged from the outset, since we believe their quality heavily depends on the competent utilisation of the applications by mathematically and didactically competent kindergarten teachers.

KINDERGARTEN CHILDREN'S REASONING ABOUT BASIC GEOMETRIC SHAPES

E.Koleza¹ -P. Giannisi²

² *Department of Science of Education and Early School Education, University of Patras, Greece*

In our study we attempted to investigate the criteria used by preschool children in distinguishing basic geometric shapes, namely circles, rhombus, squares, triangles and rectangles. Besides the detection of the syncretic level as it was described by Clements et al. (1999), analysis of our observations revealed seeds of relational thinking in very early age, which via suitable collaborative tasks designed by teachers may advance preschoolers geometric thinking.

INTRODUCTION

Researchers' interest in preschool mathematics has considerably grown during the last ten years. Many research papers have been published and lately a book by Levenson, Tirosh and Tsamir (2011) entitled *Preschool Geometry: Theory, Research and Practical Perspectives* has appeared, while during the 6th Conference of European Research in Mathematics Education (2009) a new working group in Early Years Mathematics was established. Yet, geometry and spatial thinking are often ignored or minimized in early education (Sarama & Clements, 2009).

During preschool education children's concept images are based mainly on perceptual similarities of objects in their immediate surroundings and personal experiences. Gradually, through instruction, children pay particular attention to certain common attributes of shapes, and begin to develop informal definitions of shapes; they usually "define" a shape detailing his properties. Understanding of geometric concepts involves an invocation of a set of mental images along with a corresponding set of properties for that class of objects (Fischbein, 1993). Vinner and Dreyfus (1989) pointed out that students might not understand a concept in depth, if they do not bond the "concept image" and "concept definition" appropriately.

In the research, students' understandings of geometric figures are mainly analyzed taking as framework the van Hiele's levels of geometric thinking (van Hiele, 1986) and the hypothesized geometrical shape learning trajectory developed by Clements and Sarama (2009). Clements and Battista (1992) enriched van Hiele's theory, suggesting a sixth level of thinking more primitive to the "visual level". At this *pre-recognition* level children perceive geometric shapes by attending to only a part of the shape's characteristics: "[...](Children) may distinguish between figures that are curvilinear and those that are rectilinear but not among figures in the same class; that is, they may differentiate between a square and a circle, but not between a square and a triangle." (Clements & Battista, 1992, p. 429). Gradually, experiencing

multiple examples of a shape, children mentally construct increasingly elaborated shape-schemas, which engender the formation of mental prototypes (ibid., p. 208). If children's schemes remain chained to a prototype this prototype may be the source of incorrect responses, especially in the transition phase to the next description-level. (Clements & Sarama, 2007, p. 505). Furthermore, Clements and Battista suggested that geometric levels of thinking coexist. They used the term 'syncretic level' in order to indicate "...a combination of verbal and imagistic knowledge without an analysis of the specific components and properties of figures. At the syncretic level, children more easily use declarative knowledge to explain why a particular figure is not a member of a class" (Clements & Battista, 1992, p. 211).

Our research tries to shed new light on the ways pre-school children construct geometric concepts through an investigational context that promotes communication and language exchanges. Basic assumption of this work was that a structured teaching setting with emphasis on language exchanges between participants, on the design of meaningful for children activities and on literacy practices, can promote the construction of school knowledge categories such as geometric shapes as well as children's reasoning development. In fact, the data of this paper derive from a more extensive linguistically oriented research grounded on the sociosemiotic perspective of Systemic Functional Linguistics¹ (SFL) and its model of context analysis, which interrelates the socially constructed knowledge (semiotic representation of reality) with the realization of language in context-situation (Giannisi & Kondyli, 2011; 2012). Data analysis focused on: a) *relational clauses*, which encode meanings of "being" and of "having" (e.g. *All these are circles / The square has 4 angles*) b) *Taxonomic relations*, which refer to *class/subclass* (e.g. *The triangles and some slanting triangles [classifying triangles]*) or *part/whole* relations (*These [rhombi] are two triangles stuck together, not stuck together... it is a rhombus*) c) *Reference* types realizing degrees of abstraction from closely contextualized - e.g. *This/these is a./are* (use of deictics or/and deixis – *phoric reference*)- to more decontextualized speech - e.g. *Rhombi don't go with triangles* (generic, *non phoric* reference) d) use of *causality* and *conditional* structures -e.g. *If we turn it [square], it becomes another shape.*(Unsworth, 2001)

The results here, concise the basic conclusions concerning the identification and classification of all basic shapes used in that research, as these are elaborated in order to address to a more specialized public. From this point of view, our venture gets the meaning of a cross examining revision.

DESCRIPTION AND METHODOLOGY OF RESEARCH

A total of 18 students from a sub-urban public kindergarten school participated in this study. The older students of the class (12 girls and 6 boys, aged 5:6 – 6:3) worked together with their teacher-researcher in small groups of 3 (2 girls and 1 boy) during the period between April and May of the school year 2008-2009. The corpus comprises of 20 video and tape-recorded meetings (about 13 hours in total).

Children's involvement in geometric concepts was set within a scenario frame of action: the production of books, which were to be sent to schools that couldn't afford to make such a purchase (action proposed to students on the occasion of the International Children's Book Day). Each group undertook the task of creating a book about geometric shapes as well as an insert card game of geometric shapes. The book to be produced was described from the beginning as a "learning book" (i.e. an informative leaflet/dictionary of "basic terms") for children. In this case, the knowledge of geometric shapes was considered to be a precondition for the receivers to play the card game found in the book.

The whole project was carried out during the successive meetings of each group, and was divided into activity modules, coherent and consistent with each other, according to the original context of the project (the production of the book), and, partly, to the level of their difficulty. The general objectives of each meeting's tasks were clearly explained at the beginning of the session. The teacher participated in the discussion as a coordinator, asking open, general questions, related to the aim of each activity. Special attention was given so that the teacher would not direct children's answers but encourage the discussion between the members of each group.

In brief, the tasks of all groups included the following activities:

A] Classification of flat geometric shapes (circle, ellipse, triangle, rhombus, square, rectangle) which would be pasted on the pages of the book after discussion and agreement between the members of the group (36 non identical paper geometric shapes of the same color and texture, with variations within each category regarding the shape qualities and size of the shape).

B] Addition of texts: Giving "titles" to every shape category (*categorization by naming*) as well as producing informative texts for the reader (*definitions, descriptions of their categorizations*), which were dictated to the teacher.

C] Creation of book's card game (a deck of 27 cards of 4 basic shapes: circle, triangle, square, parallelogram) -after the completion of phase B- and a sample performance of the game in a whole class meeting according to instructions read by the teacher. In order to design the game, each group was asked to collect objects found in the classroom and to classify them in different baskets by shape, according to the selected facet (designed game would preserve only the shape categories and the total number of cards of the initial game). Children were given samples of empty cards and asked to find different objects (at least 6) fitting to the size of the card in order to draw (outlining object) the 4 geometric shapes. Suitability and classification of the objects were then discussed within the group and each child undertook the drawing of 8 cards (picking 2 objects from each basket-shape category).

D] Presentation of all groups' books with the participation of the students of another kindergarten class and performance of a description game (a child picks a card from the deck and describes the shape depicted on it to the rest of the students, who try to identify it).

The whole project presupposed a) collaboration so that a common target (the production of the book) could be achieved b) linguistic interaction and negotiation of meaning in order to agree and compose book's content.

For the purposes of the research, each set of activities could function as a complementary source of information and as a means of checking coherence and progress of children's response.

RESULTS

Two sets of data are analyzed in this paper. The first set of data includes children's attempts to classify and define shapes according to the demands of the interrelated/closely connected activities of Task A and B. A second set of data includes the subsequent descriptions of shapes during the 'description game' (task D). The results presented below concerning identification and classifications of shapes focus on the decisions taken by groups of children. The accompanying excerpts of dialogues, although necessarily restricted here, are indicative of the procedures across tasks' performance, as well as of the semantic choices and of classification criteria constructed within groups.

Circles-ellipses

Based on data from the collected material, both circles and ellipses were treated as closely related categories by all groups of our sample. During their final categorization, 3 out of 6 groups classified the items of the specific categories in a unified category under the name "circle". Moreover, in all groups there are statements which correlate circles and ellipses as semantic categories of a lower semantic organization level, within a general category called "round" or "cycline/circular".

At the following excerpts, the group of children (G1, G2 etc) and each task of the project (A, B, C, D) are included in a parenthesis before the enumeration of each excerpt (e.g. G1A/). In dialogues the children are referred to with their initials and the teacher with the abbreviation (Tch).

(G1A/2) T.: *Madam, I gather all the round ones* (ellipses and circles).

(G3B/68) K: *And if we cut them like this (a virtual cut on an ellipsis), they become curves like circles.*

(G4A/84) Z: *This is the 'cycline' group* (shows only the circles).

However, in the discussion that followed about the items of the 'cycline' group, Z and A support the common inclusion of circles and ellipses in a group named "circles" (G4A/86), while N disagrees, supporting that ellipses are not circles. In that discussion Z. refers to a "circular group" including ellipses as well.

(G4A/86)

Tch: *Which ones are the circles?*

Z: *These and these* (circles and ellipses).

Tch: *Take a look you too N and A. I want you to participate. Are these all circles?*

Z: *This is the circular group, family (...) All these are circles, I think.*

Although circles and ellipses seem to be closely connected categories clearly distinguished by the others in task A, in the cases of groups of children who decided to make separate categories the distinction is accurate in 2 groups and almost accurate in one group, which added one ambiguous (circular) ellipse in cycles. The distinction between circles and ellipses is achieved mainly by reference to the circle prototype. Thus, children characterized ellipse as a “(a bit) stretched” circle, or “like a circle”, “so and so”, “(circles that) look like eggs”.

(G1A/3)

F: *Well, normally (indirect comparison to the circle prototype), this one, (showing an ellipse) is a little more stretched, it's an egg.*

(G1A/4)

F: *It's a circle, but it's a bit stretched.*

(G1B/6)

Tch: *Yes, and you said that they are circles. Are they circles?*

F: *Like circles.*

K: *Like circles, but “so and so” she said.*

(G4A/86)

Z: *This is the circular group, family.*

Tch: *N, take a look. Do you agree that all these are circles? It's you that will decide.*

Z: *I think that they are all circles.*

N: *These are not circles (he points at ellipses). Those are (he points at circles).*

Z: *They are. But they look like an egg, that's why.*

It is noteworthy that the characterization “stretched”/ “slanting”, as a critical distinctive quality between circles and ellipses, is also used with small variations in the correlations of square-rhombus, as well as for triangles in relation to the inclination of their sides ((G3A/75) K: *The triangles and some “slanting triangles”*). In all cases, children have a prototype in mind: circle, acute isosceles triangle. Besides, representations of such prototypes existed as a classroom shape chart. The wall-pictures function in an assistant way as a means of cross-examination, though children seem to use them also to enforce their arguments.

Triangles

In general the “triangle” appears to constitute a generally “obvious” and recognizable category of shapes, with which children are familiarized. Thus, there was no overlapping with the rest of the categories in the material, with the exception in some cases with the rhombus. The rhombus constitutes the shape most commonly associated with the triangle for reasons more thoroughly examined later.

In addition, some triangles are treated as more typical or representative, and some others appear to move along the edges, constituting a subject of discussion or disagreement within the groups, arousing the production of argumentation, which in

turn brings into light the more typical qualities of the category (G3A/74).

In some cases, typicality does not stem only from comparisons between members of the category, but also as a function of their relative spatial placement, as implied by the usage of the word “upside-down” or “crooked/ stretched triangle” in the following excerpts.

(G2A/191)

G: *Oh, I stuck it upside-down!*

(G3B/210)

M: *I mean... Let's say this is a pair of scissors (she holds a pencil) and I cut it a little like this (she points to a diagonal on a square). How will it become?*

Tch: *What will it become?*

K: *A crooked/bent/stretched triangle.*

Concerning the hypothesis of the prototypicality of the shapes, in relation to their spatial arrangement, more research is needed. Nevertheless, from children’s actions on the material, as well as from their corresponding comments and discussions arises a clear ranking at the representativeness of the members of the category “triangles”. The shapes that children initially recognize as triangles are the two acute isosceles triangles and the acute scalene triangle (e.g. G3A/74). It appears that the main criterion for characterizing a shape as a triangle is the existence of three acute angles.

(G3A/74)

[Takes in hand first the 2 acute isosceles triangles and then the right-angled isosceles. Then grabbing the right-angled scalene triangle, asks]

M: *Should we make this a triangle too?*

Five out of six groups agreed on a common classification of all triangles in task A (except of a case G2A/41, where a child refuses to see the right-angled triangle as a “whole” triangle) while the sixth group (G5) had difficulty to decide between several alternative classifications for right-angled triangles focusing on their distinctive attributes (the right-angled isosceles triangle, which was correlated with pyramid “like a pyramid”, was considered either as a unique representative of a possible subcategory or as the basis for the common classification of all right-angled triangles –the right-angled scalene triangles were also suggested as a separate category; see indicatively excerpt G5A/118). However, during task B, group 5 also suggested their common classification with the rest of the triangles on the basis of the number of sides.

(G5A/118)

X: *Madam, what shall we do with these? [2 right-angled triangles left apart] If we make it like this, it looks like.. (Touches the tip corner of a right-angled scalene triangle)*

Tch: *Like what?*

X: *Like a triangle I think, but (...) like a fin.*

Kind: *Are we going to leave them separately, is it another group?*

E: *Let's make it to be two, a bit separate* (she removes the two triangles from the main triangle group) *but be alike, not be with another group, so they are alike.*

Rhombus

Despite the suggestion of some children that rhombi could be included in the triangle category, finally a separate category is formed where a rhombus is described:

1) As “two triangles stuck together -G1A/13 (and vice versa, “if we cut the rhombus in half, we get two *pointy* triangles”).

(G1A/13)

F: *Separate, separate, I say. Rhombi don't go with triangles.*

K: *They do, they do, because we have... it picks here, it picks here too... and here it's the same* (he points at the vertexes and at the acute angles in triangles and rhombuses).

F: *Yes, but you can't* (you shouldn't), *yes, but they are not the same...normally (...)* *These here, these are two triangles stuck together, not stuck together... it is a rhombus...This is a triangle, right?* (she raises a rhombus and shows the 2 tangent sides to the other children; then she turns it upside down and shows its other 2 sides)...*and another triangle under it... and so it becomes a rhombus. This is only one triangle* (she shows a triangle from K's groups).

(G3B/76)

M: *when we cut this here* (shows with a motion a diagonal cut on a rhombus on the page), *it will become a pointy triangle.*

2) By enunciation of its typical characteristics: number of angles and sides.

(G2A/163)

M: *I say it's not for a group* (meaning triangles and rhombuses do not belong in the same group), (...)*this one has 3 angles...this one has one, two, three, four...*

The “theorems in action” (Vergnaud, 1996) the children apply in creating the rhombuses' categories are:

1) The rhombus is a «crooked/stretched square».

(G1A/194)

T: *If we turn it like that...*(turns a rhombus sideways so that the two parallel sides be horizontal.

F: *Well, it's a crooked square.*

2) The rhombus is an «inclined» square.

(G2B/47)

M: *The square... it has 4 angles and if we turn it, it becomes another shape(...)
It becomes the rhombus. Now, that is easy for me.*

Squares-rectangles

Five groups classify squares and rectangles in separate groups named correspondingly “Square/-es” and “Rectangle /-s” or “Parallelogram” (2 groups of children), while one group (G5) decides to unify rhombi and squares in a common category named “Rhombus” due to similarity with rhombi in attempts of square rotation (while handling shapes they used both terms “square” and “rhombus”). Regarding squares and rectangles, shape categories often correlated focusing on their contrasting characteristics, the base of children’s classification seems to be the square, as in 3 groups of children the most ambiguous rectangle is added to the group of squares (possibly as a marginal representative at the edges of the category). We should also mention that children use the words ‘parallelogram’ and ‘rectangle’ as identical. In Clements et al.’s (1999) study children also tended to accept “long” parallelograms as rectangles.

The inequality of the rectangle's sides is recognised as its basic distinctive characteristic implied or explicitly notified as in excerpt G1B/172.

(G1B/172)

Tch: *Yes. How do we distinguish these by those? (i.e. squares and rectangles)*

F: *I know, because this is a bit longer and the two lines are bigger and the other two smaller (points at a narrow parallelogram on the page consecutively the horizontal and vertical sides) and because this one (square) has the lines that are equal.*

DISCUSSION - CONCLUSIONS

Though the findings of this research are suggestive and could not be generalized, a general remark is that the children were able reliably to identify shapes. All children used formal names for shape categories (circles, triangles, rhombuses, squares, rectangles /parallelograms) except for the ellipse (described as a mirror or an egg). Children distinguished shapes into two large categories: those without angles (circles and ellipses) and those with angles (triangles, squares and rectangles). They used different criterion (visual and property) for examples and non-examples of shapes negotiating within their group the meaning of shapes’ category. Their positions do not concern stable, irreversible or of the same kind criteria, but issues introduced for further discussion in correlation with the tasks they had been assigned.

The criterion of *angle* and *line* (side), which was more or less directly employed and mentioned by all groups of children in the previous tasks, prevails at the game performance of task D, where shape should be described with no reference to its name. Adjusting to the demands of the task (more typical, school-type descriptions

/competitive game), children chose more typical-decontextualized terms like “angles” and “lines”, which they considered more appropriate in the certain context. On the contrary, plenty of “(looks) like...” type metaphors were used in shape descriptions of the more “open” texts of task A and B (e.g “circle looks like o (letter)”, ellipsis is “like an egg”, “like zero”, “like a mirror” etc). This kind of metaphors, which are also found in task A, but prevail at task B, allow for the essential qualities of the shapes, as well as the general communicational-educational goal of the project. We could say that such metaphors constitute an alternative strategy for shape identification, a kind of descriptive definition related to definitions through examples.

The procedure of shape classification children were involved, highlighted two main elements about their knowledge on geometric shapes:

1. Despite the existence of “prototypes” (in the case of triangles), their prototypical visual image was challenged by the presence of non- prototypical triangles and the communicational context. This means that if the context of the activity affects to such an extent children's way of thought, more emphasis must be placed on the kind of activities suggested at this level of education.

2. There is evidence from our study that most children were able to formulate correlations between circle-ellipse, rhombus-square and square-rectangles, a fact, which allows us to advance the hypothesis about the existence of a transitional stage between descriptive and relational level of thinking. If confirmed with further research, this finding could have significant impact for the instruction of geometry in kindergarten.

Apart from confirming the existence of the syncretic level, our study offers plenty of indices favouring our fundamental hypothesis that when preschool children collaborate in the context of a meaningful activity (van Oers, 1998) they can construct meanings that characterize levels of geometric thinking attributed by research to elder children.

BELIEFS OF KINDERGARTEN AND PRIMARY SCHOOL TEACHERS TOWARDS MATHEMATICS TEACHING AND LEARNING

Stephanie Schuler, Nadine Kramer, Rebecca Kröger, Gerald Wittmann

University of Education Freiburg, Germany

Kindergarten and primary school teachers' professional actions and beliefs are assumed as crucial factors for a successful transition. Individual interviews with kindergarten and primary school teachers, video observations in both institutions and focus groups were analysed to describe these beliefs. A spectrum of different beliefs was outlined. Kindergarten and primary school teachers have different views on mathematics teaching and learning due to different curricula and different trainings. The research results are used to support the process of professionalization.

INTRODUCTION

In Germany, there exist differences between kindergarten and primary school concerning curricula (1), teachers' qualification (2) and the organisation of (mathematical) learning (3).

(1) In the *Orientierungsplan* for kindergarten (Ministerium für Kultus, Jugend und Sport Baden-Württemberg, 2011) no standards but goals are outlined. Everyday situations and their learning potential are described. In the *Bildungsplan* – the curriculum for primary school (Ministerium für Kultus, Jugend und Sport Baden-Württemberg, 2004) – specific content and process ideas are formulated as well as standards and competencies children should gain in different subjects.

(2) Kindergarten teachers are mainly trained in vocational schools. Since 2004 students have the possibility to gain a bachelor degree in early childhood education. Primary school teachers study at university and have an academic degree.

(3) In Germany, children attend kindergarten from the age of 3 to the age of 6 in heterogeneous age groups. Daily routine in kindergarten are for example free play or open assignments. Primary school usually starts at the age of 6, depending on the federal state of Germany. Classes are mostly organised in homogenous groups. The morning is structured around lessons in different subjects.

In this study, the alignment of kindergarten and elementary school teachers' beliefs of mathematics instruction and teaching practices is seen as a basic condition for the interconnection between early childhood and primary school education. However, it is assumed that due to the different conditions differences and inconsistencies exist. Predominant beliefs in both institutions will be described.

THEORETICAL FRAMEWORK

Two aspects are important for the theoretical framework: Beliefs and aspects concerning transition from kindergarten to primary school.

There is no universal definition of ‚beliefs‘ (Pajares, 1992). Furthermore, there are different almost synonymous terms like ‚concepts‘, ‚subjective/implicit theories‘, ‚attitudes‘ or ‚values‘. The following findings on beliefs shall give an overview on what beliefs are (Pajares, 1992, p. 324f.):

- „The belief system has an adaptive function in helping individuals define and understand the world and themselves.“
- „By their very nature and origin, some beliefs are more incontrovertible than others.“
- „The earlier a belief is incorporated into the belief structure, the more difficult it is to alter. Newly acquired beliefs are more vulnerable to change.“
- „Individuals’ beliefs strongly affect their behaviour.“

Green (1971) characterised beliefs as followed: Beliefs are quasi-logical, they have a psychological centrality and are organised in clusters.

In spite of the various meanings of beliefs, there is a broad acceptance that teachers’ instructional practices are influenced by their belief systems (Calderhead, 1996). These practices impact on students’ learning and beliefs concerning mathematics (Hiebert & Grouws, 2007). Therefore, much effort was made to investigate mathematical beliefs of teachers in the recent two decades all over the world (Philipp, 2007).

In Germany, there are several studies concerning mathematical beliefs of high school teachers (COACTIV, Kunter et al., 2011), a few concerning the beliefs of kindergarten teachers (Thiel, 2010; Benz, 2012) as well as primary school teachers (Schuler, 2008; Bräunling et al., 2011).

Transition from kindergarten to primary school is marked by continuity and discontinuity. Therefore, two ideal-typical positions exist (Roßbach, 2006): (1) Differences should be reduced to increase continuity and to allow a gradual and smooth transition. (2) On the other hand, discontinuities can be seen as challenges beneficial to (personal) development.

According to Hacker (2004), there are several reasons for a gap in transition from kindergarten to primary school:

- different understanding of education of kindergarten and primary school teachers
- different training of the two professions

- different establishments who are responsible for the institutions (state, private establishments etc.)

To allow every individual a continuous educational biography (Heinze & Grüßing, 2009), cooperation between both institutions – kindergarten and primary school – is indispensable (Hacker, 2004). Goals and contents of both institutions should be made transparent (Griebel & Niesel, 2009).

RESEARCH OBJECTIVES

The goal of this interdisciplinary project is to design a well-grounded structural model of epistemological beliefs on teaching mathematics.

The data will be gathered with a questionnaire survey in two federal states of Germany – Bremen and Baden-Württemberg.

In a qualitative study data was collected for designing the questionnaire in a bottom-up process. The data was also preliminary used for analysing and interpreting the beliefs. In this paper, we will present only the qualitative study of Baden-Württemberg.

Various research questions, outlined below, guided the data collection and the data analysis. The following ones are important for the qualitative study.

1. What kind of hands-on materials are used in kindergarten and primary school?
2. How do kindergarten and primary school teachers support the transition from kindergarten to primary school in regard to mathematics?
3. What do kindergarten and primary school teachers consider relevant for the mathematical development of children?
4. What kind of transition practices can be found?

METHODOLOGY

The data was collected by using guided interviews subsequent to video-observations (Dinkelaker & Herrle, 2009) and with focus groups (Morgan, 1997).

The guided interviews were conducted with five kindergarten and five primary school teachers. All interviewees were female. They differed from age and teaching experience.

The interview manual contained the following topics: Planning and arrangements for teaching, interaction between teacher and child, materials used for learning mathematics, goals of teaching mathematics, cooperation between kindergarten and primary school. After each interview notes were taken in a postscript (Witzel, 1982): Comments on situational and non-verbal aspects, conversational contents and the explanation of priorities of the interviewees.

The professionals were asked to show a typical mathematical kindergarten situation or a typical mathematics lesson for first-graders. All situations and lessons were videotaped.

In two focus groups (Morgan, 1997), 35 kindergarten and primary school teachers exchanged their views on early mathematics education, the transition from kindergarten to primary school and the cooperation between both institutions. We invited highly experienced experts of whom some work in teacher training. We asked them to bring along typical hands-on materials, textbooks, etc.

Focus groups were conducted because they are an economic alternative to conventional interviews. More individual opinions can be gathered in one run. In addition, the atmosphere in focus groups is more relaxed than in interviews. Not everyone is needed all the time thus there are possibilities to withdraw. As well, thoughts and utterances can be stimulated by listening to other participants. Therefore, there are often more ideas than in a guided interview with only one person (Bortz & Döring, 2006).

The interviews and the audio data from the focus groups were transcribed verbatim. The data was analysed by coding according to the qualitative content analysis (Mayring, 2010). One part of this analysis, the paraphrase, was used to create items for the questionnaire.

ANALYSIS AND PRELIMINARY INTERPRETATION

The following analysis refers to the outlined research questions (1–4); ordered chronologically.

(1) Almost all shown materials and activities showed and used in both institutions refer to the content area ‚number and operations‘ (NCTM, 2000). The kindergarten teachers participating in the qualitative study used everyday objects (cf. figure 2-3), special mathematical programmes and trainings (cf. figure 1) or both.

According to kindergarten teachers everyday objects comprise objects from nature, e.g. nutshells, stones or chestnuts, as well as objects that surround children in their everyday life, e.g. Schleich figurines (authentic figures made from rubber), games, dice, etc. Kindergarten teachers use these materials because mathematics can be found everywhere and is a part of everyday life. Therefore – according to their point of view – no specific materials are needed. This way, children can understand the omnipresence of mathematics. The use of every day materials refers to the belief that learning mathematics in kindergarten can and should take place in day-to-day life.

Special mathematical programmes and trainings are inserted to prepare all children of one age group or disadvantaged children for school (*Zahlenland* Preiß, 2007; Friedrich & de Galgóczy, 2008; *Mengen, zählen, Zahlen* Krajewski et al., 2007). The key contents in the programme ‚Zahlenland‘ (English equivalent: land of numbers) (Preiß, 2007 or Friedrich & Galgóczy, 2008; cf. Figure 1) are knowledge of numerals

and counting abilities. Each numeral is presented in a separate story using special characters. Matching songs and various activities complete the examination of one numeral. Some kindergarten teachers mentioned that they work with such programmes to prepare all children ideally for school and to make the transition in mathematics easier. This reasoning refers to the belief that the preparation for school is more successful while using programmes than teaching and learning mathematics in everyday situations.

Kindergarten teachers who do not work with special programmes do so for various reasons. Either, they did not attend further education programmes for mathematical training or they do not see an importance in teaching some mathematical aspects before school as transition was no problem until now. Furthermore, some kindergarten teachers consider teaching and learning mathematics explicitly as inappropriate for this age group.

On the other hand, primary school teachers prefer didactical hands-on materials for the arithmetic instruction (cf. figure 4-6). These hands-on materials (cf. figure 3) shall help children to subitize and to develop the part-part-whole-scheme. The use of these materials reflects the primary school teachers' emphasis on the number concept.

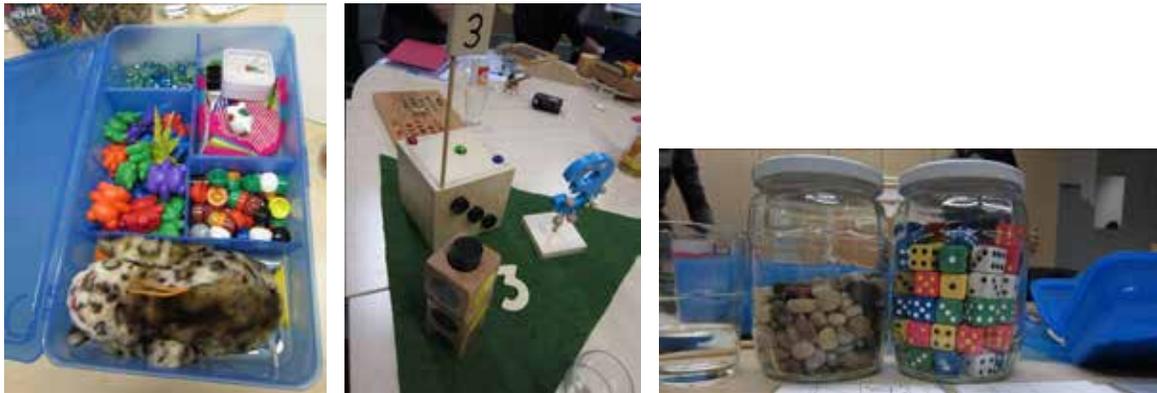

Figure 1-3: Hands-on materials used in kindergarten

Figure 4-6: Hands-on materials for arithmetic instruction in primary school

(2) In the interviews and in the group discussions the primary school teachers stress the heterogeneity of children at the beginning of their school career which influences and sometimes hinders their work. In the teachers' view the reason for the children's heterogeneity is based on the fact that the children attend different kindergartens. Because of this, they gained different mathematical experiences. Teachers try to meet the heterogeneity with group and individual work as well as action-oriented teaching. The goal is to facilitate the beginning of school for all children. Also, during the visits of the cooperation teachers in the last year of kindergarten, mutual areas and actions for a successful transition in mathematics are named in cooperation with the kindergarten teachers. The children should complete these areas and activities in kindergarten in order to obtain optimum conditions to start school. This reasoning of the primary school teachers refers to the belief that mathematical education in kindergarten should be mostly compensatory in the sense to achieve more homogeneity.

Kindergarten teachers emphasize the preparation of all children for school too (cf. (1)), but heterogeneity is often described as normal and unproblematic. Mathematical education in kindergarten is seen less as compensatory but as individualized.

(3) In connection with the question which relevant skills children should acquire before entering school, implicit demands are made towards the other institution. This is especially true for primary school teachers. In some cases the interviewed primary school teachers expressed different abilities and skills the children should master: On the one hand, these are domain specific skills like counting, subitizing up to five and on the other hand daily living skills such as to tie shoes, to hold a pencil correctly, etc. Writing numerals in kindergarten is seen critically, because the primary school teachers fear that children in kindergarten could learn something wrong. This reasoning refers to the belief that (mathematical) education in kindergarten should merely provide the basis for learning mathematics in school and should not anticipate school contents.

Some kindergarten teachers expressed several times that they consider counting as very relevant and important for the development of the children and for a successful start of their school career. Other kindergarten teachers, however, see their role primarily in mediating and arising joy and curiosity for mathematics. The primary school teachers interviewed think primarily of special skills that are important for a successful start in school. The kindergarten teachers, however, do consider some skills as relevant too but put their main emphasis on the teaching of certain attitudes. These differences are probably related to the aims of the institution. Schools have clearly defined standards to achieve but kindergartens do not. This can already be found in the underlying curricula.

(4) In Baden-Württemberg, the cooperation between kindergarten and primary school is recorded in the curricula. The way and extent of the cooperation is not described. Nevertheless, different forms of cooperation were established and used in

the last few years. Often, one teacher per school is responsible for the cooperation between kindergarten and school. This teacher is called *cooperation-teacher*. The cooperation-teacher is not always the teacher of the first-graders. He/She cooperates with those kindergartens from which children will enter their school. The cooperation-teachers visit the children in their last year of kindergarten on a regular basis, normally every second month. In this time they play with them, look for things kindergarten teachers could do with the children till entering school so that they are well prepared, etc. Part of the cooperation often is that the kindergarten children take part in a lesson in school once.

Both kindergarten and primary school teachers mentioned that there is not enough time to have an intensive cooperation. They agree that there should be much more capacities for having an in- and extensive cooperation. Nevertheless, both think that cooperation between the institutions is a key component of the transition process. The children should already get to know their future teacher and future classmates before their first day of school. They criticised the fact, that the cooperation-teacher and not the teacher of the new first grade is responsible for the cooperation. ‚Round tables‘, at which kindergarten teachers and primary school teachers meet on a regular basis, reciprocal visits, the broadening of cooperation over a longer period of kindergarten time and the integration of the entire team into the alliance in order to abolish the restriction of responsibility to only one cooperative force, were wishes expressed by the respondents.

SUMMARY AND DISCUSSION

The transcripts of individual interviews and focus groups with kindergarten and primary school teachers were preliminary analysed to describe the beliefs of those professionals.

In kindergarten, everyday objects and programmes are used primarily whereas in primary school didactical hands-on materials are used. The use of everyday objects focuses on a broad view of mathematics – mathematics is not only reduced to numbers, counting and calculations – which is at the same time non-specific. Some interviewees described how they work with these materials. Those reports suspect a limited view on mathematics as the materials are primarily used for counting. To what extent the views of the teachers are related to their choice of material needs to be proven.

The interviewed primary school teachers name different mathematical skills as helpful to be taught in kindergarten. These are mainly counting, knowledge of numbers, subizing and the assignment of number images and numerals. The interviewed kindergarten teachers name domain-specific skills less often. They strongly emphasize that they see their task in imparting fun with numbers and to arouse curiosity about mathematics, which should be continued by the teachers in school. Here, the influences of the tradition of the institutions are visible. In primary

schools standards have to be achieved. In kindergarten, a socio-pedagogical view is dominant which influences the educators' work as well as their point of view (OECD, 2006).

Between the previously surveyed teachers a consensus on the relevance of cooperation exists. Often, the children get to know the school in their last year of kindergarten. The cooperation-teacher visits the children in kindergarten and they are allowed to attend a lesson in school. Two views on the cooperation can be distinguished: (1) A child-centered/pedagogical view: Kindergarten and primary school cooperate to allow the children to get to know their possible future teacher, the new environment at school, etc. and to facilitate their first day at school. Primary school teachers and kindergarten teachers with this point of view maintain a strong cooperation. Projects are initiated together, they are organised over a longer period of time and do not only focus on future 1st-graders. (2) Cooperation and kindergarten is only seen as a preparation for school. The aim of kindergarten is to prepare the children appropriately for school to allow primary school teachers a direct start with ‚proper lessons‘. In this case, cooperation is limited. The cooperation-teacher visits the children in their last year of kindergarten approximately three times to diagnose the children and to give hints on individual training programmes.

The curricula of both institutions have an influence on the perspectives of the professionals as well as on their practices. Also, it can be interpreted that the different traditions of kindergarten and primary school are reflected in their beliefs. One example for the inconsistencies of beliefs is that some interviewees work with programmes in kindergarten and emphasize the omnipresence of mathematics at the same time.

The influences of beliefs as well as the quantitative distribution are still not clear. The questionnaire based study in Bremen and Baden-Württemberg will provide information about this issue.

Findings from the project will serve the process of professionalization of both professions in training as well as in in-service trainings.

IPADS AND MATHEMATICAL PLAY: A NEW KIND OF SANDPIT FOR YOUNG CHILDREN?

Troels Lange and Tamsin Meaney

Malmö University

In Swedish preschools, it is the responsibility of teachers to provide learning opportunities through children's play. Although anecdotal evidence suggests that ICT is becoming more common in preschools and that young children actively engage with ICT in play situations at home, there is little research on how ICT can contribute to playful mathematics activities. Data from a study of young children using iPads in home situations indicates that Bishop's six categories of mathematical activities can be seen in free, downloadable apps. It was also clear that features of some apps made the children respond to the apps in more playful ways.

ICT, MATHEMATICS AND YOUNG CHILDREN

Although there are not requirements for what children should learn in preschools, in the Swedish curriculum it is clear that preschools and teachers have a responsibility to provide learning opportunities based on play, including mathematical ones (Skolverket, 2010). Therefore, if information communication technology (ICT) is to be used to support learning then it must be through play and this means finding out from children what playful learning with ICT could be. To do this, we take the advice that Prensky (2006) gave to parents about not buying “educational” computer games for their children—“a far better strategy in my view, is to take the games your kids already play, and look inside them for what is educational” (p. 184). Consequently in this research, we identify the mathematics in the apps that one child played and begin an investigation into why they were engaging.

Almost all previous research, which has looked at how ICT supported mathematical learning, has been from the perspective of investigating what young children learnt from engaging with specifically-designed educational software in preschool settings (see for example Highfield & Mulligan, 2007). After reviewing the literature on children using ICT, Sarama and Clements (2009) suggested that the affordances of computers made them more advantageous for developing mathematical thinking than physical objects because, “compared with their physical counterparts, computer representations may be more manageable, flexible, extensible, and ‘clean’ (i.e., free of potentially distracting features)” (p. 147).

An emphasis on school mathematics in these specially designed programs is problematic in situations where learning is supposed to occur through play. This is because play has certain features, as summarised by Docket and Perry (2010):

The process of play is characterised by a non-literal ‘what if’ approach to thinking, where multiple end points or outcomes are possible. In other words, play generates situations where there is no one ‘right’ answer. ... Essential characteristics of play then, include the exercise of choice, non-literal approaches, multiple possible outcomes and

acknowledgement of the competence of players. These characteristics apply to the processes of play, regardless of the content. (Dockett & Perry, 2010, p. 175)

The use of play as the basis for learning activities affects the roles available to the teacher and children. From examining an activity where preschool children explored glass jars, we found that although the teacher could offer suggestions about activities, the children did not have to adopt them and could suggest alternatives (Lange, Meaney, Riesbeck, & Wernberg, 2012).

However, from related research (Johansson, Lange, Meaney, Riesbeck, & Wernberg, 2012), it was clear that mathematical variety was not lacking in these play situations. We found that all of Bishop's (1988) six mathematical activities, which underlie the Swedish preschool mathematics curriculum (Utbildningsdepartementet, 2010), were present in play situations that children engaged with. Bishop's activities have a different background and focus than the topics often connected with school mathematics, although there is some overlap. The activities were:

Counting. The use of a systematic way to compare and order discrete phenomena. It may involve tallying, or using objects or string to record, or special number words or names.

Locating. Exploring one's spatial environment and conceptualising and symbolising that environment, with models, diagrams, drawings, words or other means.

Measuring. Quantifying qualities for the purposes of comparison and ordering, using objects or tokens as measuring devices with associated units or 'measure-words'.

Designing. Creating a shape or design for an object or for any part of one's spatial environment. It may involve making the object, as a 'mental template', or symbolising it in some conventionalised way.

Playing. Devising, and engaging in, games and pastimes, with more or less formalised rules that all players must abide by.

Explaining. Finding ways to account for the existence of phenomena, be they religious, animistic or scientific. (Bishop, 1988)

Of the 12 situations illustrating the 6 activities that we considered in Johansson et al. (2012), 3 came from a sand pit. It was clear from what the children were doing—filling buckets, making pretend gardens, driving toy cars—that they were involved in play because, for example, the children exercised considerable choice, adopted non-literal approaches, produced multiple outcomes and were acknowledged as competent in their actions. Our thinking about how a sandpit facilitated children's play and supported their engagement with mathematical ideas made us want to explore whether ICT, iPads in particular, could provide similar mathematical learning opportunities. Anecdotal information suggests that many young children play with ICT at home and we considered that information from home situations could be informative for preschools. Our research questions for the study are:

- 1) What mathematics can be seen in apps for the iPads that young children play?

2) What features of these apps support children's play?

METHODOLOGY

Data was collected from children, aged between four and six, engaging with apps on iPads. In this paper, we use video data of a six-year-old boy, Miguel, who currently lives in England. Although he had played computer games at home, he had not used an iPad before and so was not familiar with the apps. Over four days, he played games for 1-1½ hours each day. The data discussed in this paper is from the final session. By this time, Miguel was familiar with the apps and made choices of what to play based on his interests. Being videoed was also no longer a novelty. Although he had already spent time in an English primary school, he would not have started school until the month when the data was collected if he had been living in Sweden.

Miguel was recruited as a co-researcher to evaluate the suitability of the apps for a four-year old child. We explained that he was better at making these judgements as we were too old. One of the authors, Tamsin who was his aunt, videoed Miguel's activities with a small video camera. At times, there was discussion between them, sometimes initiated by Miguel and at other times by Tamsin. The discussions were not planned but occurred as a natural part of Miguel's engagement with the apps.

Before meeting with Miguel, 33 different apps, which were recommended by one of three sources, were loaded onto the iPad. The apps were all free, although some operated only for a short period before payment was needed to move to a higher level. Fifteen apps were recommendations from *Pappas appar* (Pappa Daniel, 2011), a blog where a Swedish father had placed links to free apps for iPhones and iPads for young children, based on his own children's interests. Four apps came from Apple's store (Apple, 2012), under the category of being education and mathematics. The remaining apps came from a US mother's blog (PragmaticMom, 2012). On this site were recommendations from the mother as well as from other people. Once the apps were downloaded, Tamsin played them all. Some apps were about basic number facts. However, in most apps the mathematical ideas were less visible.

Initially the data were analysed to identify which of Bishop's six activities occurred in the apps that Miguel played. This information was recorded in a table. During this analysis, notes were made about the features of the app that seemed to support Miguel's engagement with it. Once the analysis of the mathematical categories was completed, the notes about the features were considered and general themes/points identified. One of the themes, which was connected to Miguel's willingness to use an app, appeared to relate to how visible the mathematics was.

We could distinguish 3 levels of visibility of the mathematical ideas. To clarify how this visibility was related to the definition of play we used Basil Bernstein's (1971) ideas about the degree of classification and/or framing of content. In our context, framing is about whether it is the app or the player who has control:

over the selection, organization and pacing of the knowledge transmitted and received in

the pedagogical relationship. ... Strong frames reduce the power of the pupil over what, when and how he receives knowledge and increases the teacher's power in the pedagogical relationship. However, strong *classification* reduces the power of the *teacher* over what he transmits as he may not over-step the boundary between contents, *and* strong classification reduces the power of the teacher *vis-à-vis* the boundary maintainers. (Bernstein, 1971, pp. 51-52 italics in the original).

In our case, the app and by implication its designer, replaces the teacher in the pedagogical relationship. Wang, Berson, Jaruszewicz, Hartle and Rosen (2010) discussed the importance of “the virtual world product developers who incorporate decision making options that the users can manipulate” (p. 36). As exercise of choice was one of the key features of play (Dockett & Perry, 2010), consideration of who controlled what content was used and how it could be used were of interest. Although Tamsin took part in discussions with Miguel, she made no suggestions about “the selection, organization and pacing” (Bernstein, 1971, p. 51) of what he did. The exception was after Miguel had spent considerable time having a dog in the *Talking Tom 2* app make farting noises, Tamsin suggested that he found another app to play.

In Miguel's engagement with the apps, it was possible for us, as researchers, to identify the mathematical content, such as ideas about numbers, but it often would have been invisible to others, especially young children. At the most visible level, a player could not engage with the app without being aware that they were using mathematics as was the case with *Factor Ninja*, described in the next section. In this case, the mathematics could be considered as strongly classified and well insulated from other content (Bernstein, 1971).

At the next level, the mathematics was semi-visible, lying somewhere in between a strong and weak classification. Often apps had several parts and one or more of them required Miguel to use mathematical concepts. However, the focus of the app was not on the mathematics. Instead the mathematics was used to achieve another purpose. In *Tavern Quest*, the player earned money when a meal was sold. This could be used to quicken up meal production or to buy necessary skills for a quest. In this case, the content was not strongly classified because it was integrated with other content, but it was strongly framed because there was no choice in the selection of the content that had to be used.

At the third level, the mathematics was invisible. For example, in *Toca Hair Salon - Christmas gift*, measurement ideas about the length of the Christmas Tree's hair were part of considerations of how the hair should be styled. In these cases, the designer did not insulate the mathematics from other contents and the content selection depended upon the purpose of the app. Classification and framing were weak (Bernstein, 1971). Emilson and Folkesson's (2006) research in a Swedish preschool, suggested “a weak classification and framing can promote the possibility for children to participate on their own terms” (p. 235). Therefore, classification and framing in an app is likely to affect whether it is considered as play by the children.

IPADS AND BISHOP'S 6 MATHEMATICS ACTIVITIES

Over the hour, Miguel played eleven different apps, sometimes for a very short time, such as *Tavern Quest*, and others for much longer periods, such as *Meeblings* and *Toca Hair Salon – Christmas Gift*. Only in *Talking Tom 2* was it not possible to see any of Bishop's six mathematics activities.

Counting

Factor Ninja had mathematics as its sole content and required composite numbers to be sliced into their prime factors. Therefore, the contents of this app were strongly classified (Bernstein, 1971). Miguel did not know what prime or composite numbers were but was aware that there was no choice in the selection of knowledge he needed to use. This was the only app where he went to the explanation to find out what he had to do. However, the explanation required too much reading for a six year old. He also “died” too quickly to learn the rules from using the app. Consequently, he did not engage for long. Nevertheless, he named the numbers as he was slicing.

Knattematte appeared to be very similar to a school-like number activity. In one part of the app, a simple addition was given in numerals and then with apples. Then a choice of four numerals appeared on the screen. The correct numeral had to be tapped, but when Miguel tapped a wrong numeral, it just shook. As well, he found he could eat the apples by tapping on them. Although the mathematics in the app appeared to be strongly classified and framed, the way Miguel engaged with it suggested that he was able to blur the boundaries between contents and determine what content should be used.

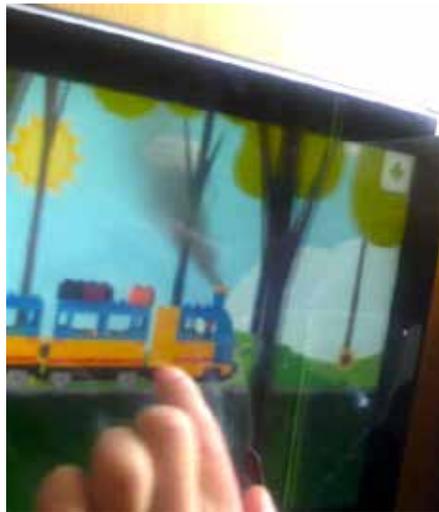

Figure 1: Duplo Jams–train activity

In other apps such as *Duplo Jams*, the counting was less visible. In one activity a train ran along a track. Duplo bricks fell from the sky and if the train moved slowly, they landed on it (see Figure 1). After a discussion about the relationship between the train's speed and catching the bricks, Miguel said “I've just got, now I've got 3”. Then another brick landed on the train and Tamsin said “There you go, how many

now?” As two more bricks fell, one after the other, Miguel stated “I’ve still got lots.” Tamsin said, “How many’s lots?”. After some distractions, Miguel counted them and said “Eight, eight”. Knowing how many bricks were on the train was not essential for the game, but the way the bricks fell, one at a time, facilitated a systematic noting of how many there were. Thus in this app, counting could be considered both weakly classified—there were no distinct boundaries between it and other content, such as the train’s speed—and weakly framed as Miguel could control what content was his focus.

Locating

Locating is about exploring one’s spatial environment. In some apps, location skills were needed and this supported them being discussed. In one part of *Bamba Ice*, Miguel had to tap a numeral between 1 and 9 on a cash register to indicate the price he should pay for an ice cream he had designed. A purse then opened to reveal an equal number of coins to the price chosen, although this match was not clear from how the coins were shown in the purse. Miguel had to drag the coins one at a time to the cash register drawer to pay for his ice cream. Sometimes his dragging meant the coin was just outside the drawer, so it was returned to the purse and he had to start again. Although in this last session, we did not discuss why it took him a long time to get all the coins from the purse to the drawer, in a previous game, Tamsin had mentioned how important it was to make the coin go wholly into the drawer. The choice of what Miguel had to do in order to move to the next stage was controlled by the app, making it strongly framed. However, the lack of visibility about what content he was expected to use—location skills—suggested the activity was weakly classified.

Measuring

Measurement knowledge was needed only for some parts of the different apps, affecting the degree of visibility. In the app *Order Up*, Miguel was expected to judge when different items were “cooked” by reading a scale. However, as was the case with several apps, the mathematical content was not always Miguel’s focus.

Miguel: Cook eggs, cooking eggs this time, I’ve never cooked eggs before.

Tamsin: No, it looks like you’ve got to cook both sides as well. Do you remember how to flip them?”

When the meter moved to perfect for one side, he flipped the egg

Tamsin: Yep, flip it, that’s it.

Then he moved to another part of the app and the “cooking” was not completed and the cooking of the egg was labelled “poor”. Then as Miguel refocused on the “cooking”, Tamsin intervened so the scale reading became part of the discussion.

Tamsin: Argh, you didn’t wait till it was all done.

Miguel: Of what?

Tamsin: Hang on, wait till that one gets up there (pointing to where the meter has to get to for it to be perfect). Remember, it’s got to be put in here (pointing out

the dinner plate which must be pressed in order to save the meal).

He tapped on the dinner plate when the meter reached “perfect” on the second side.

Tamsin: That’s it go, go!

Miguel: Perfect!

In home situations, the boundaries between school and everyday knowledge, such as between measurement and cooking, are likely to be blurred, suggesting that classification is weak. However, in a virtual environment of an iPad app, the blurring did not seem so clear to Miguel. Although he had seen eggs being cooked, it was unlikely he had cooked any himself. With Tamsin’s intervention, the need to read the scale was reinforced making the measurement knowledge strongly classified. The app design also meant that Miguel had little choice about what to do, suggesting that framing was also strong.

Designing

Designing was a large part of several apps that Miguel played over the four days. The one that he repeatedly returned to was *Toca Hair Salon*. In this app, Father Christmas or a Christmas Tree could get a new hair style, by using various equipment and accessories. In the final session, Miguel placed Christmas decorations of the tree and coloured its needles different colours. He turned his finger into a hair dryer by clicking on an icon and rearranged the needles (see Figure 2).

Figure 2: Christmas Tree gets a new hair style

Both characters in this app changed facial expressions as Miguel gave them different styles. The tree’s face showed surprise when the hair was cut and then became sad when the needles were made so long that they covered its face. Miguel said “Why is he feeling so sad? I’m putting his hair back.” Tamsin answered “Maybe because it’s a little too long for him?” Miguel said “Because he doesn’t like it on his head.” Tamsin replied “Yeah, it’s in his face. I don’t like having hair in my face either.” Although the tree’s face seemed to register happiness, sadness and surprise, it was not always clear what the connection was to Miguel’s actions. Nevertheless, the feedback that Miguel gained from the characters encouraged his continued engagement.

The designing knowledge that Miguel used was not isolated from other contents

about hair, hair styling and Christmas trees, suggesting that classification was weak. Framing also appeared weak because Miguel had significant control over what he chose to do and the order in which he chose to do it.

Playing

Apps designed for young children require them to conform to certain rules but these rules were usually embedded. Given that children have limited if any reading skills, apps need to be operated intuitively. For example, in the *Meeblings* app, different coloured Meeblings had to be tapped in a specific order to rescue other Meeblings. After several unsuccessful attempts at a level, Miguel checked the solution, by tapping on this word and watching what he had to do. This suggests that what is considered to be the content of rules is neither weakly or strongly classified. However, the constraints they placed on players' choices about what they could do indicated they were strongly framed. In the train game in the *Duplo Jams* app, Miguel had to know from other experiences, that raising railway barriers might move the train forward. When he first came to them, Tamsin had to tell him what to do. In a later attempt, Miguel did it himself and said "It's easy, see. It's easy, easy this time."

Explaining

When Miguel first engaged with the apps, he rarely talked about what he was doing even when questioned. His attention seemed focused on determining what he had to do. Only after he was familiar with the apps did he seem able to discuss them. However, when he became comfortable with the app, it still had to be challenging for him for him to continue to play it. Therefore, opportunities for discussions, including explaining what was happening, only arose on a few occasions. Of Bishop's (1988) six activities, this was the one which was the least represented.

The embeddedness of the rules also meant that models of explanations were rarely provided, although sometimes, Tamsin provided them. In *Play Lab* a shape was traced over and then appeared, as a solid shape on the screen. In one game, the shapes were combined to form a car which drove along a road. Miguel's tracing was not always recognised by the app and twice when he tried to trace a circle, a square appeared. His car ended up with two squares on its roof.

Miguel: What is that?

Tamsin: I think it's a car, isn't it? ... A car with parcels on the top.

Miguel found that by tapping on the car, which was now driving, he could make the squares wobble and eventually fall off.

Miguel: See, I'm trying to put the parcels down. See I put them down.

Miguel's explanation of how he made the squares jump off the car involved focusing Tamsin's attention on his actions. Miguel's explanations were weakly classified because what they was not clearly insulated from other content, such as making statements about what was occurring. As well, framing was weak because the control

of what was and what was not transmitted was largely up to Miguel who used his everyday knowledge to form the explanations.

CLASSIFICATION, FRAMING AND SANDPIT PLAY

Almost all of the apps that Miguel chose to use on the final day of his “research” using the iPad contained one or more of Bishop’s mathematical activities, although opportunities to provide explanations were limited. Nevertheless, as Prensky (2006) suggested, the apps that Miguel engaged in did contain educational material.

At the same time, it was clear that six-year olds, who are at the end of preschool in Sweden, may not recognise that they were doing mathematics while engaging with the apps. This was because the focus was on something else. In apps, such as *Knattematte*, which most adults would consider to be about number knowledge and thus strongly classified, Miguel found other aspects of the app to focus on. When the mathematics was invisible, there was a blurring of boundaries between mathematical and other contents as Miguel responded to the different challenges in the apps, making it weakly classified. A similar case could be made for the mathematics that children engage with when playing in a sandpit.

On the other hand, the apps that seemed to be most play-like in the ways that Miguel engaged with them were those that were weakly framed. In these cases, Miguel chose what he did and how and this facilitated him to try out different approaches and explore different outcomes, such as was the case with *Toca Hair Salon*.

It cannot be assumed that because a researcher considers an app to use mathematical concepts that children can build on the concepts or make connections to other concepts. However, it cannot be assumed that children do not do this either and so longitudinal research is needed in this area. Regardless of whether an app was considered to be weakly classified, framed or both, describing what he was doing, especially when he used explanations, seemed to provide Miguel with opportunities for his mathematical thinking to become more visible. It also seemed to allow him to be challenged in other ways than those required by the apps. Thus, apps have the potential to provide opportunities for playful mathematical learning but interaction with an adult would contribute a significant amount to realising this potential.

YOUNG CHILDREN'S USE OF MEASUREMENT CONCEPTS

Dorota Lembrér

Malmö University

This paper describes preschool children's measurement representations as they engaged in drawing a map. The use of small cars, boats, trains and aeroplanes helped the children to make the connections between two and three dimensional space. They also made connections to their awareness of length. The children's own experiences provided the motivation and stimulus to provoke their mathematical thinking about quantifying different attributes of objects.

INTRODUCTION

In this paper, I focus on children's experiences of area and different forms of length, such as breadth and height, by analysing the children's descriptions given while they were drawing a map. The children's own thoughts were used as a starting point to discuss the mathematics by myself, as the teacher. This case study is a part of a larger study which arose from a desire to understand how children's outside experiences can promote mathematical learning.

Doverborg and Samuelsson (2011) highlighted the need for children to learn from their own experiences in a way that made sense to them. Their research indicated how children perceived mathematics to be useful both at the current time and in the future. However, Uttal (2000) found that children's developing conceptions of maps were affected by their understanding of the surrounding world. Uttal suggested that younger children perhaps have not yet developed the ability to understand and connect their outside experiences to activities inside preschool. Uttal's study showed children's difficulties in encoding, remembering or understanding information. He suggested that to capture and comprehend all aspects of a three dimensional world on to a two dimensional sheet of paper is impossible for young children.

According to the Swedish preschool curriculum, early childhood settings should facilitate mathematical learning through play (Skolverket, 2011). Play has a leading role in developing children's knowledge from an early age (Vygotsky, 1933/1966). Activities can be based on a creative form of play, with opportunity for a variety of expressions. Children's everyday experiences can be represented in their visual creativity and provide opportunities for conversations. Nevertheless, it can be difficult to see children's illustrations with anything other than the adult eyes, but when we listen to children, as they draw, we can understand their thoughts, thus providing insights into their interests and background (Coates & Coates, 2006).

Social interaction in play can promote the construction of mathematical knowledge. Edo, Planas and Badillo (2009) stressed that teachers and children interactively construct shared meanings when engaging in activities, such as play. Consequently, the preschool teacher has to find meaningful situations and ways to communicate that

challenge the children to ask questions, reflect and discuss (Clarke, Clarke, & Cheeseman, 2006). The conversation between adults and children can be a part of the learning process in mathematics, where the teacher has a supporting role to help the children build an understanding of measurement.

When children attend preschool they bring with them experiences from outside preschool which can be the basis for developing children's mathematical thinking (Clarke & Robbins, 2004). However, teachers' perception that they must follow the curriculum can result in them providing activities suggested by the curriculum but which do not build on children's own understandings (Doverborg & Pramling Samuelsson, 2011).

MEASURING CONCEPTS USING CHILDREN'S OUTSIDE PRESCHOOL EXPERIENCES

Concepts of measurement are described in relationship to the concepts of attribute, unit and scale (New Zealand, Ministry of Education, 2007). The attribute that is compared can be area, length, volume and time, etcetera. Unit and scale measurement concepts can be applied to most attributes but initially it is very important for children to be able to identify what attribute is to be measured (New Zealand, Ministry of Education, 2007). Once the attribute is identified, children are then able to do direct comparisons by placing two objects next to each other. They also develop an understanding of transitivity, in which a third object is used to compare two other objects. If the first object is smaller than the third object but bigger than the second object, it is possible to say that the second object is smaller than the third object.

In measurement, units are used to measure an attribute and to quantify the amount of an object. Bush (2009) described children's understanding of measurement, with focus on usage of identical units and iteration. For an accurate measure, the units must be identical. Iteration is the repetition of a unit when measuring involves detailing an amount and is one of the underlying concepts connected to unit. Connected to the need to understand iteration, children also have to understand the idea of tiling, which is when units are placed repeatedly, with no spaces between. These are counted in order to find the measurement amount (Bush, 2009). Relativity involves understanding how units compare in size to other known objects (New Zealand, Ministry of Education, 2007). McDonough and Sullivan's (2011) research suggested that children also need to understand that a larger unit can be subdivided into repeated parts which can be counted, to produce a measurement of the object. This concept leads to the use of standard units, such as metres and centimetres.

When using a scale to measure, any point can act as the start or end point. However, without an awareness of the concept of unit, incorrect measuring can occur (McDonough & Sullivan, 2011). The concept of scale also includes an understanding that marks on a scale represent the end point of each of the units. Therefore, the end point when something is placed on a scale, indicates the amount in the same way that counting individual units does (New Zealand, Ministry of Education, 2007).

The Swedish preschool curriculum suggests that the preschool should engage children in activities that develop their ideas about measurement and space, as well as other mathematical concepts (Skolverket, 2011, p. 10). This means that teachers are responsible for building on children's understandings of attribute, unit and scale as they engage in an activity.

Children's everyday experiences outside preschool can be a starting point for building measurement strategies in preschools (Castle & Needham, 2007). Clarke and Robbins (2004) collected data that illustrated children's experiences at home and in their neighbourhood and showed a variety of mathematical contexts. For example, there were sequences of children measuring ingredients and cooking at home. These provided evidence of mathematics in everyday experiences, although they were not recognized by parents or teachers. Meaney (2011) also found that a six-year old girl engaged in a number of measurement activities at home, often associated with the child's physical engagement in a task. In particular, she suggested that measurement of time, often considered hard because of its abstract nature, was the focus of many discussions between the child and her mother. This contradicts suggestions that length is the easiest attribute to measure.

Fleer (2010) suggested that younger children in preschool probably are unaware of the value of their own experiences and the teacher has to encourage this awareness. Within preschools, there are possibilities for knowledge creation, nevertheless children should have the opportunity to form their own experiences and make choices in the light of these.

There appears to be little research which shows how children's share their previous measurement experiences and then teachers make use of them to develop their understandings. For example, Castle and Needham (2007) investigated younger children's understanding of measurement concepts, but not their thoughts about them. In McDonough and Sullivan's (2011) research, children were assessed on their preconceived understandings about how children learn length measurements.

The aim of my research is to understand how children's outside experiences can promote mathematical learning. Teachers' ability to recognize and work with children's outside preschool experiences can affect the mathematical activities that they offer to children. The research question is:

How do children use measurement concepts in an interaction that draws on their outside preschool experiences?

METHODOLOGY

This paper presents a case study which is a part from a larger study (Bryman, 2012). Over recent years, researching early childhood education by listening to and observing children has become common (Dockett, Einarsdottir, & Perry, 2009). A case study approach recognises that within social and cultural settings, children as competent participants have a right to have their voices heard and to be taken

seriously. The larger project investigates the relationship between children's outside preschool experiences and their mathematical learning in the preschool. In this paper, I present one episode in which I was involved as the teacher where children made connections to their outside preschool experiences whilst drawing a map. Their involvement showed use of many of the measurement concepts described earlier.

In order not to lose the spontaneous aspect of their play, field notes, first by myself, but later, after the children invited me into the play, by a colleague were made instead of, for example, video recordings. The latter would have provided the possibility to analyse the data several times. However, given that the wider project was about documenting naturally occurring incidences in a preschool setting, it was decided to use field notes instead.

Rather than being set by me, the activity began as a play session with a group of five children aged between two and six years before breakfast. It was the children, one boy in particular, who suggested drawing a map, which became the focus. From being an observer I became an active participant in the activity. I am aware that several of the questions that I asked had an impact on the dialogue sequences during the activity (Hasselgren & Beach, 1997). On the other hand, I was one of these children's preschool teachers and we interacted in ways that seemed typical of our normal forms of interaction.

Analysis of the interactions was done by looking for examples of the measurement concepts of attribute, unit and scale. Examples of the children's use of these concepts are provided in the next section. The exchanges were originally in Swedish but are provided in English. It is not always easy to translate young children's Swedish as their language is developing, so it has been tidied up in places to make it more understandable. This has changed the form but not the content.

CHILDREN'S STRATEGIES IN MEASURING WHILE DRAWING A MAP

The group of five children consisted of three boys and two girls. Child 1 is six years old, child 2 is two, child 3 and child 4 are both five years old and child 5 is four.

Child 1 handed out toy vehicles to the other children, at the beginning of this activity. During the activity, the children shared and swapped toy vehicles between themselves. They all had experiences about travelling and used their knowledge to draw the map. The dialogues show how the children used the toy vehicles with the measurement concepts of attribute, unit and scale.

The activity began with a boy picking up paper and pens. The following exchange then transpired.

Dorota: Why did you take out the paper?

Child 1: We must make space

Dorota: Make space? What do you mean?

Child 1: Space for boats, trains, cars, airport, roads, you can take busses.

Dorota: Are you thinking about a map?

Child 1: We will have roads, airport, harbour, train station. We will find it, we will draw on the paper.

By saying “we must make space”, Child 1 appeared unclear about which attribute he was talking about. However, he clarified this by saying that space was needed for the toy vehicles, suggesting that it was area. After that he said “we will find it”, which was followed by looking at the toy vehicles and the sheet of paper. This suggests that the child was making a visual estimation of the different amounts of area that would be needed for roads, airport, harbour, and etcetera. However, there is no explicit comparison mentioned either between the different vehicles or between the vehicles and the space on the paper. If there is a comparison, it is implicit. This is similar to what Meaney (2011) found in her study of a six-year old child’s use of measurement concepts. In this study, many of the comparisons were to an unidentified other, making them also implicit.

Later Child 4 helped a younger boy, Child 2, to count busses and draw train stations. Then Child 4 had an idea about drawing a railway and two train stations. She described this to Child 2. Child 4 had experiences of travelling by train and, therefore, may have known that trains travelled from one station to another, although she did not explain why she needed to have two train stations.

Child 4: We are drawing roads and two stations.

Dorota: Why two stations?

Child 4: I do not know, but the train has to go somewhere (Looks at child 2. He had trains, which he gave to her)

The child used physical objects to visualise her thoughts. By saying that the train has to go somewhere, Child 4 implies a comparison between the area taken up by a train, and more implicitly its journeys, and the area on the piece of paper. The presumption seemed to be that the paper had a large enough area to cater for the railway line so the train could “go somewhere”. Child 4 placed the two trains side by side and used them to draw lines on either side of this pair. Then, she moved the trains forward and drew new lines, again either side of the pair of trains and repeated this three times. After that she drew the rest of the railway without using the two trains. She had designed a railway across the paper. Each train had the role of an identical unit, as each train was the same width. In placing the trains side by side, there was no gap between them, suggesting that this child understood the unit concept of tiling. In this way, Child 4 determined the width of the railway from using the toy trains. After that, she drew a station at each end. This may indicate that she was using them as end points for the length of the railway line, which is related to concept of scale.

The next example shows Child 5’s explorations about width, from putting two vehicles side by side and using his experiences and knowledge about traffic and directions. Child 5 started by drawing a road, which he linked to the train station.

Child 5: How much space do I need? I want to have a two-lane street, so my car can drive in both directions.

Dorota: What do you think? How much space does your car need, how wide is the car?

He looked at the car and drew a straight line beside it. He moved the car sideways, and drew another line. The street was compared to how wide the car was. Child 5 used two identical units, the cars, and put them side by side on the road, to see if they fitted into the space. By doing so, he subdivided the width of the road in order that the cars could drive in both directions. The cars were placed side by side with no gaps between, indicating tiling. He estimated the width of the road by placing these cars together in a similar manner to what Child 4 had done with the trains.

The next exchange shows again the importance of the toy vehicles in supporting the children's measurement representation so that they could draw the map as they wanted it to look. The toy cars were not only used by Child 5 to draw roads of an appropriate width, but also to draw a line in the middle of the road.

Dorota: What are you doing?

Child 5: Dividing the road so the cars know on which side of the road they should drive. You know when you drive you should have this line there (pointing at the line, he drew in the middle of the road)

Dorota: Here! On the left side of the car (pointing on the line in the middle)

Child 5's experiences outside of the preschool made him aware the road should be designed so the cars knew on which side of the road they should drive. He placed two cars side by side. Then he took away one and drew a line. These two cars represented the width of the road, which can be considered as a single unit in its own right. In this case, the cars could be seen as supporting the partitioning of this large unit of a road into smaller units, the width of one car. Being able to move backwards and forwards between seeing the car or the road as the unit provides a way of seeing the complex relationship between them.

The follow exchange illustrates how child 4, the girl who drew the railway, began to draw a harbour. The harbour was needed because, as the children discussed, it was possible to travel by boat. Child 4 took a pen and drew a line in front of a boat, then she put another boat behind the first and repeated this until she has five boats, lined up one behind the other, like cars parking in a street, and drew two lines. She said:

Child 4: I'm drawing a harbour, I place my boats behind each other and I have five boats. I have to draw all five to get space

Dorota: Do you make space for your boats?

Child 4: Yes, I know how large a harbour should be now

Dorota: How do you know?

Child 4: My first boat is behind this line (she points) I have drawn two lines now, you see (she takes away the boats and points on two lines)

Dorota: Okay, a line in front of the first boat, and a line behind the fifth boat

Child 4 uses the boats, as physical objects, to find out and measure the area needed for the harbour. To do this, she builds on the attribute idea of comparison, by using length as a default for area measurement. The iteration is of five boat lengths, which forms the area of the harbour, when boats are placed one after the other. Similar to when she was drawing the railway line, child 4 used five identical units and filled a space without gaps, suggesting the unit concept of tiling. By drawing a line at the end of the last unit, she identified the end point for her measurement, which is for a component of the concept of scale. As the teacher, I took the opportunity to use ordinal terms, “a line in front of the first boat, and a line behind the fifth boat” to highlight these endpoints.

A discussion with children in relation to measurement occurred again when the children tried to draw streets and a runway for an aeroplane. The children used each other’s ideas to work out how they could make enough space on the paper for vehicles. Child 1 and Child 3 noticed what Child 5 did when he drew roads and did the same with the runway for aeroplanes.

Dorota: How is it going? Do you have space for all the planes?

Child 1: We have five aeroplanes and only two can be in air.

Dorota: Be in the air?

Child 1: One lands, and one lifts off (he points to the map), you see, we have drawn a take-off and landing runway. Other planes are here.

Dorota: Okay, what were you thinking when you drew the runway?

Child 1: The aeroplane takes a lot of space, we have tried.

The children needed the support of physical objects when, for example, they discussed the width of a runway to make sure it would be possible to fit an airport on the map. Child 1 took two aeroplanes and placed them on the runway, side by side. In this way, he compared the width of an aeroplane to the width of the runway. By placing two aeroplanes on the runway side by side, Child 1 and Child 3 used the concept of iteration, to measure the width of the runway—it was two aeroplanes wide. They used aeroplanes to determine the size of the area that they had to draw, by lifting one aeroplane and landing the other.

Sometimes physical objects were not sufficient for developing some ideas and it was myself, as the teacher, who provided the stimulus. When it was time to draw a bridge, I challenged them to think more about height and width. To begin with, I took a piece of paper and said “how long should the bridge be?” A girl replied, “as long as a car”. Then I cut a piece of paper, so that it was as long as the car the girl gave to me.

- Dorota: Is it a bridge? (I looked at Child 4. who put the piece of paper on the map), is it a bridge?
- Child 4: No, how should we make one? What should we do?
- Dorota: (took a larger piece of paper, gave it to child 5) Can you cut out a strip, which has the same width as this piece (the piece child 4 cut, which was too short). It is as wide as two cars. This has sufficient width to be a road in two directions.
- Child 4: We take two cars, put them on the piece of paper, one after the other. Is it enough?
- Dorota: How do we know that the bridge has enough width and height to allow a train to drive under?
- Child 5: A train must be able to drive under the bridge, we try (teacher takes a train, holds up the piece of paper and pushes it upwards until there is space enough to drive the train under it.)

Child 4 together with child 5 wanted to build a bridge for cars to drive over and trains to go under. The width of the paper was compared to the width of two cars. Child 4 said “we take two cars, put them on the piece of paper, side by side and cut”. In placing two cars side by side, they showed a concept of iteration. The cars were identical units and these units filled the space without gaps, thus tiling was used. Relativity in measurement takes place, when they needed to cut a piece to fit two kinds of units, cars and trains. The piece of paper, the cars and trains, are compared directly.

DISCUSSION AND CONCLUSION

This activity was initialized by the children and the map was a product of their engagement. To produce the map, the children used several measurement concepts to solve problems. I consider the children’s creativeness, in map making, to be the key for making connections between their ideas about how to measure the spaces they wanted on their map and the measurement concepts described in the literature (Bush, 2009; New Zealand Ministry of Education, 2007; McDonough & Sullivan, 2011). The children used informal units, such as the toy cars, boats and places, to measure attributes of objects, such as the area for a harbor, the width of a road, height of a bridge and length of the airport runway.

The results of this study indicate that children’s own experiences were the background for the activity and could be drawn upon whilst they were playing. Using their own experiences allowed them to link the knowledge they possessed with knowledge about measurement concepts. The activity allowed them to be creative. At times, they were not able to express their thoughts verbally but did so through gestures, when they were using the physical objects.

As a teacher I could recognise the mathematics in children's actions and drew their attention to concepts of measurement, especially in the bridge episode. I could help children to address challenges they had when building the bridge. The knowledge that the children had about the need for the bridge to be tall enough for a train to go under it and wide enough for two cars to travel on it provided them with background to what the problem was that they had to solve. Their understanding of what the problem was meant that my questions prompted them to think again about how long the paper for the bridge needed to be.

As Doverborg and Pramling Samuelsson (2011) stressed there is a need to use children's own experiences as a basis for their mathematical activity. In this case study, children's outside preschool knowledge about travelling and their experiences with cars, trains, aeroplanes and boats allowed them to use and develop understanding about measurement concepts. This illustrated how Doverborg and Pramling's ideas could become a reality when children are supported to discuss their ideas. As the teacher, by engaging in their play, I confirmed the value in these experiences through the social interaction and promoted the construction of mathematical knowledge. In many ways this was similar to what was documented in Edo, Planas and Badillo's (2009) research. Listening to what the children had to say contributed to finding a meaningful situation, in which it was possible to challenge the children to ask questions, reflect and discuss (Clarke, Clarke, & Cheeseman, 2006).

Further research is needed to understand how children's background knowledge can be used by preschool teachers in activities and discussions. The research described in this paper has shown how concepts of measurement can be used but further research is needed about how other mathematical concepts can be developed by preschool teachers drawing on children's outside preschool experiences.

EXPLORING THE FUNCTIONS OF EXPLANATIONS IN MATHEMATICAL ACTIVITIES FOR CHILDREN AGES 3-8 YEAR OLD: THE CASE OF THE ISRAELI CURRICULUM

Esther Levenson and Ruthi Barkai

Tel Aviv University

Explanations are an inherent part of mathematical activity. They serve various purposes and may take on different roles. This paper focuses on the functions explanations may serve in the preschool as well as in the beginning of elementary school. It investigates the use of explanation-related terms in the preschool and in the first and second grade mathematics curriculum in Israel.

Key words: Preschool; first and second grades; explanations; curriculum documents

INTRODUCTION

The mathematics education community has placed great emphasis on the giving and evaluating of explanations by students of all ages (Mueller, 2009; Yackel & Cobb, 1996). They are part of the reasoning processes we wish to encourage among students, "Students need to explain and justify their thinking and learn how to detect fallacies and critique others' thinking" (NCTM, 2000, p. 188). They are also part of communication processes which include "sharing thinking, asking questions, and explaining and justifying ideas" (NCTM, 2000, p. 194). From what age should we expect students to offer explanations when engaging in mathematical activity? Do the types of explanations and the purposes of giving explanations differ at various ages? This study examines the roles of explanations in official Israeli mathematics curriculum documents, focusing on the transition between preschool and primary school. We chose to examine official curriculum documents for several reasons. First, the national curriculum often sets the standards for what is learned and how that learning is assessed. Second, textbooks in Israel take their cue from national standards and must be approved by the Ministry of Education. In addition, prospective and practicing teachers are explicitly exposed to the curriculum during professional development and often use the guidelines to construct lesson plans. The curriculum is especially important for preschool teachers who often design their own activities based on curriculum suggestions as textbooks and other curricula materials are less available for this age group.

In Israel, there are separate curriculum documents for students of different ages. At the preschool level, the Israel Mathematics Preschool Curriculum (IMPC) (Ministry of Education, 2008) covers concepts and competencies that children should reach by the time they enter first grade. It also lists explicitly and separately which of those concepts may be promoted and which skills should be enhanced for children ages 3-4, 4-5, and 5-6 years old. For example, by the time children enter first grade they should be able to count backwards from ten but the curriculum suggests that this skill should be fostered from the age of 4 and not from the age of 3. The preschool

curriculum also includes examples of activities that can be used to promote and assess the required skills. The Israel Mathematics Curriculum (IMC) for elementary school (Ministry of Education, 2006) covers concepts and competencies which should be fostered among students in grades one through six. Each grade is dealt with separately. In addition, an official supplementary document to the elementary mathematics curriculum was published by the Ministry of Education entitled "Milestones" (2009). This document includes the curriculum as well as specific standards for each content topic and explicit examples of activities that can be implemented in classes. Thus, in this study we examine the preschool curriculum document and the "Milestones" document. We focus on preschool children ages 3-6 years old and first and second grade students in elementary school (ages 6-8). The main questions of this study are: (1) Are young children (ages 4-8 years old) expected to give explanations when engaging in mathematical activities? (2) What are the functions of explanations at these ages?

THEORETICAL FRAMEWORK

How may explanations be characterized? Philosophers of science tend to view the concept of explanation as a logical relationship between questions and answers. According to van Fraassen (1980) an explanation must answer a why-question. However, Achinstein (1983) takes the broader view that many different kinds of questions may be asked when attempting to gain understanding and it follows that the act of answering any of these should be regarded as an act of explanation. Within the field of mathematics, the notion of mathematical explanation is closely related to other notions such as 'generality', 'visualizability', 'mathematical understanding', 'purity of methods', and 'conceptual fruitfulness' (Mancosu, 2008).

In mathematics education, explanations may be characterized by referring to their functions and forms. Yackel (2001) views explanations given in the classroom as a social construct whereby their functions and forms are interactively constituted by the teacher and students. Thus, an explanation is considered to be an aspect of discourse and its first function is communicative, "Students and the teacher give mathematical explanations to clarify aspects of their mathematical thinking that they think might not be readily apparent to others" (Yackel, 2001, p. 13). In a traditional mathematics classroom, an explanation may describe the steps of a procedure used. In the inquiry-based mathematics tradition, explanations communicate interpretations and mathematical activity to others in order to convince others that solutions are legitimate. Krummheuer (2000) found that when learning mathematics, students "'tell' or 'narrate' how they came to their solution, or better put how one can come to a solution" (p. 24).

An additional function of explanations is to rationalize actions, both for the giver of the explanation as well as for the receiver. In that sense, explanations may also have the function of convincing oneself or another person of some assertion. In the field of argumentation (Krummheuer, 2000), an explanation may take on the role of data which supports some assertion, or a warrant which legitimizes a previous

explanation, or a backing for the warrant. Thus, one may view explanations as the building blocks of argumentation. Convincing and explaining are also related to proving. When discussing proofs, de Villiers (1990) characterized an explanation as providing insight into why a statement is true as opposed to verifying the truth of the statement. An explanatory proof (Hanna, 2000) may help students see why a theorem is true; it is both convincing as well as illuminating. Nunokawa (2010) referred to proofs as full explanations which often contain critical ideas. He further claimed that explanations not only communicate the student's existing thoughts but may also generate new objects of thought by directing new explorations which may then deepen the student's understanding of the problem at hand. Thus, an underlying function of explanations is to expand students' mathematics learning.

METHOD

The first stage of this study was simply to gather each instance of when the curricula use explanation-related terms. In Hebrew, the term 'explanation' may be translated as 'hesber' (הסבר). This is the most common translation and when translating back the term 'hesber' to English one always gets 'explanation'. There is also a second word in Hebrew which is sometimes translated to explanation and that word is 'nimuk' (נימוק). However, 'nimuk' may also be translated as justification. On the other hand, a specific word for justification, other than 'nimuk', exists. This word is 'hatzdaka' (הצדקה). Finally, as mentioned above, explanations are sometimes related to proofs; thus the term for proof, 'hochacha' (הוכחה) was included in this study. To summarize, when examining the curriculum documents, four terms were taken into consideration: 'hesber', 'nimuk', 'hatzdaka', and 'hochacha'.

The second stage consisted of an inductive process, whereby each instance of the four explanation-related terms was analysed with the help of guiding questions. This led to the development of categories. A separate analysis was conducted for the introduction sections of the curricula and the other sections. This separation was due to the more general format of the introductions as opposed to the specific examples of activities given in the other sections. In the introduction sections, the following questions guided our analysis: How do explanations fit in with the general aims of teaching mathematics at each level? To what purpose do we use explanations in a mathematical activity? In the other sections of the curricula we asked ourselves: In the given context, would an explanation be an answer to a "how" question or to a "why" question? Would the explanation be used to evaluate procedural or conceptual knowledge? Does it seem that the explanation is the culmination of some mathematical activity or reasoning process or might the explanation be a stimulus for further mathematical activity? Each of the authors of this paper categorized the instances on their own and then compared the analyses. A third researcher validated the final categories.

RESULTS

As mentioned in the previous section, we began by counting the number of instances each term appeared in the different curriculum documents. As can be seen from Table 1, the term 'proof' does not appear in any of the surveyed documents and the term 'justification' appears once. Recall that the term 'nimuk' does not have a clear translation and seems to fall somewhere between explanation and justification. To sum up, there are 15 instances of explanation-related terms in the preschool curriculum and 11 instances in the elementary curriculum.

	Preschool (ages 3-6)	Elementary school (ages 6-8)
Explanation	13	8
'Nimuk'	1	3
Justification	1	-
Proof	-	-

Table 1: Frequency of explanation-related terms found in different curricula

We now focus on how the different terms were used, beginning with the introductions to the two curricula and moving on to specific examples of suggested activities.

‘Explanations’ in the curricula introductions

The introductions relay the general aims and reasons for teaching mathematics at these ages. In the preschool curriculum there is one instance of the term justification, one instance of the term 'nimuk' and three instances of the term 'explanation':

Participating in mathematical activities develops mathematical skills such as the ability to count and enumerate, add different amounts together, and identify shapes and solids, as well as thinking skills such as such as the ability to make comparisons, the ability to sort, and the ability to **justify** oneself and it is important to develop both of these aspects when working on mathematical activities. In order to develop mathematical understanding as well as a child's (general) thinking skills, one should request the child to **explain** his actions. The **explanations** allow the child to justify (**nimuk**) his actions allowing the teacher to better understand what the child meant. (Emphasis not in the original, p. 12)

According to the introduction, there are two separate aims of engaging children in mathematical activities. The first is to promote their knowledge of mathematical concepts and skills and the second is to promote general thinking skills and abilities. How do explanations fit in with those aims? Regarding the first aim, having children explain their actions can promote their mathematical understanding. Thus, giving explanations is a means to achieving a goal. Regarding the second aim, giving explanations is the goal. We note that it does not mention that giving mathematical explanations is the goal or that explanations should be based on mathematical ideas and principles. Instead, we desire in general to promote children's ability to justify their actions and this ability can be promoted while engaging children in

mathematical activities. Another general ability, being able to verbalize one's ideas, is mentioned later on in the introduction, "mathematical discourse ... develops a child's verbal abilities, that is, his (or her) ability to formulate and **explain** in words what he (or she) is doing" (INMPC, 2008, p. 14). Finally, a child's explanations can be used by the teacher to assess mathematical understanding.

In the introduction of the elementary school curriculum the terms explanation, justification and proof do not appear but there are two instances of the term 'nimuk'. One of them is related to developing children's mathematical reasoning skills such as, "deductive reasoning, ...raising conjectures, generalization and **justification** (nimuk), ...etc." (p. 8). The second instance is related to evaluating students' thinking, "When the teacher is assessing the students, she should follow students' engagement with task... and listen to their **explanations** (nimuk) as they implement the mathematical activity" (p. 14). In the first instance, being able to offer justifications is seen as a mathematical skill which we wish to develop. The second instance reminds us of the introduction to the preschool curriculum which suggests listening to children's explanations in order to assess their mathematical knowledge.

To summarize, from the introductions we learn that explanations are both a means and an end – the means to achieve mathematical understanding but also a skill, onto itself, to be developed. In the preschool curriculum there is no direct mention that explanations should be mathematical in nature or based on mathematical principles. In the elementary curriculum they are connected to specific mathematical reasoning skills such as making generalizations. In the next section we gain additional insight into how explanations may be used in mathematical activities.

'Explanations' in suggested activities

Following the introductions, each curriculum suggests specific examples of activities which may promote different competencies. While in the introductions we find several reasons for promoting the use of explanations, we are left unsure of what is meant by the term 'explanation'. In addition, the introductions aim at general abilities and general mathematics reasoning skills, not only those related to explanations. In this section, we review the examples of activities that include explanations and analyze what the specific function of an explanation might be in a mathematical context. These functions were not explicitly written but arose from the contexts. Below, we list the functions we found along with examples of activities from the preschool and elementary school curricula which highlight these functions.

Function 1: Explanation as a description of one's thinking process or way of solving a problem (i.e. How did you solve the problem? Explain.)

Preschool curriculum

Mathematical topic: Comparing sets by counting

Suggested activity: In competitive games

Elementary school curriculum

Mathematical topic: Operations with natural numbers

Suggested activity: You can buy the

where the winner is the one with more or less cards, tokens, etc. the teacher can see the way children use counting in order to compare two sets and the way children **explain** how they acted.

following toys in the store. (A picture of several toys and their corresponding prices is given.) Tamar has 15 NIS. She wants to buy two toys. Which toys can Tamar buy? **Explain.**

In the preschool activity, the teacher is encouraged to request from the children an explanation of how they acted, what they did in order to compare the sets. In the elementary school activity, we infer from the problem situation that students are requested to explain how they arrived at an answer. The explanation can be in the form of an arithmetic sentence or a verbal description. In both the preschool and elementary cases, the explanation allows the teacher to evaluate procedural knowledge. In essence, the explanation tells us what the child did but not why he did what he did. This brings us to the second category.

Function 2: Explanation as justifying the reasonableness or plausibility of a strategy or solution (i.e. Why did I choose to solve the problem in this way?)

Preschool curriculum

Mathematical topic: Measurement

Suggested activity: When comparing the measurements of two items with the help of a mediating tool, does the child use a convenient and appropriate mediator? Can the child **explain** why he chose that specific mediating tool?

In the above activity, the child is asked to solve a problem, in this case a measurement problem. He is not asked to explain what he did but instead to explain why he chose to solve the problem in such a way. For example, when comparing the lengths of two tables, the child may use his foot to measure the length of each table. However, if asked to compare the lengths of two papers, he might use paper clips as a measurement tool. The child is then asked to explain why he chose to use his foot in the first case and paper clips in the second case. This type of explanation is thus different from the first type. Yet, in this second category, explanations do not necessarily draw on mathematical properties nor are they necessarily related to general properties. In the third category, explanations are also given as an answer to a "why" question, but tend toward more general mathematical properties. In the elementary school curriculum, no activity was found for this category.

Function 3: Explanation as an answer to a "why" question where the underlying assumption is that the explanation should rely on mathematical properties and generalizations (i.e. Why is this statement true/false? Explain.)

Preschool curriculum

Mathematical topic: Shapes

Suggested activity: The teacher will draw a picture for the child made up

Elementary school curriculum

Mathematical topic: Operations with natural numbers

Suggested activity: (a) For each of the

of different shapes in various sizes and orientation. The teacher then asks the child to color, for example, all of the triangles and asks the child to **explain** why he colored or not colored a certain shape.

numbers below, try to write an addition sentence using two consecutive numbers.

$$\begin{array}{r} \underline{\quad} + \underline{\quad} = 27 \\ \underline{\quad} + \underline{\quad} = 30 \end{array} ; \begin{array}{r} \underline{\quad} + \underline{\quad} = 13 \\ \underline{\quad} + \underline{\quad} = 81 \end{array}$$

(b) Which (kinds of) numbers could be the sum of two consecutive numbers? **Explain.**

As opposed to the first category of explanations, this category focuses on conceptual, rather than procedural, knowledge. In the preschool activity, when asking the child to explain why he did or did not color a certain shape, we are essentially asking the child to explain why that shape is or is not a triangle. This type of explanation allows the teacher to evaluate the child's conceptual knowledge of triangles as well as their preconceptions of triangles (Vighi, 2003). The elementary school activity begins with specific arithmetic examples but then asks a general question. By requesting the child to explain her answer to this general question, we are encouraging her to think about the properties of natural numbers, more specifically, the properties of even and odd numbers. In this case, the explanation allows the teacher to evaluate children's conceptual knowledge of even and odd number and of consecutive natural numbers. In addition, the one instance when the term 'nimuk' was used in an elementary school activity, it was used in this sense.

Function 4: Explanations as a step in directing new explorations leading to generalizations (i.e. Find all possible solutions and explain)

Elementary school curriculum

Mathematical topic: Geometry

Suggested activity: Cut a rectangle along a straight line generating two polygons. Which (kinds of) polygons can be the result of this action? Can you get two squares? A triangle and a pentagon? **Explain.**

We found it quite difficult to interpret the term 'explain' in the above activity. It was clear that the underlying purpose of the request was to have the child verbalize his thoughts. This, of course, may be said of each of the examples given above. But, what might we learn from the child's explanation in this case? In order to gain a better understanding of the activity, we note that it was labelled by the curriculum as an inquiry-based activity. Children are requested to investigate what might result from cutting the rectangle along a straight line. While two possible results are suggested, the underlying aim is for children to try cutting the rectangle in different ways. The function of the explanation here could be viewed as a combination of functions mentioned previously. On the one hand, children can explain the situation by saying what they did – I cut the rectangle this way and got two triangles and then I cut the rectangle this way and got two rectangles. On the other hand, an explanation might rely on mathematical properties, such as explaining under what conditions two squares will result from the cutting. In our opinion, the ultimate purpose of the explanation in this

activity is to encourage children to think of additional possibilities. If children explain what or why they did some action, it might lead them to think of other possible ways to cut the rectangle, which may possibly lead to a general conclusion covering all possibilities. In the preschool school curriculum, no activity was found for this category.

To summarize, following the introductions, there were 10 instances of explanation-related terms in the preschool examples of activities and 9 instances in the elementary curriculum. Table 2 summarizes the number of instances (%) related to each function.

Function	Preschool	1 st - 2 nd grade
1 – Explanation as a description of one's thinking process or way of solving a problem	5 (50)	3 (33)
2 – Explanation as justifying the reasonableness or plausibility of a strategy or solution	2 (20)	-
3 – Explanation as an answer to a "why" question relying on mathematical properties and generalizations	3 (30)	5 (56)
4 – Explanations as a step in directing new explorations leading to generalizations	-	1 (11)

Table 2: Frequency of explanation functions at different ages

Note that the most frequent function of explanations in the preschool curriculum was simply to have children describe what they did. These explanations are not necessarily mathematically-based. This seems to be in line with the preschool curriculum introduction which clearly stated that engaging children in mathematical activities can also promote general thinking skills. Moving on to elementary school, the functions of explanations become more mathematical in nature and less descriptive.

DISCUSSION

To begin with, we see that having children offer explanations while engaging in mathematical activities is encouraged from an early age. It is not something left to the later years. We also see that, as mentioned by the NCTM (2000), explanations are part of both communication processes and reasoning processes we wish to promote. We do see, however, a subtle shift from the preschool to the elementary school. In the preschool, it seems that more emphasis is placed on the communication aspect of giving explanations and less on the reasoning aspect while the opposite seems to be true in the first and second grade curriculum. During the early elementary years, it seems that explanations become more mathematical in nature, relying on mathematical properties and supporting mathematical explorations.

Looking back at the specific functions of explanations cited in this paper, we see much in common with the literature background. For example, both Yackel (2001) and Krummheuer (2000) claim that explanations are often given in a narrative format,

conveying what was done in order to solve a problem. This is, in essence, the first function mentioned above. However, an explanation may also clarify the rationality of an action (Krummheuer, 2000), which is the basis for the second function mentioned above. The rationality of an action may or may not be based on mathematical properties. Thus, the third function of an explanation might be to specifically ground an activity in mathematics. Finally, in line with Nunokawa (2010), the fourth function of an explanation could be to lead students to new understandings and knowledge. However, despite the relationship between explanations and proofs found in the literature (e.g. Hanna, 2000), at this age there is no mention of proofs in either document and the term justification is hardly used. The absence of these terms is notable when considering studies which have shown that young children are capable of proving or refuting conjectures raised by themselves and others (e.g., Stylianides & Ball, 2008).

We do not believe that our way of categorizing the above examples is the only way. In fact, we are in the middle of an international comparative study investigating the uses of explanation-related terms in mathematics curricula in four different countries. Initial results indicate that explanations may also serve other purposes such as interpreting day-to-day occurrences in a mathematical way (e.g., explain what it means when the carton of milk says it contains 3% fat) and clarifying personal view points (e.g., explain why statistics is important). We also do not believe that each of the examples we presented in this paper necessarily falls into exactly one category and not another. Much is dependent on the classroom context. For example, the elementary activity presented under the first function could lead to explanations of the third type based on children's knowledge of numbers. This might be encouraged if the teacher were to ask for a general statement concerning the combination of prices leading to 15 NIS, perhaps an explanation that if one toy costs more than 7.5 NIS, then the second toy must cost less. Likewise, the preschool activity presented for the second function of an explanation may lead to additional exploration and comparison of lengths and measurement, thus qualifying it for the fourth function of an explanation.

Taking into consideration that our interpretations are just that – our interpretations – one might ask, why bother analysing how explanation-related terms are used in curriculum documents. To begin with, we wanted to raise the issue that the different explanation-related terms are open to interpretation and that even among mathematics education researchers, the same word may be used but with different meanings. In addition, as mentioned in the introduction, these documents are used by teachers and others when planning lessons and activities. Our analysis can be used as a preliminary investigation into how the curriculum may be interpreted by others. Our analysis may also serve as a guide to others in understanding how explanations can serve different purposes. Finally, we hope that our study will lead others to investigate the use of the term 'explanation' in additional contexts, such as text books and curricula materials and perhaps become more sensitive to the different purposes

and functions that explanations, and perhaps justifications and proofs, may have when teaching mathematics at all ages.

SELECTING SHAPES – HOW CHILDREN IDENTIFY FAMILIAR SHAPES IN TWO DIFFERENT EDUCATIONAL SETTINGS

Andrea Simone Maier, Christiane Benz

University of Education, Karlsruhe, Germany

To investigate the geometric competencies of children from 4 to 6 years old in two different educational settings – England and Germany – 80 children were given geometric tasks via clinical interviews. The children were interviewed at the beginning and at the end of one school year. In this paper, the results of one task – the selecting shapes task – are illustrated with the focus on children’s conceptualisation of geometric shapes as well as their reasoning why certain figures were chosen as representatives of a geometric shape and why others were not.

Keywords: concept formation, geometric shapes, preschool, clinical interviews

INTRODUCTION

In the last couple of years, the importance of early learning has been widely discussed. One of the remaining questions is how the education in the early years should look like. The study at hand investigates the geometric competencies, in particular the concept formation, of children from two countries with two different concepts of elementary education: Germany (Baden-Württemberg), where learning through play and with this a constructivist view of learning is at present the main concept for kindergarten education (Schäfer, 2011; Rigall & Sharpe, 2008) and England, where the elementary education is rather systematic, curriculum based and rather instructive, and where the competencies of the children are tested via “stepping stones” which they should have acquired. There, the children enter school in the year when they have their fifth birthday, but many children go to a reception class before that. So the entering school age is about two years earlier than for children in Germany. The focus of this research is on describing the competencies the children of each educational setting acquire. As a consequence of the study, hypotheses will be formulated to what kind of competencies each way of education might lead. In this paper, one task is chosen to support some findings leading to such hypotheses.

THEORETICAL BACKGROUND

For the presented shape selection tasks, the competencies that are needed are (1) being aware how a certain shape in several varieties looks like, (2) being familiar with the properties of the single shapes, (3) being able to verbally express these properties, and (4) being able to distinguish examples of shapes from non-examples of shapes. In the following, it first will be illustrated what constitutes a concept in

general, followed by two theoretical models of concept development, before some empirical results of previous shape selection studies are presented.

According to Vollrath (1984) a comprehensive conception of geometric shapes is shown through being able to (1) name the shapes, (2) give a definition of the shapes, (3) show further examples of this category and (4) name all properties. However, this description was given for secondary school children. Concerning the development of such concepts, there are different suggestions as for example the two theoretical approaches proposed by Szagun (2008): First, the “semantic feature hypothesis”, where the general features are learned before specific features and where the features are either present or not and apply for every member of the class, e.g. “all kinds of dogs belonging to the category “dog” are four-legged and bark”. And second, the “prototype theory”, which is the generally more accepted theory, some members of a category are categorised as more typical than others (Szagun, 2008). However, in order to give a complete picture of what we know of the geometric concept formation, how a concept develops has to be complemented by research findings on geometric concepts.

With the observations of Piaget & Inhelder (1975), research focusing on children’s concepts of space and geometric shapes began. His topological primary thesis stated that children first realize topological features, such as “open”, “closed”, “interior” and “exterior”. According to Piaget, the children are not able to name and to distinguish between geometric shapes before the age of six.

Another body of research has focused on children’s reasoning about geometric concepts that they have formed (van Hiele & van Hiele, 1986). The van Hieles, who also created a hierarchical developmental description, constitute that children realise shapes as whole entities from the age of four onwards and are not able to distinguish shapes by their properties before primary school (from 6/7 up to 9/10). Several studies (e.g. Battista, 2007; Burger & Shaughnessy, 1986; Clements & Battista, 1992; Lehrer et al., 1998) concluded that such a hierarchic developmental description is not discrete or independent and that students also preferred different levels for different tasks. Some research also proposes that the characteristics of the single levels develop at the same time but in diverse intensity (Clements & Battista, 1992; Lehrer, 1998).

The shape selection task that will be shown in the following was already conducted in several studies (Burger & Shaughnessy, 1986; Clements et al., 1999; Razel & Eylon, 1991). To summarise the main results of these studies, most children identified circles accurately, only a few of the younger children chose an ellipse and another curved shape as circles (Sarama & Clements, 2009). The squares were also identified fairly well in these studies, between 80% and 90% of the children identified them correctly. Clements et al. (1999) found that children had some difficulties in selecting squares, for they were less accurate in classifying squares without horizontal sides (Clements, 2004). There are no circles deviating from the prototype and square prototypes only occur concerning position. Consequently, the children had more difficulties in recognising triangles which were identified correctly by about 60% of

the children. Some studies (e.g. Burger & Shaughnessy, 1986 or Clements et al., 1999) revealed that children's prototype of a triangle seemed to be an isosceles triangle. The majority of children did not identify a long and narrow, scalene triangle as a triangle, although they often admitted that it has three lines and three corners.

Another research also concerning the shape selections of children was conducted by Tsamir, Tirosh and Levenson (2008) in order to examine whether there are prototypical non-examples, when children are asked to determine whether a figure is a triangle or not. They found that some figures were intuitively identified as non-examples for triangles and that more children correctly identified non-triangles as such. Another study (Levenson et al., 2011) dealt with the question what it means for preschool children to know that a shape is a triangle. They investigated whether all examples and non-examples are created equal. They found that over 90% of the reasons given by the children were based on the essential attributes of a triangle.

The study at hand complements these previous studies by investigating the competencies of children in two different educational settings and by illustrating children's understanding of geometric shapes in the light of these different settings.

EMPIRICAL STUDY

Research Questions

The underlying research questions are:

- (1) Concerning the choice:
What kind of representatives do children select for a certain shape?
How do they explain their selection and how do they justify the attributes that make a figure a representative of a certain shape?
- (2) Concerning the two points of investigation:
What differences can be described after a year?
- (3) Concerning the two different educational settings:
What differences between the results of the children from different educational settings can be observed?

Subjects

The research gathered 81 four to six year old children, of which 34 are of English nationality and were attending a local primary school, near Winchester. The age of the children at this primary school ranges from four to eleven years. The other 47 children were from Germany and attending a kindergarten in Karlsruhe, where children from the age of three to six, up to primary school, can go.

Method

The study was conducted in the form of qualitative interviews, in order to get as much information about children's knowledge about geometric shapes as possible, although it might illustrate an "artificial" situation. The order of the tasks as well as the material was predetermined but in accordance with the nature of qualitative interviews this order could be altered or complemented if some of the child's answers

happened to be interesting or leading into another direction worth being examined. There were altogether two points of investigation, without a special intervention, one at the beginning of the school year in October 2008 and one at the end of the school year in July 2009. Thus, it must be taken into consideration that the English children were instructed in geometry during the year. The German children also had some kind of “instruction”, because a lot of material with geometric shapes was available in the German kindergartens and the children could choose to play with these materials.

Tasks

In order to investigate children’s knowledge of shapes and to illustrate the concept formation of the children, five different tasks were conducted in the interview of which the shape selection task – identifying and discerning shapes – will be explicitly presented in this paper. Here, the children were asked to “put a mark on each of the shapes that is a circle” on a page of separate geometric figures. After several shapes were marked, the interviewer asked questions such as: “Why did you choose this one?”, “How did you know that one was a circle?”, “Why did you not choose that one?”. A similar procedure was conducted for squares and triangles.

RESULTS

In the following, the main results are presented by illustrating both measuring times, distinct by country. The answers of the children were thoroughly examined and then categories were generated to which the single answers of the children could be grouped to. Sometimes, the answers of the children could be grouped to more than one category, therefore the added percentages could be more than 100%. In other cases, it is not illustrated if the children didn’t mark anything, so the added percentages might be less than 100%.

Identifying circles

The children were shown a picture with nine correct circles and six other shapes, like an ellipse, two twisting shapes, a semi-circle, a triangle and a square (cf. fig. 1). At both points of investigation, the majority of the children (81% of the German and 82% of the English children at the beginning and 84% of the German and 76% of the English children at the end of the school year) could distinguish between circles and non-circles correctly. In this case, “to distinguish correctly” basically means that they marked only circles as such and that they didn’t select non-circles as circles. Children who could not distinguish between circles and non-circles correctly, either marked additionally other shapes or left some of the correct ones out. At the beginning of the school year, the English children either marked the ellipse (9%) and the semi-circle (3%) additionally as circles whereas the German children, although not many, chose one of the two twisting shapes (no. 8 (2%) or no. 10 (2%)). At the end of the school year, more German (14%) than English children (6%) additionally chose the ellipse as circle. As before, the semi-circle was only chosen by English children as circle but by none of the German children.

The reasoning of the children could be grouped into the following categories (cf. tab. 1): (1) no justification, (2) visual (referring only to the appearance of a circle), e.g.

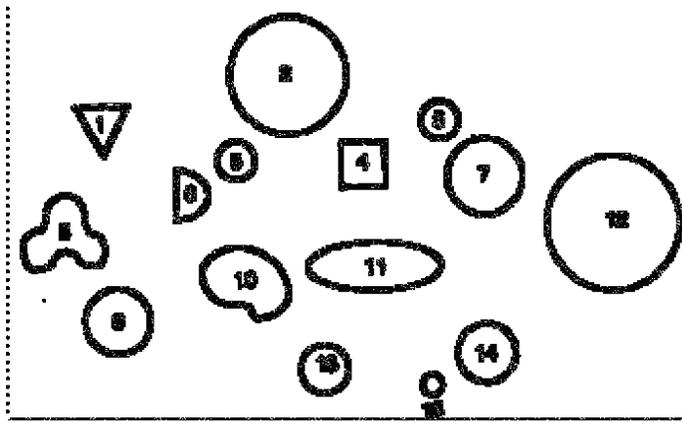

fig. 1: Identifying circles (Razel & Eylon, 1991, in Sarama & Clements, 2009).

“it looks like a circle” or “has (hasn’t) the shape of a circle” or (3) expressed by gestures “is not a circle, for it looks like this” (then they were for example drawing the shape with their fingers into the air)”, (4) using comparisons to other shapes or objects, e.g. “is not a circle because it looks like an egg”, (5) naming properties, e.g. “this is a circle, because it is (isn’t) round” or “is not a circle for it has corners” or (6) using the proper

terms for the shapes, where the children just named the shapes: “this is a circle” or “this is a semi-circle and that is a triangle”. Whatever justification was chosen, it was always correct, meaning that if a child used for example gestures to justify a circle it was drawing a circle with the fingers but not drawing another shape.

	(1)		(2)		(3)		(4)		(5)		(6)	
	G	E	G	E	G	E	G	E	G	E	G	E
2008	9%	12%	0%	9%	19%	18%	23%	15%	21%	26%	5%	21%
2009	0%	3%	5%	6%	2%	9%	47%	15%	60%	18%	12%	38%

tab. 1: Justifications for circles

Altogether, the German children used more comparisons than the English, especially at the end of the school year. At the first point of investigation, about the same amount of children from both countries used gestures and slightly more English children were mentioning properties to explain their choices. At the second point of investigation, more English than German children used gestures and far more German than English children used properties in order to justify their choices.

Identifying squares

At this task, the children were asked to put a counter on all the squares they see. Nearly half of the children in both countries (47% German children and 44% English children) marked only all correct squares at the first investigation. At the second point of investigation, more than twice as many German (44%) than English children (21%) marked all correct squares and nothing else (cf. tab. 2).

At both investigation, clearly more English than German children (more than twice as many at the end of the school year) marked only squares but not all of them. They mainly marked either only horizontal lying squares leaving out squares in other

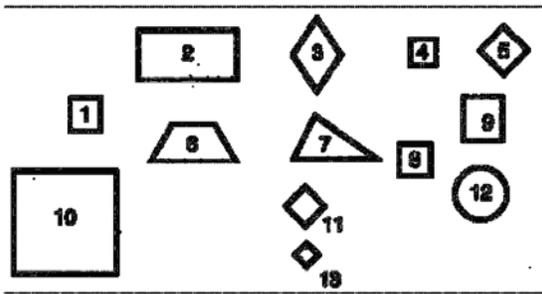

fig. 2: Identifying squares (Razel & Eylon, 1991, in Sarama & Clements, 2009).

by for example highlighting that it (no. 5) “is more alike” the horizontal lying squares and “looks different than the other two shapes (no. 11 and 13)”.

positions (no. 5, 11 and 13) or marked only all the horizontal lying square plus one square in another position (no.5). They justified this choice by either saying that “this is too aslope to be a square” or “if you turn a square it becomes a diamond” and that “only in this (horizontal) position it is a square”. The choice of the additional in another position lying square no. 5 was justified

	Only all the squares		Only squares but not all of them		All the squares and other shapes		Not all squares and other shapes	
	G	E	G	E	G	E	G	E
2008	47%	44%	28%	53%	16%	3%	9%	0%
2009	44%	21%	28%	68%	16%	9%	9%	3%

tab. 2: Selecting squares

Clearly more German than English children at both investigations marked all the squares and other shapes. The other additional shapes that were marked by the German children were mainly rectangles (16% at the first investigation and 21% at the second investigation) but also the diamond (no.3), which was selected by 14% at the beginning and by 12% at the end of the school year. The trapezoid was selected by only one German child at the first and by two children at the second investigation but by none of the English children. In order to briefly summarise the justification of the children, it can be stated that they either reasoned by mentioning (1) the visual appearance or through (2) gestures, (3) comparisons to other shapes or objects, (4) describing their properties (informally or formally) or (5) just naming them with the geometric term. One result is for example that far more German (16% at both investigations) than English children (3% at both investigations) used comparisons in order to justify their choice of examples and non-examples of squares.

Identifying triangles

Here, the children were asked to put a counter on all the triangles they see in the picture (cf. fig. 3). Altogether, there were six triangles (no. 1, 4, 6, 8, 11, 13), two shapes consisting of triangles (no. 10, 12) and six non-triangles (no. 2, 3, 5, 7, 9, 14). The triangle selection task was more demanding than the circle or square selection task, because there were less “intuitive non-examples” (e.g. Tsamir et al., 2008), meaning shapes that are clearly no triangles, but more “non-intuitive non-examples” or “nearly triangles”, lacking one attribute as for example straight sides (no. 3, 5, 7 and 14) or three corners (no. 9). So, only a few children marked all the correct

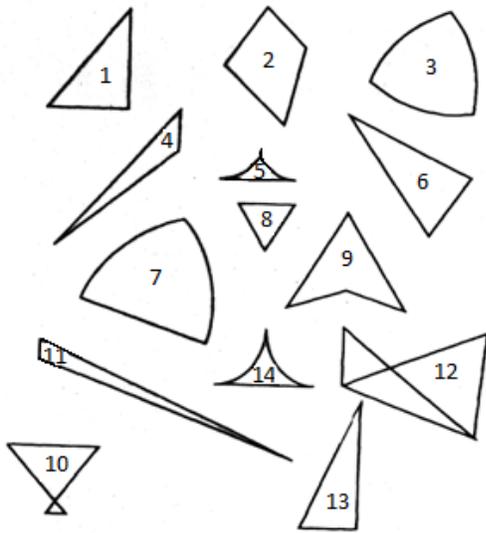

fig. 3: Identifying triangles (Razel & Eylon, 1991, in Sarama & Clements, 2009).

no. 11 and no. 4.

	Only all the triangles		Only triangles but not all of them		All the triangles and other shapes		Not all triangles and other shapes	
	G	E	G	E	G	E	G	E
2008	5%	6%	9%	26%	28%	24%	56%	44%
2009	12%	9%	26%	29%	14%	26%	44%	35%

tab. 3: Selecting triangles

Altogether, there were more children marking triangles as triangles than children marking other shapes as such. At the beginning of the school year, more German (40%) than English children (15%) marked convex shapes (no. 3 and 7) or the four-sided shape (no. 9) (65% of the German and 47% of the English) as triangles and about half of the children of both countries marked concave shapes (no. 5 and 14) as triangles. At the end of the school year the English children tended to mark slightly more frequently the concave shapes and to the same amount the four-sided shape (no. 9). The children often explained the acute triangles (no. 4 and 11) as being “too pointy”, “too thin”, “too long” or “too aslope” for a triangle or as in the case of the right-angled triangles as “too straight at the side”, “only one long side” or “so high at one side”. Altogether, the children often explained in an informal way why certain shapes – actually correct triangles – were not triangles, as for example: “too aslope for a triangle” or “not equilateral”. The non-triangles were often justified as triangles by using parts of a correct definition such as: “three sides and three corners” without regarding that the sides were not straight or There also were children, especially English children, who could give a perfect definition of a triangle at a previous task,

triangles and only these (cf. tab. 3). About a quarter of the children in both countries selected at the first investigation all triangles and other shapes. At the second investigation, there were clearly less German and about the same amount of English children selecting all triangles and other shapes. The majority of the English as well as the German children marked not all the triangles and other shapes.

Examining which shapes were selected most often, it becomes obvious that most of the children marked the equilateral triangle (no. 8) as such, although it’s representation was upside down, immediately followed by the right-angled triangle (no. 1). The “nearly triangles” no. 14 and no. 9 were chosen more often as triangles as the two scalene triangles

e.g.: “a triangle has three corners and three straight sides” but were still choosing at the shape selection tasks concave or convex shapes, obviously not having straight sides or selected no. 9 as triangle, which nearly resembles an equilateral triangle.

DISCUSSION

Altogether, the German children, although not formally instructed, more often selected correct circles and correct squares than the English children and about the same amount of children from both countries selected all the correct triangles. However, the English children chose less often wrong shapes as triangles, which shows that they are more familiar with what does not constitute a triangle, presumably due to the instruction in school. The reason why the German children identified circles more correctly is that the English children sometimes simply didn't mark one or two of the circles, but even the explanations of the children didn't reveal why they left some correct circles out. Still, what became obvious in the reasoning of the children is that the German children used far more comparisons than the English in order to explain their choices (cf. Maier & Benz, 2012). The English children rather used the names of the shape in order to explain why a shape is or isn't a circle, e.g.: “this is not a circle because it is an oval” or “that is not a circle, it's a semi-circle”. Such terms were not familiar to the German children who, for this reason, rather chose comparisons, such as: “this is not a circle, for it looks like an egg”. Why there were far more German than English children at the end of the school year using the properties of a shape to justify their choice does not become obvious through the interviews. Still, other research suggests (e.g. Levenson et al., 2011) that “young children, even those who do not attend a preschool with an especially enriched geometrical environment, (still) employ reasoning with attributes” (ibid. p. 28). This could be the case, because there were now more English children using the correct geometric term and the German children were rather familiar with some properties such as “round” or “acute” than with the geometric term. Another reason for the sometimes different choices of the children could be the material that is used in the single institutions. Consequently, one reason why the English children might only describe a horizontal lying square as a square and one that stands on one of its corners as “a diamond” and not a square anymore, could be the illustrations in the classroom or school books, only showing squares in horizontal position. The reason why they preferred marking isosceles or equilateral triangles as triangles, might be because the material they use for exercising only shows isosceles or equilateral triangles. If the children do not have a checklist of attributes in their minds, they are likely to just choose figures they know, predominantly prototypes. Still, the English children selected less often wrong shapes as triangles than the German children, revealing that the Germans were not introduced at this stage to aspects of definitions of a triangle with how a triangle has to look like. Therefore, the fact that a triangle should have *straight* sides was often not considered by German children.

CONCLUSION

The children of the research seem to conform to a large extent the first van Hiele level (the visual level) or somewhere between the first and the second (descriptive) van Hiele level. Still, the children could be on different levels for different tasks, so the levels seem not to be discrete as previous studies already revealed (e.g. Burger & Shaughnessy, 1986; Clements & Battista, 1992; Lehrer et al, 1998). Furthermore, it can be concluded that the way of teaching as well as the used material are influencing the concept formation of the children. Therefore, it should be discussed *how* to introduce shapes and how to actively support the children's concept formation to develop a comprehensive knowledge about shapes, rather than first clarifying *when* would be the best time to introduce geometric concepts to the children. In order "to know" a shape, being able to identify a wide variety of examples and non-examples is essential (c.f. Levenson et al., 2011). A careful introduction of shapes is important, because research indicates that a lot of educational materials introduce children "to triangles, rectangles and squares overwhelmingly in limited, rigid ways" (Sarama & Clements, 2009, p. 216) as was assumed in this study as well, and moreover that such rigid visual prototypes can rule children's thinking throughout their lives. The visualisation and usage of material in class rooms might be too limited as for often only prototypes are shown. However, the usage of prototypes can be very helpful but teachers as well as kindergarten educators should be aware of the variety of representatives of a certain shape and let them explain what properties a shape needs to have in order to be called "a triangle" for example. An isolated memorising of definitions is to be seen critically and more emphasis should be placed on being able to connect a concept with many representatives as examples. Still, even without being formally instructed but instead informally, children are able to acquire a comprehensive knowledge of concepts.

A FOCUS ON HIDDEN KNOWLEDGE IN MATHEMATICS THE CASE OF “ENUMERATION” AND THE EXAMPLE OF THE IMPORTANCE OF DEALING WITH LISTS

Cécile Ouvrier-Bufferet

UPEC, IUFM de Créteil – LDAR, Université Paris Diderot

The aim of this paper is to bring some elements (based on French research works) for the discussion. The curriculum of French preschool is briefly presented as well as the context of a French research which underlines that some kinds of knowledge are not identified as such but are required for the learning of counting in preschool (and also in other levels of mathematics learning). The knowledge “enumeration” is brought to light and defined (Briand, 1993). Another kind of situation is also developed regarding the construction of lists and their reading (Loubet & Salin, 1999-2000). The conclusion opens on the international perspectives of these kinds of results.

THE CURRENT FRENCH CURRICULUM OF PRESCHOOL

This curriculum (BO - 2008, June, p. 12) applies to children from 3 to 5 years old. It is split into six parts: discovering language; discovering writing; becoming a pupil; physical development; knowledge and understanding of the world; creative development. Mathematics are integrated in the wide field “Knowledge and understanding of the world” which contains the following components: discovering the objects, discovering the matter, discovering the living, discovering the shapes and the magnitudes, approaching quantities and numbers, finding one’s bearing in time and space. The main advantage of such an approach is to promote an interdisciplinarity that avoids the compartmentalization of disciplines at school. The inconvenience lies in the fact that there are no clear directions for the teachers, who have to construct an organized teaching of mathematics. In this curriculum, there is no prescription for the didactical approaches that should be used in the classrooms. Moreover, some mathematical terms are vague. That is the case of the question of “classification”, for instance. This knowledge is dispersed in several paragraphs of the curriculum (of preschool and primary school): the mathematical words (to classify, to sort, to order, to list, to define, etc.) are often neither used nor linked in a correct manner (but that would require another article focused on the topic).

CONTEXT OF A FRENCH RESEARCH

Sometimes, children require some specific hidden knowledge (i.e. not taught and not identified as such in the curricula) in order to learn an identified knowledge of the curriculum (BO - 2008, June). The teacher cannot take it into account in his teaching either because this knowledge is diffuse or because it constitutes a kind of metaknowledge. It is very difficult for a teacher to grasp a knowledge which is not an

identified knowledge in mathematics, and to connect it to some other taught kinds of knowledge; that raises the question of pre-service and in-service teacher training and the question of the components of the curricula.

The main question for a didactical research is twofold: what is precisely this hidden knowledge? How can one design didactical situations to develop this knowledge? Researchers have dealt with these questions in France for a long time (in the eighties, their results were published in the nineties and are now revisited), regarding the field of reasoning, of geometry (Berthelot & Salin, 1992), of logic (Loubet & Salin, 1999-2000), of the construction of the first numbers as well as for arithmetical operations or combinatorics (Briand, 1999 for instance; Margolinas, 2012). The main theoretical background of this research is the Theory of Didactical Situations (Brousseau, 1997), which is made up of two main steps: finding problems where the knowledge aimed at is the best tool for the resolution of the problems, and, starting from such problems, designing (a) didactical situations [1] suitable for students of a given level. Such a design uses several theoretical tools, mainly the notions of devolution of the problem [2], didactical variables [3], and institutionalization of knowledge and processes [4]. The Theory of Didactical Situations identify four stages in a learning (devolution of the problem; action of the students; formulation; and validation, mainly without the teacher, in the situation). The question of designing didactical situations works with the question of the validation.

Brousseau (1984) and Briand (1993) have underscored several preliminary steps in the learning of counting. One of them is the notion of “collection”. Indeed, in order to count, a pupil should perceive the object “collection” in order to measure it. To determine a collection brings a measurable space from a mathematical point of view; it requires several skills for a pupil including among others “pointing” (i.e. the act by which one gives a sign to an object but without structuring the set of objects; it can be the finger-pointing) and “denominating” (i.e. the act by which one gives a name to each object; it implies a structure of the collection). In the various situations designed by French researchers involving collections and actions on them, the first ones can deal with lists (to point a collection for instance, but also to match a picture and an object and then to elaborate a code to point several objects, and to represent the structure of a collection). Then, several knowledge and skills are prior to counting, such as: Constituting a collection, Dealing with lists (when memory is not enough to remember the collection), Drawing collections and each element of them, Coding the elements, Decoding a list, Pointing, Denominating, Representing the structure of a collection. Such skills are now revisited and experiments are conducted in the current school context.

This paper will deal with two kinds of fundamental knowledge prior to counting: to enumerate and to deal with lists. What enumeration is will be explained first and will be followed by starting situations dealing with lists (a wider set of didactical

situations is available in Loubet & Salin, 1999-2000 and will be discussed during the Congress).

ENUMERATION: A CRUCIAL KNOWLEDGE

A hidden knowledge which is required for counting

Several research works deal with the construction of the concept of number, exploring the manipulation of collections in particular. I will not develop here the results of Fuson et al. (1982) regarding children's elaboration of number word sequences and the five counting principles of Gelman & Gallistel (1978) (the one-one principle; the stable-order principle; the cardinal principle; the abstraction principle; the order-irrelevance principle). I will highlight a hidden knowledge which is required for counting.

The following situation comes from a wider study (50 pupils, 6 years old – see Briand, 1993; this kind of study is now revisited by Margolinas (2012) who underscores the importance of the results of Briand and proves that these results also overlap the didactic of French). The pupils have a sheet where trees are drawn (Figure 1). The teacher asks the number of trees. The pupils can draw on the sheet, as they want.

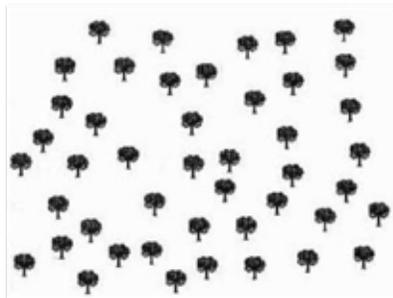

Figure 1 – Trees (in this case, the pupils have to structure the collection in order to count the trees)

In order to succeed, the pupils have to take the following steps:

- 1) *To be able to distinguish two different elements of a given set.*
- 2) *To choose an element of a collection.*
- 3) *To say a number word (which is “one” or the successor of the previous number word in the continuation of “words-number”).*
- 4) *To keep in mind the set of the chosen elements.*
- 5) *To identify the set of elements which are not yet chosen.*
- 6) *To start again (with the collection of the elements that have not been chosen yet) 2-3-4-5, as long as the collection of the objects which are to be chosen is not empty.*

7) *To know when one has chosen the last element.*

8) To say the last number word.

In this series of actions required for counting, only the steps in straight (steps 3 and 8) refer to the numerical sequence. What Briand (1993) calls “inventory” is a task represented by the steps in italics: the pupils have to look over all the elements of a finite collection one time and only one. This task characterizes a non-taught knowledge, called by Briand “enumeration”. Enumeration is clearly linked to the one-one principle (Gelman & Gallistel, 1978). The number word is a tag (and such a tag is a convention) but a tag is not necessarily a number word. Learning enumeration is not an explicit part of teaching. It is a paradox that “enumeration” is not considered as a fundamental component of counting up activities or measurement of discrete quantities (for the construction of first numbers, as well as for arithmetical operations or combinatorics). The research of Briand (1993) (following the research of Brousseau, 1984) proves the necessity of activities involving “enumeration” in the pre-numerical domain. The following excerpts underline its existence.

Analysis of some strategies: the lack of the “enumeration” knowledge

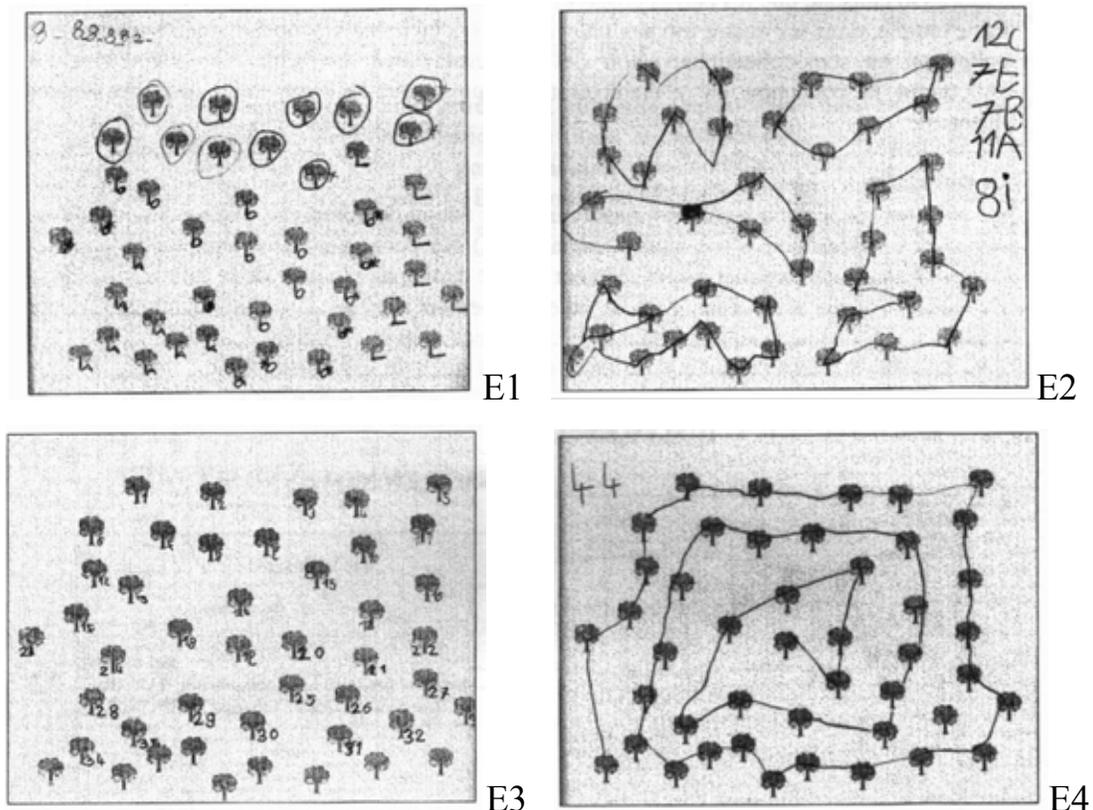

Figure 2 – Four processes (pupils are 6 years old)

Several strategies can emerge (see Figure 2). All of them need an organization of the space in order to take into consideration all the elements of the collection, without

forgetting one of them. The lack of such a spatial organization implies difficulties in counting.

The first two pupils structure the collection into subcollections.

E1: this pupil builds subsets and counts trees of each subset with a specific marking. A partition of the whole set of the trees is done. He builds the writing ‘8 8 8 8 2’. He misses the tree with a circle and a cross.

E2: some trees are linked and then constitute a subset. A partition of the whole set of the trees is done. A letter represents each subset.

The other two pupils use an order to act on the collection.

E3: this pupil explores the collection by line. The numbers are written but the pupil stops her/his counting (at 35) because there is no more line and the pupil “does not know” where 36 is or where she/he can mark 36 (although this pupil can count way after 36).

E4: this pupil draws a path like a snail that will facilitate the counting. She/he finds 44 because she/he has counted the number of jumps and not the number of trees.

These excerpts show that the “enumeration” appears as a crucial knowledge. One can define the verb “to enumerate” with the following elements (see Briand, 1993, § 1.4 to 1.7 of chapter 1):

To enumerate: this is an action that involves taking into consideration each element of a collection, one and only one time. This verb refers to numbers from an etymological point of view, even if this action does not require the knowledge of the numbers. But the action “to enumerate” is a necessary action to count a collection. The enumeration implies the mobilization of several kinds of mathematical knowledge (from the exploration of space to combinatorics): it depends on the nature of the collection (if the objects are visible or if the objects are defined by properties).

A fundamental situation for enumeration

Briand (1993) has designed a fundamental situation for enumeration, for pupils between 4 and 5 years old. A didactical analysis of this situation will be developed during the working group with the help of videos.

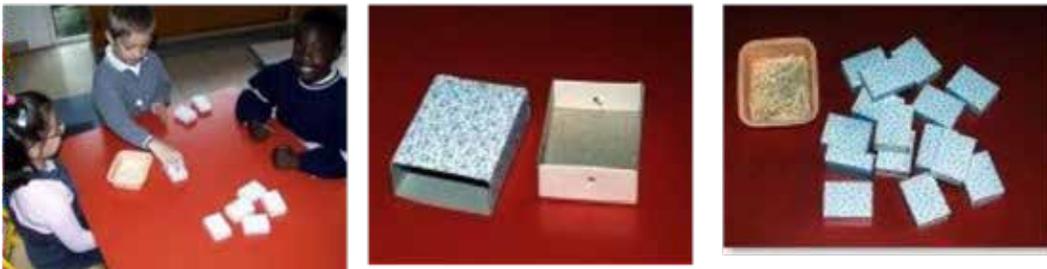

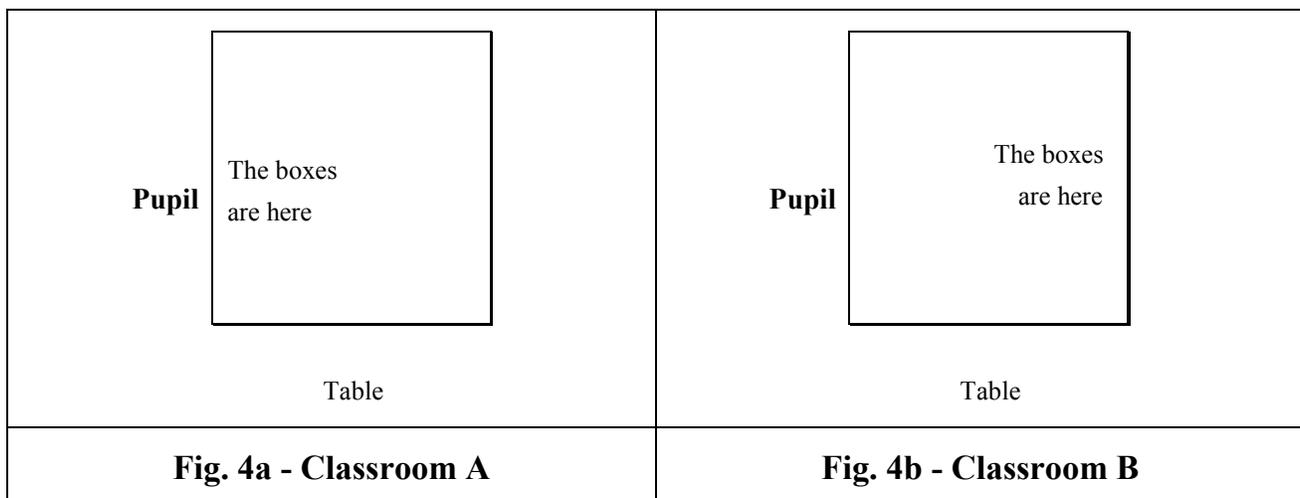

Figure 3 – The matchbox situation (pupils 4-5 years old)

A pupil has, just in front of her/him, several opaque matchboxes with a small hole (in order to put a match in the matchbox) and a lot of sticks (which are “safe matches”) in a plastic box. The task is the following: each pupil should put one and only one match in each matchbox and then declare that she/he has finished. When she/he thinks that she/he has successfully accomplished the task, another pupil (or two) comes to verify with her/him, by opening the matchboxes. The pupil has succeeded if there is one and only one match in each matchbox. It is a recurrent task that the teacher can organize for the pupils to work on their own, for instance from November to February.

Several didactical variables can be listed: the nature of the space (here, it is the table, a micro-space); the number of boxes; the fact that the matchboxes can be moved or not.

An ergonomic fact which both imply a non-built collection and an inferred enumeration

The way matchboxes are placed on the table can impact the learning (as well as the place of the box of matchsticks).

In order to put a matchstick in a matchbox, the pupil has to:

1. take a matchbox;
2. take a matchstick;
3. put the matchstick in the matchbox;
4. physically separate the filled matchbox and the empty matchboxes;
5. restart.

To succeed, the pupil has to build the collection of filled matchboxes, from the second matchbox on. In the case of Classroom B, the first stage requires the pupil to

take a few steps: the pupil has no reason to mix filled boxes with empty matchboxes. The enumeration is not learnt in such a case. In the case of Classroom A, the pupil consciously has to organize her/his collection of filled matchboxes. The difference in the place of the matchboxes can explain some differences in the results between these two classes.

DEVELOPPING REASONING AND LOGICAL SKILLS WITH THE DESIGNING AND READING OF LISTS

Several activities based on “lists” take part in the development of the logical thought in preschool: building a collection starting from a list, inventing the list as a tool in order to remember a collection or to communicate its content, building lists, building symbols in order to designate objects and then building a list etc. A list represents the easier way to designate non-structured collections of objects. Loubet & Salin (1999-2000) develop a set of situations (experimented with the COREM – Centre d’Observation et de Recherche sur l’Enseignement des Mathématiques, with several classes; all the experiments were analyzed with the tools of the Theory of Didactical Situations).

Introducing the idea of “list” for 3 year old pupils: a challenge

The following steps come from the research work of Loubet & Salin (1999-2000). It will be discussed during the working group.

1) To elaborate a collection: Doggy’s suitcase

The main goal of the teacher here is to elaborate a common background for further situations in the classroom. The recurrent story is the following: Doggy is a puppet who brings a suitcase with various objects inside (3 the first day, up to 20 – it requires around 20 sessions and 2 months). The pupils look at the objects and they learn to name them. When all the pupils have touched and named the objects, the teacher puts these objects in the suitcase which is closed and Doggie explains that he will come the next day and bring a new object if and only if the pupils remember all the previous objects.

2) The game of the pictures: the pictures will now take the place of the objects, but the objects are still here. Each pupil gets a picture (at first 1, then 4, and finally 7) and has to take the matching object.

3) The game of the lists: the need to make up a list and to build the elements for its construction

This game takes two days and requires a collection of objects, and two boxes. The first day, the teacher takes some objects from the first box and puts them into the second box. Every pupil can look at these objects and touch them. The box is then closed, nobody can touch it. The second day, each pupil is asked by the teacher to play: if she/he names all the objects of the box, she/he has won. Otherwise she/he has

failed. Each time the pupil names an object, the teacher shows her/him this object. If there are still objects in the box and if the pupil thinks that she/he has enumerated all the objects, the teacher shows her/him the objects too.

There are several didactical variables:

- the size of the hidden collections: when the number of hidden objects is small, the pupils can succeed using their memory. Memory is not useful when the number is big, hence the advantage of a list (to play with this didactical variable leads pupils to think that they have to find another idea to succeed);
- the construction of a list (invention of some pupils, diffusion in the classroom and role of the teacher): when pupils fail and think that their memory is inefficient, the role of the teacher is fundamental in order to encourage them to find another process. The knowledge now involved concerns the one-one link between the objects and their designation. It also depends on the following didactical variable;
- the composition of the collection (when the pupils have to construct the designation of the objects): a fundamental step here concerns the moment when pupils have to “decode” the written work of their friends.

CONCLUSION – CONSEQUENCES IN EDUCATION

Teaching requires knowledge that it does not support. Education is so far unable to make a didactic transposition of the enumeration leading to this knowledge. Therefore it is under the responsibility of the pupils. This generates difficulties for pupils and teachers. Current research (Margolinas, 2012 and in press) underscores that some kinds of knowledge such as enumeration are still “transparent”, even if didactical works and official documents (Emprin & Emprin, 2010, pp. 27-29) point them out. And yet teachers have knowledge about enumeration and know about the difficulty involved by enumeration.

The role of the individualization of the processes of the pupils is also important (i.e. the teacher takes care of every process in her/his classroom). The devolution of the didactical situations to the pupils is fundamental and requires a specific didactical contract. The validation of the processes of the pupils comes from the situation. What kind of posture the teacher should have? How can teachers design sequences integrating such (partially hidden) knowledge? The place and the role of oral and written formulations should be analyzed more precisely.

The role of the teacher is then twofold: he has to present the problem to the pupils, to make sure that its devolution is made, and to convince the pupils that they can succeed in performing the task and that the solution of the problem is up to them. Besides, the institutionalization can both concern knowledge (when it is identified, such as enumeration) and processes (lists). Moreover, recent research (Margolinas & Laparra, 2011) points out that some kinds of knowledge such as enumeration are also

involved in other disciplines (French). Here is an example (Margolinas, in press): the pupils (5 years old) have to fill out the paper of Figure 4, using the tools of Figure 5 (scissors, a box, a pencil, and an alphabet).

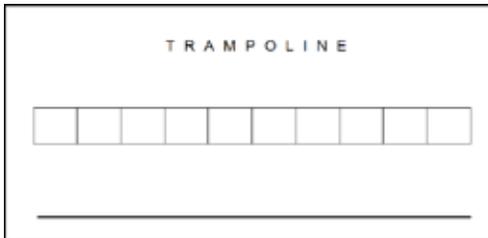

Figure 4

Figure 5

In order to stick the letters in the right position, pupils should make two enumerations (one with the first word “TRAMPOLINE” and one with the configuration of the individual letters-label). That underscores how enumeration is a transversal knowledge and not only a mathematical content. Further research should question more deeply this kind of knowledge and what it implies as far as pre-service and in-service teacher training are concerned. The case of the preschool and primary school with one teacher for several disciplines is a complex configuration, but it reveals transversal knowledge, when researchers coming from several disciplines work together.

NOTES

1. An *adidactical situation* is one in which the students is enabled to use some knowings to solve a problem “without appealing to didactical reasoning [and] in the absence of any intentional direction [from the teacher]” (Brousseau, 1997, p. 30).
2. The notion of *devolution* is “the act by which the teacher makes the student accept the responsibility for an (adidactical) learning situation or for a problem, and accepts the consequences of this transfer of this responsibility” (Brousseau, 1997, p. 230)
3. A *didactical variable* correspond to a potential (yet often implicit) choice for the teacher that modifies the accessibility of different strategies for solving the problem.
4. The teacher gives a cultural (mathematical) status to the new knowledge and he/she requests memorization of current conventions. He/she structures the definitions, theorems, proofs, pointing out what is fundamental and what is secondary.

** University of Palermo (Italy)

This is not about comparative philosophy, about paralleling different conceptions, but about a philosophical dialogue in which every thought, when coming towards the other, questions itself about its own unthought

F. Jullien

ABSTRACT

Aim of this paper is to exploit intercultural dialogue to analyze two cases of task design about straws and word problems in different cultural traditions (the Eastern and Western one). By means of two paradigmatic examples developed in Italy, we aim at showing, on the one hand, the effects and advantages of intercultural dialogue and, on the other hand, the need to take into account and to respect culturally rooted pedagogies, avoiding uncritical transfer from one culture to another.

INTRODUCTION

Why introduce a multicultural perspective in the didactics of mathematics at the beginning of primary school? Why choose specifically China? The positive international results achieved by China, and more in general by the countries of the Confucian area (China, Korea, Japan, Singapore), in the OCSE PISA 2009 judgments concerning mathematics, cannot but raise questions in those dealing with education and particularly with the didactics of mathematics. In particular, it seems necessary to study how and whether these abilities are developed from the first grades of primary school and whether there are paradigmatic elements to be considered in advance. Beside this element there is an important context fact: in Reggio Emilia there is a large Chinese community, which causes the need to constantly create new occasions for dialogue among schools, teachers and social context. For some years, the Universities of Modena, Reggio Emilia and Palermo have started a number of research projects (Spagnolo 1986, 2002; Bartolini Bussi et alii 2009, 2011b), in cooperation with teachers of primary (UNIMORE) and secondary school (UNIPA). These projects aim to question ourselves about “our” (Italian) and “their” (Chinese) teaching methodologies. We interpret this collaboration between school and university in the attitude expressed by G. Prodi: “It is important to maintain contact

with school: the ‘University - School mixed groups’ can play a very important role both in the spread of didactic innovation and in the didactic research.

These groups require the adoption of a really joint relationship: pre-university school teachers invited to participate in a didactic research have to do it fully, and not only as auxiliaries responsible to collect data and protocols.” (Prodi, 1991).

In this work we will deal with some aspects of the first arithmetic learning in the early grades of primary school (1st and 2nd grades).

COUNTING RODS: A PARADIGMATIC EXAMPLE FROM THE TEXTBOOKS OF CHINESE PRIMARY SCHOOL

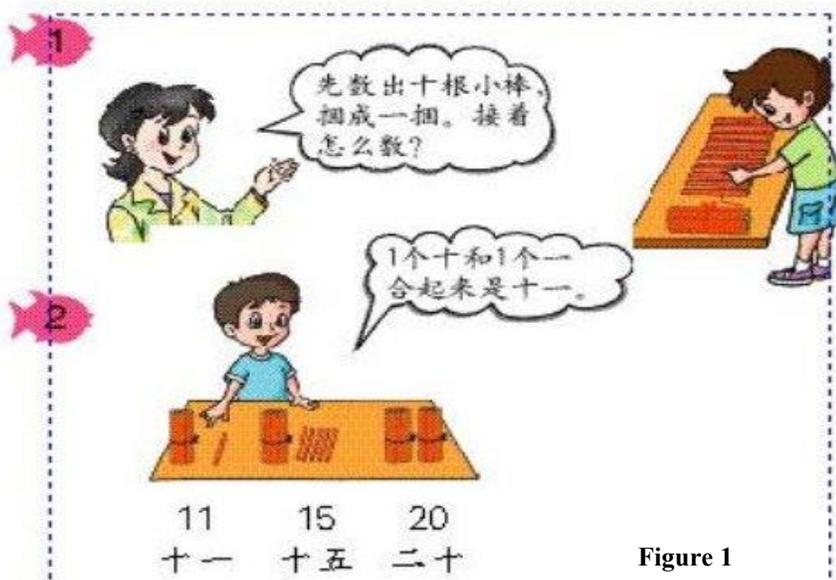

Figure 1

Our analysis focused firstly on textbooks of Chinese primary school as rigid vehicles of 2001 school curricula, reapproved in 2010. In them it seemed to grasp the strategic importance of two artifacts which are typical of mathematics in China: the *counting rods* (for which we used common straws) and the *problems with variation*.

The page below is taken from textbooks for the 1st semester

of the 1st grade of primary school. First of all, we would like to draw attention to the use of the counting rods and the practicality the child shows counting and binding them, in order to obtain numerical correspondences.

However, attention should be paid above all to the language. In the second comic strip from above it is possible to note the use of both Arabic figures and their Chinese equivalent.

This seems to lead the pupil, more or less explicitly, to conceptualize the calculation through three different “translations”. In fact, let us try to read this page from the bottom up. In the lowest part, correspondence between the two codes can be found (Chinese writing - Arabic writing). This is then exemplified with the image of the counting rods the child is observing and handling.

The pupil’s balloon refers to a multiple reading of the used codes, which are useful to the learning child to consolidate positionality. This step has to be attributed to the predominance of methodology on content, which Chinese culture brings along. Indeed, the continuous codes *contamination* is found also in other passages of the textbooks and tends to privilege the use rather than the creation of stable concepts.

To substantiate this statement, it seems interesting to show below two other images, always taken from the same book and following one another (pages 17 - 18):

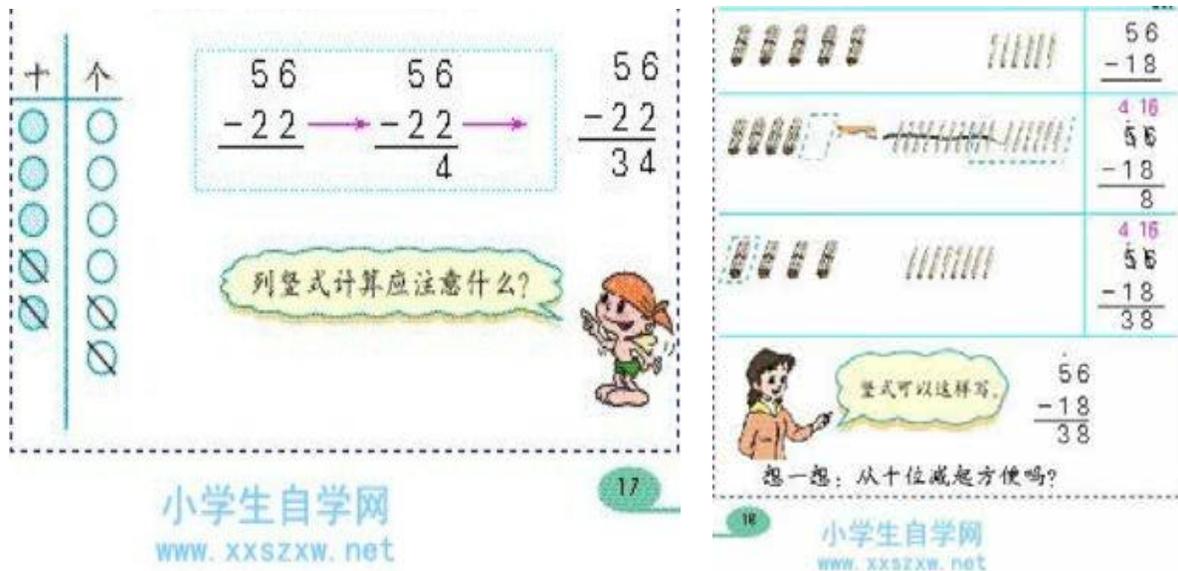

Figure 2

Here it is easy to note how the use of schemes is totally linked to a didactics focused on the research of solving *methods*, rather than on the presentation of isolated contents. This means that children in the early grades of primary school are faced with a text which, on two consecutive pages, modifies the iconic representation, appropriately replacing the column scheme on page 17 with the use of the artifact of the rods on page 18. The former, in fact, would be unsuitable and harbinger of possible cognitive hitches to perform a subtraction with the decomposition of the tens. The solving methods are so perfectly interchangeable because the reason why they are introduced is their way of using them.

PROBLEMS BY VARIATION: TWO PARADIGMATIC EXAMPLES FROM THE TEXTBOOKS OF CHINESE PRIMARY SCHOOL

If we analyse the 1st grade text carefully, we find several examples of formulation of this kind of problems, which, from a given situation, proceed by variation, integrating addition and subtraction. Let us look at picture 3 to the right.

First of all, the book shows a school where the teacher addresses the issue of the problems in a totally decontextualized way. This is clear when observing the blackboard. The represented dinosaurs are divided into a group of 6 and one of 2. What can be noted on the pieces of paper the children hold in their hands is the use of a mathematical writing code to translate the

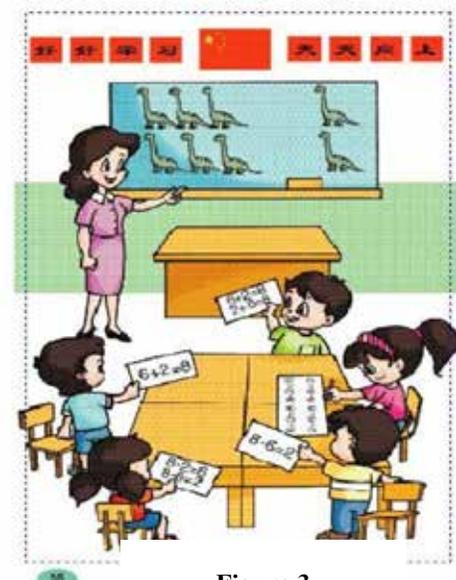

Figure 3

situation the teacher shows them on the blackboard. Referring in particular to the codes on the pieces of papers, it is possible to note how this figure introduces a first seed of problems with variation in which the child handles with a problematic situation that can be solved both with addition and subtraction. What do Chinese children do already from the 1st grade of primary school? They DEAL contemporaneously with what in the West is usually decomposed into four subsequent conceptualizations: addition, subtraction, the strong interdependence between them and the commutative property of addition.

The interdependence between the arithmetic operations is an extremely interesting factor for us, because it refers to acquisitions of western formal mathematics, in which the algorithms are not four, but only two, that is addition and multiplication. The examples pertaining problems with variation which we are going to analyse below will better explain these reflections.

OUR TRANSPOSITIONS: PARADIGMS FOR A DIDACTIC PLANNING

The intention here could be mistaken for an attempt to *translate*, or even worse *import* a Chinese text into the Italian culture and more in general in the Western. On the contrary, the educational paths we are going to analyze, developed by the group of research professors with whom we have collaborated for some years, aim to create real transpositions of the Chinese model into the Italian one. The goal of this research activity, as we said, was to try to understand if it is possible to transpose in the Italian context some of the fundamental elements which characterize Chinese mathematic didactics in the first years of primary school. The first activity was developed by Mr. A. Ramproud in his first class of primary school. He introduced the straws at the beginning of the school year. The didactic activities planning focused on this tool to convey a series of mathematical meanings.

Already from the analysis of the Chinese textbooks, it is easy to discover how, using such a tool, it is possible to try to convey to the children the structure/scheme of positionality. Directly dependent on this aspect is the importance given to the “ten-bundle” and therefore to the decimal system. Another significant element, in this initial analysis of the potentialities of the counting straws, is the fact that they allow also the manipulation of very big numbers (hundreds) already after a few days from the beginning of school.

This perspective seems even more significant if we think that in the first class of the Italian primary school, they approach numbers only up to 20. Finally, by building manipulative calculation paths, it is possible to develop the abilities of one-to-one correspondence object-straw and accompany the path towards the abstraction of numerical concepts. From these analysis, which provides some possible potentialities of the straws-tool, specific tasks for the pupils have been structured. First of all, since we work with first class-children of primary school, we asked them to freely examine the straws-tool.

The children, during this activity, handle the straws and describe their appearance and possible uses. In a second stage, the teacher asks them: “What can the straws be useful for?” The records show different possibilities, going from *playing* “They can be used to play”, to *drinking* “I use them to drink” and to *counting* “You know, we can use them to count”, “When you don’t know how many they are, you can use them to count”. On the basis of these indications, the teacher readjusts the didactic activity, proposing further reflections and choosing the most appropriate perspective to convey the desired mathematical learning.

At this point the teacher replies, having laid several hundreds of straws on the table: “You said they are used to count, but how many are these straws?”. This situation generates a series of hypothesis made by the children, who give back a ingenious mathematical learning and start different explorations in order to answer the question. It is possible to appreciate solutions linked to estimates like the following one: “I think they should be 62.99 billions...” or solutions to calculate the amount using distribution: “We can give 10 to everyone”. It is clear that this second modality is adopted by the teacher, who provides the class with a new work possibility, introducing the “ten-bundle”. In that, a link with the analyzed Chinese text can be seen. Through this procedure of continuous readjustment of the activities, the children get to discover the ten and to count all the straws, finding out that they are 512. These activities have shown an appreciable improvement and strengthening of the skills related to positionality, as observed in subsequent tests.

This path, based on Chinese mathematic didactics, through the mediation of Chinese textbooks, looks also consistent with the theoretical reference frame illustrated by A. Mariotti at the Taiwan PME 2012 (Mariotti, 2012). These elements drive to speak about a real transposition, i.e. the appropriation of methodologies, in order to reconsider one’s own way of doing school.

The other example to which we want to pay attention is the one developed by Mrs. L. Maffoni in her first class. Always starting from the introduction of the straws, she followed the path to identify the “ten-bundle”. However, here it is essential to focus on a key-element: in the definition of the “ten-bundle” the children created a very interesting neologism, which, used by the teacher, is able to convey a series of mathematical concepts. In fact, when she asked the pupils what they were doing, they answered: “we are ‘*elasticando*’ (The meaning is *binding the straws together using an elastic band*) the straws”.
