The notion of financial vulnerability can vary greatly in different contexts but encompasses individuals and families who are struggling to make ends meet financially, and who have little 'back-up money' or no safety net when confronted with a loss of income or a new necessary expense. Research into financial vulnerability identifies a wide range of influential factors including psychological dispositions such as lack of self-confidence or self-control, while others point to vulnerability linked to gender, age, income, and disability. Further research considers the financial context as a significant contributing factor such as belonging to local marginalised communities while others point to the complexity of the wider social and economic systems that people find increasingly difficult to navigate. More research into what is most important to different groups identified as disadvantaged is essential.

The US and the UK, two so-called developed economies, have at least a quarter of their populations in financial stress. The dominant thinking across many western countries is that improving a family's financial literacy skills and knowledge will enable them to reduce debt and increase their long-term financial security. While helping people understand the choice and methods of calculations of financial transactions in an economic system can be helpful, the research points to the difficulties of following orthodoxies of saving money for future negative events if families find themselves on low incomes and unable or unwilling to seek financial advice available.

Research also points to istrong links between financial literacy and numeracy skills, however current online teaching programmes in the UK tend to focus on psychological and emotional relationships with money. Research into marginalised communities highlights the need to develop resources in the Money Matters project that are relevant to people's lives, starting from the learners' input and experiences, which may or may not necessarily focus on all the financial literacy advice currently promoted through dominant orthodoxies. This requires the teaching and learning approaches used in the resources to be flexible and respond to learners' priorities while still enabling participants to develop a better understanding of their current financial situation and possibilities for the future.

Democracy and mathematics instruction for adults - three philosophical perspectives

Lena Lindenskov

Aarhus University, Danish School of Education, Copenhagen, Denmark; lenali@edu.au.dk

Some might view mathematics education and democracy as two distinct arenas without mutual relations. Contrary to such an understanding, this paper presents part of a larger study on potential relations between the two. More specifically, I explore relations between democracy and mathematics teaching or instruction for adults. The paper seeks to identify philosophical underpinnings and inspirations for describing and understanding core relations between democracy and mathematics education. I present snapshots from the works of three prominent scholars: theDane N.F.S. Grundtvig's philosophy of lifelong learning; the German Jürgen Habermas' theory ofcommunicative action; and the German Hartmut Rosa's concepts of resonance and world relation. Highlighting how these theories might offer new perspectives of how mathematics education can support democracy? The perspectives differ in their depth and breadth but share certain similarities.

Keywords: Mathematics instruction, democracy, educational environment, adult education.

Setting the scene

In my view, Nordic understandings of mathematics education for democracy that emerged around 1990 (Mellin-Olsen 1987, Niss 1994, Skovsmose 1990) remain relevant today. I believe it is time that these issues be placed high on the agenda when reflecting upon contemporary classrooms for adults and to revisit and more deeply examine the relationship between democracy and mathematics education, when exploring both contemporary research and current instructional practices in mathematics classrooms.

First, I will revisit and reiterate a double-sided view of what constitutes democracy. I argue that democracy understood in its formal sense and as a steering mechanism must be supplemented by lived democracy as comprised by people's participation and communicative interactions in and across the many levels and spheres of society. Back at ALM8, Paola Valero and I termed these two forms of democracy Democracy 1 and Democracy 2 (Lindenskov & Valero, 2002). Second, I wish to incorporate democratic reflections on the questions of what should be taught, who should be taught, and how it should be taught within mathematics education for adults?

I have combined these questions in a two-dimensional matrix model (see Figure 1) that I first presented at ALM28 (Lindenskov, 2021). The first dimension concerns formal representative democracy as a form of rule contra informal democracy in the form of everyday participation and communication. The second dimension highlights the questions of what mathematics to teach, to whom, and how. I developed the model as part of a collective effort with colleagues at the Department of Educational Theory and Curriculum Studies at the Danish School of Education. At our annual working seminar in 2017, we decided to write an anthology on democracy and 'subject didactics' [German: Fachdidaktik] (Lindenskov, 2020).

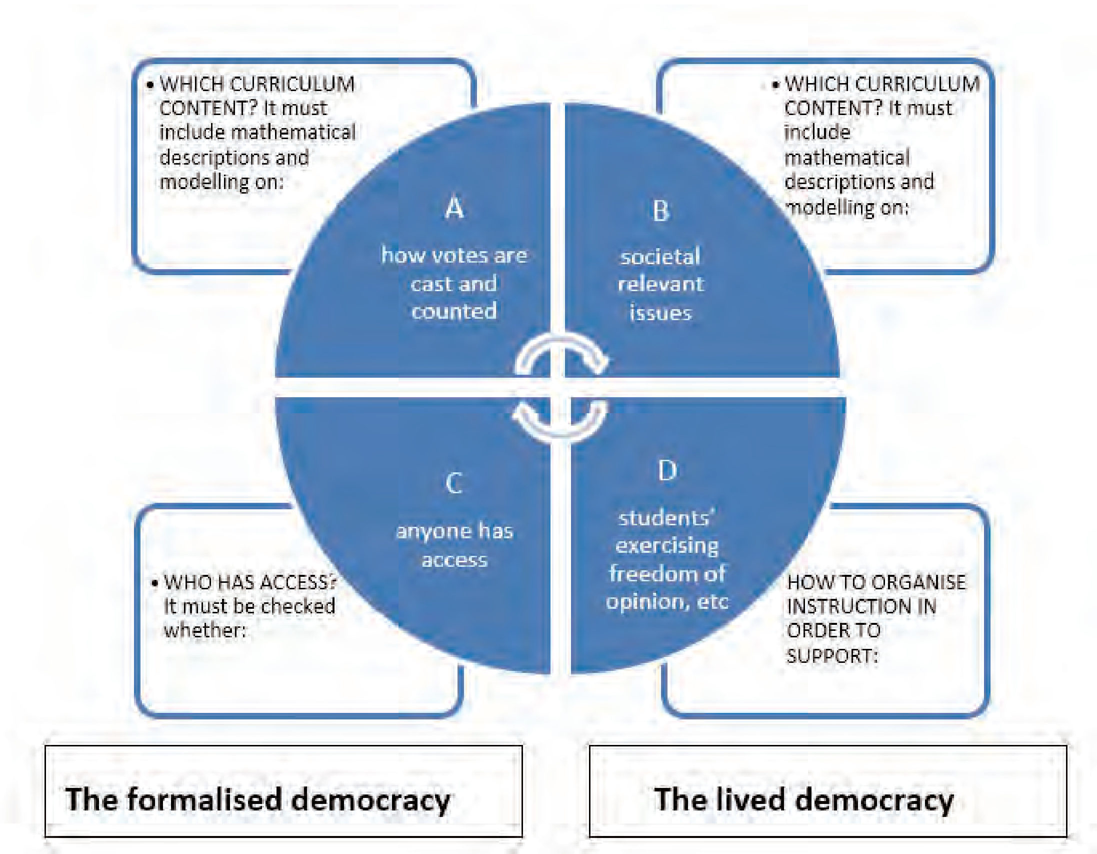

Figure 1: Matrix model for mathematics/numeracy instruction and democracy

Besides revisiting the previously mentioned Nordic understandings of mathematics education for democracy from around 1990, I re-examined my own recent analyses of Danish mathematics curricula and related public debate (Lindenskov 2018, 2019). I became convinced that the previous focus on democracy within critical studies of mathematics education has currently been replaced by other themes. This change of focus is clear in Yasukawa et al. (2018), where the thirteen contributions on numeracy as social practice make little mention of democracy. I noted that democracy is only addressed as a theme in two of the contributions – one from South Africa and one from India – but is otherwise absent. Nevertheless, the publication distils several issues contributing to what I term 'lived democracy'. In addition, democracy is a theme in the 'social injustice' framework developed by Berry III et al. (2020), exemplified by activities concerning the use of algorithms in formal voting systems.

The bottom left-hand corner of Figure 1 includes reflections on who has the right to receive high-quality mathematical education. It is essential in democracy that anyone has rights and access to acquire appropriate mathematic expertise and authority. However, history – and the present day – provides many examples of unequal access to education and unequal learning opportunities. On the right-hand side, the model presents democracy as a 'way of life' rather than a form of rule (Jakobsen, 2010). At the top right-hand corner, you see how democracy 'is done' daily in the mass media (newspapers, Radio, TV), via social media or direct person-to-person dialogues (written or oral). Much of the background information supporting political decisions at the local, national, and international levels includes numerical measures and the results of mathematical problem-solving and modelling.

The bottom right-hand corner of Figure 1 focuses on the questions of whether and how mathematics lessons constitute lived democracy. What characterizes the educational environment for mathematics and numeracy learning? Are mathematics classrooms a site for lived democracy, where students and teachers exercise freedom of opinion, discuss openly, demonstrate critical faculties, and adhere to principles of tolerance, trust, and justice? And do all students have the right to expect to bevalued equally and to experience mathematics as meaningful?

One example of a mathematical activity relating to formalised democracy illustrates part A in Figure 1 and how votes are cast and counted in different democratic voting systems. Figure 2 and 3 allow learners to compare the effects of different electoral algorithms. While figure 2 shows the representation of the various political parties in the Danish Parliament applying the algorithm used in Danish parliamentary elections, figure 3 illustrates how things would look applying a first-past-the-post algorithm such as those found in Great Britain and the USA.

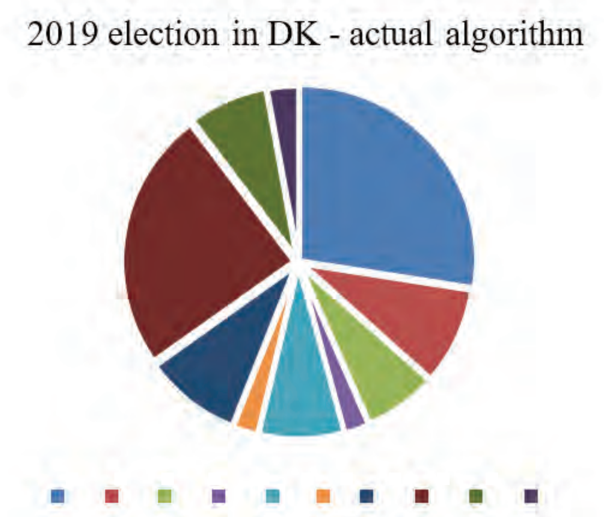

Figure 2. Actual party representatives in the Danish Parliament following the 2019 election

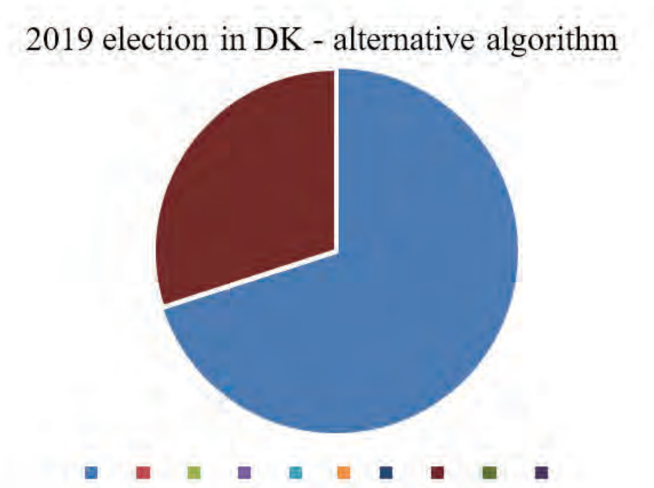

Figure 3: Hypothetical partyrepresentatives in the Danish Parliament following the 2019 election if applying a first-past-the-post algorithm

In the following, I explore possible philosophical underpinnings to help clarify the model from Figure 1 and develop tools for analysing curriculum materials, classroom activities and classroom life in relation to democracy.

N.F.S. Grundtvig – Lifelong learning

Focusing on adult education implies a concern for lifelong learning. For me as a Dane, the scholar N.F.S. Grundtvig (1783-1872) is unavoidable when considering such matters as one of the founders of adult education institutions in Denmark, termed ‘folk high schools’ (Broadbridge et al, 2011). Grundtvig is also considered an important figure in other countries. Many American scholars acknowledge the inspiration that Malcolm Knowles(1913-1997), who is widely considered the father of adult learning theory in the US, drew from Grundtvig (Warren, 1989). Furthermore, a European Union programme 2000 – 2013 to support adult learning was former named after Grundtvig, forming a branch of the Socrates programmes.

In addition, a branch of the Danish Lutheran Church is named after Grundtvig, standing in opposition to Pietistic Lutheranism. As a priest, Grundtvig wrote more than1500 hymns. For this presentation on education and democracy, the most important thing to note is, firstly, Grundtvig’s educational philosophy with its goal of making education accessible to all adults. Secondly, it is notable that Grundtvig influenced the shift from autocracy to formal democracy in Denmark, with the first democratic constitution of 1849 giving approximately 15% of the population the right to vote (Korsgaard, 2014).

All legislation governing adult education in Denmark have included the aim of empowering adults and encouraging them to participate in democracy and of offering instruction that supports participants’ active involvement. Nevertheless, as the Danish scholar Gunhild Nissen has pointed out, Grundtvig viewed mathematics with scepticism. Grundtvig used wordings as mathematics ‘neither cared for life nor for death’. The ‘folk high schools’, he argued, should be ‘schools for life’ and should offer courses that would empower ordinary people. Grundtvig refused to give mathematics teaching a place in his folk high schools. Grundtvig likewise advocated to deny giving mathematics teaching a place in primary education, convinced that mathematics with his wording would give children ‘ink in their veins instead of blood’ (Nissen, 1991).Taking a more optimistic view, Nissen drew on Habermas' concepts of the system and lifeworld to support her hope that,in the future, mathematics would not only be a tool of the system and part of its structural foundation but could be integrated within the communicative contexts that build and expand the lifeworld (Nissen, 1992). To summarize, Grundtvig espoused everyone’s right to education (part C in Figure 1) and the importance of making lived democracy part of education (parts B and D in Figure 1). Even today, his scepticism as to whether mathematics can contribute positively to the lives of ordinary peopleshould be taken seriously as a topic for discussion and reflection.

Jürgen Habermas – Communicative actions

Jürgen Habermas, born 1929, is a German philosopher and sociologist who has played a highly influential role in the development of critical theory. In the book *The Theory of Communicative Action* (1984, 1987), he outlines the elements constituting what he called ‘communicative actions’ as opposed to ‘strategic actions’. While strategic action can be considered successful when those involved achieve their individual goals, successful communicative action is when a consensus is freely reached on reasonable goals that can be achieved through cooperation. Communicative action involves a shared effort to reach a rationally motivated consensus through the medium of language. But in which ways can such consensus be achieved? Habermas has analysed the conditions for successful speech acts leading to mutual understanding. Sometimes, the listeners may immediately be able to sense whether they consider the speech act acceptable and their reasons for accepting or rejecting the proposed goal.

In other cases, there may be a need for explicit reasoning supported by empirical claims, appeals to a sense of moral or ethical good, assertions of authenticity, personal sincerity, or aesthetic value.

I find it interesting that Habermas' communicative actions are used by Jenny Cramer and Christine Knipping in their analyses of student-teacher interactions in determining whether particular mathematical results are correct (Cramer & Klipping, 2018): How do communicative actions and strategic actions between teacher and students and among students play out? Which communicative actions for reaching a consensus includes that students express and interpret mathematical claims and other types of claims? Which strategic actions are convincing other students? Cramer and Knipping focused on discourse ethics, and language, included in students' claims and discussions in mathematics classrooms. Especially Habermas' rules of discourse ethics were found to offer a range of explanations for obstacles that may hinder student participation in discussion. To summarize, Habermas' specific focus on different kinds of communicative acts provides us with analytical tools for acknowledging distinct democratic facets when organizing mathematics instruction (as in part D of Figure1). In my view, Cramer and Knipping's use of Habermas' concepts has rich potential for studying andsupporting democratic learning processes in mathematics instruction for adults.

Hartmut Rosa – Resonance and being in the world

Hartmut Rosa, born 1965, is a German sociologist who contributed to the further development of critical theory by adding a concept of resonance (Rosa, 2019). Rosa sees resonance as a way of encountering the world – people, things, matter, history, nature, and life as such. He highlights four crucial qualities of resonance. The first of these qualities is affection, which is a feeling of being truly touched or moved by someone or something. A second quality is emotion and an experience of self-efficacy. Third, by being touched and affected and by reacting and answering, transformations occur. The fourth quality characterizing resonance is that you never can be sure whether you will experience resonance.This elusiveness makes it impossible to predict or control what happens. Nevertheless, Rosa sees such attempts to get in touch with the world in the sense of resonance as inherent to human nature.

Rosa's ideas are grounded in Habermas' theory of communicative action, but Rosa goes a step further, arguing that Habermas gave too much respect to rationalism. In addition, he puts more emphasis on education, studying what resonance and being in the world might mean in an educational context.He has developed what he refers to as the triangle of resonance. This triangle consists of teacher, students and material, and he adds what he terms the axis of resonance between the students. Rosa gives an example of the role played by materials – also in mathematics, while also underlining the importance of the teacher (2019, p. 244):

> Education as a process of disclosing the world begins with the excitement of the teacher, who in a way functions as the first tuning fork, preparing her students for resonance so that in the resonance event between them the material (whether classical drama, a mathematical formula, the rules of grammar of a foreign language, or a political party platform) comes alive and begins to speak. Thought it might sound overly poetic expressed this way, it is basically an almost everyday occurrence, playing out hundreds of times in hundreds of different ways in every school on every school day.

Rosa points to four preconditions for establishing a triangle of resonance between teacher, students and material and for establishing an axis of resonance between the students. The first concerns students' freedom from fear and anxiety, expectations of self-efficacy, and mutual trust between teacher and students and among students. The second is a teacher who believes that she has something to say about the material, i.e., the material appeals to her and is important to her. The third is that students must approach the material openly, with a willingnessto engage with and be moved by it, and a belief that they can 'make it speak.' Finally, it is a precondition for establishing an axis of resonance between the students that there is an atmosphere in the classroom that facilitates students' openness to resonance–where students do not risk mockery, disparagement, malicious remarks, bullying, etc.

I fully agree with Rosa's claim that recent debates in the field of education and pedagogy assign too reductive arole to the teacher. Regarding teachers solely as professional moderators and mediators, helping students and sharing their know-how, underestimates the real importance and potentials of teachers. Rosa refers to Hattie's findings of the teachers' influence on students' learning (Hattie, 2012), and Rosa suggests that it might be teachers' influence of what he terms the web of resonance in the classroom that is the most important for students' learning. Rosa also suggests that this web of resonance might be one of the core mechanisms behind school's reproduction of sociostructural differences. He refers to Maaz et al. (2014), who state that these differences are reproduced and even exacerbated within German education (Rosa, 2019, p.246). To summarize, Rosa extends the perspective offered by Habermas' concept of communicative acts between people (as in part D in Figure 1) to include a strong focus on the relationship between materials, teachers and students in educational contexts and on peoples' relations to the world (as in part A and part B in Figure 1).

Concluding remarks

The three scholars whose ideas are at the centre of this paper share an interest in ensuring everyone has access to education and that this education supports and strengthens democratic processes within society. Meanwhile, Grundtvig's scepticism regarding whether mathematics can contribute positively to the lives of ordinary people is a warning we ought to seriously discuss and reflect upon – for instance, by using the model presented in Figure 1 to continuously ask how high-quality mathematics instruction for adults can contribute to formal and lived democracy. It is my assertion that the three scholars provide several possible underpinnings that can help clarify the model in Figure 1.

Grundtvig shows that part C in Figure 1 is underpinned by everyone's right to education and parts B and D by letting lived democracy be part of education. Habermas shows that part D is underpinned by different kinds of communicative acts that offer analytical tools for acknowledging distinct democratic facets when organizing mathematics instruction. As mentioned, Cramer and Knipping's use of Habermas' concepts has rich potential for studying and supporting democratic learning processes in mathematics instruction for adults. Rosa shows that part D is underpinned by his extended perspective on communicative acts between people, while parts A and B are underpinned by his focus on the material and the teacher and on people's relations to the world.

However, none of these scholars show any great interest in numeracy and mathematics. As such, it is up to those of us conducting research on and developing mathematics education to build on and concretize their insights. The model in Figure 1 is my modest contribution.

Numeracy-Meets: professional development and networking for adult numeracy practitioners

Mark Prendergast[1], Niamh O'Meara[2], Kathy O'Sullivan[3] and Fiona Faulkner[4]

[1]University College Cork, School of Education, Cork, Ireland; mark.prendergast@ucc.ie

[2]University of Limerick, EPI-STEM, School of Education, Limerick, Ireland; Niamh.omeara@ul.ie

[3]National University of Ireland Galway, School of Education, Galway, Ireland; Kathy.osullivan@nuigalway.ie

[4] Technological University Dublin, Dublin, Ireland; fiona.faulkner@tudublin.ie

Despite the clear and obvious need for adults to be proficient in numeracy, international studies suggest that many adults continue to struggle in this area. One of the main challenges continues to be the availability and quality of adult numeracy education. Research has highlighted an unmet demand for professional development in this area with many numeracy practitioners looking for opportunities to further develop their practice. Moreover, practitioners have expressed a desire for networking opportunities with colleagues to discuss and share their experiences. Thus, this research aims to establish a series of online 'Numeracy-Meets' for adult numeracy practitioners. These 'Meets' will be an organised but informal community of practice for practitioners to share pedagogy, practical innovations, and personal insights into teaching adult numeracy.

Keywords: Adult numeracy practitioners, needs analysis, professional development model.

Background to the Research

The development of a numerate society is an international and national priority in education. Governments, policymakers, and educators around the world have stated that numeracy is a capability that everyone needs to possess to meet the demands of everyday life (United Nations Sustainable Development Goals [UNSDG], https://sdgs.un.org/2030agenda). Numeracy skills are critically important for the adult population to allow individuals to meaningfully engage in society; to earn a good wage; and to protect their physical and mental wellbeing (Carpentieri, Litster, & Frumkin, 2010; Parsons & Bynner, 2005). Research shows that adults with higher competency in literacy, numeracy and problem solving in today's world tend to have better outcomes in attaining a job than their less-proficient peers (OECD, 2019). On the other hand, low numeracy levels amongst adults can contribute to intergenerational cycles of inequality and disadvantage in families (Carpentieri et al., 2013). For example, research has shown that adults who struggle with numeracy are more likely than others to have lower incomes, have trouble finding employment, and suffer from poorer physical and mental health (Carpentieri et al., 2010; Parsons & Bynner, 2005).

Thus, despite the clear and obvious need for adults to be proficient in numeracy, international studies suggest that many adults struggle in this area. In the UK, a study conducted by National Numeracy (2019) found that 56% of adults displayed numeracy skills which were the equivalent of that expected of a primary school child, while only a quarter of the adult population displayed levels of proficiency in the area of numeracy at or above the level of that expected of a 16-year-old. In addition to reports such as this, the Programme for the International Assessment of Adult Competencies [PIAAC] has also been used regularly by Governments and policy makers worldwide to determine adults' level of proficiency in the area of numeracy. This international assessment measures adults' skills and competencies in a number of different areas, including numeracy, and categorises their skills into one of six proficiency levels. When Ireland took part in PIAAC (2012), it revealed that over one quarter (25.3%) of adults in Ireland scored at or below Level 1 on the numeracy scale (OECD, 2013). This score ranked Ireland 19th out of 24 participating countries and suggested that 754,000 Irish people struggle with everyday maths and may be unable to do a simple maths calculation such as subtraction (NALA, 2017). In 2015, NALA undertook another analysis of the PIAAC data, this time focusing on the themes of skills in the workplace and social wellbeing. When it came to numeracy, the main findings showed that:

- Over half (60%) of the sample with numeracy at level 1 or lower were women.
- The average age of the respondents with level 1 or lower numeracy was 43 years.
- Almost half (49%) of the sample with level 1 or lower numeracy had lower secondary education or less.
- Almost one third (31%) of the sample with level 1 or lower numeracy had had no paid work in the last five years.

(NALA, 2017, pp. 15-16)

The most recent PIAAC study shows that, on average, across all 28 OECD counties surveyed, 22.7% of adults are performing at or below Level 1 (OECD, 2016). In essence, these adults are not capable of going beyond one-step processes in the area of numeracy nor are they capable of dealing with problem scenarios where the numeracy component is not wholly explicit.

In addition to the aforementioned low levels of proficiency in the area of numeracy, research also indicates that many adults also hold negative attitudes towards the domain. According to the work of Breen (2003) and Southwood (2011) fear is the emotion often reported by adults when confronted with numeracy tasks and it has a negative impact on their willingness to engage with numeracy and on their performance in the domain. Mathematics anxiety has been defined by Richardson and Suinn (1972) as "feelings of tension …that interfere with the manipulation of numbers and the solving of mathematical problems in a wide variety of ordinary life and academic situations" (p. 571). While Martinez and Martinez (1996) determine it to be a construct with multiple causes, many link its origins to negative classroom experiences from the past. Such experiences may include the use of traditional teaching methodologies, where mathematics involves the memorisation of formulas, and the following of rules and procedures (Idris, 2006; Prendergast et al., 2014). While there have been many changes to the teaching and learning of mainstream mathematics in recent years, Carpentieri et al. (2010) determine that in numeracy teaching it is sometimes easier to quantify "bad practice" than to define "good practice". According to Swain (2005), "bad" practice involves the teacher using a series of procedures, where the students learn by rote and without understanding. No connections are made to other areas of numeracy. With this in mind, and in line with the recommendations of Goos et al. (2021), there is much work to be done in relation to facilitating effective continuing professional development (CPD) for adult numeracy practitioners to help improve their practice. Effective and sustained provision is of huge importance, particularly for those practitioners who may be working in isolation in small centres and also those practitioners who may not have a background in the area.

CPD is also essential for bringing about the pedagogical transformation and educational culture change which is required for the effective implementation of innovative approaches (Bray & Tangney, 2017).

The Irish Context

In Ireland, adult numeracy provision is provided by the Education and Training Boards (ETBs) through their local adult literacy service. Each literacy service is organised by an adult literacy organiser (ALO), and numeracy tutors provide tuition on a one-to-one or group basis.

In addition to numeracy, the literacy service offers a range of programmes that include family learning, English to Speakers of Other Languages (ESOL), and workplace basic education. Goos et al. (2021) found that many adults are reluctant to admit their numeracy learning needs, and instead approach an ETB looking for courses in areas other than numeracy. However, once these adult participants develop confidence and comfort in the learning environment of the ETB, tutors and ETB staff are alert to opportunities for identifying their numeracy learning needs and directing them into integrated courses with a numeracy focus. The vast majority of adult learners engage in 'mainstream' tuition which consists of either one-to-one or group tuition, typically for two to four hours a week during the academic year.

Adult literacy services across the country design and deliver a wide range of programmes to meet the needs of adult learners. Some are accredited at levels 1 – 5 on the National Framework of Qualifications; others are non-accredited. The National Framework of Qualifications is a 10-level framework of standards for accreditation purposes. Levels 1 – 4 are of most relevance to those with basic skills needs and provide an opportunity for certification – often for the first time. Tuition is also available in a number of other education settings including community education, Youthreach, Community Training Centres, National Learning Network, probation projects, disability services and special schools

Research carried out by NALA (2013) found that over 60% of adult numeracy tutors reported that they did not have enough training in teaching numeracy to adults, and 15% reported that they had no training at all. More recently Goos et al. (2021) reported that adult numeracy provision in Ireland is predominantly dependent on part-time numeracy tutors. Only three ETBs had full-time staff members involved in adult numeracy. NALA (2015) developed a framework for meeting the professional development needs of tutors of adult numeracy in the Irish Further Education and Training sector. This framework recognises that tutors are also adult learners in the context of professional development. It recommends that professional development should be underpinned by a broad and dynamic view of numeracy that is internationally recognised. The framework also identifies important qualities and knowledge that adult numeracy tutors need to possess, including excellent understanding of elementary mathematics; digital literacy skills; and a view of mathematics as part of everyday life. Goos et al. (2021) recommended that ETBs should consider ways of supporting adult numeracy tutors to develop these qualities, and of making such opportunities accessible to tutors while avoiding costs to tutors in terms of time and financial commitment

The Study

It is imperative that if we are to meet the literacy and numeracy targets set out by UNSDG (https://sdgs.un.org/2030agenda), we must address the teaching of numeracy in adult education. This proposal seeks to address Goos et al.'s (2021) recommendation and explore ways of supporting adult numeracy practitioners. In doing so, it aims to work with the National Adult Literacy Agency (NALA) to help practitioners around Ireland in developing their skills in the teaching of numeracy to adult learners. In addition to this, another aim of this project is to create a network of expertise between partners in academia and NALA to support practitioners in fostering a positive and engaging environment for teaching numeracy within the adult education spectrum. NALA is an independent charity committed to making sure people with literacy and numeracy difficulties in Ireland can fully take part in society and have access to learning opportunities that meet their needs. They have a long track record in the provision of professional development opportunities for adult numeracy practitioners in Ireland and the researchers felt that the organisation's knowledge and networks in the area would be a very welcome addition to the project team.

Thus, this study aims to bring together expertise in the field of numeracy, teacher education, adult numeracy education and those delivering courses to adults enrolled in numeracy development programmes.

There are two main objectives to the research, namely to:

- Investigate the professional development and resource needs of adult numeracy practitioners in Ireland.
- Design, implement, and evaluate a professional development and networking model that addresses some of these needs.

Theoretical Framework – The Numeracy-Meet Model

We have termed the proposed professional development and networking model as a series of Numeracy-Meets. These are based on the TeachMeet model which was developed in Scotland in 2006 and mainly involved primary and secondary school teachers focusing on teaching strategies and classroom practices. According to Amond et al. (2018) a TeachMeet is "an event held after-hours between teachers to share practice and ideas, making short presentations and hosting conversations in a convivial and playful atmosphere." Bennett (2012) notes that TeachMeets usually last a couple of hours and are focused on teachers sharing ideas with one another based the things that they've used and found effective in their teaching. While the Meets take an informal structure, they do require some sort of facilitation to encourage participation and arrange the running order.

Although there is currently a dearth of research in this area, TeachMeets fulfil needs for CPD and communities of practice (CoP) (Amond et al., 2018; Amond et al., 2020). From an adult numeracy practitioner perspective, the TeachMeet model can meet many of the components of NALA's (2015) framework for developing the CPD needs of adult numeracy tutors. For example, the use of the TeachMeet model is accessible in terms to time and cost and can focus on understanding of elementary mathematics and viewing mathematics as part of everyday life. Thus, this study will adapt the TeachMeet model to suit the needs of adult numeracy practitioners in Ireland. It is proposed that each Numeracy-Meet will be structured around a theme, thereby allowing attendees to focus on one aspect of the broader concerns. In line with Charles (2021, p.3), our Numeracy-Meet model will be developed with the following goals:

- Create a means of communication around pedagogy
- Provide a forum for sharing of expertise and insights
- Create a pool of instructional resources and strategies
- Gain input in steering instruction and assessment
- Foster teamwork and enable networking

Proposed Methodology

There will be four stages to the study:

- Stage 1: Preplanning which includes the design of a research instrument for an online scoping survey in which practitioners can outline the types of professional development and resources necessary to improve their own teaching of numeracy. The design of this instrument is s currently underway, and it is anticipated that there will be three sections:
    - Section A will focus on practitioners understanding of numeracy and issues they identify around the teaching and learning of adult numeracy in Ireland.
    - Section B will involve a needs analysis in which practitioners can outline the types of professional development and resources necessary to improve their own teaching of numeracy.
    - Section C will seek to determine practitioners' perspectives on CoP and to ascertain any prior experience they have of engaging in such CoP and other CPD opportunities.

  The survey will be piloted with a group of five numeracy practitioners who will be invited to participate on the basis of the expertise they could bring to the research and the contemporary experiences they have in similar peer groups to the research participants.

- Stage 2: Needs Analysis to Guide the Design and Implementation of the Numeracy-Meet Model (January - February 2022). The research instrument will be circulated online through social media and existing networks (including a NALA mailing list of adult numeracy practitioners around Ireland who have signed up to be kept informed of their CPD offerings) to a sample of numeracy practitioners using a snowball sampling method. It is difficult to quantify the number of numeracy practitioners nationally and so a response rate will be difficult to quantify. The data gathered will provide an evidence base around the specific needs of adult numeracy practitioners and will guide the design and implementation of the Numeracy-Meet model.

- Stage 3: Implementation of six Numeracy-Meets (February - May 2022)
  It is anticipated that here will be six Numeracy-Meets hosted between January and June 2022 (one Numeracy-Meet per month). Potential areas of focus for each Numeracy-Meet will be guided by existing research and by the data from Stage 2 but a sample programme may include:
    1. Introduction to numeracy
    2. Family numeracy

3. Financial numeracy
4. Numeracy for health
5. Numeracy in a digital world
6. Overcoming mathematics anxiety

Each Numeracy-Meet will have a similar structure, with the exception of the Introductory Meet. It is envisaged that each Meet will be facilitated by an expert in mathematics/numeracy education who will open the Meet and share some ideas and resources about teaching a particular aspect of numeracy. Following this, the Meet will then involve active participation from adult numeracy practitioners who are in attendance. These practitioners will have volunteered to share their expertise and insights in advance of the Meet. Their involvement may see them sharing a resource that they found worked well or a teaching strategy that they found beneficial. Any lesson plans or resources discussed in the Meet will be collated and packaged by the project team and shared with all participants. As such, a folder of resources and plans would accompany each Numeracy-Meet. The Meet will conclude with participants completing out a brief online evaluation.

- Stage 4: Evaluation of Numeracy-Meets (February - June 2022)
  In parallel with Stage 3, Stage 4 will focus on the evaluation of the Numeracy-Meets. This evaluation will adopt a mixed methods research approach and as such will yield both qualitative and quantitative data. As mentioned, on completion of each of the six Numeracy Meets, participating practitioners will be asked to complete a brief online evaluation. This evaluation will allow practitioners to respond to the material shared during the Meet, outline what they feel they gained from the Meet and offer suggestions for future Meets. All evaluations will be anonymous to encourage participants to be honest in their responses and the project team will use the feedback to shape future Meets and to inform the overall evaluation of the project. Furthermore, once all six Numeracy-Meets have taken place, numeracy practitioners who attended two or more of these events will be invited to participate in a focus group which will be facilitated by the project team. The focus group will be used to ascertain practitioners' insights into their perceived effectiveness of the project and the future sustainability of such a community of practice among numeracy practitioners.

Conclusion

As recommended by Goos et al. (2021), professional development for adult numeracy practitioners needs to be widely promoted and accessible and involve practitioners in sharing their practice as well as learning new teaching approaches. It should be coordinated with the aim of establishing CoP of adult numeracy tutors while raising the profile of adult numeracy provision. The Numeracy-Meet model proposed in this study will specifically address this recommendation and offer a structure to CPD activities which are informal and led by adult numeracy practitioners. It is also anticipated that it will create a network of expertise between partners in academia and NALA to support practitioners in fostering a positive and engaging environment for teaching numeracy within the adult education spectrum in Ireland.

Changing perceptions among adult learners (19+) in further education studying GCSE mathematics:

Methodology and data analysis - the importance of the pilot

Jennifer M. Stacey

Sheffield Hallam University, United Kingdom; a0025098@my.shu.ac.uk

A Doctorate in Education in the UK generally involves four modules prior to the thesis phase. Two of the modules are focussed on the pilot study, the first on the methodological rationale, and the last on the analysis of the data collected. Although this process can be seen by post graduate researchers as a delay to the actual data collection, it can be highly informative and make a substantial contribution to the thesis. In this example, the efficacy of a questionnaire, developed from the Abbreviated Maths Anxiety Scale (AMAS) (Hopko, Mahadevan, Bare, & Hunt, 2019), was tested with adults studying GCSE mathematics, whilst developing an understanding of action research, insider research and thematic analysis.

Keywords: GCSE mathematics, further education, pilot study, perceptions, math anxiety.

Introduction

Adult learners studying GCSE mathematics in a Further Education (FE) college, whilst being highly motivated to re-engage with the classes, often due to extrinsic motivations such as career changes, can present with a degree of anxiety about either mathematics, or examinations, or both. It is unknown whether for these learners' mathematics and exam anxiety are linked, if the levels change during the courses, and if confidence, or lack of it, impacts on exam results.

The prevalence of mathematics and exam anxiety is becoming increasingly well documented. Recent research funded by the Nuffield Foundation (Nuffield Foundation, 2018) includes two studies, one on GCSE resits mathematics for 16- to 18-year-olds (Hough, Solomon, Dickinson, & Gough, 2018), and one on mathematics anxiety in pupils at Primary and Secondary schools (Szucs, McLellan, & Dowker, 2017). Research also exists which has analysed the experiences of traditional pathway students in Higher Education (Evans J., 2000). However, few studies exist which consider the effects of previous experiences in mathematics classrooms on non-traditional adult learners returning to education after a break or map the attitudes of those adults towards mathematics or examinations.

The pilot study mapped confidence levels for both mathematics and examinations against exam results for a small group of adults (n=18), to evaluate for a correlation between confidence and success. It might seem that it is likely that more anxious learners are less likely to succeed, but not all research supports this view (Mandler & Sarason, 1952; Tavani & Losh, 2019). There also seems to be a lack of clarification around whether mathematics or exam confidence, or both, are linked to exam success.

The research design for the pilot study was a mix of quantitative and qualitative methods, to gain a broad understanding of the experiences of adult learners (Clough & Nutbrown, 2007). A modified 'Abbreviated Mathematics Anxiety Survey' (AMAS) (Hopko, Mahadevan, Bare, & Hunt, 2019), a tried and tested survey in the public domain, was revised to change the labelling of the scale to include confidence, rather than just anxiety, and to gather comments from learners. It was re-named it MECS (Mathematics and Examinations Confidence Scale) to differentiate it from the original. Learners were surveyed in April, after curriculum input and as learners move into the revision phase, using the questionnaire.

Questionnaire responses were matched to examination results, to evaluate for a correlation between confidence levels of both mathematics and examinations against outcomes. This analysis is presented on scatter graphs, and expanded into gender, nationality, and age comparisons.

The doctoral thesis of which this pilot study forms a part aspires to make an original contribution to the understanding of factors in mathematics delivery for adults in the UK, which may differ from their experience in previous educational settings.

Summary of research questions

The main research questions are:

- Do courses in FE colleges change adult learners' perceptions of GCSE mathematics and/or examinations and, if so, how, and why?
- Is a relatively high confidence level necessary for exam success?
- Are more anxious students less likely to pass?
- The research questions for the pilot study are:
- Does the MECS questionnaire give sufficient information to formulate answers to these questions?
- Did participants find it easy to understand and use?
- Is an analysis by themes helpful for understanding the data collected?

Methodology and methods of the pilot study

Action Research

Action research is the phrase used to describe research, which is conducted by practitioners in the field, linking research to practice (Burgess, Sieminski, & Arthur, 2006; Munn-Giddings, 2017). It can often be linked to an intervention, which is designed to improve practice for teachers, or outcomes for students, or both (Wilson, 2017; Munn-Giddings, 2017; McNiff, 2016). The project aspires to both describe the experiences of adults returning to mathematics classes, and work towards interventions that could improve outcomes for learners, either at a micro or macro level, i.e., either for a learner, a particular classroom, adult learners in FE colleges, or even to the wider mathematics educators' community (Creswell, 2012).

In addition to describing this pilot study as action research, it can also be described as participatory action research, as participants are involved in the research process. This is because, in addition to collecting data, some participants have been asked to evaluate the questionnaire (Munn-Giddings, 2017, p. 72; Cohen, Manion, & Morrison, 2018).

Mixed Methods

A mixed method approach was chosen to allow for some 'triangulation' of data, as it can be cross referenced to show reliability of the findings (Maguire, 2019; Cohen, Manion, & Morrison, 2000). Cross referencing refers to using more than one method to collect data (Mason, 2018; McNiff, 2016), or by using more than one set of people (McNiff, 2016). In the pilot study both quantitative and qualitative data have been collected in the questionnaire.

There is an issue with a mixed method study, that it may be seen as pseudo-scientific, blurring the demarcation line between positivist and interpretivist approaches, and making the research sound more scientific than may be justified (Cohen, Manion, & Morrison, 2018; Mason, 2018).

The Survey Method: A questionnaire

The method for data collection tested in the pilot was a questionnaire, because in the mathematics education field the Abbreviated Mathematics Anxiety Scale is often mentioned in research, and has been adapted in many ways, including for use with younger children (Hopko, Mahadevan, Bare, & Hunt, 2019; Psychological Toolkit, 2018). Adapting an existing survey both adds academic weight to the main study, as it is tried and tested by other researchers, and avoids the major challenge of constructing and testing a survey from scratch (Wilson, 2017; McNiff, 2016).

Questionnaires can generate a lot of data quickly, as they are generally easy to complete, can include both quantitative and qualitative questions, and responses can be easily anonymised (Clough & Nutbrown, 2007; Cohen, Manion, & Morrison, 2018). The pilot study evaluated the questionnaire to see whether the participants could respond positively, neutrally, or negatively to the questions posed, and whether patterns emerged, even though there was a small sample size (Taber, 2017; Cohen, Manion, & Morrison, 2018).

The disadvantages of a questionnaire include that the information they generate might be quite superficial, as respondents will not necessarily answer thoughtfully and accurately, and that there is little or no opportunity for the researcher to follow up on comments, unless permission for contact has been included in the questionnaire (Cohen, Manion, & Morrison, 2000; Clough & Nutbrown, 2007)

One of the significant changes made to the AMAS questionnaire was to alter the Likert Scale (Hopko, Mahadevan, Bare, & Hunt, 2019). The original uses the word 'anxiety' throughout, as students are asked to grade themselves in the following way:

1 Low anxiety, 2 Some anxiety, 3 Moderate anxiety, 4 Quite a bit of anxiety, and 5 High anxiety.

This was altered to:

1 Very confident, 2 Confident, 3 Neutral- neither confident nor anxious, 4 Anxious, and 5 Very anxious

This was altered to moderate the potential for a presumption for anxiety. The original survey could be interpreted as leading the students to an expectation of an answer, an outcome that should be avoided, as it can lack objectivity (Burgess, Sieminski, & Arthur, 2006; Sfard, 2013; Wilson, 2017).

In extreme examples the questions "can influence respondents and alert them to ideas they had not thought about before" (McNiff, 2016, p. 184).

The second change was to include comment lines, to allow learners to add to their numerical response, which changed the questionnaire into a mix of quantitative and qualitative data and canvassed opinions on the statements. An 'any other comments' section at the end of the questionnaire was also included, to enable participants to share other issues or thoughts.

Other minor adaptations introduced were to change the American language to a more UK version of English, and to add one additional question, to ask how confident learners would feel taking any other, non-mathematics exam. This was to try to evaluate whether it is all examinations that students feel anxious about, or specifically exams in mathematics.

Sampling

Opinions on sample sizes for pilot studies can be very divided, with some sources saying that a few respondents would be enough (Burgess, Sieminski, & Arthur, 2006), but other sources specifying a minimum of 30 (Cohen, Manion, & Morrison, 2000). In this pilot study the number of participants was eighteen (n=18).

The sample for the pilot study was drawn from one FE college, so may be unrepresentative of the total population of adults studying in colleges and could also be seen to be biased (Burgess, Sieminski, & Arthur, 2006; Oates, 2006), as the learners may have modified their answers knowing that their 'teacher as researcher' was going to see them. This is described as the halo effect in Cohen et al (2018), but as the pilot study tested the format of the questionnaire, rather than used the data, it has still given a useful insight on whether the questionnaire is acceptable to participants.

There was also no attempt to gain a representative sample from the classes, such as a mix of those who might be confident or anxious, or a mix of gender, ages, or nationalities (Oates, 2006). Participation by learners was voluntary and on an opt in basis.

Data Analysis: chosen method and analysis

Thematic Analysis

In this pilot study a mix of quantitative and qualitative data has been collected in a mixed method study. Thematic analysis seems to be a suitable theoretical framework for data analysis and interpretation, as it is a flexible approach which can encompass both types of data (Nowell, Norris, White, & Moules, 2017; Braun & Clarke, 2013). It can also reflect the complexity of the data, as use of several different perspectives or data sources can be shown in the codes, and these can be used to support and illustrate the themes, and to triangulate the data (Creswell, 2012; Cohen, Manion, & Morrison, 2018).

The pilot study data analysis looked for patterns in the data around themes, such as course content and examinations, and learner characteristics such as age, gender, and nationality, to see if this way of analysing yielded useful insights and added to understanding, if only to the complexity of educational research.

Research Findings

The total score for each participant from the questionnaire was used in a number of scatter graphs to compare confidence levels with exam results; the decision to use these in the analysis was based on the need to test whether they would be a useful way to display the two forms of primary data in a single format (Burgess, Sieminski, & Arthur, 2006; Spiegelhalter, 2019). Scatter graphs are a statistical representation designed to show comparisons between two variables, which could have an appeal to wider audiences (Creswell, 2012; Thomas, 2013). In scatter graphs it is possible to see if patterns emerge, and if correlations exist between data sets (Braun & Clarke, 2013; Evans M., 2017). The numbers involved in the pilot study means that it was a small data set, and no conclusions can be drawn on the content, but the use of scatter graphs has been explored in this pilot study.

Four scatter graphs were constructed. The first two illustrated the very broad themes of confidence and anxiety compared to exam performance but contrasted the use of grades and scores. In these two graphs the slope of the trend line was virtually identical, which relieves a practical challenge for the research, as scores will be more difficult to capture than grades, as learners only receive grades. There is a further benefit as colleges that agree to participate in the main study are likely to use different exam boards with unique marking structures for grades, so scores would not be a viable method of comparison.

There was a slight correlation between the level of confidence and the outcome of the exams. This could indicate that there was a causal relationship between anxiety and success, and more anxious learners were less likely to pass (Spiegelhalter, 2019; Creswell, 2012). However, the slope of the trend line, (also known as a line of best fit, or regression line), and even its aspect, varied depending on which part of the group is investigated, which illustrates the importance of examining data by different themes, to enhance its validity (Cohen, Manion, & Morrison, 2018; Creswell, 2012).

Further scatter graphs illustrated analytical differences in gender and age, two themes identified as present in existing literature on the subject. When males are selected from the participants, there is a stronger relationship between levels of confidence and success in the exam, which means for females the correlation is weaker. However, if females are examined as a group, there are some clear examples of participants who are very anxious and high achievers, who could be seen as outliers. In this small sample size, it is not possible to draw any conclusions from this, but it does confirm the important of collecting the gender of participants for investigation and confirms the use of gender as a theme.

When participants under the average age were selected, the aspect of the trend line changed so that now more anxious students were more likely to pass; this could reflect the need for a certain amount of anxiety to maximise performance (Yerkes & Dodson, 1908), but it was unexpected, and shows the advantage interrogating data thoroughly using thematic analysis to ensure its validity (Nowell, Norris, White, & Moules, 2017). It also probably shows the danger of drawing inferences from small samples (Cohen, Manion, & Morrison, 2018; Creswell, 2012).

In addition to organising this data into themes, other calculations have taken place, such as enumeration of the range used on the Likert scale. One concern was that participants might be unlikely to use the full range of a Likert scale, as most would use 2, 3 or 4, if the scale is 1 to 5, and avoid the extremities (Cohen, Manion, & Morrison, 2018). This was tested in the pilot study and participants had no problem with using the full range of the scale, indicating that they had no problem with deciding how strongly or otherwise they felt about the content. This may reflect the strength of feeling there is about mathematics generally, either positively or negatively. The use of a Likert scale allowed for the data to be analysed in several different ways, such as by ranking the questions from most confident to most anxious, which could yield different insights and understanding.

Over half of the twenty respondents used the comments sections, and on average each person commented on approximately half of the questions.

Learners involved in the review confirmed that they felt the AMAS document was leading, in terms of anxiety, and that they preferred the MECS questionnaire. When asked about the use of questionnaires in general, they felt that the intervention had been beneficial, as it implied that it was 'okay to be anxious', that it was normal for the whole class and thus acceptable. The survey took around 5 to 10 minutes to complete, which was not too demanding on peoples' time and energy. The small group review of the AMAS vs MECS questionnaires took approximately 20 minutes.

Conclusions

To repeat, the research questions for the pilot study are: Does the MECS questionnaire give sufficient information to formulate answers to these questions? Did the learners find it easy to understand and use? Is thematic analysis a useful approach for data analysis?

The current MECS questionnaire seems to have worked well, as it covered assessment in various forms, classroom dynamics, and course content such as number work and algebra, and the language used in it seems to have been understood by the participants.

There were no negative comments from learners about the language used, or the time taken. The participants completed the questionnaire in different ways, some using the numbered scale, and some the words attached to the numbers, which demonstrated a useful flexibility.

Thematic analysis as a framework to organise, interrogate and interpret the information seems to be a useful method, both for the insights it could yield, and for the accessibility of the data in subsequent presentations.

The contribution of the pilot study to the final project and subsequent thesis is clearly substantial. The interrogation of the content and process of implementation of the questionnaire used in the pilot study, and the development of themes and codes, have all made significant contributions towards an understanding of the research issues, which will be highly beneficial for the main study. It could also lead to an expansion of the data, "to formulate new questions and levels of interpretation" (Coffey & Atkinson, 1996, p. 30; Gibbs, 2017), leading to the generation of new theories to explain phenomena in mathematics education for adults.

Introduction

The work of the Thematic Working Group 8 (TWG08) "Affect and the teaching and learning of mathematics" started with a revision of the call for papers in 2019. The call for papers included theoretical, methodological and empirical fields of research on affective constructs for students and teachers. Because of the variety of affective constructs, we could point out in the call only few examples of affective constructs in the area of beliefs, attitudes, emotions and motivation. Spreading of the COVID pandemic all over the world affected our preparation for the CERME 12 conference, which was moved from February 2021 to February 2022. In order to make the communication on affect possible, we followed the call of the program committee to offer a short virtual meeting on affect in the framework of the virtual CERME in 2021. In this virtual meeting, we presented an overview of research on affect and discussed urgent questions for mathematics education (e.g. What is the impact of COVID pandemic on research in affect?) and questions of importance for research on affect (e.g. Do emotions and motivation affect performance in mathematics?) in small groups and in the whole group. We continued with the preparation of the group's work for CERME 12, which was eventually held as a virtual conference. In this chapter, we would like to introduce our work in TWG08, discussions on affect in teaching and learning of mathematics and new developments in the field.

The sound number of submissions and participants confirmed the long-term interest of researchers in affect-related research in mathematics education. In total, 26 papers and 4 posters were submitted to our group and 24 papers and 3 posters were accepted for presentation. Of the presented studies, 23 papers and 3 posters were accepted for publication in the conference proceedings. In addition to the different European countries, our group included presentations from Australia, Canada, Israel and the United States of America. Researchers from 13 countries participated in the work of our group. Many newcomers joined the group, indicating that interest in research in the area of affect is constantly increasing.

We started our work with an ice-breaking activity. Each participant talked about his country and topic of research interest to the audience. After the ice-breaking activity, a reflection of the prior work done in CERME conferences was presented in the whole group and open questions in research on affect were discussed in breakout rooms. Following a tradition of the TWG08 group regarding importance of small group discussions for scientific activities, we scheduled a considerable amount of time for this type of work in following sessions. The contributions in each session were assigned to the topics beliefs, attitudes, motivation, emotions or other affective constructs. After a short presentation (3 – 5 slides, 5 min) and clarifying questions (3 min) for each paper in a session, we assigned participants to breakout rooms with 4 – 6 participants. In order to structure the small group work and to support the content of the discussions, at least one co-leader and one of the authors joined each group. Each small group could decide which of the presented papers or posters they would like to discuss with the author(s) and other group members (25 – 40 min). In the last 10 minutes of each session, we shared our thoughts about the topics of discussions with the whole group. In the last session, we presented a synopsis of the small and whole group discussion, which were again discussed in breakout rooms. At the end, we reminded participants on the importance of revisions of contributions in the final phase of the revision process.

Reflection on prior research in affect

Inés Gómez-Chacón presented an overview of the work that has been done in the past conferences in TWG08. An essential part of the overview was presenting the changes in research on affective concepts over the past 15 years. A part of the overview was included in the final report about the work of TWG 8 that was videotaped by Çiğdem Haser and Stanislaw Schukajlow.

A review paper by McLeod (1992) serves, usually, as the starting point for systematic research on affect in mathematics education. According to this taxonomy, research on affect can be assigned to one of the three major categories: beliefs, attitudes or emotions. In McLeod's framework, beliefs are the most stable in time, less intense and most cognitive. On the opposite side of the range, McLeod posed emotions, which are considered as less stable in time, most affective and less cognitive. Attitudes are situated between beliefs and emotions regarding temporal stability, affect and cognition.

In the last decades, researchers elaborated repeatedly on the taxonomy of affect proposed by McLeod. One influential model was proposed by Hannula (2011) in CERME 7. He analysed research in mathematics education and suggested distinguishing between cognitive, motivational and affective dimensions, unstable states and stable traits as well as social, psychological or physiological dimensions of affect.

Another possibility to think about affect is to distinguish between three characteristics: object of the affect (e.g., mathematics, problem solving or strategy use), subject (e.g., teacher, students or policy maker) or valence (positive, negative or neutral; Schukajlow, Rakoczy, & Pekrun, 2017). Further, the theoretical approach, such as acquisitionist or participationist, can be considered of importance for research on affect. A strong interdependence of affective constructs is another essential characteristic of affect. In research on beliefs, these interdependencies are reflected in the emphasis of the so-called beliefs system. A strong interdependence of affective constructs is another essential characteristic of affect. An affective system includes different affect components that are closely related to each other. Changes in one component of affect system result in changes in other components and vice versa. For example, increasing interest in mathematics may positively affect enjoyment and negatively boredom. A holistic view on the affect system might be important for getting a comprehensive view on affect and its development in students and teachers. This research perspective calls for using multidimensional approach to affect and applying different methods (e.g. qualitative, quantitative and mixed methods).

In the past, we observed growing attention to the clarification of concepts that were used in research on affect. As many affective constructs are defined as complex phenomena, different affective constructs revealed a conceptual overlapping in some parts. For example, emotions include a part of physiological, affective and expressive components, and also cognitive and motivational parts. Therefore, an emotion can overlap with motivational constructs, such as interest or self-efficacy beliefs, on the theoretical level.

A relationship between different affective constructs and cognitive outcomes, such as achievement related choices and performance, was another topic of high interest in the past. Prevalent questions were: (a) What affective reactions can be observed during learning of mathematics? and (b) Whether changes in students' emotions, motivation, beliefs or attitudes are related to students' learning and learning outcomes. The underlying theme of research was often an idea that improving students' affect will increase motivation, positive emotions, growing mindset or positive attitude.

Contributions in the TWG08

Now we would like to present the papers and posters that are published in the proceeding. Andrà et al. found out that mathematical views of undergraduate mathematics students are related to achievement and preferences for different teachers' lesson types. Haser analysed students' beliefs about problem posing and their place in mathematics-related belief systems. The poster by Brunetto and colleagues presented a methodology for clustering students' mathematical views. Vankúš at al. reviewed in their poster the methodology used in the research in affective domain.

Schukajlow and Rellensmann analysed a relationship between motivational components (self-efficacy, value, and cost) and gender. Krawitz and Hartman investigated preservice teachers' interest and self-efficacy while posing problems to descriptions of real world situations. Developing and validating survey instruments for assessing beliefs and motivation in mathematics were presented by Pedersen and Haavold. Capone and Lepore analysed engagement, motivation and participation of undergraduate students during Covid pandemic. Pan et al. were interested in indications of students' wellbeing in terms of primary students' values.

Sumpter et al. investigated gendered self-evaluation in mathematics. Herset and Ghami presented an experimental study on difficulty level marking in mathematics tasks. Biton at al. analysed students' perceptions of mathematics learning environment in a virtual communication messenger. Stereotypes in a polarized world and their relation to mathematical identity were the focus of the study by Kaspersen and Gjøvik.

Vasilopoulou and Triantafillou presented students' perspectives on inclusion and peer-collaboration. Zakariya et al. analysed the relations between attitudes, prior knowledge, self-efficacy and grades in mathematics. Kourti and Potari identified and analysed pivotal teaching moments of emerging emotions during decision making. Weber et al. investigated a development of mathematical anxiety of prospective elementary teachers. Holm explored mathematical stories of future elementary teachers and shifts in affect in mathematics. Viola and Gambini presented an analysis of cooperative group work in game theory activities. Analysis of attitudes of women and racially/ethnically minoritized students was presented by Uysal and Clark. Viitala carried out a case study on teacher identity and long-term professional development.

Báró studied changes in affect due to problem posing in Hungary and Romania. Pierri explored engagement and affect in the context of storytelling. Liljedahl analysed social persuasion through a teacher’s actions in a mathematics classroom. Courtney et al. investigated teacher’s understanding of mathematics in a remedial course and the role of affect in the process of understanding.

Evolution of the TWG

This year many passionate young researchers joined the group. The number of contributions addressed similar topics as in the past conferences (e.g., self-efficacy expectations). Some new topics, such as mathematical well-being and stereotypes, and a new group of research subjects, such as marginalized students, were addressed in CERME 12. More studies focused on the relationships between affect and cognition. New theoretical approaches emerged in the group. Some examples of these approaches are dual process theory, value-fulfillment theory, activity theory, positioning theory or model of problem posing. New measurement instruments were developed and analysed by using sophisticated qualitative and quantitative methods. In several contributions, researchers addressed gender studies and derived implications for research on affect. Different objects of affect in varied contexts, of very different sorts, were presented in the group. Some examples of these objects are drawing strategy, level marking, social media, pivotal teaching moments, intelligent tutoring systems, and digital interactive storytelling.

During our final discussion, we summarized directions for future research. One example was expanding the view on affective variables and see them (a) as independent constructs that can be manipulated in order to increase performance, (b) as dependent variables that can be affected by, for instance, different teaching methods, (c) as mediation variables that can transmit the effects of teaching methods on cognition, and (d) as moderating variables that affect the effects of teaching methods on cognition. Furthermore, we call for more research on linking affect to cognition, more attention to theorising and embodiment, more focus on equity, more longitudinal and comparative studies and stronger focus on cross-domain research.

We investigate the mathematical views of a sample of undergraduate mathematics students in their third year of studies, namely during the semester that precedes the Bachelor degree. We collected data about the students' mathematical views, their personal information and academic achievement, analysing the relationships among them. We also study mathematical views' influence on the appreciation of different aspects of teaching. Finally, we investigate the extent to which undergraduate studies can change a student's view of mathematics. Data are collected by means of multiple-choice demographic questions and Likert-scale affective questions. Results reveal that different views have an impact on third-year undergraduate mathematics students' achievement, as well as on the preference for more transmissive formats of the lesson, or more participative ones, based on different mathematical views.

Keywords: Beliefs, cluster analysis, gender, mathematical views, postsecondary education.

Introduction

There is an increasing number of studies on the crucial role of demographic and affective variables in tertiary mathematics learning. Gender is an example for demographic variables, especially for the *clichè* for female students of being more diligent, as this has an impact on their learning strategies and examination success (Griese, 2018). The students' views of mathematics is an example for affective variables. Roesken, Hannula and Pehkonen (2011) maintain that mathematical views comprise beliefs, wants and feelings. The authors also argue about the key role of different school backgrounds, different math curricula and different views and expectations towards mathematics in undergraduate students. To this regard, Daskalogianni and Simpson (2001) note that some beliefs, developed during school days, are carried forward in university, and this may cause difficulties. Liebendoerfer and Schukajlow (2017) consider undergraduate students' mathematics-related beliefs with respect to the nature of mathematics during the first year of undergraduate studies, and find out that different views of mathematics, hold by the students at the beginning of their studies, predict different interest towards mathematics at the end of the first and the second terms.

Many researches, like the aforementioned ones, focus on the first year of undergraduate studies and highlight difficulties in the secondary-tertiary transition. We, instead, focus on the effects of mathematical view at the end of undergraduate studies, to examine possible changes with respect to the first days at university. We firstly recall the theoretical background of our research.

Theoretical framework

Beliefs are propositions about a certain topic that are regarded as true (Philipp, 2007), and tend to form clusters as they “always come in sets or groups, never in complete independence of one another” (Green, 1971, p. 41). For this reason, according to Grigutsch, Raatz & Törner (1998), beliefs can be seen as “world views”, outlining four different views: a *process-oriented* one that represents mathematics as a creative activity consisting of solving problems using different and individual ways; an *application-oriented* view that represents the utility of mathematics for real world problems as the main aspect of the nature of mathematics; a *formalist* view that represents mathematics as characterized by a strongly logical and formal structure; a *schema-oriented* view that represents mathematics as a set of calculation rules and procedures to apply for routine tasks.

Di Martino and Gregorio (2019) underline that mathematical views have an impact on an undergraduate student’s choices and can prevent one to enroll in an undergraduate course only because there is some mathematics in it. Di Martino and Gregorio (2019) observe that also undergraduate *mathematics* students may face difficulties and they may develop different mathematical views that, likewise any student, may prompt them to make certain choices in place of other ones. On these premises, our research aims at answering the following four research questions. RQ1: Is there a relationship between undergraduate mathematics students’ demographic variables, such as gender or school type, and their mathematical views? RQ2: Is there an effect of university studies on mathematical views? RQ3: Are there differences in students’ academic achievement, such as the exam grade, with respect to their mathematical views? RQ4: Does the students’ appreciation of how they are taught mathematics at university differ based on their mathematical views?

Answering to RQ1 would allow us to shed some light on the origin of different mathematical views, while answering to RQ2 would allow us to understand if and how three years of undergraduate studies in mathematics can change one’s view. Answering to RQ3 and RQ4, indeed, would allow us to examine whether low- and high-achieving students tend to hold specific, yet different, world views, and the relations between such views and the aspects of teaching they mostly appreciate.

Methodology

The aim of the study is to examine the effects of undergraduate studies on students’ mathematical views, in particular the achievement at the end of their studies. Hence, the participants are 93 students enrolled *in the third (and last) year* of undergraduate studies in mathematics at the University of Torino. This sample represents 37.8% of the entire population of 246 students enrolled in the third year. They participated on a voluntary basis and have been contacted via email, proposing to participate in an anonymous online survey, in May 2021. The analyzed sample is composed of 86 responses, because 7 are incomplete data.

The investigation of the mathematical views played a central role. The main idea is to figure out whether there is any correlation between affective and cognitive variables, expecially between beliefs and the students’ ways of relating, in practice, to mathematics (i.e., passing exams, achieving good results, being satisfied with one's own choice of the curriculum, etcetera). To collect data on students’ mathematical views, we translate into Italian a 5-points Likert-scale questionnaire developed by Erens and Eichler (2019), who design a set of 24 statements concerning the nature of mathematics based on the model proposed by Grigutsch et al. (1998). Each statement is assigned to one mathematical view. Examples of statements are: “the ideas of mathematics are of general and fundamental use to society” (A); “mathematics is a logically coherent edifice free of contradiction consisting of precisely defined terms and statements which can unequivocally be proven” (F) “there is usually more than one way to solve a task or problem in mathematics” (P), and “Mathematics consists of memorising, recalling and applying procedures” (S).

Students have been clustered with respect to mathematical views through a network analysis technique that is called *community detection* (Brunetto, Tassone and Cravero, submitted). Briefly, a network with students as nodes (i.e., with 86 nodes) has been created, and a link has been established among two nodes (i.e., two students) if both agree to the same statement concerning a mathematical view. We, thus, identified the clusters of students who are, as nodes, the most connected to each other if compared to the entire network. Four clusters have been identified and each cluster has been further characterized based on the student information collected in the survey (such as the gender, so that a cluster can have a majority of males and another one a majority of females, for example).

In order to answer RQ1, the participants were asked to declare their gender (with the possibility of choosing to not declare it), and to indicate their high school type. To this respect, in the Italian high school system there is a school type that has a strong scientific and mathematical curriculum, and usually the huge majority of undergraduate students in mathematics attended it. However, there are significant differences in the extent and depth of mathematics learning that depend on the individual teacher in each school (Lombardo, 2015), hence it makes sense to investigate the views developed by individual students even if they attended the same school type. We computed the percentages of males and females in each group defined by a specific mathematical view. Similarly, we computed the percentages of students coming from the school type with a strong mathematical background.

In order to answer RQ2, we created four 5-points Likert-scale questions and asked the participants to rate their agreement about: (a) during the undergraduate studies, one has discovered -in a positive sense- aspects of mathematics that she did not imagined before; (b) during the undergraduate studies, one has been disappointed by the way mathematics has been taught; (c) one has significantly changed her beliefs about mathematics; (d) the undergraduate studies have confirmed the view of mathematics one had when she was a freshman. We compared the averages of answers (from 1 to 5) to each question in each cluster of views of mathematics, considering an average of 3 as being neutral, an average lower (higher) than 3 as discordance (accordance) for the cluster.

In order to answer RQ3, the participants were asked to self-declare their average score at exams, because the questionnaire was anonymous, and it was not possible to recollect student data from the university official database. We computed for each group of mathematical views the percentages of students with average scores falling into one of the intervals considered “low”, “medium”, “medium high” and “excellent” in the Italian university system.

In order to answer RQ4, we borrowed the questions to be asked from a National survey on undergraduate students’ appreciation of various aspects of teaching and assessment. The questionnaire is made of four 5-points Likert-scale. We also created a series of Likert-scale questions on the distance teaching experienced during the pandemic (March 2020 - June 2021). For each mathematical view, we compared the average of answers at each question, considering an average of 3 as the group being neutral with respect to a particular aspect, an average lower than 3 as disaccordance (and we distinguished different degrees of discordance), and an average higher than 3 as accordance (at various degrees).

Results

We refer to Brunetto et al. (submitted) for more details about how the students have been associated with a mathematical view. In short, the community detection algorithm makes out 4 clusters:

- 28 students have a predominately schema-oriented view (labeled S in the following).
- 21 ones have a primarily process-oriented and a secondarily application-oriented (P-a) view.
- 20 ones hold a primarily formalist and a secondarily application-oriented (F-a) view.
- 17 students show an application-oriented (A) view.

From these data, we can see that students sorted themselves almost equally in four groups with respect to mathematical views. Having identified the clusters, the presentation of results is organized in four parts, each of one dedicated to answer one of the aforementioned research questions.

RQ1: *Is there a relationship between undergraduate mathematics students' demographic variables and their mathematical views?* Within the sample of 86 respondents, 3 students selected "other/I prefer not to reveal my gender". Table 1 shows the distribution of gender in the overall sample and within each group of students identified with the same mathematical view.

Table 1: Distribution of gender in the sample of respondents

	Overall sample	**S view**	**F-a view**	**P-a view**	**A view**
Male	35%	26%	32%	38%	53%
Female	65%	74%	68%	62%	47%

Looking at Figure 1, we infer that 29 (35%) respondents are male and 54 (65%) are female. We also notice that in cluster S there is a higher percentage (74%) of female students compared to the percentage of females (65%) in the entire sample of interviewees. Conversely, there is a significantly higher percentage (53%) of males in cluster A, compared to the distribution of gender in the entire sample of valid responses. Percentages of males and females in clusters P-a and F-a mirror the entire sample's ones with respect to gender.

As regards the secondary school type, we notice that over 75% of students come from the type of school that has a strong mathematical curriculum. Furthermore, this subsample shows to divide itself almost equally in the four groups identified for the mathematical views, but a slightly higher percentage belongs to the group of those who hold a P-a one. In the group S,, 50% of students come from secondary school types where the level of mathematics is lower, while in the other 3 groups the percentage of this kind of students resembles the general one (i.e., 25%).

RQ2: *Is there an effect of university studies on mathematical views?* Looking at Table 2, we can see that students in cluster F-a discovered positive aspects of mathematics even more than the entire sample, for which the average is high, anyway (4.5 points over 5). Only S students are less in agreement with this statement. P-a students are the most in disagreement with the statement that it was disappointing to be taught in the way it has been during the undergraduate courses. All clusters agree that beliefs about mathematics change during undergraduate studies, and all students except P-a cluster disagree that "the undergraduate studies have confirmed the view of mathematics they had when they were freshmen".

Table 2: Averages of agreement to each item in the entire sample and in each cluster. Only in case of significant difference with respect to the entire sample, the cluster average is reported

Statement	**Entire sample**	**Cluster A**	**Cluster F-a**	**Cluster P-a**	**Cluster S**
During the undergraduate studies, aspects of mathematics, which have not been imagined before, have been discovered in a positive sense	4.5	same of entire sample	**4.75**	same of entire sample	**3.9**
During the undergraduate studies, the way mathematics has been taught was disappointing	2.5	same of entire sample	same of entire sample	**2**	same of entire sample
My beliefs about mathematics has greatly changed during the undergraduate studies	4	same of entire sample	same of entire sample	same of entire sample	same of entire sample
The undergraduate studies have confirmed the view of mathematics they had when they were freshmen	2.7	**2.5**	**2.5**	**3**	**2**

RQ3: *Are there differences in the undergraduate mathematics students' achievement with respect to their mathematical views?* In the Italian university system, exam pass scores range from 18 (sufficient) to 30 (excellent). Scores between 18 and 20 are considered low achieving, the range 21-24 is considered medium, 25-28 medium-high and 29-30 excellent. The sample average score is summarised in Table 3. From it, we can see that the percentage of excellent students in the A group (30%) is higher than the one computed in the general sample (18%), and that the majority of excellent students tend to hold a process-oriented view. In this group, also the percentage of medium-average students (23%) is lower if compared to the general sample (40%). No excellent student belongs to the S group and the percentage of those who have a medium score average (60%) is higher if compared with the general sample (40%). F group's percentages mirror the general sample's one. These observations lead us to conclude that there are differences in the undergraduate mathematics students' scores at exams with respect to mathematical views.

Table 3: Average scores at exams and mathematical views. The percentages in brackets refer to each total reported in the last row of the table

	General sample	Application-oriented (A)	Formalist+application-oriented (F-a)	Process+application-oriented (P-a)	Schema-oriented (S)
21-24	35 (40%)	6 (35%)	7 (37%)	5 (23%)	17 (60%)
25-28	36 (42%)	6 (35%)	10 (53%)	9 (41%)	11 (40%)
29-30	15 (18%)	5 (30%)	2 (10%)	8 (36%)	0
	86	17	19	22	28

RQ4: *Does the students' appreciation of how they are taught mathematics at university differ based on their mathematical views?* Table 4 summarises the students' average appreciation of various aspects. P-a students tend to like the least step-by-step explanations and many exercises during the lessons, but to like the most being prompted to reflect. S students like the least to be provided justifications for definitions and methods, but to like the most many exercises.

Table 4: Averages of appreciation to each item in the entire sample and in each cluster. Significant differences with respect to the entire sample are in bold

Statement	Entire sample	Cluster A	Cluster F-a	Cluster P-a	Cluster S
Exhaustive, step by step explanations in frontal lessons	3.1	3.2	3	2.8	3.2
Justification of the definitions and methods	2	2.3	3	2.2	1.5
A good number of exercises	2.9	3	2.75	2	3
Stimulating reflections on a student's side	2	2	1.5	3	2

We also asked questions about the at-distance teaching that affected these students because of the pandemic, but no significant difference can be seen with respect to the different views. The sole exception is a question about the lack of opportunities to talk and interact directly with one's mates during the lockdown, to which A, F-a and P-a students show to be in accordance (rank above 3), while S ones are in discordance (rank below 3).

Discussion and preliminary conclusions

The research presented in this paper concerns a sample of undergraduate mathematics students and aims at examining the relations among their mathematical views and their academic achievement. Having considered only the third year can be seen as a limitation, but in our study this was quite unavoidable, since we needed that the students lived at least some semesters at university and we wanted that they had experience of this in pre-pandemic times.

Our results show that a schema-oriented view attracts more females, while an application-oriented view attracts more males. Among the students with a strong mathematical curriculum at secondary school, a process-oriented view is slightly predominant. This leads us to conclude that, with respect to gender and school type, mathematical views are different and, thus, it is possible that the origin of one's view depends also on their gender and/or school type. Our findings connect both to Griese's (2018) ones about females being more diligent, as the S view that seems to be predominant for females might be seen as mirroring this schema-oriented approach to learning, and to Roesken et al.'s (2011) one that students from different school types hold different views.

Furthermore, all the students in the sample strongly agree that, during the undergraduate studies, they were positively surprised by discovering aspects of mathematics they never imagined before, but for the students with a schema-oriented view such an agreement is more modest. Furthermore, for these students, it does not hold true that the undergraduate studies have confirmed the view of mathematics they had when they were freshmen, hence it seems that, for the students in this group, the mathematics that has been faced at university was different, but not always it was pleasant to discover such novelties. We know that professors who teach in the undergraduate mathematics course tend to promote a formalist, or an application-oriented, or a process-oriented view, hence we interpret S students' more modest appreciation of such a change with respect to school mathematics as an indicator of impermeability, of these students, to the novelties embodied in new views of mathematics. Liebendörfer and Schukajlow (2017) also remark that application-oriented views are positively correlated to interest in the first term, and process-oriented, schema-oriented and formalist views do not predict interest in the first or in the second terms. For the schema-oriented cluster, Libendoerfer and Schukajlow's findings seem to be confirmed also for students at the end of the third year. If we widen our focus to consider not only students' mathematical views, but also their professors' ones, we have to admit that, to our knowledge, no research study investigated the effect of different views, held by mathematics professors, on students' achievement and views in undergraduate studies. This could be a prompt for future research in this area.

With respect to the exam scores, we firstly notice that no low achieving student answered our questionnaire. This represents a limitation and, in a follow-up study, we will investigate why these students did not show up. Secondly, it emerged that no excellent student has a schema-oriented view. Conversely, most excellent students have a process- or an application-oriented view. Most students with a formalist view have a medium-high average of exam scores, whilst the majority of students with a schema-oriented view have a medium one. This leads to the conclusion that to develop a formalist, or an application- or a process-oriented view, can be considered a proxy for higher achievement at undergraduate studies. We can also notice that the students with a schema-oriented view are those who more strongly disagree with respect to exhaustive justifications of definitions and procedures during a lecture, and those who missed less the interaction with their peers during the pandemic. Somehow, these students show a sort of passive acceptance of mathematical algorithms and models and an individualistic approach to learning. We know that this kind of attitude towards mathematical learning are proxies for general weakness in mathematical achievement, as it is also confirmed in our data, being these students the ones who achieve the lowest grades.

Positive changes in affective variables: Two-round action research in Hungary and Romania

Emőke Báró

University of Debrecen, Hungary; baro.emoke@science.unideb.hu

The author of this paper is a mathematics teacher in Romania, and she is interested in students' motivation and attitude towards mathematics. Teachers face challenges in the online learning environment, such as fewer direct social interactions, one of the effects of which is a reduced possibility of motivation. In collaboration with two academic experts and another teacher from Hungary, the research group sought answers to these challenges. In two-round action research, the impact of problem-posing on motivation was investigated. Informed by the experience of the other teacher in the first round, the author redesigned the second round, with more emphasis on emotional factors. The author argues that problem-posing can be successfully adapted during online learning, and by incorporating interpersonal interactions into the problem-posing process, the reduced motivational effect observed in online learning can be compensated.

Keywords: Action research, mathematics activities, problem posing.

Introduction

The global outbreak of the COVID-19 pandemic affected almost every country and territory in the world. Due to the pandemic, lockdown and rules of social distancing have led to closures of schools in Hungary and Romania, like in most countries, decreasing social interactions in the learning process. When teachers were asked to select their top three concerns about distance learning on students, the most common answers were: students' social isolation, a decrease in student well-being, and potential learning loss. Surprisingly, educators ranked students' social needs above learning loss (Flack et al., 2020). Hattie (2008) states that social interaction within classrooms is positively associated with learning outcomes.

The pandemic is also affecting teaching methods. However, teachers cannot give up specific methods such as problem-posing and its positive effects on learning. Problem-posing positively impacts motivation, while motivation and interest have a close relationship with context personalization of students' tasks (Walkington et al., 2013). Moreover, personalization is an energizing factor, which is significant for the student's motivation (Suriakumaran et al., 2017). Our research team, two teacher-researchers (including the author) and two experts, implemented problem-posing in an online environment. The principle was to use info-communication tools that the learners and teachers were comfortable using. In this article, the author focuses on a single aspect of the problem-posing, namely its positive impact on motivation (Silver, 1994). The online learning environment reduces interpersonal relationships, so the positive effect of problem-posing on motivation in the online environment may decrease. Moreover, decreased interpersonal relationships lead to decreased motivation since interpersonal relationships in students' lives contribute to their motivation (Martin & Dowson, 2009). As a result, the importance of emotional factors through interpersonal relationships in online education should be growing, which implies our research question: *Does the increased role of emotional factors impact the context personalization and, through this, students' motivation?* The author inferred motivation using content analysis that unfolds context-personalization characteristics. An online questionnaire followed the analysis with questions on motivation.

Theoretical background

Motivation can be described as the student's willingness or desire to participate and succeed in the learning process. Weiner (1992) defines motivation as an individual's desire to act in specific, personal ways. Walter and Hart (2009) describe sources of motivation as task interest, social environment, opportunity to discover, knowing why, using objects, and helping others. Some researchers emphasize the importance of context personalization that helps to target students' out-of-school interests and experiences (Cordova & Lepper, 1996). Walkington et al. (2013) describe context personalization as an approach to learning in school. Personalized problems may make mathematics more accessible to students, they may help bring the "real world" problem solving closer to "school mathematics," and they may attract students' attention and interests to impact motivation (Boaler, 1994).

In this paper, the author uses the concept of problem posing in the following sense.

> By problem posing in mathematics education, we refer to several related types of activity that entail or support teachers and students formulating (or reformulating) and expressing a problem or task based on a particular context (which we refer to as the problem context or problem situation). (Cai & Hwang, 2020, p. 2)

Several aspects of problem-posing (PP) are thought to have meaningful relationships to student disposition toward mathematics. For example, posing offers a means of connecting mathematics to students' interests. Within a classroom community, students could be encouraged to pose problems that others in the class might find exciting or novel (Silver, 1994).

Ellerton (2013) proposes the Active Learning Framework (ALF) for PP in mathematics classes, defining four steps: 1. The teacher models an example (processing the new content) 2. Students solve problems based on model 3. Students pose problems with the same structure as model 4. Finally, the class discusses and solves problems posed by students as "My classmate's problem." This framework considers PP in classrooms an essential activity that allows students to consolidate their knowledge and think critically about it.

The affective domain is defined in many ways in educational and psychological literature. Often it is used as a broad umbrella concept that covers attitudes, beliefs, motivation, emotions, and all other noncognitive aspects of the human mind (Hannula, 2020). This paper focuses on self-concept, anxiety, motivation, perceived usefulness, and enjoyment of mathematics. Mathematical self-concept refers to one's ability to learn and perform mathematical tasks, how confident one is in learning new mathematical topics, and one's interest in mathematics (Reyes, 1984, p. 560). Mathematics anxiety is defined as a sensation of stress and apprehension that interferes with mathematics performance ability, number manipulation, and problem-solving (Richardson & Suinn, 1972). Perceived usefulness refers to how students can relate school mathematics to real-life (Reyes, 1984). Finally, the usefulness of mathematics includes liking mathematical terms, symbols, or routine counting, but liking mathematics problems as well (Aiken, 1974).

The circumstances of the action research

The challenge of action research is how to adapt the ALF model to the online environment while retaining the motivational potential of problem-posing. This question touches on all components of ALF, i.e., how to present the model problem, how to practice, how to do the problem creation, and how to process the classmate's task.

Participants

The participants of the research are four 6th grade classes from Hungary and Romania. The teachers of the two classes in Hungary are the same person. Similarly, the two classes in Romania are taught by the same mathematics teacher. 125 students participated in the experiment: 65 from School 1 (Hungary) and 60 from School 2 (Romania). The language of instruction is Hungarian in both schools, being Hungarian the students' mother language.

Method

Curricula and syllabi are different in the two countries, which led us to divide them into rounds of our action research. The first round took place in School 1 in the spring semester of 2020, while the second one in School 2 in the autumn semester of 2020. The researchers implemented the ALF method for the following curricular lessons in both schools. 1. Proportional division (two PP activities), 2. Straight and inverse proportionality (two PP activities), 3. Percentage calculation, calculation of the percentage base (one PP activity). Both rounds were organized under online teaching conditions ordered due to the viral situation. This circumstance allowed us to focus on the challenges and experiences gained from the first round and transform them into opportunities. Table 1 contains similarities and differences between the rounds in each phase of the ALF.

Table 1: Differences between the two rounds of ALF

ALF step	Round 1	Round 2
Model problem	Slideshow that the student works up at home.	Slideshow that students work on with the teacher in an online lesson.
Practice	Self-regulated learning through a presentation.	Teacher-regulated learning through a presentation in an online lesson.
Problem-posing	Homework to be sent to the teacher.	Homework to be sent to the teacher.
Classmate's problem	Based on the teacher's selection.	Based on the teacher's selection.
		Who is the problem poser?
	Homework.	Online classroom: individual work.
Evaluating the solution	By the teacher.	By the problem poser.

Round 1: The teacher prepared a slideshow with narration and timing, which included the stages of introduction and practice. Students had the opportunity to play the slideshow several times before they started the problem-posing activity. After collecting the posed problem, the teacher selects one (or two) as “My classmate’s problem” and sets as homework that are also collected.

Round 2: The teacher prepared the same slideshow, but instead of sending it out, she presented it via Google Meet lessons, where students can comment, ask, talk. Problem posing activity is homework as in Round 1, but “My classmate’s problem” is also discussed live and solved during online lessons. Solving “My classmate’s problem” was preceded by a discussion with the topic: Who is the problem poser? Why do you think that? As a new step, after revealing the problem poser’s name and solving the problem, they added the story that inspired them in the process of the PP. Solving the classmates’ problem was an individual task followed by a discussion of whether the problem poser accepts or declines the solution of the class. Through these conversations, emotional factors were given a more significant role in Round 2, letting us know each other’s stories. Essentially, it is about bringing the task to be solved emotionally close to the students, thus making them more motivated to solve it.

Collecting Data

Parts of the research material are students’ work, students’ answers to the questionnaire, video recordings of Round 2 lessons, and teachers’ reflections. All the student works were coded, taking into account the coding frame for evaluating out-of-school interest (sports, video games, pets, sports, info-communication tools, social media, food) based on Walkington et al. (2013). It was also identified two other ways (besides out-of-school-interest) that students use to express their presence in the posed problems that the author calls personal traits:

a. Student’s direct presence in the posed problem by using the first-person singular. The personalization is given by the conjugation and pronoun “Me/I” and not the activity. For example, “My favorite T-shirt was finally on discount.” In the second case, the name of the “hero” in the story coincides with the student’s name who posed the problem: “*Zsófi* does 3 km in 50 mins.”

b. Actual or happened situations: The written context refers to an event that happened lately. For example, the following problem refers to the actual Black Friday: “Peter buys a new laptop, with a 30% discount it is 1500 Ron on Black Friday. What is the laptop’s original price?”

Results

We observed two developmental aspects of affect in Round 2: the role of different emotions, values in PP, and the role of affective factors in interpersonal relationships between students, teachers.

Role of different emotions, values in problem posing

Having different emotions, values, hobbies, and interests encourages students to remark their presence (directly or indirectly) in the posed problems. These interests were discovered in many of the students’ work. They include their personal interests in their problems; this is how they express themselves and their bonding to the subject. We managed to bring the “real world” problem solving closer to “school mathematics” problem solving, which may attract students’ attention; they could be saying, “this happened to me/might have happened to me”.

The personal trait appears in 9% of all problems (Table 2), and there is no significant difference between the two schools (21% in School 1 and 14.8% in School 2; the Fischer test result is 0.12>0.05). Thus, this form of personalization follows from the PP activity itself, and the research suggests that emotional factors have little influence.

Table 2: Number of problems with the sign of a personal trait

Appearance of personalization	Problems with a sign of a personal trait	Problems with no sign of a personal trait	Sum
School 1	46	173	219
School 2	28	160	188
Sum	74	333	407

In Round 2, we observed that more personalized context appeared in the posed problems (Table 3). For example, code “out-of-school-interest” was identified in 67 cases in School 1 (30.6% of all problems), while in School 2, this number is 76 (40.4%).

Table 3: Number of problems with the sign of out-of-school interest

Appearance of personalization	Problems with the sign of out-of-school interest	Problems with no sign of out-of-school interest	Sum
School 1	67	152	219
School 2	76	112	188
Sum	143	264	407

Personal interest was more prevalent in the second round, and the difference is significant. Fischer’s exact test result is $p = 0.047$; the result is significant at a significance level of 0.05. We explain the difference by the increased role of emotional factors because they felt motivated to use their out-of-school interest in the posed problems.

Role of affective factors in interpersonal relationships between students, teachers

During Round 2, students were asked to guess the author of “My classmate’s problem”. The following discussion was transcribed from the second online lesson.

Teacher: [sharing her screen with the posed problem] Firstly, I would like you to guess who could have written this problem?
Student 66: Mrs. Teacher, it is obviously G. (Student 82).
Student 62: This is G.
Many: Yes, G. wrote it.
Teacher: Why is it obvious that it is G? She has hens with lice?
Student 69: She has stories like this.
Student 62: She has lived on a farm.
Many: [laughing]

Teacher:	G, got your hens lice, or what?
Student 82:	[laughing] No, but my grandma used to have hens. That's where the idea came from.
Teacher:	I love this problem.

As students talked about the possible problem posers, the teacher could join the conversation and observe their relationship. The teacher found out someone's pet's name, for example, and who had known that before. These conversations offer a social interaction between students, including the teacher, improving Walter and Hart's (2009) motivational factors such as task interest, social environment, and helping others. The teacher observed that developing the online social environment had been contributing to a more inclusive classroom atmosphere. These problems were very memorable; even a few months after the PP activities, some students fondly remembered the lessons, suggesting that they liked solving problems about G's hens.

Round 1's ALF included affective factors such as self-concept and motivation via personalization of the context. Telling and listening to classmates' problems added additional factors. Figure 2 shows that listening to a story that inspired a classmate arouses other students' interest, leading to the enjoyment of mathematics, decreasing anxiety. By telling the story that inspired the student in the process of PP, he or she would pose a more realistic problem, which can change the student's view of the usefulness of mathematics.

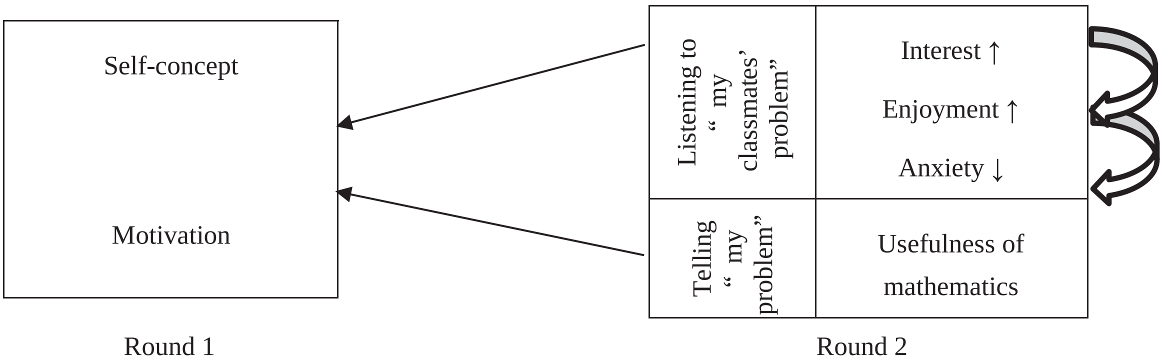

Figure 1: Affective factors added in Round 2

Knowing the background story while solving each other's problems seemed interesting to students, such as realizing that their story could have happened, which was revealed from the classroom discussions. Analysis of the answers to the questionnaire also supports this observation. At the end of the teaching unit, students were asked to answer 16 questions leaving their opinions about this new teaching-learning method. Three of them are highlighted here, I6, I8, and I9 (Table 4). We used Likert scale items with three grades according to the children's age specifics: Agree/Cannot decide/Disagree. Only definitive answers were evaluated (agree, disagree). Three items were assigned to motivation, belief, and emotion. To analyze the data statistically, contingency tables were created. The distribution of the answers is shown in Table 4.

Students enjoyed solving the classmate's problem in both schools, but the ratio of those who agreed with I9 was greater in the second round (95.7% versus 84.8%). However, the difference is not significant ($p = 0.12$). Table 4 also shows that almost 75% of students are happy to pose their problems. The author considers this fact as a sign that the adaption of the ALF paradigm was successful in both rounds. The positive answers to I8 suggest the idea that students are aware of the fact that their problems are realistic and support our finding that problem-posing positively influences students' perceptions of the relationship between school mathematics and real life. There was no significant difference between the two rounds in this respect.

Table 4: Students' responses to the three questionnaire items

	I9: I liked it when the classmate's problem was the homework.		I6: I liked to come up with my own task for math lessons.		I8: I have created tasks that can occur in real life.	
	Agree	Disagree	Agree	Disagree	Agree	Disagree
Round 1	28	5	22	8	24	4
Round 2	45	2	32	11	39	3

Conclusion

Although the participants of the two rounds were children from different countries, that could be a limitation of the study regarding the statistics, but also an advantage, which suggests a new plan for the future. The author desires to try out this method with the same students on different curricula and the same curriculum with other students; if the pandemic allows, in situ in the classroom. The author found that PP has a motivating effect in the online environment as well, and even this positive effect can be increased by including emotional factors. The author also claims that problem-posing opens up space for the expression of personality. It is an opportunity for the teacher, even in the online environment, to learn what is currently occupying the student, their hobby/circle of friends, even to conclude relationships between them. The author finds that students pose more context personalized problems by increasing emotional variables and are happier to solve their classmates' problems than with fewer affective factors. By and large, the adaption for the online learning environment went successfully. Based on the literature (Martin & Dowson, 2009) and the experiment, the author claims that more social interactions promote context-personalization, which triggers motivational factors.

This paper is part of a larger quantitative and qualitative study that focuses on how teachers and students perceive learning of mathematics via WhatsApp. The main objective of the program is to allow for both teacher-student and student-student contributions of knowledge and to boost students' sense of self-confidence and authorship in the discipline. The research participants of this study comprise 152 Grade 11 and Grade 12 students who responded to a questionnaire distributed during the 2018 program. We present a quantitative analysis of the factors that students perceive to be pertinent in the WhatsApp Bagroup learning environment.

Keywords: Social media, communication, WhatsApp in mathematics education.

Introduction

The fact that technological social platforms can be useful for the purpose of schooling and education is increasingly recognized and studied (Greenhow & Lewin, 2016). Online social networking platforms have become highly popular virtual meeting places for youth and adults (Boyd, 2010; 2014; Greenhow & Askari, 2017).

It is not surprising then that, recently, there has been an influx in research focusing on the pedagogical benefits of using social media as productive sites for promoting learning. Having said that, an examination of recent studies shows that focus has been put on post-secondary settings (e.g., Dyson et al., 2015) or teacher education (e.g., Sendurur et al., 2015). Research on the use of social media for subject-specific learning purposes, such as mathematics, among K-12 remains understudied. Given the prevalence of the use of social media in everyday life especially among teenagers, we conjecture that the use of these platforms can potentially increase student-teacher and student-student interactions. These interactions around mathematical ideas may allow almost instantaneous response and feedback from others and surface mathematical misconceptions and misperceptions that can be directly addressed in follow up posts (Biton & Segal, 2021; Freeman et al., 2016).

Literature review

Recent studies have explored the use of social media platforms such as Twitter (Carpenter & Krutka, 2014), Pinterest (Hertel & Wessman-Enzinger, 2017), and Facebook (Biton et al., 2015). These studies have suggested that interaction over social media contributes to socializing (Madge et al., 2009) and increased self-esteem and social capital (Steinfield et al., 2008). Such affordances need to be further investigated within mathematics education. With respect to learning and instruction, Asterhan et al. (2013), and Asterhan and Bouton (2017) for example, discussed how social media can be used to develop innovative, collaborative forms of online learning that extend beyond the traditional classroom. Students perceive learning through social media to be very intensive and highly collaborative in nature (Meishar-Tal et al., 2012). From the students' standpoint, social media platforms have been found to also allow for the manifestation of learners' emerging conceptual understanding in mathematics (Baya'a & Daher, 2013; Freiman, 2008).

Relatively little research focused on students' perspectives on learning mathematics through WhatsApp. A case in point is a recent study by Rosenberg and Asterhan (2018). The researchers looked into teacher-student interactions; students' evaluation of the efficacy of contact with their teachers; the social dynamics in these groups compared with that in in-person classrooms. It was found that teachers used WhatsApp not only to manage housekeeping-related matters but also for instructional and learning purposes that were initiated either by them or by students in the group. Some of the drawbacks identified revealed issues regarding information overload, social pressure due to the public nature of the communication, and accessibility to WhatsApp. Drawing on this research, it still remains to be surfaced how students perceive the use of WhatsApp as a means to learning school mathematics, which is where our research aims to contribute to knowledge.

Methods

The study presented herein is part of a larger research project that focuses on exploring how students and teachers perceive learning over a social network—specifically WhatsApp—and identifying learning opportunities to eventually inform pedagogical approaches and instructional strategies. This paper particularly aims at identifying and characterizing students' perceptions of the WhatsApp "Bagroup" program learning environment. We formulated five overarching research questions for our larger research study. In this paper, we focus on the following: What factors do students perceive to be important when learning in the WhatsApp "Bagroup" program environment?

The "Bagroup" initiative.

The "Bagroup" is a state-wide program that was set up for the Ministry of Education by the Center for Educational Technology. The purpose for this initiative was to offer the use of the WhatsApp application to high school students throughout the country and across grade levels in preparation for their mathematics matriculation exams (*Bagrut* in Hebrew). Approximately 4,000 high school students joined the mathematics WhatsApp groups 2018. (This was an increase of more than 100% with respect to the two preceding years, which had less than 2,000 registrants.) Forty groups were set up with 100 students in each. An experienced teacher of mathematics was assigned for each group. Group members are generally not acquainted with each other at the outset. Learning is divided into various topics each of which are studied over a set time period and led by a teacher. Once every few days, the teacher introduces a topic or answers questions raised by the students and uses various digital means. The lessons are accompanied by a repository of materials in the accompanying site that are available for use by the students. Learning in the group takes place in a variety of ways: text messages, voice messages, photos and video-clips, question repositories, presentations, and more.

The groups ran between two to four months up to the exam date during which hundreds of thousands of messages were sent that included mathematical content, questions, and explanations to solutions. The Bagroup project offers the following to its students: [1] Support: Students can get an (almost) immediate response from a teacher or another student from the group. [2] Equal access: Using the freely available WhatsApp technology made it possible for anyone to join at no cost. [3] Use of mobile technology: Students’ digital devices supplemented classroom instruction and extended learning to anywhere and anytime. [4] Capacity building: The program is aimed at enhancing understanding of mathematical concepts and, by extension, affective dispositions towards mathematics. [5] Variety: Students shared multiple approaches to solving mathematical problems.

The program was launched in 2015 on Facebook for mathematics only and then in 2016, was moved to the WhatsApp platform. The program saw a growth from 614 students in 2015 to 8,500 students in 2019 (unpublished figures). Also, the 2019 program added the subjects of English and Hebrew.

Participants and data collection

Participants comprised 152 students in Grades 11 and 12 who answered a questionnaire that was distributed to the students in the 2018 program. Nonprobability sampling was used based on participants’ availability and willingness to reply to the questionnaire. The questionnaire was put together by the first and third author and revised for accuracy and consistency. The student questionnaire included nine open-ended questions and twelve Likert-type questions. The open-ended questions invited students to share a memorable experience or an episode they had in any of the WhatsApp interactions. They were also invited to share the most obvious advantages and disadvantages of using WhatsApp for the purpose of learning high school mathematics and to reflect on specific characteristics of WhatsApp that make the mathematical content accessible to the students. The open-ended questions also requested possible explanations regarding students who left the group. The other part of the questionnaire provided a 6-point Likert-type scale for 12 statements concerning the experience of learning mathematics via WhatsApp with 1 = Strongly Disagree and 6 = Strongly Agree.

Data analysis

Students’ responses were analyzed and coded for themes by the first two authors through content analysis of the responses to the open-ended questions. A Varimax rotation analysis was used of the data, the goal being to detect how the WhatsApp learning environment was perceived by the students by demonstrating the items are inter-correlated for internal consistency.

In this paper, we present an analysis of the quantitative data gleaned from the students’ questionnaires.

Findings

Analysis of the twelve Likert-type scales found high internal validity of three categories that explained more than half of the variance in the students’ answers (58.06%). The three categories were the following: [1] Factors in the WhatsApp environment that support students’ emotional needs. This category accounted for about a quarter of the variance among the students’ answers (five statements). [2] Factors in the WhatsApp environment that promote learning. This category accounted for approximately another fifth of the variance of the students (four statements). [3] Factors that hinder learning in the WhatsApp environment. This category accounted for an additional 8% of the variance in students’ answers (two statements).

Table 1 presents the mean scores and standard deviations of all the statements, divided into the three categories. The results indicate that students' perceptions about learning in the WhatsApp environment was varied.

Table 1: Means and standard deviations of the categories and statements regarding the students' experience learning mathematics via WhatsApp, N = 152

Statement	Mean	SD
Category 1: Contribution of the WhatsApp environment made to students' emotional needs	3.51	1.15
I manage to follow the lesson during the WhatsApp discourse	3.46	1.65
I managed to understand the material in the WhatsApp environment at the same level as in a regular class	3.84	1.30
WhatsApp allows participation without fear of making errors	3.73	1.68
The written discourse in WhatsApp is preferable over the verbal discourse in a regular class	2.80	1.53
Learning through WhatsApp allowed me to meet my specific needs as a learner more than in a regular classroom	3.72	1.61
Category 2: Factors that promote learning in the WhatsApp environment	3.81	1.13
Learning via WhatsApp allows me to learn from others more than in a regular class	3.99	1.61
The value of a lesson via WhatsApp is different from the value of a regular lesson	4.65	1.40
Learning via WhatsApp improved my mastery of available technologies for learning mathematics	3.27	1.68
I invest more time and effort in mathematics in the WhatsApp project compared to students in a regular class	3.04	1.68
In the future, WhatsApp will become an important tool for students for learning math	4.09	1.67
Category 3: Factors that hinder learning in the WhatsApp environment	3.09	1.29
There is some mathematical content that cannot be explained via WhatsApp	3.53	1.73
I can't manage to cooperate with other students the way I do in a regular class	2.66	1.47

To facilitate analysis, the levels of agreement were reduced to three: disagree, somewhat agree, and agree. Figure 1 graphically illustrates the percentage of students that agreed, somewhat agreed, or disagreed with each of the twelve statements.

In the first category Contribution of the WhatsApp environment to learners’ emotional needs, the

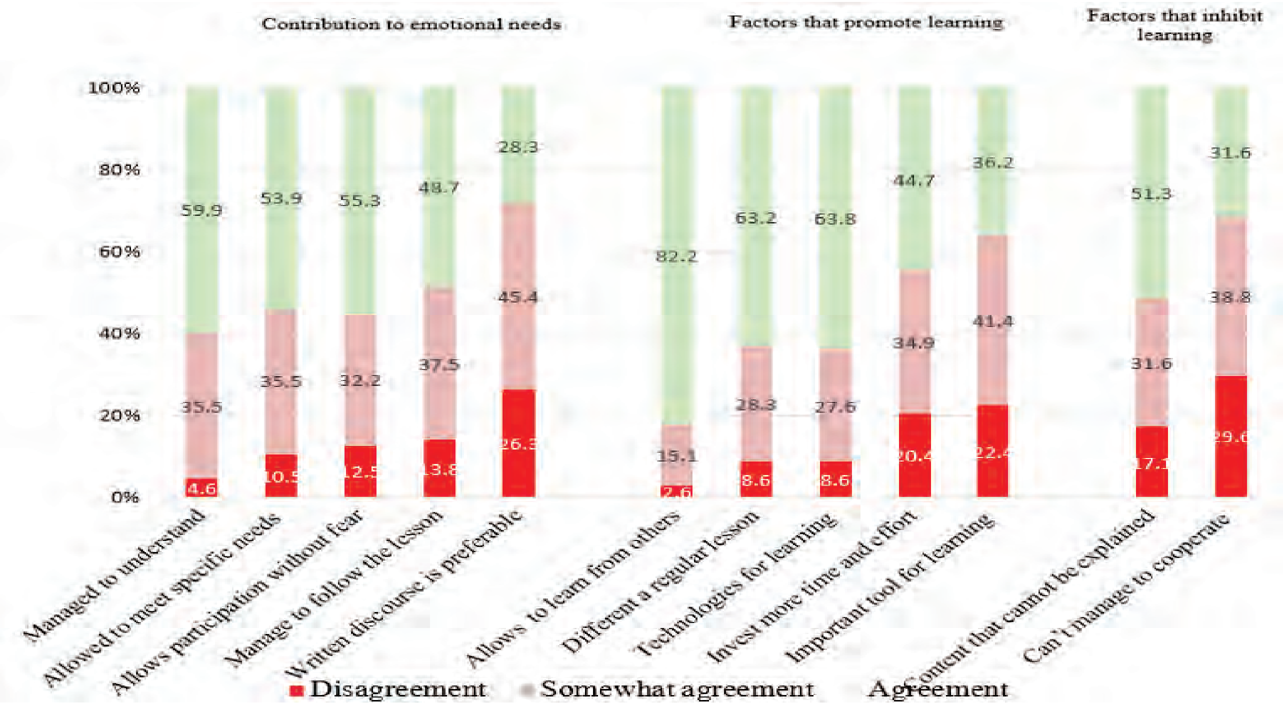

Figure 1: Proportion of students who agreed, somewhat agreed, or disagreed with the statements

highest agreement was with the statement: “I managed to understand the material in the WhatsApp environment at the same level as in a regular class.” Looking at Figure 1, we can see that 95.4% of the participating students agreed (59.9%) or somewhat agreed (35.5%) with this statement. The next highest statement in the category of emotional needs: “WhatsApp allows participation without fear of making errors,” with 55.3% and 32.2.% agreeing or somewhat agreeing with this statement, respectively. “Learning through WhatsApp allowed me to meet my specific needs as a learner more than in a regular classroom” scored third. Here, again, the great majority of students agreed or somewhat agreed with this statement (53.9% and 35.5%, respectively). However, the statement: “The written discourse in WhatsApp is preferable over the verbal discourse in a regular class” received the lowest mean score in this category, but still maintaining a high level of agreement 28.3% and 45.4%). Under the second category “Factors that promote learning in the WhatsApp environment,” there is a high degree of agreement with “The value of a lesson via WhatsApp is different from the value of a regular lesson.” Collectively, 91.5% agreed (63.2%) or somewhat agreed (28.3%) with this statement. Within this category, a high degree of agreement was also found with the statement: “In the future, WhatsApp will become an important tool for students for learning math” demonstrating that 77.6% of the students either agreed (36.2%) or somewhat agreed (41.4%) with this statement.

As well, the statement: “I invest more time and effort in mathematics in the WhatsApp project compared to students in a regular class” scored the lowest mean points (3.04%). However, overall, the great majority of the students still agree 44.7% or somewhat disagree 34.9% with the statement and the remaining 20.4% disagreeing with it. Notably, the WhatsApp environment, through students’ perspectives, allows to learn from others with 82.2% agreeing with this statement and 15.1% somewhat agreeing with this statement.

Discussion

The study examined the popular phenomenon of using WhatsApp, particularly its use to support learning through the national "Bagroup" program initiative whose objectives are to prepare students for the mathematics matriculation exams and contribute to students' self-confidence in mathematics. This paper reports some quantitative results on how students perceived learning mathematics using WhatsApp. The findings demonstrate that, for the most part, students felt that learning through WhatsApp contributed to their emotional needs. They were able to understand the material, found their peers' contributions helpful, felt confident to take an active part in the group without fear of making mistakes, and perceived the WhatsApp environment as one that was conducive to their learning from their peers more efficiently than in a regular classroom. Nevertheless, almost a fifth of the participants felt that this environment was not suitable for some mathematics topics. This requires further investigation as to the specific content they refer to and the pedagogical and instructional approaches to be adjusted. In addition, almost a third believed that the platform did not always allow the type of collaboration possible in a normal classroom. Here too, further investigation will shed more light on patterns of collaboration and learning mathematical content.

The findings also demonstrate that students believe that learning in the WhatsApp environment promoted their learning of mathematics (second category). with the most notable findings suggesting that this environment allows students to learn from each other and persevere more in solving mathematical problems (i.e., invest more time and effort in mathematics). We wonder whether opportunities to learn from other students (82.2% agreeing with the statement and 15.1% somewhat agreeing with the statement) may be associated with other factors such as not fearing making mistakes, or with the anonymity that the environment provides where classroom-related social roles become blurred and the threat of losing face (Lin & Yamaguchi, 2011) is mitigated.

The analysis of students' responses to the open-ended questions may shed some more light on the differences in students' experiences. Specifically, the relationship between students' perception of mathematical content that is not as easily managed on WhatsApp (Category 3) and their managing to understand the mathematical concepts that were taught via WhatsApp (Category 1). As well, looking into students' perception of not being able to cooperate with others (two thirds of the respondents agreed (31.6%) or somewhat disagreed (38.8%)) while noting their perception of WhatsApp allowing them to learn from others in the group (82.2.% agreeing and 15.1% somewhat agreeing).

The findings of this study suggest that using the WhatsApp environment in learning mathematics may provide positive experiences where learners receive opportunities to take ownership over mathematical ideas thus developing self-confidence and authorial identity in mathematics. This ties with Fellus' (2019) broad conceptualization of learners' mathematical identity that offers a unified framework to understanding students' experiences in learning mathematics. Specifically, how students talk to and about themselves as learners of mathematics, what opportunities they get to take ownership over mathematical content, and the socioculturally available metanarratives about who can and who cannot do mathematics. As we further investigate learners' experiences with the WhatsApp environment, we will be looking more deeply into the relationship between the affordances the platform offers and one's opportunities to take ownership over mathematical ideas and to develop tolerance towards errors as ways to deepen conceptual understanding and to foster perseverance.

Acknowledgments

This study was conducted with the support of Shaanan College of Education and Oranim College of Education. We are also grateful to Sigal Atzmon, the director of the Bagroup project, for her assistance.

Community detection for undergraduate mathematical views

Domenico Brunetto[1], Michela Tassone[2] and Ester Cravero[3]

Keywords: Academic aptitude, network analysis, postsecondary education, cluster analysis.

Beliefs are propositions about a certain topic that are regarded as true (Philipp, 2007), they are individually held (Erens & Eichler, 2019) and tend to form clusters as they "always come in sets or groups, never in complete independence of one another" (Green, 1971, p. 41). A belief is seldom isolated, but it is connected to other beliefs, which are part of the same cluster of beliefs. According to Green (1971), belief clusters are coherent families of beliefs across multiple contexts. For this reason, beliefs can be understood in terms of views of mathematics (Grigutsch, Raatz & Törner, 1998), namely as epistemological beliefs about mathematics, its teaching and learning. According to Grigutsch et al. (1998), it is possible to outline four different views: a process-oriented (P) view that represents mathematics as a creative activity consisting of solving problems using different and individual ways; an application-oriented (A) view that represents the utility of mathematics for real world problems as the main aspect of the nature of mathematics; a formalist view (F) that represents mathematics as characterised by a strongly logical and formal structure; a schema-oriented (S) view that represents mathematics as a set of calculation rules and procedures to apply for routine tasks. Erens and Eichler (2019) operationalised these four views into a Likert-scale questionnaire made of 24 statements, each of which is assigned to a specific view. Examples of statements are: "mathematics helps to solve tasks and problems that originate from daily life" (A), "logical strictness and precision are very essential aspects in mathematics" (F), "in order to comprehend and understand mathematics, one needs to create or (re-)discover new ideas" (P), "doing mathematics demands a lot of practice in adherence and applying to calculation rules and routines" (S).

In this poster, we aim at showing a methodology for clustering these statements and checking whether the four categories defined for the aforementioned four views are a posteriori confirmed by a survey administered to 93 students enrolled in the third year of undergraduate studies in mathematics at the University of Torino (more details can be found in Andrà, Magnano, Brunetto & Tassone, submitted). On one hand, we claim that the need for an a posteriori analysis resides in the importance to verify the reliability of the measurement tool. On the other hand, the methodology shown here represents a novelty, as it is based on network analysis.

A network is a set of nodes connected to each other through an edge. Indeed, a network N is a pair (V, L) where V is the set of nodes and L is a subset of the Cartesian product $V \times V$. There are two mathematical tools that allow one to analyze a network: (i) the graphical representation of the network, and (i) the adjacency matrix, which describes the connections between nodes as its component $a_{ij}>0$ if the nodes i and j are connected by a link, otherwise is it null.

One of the potentialities of network analysis is the possibility to use clustering tools that do not require particular metric definitions. These techniques are called community detection as the goal is to identify subnets of nodes characterized by relatively large internal connectivity, namely nodes that tend to connect much more with other nodes in the group than the rest of the network. To this end, we used the so-called "Louvain method" which is based on the optimization of a quantity called modularity (Q). Given a partition into k sub-graphs $\{C_1, C_2, \ldots, C_P\}$ of the network, the modularity (Q) is the normalized difference between the total weight of the links inside the sub-graphs C_k and the expected value of total weight in the randomized "null network model" (Newman, 2010).

It is also important to recall that a network can be built as a projection of a bipartite network, namely one made up of two distinct classes of nodes V_n and V_m, and links can only connect nodes of different classes. This is the case of the data analysed in our study, since the network has been built with nodes identified by both the 93 students and the 24 items. A student-node is connected to an item-node with an edge weighted 1, 2, 3, 4, or 5 depending on the rank assigned to it on a 5-point Likert scale. Student-nodes are not directly connected to each other, as well as item-nodes. Another typical example of a network of this sort is the Amazon network, where consumers are linked to each product if they have purchased it at least once. However, it is possible to define a link between consumers if they have purchased the same product, or a link between products if they were purchased from at least one same consumer. This method allows one to create a similarity metric between participants or between questions in the context of questionnaires (Brunetto, 2017).

In our poster, we confirm an almost perfect correspondence between a priori classification of Erens and Eichler's (2019) work and our investigation on a sample of undergraduate mathematics students a posteriori, and we extend clustering to other aspects of mathematics teaching and learning.

Fuzzy cognitive analysis in undergraduate mathematics class on engagement, motivation, and participation during covid-pandemic

Roberto Capone[1] and Mario Lepore[2]

[1]University of Bari, Mathematics Department, Bari, Italy; roberto.capone@uniba.it

[2]University of Salerno, Mathematics Department, Salerno, Italy; marlepore@unisa.it

This work focuses on Distance Learning during the COVID-19 pandemic to improve undergraduate students' motivation, participation, and engagement. Experimentation in a Mathematics STEM class evaluated the impact of Distance Learning on students' motivation, participation, and engagement levels, computed through a Fuzzy Cognitive Map. It was performed on some affective and interaction parameters derived from using an adaptive e-learning platform and from the answers of a semi-structured questionnaire. The results have been analyzed through Technological Pedagogical Content Knowledge and Instrumental Genesis theories.

Keywords: Virtual environment, fuzzy cognitive map, motivation, participation, engagement.

Introduction

Distance Learning (DL), at the time of COVID-19, was a didactic of "being there", as defined by the philosopher Heidegger, in the etymological sense of "being-out" (ex-sisto), in which “being” is meant as the projection to the future, an opening to possibilistic horizons. DL was characterized by using methodologies and technological tools to keep students' participation, engagement, and motivation high. It was not just a question of using technologies in teaching but an actual adaptive process to using technologies as the only way to learn. This study is framed by the theory of instrumental genesis (Verillon and Rabardel, 1995), integrated into the Technological Pedagogical Content Knowledge Framework (TPCK), showing how the didactic contents delivered in the presence have taken on a new aspect with distance learning (Mishra and Koehler, 2007). Some theories on motivation (Skinner, 1935; Fredricks et al., 2004) were used to analyze the students' motivation to follow lessons at a distance, to be virtually present in the classes (Shonfeld et al., 2020), and to use the teaching tools made available by the teachers. It is not rare to find many students who leave the online learning course shortly after the beginning; such a phenomenon, called dropout, is always more frequent among the students who are not sufficiently engaged and motivated with the learning experience. The root causes of students dropping out are the lack of motivation, engagement, and participation (J. Keller and K. Suzuki, 2004). Our contribution, in this paper, is to model teaching in an adaptive way using adequate technological tools to cope with panic and frustration in which students suddenly found themselves trying to stem a possible wide phenomenon of dropout (Capone, 2022). The motivation considers the level of interest in the course, the engagement represents the level of involvement in the learning experience (Kuh, G. D., 2003), whereas participation (Dominguez, R. G., 2012) refers to the action of taking part in activities and projects, the act of sharing in the activities of a group. For these reasons, a modern course cannot be limited to the simple learning content delivery task. Still, it should support the learners in their whole learning experience, leading them to reach their learning objectives successfully. A case study was conducted to evaluate whether our didactic models adapted to this emergency have helped to maintain a sufficient level of engagement, motivation, and participation. The study was carried out with first-year engineering students of 2019-2020 in mathematics class. The case study has nomothetic and ideographic intentions by collecting quantitative and qualitative data. The quantitative data include the students' interactions on the used e-learning platform, the results of the tests, and a semi-structured questionnaire according to the Likert scale. In addition, the questionnaire anonymously proposed to students also included open-ended questions from which to infer, through qualitative analysis, the motivational state of the student. Finally, from the qualitative and quantitative data that emerged, a Fuzzy Cognitive Map (FCM) was built to derive the levels of the students' engagement, motivation, and participation parameters. Based on completely remote teaching, the obtained results are compared with those obtained in a previous experiment (Capone and Lepore, 2021). The data seem to show that, thanks to the use of an adaptive e-learning platform and restructuration of the educational content through technologies, the students have maintained an adequate level of engagement and motivation parameters comparable to those of the previous years. On the other hand, participation was lower than the previous experience due to a drop in concentration and frustration of being at the computer the whole day to follow the online lectures. The dropout was instead contained within acceptable values, and in terms of students’ achievement of competencies, the results are comparable.

Conceptual Framework

The framework of the Technological Pedagogical Content Knowledge (TPCK), the idea of instrumental genesis proposed by Vérillon and Rabardel (1995), and the theory of Fuzzy Cognitive Map are tools to describe and model complex systems/environments.

Technological Pedagogical Content Knowledge Framework

The Technological Pedagogical Content Knowledge (TPCK) framework conceived by Shulman in 1986, defines which elements can characterize teaching supported by technologies without neglecting the pedagogical aspects and the specific teaching contents of the discipline. We follow Mishra and Koehler (2006) that make further clarifications by describing the meaning of the intersections between TK and CK, between PK and CK and between TK and PK. They specify the following: Pedagogical content knowledge (PCK) is concerned with the structure, organization, management, and teaching strategies for how the particular subject matter is taught; Technological content knowledge (TCK) is related to how one specific subject matter is represented in technology-rich environments. Teaching with technology requires knowing the subject and how subject matter can be changed with the application of technology, and this knowledge is called TCK; Technological pedagogical knowledge (TPK) is concerned with how teaching and learning change due to integrating technology into instruction and how a teacher should choose a particular tool for a specific task considering its affordances and limitations. Technological Pedagogical Content Knowledge (TPCK) "is an emergent form of knowledge that goes beyond all three components" (p. 1028). According to the transformative model, TPCK is different from "knowledge of a disciplinary or technology expert and from the general pedagogical knowledge shared by teachers across disciplines" (p. 1029). This model helps to interpret the attitude of teachers in the face of innovation in their didactic.

The Instrumental Genesis

The idea of instrumental genesis (Verillon and Rabardel, 1995) seems suitable to describe the use of Distance Learning in mathematics education. The instrumental genesis distinguishes an artifact (an artificial object/instrument) from an instrument (a psychological construct) by defining the instrument as a mixed entity composed of both components related to the characteristics of the artifact and subjective components (patterns of use) that come out from the situated instrumented activity or the activity involving a subject (as a user), an artifact (as an instrument) and an object (as epistemic transformation, for example, the knowledge of functions in two variables). This hybrid entity considers the thing and describes its practical use for the subject. A scheme is a systematic procedure for using a given instrument to achieve a given purpose. The elaboration and evolution of instruments is a long and complex process that Rabardel calls instrumental genesis. It is articulated in two processes: instrumentalization, related to the appearance and evolution of the different components of the artifact, for example, the progressive recognition of its potentials and limits; instrumentation, related to the appearance and development of patterns of use. In our case, the didactic activities carried out with AR involved students (as users and protagonists of the didactic-educational path), technological objects such as 3D glasses, tablets, and PCs (as instruments), and an object, intended in an educational sense as a mathematical item to be recognized, internalized and contextualized (the real functions of two real variables). The teacher thus makes use of technological artifacts that undergo a triple process of instrumental genesis: from the didactic point of view, because their use is aimed at generating knowledge and enhancing skills; from the pedagogical point of view, because their use is subordinated to suitable teaching methods activated by the teacher and aimed at the construction of mathematical meanings; from a technological point of view, because the use of technologies is not an end but implements an effective mobilization of strategies aimed at learning.

Fuzzy Cognitive Map

In this work, parameters related to Interaction, Participation, and Motivation, and their causal relationships, have been identified and analysed through a Fuzzy Cognitive Map to describe the student's state during the course. Kosko defines an FCM as a graph structure for representing casual relationships. It can symbolically describe complex systems/environments, highlighting events, processes, and states. In an FCM, a node of the graph is called a concept, and an edge is called weight. The edge allows for implementing a causal relationship between two concepts. The weight represents the strength of the influence of the relationship, described with a fuzzy linguistic term (e.g., low, high, very high, etc.).

An FCM can be formalized through a 4-tuple (N, E, B, f), where:

1. $N = \{N_1, N_2, \ldots, N_n\}$ is the set of n concepts that are represented by the nodes of the graph.
2. $E: (N_i, N_j) \rightarrow e_{i,j}$ is a function $(NxN \rightarrow [-1,1])$ which associates the weight $e_{i,j}$ to the edge between the pair of concepts (N_i, N_j);
3. $B: N_i \rightarrow B_i$ is the activation function which associates to each concept N_i a sequence of activation values, one for each time instant t: $\forall t, B_i(t) \in [0,1]$ is the activation value of the

concept N_i at time *t*. $B(0) \in [0,1]^n$ is the initial activation vector containing the initial values of all the concepts; $C(t) \in [0,1]^n$ is the state vector at a specific time instant *t.*

4. *f*: R → *[0,1]* is a transformation function with a recursive relation for $t \geq 0$ between $B(t + 1)$ and $B(t)$:

$$\forall i \in \{1, \dots, n\}, B_i(t+1) = f\left(\sum_{\substack{i=1 \\ j \neq i}}^{n} e_{ji} B_j(t)\right) \text{ (Eq. 1)}$$

FCM is developed by integrating existing experience and knowledge related to a system. As *f (x)*, different functions can be used. FCM can be used to make a what-if inference, starting from a given initial activation vector *B(0)*, to understand what will happen next to the modelled system/environment. Our FCM has been defined by a team of four experts. Each expert, starting from the status model we have defined, has proposed his FCM to identify the causal relationships and weights between the available concepts. The weights are represented by seven linguistic terms: *no impact 0.00, very low = 0.165, low = 0.335, medium = 0.50, almost high = 0.665, high = 0.835, very high = 1.00*. Then, we aggregate the different maps proposed by the experts to obtain one FCM. When some differences arise between the relationships and weights proposed by the experts, we asked them to discuss these differences and try to find an agreement, until they achieve a sufficient degree of consensus. This allowed us to obtain the FCM widely discussed in D’Aniello et al, 2020.

Methodology

The methodology is based on a single case study to identify intervention strategies on the specific situation of didactic hardship following the pandemic. Direct observation, understood as student-teacher interaction through information technologies collected empirical data on teaching effectiveness. The approach was both of an ideographic nature based on qualitative methods through a questionnaire to students (fully reported in appendix A) and of a nomothetic nature based on quantitative data that emerge from the results of the tests, from the responses to the questionnaire based on the Likert scale, and from students' interactions with the e-learning platform. Further qualitative information was collected from the protocols from the dialogues between students and between students and teachers on the e-learning system used. A specially created FCM summarizes both qualitative and quantitative data in terms of participation, motivation, and engagement, comparing them with the data of the previous cohort. As for the analysis of the disciplinary skills, a comparison between the results of the first and second mid-tests of two years was carried out.

The Case Study

The didactic experimentation involved the students of the first year of Mechanical Engineering and Management Engineering at the University of Salerno, the course teacher, two experts of the discipline for the exercises, three students attending the master's degree in engineering with the function of the tutor. The course was carried out during the second semester of the first year after students had attended and/or taken a Calculus 1 exam. Because of the COVID-19 pandemic, after the first two face-to-face lessons, the teaching activities of the Calculus II course were conducted through Distance-Learning. They were articulated into Asynchronous Online Learning and Synchronous Online Learning. The course has been restructured following the constructive alignment suggested by Biggs and Tang (2010). The course included 90 hours of lessons (six hours per week), divided into 54 hours of theory lessons and 36 hours of training; also 24 hours of exercises with the tutors, dividing the students into two sub-groups, 12 additional hours of activities for students who have reported an insufficient evaluation at the first test. The course has been designed considering the indications of the Teaching Council and the Lisbon descriptors. The following online resources have been used: custom adaptive e-learning platform (D'Aniello et al, 2020), Microsoft Teams, Doceri, Edmodo, the teacher's website, the teacher's YouTube channel, Geogebra AR. The use of these resources follows the framework proposed by Bray and Tagney (2016). This approach focuses on creating activities within the Transformation space: transformative uses of technology allow significant task redesign (modification) or permit the creation of tasks that would not be possible without the digital tools (redefinition). These aspects have contributed to implementing this course's activities, especially regarding engagement. The results obtained from the data available for completely remote teaching were compared with the data collected in a previous experiment. The course was conducted in blended mode, i.e., in the 2018/19 academic year. The Engagement parameters have been made available by the systems used through the collection of student interactions. The parameters relating to Motivation were determined through the analysis of questionnaires administered during the course. The parameters related to Participation or Emotions and social activities are established through sentimental analysis on the video streaming of the webcams filming the students and through the answers to the questions in the questionnaire. Dropout was calculated as the ratio of the number of students who attended the whole course to those who were present at the beginning of the course. The data provided by the system for the different parameters of interest are analysed through FCM execution to create the student's status; by comparing the parameters of the participants it will be possible to understand if the use of completely remote teaching did not negatively affect the status of students. The two classes are made up of 131 and 112 students respectively. For the experimentation, 60 samples from the first group and 60 samples from the second group were randomly selected. Cochran's formula was used to calculate the sample size: $n_0 = \frac{Z^2pq}{e^2}$ (Eq. 2), where: e is the desired level of precision (i.e. the margin of error); p is the (estimated) proportion of the population which has the attribute in question; q is $1 - p$; the z-value is found in a Z table. It is s the abscissa of the normal curve that cuts off an area α at the tails ($1 - \alpha$ equals the desired confidence level, e.g., 95%); n_0 is the sample size.

In our experimentation the chosen parameters were: $Z = 99\%; p = 0.90; e = 0.10$.

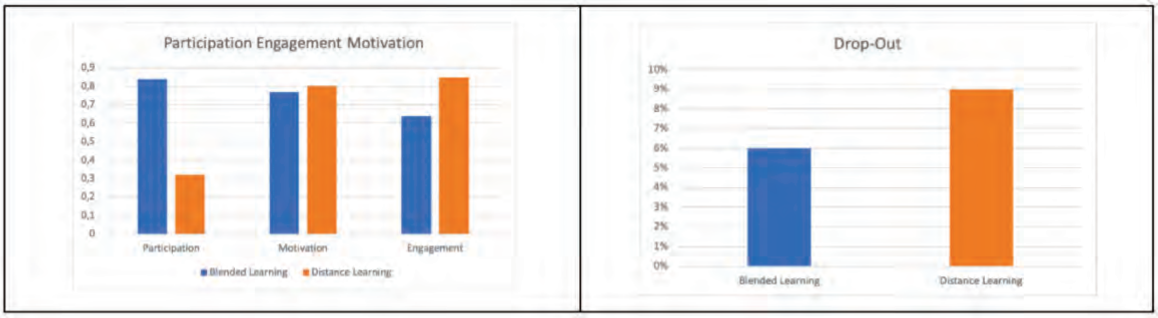

Fig. 1: a) Participation, Engagement and Motivation results. b) Dropout results

The average levels of engagement, motivation, and participation calculated through the execution of the FCM are shown in Fig.1a. The parameters used to obtain the motivation level were determined by analysing questionnaires administered during the course. The parameters related to participation were established through sentimental analysis on the video streaming of the webcams filming the students and through the answers to the questions in the questionnaire. At the same time, the parameters related to engagement were obtained, analysing mainly the data coming from the e-learning platform. The decline in student participation in the year 2019/20 compared to the previous year seems to be due to the negative impact of the emergency for the pandemic on the emotional state of students. In addition, the sense of alienation and frustration has led to a loss of concentration and poor social activity. The level of motivation is comparable for students of the year 2018/19, it is determined by intrinsic and social motivation for students of the year 2019/20 by an external tax. The engagement is slightly greater for students of the academic year 2019/20 who have massively used the e-learning platform as the only tool to follow the course and access the content made available by the teachers. Finally, the dropout graph shown in figure 1b shows how the two values are comparable (6% in the year 2028/19 and 9% in 2019/20) and how they remained below an acceptable threshold. The use of an adaptive e-learning platform and the restructuring of educational content using technologies, which led students to have a high level of engagement for the course duration, seem to have contributed to containing the phenomenon of dropout feared at the beginning of the course through distance learning methods. In addition, from the hierarchical questions of the questionnaire, it emerges that in the year 2019/20, 69.77% of students answered 4 or 5 on the Likert scale to the question of how frequently they confronted each other on the teaching activities of the course; while in 2018/19 40%. 92% of the students declared that they had interacted on the e-learning platform forum either assiduously or frequently (4 or 5 on the Likert scale) in 2019/20. As they declared, the forum allowed them to recreate the study room environment, although virtual, in which to discuss the solution of the exercises proposed in class. In 2018/19, however, only 25%. As a further element of qualitative analysis, it was decided to compare the data that emerged from the tests during the two academic years, shown in Fig.2.

Mark	First mid-term test 2018/2019	First mid-term test 2019/2020	Secondo mid-term test 2018/2019	Second mid-term test 2019/2020
A	4%	6%	15%	10%
B	12%	17%	18%	15%
C	31%	30%	23%	31%
D	22%	19%	12%	15%
Fail	32%	25%	32%	28%

Fig. 2: Results of the tests done by students during the two academic years

A less critical situation seems to emerge from the data in Fig. 2 than from the qualitative data. There is no statistically significant difference between the two data; indeed, it is possible to note that the percentage of those who failed the tests in 2019/20 is slightly lower than that of 2018/19. A possible interpretation of these data is suggested by having completely restructured the didactic activities. TCK, PCK and TPK have been intersected to convey the contents of the discipline using alternative teaching methodologies supported by the use of technologies. So, the main findings are:

Distance Learning is excellent as an additional and support methodology but highlights the ineffectiveness of completely remote teaching; the emergency alters motivation, participation, and engagement, and the distance learning used. The motivation went from intrinsic to extrinsic given the external constraint to take the online course as the only way to obtain attendance. Participation plummeted because the emotional state and the desire for socializing were adversely affected. Engagement increased as a result of massive use of adaptive learning platform and all the technological tools as the only means to follow the course and feel part of a community; by integrating TCK, PCK and TPK to use an adaptive e-learning platform, students have reached adequate levels of competence.

Conclusions

Distance learning, already widespread in recent years, has taken on a new meaning in this pandemic time. It has taken on the role of proximity education, as openness to the world and a willingness to enter into a relationship with things and others. It was indispensable for strengthening the web of relationships between teachers and students and between teachers. Distance Learning could lead to unexpected connections that are not just accessing a server from a client through protocols or software but could instead favour synaptic connections that produce cognition and generate positive emotions that do not make us become victims of an emotional abduction and transported by fear, by anguish in a non-adaptive way. This research focused on distance learning and the virtual environment during the Covid-19 pandemic, highlighting how motivation, participation, and engagement are affected. The purpose of the experiment was to verify how the use of completely remote teaching influences the student's status in terms of participation, interaction, engagement. A student with a high level of these indices proved to be more motivated to study the discipline, positively influencing skills improvement. It was possible to understand that completely remote teaching did not negatively influence the student's status, assessed through FCM, and allowed satisfactory results to be achieved in terms of acquired skills. The dropout was contained within acceptable values. The strategies implemented by the course lecturers aimed at integrating TK, PK, and CK following the TPCK framework. Finally, the processes of instrumentation and instrumentalization have caused an instrumental genesis of technological artifacts. The findings of this case study provide a fresh perspective and set the stage for future related research. The authors hope to undoubtedly return to face-to-face teaching, where human values and relationships take on a concrete and visible form while trying to exploit the potential of distance learning, integrating the strengths of the two methodologies. Distance learning offered the opportunity to rethink educational action from the point of view of contents, methodologies, and student-teacher interactions alike. At the end of the pandemic, as the next step, we think that some positive aspects of distance learning can be integrated with traditional teaching and enhance a blended modality of didactic action called Integrated Digital Teaching.

Exploring Teachers' Affective Schemes through a Networking of Theories Approach

Scott A. Courtney[1], Christine K. Austin[1] and Kristine C. Glasener[1]

[1]Kent State University, USA; scourtn5@kent.edu, causti17@kent.edu, kglasene@kent.edu

In this report, we network the documentational approach to didactics and a theory of meanings to explore and develop models of one tertiary teacher's (Evelyn's) understandings of developmental mathematics, its students, and the resources she utilizes to support instruction. In addition, we discuss the affective aspects of the schemes of meanings that came to Evelyn's mind as a result of these understandings. Finally, we discuss future research to explore the design of interventions (e.g., professional learning experiences) that provoke changes in tertiary teachers' schemes of meanings to more productive structures.

Keywords: Affect, caring communities, sense of belonging, theory of meanings.

Introduction

In the United States, college and university policies typically require new students to be assessed in mathematics through some form of placement test. These tests are commonly designed and evaluated by a third-party (e.g., ALEKS, COMPASS). Students assessed as needing mathematics remediation are required to complete remedial (or developmental) math courses prior to taking a college-level math course. The need for remediation in math is not uncommon for students at both 2- and 4-year public institutions. Chen's (2016) analysis of beginning tertiary students' course taking between 2003 and 2009 found 59.3% of students who began their tertiary education at a 2-year public institution and 32.6% of students who began their tertiary education at a 4-year public intuition, took one or more remedial mathematics course. Unfortunately, a large percentage of students enrolled in developmental courses fail to pass them. According to Chen (2016), 20% of remedial math course takers beginning at both public 2- and 4-year institutions did not complete any of the remedial math courses they attempted. There exists substantial research documenting the characteristics (e.g., academic preparedness, age, ethnicity, socioeconomic status) of higher education developmental mathematics students that relate to retention and success (e.g., Benken et al., 2015). In addition, extensive research on efforts to reform developmental mathematics in higher education have focused on restructuring coursework, reforming developmental placement, redesigning curricula, and enhancing student support (e.g., Bickerstaff et al., 2019). Missing from this research are investigations into those at the forefront of attempts to implement such changes—the instructors of developmental mathematics courses. In this report, we focus on teaching and learning developmental mathematics at the tertiary level and addresses the following research questions: 1) How do tertiary mathematics teachers understand developmental mathematics? 2) How do tertiary mathematics teachers understand the students enrolled in developmental mathematics? 3) How do tertiary mathematics teachers understand the resources they utilize to support developmental mathematics instruction?

Theoretical Framework

The study utilizes a networking of theories approach (Bikner-Ahsbahs & Prediger, 2010) to connect frameworks and explore the research questions; specifically, we "network" the documentational approach to didactics (Trouche et al., 2020) and a theory of meanings (Thompson et al., 2014).

The Documentational Approach to Didactics

The documentational approach to didactics (DAD) analyses "teachers' work through the lens of 'resources' for and in teaching: what they prepare for supporting their classroom practices, and what is continuously renewed by/in these practices" (Trouche et al., 2020, pp. 237–238). In DAD, resource is defined as anything "developed and used by teachers and pupils in their interaction with mathematics in/for teaching and learning, inside and outside the classroom" (Pepin & Gueudet, 2020, pp. 172–173). Such resources include text (e.g., textbooks, worksheets, tests) and other material resources (e.g., calculators); digital-/ICT-based resources (e.g., online textbooks, GeoGebra); discussions between teachers, orally or online; students' written work; and teachers' discussions with mathematics teacher educators (Pepin & Gueudet, 2020). Integral to DAD is documentational genesis, which comprises two interrelated processes (Trouche et al., 2020): instrumentalisation, where a teacher's knowledge guides the choices she makes among various resources and the way these resources are appropriated; and instrumentation, where the features of the resource(s) impact the teacher's practice. Documentational genesis "gives birth" to a mixed entity (i.e., a document) linking resources and a utilization scheme for these resources, represented by the equation: Document = Resource(s) + Utilization Scheme. The concept of scheme, which can be viewed as a structure organizing a subject's activity with a resource or set of resources for a given goal, is central in DAD.

Theory of Meanings

Thompson and Harel's theory of meanings (Thompson et al., 2014; Table 1), is based on Piaget's notion of assimilation to a scheme, and focuses on teachers' (schemes of) meanings, where a scheme is defined as "an organization of actions, operations, images, or schemes—which can have many entry points that trigger action—and anticipations of outcomes of the organization's activity" (Thompson et al., 2014, p. 11).

Table 1: Definitions of Understanding, Meaning, and Ways of Thinking (Thompson et al., 2014)

Construct	Definition
Understanding (in-the-moment)	Cognitive state resulting from an assimilation
Meaning (in-the-moment)	The space of implications existing at the moment of understanding
Understanding (stable)	Cognitive state resulting from an assimilation to a scheme
Meaning (stable)	The space of implications that results from having assimilated to a scheme. The scheme is the meaning.
Way of Thinking	Habitual anticipation of specific meanings or ways of thinking in reasoning

As characterized by Thompson and Harel (Table 1), an understanding is a cognitive state of equilibrium, which may occur from assimilation to a scheme (i.e., stable understanding). According to Thompson et al. (2014), "A scheme, being stable, then constitutes the space of implications resulting from the person's assimilation of anything to it. The scheme is the meaning of the understanding that the person constructs in the moment" (p. 13). Alternatively, a cognitive state of equilibrium might be a state the "person has struggled to attain at that moment through functional accommodations to existing schemes . . . and is easily lost once the person's attention moves on" (i.e., in-the-moment understanding; Thompson et al., 2014, p. 13).

Methods

Since the study attempted to reveal teachers' understandings and explore how these conceptions impacted their teaching of developmental mathematics, it was necessary to make models of teachers' conceptions. The case study described in this report expresses our second- order models of teacher's understandings at various points throughout the study; that is, throughout the activities (i.e., interventions) designed to make teachers' meanings explicit.

Study Participants

In this report, we focus on one of two study participants (i.e., Evelyn). Evelyn had 16 years of tertiary teaching experience and was teaching a fully remote Beginning Algebra community college course during an 8-week summer course with 13 non-traditional college students. The course met twice each week for 90-minutes. Although Evelyn's summer course encompassed 8 weeks, the study itself was 12 weeks in length and included weekly group meetings before, during, and after the conclusion of her summer course. Eleven of the 13 students (84.6%) passed the course, a rate higher than results from Chen (2016), indicating Evelyn may serve as a model for effective developmental mathematics practices.

Data Collection

The study employed a modified version of the reflective investigation methodology (Trouche et al., 2020) for data collection, a methodology naturally associated with case studies and grounded by five main principles: (1) broad collection of resources; (2) long-term follow up; (3) in- and out-of-class follow-up; (4) reflective follow-up; and (5) confronting a teacher's views on her documentation work. Due to the length of the summer course and limits precluding in-person interactions, some principles could not be strictly adhered to, resulting in a modified version of the methodology. The data corpus consisted of Evelyn's semi-weekly self-recorded videos discussing her lesson plans, with accompanying documents and internet links to all materials she utilized during instruction and assessment; her reflections of lesson implementations; and video recordings and field notes from weekly online discussions designed to probe Evelyn's understandings in more detail. Data also included two tools specific to reflective investigation methodology: reflective mappings of Evelyn's resource system (RMRS) and inferred mappings of Evelyn's resource system (IMRS). According to Rezat et al. (2019) an RMRS is a methodological tool created by a teacher where the teacher is asked to draw a map (based on her own reflections) to present her resources in a structured way; whereas an IMRS is a methodological tool created by "the researcher based on the observations of and interviews with the teachers about their resource work" (Rezat et al., 2019, pp. 357–358).

Results

Making sense of Evelyn's understandings of developmental mathematics and her students required us to develop models of Evelyn's ways of operating—models that represented our interpretations of

Evelyn's interactions with study activities and digital resources. Using data generated from study activities and reflective investigation, these models were tested, modified, and refined through ongoing and retrospective conceptual analysis of the data corpus. Evelyn utilized a student survey at the beginning of her course to obtain information about her students' perceptions of mathematics. The survey was posted as an online assignment and asked students a variety of questions, including: "How do you feel about taking a math course synchronously/online?"; "What are your strengths and weaknesses in mathematics?"; and questions regarding students' experiences with the institution's videoconferencing application (i.e., Webex) and learning management system (i.e., Blackboard). As part of the Week 6 meeting, Evelyn described her initial RMRS. During the Week 7 meeting, the first author created an inferred mapping of Evelyn's resource system (IMRS), based on her RMRS and the Week 6 discussion. During the Week 9 meeting, Evelyn was confronted with this IMRS and her original RMRS. The Week 9 meeting resulted in the refined IMRS shown in Figure 1, which illustrates Evelyn's resources partitioned into three groups: resources specific to mathematics content, tools for communication and dissemination, and tools to deliver instruction.

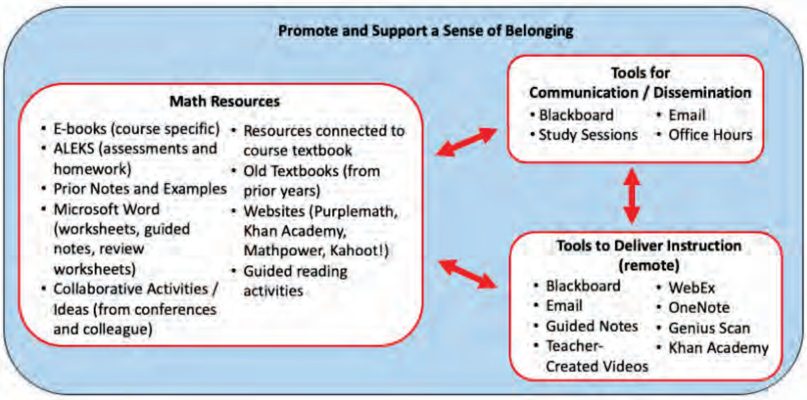

Figure 1: Refined Inferred Mapping of Evelyn's Resource System (IMRS)

Evelyn's RMRS did not include the arrows. Comments made during group meetings emphasized Evelyn's integration of these three types of resources. For example, whenever Evelyn spoke about "Math Resources" she used, she invariably included ideas about and a rationale for utilizing "Tools for Communication / Dissemination" and "Tools to Deliver Instruction." During the Week 11 meeting, Evelyn indicated her use of guided notes, Khan Academy, Microsoft Word, and ideas from her colleagues were "dependent on her students' needs . . . [and] were provided to help develop, promote, and support a caring community in the classroom." Throughout the data corpus, Evelyn indicated her "students' needs" referred to each student's individual circumstances and challenges, which included (Goldin, 2002; Hannula et al., 2019): math anxiety – "my students are so intimidated and scared of mathematics because of bad prior experiences" (Instructor 2, Week 2 meeting); test anxiety – "testing is always a traumatic experience for these students" (Instructor 2, Week 9 meeting); low math self-efficacy – "part of my job is to get these students to believe they can actually do the math" (Instructor 2, Week 11 meeting); and frustration – "many of my students with families and work get fed up trying to navigate school" (Instructor 2, Week 6 meeting). Therefore, Evelyn enacted her intent to "support a caring community in the classroom" through listening to and observing her students; demonstrating respect for her students; thinking and reflecting on ways to support her students; being approachable, available, and responsive to her students; and creating an environment where caring relations can flourish.

Throughout the group meetings, Evelyn's comments also emphasized an image that resources were in the foreground of her practice, whereas promoting and supporting a sense of belonging in the mathematics classroom was always in the background. Comments and assertions that illustrate this image include: mathematical identity – "I want to make sure each student believes they can be . . . they are a contributor to the mathematics classroom . . . to view themselves as mathematicians" (Instructor 2, Week 6 meeting); and values – "since most of my classes have both traditional and nontraditional students, I have to make certain to provide activities that encourage each group to value mathematics" (Instructor 2, Week 9 meeting) (e.g., Goldin, 2002; Hannula et al., 2019). According to Thompson and Harel (Table 1), the meaning of an understanding is the actions or schemes the current understanding implies. Therefore, the meaning of Evelyn's understandings "to develop, promote, and support a caring community in the classroom, dependent on my students' needs" and "to promote and support a sense of belonging in my students, as learners of and contributors to mathematics"—what comes to Evelyn's mind in situations related to developmental mathematics and its students—are comprised of affective aspects of her students (e.g., anxiety, frustration, identity, self-efficacy, values). Goldin (2002) defines beliefs as "internal representations to which the holder attributes truth, validity, or applicability, usually stable and highly cognitive, may be highly structured" (p. 61). For Philipp (2007) beliefs are "the lenses through which one looks when interpreting the world" (p. 258). Therefore, Evelyn's stable understandings related to developmental mathematics and its students are indicative of her beliefs about developmental mathematics and its students.

Teachers' Understanding of Remedial Mathematics

Evelyn exhibited meanings for development mathematics that involved more than just a series of pre-tertiary math topics (e.g., operations of real numbers, order of operations); rather, as described by Evelyn, "Developmental math involves content that is foundational to my students' future mathematics learning" (Week 10 meeting). Evelyn also indicated a desire to prepare students for subsequent math courses by helping her students "build or strengthen their mathematics foundation for their next course, including study strategies" (Week 3 meeting). Therefore, as characterized by Thompson and Harel (Table 1), Evelyn's stable understanding of developmental math is "*content foundational to students' subsequent math courses and dependent on each student's needs*." Although one might question how this stable understanding can be defined as a "cognitive" state resulting from an assimilation to a scheme, it is important to note that when "Piaget spoke of schemes, he had in mind organizations of mental and affective activity whose contents could be highly nuanced and could contain several layers of structure" (Thompson, 2016, p. 432). For Piaget (1973), the "affective and cognitive mechanisms always remain interrelated though distinct" (p. 261). Similarly, for Vergnaud (2013), "[c]ognition is affective, or it is not, and affectivity is cognitive, or it is not. A scheme conveys both characteristics" (p. 52). Therefore, we interpret a "cognitive state" as being inclusive of all cognitive, affective, and social activity. This interpretation aligns with A. G. Thompson (1992), who referred to teachers' understandings "as a more general mental structure, encompassing beliefs, meanings, concepts, propositions, rules, mental images, preferences, and the like" (p. 130). Finally, since meaning is implicative, Evelyn's meaning of developmental mathematics has implications for her further action. Specifically, Evelyn's actions focus on highlighting the "foundational to subsequent mathematics courses" aspect of development mathematics and affective aspects of "each student's needs" (e.g., anxiety, frustration, identity, self-efficacy, values).

Teachers' Understanding of the Students Enrolled in Remedial Mathematics

In addition to the initial survey, Evelyn also asked her students how they were thinking about the course (e.g., what they struggled with, what was useful) throughout the course. Evelyn developed models of her students based on her interpretations of students' responses to these queries. For example, one of Evelyn's students who had not taken a math class for over seven years asserted, "I had a lot of college credits, but just [gave] up on myself . . . [and] want to prove to myself and my children that it's never too late." As such, Evelyn made a point to "check-in" with this student on a regular basis to make certain she was feeling comfortable and achieving her goals. Since Evelyn was teaching remotely, she provided a live tutorial for her students, where she went through the Blackboard and Webex environments, making certain students had a sense for where to find the calendar, weekly and daily folders, assignments, assessments, video links, and chat box. Evelyn also provided her students with an unlimited amount of time to complete online quizzes, since she wanted to "make certain [they] feel like they have enough time to do really good work, to be thorough, and to show all of their work" (Week 10 meeting). Evelyn indicated this action helped reduce some math anxiety because students were not watching the clock. Furthermore, Evelyn promoted a collaborative and supportive environment by encouraging students to use "clapping" and "thumbs up" emojis to show appreciation for student or group virtual demonstration work. Finally, Evelyn utilized her understanding of her students' future courses to emphasize concepts and behaviors important to students' continued success. Therefore, Evelyn understood her (developmental) students as "*individuals with varying mathematics and school experiences in need of a caring environment and a sense of belonging as learners of and contributors to mathematics*"—indicative of Evelyn's beliefs about her students. Since meanings are implicative, Evelyn's actions focused on affective aspects of her students (e.g., anxiety, frustration, identity, self-efficacy, values).

Teachers' Understanding of the Resources They Utilize to Support Instruction

Evelyn selected resources that provided her students with opportunities to engage in mathematics in a supportive environment. This way of thinking is demonstrated by examining those resources Evelyn utilized to find and generate mathematics content and environments (e.g., Khan Academy, Microsoft Word; see Figure 1). Evelyn indicated she used Khan Academy because most of her students were familiar with it, either through a prior high school math course or their own children's use of the resource. Regarding use of her prior notes, Evelyn indicated her students had found guided notes to be quite beneficial during asynchronous classes over the past year. As such, she decided to utilize these same notes in the remote setting. Finally, Evelyn provided self-made video tutorials corresponding to her guided notes, again prepared over the past year, as an additional resource to support her students. Evelyn indicated her Word documents could easily be changed to pdf format and uploaded to Blackboard Ally, a tool that generates alternative formats for students to download, provides accessibility scores, and gives instructor feedback on how to improve their accessibility score. Finally, Evelyn indicated making digital course content more accessible to all her students supported her attempts to support student engagement and sense of belonging. Therefore, Evelyn understood these resources as "*tools to support each student, based on their individual needs, as they engage with mathematics and interact with their classmates and herself*"—indicative of Evelyn's beliefs about developmental mathematics and her students. Finally, since meanings are implicative—and as a result of the instrumentalisation process—Evelyn's actions with respect to these tools focused on her students' "individual needs" (e.g., anxiety, frustration, identity, self-efficacy, values).

Discussion and Conclusion

As illustrated here, Evelyn's schemes of meanings, indicative of her beliefs, focused on affective aspects of her students' varied needs and experiences. Aligned with Hackenberg (2005), we posit that Evelyn's assimilatory structures involve a scheme of decentering (Piaget, 1962), where decentering is the attempt to imagine one's experience from another perspective. Given the case study only included one participant, our findings are not generalizable. The study's small sample size and lack of range within teaching styles are a few additional notable limitations. Future research should explore the understandings of a larger sample of tertiary teachers of developmental mathematics to determine the meanings by which teachers operate; specifically, the ubiquity of schemes of decentering. Such research should also include examination of the types of professional learning experiences most propitious to fostering schemes of decentering in tertiary mathematics teachers. Furthermore, the "networked" approach presented here provides researchers and mathematics teacher educators with a framework focused on teachers' documentation work that supports identification of the schemes of meanings with which teachers teach—including teachers' belief structures—and has the potential to support the design of productive professional learning experiences for both pre-service and in-service teachers. Finally, such research should explore the role the instrumentation process might play in transforming teachers schemes of meanings, where the features and teacher's understanding of a resource or set of resources impact that teacher's schemes as a result of their interactions with the resource(s).

Beliefs about problem posing

Çiğdem Haser

University of Turku, Faculty of Education, Finland; cigdem.haser@utu.fi

Beliefs about problem posing are rarely addressed in mathematics education. The study explored 43 senior preservice middle grades mathematics teachers' (PTs) beliefs about problem posing and their possible place in their mathematics-related belief system with two open-ended surveys and one problem posing task. In line with their mathematics-related beliefs, PTs believed that problem posing was important because it supported students' conceptual understanding. However, they believed that problems for the low-level students should require applying simple procedures and these students would not be able to pose problems. Problems including challenging tasks could be posed for high-level students and they had skills to pose such problems. PTs' problem posing beliefs may be linked more to their beliefs about students' learning than those about nature of mathematics and problems.

Keywords: Problem posing, preservice mathematics teachers, beliefs, belief system.

Introduction

Problem posing is (a) producing new problems by rearranging an existing situation to a problem or (b) revising existing difficult problems to formulate more solvable problems (Silver, 1994). It is an important, challenging, and cognitively demanding mathematical activity as it enhances students' conceptual understanding, reasoning and dispositions towards mathematics (Singer et al., 2013), and enables teachers explore students' mathematical understandings and experiences (Silver, 1994). Hence, there is a demand for teachers to encourage students for posing problems (Crespo & Sinclair, 2008; Rosli et al., 2015). Inservice and preservice teachers' mathematics-related beliefs influence their response to the demands for meaningful mathematical experiences and their conceptualization of teaching and learning mathematics (Philipp, 2007). Despite the importance of problem posing in mathematics education and of inservice and preservice teachers' beliefs, beliefs about problem posing have received less attention (Li et al., 2020) within the studies about mathematics-related beliefs.

Middle school mathematics in Turkey aims to enhance students' conceptual understanding of mathematics by guiding them to construct new mathematics concepts on existing ones, focusing on conceptual understanding, emphasizing connections to other content area and real-life, and utilizing multiple representations (Milli Eğitim Bakanlığı (MEB), 2018). This approach is supported by mathematics teacher education programs that train teachers specifically to teach middle school mathematics. Problem posing is an effective tool to enhance students' and preservice and inservice teachers' conceptual understanding of mathematics, yet it is addressed less in teacher education programs compared to problem solving (Crespo & Sinclair, 2008). Teachers' beliefs about problem posing may influence their tendencies to utilize problem posing in their teaching (Li et al., 2020). Therefore, this study investigated preservice middle school mathematics teachers' (PTs) beliefs about problem posing in the beginning of a short problem posing module to draw conclusions for how these beliefs might be related to each other within the web of PTs' beliefs and inform the teacher education programs with the following research question: How are PTs' beliefs about problem posing related to their mathematics-related beliefs and beliefs about problem solving?

Belief Systems

It is often accepted that beliefs are held in *belief systems* including the following characteristics as identified by Green (1971): (i) Beliefs are located in *clusters* in which we hold non-conflicting beliefs; (ii) some beliefs are constructed in relation to others in our belief system, which makes them *quasi-logical*, where we have *primary* beliefs and their *derivatives*; (iii) strong and important beliefs are located at the *center/core* of the clusters and those that are less strong at the *peripheral*; and (iv) we hold some beliefs *evidentially* (based on evidence/reason and can be changed by rational criticism) and some *non-evidentially* (not evidence-based and not changed easily). He suggested that teaching should aim for developing evidential beliefs and a quasi-logical belief system as logical as possible.

Beliefs in a cluster may be considered as a web of primary and derivative beliefs (Beswick, 2018). If we have experiences that conflict with our existing beliefs, we (our belief system) tend to adapt to these new beliefs or try to explain our existing beliefs in different ways as an attempt to limit the conflicts. This adaptation takes place when we reflect on our experiences and reorganize our understandings from our observations (Philipp, 2007). In the end, we have new beliefs and a new (sub-)web of beliefs linked to the existing web, which illustrate adaptation of our belief system when there are new experiences and knowledge (Beswick, 2018).

Beliefs about Problem Posing

Previous studies revealed that PTs considered having problem posing skills as important and beneficial for teachers and students especially to increase students' interest in mathematics (Hošpesová & Tichá, 2015). They also believed that problem posing increased students' mathematical thinking, made students the owners of their mathematical knowledge, and served as an effective process to assess their learning (Hošpesová & Tichá, 2015). PTs tended to believe that problem posing could help students develop a better understanding of mathematical concepts, think beyond solving and posing problems, become more creative, and develop positive attitudes when they worked on the problems posed by students (Grundmeier, 2015). PTs mostly believed that the connection between real-life and mathematics would be useful for students while posing problems, but they did not focus on the benefits on students' learning (Lee, 2012).

When PTs posed problems, they paid attention to the difficulty of the problems for the age and grade level of students, authenticity of the problems, mathematical concepts in the problems, and realistic and understandable nature of the problems (Rosli et al. 2015). Yet, analysis of their problems showed that the problems they posed were not in high quality (Hošpesová & Tichá, 2015), did not focus on conceptual understanding but promoted memorization (Crespo & Sinclair, 2008), and their solution required one or two arithmetic operations (Lee, 2012). PTs did not increase the reasoning and thinking skills required to solve the problems; rather, they added another operation for solution to increase the complexity of the problems (Leavy & Hourigan, 2020). It is possible that since PTs tended to pose problems similar to the ones they solved earlier in teacher-assigned tasks and textbooks because they were generally were not given opportunities to pose problems (Crespo & Sinclair, 2008).

Studies showed that training on problem posing provided teachers and PTs with new perspectives on problem posing (Barlow & Cates, 2006; Leavy & Hourigan, 2020). Teachers developed favorable beliefs about employing problem posing in the classroom and tended to do so in their lessons because they observed that problem posing helped their students construct mathematics knowledge and increased their interest in mathematics and discussions in the lessons (Barlow & Cates, 2006). However, teachers and PTs believed that problem posing might be confusing for students in the beginning, consume time, result in ineffective mathematics lessons, and students might be more inclined to pose simple questions but not problems that require reasoning (Hošpesová & Tichá, 2015).

PTs can develop beliefs to support their practices for effective learning, such as beliefs about problem posing that will enable them to integrate problem posing effectively in their future teaching, when teacher education programs address their existing beliefs and aim for new ones (Philipp, 2007). However, this process requires knowing how PTs' existing mathematics-related beliefs are organized, where their (probably derivative) problem posing beliefs might be placed within their belief system in relation to the other beliefs, and what possible belief connections should be targeted while designing problem posing experiences for them. Therefore, the study focused on PTs' beliefs about problem posing in the beginning of a short module aiming to provide initial ideas on problem posing.

Method

A basic qualitative research design was employed to explore PTs' beliefs (Merriam, 2009) by open-ended surveys and problem posing tasks, which PTs provided written responses. The problems posed by PTs during the implementations were not the foci of the study and therefore, not reported.

Context and participants

The study was conducted in a four-year middle-grades (5 to 8) mathematics teacher education program in Turkey with 43 PTs (6 males and 42 females) who were taking the Practice Teaching course and consented for the study. Practice Teaching is offered in the last semester of the program and required 60 hours of observation of and teaching middle school mathematics lessons, and two-hour University component every week to discuss PTs' experiences and observations at schools.

Instruments and procedures

PTs participated in a four-hour module (2 two-hour meetings) on problem posing that took place at the University component of the Practice Teaching course. The study focused on the first two-hour meeting where PTs completed two open-ended surveys and one individual task. Surveys targeted PTs' thoughts, experiences, and observations about teaching and learning mathematics, problems, problem solving and posing. The reason for targeting a broad area of beliefs was to understand PTs' larger web of mathematics-related beliefs and possible derivative beliefs about problem posing within (Beswick, 2018). The task asked PTs to pose problems for students with different levels of knowledge and skills, and reflect on the process. Information about the data collection procedure is in Table 1.

Data analysis

Data analysis started by extracting belief statements after repeated careful reading of all responses (Beswick, 2018) where PTs expressed their understandings and reasons (Philipp, 2007) for the question content. I developed a code list based on the studies about PTs' mathematics-related beliefs in these programs (e.g., Haser & Doğan, 2012) and based on my repeated reading of the data with room for emerging codes especially for beliefs about problem posing. While I kept a list of possible codes from the literature (above) for problem posing, my focus was more on codes extracted from the data because I tried to see the connections among the beliefs within this specific data set. After determining the initial code list, I coded the data with some emerging codes, revised my coded data for consistency, and listed examples of belief statements for the codes. After coding was completed, I determined the themes and revised the examples of belief statements and data to ensure an adequate representation of PTs' beliefs by the themes. I summarized the themes narratively to see a clearer picture of connections which revealed a web of PT's beliefs grounded in data and their conflicting beliefs. I revised the conflicting beliefs one more time in detail for a better interpretation.

Table 1: Examples of questions, (*) notes, and the number of PTs responded

Survey 1: What are the behaviors of a middle school student with an in-depth understanding of mathematics concepts? / Based on your observations at schools, what can you tell about what teachers pay attention to in their teaching? (43 PTs, 12 questions)
Survey 2: Based on your observations at schools, how do the middle school teachers address problem solving in their teaching? / Can middle school students pose mathematics problems? Why? (43 PTs, 12 questions)
Task: Pose a problem which requires the multiplication of two simple fractions (and if necessary, other operations and thinking) and which low-/mid-/high-level students can solve by spending some effort. Please indicate the grade level. ((*)Adapted from Singer et al. (2011). Targeting a 6th grade objective (MEB, 2018), 39 PTs, 3 questions)

Findings

Mathematics-related beliefs

PTs believed that mathematical knowledge was about understanding the reasons and connections between the mathematical concepts by asking questions and thorough thinking. School mathematics had certain "definitions", "important terms, [and] proofs" of key importance as they were connected to other concepts and daily life. Although PTs expressed the importance of these connections for mathematical knowledge, they did not mention abstract concepts and relationships. Rules, formulas, the reasoning behind them and their connections were also part of the mathematical knowledge.

Teachers should "conduct activities that would increase students' interest", ask "questions that would make students question," and teach accordingly to ensure students' learning. PTs believed that students should not memorize rules and formulas; therefore, teachers "should reach the rule by proving with the students." Teachers should monitor students' learning by questions "that require making connections with other concepts" and by asking them to try different ways, generalize, build patterns, give counter examples, and use multiple representations. PTs criticized teachers' practice of solving several questions in the lessons. They would like to ask questions "that students will inquiry the most [and] will build cause and effect relationship" after "teach[ing] the rationale behind the concepts". It is better if students solved questions after the lesson because "they may forget easily and not be able to see their missing [knowledge] if they do not solve questions."

PTs believed that knowing fundamental concepts and building relationship between them were important for students. These required reasoning, questioning, and deeply thinking about the reasons and meanings. They stressed the use of formulas, but were against memorizing them. PTs believed that students, who paid attention to their teachers with utmost care and spent effort on learning during the lesson, would learn mathematics effectively.

Beliefs about problems, problem solving, and problem posing

Mathematical problems were real-life situations for PTs which required “understanding and thinking” of mathematical knowledge and “building relationships and logical inferences”. Problems could be solved in different ways with multiple results, but not immediately by a procedure or a formula. Middle school level problems were the same except for the level of the mathematical knowledge. Problem solving at schools, as observed by PTs, was the activity where teachers first asked a question and answered it, and then asked a similar question to the students to be solved in a similar way. “Unfortunately” they observed that some teachers assigned closed-ended drill-and-practice questions, which did not match PTs’ definition of problems, and students were not asked about their reasoning.

PTs would like to employ problem solving in the future with problems that would target students’ mathematical thinking or understanding of mathematical concepts and more difficult than what students were used to solve. PTs’ problems would require attention to and discussion of the problem situation, and the daily life contexts to be solved. Students were the problem solvers, not the teachers.

> I would like to consider a situation that actually requires a solution. I would like students to follow a solution [strategy] by considering what kinds of external factors would influence the results they would reach had they been in such a situation, instead of [asking a problem] that they would reach a single result directly by multiplication [and] division.

On the other hand, PTs did not have much experience in problem posing in their courses and only some of them were able to design and ask problems in real classroom settings, which received positive reaction from students and collaborating teachers. They gained initial ideas for their problems from course books or internet resources. Some focused on connections between the mathematical concepts and real life problems, and they employed real data.

The problems PTs posed in the study provided data on PTs’ thinking about problems for students with different levels of knowledge and skills, and the factors they would consider while posing problems. PTs posed problems requiring more/difficult operations for high-level students and those requiring “implementation of a known procedure” or “a memorized operation” for low-level students, contrary to their definition of problems and statements disaproving memorization. Although they indicated in the survey that problems did not have immediate solutions, some PTs posed problems that “would not lead [students] to difficulty and enable them to understand the concept and the question.” They did not take into account the properties of problems that they identified when they posed problems especially for low-level students. For example, one PT wrote a mathematical expression of multiplication of two simple fractions without a problem statement and stated that “[Students] will only implement what they have learned. Knowing the rule would be sufficient.”

PTs stated that they prioritized students’ knowledge, possible difficulties, the national curriculum, own experiences from the courses, and daily life connections and links to other mathematical concepts while posing problems, and targeted students’ thinking. The problems they posed for low-level middle grades (5 to 8) students included fundamental concepts most of which were covered in the elementary grades (1 to 4), such as the meanings of fractions and fraction multiplication, part-whole relationship, fair sharing, and part-of-a-part. Their problems for high-level students were about connections among the mathematics concepts and the meaning of other fraction operations. Some problems required more/difficult operations as students' level increased: "I identified simple, medium [and] difficult level operations and I identified the context of the question for these."

Beliefs about students' problem posing

Many PTs believed that students had the capability to see the mathematics in daily life because they had to deal with several problems in their daily lives, which illustrated the contexts for students' problems. They indicated that students were creative, better and quick learners, and their prerequisite knowledge was sufficient to pose problems.

> They have reasoning, they are involved in real life. They gain experiences [and] deal with troubles. Don't these show that they have a natural tendency to solve problems? [So] they can pose problems about some of the obstacles/questions that are in front of them while they improve their lives.

Yet, several PTs believed that middle school students could pose problems only "if [teachers] enable them to understand and conceptualize the topics [effectively]." Some believed that students' understanding of problems were limited and "they cannot examine what should be thought [and] whether it can be solved in multiple ways or not while posing the problem" because "posing a problem is more difficult than solving that problem" and students were "not used to posing problems". Therefore, "[problems] should be posed only by the people who know the concepts well."

Discussions and Conclusions

PTs' problem posing beliefs and mathematics-related beliefs seemed to be in line. They believed that problem posing provided students with deep thinking of mathematics concepts in context, and their connections to each other and daily life. These beliefs were probably derivative of PTs' primary beliefs because (a) PTs' experiences were not sufficient yet to build primary problem posing beliefs and (b) they had some observations and experiences of teaching mathematics in classrooms on which they were able to elaborate to develop new understandings of problem posing.

Even though PTs identified certain characteristics for problems, their related problems mostly lacked these characteristics. Their problems for high-level students were different from those for low-level students in terms of the number of operations involved in the solution, but not the thinking level, as can be seen in other studies (Leavy & Hourigan, 2020). PTs believed that problems should point to the links among the mathematical concepts, but they illustrated this link in their problems only for high-level students to some extent, not for low-level students. These differences showed that some of PTs' problem posing beliefs might be connected to their beliefs about students' learning more than to their beliefs about the nature of mathematical knowledge. They might develop contradictory beliefs within the same belief system in different clusters (Green, 1971) with an effort to reach stability by adapting to the new problem posing experience (Beswick, 2018).

PTs' beliefs about problems to be posed to high-level students (who are good at reasoning and dealing with challenge) seemed consistent with their beliefs about problems (challenging situations that required thorough thinking) and teaching and learning mathematics (mathematical knowledge is not for memorization). These beliefs, however, conflicted with their beliefs about problems to be posed to low-level students (simple problems as they could handle only certain and memorized mathematical procedures, but not challenge). PTs possibly observed certain practices at schools where teachers posed several questions solved by routine procedures and believed that this practice was better for low-level students, even though they criticized it. They might also tend to replicate the problems they have seen in mathematics lessons and resources (Crespo & Sinclair, 2008) due to their insufficient problem posing experiences. PTs might believe that certain less risky practices would be better in classrooms when they lacked problem posing experiences; therefore, tended to pose easier problems for low-level students. Although PTs prioritized approaches that would lead students to conceptual understanding of mathematical concepts, they might keep a consistent belief system by thinking about low-level students as a special case that required a different understanding, and accordingly holding beliefs about low-level students in different clusters (Green, 1971).

Longer and intensive problem posing experiences would provide PTs with opportunities to develop more consistent web of beliefs. The beliefs documented here revealed that when PTs did not have sufficient problem posing experiences, they tended to develop derivative beliefs, which should be explored and addressed carefully when providing PTs with problem posing training. It is advisable that such training for PTs should include more and varied experiences of posing problems and require reflection on experiences and rationale. Further studies should explore PTs' initial beliefs about problem posing in-depth before they are trained for it and how their problem posing beliefs are linked to their beliefs about students, problem solving, and teaching and learning mathematics while preparing for and teaching through problem posing.

It should be kept in mind that the instrument in the study revealed certain beliefs of this specific group of PTs, but not the others, limiting the conclusions of the study. The analysis presented here was an initial exploration of PTs' beliefs about problem posing with a more general perspective. Their actual belief system could be revealed when a further analysis for each PT is conducted to map their belief systems. The present data set would allow only for a limited view of this map. A more comprehensive and detailed illustration of belief system can be possible with additional data set including task-based interviews with PTs and observation of their problem posing practices in the classroom.

The effect of level marking mathematical tasks on students' time spent on it: An experimental study

Maria Herset[1] and Mohamed El Ghami[2]

[1]Nord University, Faculty of Education and Art, Nesna, Norway; maria.herset@nord.no

[2]Nord University, Faculty of Education and Art, Nesna, Norway; mohamed.el-ghami@nord.no

The purpose of this pilot study was to investigate the effect of level-marking mathematical tasks on students' time spent on such tasks and correct solutions. The study was conducted among students in lower secondary schools in Norway. The effect was measured by comparing the control group with the experimental group. An independent samples t-test suggested that even if the students were given the same mathematical task, the time spent on the task depended on the level-marking. The results suggest that the level-marking of tasks has a significant effect on students' time spent on solving the task. In addition, the preliminary results show a negative effect of level-marking on the correct solutions of the given task.

Keywords: Ability grouping, textbook, self-efficacy, mathematics education, level of difficulty.

Introduction

In Norway, it is common to use mathematics textbooks in which tasks are grouped according to their difficulty. Several textbooks use different symbols (e.g., geometric figures or colours) to identify the level-marking of the tasks and indicate whether the task is easy, medium, or hard. This is called ability grouping and is used to adjust teaching to the students' ability. In this way of grouping abilities, a student with low skills in mathematics can choose to work with easy tasks by focusing on the tasks marked with a specific colour. The purpose of differentiation is to achieve an optimal learning effect and to improve self-efficacy (Dale & Wærness, 2003, pp. 90). The results from TIMMS (Trends in International Mathematics and Science Study) show that Norwegian students in 8th grade score lower in algebra compared to statistics, geometry, and numbers (Bergem, Kaarstein & Nilsen, 2016). Most textbooks in Norway use level-marking on the tasks; for example, in the textbook *Faktor* 61% of the tasks in algebra are grouped according to difficulty level, in *Maximum* 76% are grouped accordingly, and *Grunntall* has the highest proportion of level-marking, where 98% of the tasks have level markings and almost 1/3 of the marked tasks have the level-marking 'hard'. Therefore, it is important to study how this can affect mathematics education. As in Norway, Sweden also uses textbooks with ability grouping in mathematics, and Brändström (2005) concluded that tasks have a low difficulty level for all students regardless of their mathematical abilities. Earlier studies have shown extensive usage of textbooks in mathematics (Dolonen et al., 2016), but although there is a lot of research on textbooks in mathematics (Brändström, 2005; Howson, 1995; Jablonka & Johansson, 2010; Stein et al., 2007; Tesfamicael & Lundeby, 2019) there is still a lack of research on how the textbooks affect student's achievement in mathematics (Fan et al., 2013). The aim of this paper is therefore to study how level-marking of tasks in textbooks can affect students' time spent on given mathematics tasks. The idea behind this study was drawn from previous research that claims the amount of time spent on homework positively affects achievement (Keith, 1982; Cheema & Sheridan, 2015).

Theoretical framework and research question

In Norway, the Education Act § 1-3 states: “Education must be adapted to the abilities and aptitudes of the individual pupil, apprentice, candidate for a certificate of practice and training candidate” (Opplæringsloven, 1998). Adapted training is characterized by variation in working methods, use of teaching materials, varied teaching aids, the learning environment, curricula, assessments, and variations in the intensity and organization of the training (Utdanningsdirektoratet, 2020). The focus is on pedagogical differentiation, which is implemented by differentiating the teaching in an overall class (Imsen, 1997). The teacher can adapt the teaching by varying the degree of difficulty, called level differentiation as defined in (Imsen, 1997). This form of differentiation is widely used in mathematics teaching, where the teaching is adapted so that the students work on tasks that are adapted to their skills. To differentiate the teaching in an overall class, it is therefore suitable to use textbooks that contain mathematics tasks with different levels of difficulty so that all students can be in the same classroom even if their abilities are different. Diverse studies claim that mathematics textbooks are the major resource for planning and executing the teaching and thus have a strong position in mathematics teaching (Stein et al., 2007; Jablonka & Johansson, 2010; Howson, 1995). Robitaille and Travers (1992) argued that a textbook is ‘‘perhaps more characteristic of the teaching of mathematics than of any other subject’’ (p. 706). Howson (1995) also argued for the importance of the textbook and claimed that a textbook is one step nearer to the classroom reality than a national curriculum.

As discussed before several studies have investigated the importance of spending time on tasks (Cheema & Sheridan, 2015; Keith, 1982), but the hypothesis that more time spent on a given task by the student should result in better learning outcomes has not been confirmed. Karrie et al. (2021) showed a weak relationship between time and learning, and it has also been shown that the time spent on a task is affected by self-efficacy (Multon et al., 1991). Self-efficacy can be explained based on the social-cognitive theory of learning, and it is defined as “beliefs in one's capabilities to organize and execute the courses of action required to produce a given attainment” (Bandura, 1997, p. 3). Self-efficacy has significant effects on cognitive, affective, selective, and motivational processes, and it influences task choice, effort, persistence, resilience, and achievement (Bandura, 1997; Pajares & Miller, 1995; Zimmerman & Martines-Pons, 1990).

There is a limited number of empirical studies on the effect of level-marking a mathematical task on students' time spent on the task. However, there are several studies on how mathematical problems with *different* difficulty levels affect effort and persistence. Chen (2003) showed that the average effort judgment decreases linearly as the problems become more difficult. Montague and Applegate (1993) concluded that the difficulty of the task has a direct influence on persistence. The concept of *time spent on a task* and *effort* are related to each other, but they are still different because students' time is not necessarily used to do their best to solve the assignment. Persistence is about the person's ability to work with relatively high intensity over a long period and can be related to *time spent on a task* if the task is difficult. In the present study, we investigated persistence by measuring the time taken to solve a task with a high level of difficulty. Measurements of persistence in terms of students’ actual behaviour have been conducted previously by Shen et al. (2016). The authors measured persistence where students were solving challenging mathematics problems, and they claimed that it would be problematic to measure persistence based on easy problems because “more competent individuals may find solutions more quickly than less competent individuals” (Shen et al., 2016, p. 42). Based on the previous theoretical and empirical literature, our research questions were formulated as:

- *Can the level-marking of the mathematics task affect students’ time spent on such tasks?*
- *Can the level-marking of the mathematics task affect whether the students get the correct or incorrect answer to the task?*

Method

This paper is based on the collection of data through an empirical survey among lower secondary schools in Norway by distributing an online questionnaire and exploring students’ perceptions of level-marking tasks in algebra. A total of 28 female (54.9%) and 23 male (45.1%) participants took part in the pilot study. Participants were students in grade eight (80.4%) and grade nine (19.6%). The current study compares the questionnaire responses of students concerning students' time spent on solving the task. The survey was distributed randomly to the participants, and all students were given the same algebraic task (see Figure 1 and Table 1). The experimental groups got Task 1 with level marking “Difficult”, while the control group got the same task without level marking. To measure time, we chose a task with a high degree of difficulty because the students would take a long time to try to solve it. The high degree of difficulty of the task is an important criterion for choosing the task in order to provide information about the student's perseverance rather than how fast they solve a task (Shen et al., 2016). Given our illustrative focus, a total of 51 students who received Task 1 marked as difficult (Hard) (N = 21) and who received Task 1 without marking (N = 30) responded to the questionnaire in 2021. The analysis draws on two items from the student’s questionnaire.

Table 1: Task and description of the groups

<table>
<tr><th>Participant</th><th>Description</th><th>Task 1 (Authors’ translation)</th></tr>
<tr><td>Control group</td><td>Students who got the task with no level-marking</td><td rowspan="2">The father is retired. If you change the position of the two digits of the number of his age, you get the son's age. One year ago, the age of the father was twice the son's age. How old are father and son now?</td></tr>
<tr><td>Experimental group</td><td>Students who got the task with difficult level-marking</td></tr>
</table>

The computer measured the time each student spent on solving the task. The students got access to the electronic survey, and the computer registered the time from the students opening the questionnaire until they pressed the “send” button (see Figure 1). The time spent on the page included the time used to read the task and to solve it. The survey did not allow students to navigate between pages.

Figure 1: The questionnaire for the experimental group (for English version of the task, see Table 1)

The independent variables in this analysis were the control group and experimental group (see Table 1). Independent samples t-test was used to analyse the data.

Results

In the following, we will investigate and discuss the effect that level-marking of mathematics tasks has on students' time spent on the tasks. To do this, we used an independent samples t-test. Levene's test for equality of variances was significant ($p = 0.004 < 0.01$), which means that the variances in the two groups were assumed to be unequal. The questionnaire responses showed significant differences in the time spent when level-marking was used compared to the time spent when level-marking was not used. These differences are presented in Table 2, which indicates that students in the control group reported that they spent more time on the task ($M = 223.4$ s, $SD = 239.3$ s) than students in the experimental group ($M = 109.7$ s, $SD = 105.2$ s; $p = 0.027 < 0.05$). Note that the standard deviation in the control group was larger than the experimental group, meaning that students who received the task marked as difficult had less variation in time spent compared with students who did the task without level marking.

Table 2: Students' time spent on the task and correct solutions

	N	Mean (M)	Std. Deviation (SD)	Correct solutions
Control group	30	223.4*	239.3	17%
Experimental group	21	109.7*	105.2	14%

Note. Time: Seconds; M: mean; SD, standard deviation. Levene's test for equality of variances was significant ($p = 0.004$). * The mean difference is significant at the 0.05 level ($p < 0.05$).

The findings show that the time spent by the experimental group was significantly lower than time spent by the control group. The percentage of the students in the experimental group (14% ($N = 3$)) who correctly solved the task was lower compared to the control group (17% ($N = 5$)) (see Table 2.

Discussion

Due to the strong position of mathematics textbooks in mathematics teaching (Stein et al., 2007; Jablonka & Johansson, 2010), it is important to investigate whether level-marking can affect other aspects in mathematics education. However, previous research states that there is a lack of research on the relationship between textbooks and students' learning outcomes (Fan et al., 2013). In this study, we investigated whether level-marking on a mathematical task can affect the student's time spent on the task. The results from the experiment show that the control group spent more time with the mathematics task compared to the experimental group. It is therefore reasonable to hypothesize that there is a significant relationship between level-marking and time spent on the task. This result is important since previous research claims that time spent on a task positively affects achievement (Cheema & Sheridan, 2015; Keith, 1982). The preliminary results from our study show a negative effect of the level-marking on the correct resolution of the given task. The percentage of the students in the experimental group (14%) who correctly solved the task was lower compared to the control group (17%), which means a reduction of almost 18% of the percentage of students who solved the challenging task without level-marking. As mentioned before, a difficult task was chosen in order to measure time spent on the task. This could explain the lower percentage of correct solutions of the task in both groups and the slight differences between the two different groups. However, this shows the potential of a new research direction for investigating other mathematics tasks. The findings suggest that tasks without level-marking will lead students to spend more time on each assignment, which can positively affect the correct solutions (Cheema & Sheridan, 2015; Keith, 1982; Multon et al., 1991). On the other hand, this result suggests that tasks marked as difficult will lead the student to spend less time on the same task. As discussed in the method section, the grade of the chosen task was difficult in order to examine the time they spent *trying* to solve the task rather than how fast they solved it. It should also be noted that the interpretations of the findings in this paper have limitations related to the voluntary nature of participation in the survey and the sample size. The present study investigated only 51 students from nine different schools in Norway, and future research should take these limitations into account.

Conclusion

The results from this pilot study demonstrate that students' time spent on a task is predicted by the level-marking of the task's difficulty. Students who got the task with no level-marking spent significantly more time on the problem compared to students who got the same task marked 'hard'. Spending enough time on a given task can positively affect performance (Cheema & Sheridan, 2015; Keith, 1982). The preliminary results of this study show a negative effect of level-marking on the correct solutions of the given task and suggest that we should be careful in marking tasks as difficult. It is important to let the student assess the task and spend enough time thinking about the possibility of solving the problem. The results show that the standard deviation in the control group was larger than in the experimental group. The tasks might have a low difficulty level for all students regardless of their mathematical abilities even though they are marked difficult (Brändström, 2005). However, more research is needed to fully understand the relationship between level-marking and the time spent on the task by collecting larger amounts of data and investigating the relationship with other variables such as grades, gender, and self-efficacy. In addition, it is important to investigate other tasks with different degrees of difficulty.

Exploring mathematical stories of future elementary teachers: an analysis of shifts in affect in mathematics

Jennifer Holm

Wilfrid Laurier University, Faculty of Education, Waterloo, Canada; jholm@wlu.ca

This research focuses on examining shifts in emotions related to mathematics learning that impacts the attitudes that future teachers hold about mathematics. Initial analysis showed that almost half of the sample did not hold consistent emotions related to mathematics. In examining the catalyst events related to shifts in emotions, many of the shifts to a positive emotional reaction were related to internal structures, and those that shifted to a negative emotional reaction were external motivators. Understanding the events that lead to changes in emotion is important for supporting future teachers in considering how to support future students.

Keywords: Learning and perceptions, mathematics education, affect, emotions.

Introduction

The focus of this paper is understanding the timing and events that influence a change in future teachers' attitudes and emotions towards mathematics. Past research has shown a potential relationship between attitude and achievement (Ma & Kishor, 1997), as well as interconnections between attitudes and beliefs about teaching mathematics (e.g., Philipp, 2007). In Ontario, the teacher education program is a two-year after degree program, so the time with future teachers in a mathematics course is limited. If attitudes have an impact on beliefs and beliefs have an impact on choices made in the classroom (Wilkins, 2008), then understanding where changes in affect occur, is important. Initial research around emotions related to mathematics shows that there is not an exact classification of what makes a student enjoy or dislike mathematics with some things that individuals enjoy about mathematics (e.g., a focus on right and wrong) are the same reasons that others hate it (Holm, 2021). Philipp (2007) notes that in a review of literature around affect, the negative attitudes towards mathematics tend to be rooted in their experiences as learners, so this study seeks to explore further how previous experiences in mathematics impacts shifts in emotional response.

Literature Review and Framework

In Liljedahl and Andrà's (2020) work with future teachers, they note that "emotions are not to be avoided or controlled in mathematical activities, but they have to be provoked, made visible and talked about" and strive to include activities in preservice programs to call attention to emotions (p. 9). In the research study discussed in this paper, the attempt was made to have participants call attention to the emotions that have been provoked during their experiences with mathematics through recalling and writing about their mathematical histories. Hannula (2002) examines attitude as a connection between emotion and cognition in order to understand the influences with attitude, yet notes that although emotion and cognition are separate constructs, they are highly connected and cannot be fully understood separately. My intention in having participants write their stories was for them to understand how their feelings about mathematics were connected to their experiences, their attitudes, and their beliefs through reflection. In this research paper, the focus is on how their emotions were connected to their experiences in order to understand more about the factors influencing emotion and consequently their attitudes related to mathematics.

According to Zan et al. (2006) and Antilla et al. (2016), the area of emotions needs further research to add to the relatively low number of studies currently, and this research project attempts to continue filling this gap in the literature by adding to the discussion. Schukajlow et al. (2019) note that "emotions are defined as phenomena that included cognitive, affective, motivational, physiological and expressive parts. Affect and motivation are used in this definition thus for characterization and grounding of emotions" (p. 3). Emotions are a complex portion of the work in mathematics education research, so an understanding of the types of events that can trigger strong emotions (both positive and negative) can add to the body of work to support future teachers in moving forward.

To ground this research within its focus on emotions, the definition of emotions from DeBellis and Goldin (2006) is utilized: "Emotions describe rapidly-changing states of feeling experienced consciously or occurring preconsciously or unconsciously during mathematical (or other) activity. Emotional feelings range from mild to intense, and are local and contextually-embedded" (p. 134). Since emotions are tied to particular events within mathematics, participants in my research have been requested to write about their emotions connected to mathematical situations, in order to understand what events trigger a change in their connection with mathematics. Ekman (1992) notes that the basic emotions are anger, fear, sadness, enjoyment, disgust, and surprise, with contempt, shame, guilt, embarrassment, and awe being considered basic but share commonalities with the others.

Future teachers will be bringing their emotions about mathematics into their future classrooms, so it is important to understand the root causes of these emotions to help future teachers understand the impact on their own students. Although it is unrealistic to assume that all students will maintain a positive attitude towards mathematics due to the complexities of beliefs, emotions, and affect described in the research cited, an understanding of what causes shifts in attitudes can illuminate some areas of concern in teaching.

The study in this paper uses a portion of the framework that Hannula (2002) has suggested for understanding and analyzing attitude. Although considering all four categories of the framework would have added to the discussion, this paper focuses on two specific areas that could be observed in the data set "the emotions the student experiences during mathematics related activities" and "the emotions that the student automatically associates with the concept 'mathematics'" (p. 26). By focusing specifically on the emotional aspects of the attitude framework, this report looked at what emotionally charged events impacted their attitudes towards mathematics. The basic emotions in the work of Ekman (1992) was used to categorize the emotions in the stories. The basic emotions were categorized as "positive" if they could conceivably lead to a positive outcome in a classroom if presented by the teacher (enjoyment, surprise, and awe), or "negative" if they could conceivably lead to a negative outcome if presented by the teacher (disgust, fear, sadness, contempt, shame, and guilt). The goal of the study was to understand more about how and when future elementary teachers encountered a shift in their emotions related to mathematics. This information will inform how teacher education programs can both support a potential change during a limited time with future teachers, and raise awareness of future teachers on the impact of events within their own classrooms.

Methods

The data for this research paper focuses on three years of written stories collected from future teachers at an Ontario Faculty of Education. The participants would all be in the Bachelor of Education program, either in the Primary/Junior program (K to grade 6) or the Junior/Intermediate program (grade 4 to 10). The Bachelor of Education is a two-year, after degree program, so the participants completed another degree in any subject, including mathematics, although having a mathematics degree is rare in our Bachelor of Education program. The majority of participants will be teaching in K to 8 schools following the completion of their degree.

The stories were part of an assignment that all future teachers would complete in their first-year of the program as part of their initial mathematics methods course. The description of the portion of the assignment relative to this research is as follows: "Create a discussion about your own experiences as a mathematics student. Be sure to include a description/picture of your experiences and how you felt as a mathematics student." Participants would complete the initial assignment draft in the first two weeks of class (November), and then would have the opportunity to edit or add details to submit at the end of the first class (February) to allow for the opportunity for reflection. The research questions in this reported study were as follows: When in school do shifts in affect occur in mathematics? What do participants indicate causes the shift in affect in mathematics?

The initial analysis focused on emotions presented by the future teachers by highlighting events or portions of the stories related to mathematics activities or emotions immediately associated with mathematics (Hannula, 2002), providing a narrower scope for determining when or if a catalyst event occurred. Then the highlighted portions were coded based on the emotions in Eckman's (1992) work. The initial data analysis of the stories resulted in sorting them into different categories based on how they described their emotions about events in mathematics: neutral (no feeling included), only positive (enjoyment, surprise, and awe), only negative (disgust, fear, sadness, contempt, shame, and guilt), and ones that showed a shift from one emotion category to another. Initial descriptive statistics are presented to gain a picture of the total cohort over the three years. The category of neutral was not meant to convey future teachers who did not feel strongly in a single direction but instead a place to sort those who did not mention something related to the basic emotions at all in their responses related to mathematics. Liljedahl and Andrà (2020) note a concern over using a binary construct for considering attitudes and emotions, so this construct was only used as a means to show the range of story types, focusing on the ones where participants noted shifts in how they felt about mathematics. Approximately ten percent of the total number (18) were randomly selected to be independently coded by a critical colleague to determine initial reliability of the sorting of the papers. The independent coder sorted the papers as only positive, only negative, neutral, or showing a shift (including if positive to negative or negative to positive). Coding was compared to the author's codes showing an initial agreement of 83% (15/18) was achieved and after a conversation, the three disagreements were agreed upon between the reviewers further strengthening the lens for coding the remainder of the papers.

Further analysis was conducted on only the stories that described a shift in emotions for the purposes of this paper. These papers were chosen in order to investigate what causes a shift from either positive to negative or vice versa. With the Ontario program only being two years and only having two, ten-week mathematics education courses, time is limited, so it is important to understand how changes occur. The stories were grouped into subcategories to explore: those that shifted from positive to negative, those that shifted from negative to positive, and those who experienced multiple shifts over the course of their experiences. A fourth category was later created for those who did not have a "shift" in emotion but did not convey the same emotion throughout the story. These individuals related to Hannula's (2002) category of automatic response as opposed to reactions to mathematics. A thematic analysis (Braun & Clarke, 2006) was conducted on the stories in each of the sub-categories to understand what caused the shift. Sections of stories where the change was described were initially coded with a descriptive term. Descriptive terms were then gathered and collapsed to determine overarching themes to describe what caused a change in affect in mathematics. The collapsed codes were reviewed by and then discussed with the critical colleague to ensure that all initial codes were accounted for in the final analysis.

Results

In total 182 different stories were considered for the data analysis. Table 1 shows the stories by classification to begin the discussion. Words like "struggle" and "hard" were coded as neutral since they were not coupled with an emotion related to the event. Some individuals did attach an emotion, but some noted enjoyment because of the struggle and some noted dislike because of struggle.

Table 1: All stories categorized by emotion

Type of Emotion	Number	Percentage
Positive	38	20.9%
Negative	50	27.5%
Neutral	16	8.8%
Shift	78	42.9%

Table 2: All stories grouped by the type of shift

Type of Emotion	Number	Percentage
Positive to Negative	37	47.4%
Negative to Positive	17	21.8%
Multiple shifts beginning with positive	13	16.7%
Multiple shifts beginning with negative	6	7.7%
Multiple emotions throughout	5	6.4%

Based on the initial data analysis, only 78 were considered for the second analysis to determine what impacted a shift in the emotions of the future teachers when discussing their mathematical histories. Table 2 shows the breakdown of the new subcategories for this group, and each of the results from the subcategories will be discussed in detail below.

Positive to Negative Stories

In examining the stories for when a single shift occurred from positive to negative, only 35 of the total 37 stories included an approximate time frame. Table 3 shows a breakdown of the time bands.

Table 3: When the shift from positive to negative occurred

Type of Emotion	Number	Percentage
Grades 3-5	4	11.4%
Grades 6-8 (middle school)	3	8.6%
Secondary school (Grades 9-12)	21	60%
University	7	20%

The codes in this group of stories could be sorted into five overarching themes: external motivating factors, societal pressure, internal motivating factors, perception of purpose, and content. External motivating factors and societal pressure were the most commonly noted themes in this portion of the data set. External motivating factors included unhelpful or unapproachable teachers, classroom management styles, grades, and teaching pedagogy. Examples of societal pressure included teacher humiliation, peer pressure, family pressure, and a fear of looking “dumb” in front of peers. Internal motivating factors included frustration, a lack of understanding, fear of failure, and the work being harder that previous grades or units. Perception of purpose related to participants finding the mathematics unconnected to real life or any real-world application for being studied. Content included timed drills, functions, calculus, data management, and algebra.

Negative to Positive Stories

All 17 stories of a single shift from negative emotions to positive emotions related to mathematics contained a time frame for when the shift occurred. Table 4 notes the breakdown of the times that were included. As a note, only grades 11 and 12 were specifically mentioned, other participants noted “high school” in general as the time frame for when the shift occurred.

Table 4: When the shift from negative to positive occurred

Type of Emotion	Number	Percentage
Grades 6-8 (middle school)	4	23.5%
Secondary school (Grades 9-12)	7	41.2%
University	3	17.6%
Adult (after school years)	3	17.6%

The codes in this category could be broken into four overarching themes: internal motivating factors, external motivating factors, perception of purpose, and content. In this subcategory of stories, internal motivating factors was credited the most times as being why the shift occurred. Internal motivating factors included a feeling of confidence, skills development, success, and a feeling that the mathematics made sense. External motivating factors that caused a shift to a positive emotion related to mathematics were all related to specific traits of teachers: engaging teachers, feeling understood, appropriate pedagogy, and caring. Perception of purpose related to finding a connection with real life and application of the mathematics or being able to support their own children in mathematics. The only content mentioned in a positive shift was data management.

Multiple Shifts

When considering the stories that had multiple shifts, these were grouped together since their themes mirrored most of the categories already presented. In looking at those that started positive and had multiple shifts, as well as those that started negative and had multiple shifts, the most common threads were the importance of the teacher and the reliance on grades or success. The participants often pointed to having a singular moment with a teacher who caused a positive emotion that was often shifted by a singular teacher who caused a negative emotion. The feelings of confidence based on success in grades, as well as the feelings of frustration based on a lack of understanding were also often cited as reasons for going back and forth on the like/dislike of mathematics.

Multiple Emotions

Although a much smaller group of the sample, these five participants provided an interesting subgroup to consider. These participants did not have an actual "shift" in feeling around mathematics, but they included multiple emotions throughout the story that ranged from neutral to positive to negative. What was interesting about this group was the reasoning for the changes. Again, the teacher played a role in the feelings reported, where the participants would admit they liked mathematics but hated the class due to the teacher (or vice versa). Oftentimes it was different content areas or aspects of the pedagogy, like collaboration, that were enjoyed but the overall feeling towards mathematics was negative. One participant also changed opinions of the subject based on their feelings around success or failure in relation to the topic.

Conclusion/Discussion

The data from this study pointed to some interesting information of when students shifted from one emotion to another, which showed no discernable pattern, although the majority of the participants saw a shift in later years. Philipp's (2007) review of the literature pointed to affect being determined before college, but this research does not support this finding. A number of individuals found their opinions of mathematics shifted to a more positive outlook in either university or once they were part of the workforce and needing mathematics in real-life. University mathematics was also credited by multiple participants as causing a shift to a negative emotion towards mathematics. Not reporting on shifts in earlier years of school could also be a result of the recency of the events to the time of the reflection instead of attributed to the school or mathematics classes in the early years. One limitation of this study was that the stories were entirely self-reported, so there could potentially be missing details or memories that are not entirely accurate based on the time since the events had occurred. Not all stories started from the same point, so some individuals only reported on what they felt was most important to tell.

In comparing the motivating factors that caused a shift from negative to positive and positive to negative, it was interesting to note that internal motivation most often was credited for the shift to positive, and external or societal pressures were most often credited as a shift towards a negative conception of mathematics. Emotions related to motivational elements (Antilla et al., 2016) suggests that attitudes towards mathematics could continue to be affected with negative emotions that would lead to a decrease in motivation which could continue a cycle of negativity, raising concerns over the impact of emotions with motivation. This finding is particularly interesting for considering preservice teachers so that they understand the power they could have over the emotions of their own students.

The findings showed that some participants credited being challenged in mathematics as being the reason that they felt more positively about mathematics, while others noted that perceiving the mathematics as harder was the reason they now felt negatively about it. This research links to how mindset may affect the entire perception of the mathematics classroom; therefore, the need for a growth mindset (Boaler, 2016) as it may shift the entire perception of mathematics overall. The findings in this study also link to the caution by DeBellis and Golden (2006) that in their research they advocate for developing meta-affect that would allow them to use the negative feelings in a way that would lead to productive learning. Developing this meta-affect with future teachers could prove to be important, but also to make them aware of how to structure their classroom environment to encourage this outlook in their future students.

The smaller group of participants who reported a range of automatic emotions throughout their stories showed that the most prevalent portion of the Hannula (2002) framework in the study was emotions connected to mathematics events and not just automatic responses. This highlights the importance of considering the emotions related to specific events in teaching. This smaller group showed that their responses were caused by mainly external factors in that their feelings towards mathematics were entirely influenced by grades, success, or teacher impacts. As soon as grades dropped, success was less, or as the teacher was perceived as being unhelpful, mathematics was now seen with negative emotions. When the opposite was true, the mathematics was then seen in a more positive light. This research finding also aligns with what Philipp (2007) noted that there is a connection between perceived proficiency and affect.

One smaller theme that came out of this data was around English speakers taking mathematics in French while in French Immersion programs in elementary and secondary school. Although only a small number reported the category, there was a theme around a dislike of math when in the French Immersion program that was resolved when returning to an English program. The participants often cited they felt like the language was a barrier, so this would be a worthwhile area to study further to investigate how this may impact the emotions that a future teacher holds around mathematics.

Even though Philipp's (2007) review found no research linking affect to classroom decisions but notes that there is support for teachers in developing a positive affect. This research sought to begin the conversation about how to support future teachers in developing a more positive relationship with mathematics through understanding what causes shifts in their emotions related to mathematics. Future research directions could consider the intersections with beliefs and practices in mathematics.

Stereotypes in a polarised world and how they relate to mathematical identity

Eivind Kaspersen and Øistein Gjøvik

Norwegian University of Science and Technology, Norway; eivind.kaspersen@ntnu.no

Previous studies have indicated that men are stereotyped as more mathematical than women. Since these stereotype images have shown psychological effects—particularly for negatively stereotyped groups—it is relevant to ask how variables other than gender relate to mathematics. In this study, we examined how stereotype characteristics of gender, occupation, political views, and personality relate to mathematical identity. From statistical analyses of Comparative Judgement data, we show significant associations between mathematical identity and extreme stereotypes (related to occupation, political views, and personality). No significant association was found between mathematical identity and gender.

Keywords: Stereotypes, mathematical identity, gender, occupation, political views, personality.

Introduction

Men are often stereotyped as more mathematical than women (e.g., Picker & Berry, 2000). Regardless of how accurately such stereotype images reflect reality; they affect people (e.g., Danielsson et al., 2019; Herzig, 2004; Jugović et al., 2012). An experimental study showed, for example, that women underperform relative to equally qualified men when they, incorrectly, are told that mathematics achievement tests are gender-biased. When they are not informed about this made-up gender bias, men and women perform equally (Spencer et al., 1999). Studies like these exemplify that stereotype images in mathematics are both real and significant.

If there exist stereotype images about gender and mathematics, and if these images affect people, then similar phenomena might exist for other variables. We argue, therefore, that stereotype research in mathematics education should examine: (1) how stereotype images other than gender relate to mathematics, and (2) how such images—insofar as they exist—affect people (in particular, how they affect those who are stereotyped negatively).

In the study on which we report in this paper, we addressed the first of these issues. That is, in addition to gender, we examined how people associate mathematics to three variables: occupation (income, education, and practical/theoretical work), political views (regarding the environment, taxes, state regulations, the EU, and immigration), and five facets of personality traits, known as “the Big Five” (Goldberg, 1993). We chose these variables based on a conjecture that they represent a tendency in Europe and elsewhere, namely that, besides gender, people identify themselves (and others) in extreme opposites; people regard themselves and others, not only as males and females, but also as left-wingers and right-wingers, practical and theoretical, extroverts and introverts, and so forth. How such variables relate to mathematics is unclear.

Using a Comparative Judgement (CJ) design (which we describe later), 34 Norwegian university students were first introduced to the term mathematical identity (MI), which we define in the next section. Subsequently, the students were shown multiple pairs of extreme characteristics (e.g., one person who is against eco-friendly policies; another person who has a high education), and they were asked to judge which of these characteristics that best reflect a person with a strong MI. The results on which we report in this paper answer the following research question: *How do stereotype characteristics of gender, occupation, political views, and personality relate to MI?*

Theoretical framework

Mathematical identity

Similar to Deaux (1993), we view in this paper MI as a relationship between *social MI* and *personal MI* (e.g., Kaspersen et al., 2017). When we refer to social MI, we mean a set of (relatively) agreed-upon characteristics of what it means to be mathematical within a specific context. For example, “making sense of proofs” is a member of social MI, but only insofar (1) most persons within an observed context agree that making sense of proofs is a characteristic of MI and (2) that they interpret in similar ways what proofs are and what it means to make sense of them. Limits for what counts as “most persons” and “in similar ways” depend on the context of the study.

When we refer to personal MI, we mean the extent to which individuals identify with the set of characteristics that constitute social MI within the activity in which they participate. For instance, if a person usually tries to make sense of proofs when she sees one, this characteristic is a part of her personal MI, but only if she participates in an activity where the characteristic is also a member of the social MI.

These definitions are motivated to allow sentences that include measures (e.g., “person A has a stronger MI than person B”). As described in Kaspersen (2018), these sentences are nonsense unless there exists a body of reference, and this is the role of social MI: It is the body of reference to which personal MIs can be measured. When people respond to a MI instrument, a rough interpretation is this: the items (and their psychometric properties) represent the social MI; how person A responds to the items represents person A’s personal MI.

Twenty characteristics of social MI have proven to have relatively robust psychometric properties within (but not necessarily between) a wide range of contexts (Kaspersen, 2018). The characteristics include: “liking to discuss mathematics”, “trying to understand formulas/algorithms”, “struggling with putting mathematics problems aside”, “taking time to understand why some methods in some cases do not work”, and “taking the initiative to learn more mathematics than what is required”. That the characteristics have robust psychometric properties means that they can be applied in instruments (e.g., questionnaires) that measure MI.

In this study, the expression “individuals with low MI” means persons who select the lower categories (e.g., “never”) when they respond to an MI instrument that contains characteristics of social MI. By contrast, “individuals with high MI” means persons who select the higher categories (e.g., “always”) when they respond to the same instrument.

Stereotypes

Stereotypes have been studied for more than a century (e.g., Brauer et al., 2001; Brigham, 1971; Spencer et al., 1999). Nonetheless, researchers disagree on how the term should be defined. In a review of stereotype definitions, Kanahara (2006) documented that some researchers include truth-values in their definitions. Some define stereotypes as relatively true beliefs; others define them to be mostly false. In this paper, we take Kanaharas (2006) position, namely, that the truth-value of a stereotype is a question of empirical matters: In some cases, stereotypes are relatively accurate; in other cases—for example, when mathematics is portrayed as a male domain—they represent the matters of facts fallaciously.

In his synthesis, Kanahara (2006) claimed that definitions of stereotype share two characteristics: (1) they describe stereotype as related to beliefs (e.g., Allport, 1958); and (2) they describe stereotype as a group concept (Giddens, 2001; Krech et al., 1962). Accordingly, Kanahara (2006) defined stereotype as "a belief of a group of individuals", and this is the definition we use in this paper. Specifically, we report in this paper on how students compare beliefs about several groups of individuals—males, females, left-winger, right-wingers, etc. —and how these stereotypical images associate with MI.

The four variables used in the study

We have studied how students compare stereotype images of persons with different genders, occupations, political views, and personality traits. Although none of these variables is dichotomous, the students in this study were asked to consider only extreme opposites. For *gender*, the students stereotyped males and females only. For *occupation*, the students stereotyped persons with six characteristics: low income, high income, low degree of education, high degree of education, practical work, and theoretical work. For *political views*, the students stereotyped persons with ten values: positiveness towards environment-friendly policies, low taxes, state regulations, the EU, and immigration, and negativeness towards these issues. For *personality*, the students stereotyped persons with high or low measures of the facets of the Big Five (Goldberg, 1993), that is, persons with high or low measures of conscientiousness, openness, extroversion, agreeable to experiences, and neuroticism. These characteristics and measures of how much the students associated them with MI are represented in Table 1.

Methods

Participants and data collection

The participants of the study were a convenient sample of 34 student teachers at a Norwegian university. In the first phase, each person responded to an instrument for measuring MI (Kaspersen et al., 2017), which contained 19 statements of MI (one item in the original instrument is reversely coded and was removed in this study). When they had finished, the participants were told that the instrument measures MI and that persons who respond in the lower categories have lower MI than persons who respond in the higher categories. Moreover, the participants were told that the purpose of this first phase was only to familiarise them with the concept of MI.

In the second phase, each participant responded to items of a CJ instrument. A detailed description of CJ methodology and how it can be applied in mathematics education was described by Jones and Inglis (2015). Here, we present a rough outline only. Briefly, CJ is based on a psychological principle: humans are poor at estimating measures but good at comparing them. For instance, it is easier for teachers and other experts to compare the qualities of two mathematical arguments, two mathematical texts, two forms of instructions, and so forth than for them to give measures to each of these things.

The data collection of CJ follows this principle: multiple individuals compare multiple pairs of items, usually using a digital platform. In this study, NoMoreMarking (nomoremarking.com) was used for data collection. For each comparison, the participants were asked: "Which of these persons do you think have the higher MI?" They could then choose between two stereotype descriptions, each holding one of the characteristics listed in Table 1.

For the personality traits, the respondents were not given category labels (e.g., "highly conscientious"), but instead a brief description of those categories (e.g., "a person that is performance-oriented, orderly, self-disciplined, and thorough"). For simplicity, however, we use the category labels when we report the results in this paper.

A sample task is presented in Figure 1. For the respondents, the pairs of items that appeared on the screen seemed to be randomly selected, although they were adaptively chosen by the software to increase the statistical information. Each person made 28 comparisons; thus, the data comprised 952 comparisons in total. To increase the statistical information further, we allowed comparisons of non-opposite characteristics (as the case in Figure 1 illustrates).

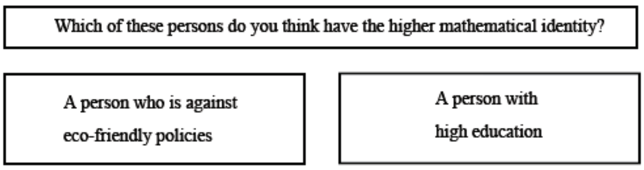

Figure 1: Sample task

Analyses of CJ data is, in principle, similar to Rasch analysis: A maximum likelihood estimation is conducted to estimate the most likely measures of each item (in this study: stereotype characteristics) given the observed data. Subsequently, analyses are conducted to assess dimensionality, judge agreement (i.e., the extent to which the results depend on individual judges), and reliability.

Regarding dimensionality, a crucial question is this: does it make sense to compare the items in the instrument? For instance, does it make sense to make the comparison in Figure 1? In the CJ paradigm, an answer is this: If the judges (here: the students) respond in ways predicted by the Rasch model, the items are sufficiently unidimensional; by contrast, if the judges respond unpredictably, the items are too multidimensional for comparisons to make sense. Infit Mnsq—an information-weighted squared difference between modelled and empirical data—is one indicator of uni-dimensionality. Roughly, when the Infit Mnsq of one item is substantially greater than 1 (in this study, we used 1.3 as a threshold), it indicates that this item is so different from the other items (i.e., it belongs to a different dimension) that it does not make sense to include it in the comparisons.

Regarding judge agreement, a crucial question is whether different judges make different comparisons for similar pairs of items. For instance, will different judges make different judgements on the task in Figure 1? In the CJ paradigm, each judge is associated with an Infit Mnsq value. The interpretation of judge Infit Mnsq is about the same as for item Infit Mnsq: If a judge Infit Mnsq is substantially greater than 1 (in this study, we used 1.3 as a threshold), it indicates that the judge makes judgements that differ substantially from the rest of the judges.

Overall, the analyses showed good psychometric qualities. The reliability was .91, and the largest item Infit Mnsq was 1.3 (“a person who has a theoretical work”). Two persons had Infit Mnsq greater than 1.3 (1.4 and 1.5 respectively), which means that they in some cases made unpredictable answers relative to the rest of the group. However, removing these persons from the analyses had no statistical implication. Thus, the results on which we report in the next section represent a shared agreement amongst the students who participated in the study.

When measures for the items had been estimated, we conducted classical t-tests for each pair of contrasting items using a Bonferroni adjusted alpha level of 0.004. For instance, a t-test was conducted to assess whether the students associated individuals with high income and those with low income differently to MI. To more directly compare the null hypothesis with the alternative, Bayesian t-tests were conducted. Under the null hypothesis, we expected an effect size of 0, and the alternative hypothesis was two-sided. Before observing the data, we assumed that δ followed a Cauchy distribution with scale $r = \frac{1}{\sqrt{2}}$. All analyses were conducted in R (R Core Team) and JASP (JASP Team, 2020), and all measures are reported in logit units.

Results

Gender

In contrast to previous studies, the results in this study indicated no significant differences ($p = .583$) in how students related gender to MI. The Bayes factor was $BF_{01} = 4.7$, which means that the observed data was almost five times as likely under the null hypothesis (i.e., that males and females are associated equally with MI) than under the alternative (i.e., that males and females are associated differently with MI).

Occupation

Three characteristics of occupation—income, education, and work—showed significant ($p < .001$) associations with MI. In effect, the students stereotyped persons with low income, low education, and practical work as having lower MI than persons with high income, high education, and theoretical work, who were stereotyped as having higher MI. In all cases, the Bayes factors ($BF_{10} = 6.9e + 10$ being the least) showed decisive evidence for the alternative hypothesis, namely that occupation characteristics associate differently with MI.

Political preferences

Associations between MI and five contrasting political preferences were assessed. The overall image is that students stereotyped persons positive towards immigration and environment-friendly policies as having a higher MI than persons hostile towards these issues ($BF_{10} = 18.1$ and $BF_{10} = 6760.2$ respectively). There was no significant difference between left-wing and right-wing values for the remaining political issues: attitudes towards taxes, state regulations, and the EU.

Personality

There were also significant differences in how the students connected personality traits and MI. Roughly, the students stereotyped conscientiousness persons as having a higher MI; persons with high measures on the remaining personality traits—extraversion, agreeableness, openness to experiences, and neuroticism—were stereotyped as having a lower MI. The most significant differences were found in conscientiousness and neuroticism. That is, persons that are laid-back, messy, and careless (low conscientiousness) were stereotyped as having a lower MI as compared to individuals that are performance-oriented, orderly, self-disciplined, and thorough (high conscientiousness). Moreover, persons that are sensitive, worried, cheerless, and have mood-changes (high neuroticism) were stereotyped as having a lower MI as compared to individuals that are emotionally robust, handling stress, and balanced (low neuroticism).

Table 1: Characteristics of stereotyped MI

	Stereotyped as lower MI	Measure	Stereotyped as higher MI	Measure	*p*
Gender					
	Male	0.23	Female	0.44	.583
Occupation					
	Low income	−2.43	High income	1.31	< .001
	Low education	−3.26	High education	4.09	< .001
	Practical work	0.14	Theoretical work	4.02	< .001
Political views					
	Non-environmental	−1.03	Environmental	0.22	.002
	Against low taxes	−0.49	Pro high taxes	0.22	.069
	Against state regul.	−0.91	Pro state regul.	−0.23	.077
	Against EU	−1.06	Pro EU	−0.81	.506
	Against immigration	−2.51	Pro immigration	−0.51	< .001
Personality					
	Conscientiousness (low)	−2.47	Conscientiousness (high)	4.28	< .001
	Openness (high)	−0.91	Openness (low)	1.88	< .001
	Extroversion (high)	−0.60	Extroversion (low)	1.42	< .001
	Agreeable to exp. (high)	−1.58	Agreeable to exp. (low)	−0.30	.001
	Neuroticism (high)	−1.28	Neuroticism (low)	2.18	< .001

Discussion

We have maintained that research in mathematics education should examine: (1) how stereotype images other than gender relate to mathematics, and (2) how such images affect people (in particular, how they affect those who are stereotyped negatively). In this study, we considered the first of these issues, and we have shown that there are significant associations between extreme stereotypes (related to occupation, political views, and personality) and MI. No significant association was found between gender and MI.

It is worth noting that the format of the questions in the instrument in this study has some consequences. That is, the respondents in the study were asked: «compare X with Y; which one do you believe have the strongest MI?» They were not asked: «imagine a person with a strong MI; is the person an X or a Y?» Accordingly, it is crucial to make clear which inferences we can draw from the results presented in this paper. We conclude on the form «X are stereotyped as having higher MI than Y»; not on the form «persons with strong mathematical identities are stereotyped as X».

Having made this distinction, we maintain that the significance of the results presented in this paper depend on answers to the second issue, namely, how stereotype images of MI affect people. This is an issue on which we have no data. Nonetheless, we propose a working hypothesis for future research: stereotype images of MI cause similar effects as they do in nearby domains, namely, a stereotype-threat (ST) (Spencer et al., 1999) for people who are stereotyped negatively and a stereotype-lift (SL) (Walton & Cohen, 2003) for those stereotyped positively. In effect, ST and SL function as a self-fulfilling prophecy: If people belong to a group that is stereotyped as having a low MI, they will develop it as such, and vice versa.

We emphasise that SL and ST do not depend on stereotype images to be true (e.g., Spencer et al., 1999). Nevertheless, it is relevant to ask whether the stereotype images presented in this study reflect reality accurately. Suppose that persons with certain occupations, political views, and personality traits have stronger MIs than others. In that case, we might ask ourselves: how do we establish an educational system so that everyone can participate equally (and agree upon the standards) in complex questions that require scientific evidence: questions regarding equality, immigration, vaccination, and global warming? Alternatively, if the students in this study were inaccurate in their descriptions, we might wonder why some groups in society are falsely portrayed as having a lower MI than others and what the practical implications of these images are.

Although we have no empirical answers to these issues, we maintain that future research on stereotypes and mathematical identity should confront the most urgent issues in what seems to be an increasingly polarised society.

Emotions and decision-making in handling pivotal teaching moments

Styliani-Kyriaki Kourti[1] and Despina Potari[1]

[1]National and Kapodistrian University of Athens, Department of Mathematics, Athens, Greece;
[1]stellakour@gmail.com, dpotari@math.uoa.gr

The present study focuses on teachers' emotions in relation to their decision-making in handling Pivotal Teaching Moments (PTMs), adopting an Activity Theory perspective. We study a case of an experienced mathematics teacher, who participated in a professional development (PD) program. Data comes from videotaped lessons, PD sessions and interviews with the teacher. From the first interview we identified teacher's motives and goals. From the other three interviews and the videotaped lessons we identified relations between PTMs, emotions and actions. According to the results ten PTMs appeared, accompanied by negative, positive, mixed or neutral emotions. Teacher's emotions seemed to reflect his sense of possibility of achieving his goals while his actions move towards his goals' achievement.

Keywords: Teachers' emotions, decision-making, activity theory, pivotal teaching moments.

Introduction

Emotions set the context for teaching, affect social relations, and reveal effects of power in the classroom (Zembylas, 2004). Emotions has occupied much of the international literature, but very little research focuses on teachers' emotions (Hagenauer et al., 2015), and much more on emotions that arise in mathematics teaching. This is probably due to the methodological difficulties that lie in the qualitative study of emotion, due to its ambiguous nature, which is why most of the studies that have been carried out, mainly concern quantitative approaches. Teachers' emotions are related to the quality of teaching and are a key factor in teachers' decision making (Di Martino et al., 2013). Bishop (2008, p. 30) considers decision making at "the heart of the teaching process" and he argues that if we know about teachers' decisions, we can link teaching to a number of different aspects (e.g., objectives, intentions, children's attitudes, children's mathematical development) and so search for ways of improving its quality (Potari & Stouraitis, 2019). Zembylas (2004) highlights that teachers' decisions are influenced by emotions and reflect teachers' values and beliefs about teaching. Yet, the affective dimension of mathematics teacher decision-making is rarely the focus of research. Teacher decision making is triggered usually on what Stockero and Van Zoest (2013) call pivotal teaching moments (PTM). The tensions that arise during PTMs are considered stressful for teachers and usually negative emotions accompany their management (Pillen et al., 2013).

Therefore, we attempt deepening our understanding on teachers' on-the-moment decision-making while handling PTMs, and their emotions involved in the process. The study of mathematics teaching through these lenses can offer new perspectives on the management and the quality of teaching and consequently on student learning. Our research question is: How do emotions relate to teacher's decision-making in handling PTMs?

Theoretical Framework

In our study we see emotions being formed within the context of the activity in which the individual participates. We adopt the Activity Theory (AT) framework where the activity (mathematics teaching) with the teacher as the subject, is directed towards an object (students' learning) and is expressed through actions with conscious goals. Engeström (1999) takes joint activity as the unit of analysis focusing on the process of social transformation and emphasizes upon the conflictual nature of social practice. The activity is dialectically related to subject's actions: the motive of the activity is concretized as the goal of the action and the action is the one that affects the object of the activity. Action is the way in which the subject engages with the object, that is, the way in which the individual performs the collective activity. Within this context, emotion is a holistic expression of the subject's current state in relation to the object, and the subject's sense of the possibility of success in realizing the object/motive he/she has accepted (Leont'ev, 1978). According to Burkitt (2021, p. 13), emotions are integral components of social interactions, and "they function in complex ways, not only as internal signals to one's self, but also as signals to others, which are frequently spontaneously expressed in the moment without full consciousness of our intention". Thus, the emotion moves together with the activity as a whole, and is one of its manifestations in the actions of the subject in the effort to achieve his conscious goals. Instability, tensions and contradictions, that may occur, may affect subject's emotions in relation to its goals, and thus his actions, reforming the whole activity's context. According to Ekman and Cordaro (2011) the basic (seven) emotions are discrete physiological responses to fundamental life situations that have been useful in our ancestral environment. Plutchik (2001), in his three-dimensional model, presents the characterizations of the primary emotions' intensity and also refers to the "primary dyads" emotions, that are mixtures of two of the primary emotions.

Stockero and Van Zoest (2013, p. 127) define a pivotal teaching moment (PTM) to be "an instance in a classroom lesson in which an interruption in the flow of the lesson provides the teacher an opportunity to modify instruction, to extend/change the nature of students' mathematical understanding". When a PTM occurs, the teacher should at first recognize it and then decide how to handle his/her interruption. Five types of PTMs were identified: extending, incorrect mathematics, sense making, mathematical contradiction and mathematical confusion.

The teachers trying to manage the PTMs that occur in their classrooms, they are called to take on the moment decisions. According to Engeström (2001, p. 281) "decisions are not made alone; they are indirectly or directly influenced by other participants of the activity (e.g., students in the classroom, other teachers). Decisions are typically steps in a temporally distributed chain of interconnected events". In terms of responsibility and power, decisions have moral and ideological underpinnings. Decisions shape the future of the broader activity system within which they are made, not just the ostensible problem or task at hand (Engeström, 2001).

Methodology

The context of the study and the case of the teacher

The present study is a case study of one high school mathematics teacher in Greece with 30 years teaching experience, a master's degree in special education and rich professional development (PD) experiences. This study is carried out in the context of a professional development program EDUCATE (http://www.ucy.ac.cy/educate/en/general-information/the-project), aiming to support teachers to balance differentiated learning and mathematical challenge. In the context of EDUCATE, he worked in a video club setting with five other high school teachers to conceptualize the meaning of differentiation and mathematically challenging tasks and enact them in the classroom teaching. In particular, seven two- hour PD sessions took place along a period of a school year (2017-2018) and in between the teachers had to plan lessons, enact in their classrooms to address the focus of EDUCATE and share video-excerpts from their lessons with the other teachers in the PD sessions. The teacher of our study designed three lessons two for grade 10 class and one for grade 11 class (mixed ability classes). The aim of balancing differentiation and mathematical challenge, to which the teacher is called to respond, is a fertile ground for creating PTMs and the emergence of emotions as it is new and demanding enough for him. The above process was followed by all the teachers in the group but in this article, we focus on the teacher with the characteristics we described above.

Data and Data Analysis

The data has been generated from the three videotaped lessons, the seven PD sessions and four semi-structured interviews with the teacher. Initially, we analyzed the videotaped lessons to identify the PTMs, teacher's emotion(s) and his actions dealing with each incident, drawing additional data from teacher's reflections on his lessons during the PD sessions. The interviews were conducted by the first author. The first interview's aim was to outline the teacher's teaching profile and his overall teaching goals. For each one of the other three interviews, the teacher was asked to watch the videotaped lessons and identify incidents that he considered important and/or that indicate emotions from his side. In the first part of each interview, we discussed the moments chosen by the teacher, while in the second part the moments chosen by the researcher, in relation to his emotions and actions. Some of the questions addressed to the teacher, when discussing about each incident, are: Why did you choose to discuss this incident? How do you feel at that moment? Why do you feel that way? How you usually feel in similar moments? How did you act/react? Why did you act that way?

Table 1: Coding PTMs, emotions and actions

<table>
<tr><th rowspan="2">Emotions</th><th>Basic (and intensity)</th><th colspan="2">Dyads</th></tr>
<tr><td>Joy (Pleasure, Enthusiasm),
Sadness (Disappointment), Fear, Surprise, Anticipation</td><td colspan="2">Pride (Pleasure + Satisfaction), Delight (Joy + Surprise),
Anxiety (Fear + Anticipation), Disapproval (Sadness + Surprise)</td></tr>
<tr><th>PTMs</th><td>Extending (E), Incorrect Mathematics (I.M.), Sense-making (S.M.), Mathematical Confusion (M.C.), General Confusion (G.C.)</td><th>Actions</th><td>Extends and/or Makes connections, Pursues student(s) thinking, Continues as planned, Ignores/Dismisses, Giving extra time to students</td></tr>
</table>

To identify the PTMs and teacher's actions during teaching we used an expansion of Stockero and Van Zoest's (2013) framework. To identify teacher's emotions during the PTMs, we used semiotic tools such as gestures, facial expressions, gazes (see Ekman & Friesen, 2003) and voice pitch. Then we transcribed the interview data and grounded analyzed them in order to verify teacher's emotions and find relationships between the PTMs, decision-making and teacher's emotion(s). Our emotion characterization was based on a synthesis of Plutchik's (2001) and Ekman and Cordaro's (2011) models. Through this process, the coding schemes used for the analysis of PTMs, teacher's actions and teacher's emotions, are presented in Table 1. Categorizing the data about "why" the teacher feels or acts in this way, we captured the categories that are presented in Table 2 along with their meanings.

Table 2: Coding the "why"

Why feels that way?	*Expecting goal:* the teacher expects the goal to be achieved *Moving away from goal:* the teacher feels that he is moving away from achieving his goal *Slow on goal:* the teacher feels that the process of achieving the goal is delayed *Conflicting goals:* when his thought is attracted in different goals at the same time *Achieving goal:* the teacher thinks he is approaching his goal *Contributing to goal:* when he contributes more than intended to achieve the goal
Why acts that way?	*Redirecting to goal:* when acting so that the lesson progresses back to achieving his goal *Holding on to goal:* when acting in such a way that the flow of the lesson doesn't deviate from the achievement of the goal *Processing goal:* when a goal has been achieved and he extends it through his actions *Globalizing goal:* when he had a goal about one student and momentarily makes it a goal for all the students of his class

Results

Motives and goals

Through the initial interview some information was gathered about teacher's motives and goals. Below is an excerpt from the interview with the teacher:

Interviewer: What characterizes your teachings?
Teacher: Students' engagement.
Interviewer: What do you mean by that?
Teacher: It's obvious. It makes no sense to just copy a solution from the board into their notebook or "parrot" procedures and operations to be able to solve an exercise. It is necessary for them to get involved in the resolution process….to think. Only then is it possible for them to make sense of what they are doing, to see some utility, and I am referring to the mathematics they use.
Interviewer: I see that this is of great importance. But it is also difficult to succeed. How do you do that?
Teacher: I improvise a lot. Depending on where the flow of the class will throw me or I will think what I want to do.
Interviewer: So?
Teacher: (pause) So, I try to play, challenge them with questions and arouse students' interest. It is important because the student will be bored, and secondly, I am bored too talking all by myself (laughs).

The above extract illustrates teacher's image of the object (motive) of the activity which is students' engagement and making sense of mathematics. To achieve students' engagement, he poses two main goals, to attract students' interest and to involve as many students as possible. He rejoices when the majority of students interact with each other and with him during the lesson as he considers learning a collective process. He wants even for the students that won't follow a mathematical orientation, to develop a mathematical way of thinking. It is also important for him to build a safe classroom environment for the students to feel free to express their ideas.

Emotions and Decision-making: Approaching "why"

In our data ten PTMs appeared: four are accompanied by negative emotions (I.M., M.C., G.C and E.), four by positive emotions (S.M., M.C., G.C. and E.), one by positive and negative emotions (S.M.) and one by neutral emotion (M.C.). In Table 3 we illustrate our findings about five out of the ten PTMs, the most representative of each category (based on the intensity of emotions' expressions).

Table 3: PTMs, emotions, actions and "why"

<table>
<tr><td colspan="4">1st PTM (Incorrect Mathematics): The teacher asks why we use the root symbol. Students give insufficient or incorrect answers. The teacher seems a bit irritated. He listens to all students' answers without correcting them. After summing them up, they come to a correct conclusion.</td></tr>
<tr><td rowspan="2">Negative Emotions</td><td rowspan="2">Anxiety
Disapproval</td><td>Why?</td><td>Interview's Excerpt</td></tr>
<tr><td>Expecting goal
Moving away from goal</td><td>"it is a crucial point what the students will answer for the development of the lesson" … "this knowledge should have been acquired in previous classes".</td></tr>
<tr><td>Actions</td><td>Extends and/or Makes connections
Pursues student(s) thinking
Ignores/Dismisses</td><td>Redirecting to goal</td><td>"It is important to hear all the views of the students so that there is a "game" between them." … "when something is heard from their classmate, it is more easily accepted by the students because it is not something "alien sounds" that is heard by the authority".</td></tr>
<tr><td colspan="4">2nd PTM (Extending): A student presents an alternative (correct) way of solving that goes beyond the mathematics that the teacher had planned to discuss. The teacher doesn't seem to fully understand it at that moment and skips it.</td></tr>
<tr><td rowspan="2">Negative Emotions</td><td rowspan="2">Anxiety</td><td>Why?</td><td>Interview's Excerpt</td></tr>
<tr><td>Slow on goal</td><td>"Because then I didn't fully understand what the student were saying". Also, "there was no time to devote to it" and had to remain in the original lesson plan.</td></tr>
<tr><td>Actions</td><td>Ignores/Dismisses</td><td>Holding on to goal</td><td>"You want to move forward, you also have a flow, a path of thought and you skip it".</td></tr>
</table>

<table>
<tr><td colspan="4">3rd PTM (Mathematical Confusion): There is interaction between the students. They ask questions, they are confused about the concepts of decimals with infinite number of digits and irrational numbers. A student says “it is not possible to draw a length of 1.4… and infinite decimals, right?”, he is troubled. The teacher tells him that if he gives him a ruler, he can draw it. After a few minutes of talking with the students, he states that this problem has preoccupied the Pythagoreans, and that in another lesson they will prove/construct the line segment with length $\sqrt{2}$.</td></tr>
<tr><td rowspan="2">Positive Emotions</td><td rowspan="2">Delight</td><td>Why?</td><td>Interview’s Excerpt</td></tr>
<tr><td>Achieving goal</td><td>“This shows that the lesson works, there is interaction, the students have entered the “game” and it starts working in their mind, the student has something to say and the teacher has something to teach”.</td></tr>
<tr><td>Actions</td><td>Extends and/or Makes connections
Ignores/Dismisses
Continues as planned</td><td>Holding on to goal</td><td>“I didn’t want to escape tangible planning. The goal for this course was to reach the definition of the ninth root, so time would not be enough.”.</td></tr>
<tr><td colspan="4">4th PTM (Sense Making): A student unfolds his thinking and explains everything very correctly and in detail. The teacher does not confirm anything and asks for the others students’ ideas.</td></tr>
<tr><td rowspan="2">Mixed Emotions</td><td rowspan="2">Joy
Disappointment</td><td>Why?</td><td>Interview’s Excerpt</td></tr>
<tr><td>Conflicting goals</td><td>“Because the student has understood from a previous lesson what he says and reproduces it now… I don’t want it to end like this for the other students”.</td></tr>
<tr><td>Actions</td><td>Ignores/Dismisses
Pursues students’ thinking</td><td>Globalizing goal</td><td>“If I had verified that this was the correct answer, the other students would have never tried to do something like that”.</td></tr>
<tr><td colspan="4">5th PTM (Mathematical Confusion): In classroom they complete the root-definition (on board) and a student does not understand why the constraint θ≥0 is needed since it is in the square. Then the teacher asks them: if $\sqrt{a} = -5$ then $a = 25$ and then $\sqrt{25} = -5$? He uses a non-example so that the student can see the error in his reasoning. He had “expected the students to have difficulty with the constraint”.</td></tr>
<tr><td colspan="2" rowspan="2">Neutral Emotion</td><td>Why?</td><td>Interview’s Excerpt</td></tr>
<tr><td>Achieving goal</td><td></td></tr>
</table>

Actions	Pursues students' thinking	Processing goal	"I don't feel anything. The use of a constrain is a common confusion-point for the students, you know that too. Every year with each class we have the same talk about constrains and their use."

The first and the second PTMs are accompanied by negative emotions which are seemed to be created due to the unexpectedness of these incidents and their potential to make the teacher deviate from the initial lesson planning and his goals. Nevertheless, teacher's actions seem to target on redirecting or holding on to his initial goals. Teacher's positive emotions in PTMs seem to be created due to the positive outcomes of his interaction with the students in relation to his goals. Although in the third PTM it could be expected that his feelings were negative, he feels surprised and pleased because his students' mathematical confusion is a sign for him that the lesson he planned, triggered their mathematical thinking, something that is of extreme importance for him. In the fourth PTM, on one hand he is joyed due to his student's understanding and rigorous explanation but on the other hand he feels disappointed because he thinks that if he confirms the correctness of this answer, the other students' engagement would be minimized. His decisions once again align with his main goals and are oriented in confronting that negative emotion. The neutral emotion that accompanies the fifth PTM may be due to the fact that the teacher had been expecting this to happen. This also can be confirmed by his readiness to deal with this incident in such procedural way.

Discussion

In our study we try not just to describe the teacher's emotions and decision-making in handling PTMs, but also to find a way to make sense of his on-the-moment decisions through his emotions. Our teacher's case indicates that his emotions aren't directly dependent upon the type of each PTM (e.g., 3rd PTM in Table 3), but they reflect his sense of possibility of success in realizing the motive he has accepted (Leont'ev, 1978). Our findings agree with what Schoenfeld (2011, as cited in Potari & Stouraitis, 2019) claims that decisions are consistent with the teachers' goals consciously or unconsciously. Through his decisions, the teacher seems to be led by his need to refocus his thinking and actions on the aspects of his environment (classroom interaction and management) they could change for achieving his goals, but also to be able to push back on the unpleasant emotions and try to maintain a positive disposition. A number of appraisals such as valence, goal congruency, expectedness, or controllability are assumed to influence human emotions; they can be classified as situational appraisals and appraisals about the self (Scherer et al., 2001, as cited in Schukajlow et al., 2017). The teacher's long teaching experience may justify his flexibility in how he moves towards his goals (Westerman, 1991) and in handling his emotions, but further research into this aspect is necessary. The study of teachers' emotions in relation to their decision-making in more cases of teachers could give us insights for understanding better how these interrelate in the complex context of mathematics teaching and learning.

Preservice teachers' interest and self-efficacy beliefs while posing problems

Janina Krawitz[1] and Luisa-Marie Hartmann[1]

[1]University of Münster, Department of mathematics, Germany; krawitz@uni-muenster.de, l.hartmann@uni-muenster.de

Problem posing is considered to have great potential to foster students' motivation because it provides the opportunity to create problems on the basis of individual interests and abilities. However, whether learners indeed use this opportunity is an open question. The aim of the present study was to investigate the role of interest and self-efficacy expectations in problem posing. In interviews, we asked preservice teachers (N = 7) why they decided to pose a certain problem, and we focused on their interest and self-efficacy expectations when we analyzed the data. The most important factor was preservice teachers' interest in the answer to the posed problem. Self-efficacy expectations have been also revealed as important for their decision to pose a certain problem. Preservice teachers wanted to be able to solve the problem or to master problem posing by posing multiple problems or a problem with adequate difficulty.

Keywords: Problem posing, interest, self-efficacy, real-world problems, preservice teachers.

Introduction

Problem posing has recently been receiving greater attention from the scientific community. Researchers have emphasized that problem posing has the potential to help students learn mathematics and may be particularly beneficial for students' motivation (Cai & Leikin, 2020). Problem posing conveys the experience of autonomy and control by allowing students to generate problems that fit their own interests, needs, and abilities. Consequently, learners' interest and self-efficacy expectations can be expected to be important for their problem posing processes. There is little research on the relationships between interest, self-efficacy, and problem posing, and prior studies have rarely addressed how interest and self-efficacy can influence the posing of problems. The present study is aimed at gaining a better understanding of the roles that interest and self-efficacy play for problem posing by investigating learners' beliefs about factors that affect the development of self-generated problems.

Theoretical background

Problem Posing

Problem posing is typically defined as the generation of new problems and the reformulation of given problems (Silver, 1994). It is considered a powerful learning approach for improving students' motivation and problem solving abilities and is also an important learning goal in itself (Cai et al., 2015). Even if some progress has been made in recent years, problem posing is still a rather young and evolving field in which scholars are just beginning to develop an understanding of the processes that take place and the benefits problem posing can have for the learning of mathematics. Here, we look at problem posing from the perspective of modelling and applications in mathematics education. We focus on modelling-related problem posing, which we define as the generation of real-world questions that can be solved with the help of mathematics on the basis of stimuli that are connected to the real world (e.g., textual descriptions of real-world situations, pictures, or artefacts from the real world) (Hartmann et al., 2021). An example of problem-posing stimuli used for modelling-related problem posing is depicted in Figure 1.

Cable Car

For more than 90 years, the cable car *Nebelhornbahn* took numerous guests up into the heights. Now it can go into well-earned retirement. Starting in the summer of 2021, a new cable car will transport enthusiastic outdoor fans to the mountains on the Nebelhorn. The aim of the project is to avoid long waiting times, provide seated transportation with an optimal view at every seat and increase the carrying capacity.

Technical data of the old cable car:

Model:	Large-cabin aerial tramway
Weight empty cabine:	1600 kg
Weight full cabine:	3900 kg
Height valley station:	1933 m
Height top station:	2214.2 m
Horizontal difference:	905.77 m
Speed:	8 m/s
Carrying capacity:	500 persons/h
Power unit:	120 PS

Figure 1: Real-world situation used as a stimulus for modelling-related problem posing

Problem posing and interest in solving self-generated problems

Motivation is an important variable that affects students' behavior, decisions, and performance (Middleton & Spanias, 1999). Closely related to students' intrinsic motivation is students' interest, which is defined as a person-object relationship that refers to both the state of attention and affect toward a particular topic (situational interest) and an enduring predisposition to reengage with a topic over time (individual interest) (Hidi & Renninger, 2006). Learning environments can foster the development of individual interest by triggering situational interest and building upon prior individual interest (Hidi & Renninger, 2006). Problem posing provides opportunities to generate problems according to a person's own interests, and thus, incorporating problem posing in class has the potential to improve students' motivation (Cai & Leikin, 2020). Prior research has shown that teaching interventions that include problem-posing activities positively affect students' individual interest in mathematics (Xia et al., 2008) and their situational interest in the topic that is being addressed in class (e.g., algebra) (Walkington, 2017). However, the extent to which students' interest influences their decision to generate a certain problem is an open question. Learners' affect and more specifically learners' interest could refer to different objects (Schukajlow et al., 2017). For modelling-related problem posing, they could either center their interests on the real-world context or on an inherent intramathematical topic. In addition, the people whose interests are being evaluated might differ. If teachers pose problems for their students, they might refer more to what they think their students find interesting than to their own interest. Preservice teachers might already identify with their role as teachers, but it is also possible that they still identify more with the student role, particularly because they do not yet have students of their own to relate to.

Problem posing and self-efficacy in solving self-generated problems

Self-efficacy is defined as the perceived ability to successfully perform an action in the future (Bandura, 1997). Prior research has demonstrated that self-efficacy is positively related to performance and is an important factor that influences students' decisions while learning (Pajares, 1996). For problem posing, the criteria for estimating students' success varies according to the goals of constructing a problem. Voica et al. (2020) showed that self-efficacy in problem posing occurs in relation to several goals. The preservice teachers investigated in this study reported on their self-efficacy to construct a large number of problems, difficult problems, original problems, or problems that matched the abilities of a problem-solver. Further, a person's problem solving self-efficacy could also influence his or her decision to pose a certain problem because learners might generate only the kinds of problems that they are confident they can solve. This could explain why learners tend to pose simple and closed-ended problems (English, 1998; Hartmann et al., 2021). The present study is aimed at shedding some light on this potential reason. As the participants of our study were preservice teachers, it is also possible that their expectations refer more to the success of their students than to their own expectations of success with respect to being able to solve the problem. However, it is also possible that preservice teachers consider it as particularly important that they are themselves able to solve their self-generated problems, because they might imagine their future selves as teachers. The study of Marschall (2021) shows that preservice teachers' self-efficacy appraisal is closely related to narrative self-schema and the development of professional identity. Thus, it is important to take into account the different perspectives they adopt when evaluating their problem posing process or the potential success of a student in solving the problem.

Research questions

The aim of the present study was to investigate the role of interest (RQ1) and self-efficacy expectations (RQ2) in problem posing. In particular, our research questions were:

RQ 1a: What are the objects of interest that preservice teachers refer to when posing problems?

RQ 1b: What are the perspectives of preservice teachers when they evaluate interest?

RQ 2: What are the goals that preservice teachers' self-efficacy refers to?

Method

Sample and data collection

Seven preservice teachers (three women, four men; between the ages of 20 and 26 years) from a German university participated in the study. The preservice teachers participated voluntarily in the study and were selected under maximum variation sampling criteria in order to gather information rich data and to analyze the existence of patterns across the variation. As selection criteria, we focused on their mathematical performance levels, their experience with problem posing and solving, and on their study programs. Five of the preservice teachers studied for a teacher profession at high track secondary schools and two of them for a teacher profession at middle track secondary schools. Four of them were in a master program and three in a bachelor program. Pseudonyms were used for the names of participants. In a laboratory setting, each of the participants received three real-world situations (Cable Car, Fire Brigade, Chopsticks) with the request to first pose problems on the basis of the given situation by instructing them "Read the description of the situation aloud. Then you think about what mathematical question you can ask yourself about the situation." and afterwards to solve their problems. One of the situations is depicted in Figure 1. A shortened version of the other problems is presented in Table 1. After posing and solving the problems, the participants were asked in stimulated recall interviews about why they generated the particular problems at hand. The interviews were video-recorded, the video material was transcribed and sequenced into classification units.

Table 1. Shortened version of the additional problem posing stimuli

Fire Brigade. The Muenster fire department has a total of 16 locations in downtown Muenster, so that there is a maximum distance of 6 km from a burning house. On average, a truck manages to drive about 40 km/h in Muenster city traffic. A central component of the Muenster fire-brigade is a fire engine with a turn-ladder. The dimensions of such a fire engine with a 30 m turn ladder are specified in the fire department's guidelines. [Table with data about the fire engine]. Using a fire-engine the fire-brigade can rescue people from great heights. The rescue is carried out via a cage attached to the end of the ladder. […] So called HAUS-rules, in which minimum distances of the vehicle are specified are applied [List with distance rules]. [Picture of a fire engine]
Chopsticks. Lisa is looking online for a gift for her mother's birthday. […] Lisa decided to buy her mother chopsticks. She finds the following offer: [Picture with product details including the price, and the length of the chopsticks, and the number of product reviews]. Lisa finds a nice storage box for the chopsticks [Picture with product details including measures, weight, price and product rating]. To save some money, Lisa researches online for a discount promotion. She discovers a discount promotion where she gets a 10% discount on her entire purchase if her purchase is worth 20€ or more, and a 20% discount if her purchase is worth 30€ or more.

Data analysis

A qualitative approach was used for this study to gain in-depth insights about preservice teachers' reasons for posing a certain problem. We focused on preservice teachers' interest and self-efficacy, because these constructs revealed as important during the interviews. The transcripts were analyzed using a qualitative content analysis. A category system was developed using a data-driven approach. The sequences were coded with regard to the objects of interest, the perspective of interest, the goals of self-efficacy expectations and the perspective of solving expectations. The material was analyzed by a trained coder; the coding was discussed among the members of the research team using consensual coding principles and checking for reliability (Cohens' $\kappa \geq .662$).

Findings

An overview of central categories and sub-categories that were derived from the material is presented in Table 2.

Table 2. Categories for reasons that explained the self-generated problems

Main category	Subcategory	Description	Example

Objects of interest	Interest in the answer	Interest in the answer to the posed problem	…because I was interested in knowing whether the chopsticks were free.
	Interest in the real-world situation	Interest in specific aspects of the real-word situation	…because if I think about what I find most interesting...
	Interest in the mathematical topic	Interest in the mathematical topic that is related to the problem	…because I like to have tasks with functions.
Perspective of interest	One's own interest	Statement of interest refers to the preservice teacher's own interest	…what I am personally interested in.
	Interesting to the protagonist	Statement of interest refers to the protagonist's interest	…I thought about what Lisa wanted to know.
	Interesting for students	Statement of interest refers to the interest of the imaginary students who would work on the problem	…because I thought that would be interesting for the students to know.
Goals of self-efficacy expectations	Solving	Reasons that address the problem-solver's self-efficacy with respect to solving the problem	…that I am able to solve the problem.
	Posing	Reasons that address the problem-solver's self-efficacy with respect to mastering problem posing	…that I am able to construct a problem with an adequate level of difficulty

Preservice teachers' interest in posing problems

Interest was often mentioned by the preservice teachers when explaining why they decided to pose a certain problem. Thereby the participants refereed to different objects of interest. Most frequently they were interested in the answer of their self-generated problem (18 sequences, 5 out of 7 participants). For example, Anna posed the following problem to the Chopstick task: "How much money can Lisa save?" She explained that she posed this problem because she wanted to know whether or not the chopsticks would be free.

Anna: (Chopstick task) Hm, [.] Definitely interesting for me too, because [.] I was also interested in whether the chopsticks would ultimately be free, that is, were given for free.

Their interest in aspects of the real-world situation was also often mentioned by explaining their decision to pose a certain problem (9 sequences, 5 participants). For example, Theo said that he included his personal interests in his problem posing process.

Theo: (Cable car task) […] and then I have linked the [.] knowledge [.] [.] with what would be of further interest to me personally. [.] So [.] How does it look if I [.] in particular limit the people to the window seats [.].

In addition, interest in the mathematical topic behind the problem was mentioned by three participants (3 sequences).

Further, differences were found regarding the perspective of who might find the problem interesting (Perspective of interest). Most preservice teachers referred to their own interest or what in general could be seen as interesting (15 sequences, 6 participants). However, some participants took the perspective of the protagonist of the given real-world context and generated a problem that they thought would be interesting for this person to solve (7 sequences, 4 participants).

Theo: (Chopstick task) So practically I put myself in her [the protagonist’s] position [.] and thought I would like to save money on the one hand, but also have as many chopsticks as possible [.].

One participant (Lea) also took the perspective of an imaginary student who could work on the problem (2 sequences).

Lea: (Fire brigade task) Because I also thought that the students might be interested in this. Or because they understand why they / because they don't think: This is a useless task [..] well, because somehow you [.] understand why you want to know.

Preservice teachers’ self-efficacy when posing problems

Regarding self-efficacy, we found that the preservice teachers in our sample often referred to their self-efficacy expectations to explain why they posed a certain problem. In particular, their expectations that they would be able to solve the self-generated problems played a major role in posing the problem. (12 sequences, 5 participants).

Fabian: (Chopstick task) It was not a known task, but of course a task that I could solve myself, that / exactly. Um, now with this task, I already had my solution method in my head. So, I knew straight away how / how to / so I didn't have to think about the right solution for a long time but already knew the procedure, um how to proceed.

In addition, their self-efficacy expectations of mastering problem posing was also mentioned by two of the participants (4 sequences). Thereby, the preservice teachers set different goals that they wanted to achieve. One of the participants (Leon) wanted to pose multiple problems with increasing difficulties. For each situation, he constructed at least three problems, beginning with an easy problem and ending with a difficult one.

Leon: (*Cable car task*) Again from easy to difficult. In the beginning, it was [.] the simple task with the Pythagorean theorem [..] um, and then it should get more and more difficult with a variable [.] that has to be calculated.

For the cable car situation, Leon generated the following four problems (Figure 1): “How long is the distance between the valley and the mountain station? How much time does it take to go one way? What is the maximum number of times per hour that the cable car can run? How many people would be in the cabin on average?”

Lea had a different goal, for her it was important to construct problems with an appropriate level of difficulty.

Lea: (*Cable car task*) So it was a compromise between: It's not too difficult, it's not too easy, it's somehow feasible.

The preservice teachers' expectations for solving the problem mainly referred to their own self-efficacy (11 sequences, 5 participants). However, the one participant (Lea) who considered students' interest also took into account students' potential solving success and constructed a problem that she was confident the students would be able to solve.

Summary and discussion

In the present study, we investigated how interest and self-efficacy contribute to preservice teachers' decisions to pose a certain problem. Our findings support the idea that problem posing could be a powerful tool to foster motivation (Cai & Leikin, 2020). The preservice teachers in our study often posed problems to which they were interested in knowing the answer. This indicates that learners use the opportunity that problem posing provides to integrate their interests in their problem-posing processes. Their interest in the answer of the self-generated problem might have benefits for their perseverance and the effort they put into problem solving or might positively affect their interest in the math that is needed to solve the problem (Walkington, 2017) or might contribute to their interest in mathematics in general (Xia et al., 2008). Future studies should investigate how this potential of problem posing can be used in learning environments that are aimed at fostering students' motivation. Our findings highlight the importance to distinguish between objects of interest (Schukajlow et al., 2017). Besides interest in the answer and in certain aspects of the real world situation, interest in the mathematical aspects behind the problems was also a reason for preservice teachers' self-generated problems. Further, preservice teachers mostly referred to their own interest, but they also took other perspectives and generated problems that they thought would be interesting to the protagonist of the real-world situation or to the students who would be working on the problems.

In addition, we focused on the role that preservice teachers' self-efficacy expectations play in problem posing. We found that some of the learners stated that it was an important criterion for the self-generated problems that they were confident they could solve the problems themselves. This contributes to explaining learners' tendency to pose simple problems as found in prior studies (English, 1998; Hartmann et al., 2021). However, in line with the results from the study conducted by Voica et al. (2020), their self-efficacy referred not only to their expectation that they would be able to solve the problem but also to their expectation that they could successfully pose a problem. Thereby, constructing multiple problems and constructing problems with an appropriate level of difficulty were identified as problem-posing goals. This finding exemplifies the idea that preservice teachers' self-efficacy appraisal is linked to their different roles such as their role as future teachers (Marschall, 2021). In addition, it shows the importance to take into account different goals associated with problem posing. For further research it seems necessary to better understand these goals to develop evaluation criteria to assess problem posing performance.

As a practical implication, our study shows that it was important for the preservice teachers to construct problems that they were confident they would be able to solve. When teaching problem posing in class, it therefore seems necessary to encourage students to also pose difficult problems that allow for progress in their learning. In addition, teachers should be aware of the different goals that come up with problem posing (e.g., posing multiple problems) and make them transparent to the students.

Actions Speak Louder than Words: Social Persuasion through Teaching Practice

Peter Liljedahl

Simon Fraser University, Vancouver, Canada; liljedahl@sfu.ca

What a student believes about their abilities to do mathematics has a significant impact on the ways in which they then do mathematics. If they believe they can solve a problem they behave very differently than if they believe they cannot. As such, the development of self-efficacy needs to be paramount in the conversation of what it means to teach mathematics. In this paper, I look at the subtle ways in which students' self-efficacy is developed within the specific teaching paradigm of Building Thinking Classrooms. Results indicate that what a teacher does is just as important as what a teacher says when it comes to developing student self-efficacy in mathematics.

Keywords: Self-efficacy, affect, social persuasion, thinking classrooms.

Introduction

Henry Ford is famously credited with stating that "whether you think you can, or think you can't … you're right". Ford believed that beliefs in your abilities to achieve something are central determinants on whether or not you do, indeed, succeed. Believe you can—and you likely will. Believe you can't—and you probably won't. This maxim likely emerged from Ford's belief that success is the product of hard work. And in order to persevere in the face of the work that is needed to succeed you have to first believe that your hard work will be met with success.

Bandura (1997) refers to this belief in your abilities to succeed as self-efficacy and argues that these beliefs affect how a person thinks, feels, and behaves within a given situation. "It affects the choices they make, the effort they put forth, the perseverance they display in challenges, and the degree of anxiety or confidence they bring to the task at hand" (Rouleau, Ruiz, Reyes, & Liljedahl, 2019). And because these self-efficacy beliefs affect the way you act, they "can powerfully influence the level of accomplishment that people ultimately realize" (Pajares, 2006, p. 341).

Self-efficacy has long been seen as having a significant influence on student performance in mathematics (Hackett & Betz, 1989; Hannula, 2012; Skaalvik et al., 2015). As such, helping students to develop positive self-efficacy beliefs about their mathematical abilities should be an important part of what it means to teach mathematics. In this paper I look at how this is achieved through a teaching paradigm called Building Thinking Classrooms (Liljedahl, 2020).

Development of Self-Efficacy

Whether a person believes they can, or believes they can't, Bandura (1986, 1994, 1997) argues that these beliefs emerge from an individual's encounters with one of four sources—mastery experiences, vicarious experiences, social persuasions, and emotional/physiological reactions. The first of these, mastery experience, is the most influential of the four and is the result of one's previous experiences with success and failure. If you have had a lot of experiences of success you are more likely to believe that you can be successful in future endeavors. Likewise, if you have had repeated experiences of failure, you are less likely to believe that future efforts will be met with success. In essence, self-efficacy is strengthened by success and weakened by failure and that once a trend is established, single contradictory experiences are less likely to affect a person’s overall self-efficacy belief. That is, if a person is accustomed to succeeding and has, as a result, developed positive self-efficacy beliefs, a single encounter with failure is unlikely to affect their overall positive belief in their own abilities (Skaalvik, Federici, & Klassen, 2015). Conversely, a person with negative self-efficacy is unlikely to change their view of their abilities after only one encounter with success unless that encounter was an AHA! experience (Liljedahl, 2008) or occurred on a task others found especially challenging (Bandura, 1997).

The second source of self-efficacy is through vicarious experiences—seeing a peer experience success or failure through their actions. This source of self-efficacy is greatly heightened when they perceive a strong similarity between themselves and the peer they are observing. For example, a student watching a friend be successful at solving a mathematics problem will create a stronger belief in their own abilities than watching a teacher solve the same problem. The teacher is perceived as being too capable and too knowledgeable for their successes to be seen a reasonable approximation of what will occur when the student tries it on their own. A friend’s success, on the other hand, is a better proxy—similarity trumps expertise.

The third source of self-efficacy, social persuasion, draws on persuasive communication and evaluative feedback to build up beliefs about one’s abilities. Unlike vicarious experiences, social persuasion is enhanced when coming from a source perceived to be knowledgeable. That is, the words of a teacher expressing confidence in a student or reminding a student what they are capable of is more effective at building up their self-efficacy than the same words from a peer. For social persuasion, expertise trumps similarity.

The final source of self-efficacy is emotional/psychological reaction and comes from how a person perceives their own emotional reaction to a situation. For example, if a student works very hard to try to solve a problem, persisting in the face of much frustration and several failed attempts, they may perceive this experience in a number of different ways. They may focus on the time it took and how much of that time was spent being frustrated and how many failed attempts there were and conclude that they are not good at solving problems. Alternatively, they may focus on the fact that they endured, persevered through the hardship of frustration and failed attempts, and conclude that they are strong and capable. The same experience can result in different reactions which, in turn, can result in different self-efficacy forming. “It is not the sheer intensity of the emotional and physical reactions that is important but rather how they are perceived and interpreted” (Bandura, 1994, p. 3).

Building Thinking Classroom

Building Thinking Classrooms (Liljedahl, 2020) is a teaching framework that was developed in response to the realization that much of what happens during a mathematics lesson is not thinking. In particular, the baseline data that emerged from this research showed that in a typical lesson about 20% of students spend approximately 20% of the time thinking—8-12 minutes per hour—while the other 80% of students spend no time thinking (Liljedahl, 2020). Research has shown that the normative practices present in many classrooms are promoting, in both explicit and implicit ways, non-thinking behaviors such as mimicking among students (Liljedahl & Allan, 2013). These normative structures permeate classrooms around the world and are so entrenched that they transcend the idea of classroom norms (Yackel & Cobb, 1996) and can only be described as institutional norms (Liu & Liljedahl, 2012)—norms that have extended beyond the classroom and have become ensconced in the very institution of school and fabric of what it means to teach.

Much of how classrooms look and much of what happens in them today is guided by these institutional norms—norms which have not changed since the inception of an industrial-age model of public education. Yes, desks look different now, and we have gone from blackboards to greenboards to whiteboards to smartboards, but students are still sitting, and teachers are still standing. Although there have been many innovations in assessment, technology, and pedagogy, much of the foundational structure of school remain the same. If we want to promote and sustain thinking in the classroom, these norms are going to have to change (Liljedahl, 2020).

Over the course of 15 years, and through the conducting of thousands of micro-experiments with over 400 practicing teachers, a series of 14 practices emerged that break away from the aforementioned institutional normative ways of teaching and have been proven to get more students thinking and thinking for longer (Liljedahl, 2020). Each of these 14 practices is a response to one of the following 14 questions:

1. What are the types of tasks used?
2. How are collaborative groups formed?
3. Where do students work?
4. How is the furniture arranged?
5. How are questions answered?
6. When, where, and how are tasks given?
7. What does homework look like?
8. How is student autonomy fostered?
9. How are hints and extensions used?
10. How is a lesson consolidated?
11. How do students take notes?
12. What is chosen to evaluate?
13. How is formative assessment used?
14. How is grading done?

Although each of these 14 practices, on their own and in concert, have been empirically shown to increase student thinking in the classroom (Liljedahl, 2020) the visually defining qualities of a thinking classroom is that students work together to solve thinking tasks in random groups of three while standing at vertical whiteboards (see figure 1).

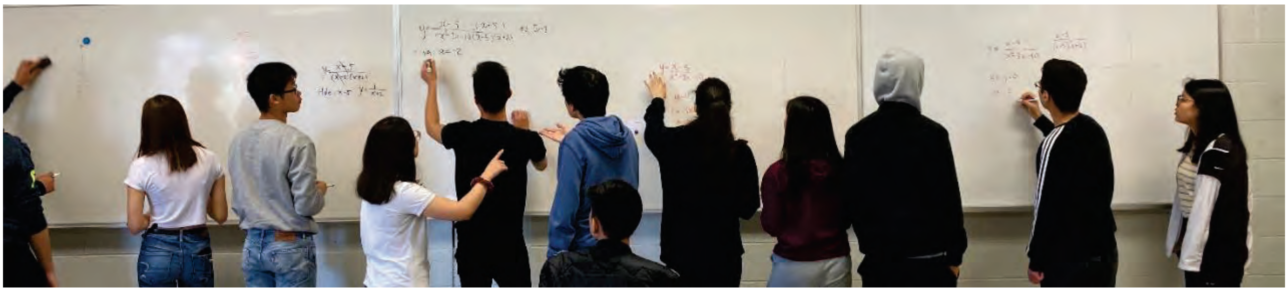

Figure 1: A thinking classroom

When put together, these 14 practices build a classroom ethos, routine, and culture of students thinking individually and collectively to do and learn mathematics. And it radically improves on the baseline data stated above. Rather than 20% of students thinking, we are now seeing upwards of 90%. And rather than thinking for 8-12 minutes students are thinking for 50 – 85 minutes.

Aside from getting students to think, building a thinking classroom has also been seen to fundamentally change other aspects of the student experience, one of which is their self-efficacy beliefs. The repeated and ubiquitous opportunities to persevere and be successful through the use of thinking tasks creates mastery experiences. In addition, the constant work in groups provides ample opportunities for vicarious experiences to occur. And the close proximity within which they work allows for the spread of positive emotional reactions.

What I am more interested in, however, and what is the phenomenon of interest for this paper, is the ways in which social persuasion manifests within a thinking classroom. Whereas social persuasion is most often seen as explicit verbal encouragement, in this paper I am going to look at the more subtle forms of social persuasion that are communicated through the thinking classroom practices.

Methodology

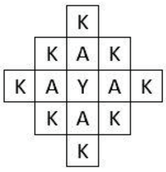
Data from this study are harvested from the aforementioned larger research project into building thinking classrooms that involved hundreds of teachers and thousands of students and took place across a wide range of grades (K-12) and settings (low socio-economic—high socio-economic, private—public, French—English). Regardless of grade and setting, however, the research followed a general research methodology that I refer to as rapid prototyping wherein the unit of analysis was a two-week micro-intervention. That is, for two weeks, a given teacher would enact a unique practice within their classroom and we would study the effect that this change in practice had on student thinking behavior—were more students thinking and were they thinking for longer than they had prior to the intervention? Based on the results of this micro-experiment, adjustments would be made to the intervention to try to increase the amount of thinking that was happening in the room and the teacher would enact this adjusted practice for the next two weeks. And so on. Once the data showed convergence towards an effective practice that practice was distributed to many different practitioners and longer studies were conducted (6 weeks – 10 months), and more adjustments to the practice were made. Despite the fact that we were focused on student thinking behaviors, a number of other aspects of the student experience were also captured—in particular, their reactions to the interventions. It is from these reactions, across a wide variety of micro-experiments that the data for this study were harvested. That is, the data does not come from any one study. As such, participants vary in ages from 5 to 18 and were in classrooms in varying socio-economic settings and geographic locations.

Results

In what follows, I use excerpts from these data to showcase the subtle and surprising ways in which three of the thinking classroom practices communicate social persuasion.

Thinking Tasks

If we want our students to think, we need to give them something to think about—something that will not only require thinking but will also encourage thinking. In mathematics, this comes in the form of a problem-solving task, and having the right task is important. The research (Liljedahl, 2020) revealed that when first starting to build a thinking classroom it is important that these tasks are highly engaging non-curricular problem-solving tasks. The tasks, the research showed, need to have a low-floor (accessible to everyone in the room), a high ceiling (evolving complexity), and be novel (because thinking is what we do when we don't know what to do). For example, see figure 2.



For this image, can you see a path from one letter to an adjacent letter that spells the word KAYAK? Can you see another one? Another one? How many unique paths are there that spell KAYAK?

Figure 2: A thinking task

When these types of tasks were used, we saw a significant increase in student thinking in the classroom. We also saw an increase in student self-efficacy as their efforts were met with success (master experiences). More subtle, however, was what began to emerge in the data after students' third or fourth experience with such thinking tasks. Consider this excerpt from week five of a three-month longitudinal study into the effects a teacher using the first three thinking classroom practices in a grade 8 (ages 13-14) classroom (thinking tasks, random groups, vertical non-permanent surfaces).

Researcher	Before you start, any thoughts about this task?
Kyla	Hmm! This one looks hard.
Researcher	Hard?
Kyla	Yeah! I mean, I don't even have a clue how we would start.
Researcher	So … what does that mean?
Kyla	It means we better start.
Researcher	Oh?!?
Kyla	Yeah. I mean, we almost never know where to start, but we always get there in the end. I'm sure it will be fine.
Researcher	How do you know?
Kyla	Our teacher wouldn't give it to us if she didn't think we could do it.

The repeated positive experiences with these types of tasks were not only building mastery experiences. These experiences were also building a confidence in their teachers' confidence in them. That is, the teacher was communicating to the students, through the use of carefully selected thinking tasks, that they were capable of solving the tasks at hand.

Visibly Random Groups

Once we have the thinking task students need someone to think with. We know from research that student collaboration is an important aspect of classroom practice because when it functions as intended, it has a powerful impact on learning (Hattie, 2009). How groups have traditionally been formed, however, makes it very difficult to achieve the powerful learning we know is possible. Whether students are grouped strategically (Dweck & Leggett, 1988; Jansen, 2006) or students are allowed to form their own groups (Urdan & Maehr, 1995), 80% of students enter these groups with the mindset that, within this group, their job is not to think (Liljedahl, 2020). However, when frequent and visibly random groupings were formed, within six weeks 100% of students entered their group with the mindset that they were not only going to think, but that they were going to contribute. In addition, frequent and visible random groupings was shown to break down social barriers within the room, increase knowledge mobility, and increase enthusiasm for mathematics (Liljedahl, 2014).

Visibly random groups gave lots of opportunity for both mastery and vicarious experiences to occur. But it also proved to provide social persuasion. Consider this excerpt from week two of a two-week micro-experiment into using random groups in a grade 7 (ages 12-13) classroom.

Researcher	So, the teacher has had you working in groups for a few weeks now. Any thoughts?
Sara	I love it.
Researcher	Why?
Sara	I love being in random groups. It’s like a new adventure every day.
Researcher	Do you think this is why she does it?
Sara	Sure. But I also think she does it randomly because it doesn’t matter what group we’re in. We’re all the same. We can all do it.

By forming the groups randomly, the students were interpreting this to mean that the teacher believed that they were all the same—that they were all capable. Incidentally, the students did not say the same things in classrooms where the teacher grouped students strategically. In those settings, the teacher's deliberate and careful selection of groups communicated the exact opposite—that some student were capable and some were not.

How we answer questions

In an institutionally normative classroom teachers answer between 200 and 400 questions in a day (Liljedahl, 2020), all of which fall into one of three categories:

1. Proximity questions: These are questions asked only because the teacher is close. Interestingly, in 90% of the cases, students make little or no use of the information they gain from the teacher’s response. They are only asking the question to show that they are on task—that they are being a good student.
2. Stop-thinking questions: These are questions student ask to get the teacher to help them avoid or to stop thinking. These are most often of the form “is this right”, “are we doing this right”, “are we going in the right direction”, or “is this what you wanted”. Thinking is difficult and if they can convince the teacher to help them, things would be easier.
3. Keep-thinking questions: These are questions that students ask so they can get back to work and are most often clarifying or extending questions. Often the students are in a hurry because they want to get back to the thinking.

To build a thinking classroom, only keep-thinking questions should be answered (Liljedahl, 2020). But this still leaves the question of how to answer proximity and stop-thinking questions. In the research, we found that the simplest way of dealing with these types of questions is to smile and nod as they are asking the question and then, when they are done, simply turn and walk away. At first, students hate this. But an interesting thing begins to happen after a few weeks. Consider this excerpt from week three of a three-month longitudinal study into not answering students' proximity and stop-thinking questions in a grade 9 classroom (ages 14-15).

Researcher	What was that? You asked her a question and she just smiled and walked away.
Morgan	Yeah. She does that a lot.
Researcher	She does!?! What does that mean?
Morgan	It means she thinks we can figure out for ourselves.
Researcher	What do you think?
Morgan	Yeah. We probably can. She's usually right about these kinds of things.

By smiling and walking away, it turns out that the teacher is communicating to the students that she believes that they are capable of figuring this out on their own.

Conclusions

The 14 building thinking classroom practices emerged out of empirical work wherein the goal was to increase the number of students who are thinking in class and for how long they are thinking during a lesson. Aside from achieving this, the research also produced a number of other results pertaining to how students experience mathematics, one of which pertains to their self-efficacy beliefs. Although this was not the intention of the research, data from across a wide variety of interventions and settings showed that aspects of the thinking classrooms improved students' self-efficacy beliefs. And although these changes are happening in part through the ubiquitous opportunities to have mastery and vicarious experiences, and to interpret those experiences with their peers, changes in self-efficacy is also happening through the non-verbal ways in which these practices communicate social persuasion—that the teacher has faith in the students' abilities. What these practices seem to communicate is not that "you can do it" but, rather, that "I believe you can do it". This is a subtle difference, but it intimates that before a student believes in their own abilities, someone else needs to believe in them. And the students need to see these beliefs. Before students can have confidence in their own abilities, they need to have confidence in their teacher's confidence in them.

Values which facilitate mathematical wellbeing of Chinese primary school students: A preliminary study

258 Grade 3 students from six classes taught by three mathematics teachers in a primary school located in suburban Chengdu, China were surveyed in 2021. The data reflect the values they embrace in mathematics learning as these are associated with mathematical wellbeing, namely, relationship, engagement, bliss, accomplishment, perseverance, meaningfulness, and learning. Although these values are similar to those identified in a similar and recent Australian study, the mathematics learning activities which embody the values are not all the same. Preliminary analysis also indicates that some of the seven values are embraced more than the others, and that school/teacher representation and teaching of values in China might be consistent across different classes.

Keywords: Chengdu, conation, mathematics education, values, wellbeing.

Student wellbeing in the context of mathematics learning

The wellbeing of students in mathematics education has been an ongoing concern for teachers, researchers and politicians (Clarkson, Seah, & Bishop, 2010; Hill, Kern, Seah, & van Driel, 2020). Students' general dislike of mathematics is often carried through into adulthood. In many societies, it is normal or even desirable to claim to be weak at mathematics. Also, mathematics anxiety is affecting increasingly younger children (Tomasetto, Morsanyi, Guardabassi, & O'Connor, 2021).

TIMSS 2019 (Mullis, Martin, Foy, Kelly, & Fishbein, 2020) results reaffirm the general lack of wellbeing amongst mathematics students worldwide. On average, across the participating economies, 20% of Grade 4 students and 41% of Grade 8 students "do not like learning mathematics" (p. 426). Also, 23% of Grade 4 students and 44% of their peers in Grade 8 were not confident in mathematics.

The COVID-19 pandemic – and the subsequent and sudden disruption to schooling all over the world – have affected students' wellbeing generally (O'Toole & Simovska, 2021; Schwartz et al., 2021). Thus, being able to effectively foster positive wellbeing in mathematics learning has assumed greater urgency, given that domain-specific wellbeing contributes towards general wellbeing.

Wellbeing as values fulfillment

There are traditionally two main perspectives of wellbeing, namely, hedonic and eudaimonic (Ryan & Deci, 2001). More recently, hybrid perspectives reflect how hedonism and eudemonism can both inform wellbeing at the same time. Australian researcher Julia Hill emphasises the links between values and wellbeing, citing Tiberius' (2018) values-fulfillment theory of wellbeing. According to this theory, "well-being is served by the successful pursuit of a relatively stable set of values that are emotionally, motivationally, and cognitively suited to the person" (p. 13).

In other words, student wellbeing can be seen as a function of fulfilment of what the student values. Fostering positive wellbeing in students' mathematics learning, then, would involve the provision of opportunities for students to realise their subjective and personal values, especially those which are related to mathematics and mathematics pedagogy. This domain-specific form of wellbeing is known as mathematical wellbeing [MWB], first proposed by Clarkson, Bishop, and Seah (2010). In this original conception too, there is association with mathematical and mathematics educational values.

Mathematical wellbeing and values

Hill, Kern, Seah and van Driel (2020) conducted a combined deductive/inductive thematic analysis of 488 Grade 8 students' responses in Melbourne, which confirmed that students' sense of wellbeing with mathematics learning was associated with the fulfillment of particular values. These values were grouped into eight categories, namely, *relationships, engagement, cognitive, accomplishment, positive emotions, perseverance, music,* and *meaning*. Examples of student-nominated learning activities which reflected these values are shown in Figure 1 below.

Themes & nodes	Student examples
Relationships	
Teacher support	*A supportive or good teacher*
Peer support	*Having friends to help me*
General support	*When I get help with my learning*
Engagement	
Interesting/hands on	*Learning interesting stuff*
Focused working	*Being absorbed in my work*
Independent/quietness	*When it is quiet and I'm by myself*
Music (engagement)	*Music helps me concentrate well*
Cognitive	*When I understand the material*
Accomplishment	
Good marks	*When I do good in a test*
Accuracy	*When I get the answers right*
General mastery	*When successful at learning something*
Completing tasks	*When I complete my work*
Confidence	*When I'm really confident*
Positive emotions	
Enjoyment/fun/happy	*If the maths class is enjoyable*
Relaxed/no pressure	*When there is no pressure*
Music (emotions)	*Music to listen to, to enjoy it more*
Perseverance	
Challenge	*Having work I find challenging*
Working hard/practice	*When I work hard*
Music (no reasoning)	*Listening to music in class*
Meaning	
Future skills	*Knowing these skills will help me in life*
Real world relevance	*I like when problems relate to real life*

Figure 1: Values and learning activities associated with mathematical wellbeing

More recently, further analysis has allowed for the valuing of *music* to be subsumed under the other seven values (Hill, personal communication). Nevertheless, the authors had called for further research to be conducted to assess the stability of this MWB framework. This includes the "extending [of sources of student input] to other year levels and populations" (Hill, Kern, Seah, & van Driel, 2020, p. 279). It is in this context that the current study has been set up, and it examines the following research questions in particular:

(1) What values related to mathematics learning do primary school students in Chengdu, China associate with positive mathematical wellbeing?

(2) To what extent are these values similar to the 7 values in the mathematical wellbeing framework constructed by Hill et al (2020)?

China as research context

China was chosen to be the research context for the current study, given that the East Asian cultural setting would be a contrast to the Australian mathematics classroom. Chinese students (and their parents) have been experiencing tremendous pressure and stress in schooling, including in mathematics, in part due to the high-stakes 'gaokao' national examinations which determine student access (or not) to prestigious universities around the most populous nation on Earth. In fact, the Chinese central government has introduced several measures in mid-2021 to reduce the negative wellbeing experienced by students in mathematics and other school subjects (The Economist, 2021).

As a preliminary study, only one school was chosen as data source. Since the Australian data were collected from secondary school students, the current study sought to gather data from a primary school. The volunteer school is a mid-size government school located in suburban Chengdu, reasonably popular amongst parents in the community. 258 Grade 3 students from six different classes taught by three mathematics teachers from the school provided the data for this study. Chengdu is the capital city of Sichuan province, located in southwestern China. With a city population size of more than 16 million occupying some 14,000 square kilometres, it is one of the 6 largest cities in the world by population or land area. Putting this in perspective, Chengdu has double the population and nine times the area of London.

Data collection

Data were collected via an anonymous student survey, completed during class time in 2021. Instead of using the learning moments such as those in Table 1, which would have been too leading, we listed 22 learning moments which were representative of Grade 3 Chinese mathematics classrooms, such as 'when you cooperate with friends to complete a mathematics task' and 'when your mathematics teacher praises you'. An 'others' item also allows for respondent-generated learning moments.

Each of these phrases was accompanied by a geometrical shape, which student respondents were asked to shade in yellow if it is associated with extreme happiness and wellness, and green if the happiness and wellness are not as intense. Given that 'mathematical wellbeing' might not be easily understood by the young children, the survey asked them to consider 'happiness and wellness' instead. The survey was presented in the Chinese language, and Figure 2 shows part of it with the content translated into the English language.

Of course, the survey items could have been presented in the form of a Likert scale. However, given that the student respondents were only 8 years of age, we had decided to design the survey so that it is aesthetically attractive, and such that it would be fun responding to the items through colouring in.

The Chinese teacher researcher in our team was personally present in all the 6 classes when the survey was administered, so that student queries were attended to on-the-spot.

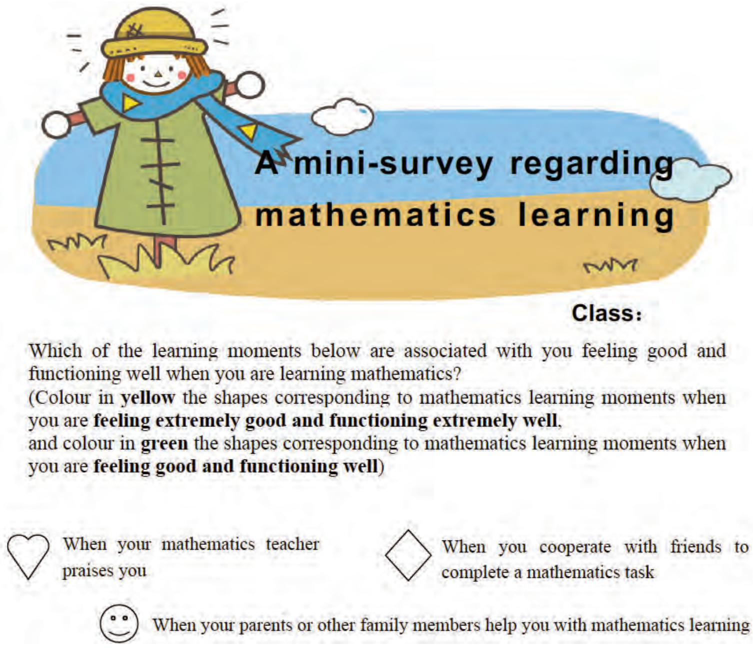

Figure 2: Part of the student survey (translated into the English language)

Data analysis

The 258 student responses on the hardcopy survey were entered into a Microsoft Excel spreadsheet, with the numerals 2, 1 and 0 used to represent yellow, green and no shading respectively. In other words, a score of 2 represents a strong association between the learning moment concerned with MWB, while a score of 0 represents the absence of any association.

Discussions within the research team were held to associate each of the 22 learning moments with an underlying value. For example, ‘feeling relaxed during mathematics lessons’ is regarded as reflecting the valuing of *bliss* or positive emotions. This discussion took place over several virtual, online meetings, given the prevailing ban on international travels resulting from the COVID-19 pandemic. Whenever general agreement could not be achieved for any learning moment, the team privileged the views of the Chinese teacher researcher, acknowledging that she possessed the relevant insider, cultural funds of experience to interpret the learning moments more accurately.

106 of the 258 students had shaded the ‘others’ item, with 84 of them nominating learning moments which were not amongst the given ones. During these discussion sessions, the research team also examined these nominations, allocating them to agreed-upon values. For example, ‘interacting with my mathematics teacher’ is associated with the valuing of *relationships*, and ‘helping my mathematics teacher out’ is associated with *accomplishment*. By the end of the discussion, seven value categories emerged. Based on these allocations, mean scores for the seven dimensions were

computed for each student, as well as mean scores for the seven dimensions for the entire student sample. A paired sample t-test was conducted with SPSS version 27 to determine if the differences in means between pairs of values were statistically significant.

Results

The seven value categories that emerged from the in-depth discussions are, namely: *relationship, engagement, bliss, accomplishment, perseverance, meaningfulness,* and *learning*. Comparing this list with the values in Hill, Kern, Seah, and van Driel (2020), correspondence could be observed for the two sets of seven values. In particular, the valuing of *relationship, engagement, accomplishment,* and *perseverance* are named similarly in the two lists. Whereas the Australian list has the value *meaning*, this is considered to be the same as *meaningfulness* listed in the current study. Similarly, *positive emotions* in the Australian list can be considered to be the same as *bliss* in the current study with Chinese data. We decided to adopt the term *bliss*, since it may be confusing for some people when considering *(positive) emotions* as a value. Last but not least, *cognitive* in the Australian list is regarded as being similar to *learning* as it is named in the current study. Similarly, we were concerned that considering *cognitive* as a value may interfere with people's understanding of the three aspects of mental processes, that is, cognition, emotions, and motivation (see Hannula, 2012).

It is important to note, however, that even though the same values might relate to MWB amongst Australian and Chinese students, the learning moments that operated in one culture may or may not be seen in the other culture. For instance, 'when my mathematics teacher gives us less homework' might be a learning activity that is hard to find in a typical Grade 3 Australian classroom. The same may be said of 'helping my mathematics teacher assess my peers' oral computation'. At the same time, we also looked out for learning moments which appeared to be unique to China, but which actually is due to the fact that the study has been designed to collect data from primary (instead of secondary) students. Thus, 'helping my group earn achievement stars' and 'interacting with my mathematics teacher' which are learning moments in the Chinese data may well be observed amongst Australian primary school students too, had the Australian study been conducted in primary schools.

The seven values are not equally associated with MWB. As shown in the radar chart (Figure 3), which maps how each of the 258 students valued the 7 dimensions, the arcs are concentrated away from the centre of the circle for *engagement, relationship, bliss* and *accomplishment.* Given that distance from the centre represents greater valuing, we can see that the Chinese students' MWB was more often associated with these four dimensions.

Indeed, results of the paired-samples t-test show that:

- *engagement* and *bliss* are valued differently at the .05 level of significance ($t=4.964$, $df = 257$, $n = 258$, $p < .05$, 95% CI for mean difference 0.076 to 0.176). On average *engagement* was about 0.13 point more valued than *bliss*,

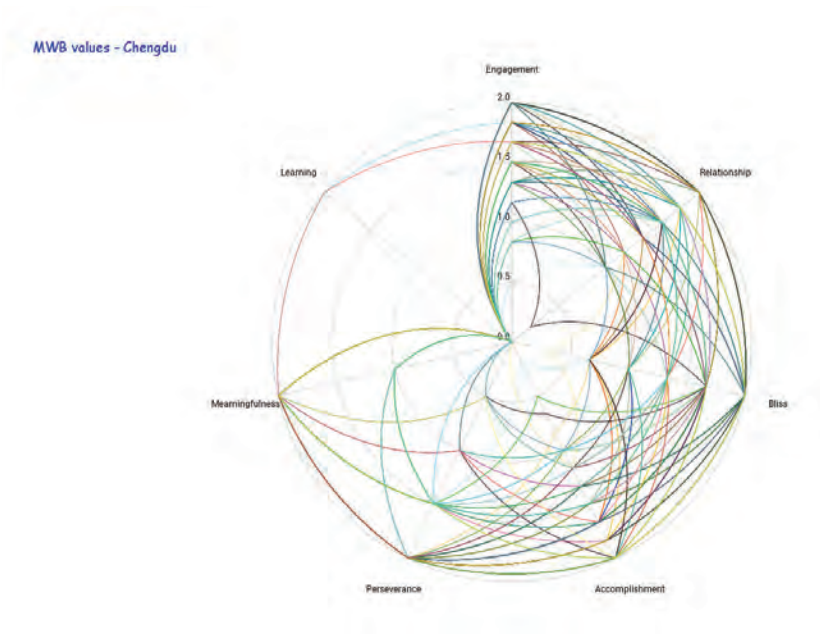

Figure 3: Differential valuing amongst Chinese primary school students

- *engagement* and *accomplishment* are valued differently at the .05 level of significance (t= 2.075, df = 257, n = 258, p < .05, 95% CI for mean difference 0.002 to 0.094). On average *engagement* was about 0.05 point more valued than *accomplishment*,

- *engagement* and *meaningfulness* are valued differently at the .05 level of significance (t= 2.442, df = 257, n = 258, p < .05, 95% CI for mean difference 0.018 to 0.165). On average *engagement* was about 0.09 point more valued than *meaningfulness*,

- *relationship* and *bliss* are valued differently at the .05 level of significance (t= 3.244, df = 257, n = 258, p < .05, 95% CI for mean difference 0.036 to 0.148). On average *relationship* was about 0.09 point more valued than *bliss*,

- *bliss* and *accomplishment* are valued differently at the .05 level of significance (t= -2.675, df = 257, n = 258, p < .05, 95% CI for mean difference -0.135 to -0.020). On average *bliss* was about 0.78 point less valued than *accomplishment*,

- *bliss* and *perseverance* are valued differently at the .05 level of significance (t= - 4.097, df = 257, n = 258, p < .05, 95% CI for mean difference -0.209 to -0.073). On average *bliss* was about 1.41 point less valued than *perseverance*,

- *accomplishment* and *perseverance* are valued differently at the .05 level of significance (t= -2.136, df = 257, n = 258, p < .05, 95% CI for mean difference -0.123 to -0.005). On average *accomplishment* was about 0.06 point less valued than *perseverance*,

- *perseverance* and *meaningfulness* are valued differently at the .05 level of significance (t= 2.754, df = 257, n = 258, p < .05, 95% CI for mean difference 0.030 to 0.183). On average *perseverance* was about 0.11 point more valued than *meaningfulness*.

The extent to which a student valued the seven values can be represented by the sum of the seven mean value scores, ranging from 0 (i.e. embracing none of the seven values) to 14 (i.e. embracing all seven values extremely). Given that students indicated their respective classes in the survey, and that the surveys were administered class by class, the 258 student data sets could be arranged according to class groups. When plotted against total mean value scores, we obtain the representation as shown in Figure 4. The graph suggests that the students' valuing has not been particularly strong (or weak) in particular classes (and taught by possibly different teachers). Thus, school/teacher representation and teaching of values in China might be consistent across different classes.

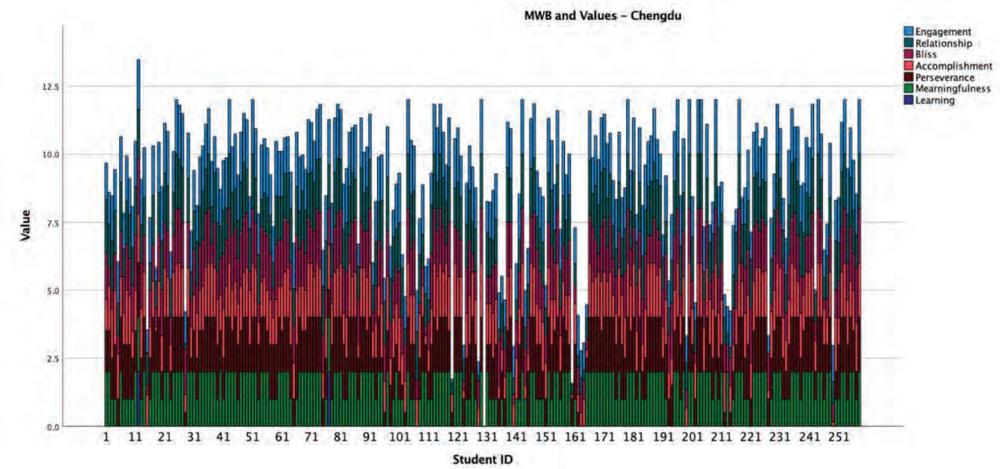

Figure 4: Total mean value scores for the Chinese student sample

Discussion

The current study responds to the call by Hill, Kern, Seah and van Driel (2020) to extend the investigation of values related to MWB to other grade levels and populations. The data collected from Grade 3 students in Chengdu suggest that MWB is associated with the students' fulfillment of the values of *relationship, engagement, bliss, accomplishment, perseverance, meaningfulness,* and *learning*. This thus answers Research Question 1.

Considering Research Question 2, the seven values identified in this study are similar to the seven values listed in Hill, Kern, Seah and van Driel (2020). The current study thus reaffirms the stability of the MWB framework proposed by the Australian study that was led by Julia Hill, in terms of the seven values which underpin it. However, these values could be expressed through different culturally specific mathematics learning moments in the two different contexts. It is important that teachers are aware of this attribute of values as they are embraced across different sociocultural settings.

It appears from our data that some of the seven values were embraced more than the others. Whether this was due to the nature of the local cultural traditions, of the mathematics education system and/or of MWB is unknown from the quantitative data. Further, qualitative research planned with selected students should be able to shed light on this observation. In particular, the paired samples t-test results suggest that *engagement* and *perseverance* were valued by the Chinese students more than they did with *relationship*, all of which were valued more than *accomplishment* and *meaningfulness*. *Bliss* is next, which the Chinese students appeared to value more than *learning* only.

Considering the extent to which the seven values as a whole were embraced by the 258 students across six classes taught by three different teachers, there was no evidence of class-level variations.

This suggests that values representation / teaching across different Chinese mathematics classrooms (in the same school) was consistent. This might facilitate values associated with positive MWB to be promoted amongst – and fulfilled by – students as they engage with mathematics learning.

Next steps

The intention of this paper is to report preliminary results and findings, providing teachers with some approaches to enriching mathematics teaching further with affective and conative considerations. The next stage of the study will be to both deepen our understanding of the available data and broaden the data sources, thus contributing to existing social theories of mathematics pedagogy.

Developing and validating survey instruments for assessing beliefs and motivation in mathematics

Ida Friestad Pedersen[1] and Per Øystein Haavold[2]

[1]UiT The Arctic University of Norway, Department of Mathematics and Statistics, Norway; ida.pedersen@uit.no,

[2]UiT The Arctic University of Norway, Department of Education, Norway; per.oystein.haavold@uit.no

In this article, we describe the development and validation of two short questionnaires for assessing beliefs and motivation in mathematics that are (1) linked to Inquiry-Based Learning (IBL) and (2) short, concise and easy to administer quickly within the parameters of regular classroom instruction.

Keywords: Mathematical beliefs, motivation, IBL, scale validation.

Introduction

Research has shown that Inquiry-Based Learning (IBL) has the potential to improve students learning of and motivation for mathematics and science, as well as change students' beliefs about the subjects (Bruder & Prescott, 2013). However, many teachers report challenges with implementing IBL in their own classrooms (Engeln et al., 2013). The context of this study is a project called SUM, which aims to explore how IBL could be integrated in teachers' day-to-day mathematics teaching. One of the key research tasks of the SUM-project is to document and explain students' long-term development in terms of motivation for and beliefs about mathematics. In order to achieve this, the project needs survey instruments that can be quickly and easily administered to a large number of diverse-aged students in a classroom context. Several questionnaires have previously been developed to explore students' beliefs and motivation, but a review of the literature disclosed multiple reasons why there is a need for new instruments, particularly with respect to beliefs. First, we identified no instruments that have been conceptually linked to IBL. Second, most existing survey instruments were long with many items. Brevity is important when instruments are administered in classroom contexts, as the longer the inventory, the less students may take care completing it (Entwistle & McCune, 2004). Finally, earlier scales used to measure beliefs have mostly not been systematically validated, and according to Diego-Mantecon et al. (2019), there is still a need for a more thorough methodological analysis of these variables, particularly in the case of beliefs, using advanced psychometric tools.

In this paper, we describe how the aforementioned issues have been addressed through developing and validating a questionnaire assessing students' beliefs about mathematics, and adapting and validating existing scales measuring motivation. This resulted in the *Mathematical Beliefs Questionnaire* (MBQ) and the *Mathematical Motivation Questionnaire* (MMQ). Our main research questions are: a) What is the factor structure of the MBQ and the MMQ, and how can we achieve robust scales measuring the underlying constructs with as few items as possible? and b) Do the six proposed scales in the MBQ and MMQ have acceptable internal reliability and discriminant validity?

Theoretical foundation and initial development of instruments

Mathematical beliefs – the MBQ

The affective domain is characterized by many overlapping and related term such as beliefs, attitudes, values and emotions – that are not used in a uniform way (Philipp, 2007). As such, research on beliefs is complicated by numerous factors, including both methodological and conceptual issues. However, empirical work on an unclear concept can invite dialogue and serve to clarify it (Skott, 2015). Furthermore, although beliefs are not easily defined, reviews of the research literature have identified certain consistent features. In general, beliefs can be described as subjective knowledge (Philipp, 2007), and according to Skott (2015), beliefs are usually value-laden mental constructs that are relatively stable results of prior experiences. Beliefs are also organized in complex and quasi-logically connected clusters (Philipp, 2007). Although it is possible to group these clusters in a variety of manners, beliefs about mathematics have commonly been grouped according to beliefs about the nature of mathematics, beliefs about mathematics learning, and beliefs about mathematics teaching (Ernest, 1989; Beswick, 2012). Each of the three belief clusters can be mapped on a on a continuum that ranges from formal beliefs at one end to informal beliefs at the other (Collier, 1972). Formal beliefs about the nature of mathematics views mathematics as a hierarchically structured subject of procedures, rules, algorithms and formulas. Knowing mathematics is equivalent to recall and application of these procedures, and teaching mathematics is envisioned as a teacher-centered activity in which the teacher present and demonstrate the use of said procedures. Informal beliefs about the nature of mathematics identifies it as a creative subject of investigative processes tied to problem solving, proof, reasoning, communication, connections and making sense of the world around us. Knowing mathematics is displayed through active and successful engagement in these processes, and teaching mathematics is envisioned as a student-centered activity in which the teacher facilitates students' active knowledge construction through exploratory and open-ended processes.

In the development of the MBQ, we sought to relate each of the aforementioned three belief clusters to key characteristics of IBL. First, IBL is premised on an epistemological belief of mathematics as a dynamic and creative endeavor, where the focus is primarily on the process of mathematics and not necessarily on the product (Ernest, 1989; Artigue & Blomhøj, 2013). A belief cluster we may call Mathematics as a creative subject (Creative) points to the view of mathematics as a creative and human endeavor, where the purpose is to solve interesting problems and understand the world around us using creative and original thought. Second, a belief cluster we may call Mathematics instruction should be inquiry based (Inquiry) points to the view that teaching should be based on inquiry related activities, where students are provided with opportunities to explore and try out their own ideas (Artigue & Blomhøj, 2013). Third, a cluster we may call Mathematics is not an innate ability (Adventitious) rests on the premise that education should be for all, and, more importantly, that all students have the capacity for learning and becoming proficient in mathematics through effort and dedication (Kloosterman, 2002).

A literature review confirmed that there were no existing previously validated instruments for measuring students' epistemological beliefs about mathematics along these three domains. Therefore, a panel of researchers in the SUM-project generated a pool of items that captured aspects of each of the three aforementioned belief clusters. This item pool was generated based on an approach consisting of: a) identifying key characteristics of the theoretical definitions, and b) selecting and translating the most relevant items from existing literature (particularly Tatto, 2013; Collier, 1972) as well as supplementing this by formulating some new items. This process resulted in 17 items – significantly longer than the target length.

Motivation – the MMQ

Like beliefs, motivation has long been the focus of educational research, and there exists a number of theoretical approaches and associated concepts – many of them appearing related or partially overlapping. In the context of mathematics education, Schukajlow, Rakoczy and Pekrun (2017) identified expectancy-value theories and self-determination theory as especially important theoretical approaches, and the conceptualization of motivation in the MMQ encompass features of both.

The choice of motivation constructs in the MMQ was mainly influenced by the expectancy-value theory of Eccles et al. (Eccles & Wigfield, 2002), whereby students' motivation for engaging in an activity is thought to depend on both their expectations for success and how they value the activity. Specifically, our review of the motivation literature led to the conceptualization of students' motivation for mathematics through three constructs: Perceived competence, which relates to their perception of their mathematical ability and expectation for success, Intrinsic value, which can be linked to intrinsic motivation in self-determination theory (Ryan & Deci, 2000) and relates to the enjoyment they may experience when engaging in mathematics or the subjective interest the students' have in mathematics, and Utility value, which relates to how engaging in mathematics may be useful to the student, for instance with respect to pursuing future career goals (Eccles & Wigfield, 2002). These constructs are not only widely supported in the motivation literature, they can also be related to key characteristics of IBL. For instance, Fielding-wells et al. (2017) demonstrates the use of expectancy-value theory for developing insights into how engaging with IBL affects student's competence-related beliefs, sense of autonomy, and intrinsic valuing of mathematics, and calls for further research on how IBL may foster a perception of the utility of mathematics.

A number of scales for measuring aspects of student motivation exists, and the MMQ combines translated and adapted versions of items from the IMI - Intrinsic Motivation Inventory (Center for Self-Determination Theory) in order to address Perceived competence and Intrinsic value, as well as adapted items from the Usefulness scale in the Conceptions of mathematics inventory (CMI, retrieved from (Star & Hoffmann, 2005)) to address Utility value. This resulted in 20 items – again significantly longer than the target length.

Method

Many of the items in the item pool originated from well-known instruments, but in the MBQ and MMQ they are combined and adapted to our specific situation (IBL, mathematics, students aged 10-19). Furthermore, our aim is to achieve robust scales measuring the underlying constructs with as few items as possible. Therefore, we have conducted a validation study in order to explore the factor structure of these items and establish internal reliability and discriminant validity.

Participants and procedure

Data for the validation study was collected in the fall of 2019, and the participants were 377 students in the age range 10-19 (48% male) from 10 different schools in the SUM-project. Note that this constitutes a convenience sample where the students are nested in classes, and as one might expect a greater similarity between students in the same class, this is a limitation of the present study.

The participants responded to an electronic questionnaire consisting of 49 items, all answered along a 5-point Likert scale, as well as five background questions. The 49 items were separated into three sections: 1) 17 items from the MBQ, 2) 20 items from the MMQ, and 3) 12 items assessing students' past experiences in mathematics classroom. Before analyzing the data, missing values were handled by interpreting them as a "neither agree or disagree"-response and imputing the Likert-scale midpoint value 3. To assess the theorized scales in both the MBQ and the MMQ, the sample was randomly split in half and an EFA (exploratory factor analysis) was conducted on the first half (196 students) and a CFA (confirmatory factor analysis) was conducted on the second half (181 students). Small sample sizes can result in unstable factors, but ca. 200 is considered fair – especially if communalities and factor loadings are high.

Results

Exploratory factor analysis (EFA)

In line with Carpenter's (2018) summary of recommendations for non-normally distributed variables and possibly correlated factors, we conducted separate exploratory factor analyses using Principal Axis Factoring and oblique rotation to identify the latent factor structure of the MBQ and MMQ. In both cases the factorability of the items was deemed satisfactory, as the Kaiser-Meyer-Olkin measures were .74 for the MBQ and .93 for the MMQ, and the Bartlett's Tests of Sphericity were significant.

For the MBQ, five items were excluded to improve the interpretability due to low communalities and high cross-loading. The number of factors retained was based on several criteria. First, the Kaiser "eigenvalue greater than one" rule led to an initial extraction of three factors and the scree plot indicated the extraction of three or four factors. Second, a parallel analysis (100 datasets; CI 95%) indicated the extraction of three factors. Finally, the following criteria were also taken into consideration: the factors should be homogenous and theoretically meaningful, Cronbach alpha has to be sufficiently high (>.65), each factor should contain enough items (>2) with high loadings (>.50) and the total amount of variance explained must be sufficient (approx. 50%) (Carpenter, 2018).

A three factor-solution was preferred in the end because of its simple theoretical interpretation, sufficient number of items per factor, and general parsimony, along with sufficient total variance explained. Factor one (eigenvalue = 3.63, 24.70% of variance) was Mathematics as a creative subject (Creative). The three items retained all reflect seeing mathematics as a subject that is creative, humanistic and related to the world we live in (e.g.: C3 - "Mathematics is first and foremost about understanding the world around us"). Factor two (eigenvalue = 2.10, 14.13% of variance) was Mathematics instruction should be inquiry based (Inquiry). The three items reflect a belief that mathematics teaching and instruction should allow students to explore and understand mathematics in settings similar to how mathematicians work (e.g., I2 – "In mathematics class we should first and foremost experiment and try out our own ideas”). Factor three (eigenvalue = 1.95, 12.18% of variance) was Mathematics is not an innate ability (Adventitious). The three items retained in this scale reflect the belief that mathematical ability is the result of hard work and not innate (e.g.: A3 – “Everyone can become proficient in mathematics”). The three factors explained 51.01% of the total variance, and the factor loadings are summarized in Table 1.

Table 1: Factors and loadings for the MBQ and MMQ. Note: Factor loadings < .5 are suppressed

	Item / **Factor**	C1	C2	C3	I1	I2	I3	A1	A2	A3				
MBQ	1	.65	.62	.59										
	2				.73	.64	.53							
	3							.74	.68	.63				
MMQ	**Item** / **Factor**	IV1	IV2	IV3	IV4	IV5	UT2	UT6	UT7	UT8	PC1	PC4	PC5	PC6
	1	.84	.74	.84	.72	.95								
	2						.78	.76	.64	.63				
	3										.80	.84	.81	.87

For the MMQ, inspection of the communalities and the rotated pattern matrix led to the identification of 7 items with either low communalities (<.4) or relatively high cross-loadings. After a closer inspection of the wording of these items, we decided that it would be theoretically meaningful to remove them from the analysis. Most of the 7 removed items belonged to the proposed Utility scale, and referenced mathematics being useful to the student in the present (e.g. UT1 – “Mathematics is a useful subject in school”).

Repeating the EFA with the 13 remaining items indicated the extraction of three factors (see Table 1), together explaining 73.63 % of the total variance. Factor one (eigenvalue = 6.51, 50.07 % of variance) was Intrinsic value. The five items all reflect the notion that mathematics is a fun, enjoyable and interesting activity (for example, IV1 “I enjoy doing mathematics”). Factor two (eigenvalue = 1.87, 14.36 % of variance) was called Utility for future life. This is a slight narrowing of the original theorized scale, as the four items retained reflect the view that learning mathematics in school will be advantageous for the student in the future (e.g. UT6 “Mastering mathematics will help me get a job later in life”). Finally, the third factor (eigenvalue = 1.20, 9.20 % of variance) was called Perceived competence. The four items belonging to this factor all reflect a perception of oneself as being competent in the field of mathematics (for example PC4 “I have good mathematical skills”).

Confirmatory factor analysis

To assess the stability of the three-factor solutions, we conducted confirmatory factor analyses using the AMOS software. In both cases, the chi-square value in relation to the degrees of freedom gave p-values larger than .05 (MBQ: $\chi^2(24) = 28.61$ and $p = .24$, MMQ: $\chi^2(62) = 28.61$ and $p = .11$), indicating that the hypothesized models do not significantly deviate from the observed data. Model fit was further assessed using the goodness-of-fit index (GFI); the comparative fit index (CFI); the root mean square error of approximation (RMSEA); and the standardized root mean square residual (SRMR), with acceptable values near .95, for the two former and $\leq$.05 for the two latter (Byrne, 2010). The analyses indicated a good model fit in both cases, with fit parameter values GFI = .97, CFI = .98, RMSEA = .03, and SRMR = .05 for the MBQ, and GFI = .94, CFI = .99, RMSEA = .035, and SRMR = .035 for the MMQ.

Internal reliability and discriminant validity

We assessed internal reliability using Cronbach's alpha and the validation dataset. For the MMQ, the alpha values for Intrinsic value, Perceived competence and Utility for future life were .93, .92 and .76 respectively, indicating that the motivation scales were remarkably robust to our translation, adaptation and shortening. For the MBQ, the alpha values for Adventitious, Inquiry and Creative were .76, .68 and .70 respectively. Although alpha values greater than .70 is often referred to as a rule of thumb, this appears to be a rather arbitrary cutoff and lower values may be considered satisfactory for scales with few items. As such, we conclude that all six subconstructs have acceptable internal reliability.

Table 2: Scale intercorrelations. Coefficients marked with ** are significant at the 0.01 level.

	1	2	3	4	5	6
1 Creative						
2 Inquiry	.34**					
3 Adventitious	.20**	.08				
4 Intrinsic value	.56**	.04	.47**			
5 Perceived competence	.36**	.08	.37**	.66**		
6 Utility for future life	.37**	.13	.45**	.53**	.32**	

Table 2 shows the bivariate Pearson correlation coefficients between all the subscales. Significant correlations are observed between all scales except for Inquiry, and this is to a large extent expected as the subscales Creative, Adventitious, Intrinsic value, Perceived Competence, and Utility for future life all reflect optimistic beliefs and motivations about mathematics and mathematics learning, as well as mathematics being important for one's own future life.

Given the rather high correlation between some of the subscales, we assessed the discriminant validity using the Fornell and Larcker criterium (1981). The Average Variance Extracted (AVE) was calculated for each of the six subscales, and compared to the highest squared correlation with any other subscale within MBQ and MMQ respectively. For all the subscales, the AVE exceeded the highest squared intercorrelation, indicating that the subscales may be reliably distinguished.

Concluding remarks

Our analyses show that we can achieve robust measures of subscales pertaining to mathematical beliefs (Mathematics as a creative subject, Mathematics instruction should be inquiry based, Mathematics is not an innate ability) and motivation for mathematics (Intrinsic value, Perceived competence, Utility for future life) with relatively few items. Furthermore, these six proposed scales all have acceptable internal reliability and discriminant validity.

Digital interactive storytelling in mathematics: an engagement structure enriched by the Guru stimuli

Anna Pierri

University of Salerno, Italy; apierri@unisa.it

This work means to highlight the reactions of the students when their interactions with a digital storytelling in mathematics are influenced by the feedback of an expert. That causes affective reactions among the students that, taking a specific role, are immersed in the digital story and act to build an original version of it. In particular, this research is interested in analyzing the students' affective pathway in connection with some Goldin's engagement structures that emerged from group discussions. The qualitative data emerged from a pilot study lead us to explore this aspect in order to define specific categories that include affective and cognitive aspects.

Keywords: Affective pathways, digital storytelling, engagement structure, teacher's role.

Introduction

In the recent period of pandemic emergency there has been much talk about Distance Learning, with teachers of all levels finding themselves transforming into distance learning teachers, with difficulties and constraints that this sudden change would mean from a pedagogical, didactic and social standpoint, and also with all problems connected with the greater or lesser technological competence of teachers and the extent of technological equipment available for students. In such a situation, we are called to reflect on the potential of technologies to integrate, improve and rethink some aspects of face-to-face didactics. Studies developed within the PRIN 2015 project "Digital Interactive Storytelling in Mathematics: a competence-based social approach "[1], go in this direction.

The basic idea is, on the one hand, to use technologies to involve the student in the story and make them interact with other teammates; and, on the other hand, to create problematic situations (mathematical) which the student-actor has to deal with during the story. Similarly, the student is faced with solving problems that may concern their character. On the basis of a plot prepared by the teacher, the students therefore become actors of a story that they themselves contribute to creating, also through choices made in problematic situations they progressively encounter and by interacting with their teammates.

The main objective is to allow, through a DIST-M (*Digital Interactive Storytelling in Mathematics),* for the active involvement of each student, who will have to think and act as a character in the story, having their own role, and taking on the emotional load that this condition entails. However, the whole group is the actor being in the narrative and in the mathematical challenges proposed. Each participant has a role and can make their own contribution; in fact, the student can be supported and is supposed to deal with peers, in a perspective that is not only inclusive, but also able to promote communication skills in mathematics. The study, whose first experiments were already presented

[1] This work is part of the project PRIN 2015 "Digital Interactive Storytelling in Mathematics: A Competence-based Social Approach", funded by MIUR, effective from 5 February 2017.

during TWG08 CERME11 conference (Albano et al., 2019), is based on a group of learners being engaged in a mathematical problem solving supported by an expert (Guru) who intervenes in the group discussion at various times, primarily when she feels the process is slowing or stops, acting as a motivator. So, through peer and expert interactions we attempt to answer the following two research questions: RQ1: How does an expert, that acts as a guide, a facilitator, know when to intervene in group learning? RQ2: What does feelings Guru's presence provoke in the students when they are playing in the digital story?

Starting from scholars such as Hannula (2002) and Cobb et al. (1989), who have investigated students' affect during problem solving-focused teaching experiments over a period of time, we mean to analyze the affective field in collaborative problems solving, such as digital storytelling, and how the affective field is addressed by the Guru's contribution.

Theoretical background

Most of the research on students' emotions in the field of mathematics education focuses on their role in mathematical problem solving activities (McLeod &Adams, 2012; DeBellis & Goldin, 2006). Indeed, mathematical problem solving activities also become fruitful ground for investigating the influence of affective factors in mathematical thinking processes (Gómez-Chacón, 2000; Pesonen & Hannula, 2014). In particular, DeBellis and Goldin (2006) talk about "*affective pathway"* as "established sequences of (local) states of feeling that interact with cognitive configurations" (p.134). They also underline the importance of meta-affect, defined as "affect about affect, affect about and within cognition about affect, and the individual's monitoring of affect through cognition" (p. 136). From a methodological point of view, the interplay between affect and cognition is quite a complex topic to be investigated. Such an interaction is far more present in problem solving situations where, given the nature of the same activity, students live experiences of impasse and construct new representations. In the context of problem solving activities, terms such as *engage* and *engagement* are used. In particular Goldin et al. (2011) refer to "engagement structure" as a tool for framing the analysis of the complex nature of affect, and particularly the interaction between individual and social aspects of students' problem-solving experiences in mathematics. In this kind of "framing" situation, affect, cognition and motivation interact to influence students' mathematical engagement in a social environment; the affective pathway is, therefore, one of the components of the structure. Goldin (2017) describes various examples of engagement structures (ES) constructed from observation. In this work we recall and adapt those that emerged from chat room discussions such as: *I'm Really Into This* (the desire to enter and maintain the experience of learning mathematics), *Help Me* (the desire to obtain help or support for solving a mathematical problem or understating mathematics). These ES relates the role mathematical affect has on ones' "doing" mathematics as a learner. Hence, our theoretical framework makes reference to Goldin's (2017) understanding of engagement while our approach is based on the use of collaborative scripts (King, 2007) that consider a sequence of Vygotskian activities (Vygotsky, 1980) embedded in a framework of digital storytelling. Eventually, the methodology involves the interaction among peers (Albano et al., 2019) on an e-learning platform (Moodle).

Methodology

The design of the activity

The macro-script of the story consists of five activities corresponding to stages of a mathematician's work during a problem-solving process (Boero, 1999). First we have an **Exploration** phase, where the problem is explored and first hypotheses of solution are proposed, followed by the **Conjecture** phase, devoted to refine the hypotheses (often in spoken language) to obtain a clear and complete conjecture. Third and subsequent phase is called **Formalization**, in which the "best" (or more promising) conjecture is translated into mathematical language; this represents an essential step to fully trigger the following phase, namely, the **Proof**, where all current mathematical knowledge is applied to prove (or confute) the mathematical conjecture. Finally, a **Reflection** phase, which allows mathematicians to possibly retrace the story from the mathematical point of view and produce a statement to be shared with the community. All these phases are translated and modeled with structured learning activities within a storytelling framework; each of them corresponding to an episode in the story. Along the above steps, various situations that a mathematician may face in solving a problem have also been identified: a) problem solvers observe the path for finding a solution; b) they take action to find a solving strategy; c) if they think they are failing or feel stuck, they try to reassure themselves in order to restart successfully; d) they try to find an insight or ask for help from an expert or from external sources (books, journals, etc.); e) they ask themselves whether the solution path is working or not; f) they look for evidence to justify their conjecture; g) in case they find something to be corrected, they give the new solution in the exact form. The sequence is not necessarily linear, and could be cyclical or could not include all of the situations mentioned above. However, in all these situations, we can identify an interaction among different forms of thought and discourse, which we have modeled as cooperation among characters.

The story and its characters

The key attitudes illustrated beforehand are "embodied" by 5 distinct characters (or roles) within our storytelling. Specifically, the characters will work as a team within the storytelling, each one contributing to a step: *Pest* keeps asking questions, trying to make everything clearer; *Blogger* records and shares all team's achievements in a written form; *Boss* keeps the group working and well-focused on the objective; *Promoter* suggests new ideas and searches for directions. In case of difficulty, the Promoter can ask the fifth character for helping them, *Guru* (an external expert, typically the teacher or a researcher) who, otherwise, would not be fully involved in the story. Guru intervenes during the interactions among the actors with the aim to let them clarify their comments and remarks or improve the communication. This type of personalized approach promotes first-person engagement within the story, while team working supports the social construction of (possibly new) shared knowledge. To sum up, we have a story, organized in 5 episodes, where students play as characters. They are given a proper role (which changes from one episode to the other) and specific actions to perform according to their role in the episode. Some tasks are individual, some other are collaborative and therefore require a good level of communication and coordination (students are not allowed to directly talk to each other). It is worth saying that students, based on our storytelling approach, do not "create" the story that they are playing (since by doing so it would be difficult to predict its directions and success).

The designed model allows to the students to participate in the story in two different ways. For each episode we have: 1) One group acts as Actors: each student in the group takes on the role of one of the characters described above; 2) The other groups act as active and aware Onlooker: each student takes charge of observing a specific character in the story and reflects on how the observed character behaves with respect to both the mathematical problem and the role she is playing.

The immersive aspect of DIST-M is strongly related to *I'm Really Into This* engagement structure: each student "comes into the story" as a character, as an Actor or as an Onlooker. Associated to *Help Me* engagement structure could be considered the role played by the teacher in the story (Guru), who will provide (explicitly or implicitly) for a variety of ways in which students' needs can be satisfied, overcoming the impasse responsible for disrupting the learning process. So, she embodies the role of "wisdom" and represents a source of knowledge for students to draw upon when needed. In order to allow each student to take part and play within the story, we arranged all students in teams of 4 members (one for each of the above characters). In unstructured collaborative problem solving, students often remain in the role in which they feel most comfortable. In the proposed model, however, both the groups of Actors and Observers rotate, as do the roles within each group. For example, if in the first episode a group played as Actors, in the second episode they will play as Observers and a group that played as Observers will play as Actors. Also, if a student played as Boss in the first episode, they will play as an Observer of a different role than Boss in the second episode. In this way, each student experiences (as Actor or Observer) all of the cognitive functions, and this can lead to ownership of those functions by each. The constant change of perspective, moving from Actor to Onlooker and from one role to another are intended to help internalize all the roles and phases (Vygotsky, 1980).

The chosen problem

The mathematical problem proposed concerned an algebraic regularity of four consecutive numbers (Mellone & Tortora, 2015) as follows: "*Choose four consecutive natural numbers, multiply the two intermediates, multiply the two extremes, and subtract the results. What do you get?"*

The problem was presented within the story in a more implicit way by means of some quadruplets and operations. Students were expected to explore the situation, to formulate conjectures, concluding that the result was always 2, and, thus, to prove it. At the end of the story we submitted a questionnaire to the students in order to investigate their feedback on the whole experience. In this work, we are interested in analyzing the students' feelings about Guru's involvement and the way they experienced her interventions in the discussion group. The interactions among peers try to give us an answer to RQ1; while through the answers that the students have given to a final questionnaire, we try to answer to RQ2. The sentences, considered in our analysis, are the students' answers to a specific question: "*Did you feel comfortable enough or would you have felt more comfortable if she had been closer in age to you, but still more experienced? To what extent? Justify your answer*".

The experimentation

The DIST-M was experimented with 26 first-year high school students. All students, enrolled in a Moodle course, were divided into groups of 4, or 5 if the total number of students was not a multiple of 4. Thus, we had four groups of four students and two groups of five students. In the case of groups of 5 students, the role that is duplicated is Pest (and Pest Onlooker) since this role is necessary to encourage the production of conjectures, arguments within the group, necessary to reach mathematical formalization and, therefore, the proof. The role of the expert, Guru in the story, was played jointly by a researcher together with the teacher. The flexibility of Moodle provided useful tools for both educational activities and social interactions. For instance, we used Chat rooms for all informal communication among students in the same group and as a privileged channel between the Promoter and Guru. Forums and Questionnaires, instead, were used in all formal communications between Actors and Guru. This shift, which mimics the transition from spoken to written language, was also intended to promote the transition to literate registers problem.

Data analysis and Results

In order to find an answer to the research questions and to investigate the affective factors (emotions, attitudes, interest) at stake in the interactions within the digital storytelling, we used both information extrapolated by the e-learning platform and data of the final questionnaire submitted at the end of the experimentation. In this regard, we looked at the transcriptions of the conversations extracted from the group chat room among all the characters and from the private chat room between Promoter and Guru. That provides us with information about possible interventions made by the Guru at various times of the group discussion, and primarily when she feels that the process is slowing or stops, acting, consequentially, as a motivator. Let us read excerpts of a Chat room discussion within Episode 2. In the first excerpt (lines 1-6) we can easily observe that Guru (named Gianmaria in the story) does not intervene during the discussion. He simply reads and observes, postponing her intervention to a later moment (line 7).

1	Promoter:	I told Gianmaria that we have found a formula
2	Pest:	I don’t think
3	Promoter:	He’s telling me that now
4	Promoter:	Eh…but I’m stuck
5	Promoter:	How should we proceed?
6	Blogger:	Let’s summarize: if we subtract the product of medium and of extremes of 4 consecutive numbers, the result is always 2
7	Gianmaria:	Fede, are you there?
8	Gianmaria:	Look, I have an app that can help you with words
9	Promoter:	A lot of useful words appear to explain the formula
10	Boss:	Yes
11	Promoter:	We have to reconstruct a theorem from those words

The students, starting from the discussion between Promoter and Guru, try to formulate the conjecture, showing some difficulties. Blogger (line 6) tries to summarize, but her attempt is not enough to overcome the impasse. Guru, then, observing the discussion, decides to activate the digital tile app so as to direct the students towards the construction of the conjecture. The intervention of the Guru (as confirmed also by teacher/expert of the class) has conducted to a reflection about her role: her facilitator function does’ not mean providing some specifics contents but guiding the students in the discovering of the solution. The role of facilitator was also recognized to the students, as some of their statements show:

41	Pest:	I think she is the most important character in the story.
42	Promoter:	I think Gianmaria was helpful in solving the puzzle because she was able to prop the guys up

43	Boss:	I think Gianmaria' s character was helpful and is a good character.
51	BLO1:	I think he was very helpful, since she has made us deepen our ideas.
52	BLO2:	She is very good. She helped us when the solution was not correct.
61	BO1:	She has been very good at removing doubts and making changes to the solution when necessary.
63	BO3:	She is very nagging, and it is lot of fun to answer her questions.
71	PO1:	Nice idea, but when she asks questions it feels like taking a real test; she should involve the characters more and make the questions simpler.
72	PO2:	I think that she is the main component of the story, although she could be a bit faster:)".
81	PRO1:	Thanks to her involvement we could engage with a person who knew more than us on the topic and was able to back us when we asked for help.
83	PRO3:	I think that sometimes Gianmaria asks too many questions, but that is acceptable since her job consists in finding the right solution.
84	PRO4:	Gianmaria is a character who helps solving the enigma by asking questions to the interlocutors to help them understand better.

However, there are also some expressions of disappointment regarding the role played by Guru: boredom expressions "*she should involve the characters more*" (line 71); or expressions that evoke mixed feelings: "*she could be a bit faster"* (line 72) in opposition to positive aspects: "*Nice idea*" (line 71); "*Nagging…and a lot of fun*" (line 63).

At the conclusion of our analysis, performed by crossing the conversation in the chat of the characters with Guru (lines 1-11) and the answers to the question of all students 'statements (lines 41-84), a first consideration concerns the fruitful participation of the students into the story: indeed, the lively conversation in all episodes, either among the peers or between peers and Guru, evokes the desire of the participants to feel immerged into the story. Next extracts from students' answers give us a perception of the students' feelings regarding the influence of the Guru in the story.

100	Pest:	Being in contact with your peers gives greater freedom and understanding of dialogue.
101	Promoter:	Speaking to a person closer to my age would make me feel more at ease; I think I would be able to speak more confidently and in a more relaxed way.
102	Boss:	In some cases, I found it difficult to express my views to Gianmaria.
103	BLO1:	It wouldn't have changed anything because I basically don't feel comfortable talking to people I don't know.
104	BLO2:	I get along great with people older than me, I enjoy talking to them and comparing notes.
108	PO2:	Because Gianmaria was nice and could make us feel at ease.
109	PO3:	Because an age gap doesn't have much effect on me.
110	PO4:	Her age doesn't change anything since she is behind a screen, anyway.
111	PRO1:	I believe that it would not have changed anything, even if she had been my age.
114	PRO4:	Because, anyway, a person who is closer in age to us knows better our way of thinking/reasoning.

We want underline as the full involvement of the students in the story has really motivated the student. Referring to specific words used by themselves with the teacher, they affirm "*I enjoyed mixing math with stories*"; so this put in result as being immersed in an interactive story has motivated the student, that is in line with the aim of the ES "*I'm Really Into*".

If we look at the affective pathways of the engagement structure "*Help me*" we can observe alternate feelings of confidence and discomfort in connection with the presence of Guru in the story. The mixed feelings regarding Guru's suggestions could be linked to critical thinking development.

Discussion

The findings lead us to define, a posteriori, some possible categories that will explored in some future works:

Category 1*- confidence vs development of critical thinking.* The expressions used by the students in their interviews, such as "*I get along great with people older than me*" (line 104); *"Gianmaria was nice"* (line 108); "*an age gap doesn't have much effect on me"* (line 109); "*her age doesn't change anything*" (line 110) induce us to suppose that these students are not embarrassed by the presence of an expert. So, they probably recognize also the added value that the Guru's presence, in their interactions, could give to the cognitive aspects. The interactions among them and with Guru could generate new knowledge in a collaborative and individual manner and, for consequence, to develop argumentative competences. Moreover, the use of digital in the learning can go in the same direction; indeed, the used expression by a student "*behind a screen*" (line110) leads to thinking about how the use of digital in learning contexts can foster the development of knowledge.

Category 2- *anxiety vs use of communicative registers.* The expressions used by the students in their interviews, such as "*greater freedom"* (line 100);*" more confidently and in a more relaxed way"* (line 101); "*I found it difficult to express my views to Gianmaria"* (line 102) highlight linguistic difficulties in interacting with Guru, and, therefore, a need to use literate registers. For this kinds of the students the presence of an adult, in the chat among peers or in a Forum session, provokes feelings of anxiety, embarrassment, as also remarked in the line 114 "*a person who is closer in age to us knows better our way of thinking/reasoning*". Probably, these students perceive the difficulty of using difference communicative register. It is clear that communication is influenced by context: the context of the situation, i.e., space, time, the participants as individuals, the context of the culture, which concerns the beliefs and knowledge about the participants and the topics of communication (Ferrari, 2021).

Category 3- *indifference vs passive learning.* Few students express feelings of indifference respect to the new situation. The expressions used by the students in their interviews, such as "*I basically don't feel comfortable talking to people I don't know"* (line 103);*" I believe that it would not have changed anything, even if she had been my age."* (line 111) underline a poor interaction with the peers and Guru. However, this type of feedback is also useful because it allows the teacher to detect errors and misconceptions in a timely manner, to be taken up and discussed later, outside the activities of the story.

Acknowledgment

We would like to thank the teacher and all her students who participated in the experimentation.

Dual processes and cognitive reflection in mathematics reasoning and archievement

Introduction

Mathematics problem solving is a complex cognitive task that requires solvers to activate their mathematical knowledge, cognitive and metacognitive abilities, as well as their positive math related beliefs. The present study addresses the relationship that reasoning abilities and math beliefs system have with problem-solving efficacy and academic achievement in Mathematics, focusing not only on problem solving accuracy but also on cognitive reflection and math beliefs measures. Secondly, we tested the predictive capacity of these variables on Mathematics achievement in secondary school students.

Different theoretical approaches have been proposed to explain mathematical reasoning. Among them, this study is based on the dual-processes theories of thinking and reasoning (e.g., Evans & Stanovich, 2013). These theories assume two types of thinking processes: (a) Type 1 thinking is fast, guided by data, intuitive and believe based; and (b) Type 2 thinking is relatively slow and reflective, guided by will and conscience.

The balance between intuitions and conscious reflection on the mathematical reasoning is key. The Type 2 thinking is particularly relevant in problem solving when problems combine complexity with novelty and require explicit conscious, effortful reasoning to solve, whereas people have to detach or disregard what they already believe. In this line, Cognitive Reflection Test (CRT; Frederick, 2005) constitutes a mathematical instrument that evidences the propensity to be reflective, to think analytically despite having what initially appears to be a suitable response.

Dual process theories have associated Type I processes with various kinds of cognitive bias. For the purposes of this research, the effects of beliefs based biases on reasoning are particularly relevant in the field of mathematical learning and problem solving (see, e.g., Gómez-Chacón et. al, 2014; Stavy & Tirosh, 2000). Particularly, we consider the role of students' math related beliefs (e.g., beliefs about learning and solving math problems, maths self-efficacy) in problem solving performance that requires analytic reasoning processes.

Research study

Hypoteses

We argue that cognitive reflection and maths related beliefs are involved in mathematical problem solving students commonly face at school and, at the same time, underlie academic achievement in Mathematics. Accordingly, we hypothesized that 1) measures of cognitive reflection and beliefs should correlate with measures of problem solving accuracy, and that all these measures should correlate positively with Mathematics academic achievement; and 2) we expected that those three variables should show evidence as predictive measures of mathematics achievement.

Method

The study involved 121 students attending the 2nd grade of secondary school (age 13-14), each of whom performed three testing instruments, corresponding to the three aspects of this study: (1) Cognitive reflection Test (CRT); (2) Mathematics-Related Beliefs Questionnaire (CreeMat; adapted and validated by Gómez-Chacón et al., 2014); (3) Math problem-solving task (MPST).

The CRT assess cognitive reflection processes in the context of problem-solving tasks. We measured percentages of correct and superficial/intuitive answers in CRT. The MPST evaluates participant´s ability to solve math problems that require analytic thinking. It was also measured a students´ estimation of self-perceived task difficulty. Concerning the CreeMat, several measures were considered: students' beliefs about mathematics, beliefs about learning and solving math problems, and students' beliefs about oneself. Academic achievement was assessed by student´s grades in Mathematics.

Results and Conclusions

Results in both cognitive reflection and mathematical problem solving tests showed a greater number of superficial responses than correct solutions (CRT: $t(120)=6.88$, $p<.001$; and MPST $t(120)=6.95$, $p<.001$). Considering the metacognitive component of CRT, participants underestimated the difficulty of the problems ($r= -.18$, $p<.05$). As expected, we found a pattern of correlations between the cognitive reflection, math beliefs and math problem solving measures are significant, corroborating previous findings (Gómez-Chacón et al., 2014). Regression analyses showed the specific roles played by CRT and self-efficacy on the mathematical achievement ($r=.21$, $p<0.01$).

Findings indicate Type I thinking processes are more commonly used than Type 2 thinking by students (Evans & Stanovich, 2013). The results confirmed the association of students´ reasoning processes, as measured by CRT, with problem-solving processes efficiency and, ultimately, with mathematical achievement at secondary school. They also indicate that the metacognitive processes are not efficient enough at this stage of development.

Strategy-based motivation to use the drawing strategy. The relationships between self-efficacy, value, cost, and gender

Stanislaw Schukajlow[1] and Johanna Rellensmann[2]

[1]University of Münster, Germany; schukajlow@uni-muenster.de

[2]University of Münster, Germany; johanna.rellensmann@uni-muenster.de

Motivation and strategies are important for students' learning. In this contribution, we investigated the motivation to use the learner-generated drawing strategy. On the basis of expectancy-value theory, we analyzed the relationships between three components of strategy-based motivation (self-efficacy, value, and cost) and gender differences in these three components of motivation. To address research questions and test hypotheses, we re-analyzed the data from a prior study (N = 402) that assessed low-secondary school students' motivation at two measurement points. Results indicate (1) a positive relationship between self-efficacy and value and a negative relationship between self-efficacy and cost and (2) lower self-efficacy and a higher value given to the drawing strategy in female students. One important implication is that gender differences should be taken into account in strategy-based motivation in research and practice.

Introduction

Motivation is a central construct in theories of affect (Hannula, 2011). In a broader sense, motivation comprises reasons for human behavior (Middleton & Spanias, 1999). One of the most influential motivational theories in the area of educational psychology and education is the expectancy-value theory of achievement choice (Eccles & Wigfield, 2020). According to expectancy-value theory, expectations of success (including self-efficacy expectations), task value, and personal costs are crucial for achievement-related outcomes. Following the idea that affect can address different objects (Schukajlow et al., 2017), we address the concept of strategy-based motivation (SBM) in this contribution. SBM is motivation that derives from characteristics of strategies and their use. The strategy we chose for this study is the learner-generated drawing strategy, which has repeatedly been demonstrated to be very important for problem solving in mathematics (Hembree, 1992). The drawing strategy has specific importance for solving problems that require the construction of mathematical models that rely on the spatial structure of the problem, such as geometrical modelling problems (Rellensmann et al., 2017). Further, we were interested in gender differences in SBM. To the best of our knowledge, prior research has not addressed the relationships between the components of SBM, and we do not know much about how female and male students differ in SBM. The aims of this study were to analyze the relationships between self-efficacy, task value, and cost regarding the drawing strategy and to analyze gender differences in students' SBM to use the drawing strategy. To collect indications of the stability of our findings, we collected and analyzed data at two time points that served as pretest (T1) and posttest (T2) in the original study to uncover the effects of the strategy training on students' performance.

Strategy-based motivation and gender

Expectancy-value theory

Initial intentions in the development of control-value theory were to integrate findings from motivational theories and to clarify why women make different educational choices than men and rarely study STEM subjects (Eccles & Wigfield, 2020). Expectancy-value theory proposes that students' subjective beliefs are important for career choices, interest, performance, and strategy use. Expectancies are defined as beliefs about one's ability to perform an activity (here, making a drawing), and they are related to the self-efficacy expectations proposed by Bandura (2003) in social-cognitive theory. In the case of the drawing strategy, students with high expectations give a positive answer to the question "Can I make a drawing?" Task value is another component in expectancy-value theory. If students value a strategy, they will use this strategy more often. Students who value the drawing strategy give a positive answer to the question "Do I value making a drawing?" Three types of values are attainment value, intrinsic/interest value, and extrinsic/utility value. Attainment value implies that an activity (e.g., making a drawing to solve a problem) is part of an individual's personal identity. Interest value implies the feeling of enjoyment that is associated with performing an activity (e.g., enjoyment in making a drawing). Utility value refers to the students' view that an activity can help them achieve their goals (e.g., applying the drawing strategy will help them solve a problem). Personal cost is another component of motivation. Cost includes the amount of time and effort that a person will invest in an activity. Students who ascribe low cost to the drawing strategy give a positive answer to the question: "Am I free of blockages that prevent me from investing time and effort into making a drawing?" Originally, cost was suggested as part of value. There has recently been a discussion about whether cost should be a component that is distinct from task value and expectations on a theoretical and an empirical level (Eccles & Wigfield, 2020).

Expectancies, value, and cost were found to predict learning outcomes, such as educational choices and academic achievement in mathematics (Eccles & Wigfield, 2020). In our recent study, we found that self-efficacy expectations and cost with respect to the drawing strategy affected the quality of drawings and performance in solving geometry modelling problems (Schukajlow et al., 2021).

Relationships between components of motivation

Since the later eighties, researchers have intensively discussed whether the components of motivation in expectancy-value theory can be empirically separated from each other and can be assessed as distinct constructs. They found that even first-graders differentiate between expectancies and task values, and this distinction persists for school and university students (see an overview in Eccles & Wigfield, 2020). Although the magnitudes of the relationships between self-efficacy, value, and cost are related to the question of whether distinct assessments of these components are possible, these relationships have not yet been the focus of research and need further elaboration with respect to the objects of interest targeted in motivational constructs. In the case of the drawing strategy, one open question is whether students who believe they are able to make a drawing also value this strategy and assign lower costs to this strategy than students who are not sure about whether they can apply this strategy while solving a problem.

It is plausible to assume that students who value an activity are likely to engage in this activity, to gain higher proficiency in doing this activity, and to consequently report higher self-efficacy regarding the respective activity. Further, self-efficacy might be related to cost, as students who ascribe low cost to an activity may engage in the activity more often, may be more successful in this activity, and may improve their expectations. Expectancy-value theory posits what factors can affect students' task value and cost. For example, students' interpretations of their prior experiences (which are related to self-efficacy) influence their affective reactions (e.g., enjoyment and pleasure), which in turn affect task value and cost. A positive relationship between the value and cost components results from their close relationship in expectancy-value theory. Eccles and Wigfield (2020) argued that the overall value of a task depends on its costs. If students think that an activity is too time consuming and too difficult, the value of this activity decreases. For example, if a student assumes that making a drawing is not worth the time, he or she might value making drawing less than a student who ascribes low cost to the drawing strategy. Most studies have reported significant relationships between the three components of motivation. The relationship between expectations and the intrinsic value of mathematics ranged widely between .36 and .68 for students in Grades 1 to 9 in the United States (Gaspard et al., 2020). In a study of adolescent students in mathematics in Korea, cost was negatively related to expectancies (-.24) and to task value (-.23) (Jiang et al., 2018).

Gender differences in self-efficacy, value, and cost

Gender differences were one of the main starting points for the development of expectancy-value theory. According to this theory, gender differences in choices in STEM subjects can be explained by differences in expectancies and values and go back to gender stereotypes in society. Indeed, an analysis of public views in many countries confirmed inequities in expectations and achievement in mathematics between female and male students (Forgasz & Leder, 2017). Such inequities were in turn found to increase self-efficacy expectations in male students and to decrease them in female students. Consequently, there are well-documented differences between female and male students in self-efficacy in mathematics across many countries all over the world (Else-Quest et al., 2010). According to expectancy-value theory, students value activities and tasks that correspond to their social and personal identities (Eccles & Wigfield, 2020). By engaging in these tasks, students can express themselves. Given that mathematics is seen as a male domain in many societies, many female students do not see mathematics as part of their identity, and they value mathematics less than male students do. As a result, many students demonstrate a gender gap in expectancies and value. In PISA 2012, female students reported lower self-efficacy and lower interest in mathematics than male students in Germany (Cohen's d of 0.53 and 0.39 in Schiepe-Tiska & Schmidtner, 2012). However, we do not know the extent to which self-efficacy, value, and cost with respect to strategy use might differ between female and male students. As making a drawing to solve modelling problems is part of the solution process, one can have lower expectations for female students. A gender difference in anxiety with respect to strategy use supports this expectation (Schukajlow et al., 2019). For differences in value and cost, we do not have specific expectations. It might be possible that female and male students value the use of the drawing strategy to a similar extent and assign a similar level of cost to this activity while solving mathematical problems.

Research questions and hypotheses

On the basis of expectance-value theory and prior research, we investigated the following research questions in this study:

RQ1: Are the components of strategy-based motivation (self-efficacy, task value, and cost) related to each other with respect to the drawing strategy?

H1: Self-efficacy will be positively related to task value and self-efficacy and task value will be negatively related to cost.

RQ2: Do female and male students differ in self-efficacy, task value, and cost with respect to the drawing strategy?

H2: Female students will have lower self-efficacy for the drawing strategy than male students, but no clear expectations in gender differences regarding value and cost could be derived from prior research.

Method

Present study, sample, and procedure

To address the research questions and test the hypotheses, we reanalyzed a sample collected in the framework of the Visualizations While Solving Modelling Problems project. This project is aimed at clarifying the role of learner-generated visualizations in solving modelling problems, including the effects of motivation and emotions on strategy use, quality of drawings, and performance. In one of the studies, students ($N = 435$; 6 middle-track schools) in each class were assigned to one of four groups. Three groups were trained in knowledge about the drawing strategy, whereas one group practiced algebraic procedures (e.g., solving equations). A prior analysis indicated indirect positive effects of the strategy training on performance with strategic knowledge about drawing and quality of drawings as intervening variables (Rellensmann et al., 2021). Before (T1) and after (T2) the training sessions, students filled out a questionnaire on self-efficacy, task value, and cost, among other tests. At T1, they reported their gender. At T2, some students were missing, or students did not answer all the scales on the questionnaire. Thus, the overall sample included 402 students (46% female; 14.6 years of age) from all four treatment groups.

Scales on self-efficacy, value, and cost

We used 5-point scales on self-efficacy, value, and cost with respect to the drawing strategy ranging from 1 (*not at all true*) to 5 (*completely true*). We adapted the items for this study from a prior study on motivation and learning strategies in mathematics (Berger & Karabenick, 2011) by focusing the items on learner-generated drawings while solving difficult word problems (Schukajlow et al., 2021). Self-efficacy regarding the drawing strategy was assessed with three items (e.g., "I'm confident I can make a very good drawing to solve any word problem"; Cronbach's $\alpha = .79$). Task value was assessed via interest value (2 items; e.g., "I like making drawings to solve difficult word problems"), attainment value (4 items, e.g., "making a drawing to solve difficult word problems is an important part of who I am"), and utility value (3 items, e.g., "I believe that it is important to make a drawing because drawings help me solve difficult word problems"). Cronbach's α for the task value scale was good ($\alpha = .88$). Personal cost was assessed with three items (e.g., “It takes a lot of effort for me to create a drawing to solve a difficult word problem”; α = .70). A confirmatory factor analysis confirmed the structural validity of the motivation to use the drawing strategy scale (Schukajlow et al., 2021).

Results

Relationships between self-efficacy, task value, and cost

Our first research question addressed the relationships between the three components of motivation: self-efficacy expectations, value, and cost. To address the first research question, we calculated Pearson correlations. In line with our expectations, the analysis revealed a positive relationship between self-efficacy and value with respect to the drawing strategy at T1 (.394) and T2 (.482; *p*s < .001). We also found a negative relationship between self-efficacy and cost with respect to the drawing strategy at T1 (-.386) and T2 (-.154; *p*s < .001) as expected in our study. Value and cost with respect to the drawing strategy were negatively related at T1 (-.141; $p < .01$) and the two motivational variables were not related at T2 (.027; p = 573). These results partly confirmed our expectations.

Gender differences between self-efficacy, task value, and cost

We applied an ANOVA with the factor gender and the dependent variables self-efficacy, value, and cost to address RQ2 on gender differences in SBM (see the descriptive statistics in Table 1).

Table 1: Means and standard deviations for self-efficacy, value, and cost at T1 and T2

	Self-efficacy		Value		Cost	
	T1: *M(SD)*	T2: *M(SD)*	T1: *M(SD)*	T2: *M(SD)*	T1: *M(SD)*	T2: *M(SD)*
female	2.94(.77)	3.15(.90)	3.31(.75)	3.34(.75)	2.64(.87)	2.83(.94)
male	3.17(.85)	3.30(.82)	2.96(.79)	3.12(.76)	2.57(.90)	2.82(.91)

At T1, the ANOVA revealed overall differences between female and male students regarding SBM, $F(3, 432) = 18.319, p < .001, \eta^2 = .113$. Similarly, at T2, the ANOVA showed differences in SBM regarding drawings between female and male students, $F(3, 401) = 7.772, p < .001, \eta^2 = .055$. A post hoc analysis confirmed our expectations about low self-efficacy in the use of the drawing strategy in female students compared with male students at T1 and T2; T1: $F(df = 1) = 8.836, p < .01, \eta^2 = .020$; T2: $F(df = 1) = 2.287, p = .078, \eta^2 = .008$. Moreover, female students assigned a higher value to the drawing strategy than male students at T1, $F(df = 1) = 8.836, p < .01, \eta^2 = .020$. At T2, the value of the drawing strategy tended to be higher in female students; T2: $\mathrm{F}(df = 1) = 2.287, p = .078, \eta^2 = .008$. The cost of the drawing strategy did not differ between female and male students; T1: $F(df = 1) = .733, p = .392, \eta^2 = .002$; T2: $F(df = 1) = 2.287, p = .851, \eta^2 < .001$.

Discussion

The aim of the present study was to analyze the relationships between three motivational components (i.e., self-efficacy, value, and cost) and to examine the gender gap in motivation.

The theoretical basis of our study came from the expectancy-value theory of achievement choices (Eccles & Wigfield, 2020). We followed the theory about the importance of the object for the investigation of effects (Schukajlow et al., 2017) and addressed SBM in our research. As a strategy, we selected learner-generated drawings, which were found to be beneficial for solving geometry modelling problems in prior studies (e.g. Rellensmann et al., 2017).

We found that self-efficacy was positively related to value and negatively related to cost at two time points. This finding indicates that students who demonstrate higher self-efficacy with respect to the use of the drawing strategy value this strategy and assign it a low cost. Our result is in line with the assumptions of expectancy-value theory about the relationship between expectancy and value beliefs and indicates the possibility of a feedback loop between expectancies on the one side and value and cost on the other side. The mechanism behind the relationship between self-efficacy and value should be investigated in future studies. One way this mechanism might work is that value increases students' engagement, and engagement positively affects performance, which in turn affects self-efficacy. Similarly, students who assign a low cost to a task are more engaged in doing this task, improve their performance, and increase their expectations of doing well when performing this task in the future. This relationship was stable across the two time points. This finding indicates stability in self-efficacy's relationship to value and cost. Cost was negatively related to value at T1, but it was not related to value at T2. This result is partly in line with our expectations. Moreover, cost's relationships with self-efficacy and value were weak at T1. Indeed, the relationship between cost and value was also weak in a prior study (Jiang et al., 2018). Along with other findings, our finding indicates that cost should be addressed as a distinct component in future studies. This is important because self-efficacy and cost have been shown to affect the quality of the drawing strategy and performance in solving modelling problems (Schukajlow et al., 2021). Another important result is that the relationships between cost and the two other components of motivation were slightly weaker at T2, and the relationship between cost and value was not even significant, which might be an indication that motivation to use the drawing strategy is not very stable. Solving problems that require the application of the drawing strategy might change students' perceptions of the cost of this strategy, which in turn might influence the relationships between cost and the two other components of the SBM. Our findings add to prior research on the relationships between the components of motivation (Gaspard et al., 2020; Jiang et al., 2018). Moreover, a new theoretical contribution of this study is that it expands the predictions of expectancy-value theory to SBM. Addressing the motivation to use the drawing strategy and investigating relationships between the three components of motivation are novel contributions of this study and, to the best of our knowledge, have not been made before.

Our analysis of gender differences in SBM revealed overall differences between female and male students at two time points. Female students reported lower self-efficacy expectations compared with male students at both T1 and T2. These differences are in line with prior findings on female students' low self-efficacy expectations regarding mathematics and confirm the existence of a gender gap (Schiepe-Tiska & Schmidtner, 2012). Interestingly, female students tend to value the use of the drawing strategy for solving modelling problems more than male students. This result was significant at T1, and the difference just missed the significance level at T2. A higher valuing of the drawing strategy in female students was unexpected because prior research has revealed that female students often value mathematics less than male students do. Consequently, gender stereotypes are not transmitted to all problem-solving activities in mathematics, and this is an important theoretical contribution of our study. One explanation might be that doing mathematics in school and in society might be more strongly associated with calculations or numbers and less with drawing activities. An open question with possible practical implications is whether focusing on strategies in mathematics classes and offering a more complex image of mathematics in society—one that goes beyond calculations or working with numbers—can contribute to changing gender stereotypes and can decrease the gender gap. The cost of applying the drawing strategy did not reveal any gender differences in SBM. Summarizing our results regarding SBM, we see a mixed picture: Female students have lower self-efficacy expectations and place a higher value on the drawing strategy than male students, whereas female and male students ascribe similar costs to the drawing strategy. An important practical implication of our study is that it uncovered different ways in which female and male students' SBM can be supported in mathematics classrooms. To increase female students' SBM, teachers should pay more attention to self-efficacy regarding strategy use (e.g., by giving positive feedback on the quality of students' drawings), whereas male students might benefit more if teachers emphasize the value of a strategy (e.g., by emphasizing the positive effects of using drawings to solve geometrical problems.)

Acknowledgments

The study was funded by the German Research Foundation [SSCHU 2629/3-1] and the Swiss National Science Foundation [100019E-164816/1]. We thank Judith Blomberg and several student assistants for their help in organizing and carrying out the study.

Self-evaluation is considered one of the key concepts when trying to understand motivation, and it is gaining more interest especially when looking at the age span 15-18 years. Previous studies in self-evaluation and mathematics tend to use data from international large scales assessments, arriving with rather ambiguous conclusions, and smaller studies tend to use only one measure without control factors. The aim of this paper was to test the hypothesis that boys are more confident than girls in mathematics, while using Swedish as a control subject. A questionnaire was handed out to 399 upper secondary school students from different regions in Sweden, both vocational programmes and programmes preparing for further studies. Using both non-parametric analysis and linear regression, the results support the hypothesis. The relationship to the idea of confidence gap is discussed.

Keywords: Gender, mathematics, self evaluation, upper secondary school.

Introduction

One of the key concepts in affect in general and motivation in particular is self-evaluation (Nagy et al., 2010; Pajares, 2005). It contributes to perceived self-efficacy (Bandura, 1997), and can be seen as students' self-perceptions of their competence or ability. Previous studies have concluded that students base their mathematics self-concept largely on their experiences and history of achievement (Usher, 2009), and sex differences in grades cannot explain the gendering of career choices (Dekhtyar et al., 2018). In addition, meta-studies have concluded that girls most often have higher grades than boys, with the largest difference in language and smallest difference in mathematics (e.g. Voyer & Voyer, 2014), meaning that differences in self-concept most likely are not only due to grades. On a micro-level, self-evaluation as a concept is relevant since studies indicate that when students are asked to self-evaluate their capabilities or progress in learning a particular task, it encourages them to develop a higher level of competence and their self-efficacy beliefs are strengthened (Ramdass & Zimmerman, 2008). On a macro-level, some gender patterns have been identified where the overall conclusion is that boys tend to report higher levels in measures of self-evaluation (OECD, 2013), but studies also report that gender differences in mathematics self-concept are smaller in more egalitarian countries (Goldman & Penner, 2016), and that students' mathematical self-concept was strongly linked to their mathematical achievement, and that students that have low scores were the ones who overestimated their mathematical competence (Chiu & Klassen, 2010). It appears to be no unified picture how gender, mathematics, and self-evaluation is connected. The specific age span (15-18 years) is also of interest since this is when children/ adolescents are developing their academic self-perception, something that is gaining more attention especially with respect to gender differences

(Nagy et al., 2010). One interesting case is Sweden, a country with a reputation of its gender equality: Sweden is a country that is both wealthy and egalitarian, and a possible conclusion is that students should either have little gender differences and indicate low self-concepts (e.g. Goldman & Penner, 2016), or close connections with self-concept and achievement (e.g. Chiu & Klassen, 2010). Previous research signal mixed finding (e.g. Frid et al., 2021; Sumpter, 2012), including indications of gender confidence gap (e.g. Zander et al., 2020). This paper aims to look closer at upper secondary school students' self-evaluation in mathematics with respect to grades. We test the hypothesis that boys are more confident than girls in mathematics, a hypothesis that functions as the research question.

Background

The starting point for the overview of the concept self-evaluation here is Festinger's (1954) theory of social comparison processes, where the focus is on social standards with the conclusion that there are no objective standards. The focus then was mainly on interpersonal comparisons, which was extended to include intergroup comparisons (Tajfel, 1974), that group membership provides a basis for self-evaluation. Other concepts describing similar aspects are self-concept (Shavelson, et al., 1976), and self-beliefs specific to one's perceived capability which includes, for instance, task-specific self-concept, self-concept of ability, and academic self-concept (Pajares, 2005). Here, the focus will be on self-evaluation, emphasising the process of evaluation: "the evaluation or judgment of 'the worth' of one's performance" (Klenowski, 1995, p. 146). Looking at gender, the chosen theoretical stance is that gender is a social construction, more than just a consequence of a biological sex (Connell, 2006). It means that gender is a pattern of social relations, which means that definitions of women and men depend on the context and under constant negotiation. In order to understand these patterns, one can divide gender into four different aspects: structural, symbolic, personal, and interactional gender (Bjerrum Nielsen, 2003). Structural gender covers social structures, and symbolic gender focus on the gender as attributed symbols and discourse. The symbols could be attributed in both ways. It can be that an object or an abstract concept that is considered male or female, such as the idea of mathematics as a male domain (e.g. Brandell & Staberg, 2008). It could also be about how men and women are perceived such as the 'the hard working female' and 'the male genius' (Leslie et al. 2015). Such symbols inform us what is considered normal and what is deviant (Bjerrum Nielsen, 2003). The third aspect, personal gender, focuses on how the individuals perceive the structure and the different symbols, which includes self-evaluations. The fourth aspect, interactional gender, covers interactions of individuals that take place within this context that comprises the structure and symbols.

Regarding the process of determine one's value, studies have shown that students are using multiple frames of reference when evaluating their mathematics ability and these self-evaluations are pretty robust (Skaalvik & Skaalvik, 2004a). Self-evaluations that were made using other students in class as an external frame of reference, and on comparison of mathematics achievement with achievement in other school subjects which function as an internal frame of reference, were both strong predictors to mathematics self-concept and self-efficacy. This implies that when studying self-evaluation in one subject, such as mathematics, using other school subjects as well calibrates the evaluations. Recent studies have shown that social economic status can play a role (e.g. McConney & Perry, 2010), but due to space the focus here is on gender. When following students from grade 7 and onwards, in the beginning boys expressed more positive self-concept and these differences persisted over time (Nagy et al., 2010). Studies on older students reported similar results (e.g. Skaalvik & Skaalvik, 2004a). Others confirm the gender confidence gap: despite having higher or similar grades, girls reported lower self-evaluation/ self-efficacy and self-esteem in mathematics (Brandell & Staberg, 2008; Sumpter, 2012; Zander et al., 2020), but there is also indication that there is no significant difference looking at students (age 15) at lower secondary school (Frid et al., 2021). Further, when comparing mathematics with language, studies has indicated that male students, with respect to mathematics, signalled not only higher self- concept, intrinsic motivation, and self-enhancing ego orientation but also higher performance expectations compared to the female students (Skaalvik & Skaalvik, 2004b). However, when the focus was on language, women expressed higher intrinsic motivation.

Methods

The data was generated through an online questionnaire that was part of a study of upper secondary school students and their work with a mathematical model exploring segregation (see Tsvetkova et al. (2016) for more information of the full study). In the study, a questionnaire was included with questions such as "How would you evaluate yourself in mathematics?" and a control question using an equally important subject, Swedish. The scale was Very good/Good/ Average/ Below average/ Weak, the same scale as in previous research allowing us to make comparisons (e.g. Brandell & Staberg, 2008; Frid et al., 2021). There was also a question about which grade they got in mathematics and Swedish in their latest course. There were also questions about factors related to their social economic status such as what their parents worked with and if they were planning to go to university. These questions are not analysed in the present study. In total, 399 participants (233 boys, 166 girls) from 20 upper secondary school classes were part of the study. The classes came from three different regions in Sweden (east, middle and west), covering all three grades meaning the age span was 16-19. Each class had between 13 to 25 students and they came from different educational programmes, both vocational ones and programmes preparing for university studies. The data were analysed in two stages. In the first stage we adopted a non-parametric approach, looking at the difference in proportion of combined answers to the two questions. For each self- grade, we calculated the proportion of girls and the proportion of boys who gave each of the five possible answers to the "How would you evaluate yourself in mathematics?" question. We then took the difference and expected a strong correlation between self-reported grades and self-evaluation, and by looking at differences within each grade division we could visualise differences for each grade independently. In the second stage, the data were analysed using linear regression to predict self-evaluation from self-reported grades, stated gender, and whether one parent (or more) was born in Sweden. In order to perform the regression, we converted both the self-reported grades and the self-evaluations to a numerical scale. Such a transformation is never entirely justifiable (hence the first stage of the analysis) but they can be seen as reasonable given the nature of the grade scale and self-reporting. Again, we expected that self-evaluation to be correlated with self-reported grades, so we included the variable in order to see how much additional predictive power gender has over and above this relationship. The background of parent was included as a control variable, allowing us to see whether one factor linked to social economic status could play a role (e.g. McConney & Perry).

Results

The first results are about the responses about students' stated grades in mathematics and Swedish, see Table 1:

Table 1: Distribution of stated grades in mathematics and Swedish, n(%)

Subject/ Grade	A	B	C	D	E/F	No reply	Total
Mathematics	79 (19.8)	73 (18.3)	100 (25.1)	72 (18.0)	57(14.3)/ 8(2.0)	10 (2.5)	399
Boys	43 (18.5)	39 (16.7)	53 (22.7)	47 (20.2)	43 (18.4)		233
Girls	36 (21.7)	34 (20.5)	47 (28.3)	25 (15.1)	22 (13.2)		166
Swedish	92 (23.1)	123 (30.8)	115 (28.8)	34 (8.5)	20(5.0)/ 1(0.3)	14 (3.5)	399
Boys	37 (15.9)	64 (27.5)	80 (34.3)	24 (10.3)	18 (7.7)		233
Girls	55 (33.1)	59 (35.5)	35 (21.1)	10 (6.0)	3 (1.8)		166

In Table 1, Grade E and F is joined since so few students reported F. Girls report higher grades both in mathematics and in Swedish. The distribution of the self- evaluation was the following (Table 2):

Table 2: Distribution of self-evaluation with respect to gender, n(%)

Subject/ Self-evaluation	Excellent	Good	Average	Below average	Weak	No reply	Total
Mathematics	60 (15.0)	134 (33.6)	147 (36.8)	36 (9.8)	12 (3.0)	10 (2.5)	399
Boys	39 (16.7)	75 (32.2)	84 (36.1)	20 (8.6)	7 (3.0)		233
Girls	21 (12.7)	59 (35.5)	63 (37.9)	16 (9.6)	5 (3.0)		166
Swedish	85 (21.3)	165 (41.3)	116 (39.1)	15 (3.8)	4 (1.0)	14 (3.5)	399
Boys	38 (16.3)	95 (40.8)	75 (32.2)	13 (5.6)	2 (0.8)		233
Girls	47 (28.3)	70 (42.1)	41 (24.7)	2 (1.2)	2 (1.2)		166

Table 2 illustrates that boys tend to rank themselves higher compared to girls in Mathematics, but vice versa in Swedish. To analyse the different distribution presented in Table 2, which is only descriptive, we looked at students' self-evaluation in mathematics and stated grades in relation to expressed gender. As a calibration of the results, Swedish is used as a comparison. The results are from the calculation of the proportion of girls and boys evaluating in each category for each grade, then taking the difference. The darker blue colour indicates a more common answer by boys, whereas a darker red colour means a more common answer by girls, see Figure 1:

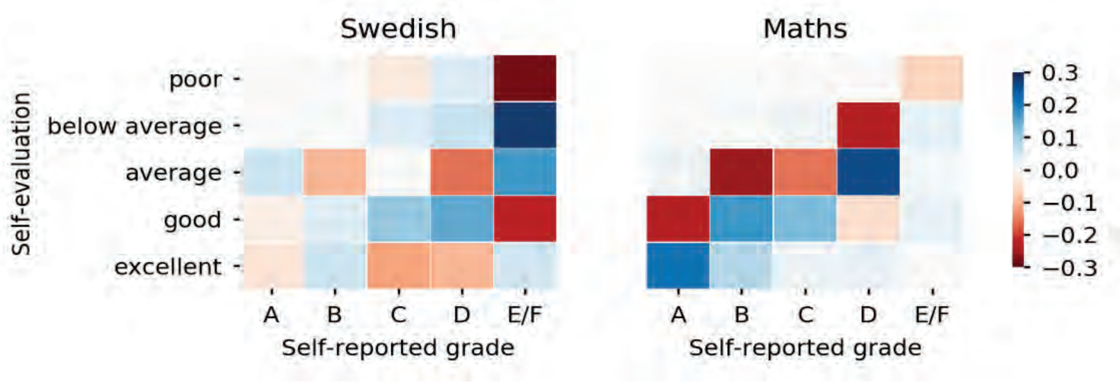

Figure 1: Difference in proportion of boys minus girls' self-evaluations for each self-reported grade

Figure 1 shows how the difference in self-evaluation between boys and girls depended on grade for both Swedish and Mathematics. For mathematics, we see that girls with a self-reported grade 'A' were more likely to rank themselves as 'good' than boys, while boys were more likely to rank themselves as 'excellent' than girls. Similarly, boys with a self-reported D were more likely to report themselves as 'average' than girls. The same pattern was repeated over all grades except E/F. In Swedish, the control factor, no such pattern was observed, with the possible exception of the self-reported grade 'E/F', where boys took 'below average' and girls took 'weak'. Based on this analysis, the conclusion is that girls under-valued themselves or boys over-valued themselves. The limitations are the small numbers, and therefore the next step is to validate these results using linear regression:

Table 3: Titles of tables, figures, diagrams, are in the style FigTitle, no dot at the end

Mathematics: Self-evaluation	Coefficient	Std. Error	t	*p*
Reported grade	0.512	0.031	16.20	< 0.001
Male	0.206	0.059	3.50	0.002
Swedish parent	-0.030	0.105	-0.28	0.782
Constant	1.83	0.127	14.32	< 0.001
Swedish: Self-evaluation				
Reported grade	0.454	0.045	10.04	< 0.001
Male	-0.015	0.076	-0.19	0.848
Swedish parent	-0.016	0.076	-0.20	0.841
Constant	2.20	0.210	10.47	< 0.001

The linear regression, Table 3, showed a strong relationship between self-reported grades and self-reported confidence in both mathematics ($t = 16.20$; $p < 0.0005$) and Swedish ($t = 10.04$; $p < 0.0005$). This reflects the correlation we see in Figure 1, model R-squared of 0.520. Only in mathematics did the 'boys' factor statistically significant in predicting self-reported grades ($t = 3.50$; $p = 0.002$). Table

3 provides non-standardized coefficients so we could reasonably interpret being male is associated with an average increase in self-evaluation of 0.206 points (where 1 point indicates a shift from average to good, or from average to excellent, etc.). In Swedish, being male was not statistically significant ($t = -0.19$; $p = 0.848$). The model R-squared was lower at 0.343. A control variable, whether the respondents had a Swedish-born parent, was not statistically significant in either regression. Taken together, these results strongly support the hypothesis that boys give themselves a higher level of self-evaluation compared to girls in relation to stated grades in mathematics.

Discussion

The aim of this paper was to study upper secondary school students' self-evaluation with respect to stated grade and gender. The overview of the grades show that they are higher for girls, both in mathematics and Swedish, which is in line what have been reported earlier (e.g. Voyer & Voyer, 2014). The hypothesis that we tested was that boys are more confident than girls in mathematics. Just as in previous studies, both national (e.g. Brandell & Staberg, 2008; Sumpter, 2012) and international (e.g. Nagy et al., 2010; OECD, 2013; Skaalvik & Skaalvik, 2004a), the results, from the non-parametric analysis and linear regression, confirmed that boys choose higher self-evaluation in relation to stated grades compared to girls. The results are to some degree in contrast to Frid et al. (2021), and compared to the PISA study (i.e. Chiu & Klassen, 2010), boys overestimated their ability at all levels or girls undervalued themselves. It indicates that several studies are needed in order to understand the concept self-evaluation from a gender perspective: since individuals are using multiple frames of reference when they judge their evaluations (e.g. Skaalvik & Skaalvik, 2004a), such discrepancies can be related to which frame that is in focus (e.g. Sumpter, 2012). Given that the present study used a limited scope of the definition of self-evaluation compared to Klenowski (1995), there are room for further development of the instrument that was used.

Nevertheless, combining the results from the present study and previous research, the conclusion is that boys appear to over-value themselves or girls tend to under-value themselves. This supports the so-called confidence gap (Zander et al., 2020). In the present study and the results from the non-parametric analysis, the confidence gap was visible mainly in mathematics and only partly in Swedish where in the group of self-reported grade 'E', boys more often picked 'below average' and girls more often took 'weak'. Here, the results differ slightly from what has been previously reported regarding girls and language (e.g. Skaalvik & Skaalvik, 2004b). This could be interpreted as an indication of patterns within a more general pattern in self-evaluation. Also, if students construct their mathematics self-concept on their experiences and history of achievement (e.g. Usher, 2009) and girls have better grades (Voyer & Voyer, 2014), the history of achievement appears to be cancelled out. If we, for instance, want to understand why we have gendered careers (e.g. Dekhtyar et al., 2018), we need to look beyond grades. The confidence gap is nonetheless an interesting phenomenon especially if used to blame girls for being not confident enough, given that they are already confident (e.g. Sumpter, 2012) or not having good enough grades (e.g. Dekhtyar et al., 2018). This is important when ideas such as 'the hard-working female' and 'the male genius' (e.g. Leslie et al. 2015) still exists.

Attending to voices of women and racially/ethnically minoritized students: Conflicting perceptions of mathematical competence

Seyda Uysal[1] and Kathleen M. Clark[2]

[1]Florida State University, Tallahassee, United States; su17b@my.fsu.edu

[2]Florida State University, Tallahassee, United States; kclark@fsu.edu

We present our findings from a pilot study that was conducted between Spring 2019 and Spring 2020. Our overall project goal was to gain a deeper insight into women and racially/ethnically minoritized students' experiences during the secondary school-tertiary transition in mathematics. In the report, we used aspects of the three-dimensional model of attitude (Di Martino & Zan, 2010). The model consists of three dimensions, which are vision of mathematics, perceived competence, and emotional disposition toward mathematics. We particularly focus on emerging mathematicians' conflicting perception of competence in mathematics and address the concomitant emotions. We documented voices of women and racially/ethnically minoritized students to address gender stereotypes and raise awareness about their struggles for a sense of belonging in mathematics from affective and sociocultural standpoints.

Keywords: Affect, gender, inclusion, women and minoritized students, perceived competence.

Introduction

Many scholars have researched the phenomenon of the secondary school-tertiary transition (STT), in mathematics considering cognitive, didactics, sociocultural (De Guzman et al., 1998), and affective dimensions. The nature of mathematics at university is different than secondary school mathematics, resulting in certain affect-related outcomes that prevent students from becoming competent mathematicians (Di Martino & Gregorio, 2019). Holding a positive attitude about ourselves is one of the key aspects of meaningful participation along with the ability to effectively communicate mathematically in becoming involved in a new community (Lave & Wenger, 1992). Women rate a lower mathematical self-conception than men even though mathematics has a slightly better gender representation in mathematics than other STEM domains (Sax et al., 2015). However, increased representation does not always provide women and racially/ethnically minoritized students with equal representation in public mathematical spaces, such as classrooms. Because of the strong beliefs of men on self-concept, they are more likely than women to be identified as full participants in mathematics environments (Mendick, 2005). It is documented that women in mathematics often experience challenges in a way that positions them at the periphery of mathematical participation (Solomon, 2007). Women have difficulties in acknowledging their potential in mathematics due to gendered stereotypes in many mathematical communities (Solomon, 2007). When women are exposed to environments with fixed ability views and gender stereotyping, their sense of belonging and perception of competence tend to decline (Good et al., 2012). STT research is limited in its ability to address the intersectionality of identities such as race, gender, or ethnicity in the examination of affective dimensions of mathematics learning. Therefore, we examined the obstacles in the STT by using affective aspects such as perception of competence in mathematics, particularly among racially/ethnically minoritized populations. We also highlighted perceived competence in mathematics (Di Martino & Gregorio, 2019) with an emphasis on emotional expressions, as well as the notion of belonging considering legitimate peripheral participation of women (Solomon, 2007). Further, we point out gender stereotypes and some concomitant emotional states play a role in how women construct their identities as they become members of mathematical communities (Solomon et al., 2011). Accordingly, our guiding research question is: *How do women and racially/ethnically minoritized students in the mathematics major position themselves as mathematics learners considering their perceptions of mathematical competence?*

Theoretical Perspectives

The three-dimensional model for attitude (TMA) characterizes attitudes in relation to beliefs and emotions (Di Martino & Zan, 2010). We adopted the TMA for our conceptualization of the relationship between beliefs and emotions as components of students' experiences with mathematics in university. The three dimensions are vision of mathematics, perceived competence in mathematics, and emotional dispositions towards mathematics. Students' vision of mathematics as being more relational or instrumental (Skemp, 1978) are linked to their beliefs of mathematics. Students' beliefs about themselves as mathematics learners, which are influenced by their vision of mathematics, can be thought of as perceived competence in mathematics (Di Martino & Gregorio, 2019). Finally, Di Martino and Gregorio (2019) identified associations between the vision of mathematics and perceived competence, which often manifested through emotional responses. In the study, we particularly addressed the component of perceived competence on students' mathematical experiences. We also discovered that the notion of belonging deserved more attention when it comes to the identity development of women and racially/ethnically minoritized mathematics students (Good et al., 2012). The TMA offered useful perspectives in analyzing the perception of competence as students reflected on their mathematical experiences from affective perspectives.

Method

Participants and Settings

We conducted a pilot study, the Women and Underrepresented Minorities in Mathematics (WURMM) study, from Spring 2019 to Spring 2020 in which 13 students participated. The pilot study focused on mathematics majors who were from racially/ethnically minoritized populations (e.g., students of color, women). The pilot study consisted of multiple data sources such as interviews, survey responses, students' reflection diaries, and seminar[1] artifacts. Considering our aim to address students' perceived competence, our paper focuses on the activity conducted in the second seminar which was held in Spring 2020 with four participants. We report data from three of the four participants (Table 1) for whom we have complete data profiles. Two students were pure mathematics (PM) majors and one student was a secondary mathematics teaching (SMT) major. The goal of this seminar was to gain insights into students' STT experiences from affective perspectives. We

[1] We use the term "seminar" to describe the intervention we included during the pilot study. These seminars (one in Summer 2019 and one in Spring 2020) consisted of four sessions each (each session was 2- to 3-hours in duration), and included mathematical tasks, discussions, and short presentations.

prompted students to talk about the attributes of mathematicians by addressing perceived competence in mathematics and mathematical identity during the seminar activities. The data sources for this paper consist of video recordings from four seminar sessions (two hours each) conducted in Spring 2020. We also collected data through students' written artifacts from the fourth seminar session's activity and post-survey responses. Finally, we draw on interviews conducted in Spring 2019, which included information about demographic, secondary school experiences, perception of mathematics, and perceived competence in mathematics. We were able to analyze the affective components of STT experiences by comparing secondary school to university experiences related to perception of competence and vision of mathematics.

Table 1: Demographic information of selected participants

Participants	Major/Year	Gender	Ethnicity
Dana	PM/Sophomore	Female	Hispanic/Latino
Manuel	SMT/Sophomore	Male	Hispanic/Latino
Sunny	PM/Sophomore	Female	Non-Hispanic/Latino

Session 4 activity: Exploring attributes of mathematicians

We designed an activity to capture the salient attributes of a mathematician's identity. The activity was useful in prompting students to articulate the attributes of a competent mathematician and accordingly to understand students' beliefs on their perceived competence in mathematics. Also, the activity enabled us to observe students' emotions while they talked about mathematical competence. We shared a Google document with students which was divided into four quadrants with a guiding question for each: (1) Who is a mathematician?, (2) What does a mathematician do?, (3) What does a mathematician say?, and 4) What do you consider a mathematician is not?

We asked participants to individually think about their responses to the questions and then each participant populated the Google document with their comments. Since participants were asked to use only short phrases or terms within the document, we also facilitated a discussion in which participants could more thoroughly share their perspectives. The activity helped elicit students' opinions on mathematicians' identity attributes and how they relate to emergent characteristics. We asked the same questions in the post-survey to provide students with a chance to express their personal opinions, without being influenced by responses from other participants.

Preliminary Findings

Using aspects of the TMA, we highlight our findings related to perceived competence and accompanying emotions. We present excerpts that reflect students' views on the attributes of a competent mathematician, as well as the emotions evoked when they reflect their own mathematical competence.

Attributes of a mathematician

Participants reflected on the attributes of a competent mathematician (Figure 1) including mathematicians' identity, discourse, and actions. Sunny used the expressions of "creative and logical" by stating that a mathematician communicates by "clearly indicating logical processes and reasoning as well as the goal of the problem" (Post-survey, 2020). Sunny valued logic and clarity as part of a competent mathematician's identity. Manuel similarly articulated that a mathematician is a "problem solver and logical" and asks "why?" Dana's reflection included: "The way in which they communicate automatically provokes thinking critically and stimulates conversation" (Post-survey, 2020). Dana's response underlined the importance of communication aspects. That is, she valued a mathematician who contributes to the common discourse within a community of practice.

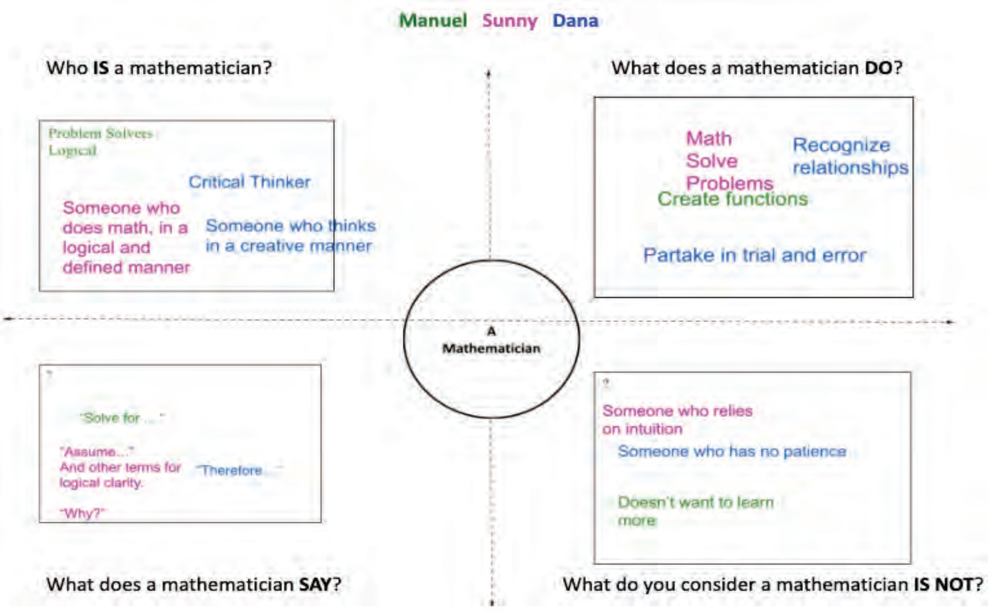

Figure 1: Students' artifact from the activity for exploring the attributes of mathematicians

Next, students elaborated on the prompt which was related to how mathematicians can change their confidence. Sunny reflected on the prompt from a personal standpoint and responded with "expanding her course work and exploring more areas of mathematics" as a way to help her to improve her confidence. Interestingly, Manuel referred to a mathematician's identity as a "title" rather than an "action" (Post-survey, 2020), which he thinks could help to improve how mathematicians do mathematics. We speculated that the basis of this idea of a mathematician might have its roots in the conventional view of a mathematician, which positions them as naturally capable in society regardless of their actions. Dana responded with: "by 'doing' more mathematics, and by surrounding themselves in a supportive environment that promotes intellectual conversation about mathematics without rejecting the ideas of others" (Post-survey, 2020), which aligned with her earlier comment during the seminar. Dana's responses reflected her perceptions of a competent mathematician that were closely related to social participation in mathematical communities. Dana valued a mathematician who is also precise in communicating mathematical ideas and creates a dialogue. From her perspective, the latter also stressed the significance of discourse, which was aligned with social aspects of a mathematician's identity.

Perceived competence in mathematics

We asked further questions about students' perception of their competence in mathematical communities. Dana's mathematical confidence was supported by her vision of mathematics. That is, she emphasized a key aspect of her mathematical confidence related to being able to develop relationships between abstract concepts as she progressed through the course work.

> I feel as if in a way... it has made me feel *more confident, but also less confident*[2] for different reasons. Like, *I feel more confident because of these higher-level math courses*. I'm learning about math as this abstract concept and the more I'm just learning about these different concepts and I'm able to connect different relationships that are allowing me to just form different connections. And so, in that way, *I begin to feel more confident*. (Seminar, 2020)

We also noticed certain negotiations concerning perceived competence in mathematics in Dana's articulations. It appears that Dana's perceptions of a competent and confident mathematician that she described earlier was conflicted with how she felt about participating in mathematical spaces. In the preceding excerpt, Dana outlined some perturbations in her perceived competence, including doubts when surrounded by "brilliant people" and questioning of her abilities in mathematics.

> …But also [I'm] just *less confident*. The more I'm surrounded by people that are just really brilliant and I just, I tend to… I don't know how to explain it. I feel as if, even though I am in the same classes as them and I do have a right to be there, I always just, *never built up enough confidence* to, like, for example, just ask a question or just be involved and I feel, not to turn this into a whole gender thing, but I feel as if… Because like STEM and mathematics still are more of a male-based subject, *it's hard for me to really voice my opinions and voice what I feel.* When I am in a group of all guys during a study group or like when I'm just doing partners, you know, I just *tend to get less confident*. (Seminar, 2020)

Dana's negotiations of her perceived competence in mathematics accompanied by emotional states and doubts about her belonging to her mathematics community. Affect was not only associated with vision of mathematics but also certain sociocultural factors in her experiences. When we raised the notion of societal norms that shape women's perceived competence in mathematics, her responses reflected a feeling of underrepresentation in mathematics classes starting in high school and dealing with norms and stereotypes regarding women's abilities attached to it. The next excerpt captures Dana's sensemaking of her participation in mathematical spaces, in which she reflected on her experience in high school and her ongoing negotiation of a sense of belonging in a mathematics community.

> ...I think we all know our capabilities and we all know that we deserve to be where we are in the mathematics department, but I also think, you know, we hear all these things and we hear these societal standards that *it's hard to just ignore those facts*, you know? And *it's hard to just push that aside*… I don't think as much in the university as it was in high school... in math classes where, at least for me, I would be one of the only few girls and sometimes the only girl in some of

[2] Italics are used to indicate expressions which we considered aligned with the emotional dimension of TMA.

my math classes. And I know that just *inhibited my ability to ask questions* and to, you know, *participate as much as all the other people* in my class because I just felt as if *I ...wasn't worthy enough* to ask these questions, but just *scared* and just that I don't know, I just *felt like always out of place* because of that. (Seminar, 2020)

Dana pointed out that gender-related factors hindered her participation in the mathematical discourse during high school mathematics classes. It is worth noting that Dana went to a small, private, and predominantly White high school in the southeastern United States. Her expression of discouragement to participate in such mathematical discourses focuses attention on the stereotypical positioning of women as dissociated from the mathematics discipline. Tensions surfaced during Dana's negotiation of her mathematical identity, specifically in the case of taking part in mathematical spaces. Her experiences in high school mathematics classes, such as being one of few females, made her question her belonging to mathematics. Moreover, Dana articulated her challenges with rejecting societal norms against women, which may have restricted her participation in mathematics classes despite her achievement.

Sunny also expressed her perception of competence in mathematics in emotionally laden ways, which raised questions regarding the definition of competence for students in the major. Considering Sunny had grades of over 90% (out of 100%) in her major, it was remarkable to detect conflicting patterns in her beliefs about confidence in mathematics during the seminar. The following excerpt highlights how Sunny attributed aspects of her self-concept to both the nature of mathematics being broad and unknown as discipline as well as to the social comparison.

Sunny:	*I don't think I'll ever be confident in mathematics*, to be honest, I feel like there's, it's just such a wide thing. And there's so much to learn. And there's so much that goes into it. I feel like I could like, have a Ph.D., and have like 10,000 awards and *still not feel confident* beyond it…
Interviewer:	And there is nothing to change that?
Sunny:	Oh, I don't think there is. I mean, in my case. I'm always going to feel like there's more to learn. And there are people who know more than I do.

Her negative statement about her confidence seemed to contrast with her previous view regarding improving her competence by expanding her course work. Though Sunny did not mention gendered discourses, her identity as a young woman in mathematics might have been shaped by the masculine nature of mathematics. Her reflections aligned with Dana's statement that being around smart people led to doubts about one's competence in mathematics. Finally, Manuel's reflection on the perceived competence in mathematics differed from those of Dana and Sunny regarding being surrounded by other smart people in the classroom. Manuel expressed that "I find more … drive and competitiveness about the idea that they know more than I do. I understand more" (Seminar, 2020). Evidently, Manuel distanced himself from his peers in his perception of competence in mathematics.

Discussion and Conclusion

We captured students' ideas of a competent mathematician and how those perceptions related to how they view themselves as competent in mathematics. We noticed that the nature of mathematics becoming an abstract and broad discipline had some favorable influences on how Dana and Sunny reflected on their competence. Talking about perceived competence in mathematics elicited some emotions for students such as being scared away from participation (Di Martino & Zan, 2011).

Moreover, we explored perceived competence of women and minoritized students in mathematics while illustrating the negative influences of gendered discourse on their identity development. We detected issues in the participatory nature of mathematical spaces, which seemed to exclude women from becoming full participants in it (Solomon, 2007). The emotional tensions we observed on competence could be an outcome of the patriarchal society's limited options for available identities as a woman and a mathematician (Solomon et al., 2011). While Sunny articulated her perceived competence in mathematics similar to that of Dana's, interestingly, Manuel, a male student, referred to becoming a confident mathematician as being subtly connected to one's personal qualities. Manuel possibly felt tasked to negotiate his masculine mathematical identity as a way to "prove" his abilities due to societal norms that value innate mathematical abilities (Mendick, 2006).

We also explored how women are challenged emotionally, which led to identity negotiations regarding their capabilities. While Dana believed that she was a capable mathematician (as evidenced by other survey data), gendered stereotyping (Leyva, 2017) may have created barriers for her towards participation in mathematics. In fact, Dana and Sunny were both emerging women mathematicians who possess superb mathematical ability and were extremely enthusiastic. Our analysis also uncovered alternative forms of becoming successful in the discipline of mathematics (Solomon, 2007) including legitimate peripheral participation (Lave & Wenger, 1992). In our investigation of perceived competence and emotions, we also gained insights on the need for belonging, particularly for women and racially/ethnically underrepresented groups participating in mathematical communities (Good et al., 2012). Belonging and perceived competence seem to be interrelated (Lahdenperä & Nieminen, 2020) and are specific to women and minoritized groups' participation and persistence in mathematics. Considering that small numbers of women and racially/ethnically minoritized students pursue mathematics related fields (NSF & NCSES, 2019), mathematics environments should foster inclusion for these populations (Pinheiro, 2021).

Review of the methodology used in the research on the mathematics-related affective domain

Peter Vankúš[1] and Adam Jakubička[2]

[1]Comenius University in Bratislava, Faculty of Mathematics, Physics and Informatics, Bratislava, Slovakia; peter.vankus@fmph.uniba.sk

Keywords: Teacher attitudes, methods research, beliefs, literature review.

Introduction

Mathematics-related affective domain we understand using the framework of Hannula (2012) as having three different types of affect: cognitive (e.g. beliefs), motivational (e.g. values), and emotional (e.g. feelings). All these three aspects of mathematics teachers' affective domain are important to determine if they lead their students to an active and creative approach to mathematics learning (Boaler, 2015). Therefore, we decided to research key points during the university study, which influence affective domain of future mathematics teachers. In this poster we prepare a theoretical background for our research. We do this by reviewing methodology of related journal articles to identify methodological practices in the research on this topic. We hope that our paper will inspire discussion about the best methods to study mathematics-related affective domain and also possible collaboration with our team in this subject.

Literature Review

To obtain the journal articles suitable for our review we performed the search in the Web of Science Database on 18th July 2021. The search terms were 'mathematic*' combined with a Boolean operator AND with the terms 'teacher*' and with three words characterizing affective domain combined with a Boolean operator OR: 'attitude*', 'belief*', 'affect*'. The refined specifications of the search were that articles need to be open access and the publication years should be 2020 or 2021, to include just the newest and accessible papers. The papers were carefully studied, with the focus on the methodological parts and the finding were compared and discussed by both authors.

Results

Altogether, based on the search in the Web of Science database, 15 journal articles were included in this methodology review. One article was excluded because of focus on primary students instead of teachers. The list of the articles with complete references is because of the page limitation of the poster here: www.comae.sk/reference1.pdf. The most used research approach was quantitative (10 articles - for example Jeong & Gonzalez-Gomez, 2021, published in the journal *Mathematics*), followed by mixed approach (3 articles - for example Liebendorfer & Schukajlow, 2020, published in the journal *Educational Studies in Mathematics*). The least used approach was qualitative (2 articles - for example Lo, 2021, published in the journal *International Journal of Instruction*).

Following topics were researched in articles using **quantitative approach**: (1) self-efficacy - relationship with other constructs, impact on intention to leave profession, (2) (epistemological) beliefs about the nature of mathematics, (3) beliefs about teaching and learning mathematics, (4) development of attitude towards mathematics and (5) attitude to students' struggle when learning mathematics. In all 10 quantitative studies, a questionnaire was used as an instrument for data collection, containing various statements scaled by a Likert scale. Statistical methods were used to analyze the quantitative data, mostly analysis of variance and various correlation analysis methods.

Following topics were researched in articles using **mixed approach**: (1) perception of attitudes towards mathematics, (2) interest in mathematics and (3) attitude to student's struggle when learning mathematics. All three articles in this category used a questionnaire as an instrument to gather quantitative data. In these articles, additional qualitative data was gathered as a support either to ensure validity of the interpretations of the questionnaire data, or to uncover new themes (variables), which could be then analysed quantitatively. Open-ended items in questionnaires, written reflections and semi-structured interviews were used to gather such qualitative data.

Following topics were researched in articles using **qualitative approach**: (1) beliefs about mathematics and language and (2) beliefs about teaching mathematics. The only method used to gather qualitative data was a semi-structured interview. In both articles, the interviews were audio-recorded, transcribed and analysed either thematically or inductively.

Inclusion and peer-collaboration in mathematics classrooms: The case of students' perspectives

Maria Vasilopoulou[1] and Chrissavgi Triantafillou[1]

[1]National and Kapodistrian University of Athens, Athens, Greece; vasilopouloumath@gmail.com, chrtriantaf@math.uoa.gr

This study aims to highlight students' perceptions of team collaboration in mathematics classrooms. We focus on students with easy access to mathematics (GR1) and who admitted that they struggle with access to mathematics (GR2). Positioning theory is used to study participants' narratives about mathematics group work. Nine online one-hour interviews were conducted. The analysis of research data was done with grounded theory. The results indicate the following categories of participants' perspectives: Students' emotions while involved in peer-collaboration activities; Students' role in peer-collaboration activities; Participants' setting rules on how and with whom to collaborate; Participants' rationale for collaborating with their classmates. Similarities and differences between the two groups were identified as well as implications for promoting inclusion in peer-collaboration activities.

Keywords: Inclusion, peer-collaboration, mathematics, students' perspectives.

Introduction

Inclusion is built on the principle that all students should be valued for their exceptional abilities and included as important members of the school community (Civil, Hunter & Crespo, 2019). Recent studies argue that students' collaborative learning, where a small group of students work together to complete a mathematical task, could promote inclusion and equity in classrooms settings and affects students' identity as mathematics learners (César & Santos, 2006; Florian & Black-Hawkins, 2011; Kotsopoulos, 2014). Particularly, César & Santos (2006) argue that the role of collaboration in mathematics classrooms seems to facilitate students' positive attitudes towards learning and school achievement. Florian and Black-Hawkins (2011) suggest that teachers in inclusive practices should provide students with options to choose 'how, where, when, and with whom they learn,' in conditions that are designed to respond to their individual needs. On the other hand, students' experiences in collaborative learning activities may create roadblocks in the way they position themselves as mathematics learners (Kotsopoulos, 2014); while a 'distributed balance' between students' contributions in teamwork was identified by Dekker, Elshout-Mohr and Wood (2006). The latest findings could create inequitable learning opportunities and a sense of not feeling included in school activities for some students. Hence, the prerequisites for group work which are enacted in an inclusive manner still remain an open issue (Forslund Frykedal & Hammar Chiriac, 2018).

The current study focuses on how students are positioning themselves in peer-collaboration activities in mathematical classrooms. The participants are nine students, ranging from 11 to 16 years old, who are placed in two groups (GR1 and GR2). Participants in GR1 are five students who feel competent in mathematics and participants in GR2 are four students who feel that they struggle accessing mathematics. The two groups were distinguished in their own words. Additionally, some of them are certified by certain Greek institutions as gifted (GR1) or with mild disabilities in mathematics (GR2). We consider that all participants in this study are students with Special Needs in Mathematics (SEM)

(Scherer et al., 2019). The research questions are: RQ1: What characteristics do we identify in all participants' perceptions when talking about their experiences from peer-collaboration in mathematics classroom activities? RQ2: Which similarities and differences can we identify in the two group members' perceptions? By responding to the above research questions, we expect to identify if and how participants' experiences on peer-collaboration activities might affect their inclusion in mathematics activities. We view inclusion as equal opportunities for someone to participate and learn in mathematics classrooms (Esmonde, 2009; Civil, et al., 2019).

Theoretical framework

We view students' perceptions about their cooperative learning under the *positioning theory* perspective (Harré, 2005). Positioning involves the process of ongoing construction of the self through personal storylines that describe relations and interactions of people jointly engaged in an activity. This research also draws on related research in mathematics that considers the potentiality of positioning in studying students' conceptions of what doing and knowing mathematics entails (e.g., Evans, 2003). In particular, researchers argued that students' perceptions and emotions about their participation in any classroom activity may form their positional identities as mathematics learners. Esmonde (2009) argued that students' positioning and identity-related processes are just as central to their mathematical development as their content learning.

Students' perceptions about peer-collaboration in mathematics classrooms

Since students' sense of belonging in mathematical activities seems to be critical for forming their positional identities as mathematics learners, researchers tried to understand and compare the experiences of different students in peer-collaboration activities. In Mulryan's (1994) study perceptions of high mathematical achievers with low achievers were compared. She concluded that both groups focus on the social dimension of the collaboration experience while high achievers emerged as having a more complex understanding of cooperative small-group work than did low achievers. Webel (2010) when comparing the perspectives of two high school math students, showed that both students see collaboration as knowledge transfer from capable students to struggling peers. Kanevsky, Owen and Marghelis (2021) studied mixed ability students' considerations that influence their preferences for working alone or in collaborative settings. The results indicate that high ability students were more concerned about content characteristics (e.g., efficiency and quality of their work) while others were more concerned about social characteristics (e.g., potentiality for fun) in these type of school activities. Kotsopoulos' (2014) study illiustrated how one student (Mitchell) experienced his peers' rejection of his contributions when solving a mathematical task. Mitchell reacted to how his peers were positioning him by taking a 'silenct' stance. In this way, he created a wall between his mathematical thinking and his involvement in the peer-collaboration activity.

The above outcomes highlight the critical role of different students' perceptions about peer collaboration activities. In this study we attempt to highlight how two groups of students, who view in different ways their involvement in mathematical activities (struggle to gain access and have easy access) position themselves in peer-collaboration activities and how these positions might affect their inclusion in mathematics classroom activities.

Methodology

This study is a part of a PhD program which aims to highlight issues of inclusion in Greek mathematics classrooms. Even though in Greece, according to law 2817/2000, inclusive education is a legitimized school obligation to facilitate all students' educational needs for many Greek teachers, this is still a challenging issue when trying to accommodate different students' needs in mainstream classrooms (Avramidis & Kalyva, 2007).

Participants

The participants were nine students who voluntarily participated in this study. The nine students were placed into two groups. The first group, which we call GR1_stX (Group 1, student X) includes five students who felt that they are competent in mathematics, and they feel that they understand math quicker than their classmates. Three of them are certified as gifted by the Hellenic MENSA association. The second group, for which we use the abbreviation GR2_stX (Group 2, student Y), consists of four students who feel that they struggle to gain access to mathematics, and they think that their classmates are better than them. Three of the students are certified with learning disabilities from training and counseling centers of the Hellenic Ministry of Education. The rest of the students were placed in groups we formed based on the way the manner in which they talk about their access to mathematics (in their own words). The students varied from fifth to ninth grade (See Table 1).

Table 1: Participants' profile

Name	Sex	Age	Class/Grade	Certified or Words
GR1_st1	Female	15	9th	In their own Words
GR1_st2	Male	15	9th	Certified
GR1_st3	Female	16	10th	Certified
GR1_st4	Female	11	5th	Certified
GR1_st5	Male	12	6th	In their own Words
GR2_st1	Female	13	7th	Certified
GR2_st2	Male	13	7th	Certified
GR2_st3	Female	14	8th	In their own Words
GR2_st4	Male	14	8th	Certified

The researcher (first author) recruited the participants from three different institutions where she was working as a math tutor. Those institutions are the Hellenic Mensa Institution (certified students in GR1), a private study center (certified students in GR2), and a music school, and encompassed students that admitted, in their own words, that they have easy access or a struggle to access mathematics.

Research Data

Nine online interviews were conducted. The interviews lasted approximately one hour and were recorded after the researcher obtained permission from students' parents. In the beginning it was made clear to the participants that we are interested in identifying instances that they feel included or excluded in mathematics classroom activities. We used open-ended questions to build upon and explore their responses, so students themselves could reconstruct their experience within the topic under study. The interview consisted of three main areas of students' experiences: a) about specific mathematical lessons and tasks e.g., "*on which mathematical task did this happen*?" or "*give me more details about this lesson*"; b) about instances of mathematics teaching (e.g., "*Describe a case in which you felt you were actively involved in the lesson and how often does this happen?" "Are there cases where you think that you could be involved but you didn't have the chance?'; "What is your opinion of an ideal math lesson?"*; c) about peer-collaboration activities (e.g., *"Do you prefer to work alone or with your classmates?"; "What kind of working groups you want to be part of and why?" "If you were a teacher, in what ways could you form a group?"*). In this article, we focus on data in regard to the last area. Through students' answers, more close questions emerged about their perceptions or/and preferences in learning conditions.

Data analysis

Giving a voice to students is the main concern because discourse is socially constructed, and words have meaning when used by participants. The analysis of research data was done with the help of grounded theory. Specifically, our study lines up with Charmaz's (2006) approach in which feelings and views of the participants are emphasized and make sense depending on readers' and researchers' perspectives, practices, and purposes. The analysis of the data was carried out in four steps. Firstly, students' interviews were transcribed. In the second step of the analysis, we distinguished parts of the participants' interviews that refer to peer collaboration. Thirdly, we tried to focus on the main issues that characterize participants' positions about collaborating in learning activities. In this step, categories of participants' positions emerged. These categories were under negotiation among researchers until the final categories were established. In this way, we tried to respond to the first RQ. In the last step, we tried to focus on differences in the two groups' perceptions about peer collaboration and respond to the second RQ of our study.

Results

Participants' perspectives about peer-collaboration

Through analyzing students' answers, we came up with the following categories of participants' perspectives: *Students' emotions while involved in peer-collaboration activities*; *Students' role in peer-collaboration activities; Participants' setting rules on how and with whom to collaborate; Participants' rationale for collaborating with their classmates.*

We present each category and characteristic students' responses:

a) ***Students' emotions when involved in peer-collaboration activities.***

Most students expressed positive emotions like 'happiness' or 'satisfaction' while collaborating with their peers. These feelings are related mostly with a positive outcome from this collaboration like 'helping the others understand.'

Some characteristic examples of both groups' responses are: "When they understand, I feel happy" (GR1_st1); "It's a good feeling, it is a satisfaction that I know that and I can help others" (GR1_st2); "I like math and I like to show what I know and help others understand" (GR1_st3);"I like to explain math" (GR1_st5); "I feel enjoyment and satisfaction when they have understood them" (GR1_st4); "I feel glad that I helped my classmate"(GR2_st1).

Only two students expressed negative feelings like 'dislike', 'shame', or 'anxiousness': "I feel a little uncomfortable" (GR2_st1); "I don't want to…I feel ashamed. I'm a little anxious that the children will say something like 'look, you did it wrong' and stuff like that… this is what happened when I was in elementary school" (GR2_st2)." Student GR2_st4 expressed an insider in the community feeling while participating in peer-collaboration activity "I felt that my classmates like me, otherwise they wouldn't tell me anything…they wouldn't help me… this means that I have an active role at school."

b) Students' perceptions of their role in peer-collaboration

We identified two participants' perceptions of their role during collaboration activities: as *helpers* (e.g., 'I explain' 'I share ideas') or *help receivers* (e.g., 'I am asking for their help').

Students that position themselves as helpers said: "Usually, my classmates ask for my help (laughs) […] I try to explain it to them […]" (GR1_st1); "My classmates ask me about their homework and how we might solve this exercise" (GR1_st3); "Many of them who need help in math come to me" (GR1_st5); "If they ask for my help, I'll try to explain to them what they need, the best way I can, it doesn't happen a lot, It only happened once […]" (GR2_st4); "I just give them a little push when they have fallen behind" (GR1_st4). Other students position themselves as help receivers. Some characteristic examples are the following: "I am the one who asks for help a lot" (GR2_st1); "Yesterday I asked for their help since I couldn't figure out how exactly I would define x and y'' (GR2_st3).

c) Participants setting rules on how and with whom to collaborate

Some of the participants would prefer to work with others under certain conditions or rules. Students GR1_st1 and GR1_st5 expressed the *No competition* rule especially when collaborating in mixed-ability groups. Characteristic responses: "I wouldn't prefer it to be a competition, it just makes me feel nervous. […] because I don't like to fail." (GR1_st1); "Not to be competitive […] if you fail you get really upset (GR1_st5). At the same time, the above participants' *no competition rule* hides their perception that a mixed-ability group is likely not to have a successful outcome.

Students GR1_st1 and GR1_st2 expressed the *collaborating with those who really want to work* rule regardless of his/her mathematical competence.

GR1_st1: I wouldn't like to be in the same group with others who don't pay attention. I wouldn't mind if students who have difficulty were in my team, but not those who don't pay attention and want to copy my answers… in that case I just get angry because I would probably end up doing the whole project myself as it happens many times in other courses' teamwork.

GR1_st2: I don't see it only with students who have the ability to learn easily, but with the ones who have an interest to work. Even if they have never studied math, but they want to contribute to the team, that's ok for me.

Student GR2_st2 expressed the *collaborating only with friends* rule: “I like sharing ideas with each other […] but only with my friends.” No participant expressed rules for collaborating with students sharing the same math ability with high achievers in mathematics.

d) Participants' rationale for collaborating with their classmates

When students were asked if they prefer to work individually or in groups, they all tend to choose to work in groups and especially in mixed-ability groups. Here are some examples of their rationale for collaborating with their peers, which are linked with either *collective gains* (‘team progress’ or ‘team building’ or ‘socializing’) or *personal gains*. Analyzing students’ words, two dimensions came up: *collective with specific direction’s gains,* in which there are specific types of students that benefit from the others, and *general collective gains* in which each student can benefit from one another. On the other hand, personal gains seem to have three reasons which are: *making repetitions*, *listening to a new idea*, and *not losing teaching time* with the teacher’s explanation.

Students GR1_st3 and GR2_st3 seem to refer to collective gains when the students might benefit from each other, but this has a concrete direction i.e., the students who have access in mathematics to help the others who struggle to have access, or they are afraid to be unsheltered. Characteristic responses are: “Those of them who are good at math and understand them, should help the ones they aren’t’’ (GR1_st3); “When it is difficult for someone to understand, another one from the same group could guide the rest of them […] those who had questions and wouldn’t have the courage to ask” (GR2_st3). Furthermore, GR2_st4 “sees” that the whole team might help one member: “To work in groups, when a member has difficulty incomprehension, the team could help”.

GR1_st2 and GR2_st2 refer to collective gains when the students might benefit from each other but without concrete direction: “For me, it’s not the ability that matters, it has to do with someone’s interest to work. Even for someone who has never studied math, the willingness to help will somehow contribute to the team” (GR1_st2); “Not only the high achiever has some nice ideas but also the underachiever” (GR2_st2). The same students highlight the reasons ‘team progress’ and ‘helping each other’: “We try to make progress altogether” (GR1_st2); “To help one another” (GR2_st1).

GR1_st3 except the collective gains refers to socializing with peers. “In that way, we are able to talk to each other. Because there are times we don’t even talk in the classroom. I might haven’t talked to my classmates at all. That makes us feel gratified too.”

Three students prefer working in mixed ability groups but for *personal reasons*. GR1_st4 likes to help others because this is the only way (as she feels) she can move on and learn new things. “I was pleased that everybody understood because when they don’t, the whole group falls behind [in classroom teaching].*”* The other two participants take the opportunity to improve their mathematical knowledge *“*I do repetitions [on the classroom material] and I definitely understand it better when I am explaining something to someone else” (GR1_st2) or “actually I prefer working in groups whereas I can listen to others’ point of view since there might be another solution I haven’t thought about” (GR2_st1).

Comparing two group members’ perceptions

GR1’s participants feel positive emotions when they work with their classmates for both collective and personal reasons. They all perceive themselves as helpers and some of them expressed specific rules and conditions for participating in such activities. GR2's students feel positive too when they collaborate with their classmates, but they mostly perceive themselves as help receivers. They also prefer to work with mixed ability groups, like GR1, for collective gaining or personal reasons. They didn't set criteria and rules for participating in such activities except for one student who wants to work only with his friends.

Conclusion

This study aims to highlight students' perceptions of team collaboration. We focus on students who feel that they have easy access to mathematics (GR1) and students who feel that they struggle to gain access to mathematics (GR2). Comparing the two groups' perceptions about peer collaboration, we came upon the following observations: All participants prefer to work in mixed-ability groups in mathematic class and they highlight the inclusive dimension since no one considers math skills problematic in collaborating with their peers unless there is a competition among mixed ability groups. The last was identified in the case with students who have easy access to mathematics. Some participants expressed their options to choose their classmates in peer-collaboration activities (e.g., working with friends or students willing to contribute to the discussion). Students who feel that they have easy access to mathematics see themselves as helpers or knowledge-givers (Webel, 2010).

Viewing students' perceptions from an inclusion perspective we noticed that the participants who admitted that they have easy access to mathematics seem to implicitly position themselves as *directors of the peer-collaboration activity* since they consider themselves as the helpers, they set certain criteria with whom to collaborate while one of them is taking up the role of the teacher to move on with the lesson. Conversely, participants who admitted that they struggle to gain access to mathematics seem implicitly to position themselves as the *followers of the peer-collaboration activity* since they see themselves as the help receivers. The above two groups' perceptions may cause a 'distributed balance' between students' contributions in teamwork (Dekker, Elshout-Mohr & Wood, 2006) thus it challenges the fair distribution of all group members' opportunities to participate and learn in teamwork, which is a prerequisite for equity and inclusion (Esmonde, 2009). The above outcomes indicate the challenges mathematics teachers face when trying to include students who view differently their involvement in mathematical peer-collaboration activities. Managing equity issues among students' contributions in mathematics classrooms is a complex issue (Esmonde, 2009) but it is critical to establish meetings amongst and between students' differences (Skovsmose, 2019).

Finding my way: a search for teacher identity

Hanna Viitala

Åbo Akademi University, Finland; hanna.viitala.edu@gmail.com

Ashley, a lower secondary mathematics teacher has a personal goal for professional learning: to find a teaching method that feels her own. She participates in a 1-year problem-solving intervention that aims to increase pupil thinking and engagement in mathematics classrooms. The purpose of this paper is to explore the opportunities that Ashley has, to develop her mathematics-related teacher identity within the problem-solving project. The results show that while the problem-solving intervention creates rapid change into Ashley's classroom practices, it also succeeds to influence positively the development of her mathematics-related teacher identity.

Keywords: Professional development, teacher identity, tensions, mathematics.

Introduction

The descending trend of Finnish pupils' mathematics performance and interest to study mathematical sciences on a tertiary level has brought about national discussion about mathematics teaching in schools. While policymakers have slowly recognized the need to take actions to stop the alarming development, on a local level, mathematics teachers have witnessed the descending trend of pupils' performance and problem-solving skills for over a decade (cf. Vettenranta et al., 2016). The descending trend in mathematics performance, coupled with Finnish pupils' low emotions, attitudes and self-efficacy beliefs in mathematics (Metsämuuronen & Tuohilampi, 2014) challenge teachers in their everyday practices.

The needed changes in classrooms do not happen without motivated teachers. Generally, teachers who agree to participate in a professional development project can be considered as motivated to develop their teaching. However, previous studies indicate that teachers tend to receive new information as well as accept and adapt it into practice at different rate (see e.g. Laine, Näveri, Ahtee, Pehkonen & Hannula, 2018). This might be due to the different needs and goals teachers have for professional learning that also affect their openness to learn new knowledge and to adapt it into their classroom practices (Liljedahl, 2014).

This paper is about one teacher, Ashley, and her search for a mathematics-related teacher identity within a professional development project. Ashley takes part in a radical problem-solving intervention in lower secondary mathematics classrooms with four of her colleagues. All five teachers report to be highly motivated to try new methods in their mathematics classrooms (Viitala, accepted). However, they all have somewhat different goals for their professional learning within the project. While these goals in most parts are connected to enhancing pupil engagement in mathematics, one of the teachers, Ashley, emphasises also a more personal need: finding a teaching method that would become a natural part of herself (Viitala, accepted).

Ashley's personal need for the professional development project motivated me to look closer into Ashley's teacher identity and mathematics teaching within the project. I was curious of the reasons behind her feeling of incompleteness as a mathematics teacher, and how the problem-solving intervention succeeds to answer her needs for personal development. The feeling of incompleteness as a mathematics teacher connects affect to Ashley's mathematics-related teacher identity (see Lutovac & Kaasila, 2018) that in this paper is studied through view of mathematics (Op't Eynde et al., 2002). Furthermore, the feeling of incompleteness is a strong motivational aspect for Ashley to participate in the professional development project. This emotional strain can positively impact the transition from professional learning into the mathematics classrooms (cf. Andrá et al., 2019).

The purpose of this paper is to explore Ashley's mathematics-related teacher identity through her view of mathematics and changes in her teacher identity, as well as through the link between identity and teaching practices (see research themes in Lutovac & Kaasila, 2018). These issues are studied through affective lenses, that have seldom been done in the case of mathematics teachers, with an individual emphasis, a view that has often been neglected (Lutovac & Kaasila, 2018).

The paper aims to answer the following research questions: (1) *How does Ashley characterise the growth of her teacher identity over time?* (2) *What kind of tensions can be found between Ashley's experienced teacher identity and her view of good mathematics teaching?* (3) *How does the problem-solving intervention answer to Ashley's needs for professional development?*

Mathematics-related teacher identity

Many review papers on identity emphasise the importance of studying teacher identity in connection to professional learning but, at the same time, highlight the vast variety of views on identity and the lack of clarity in its definitions (see e.g. Lutovac & Kaasila, 2018). This realisation stresses the importance of situating the study within the field.

Following Lutovac and Kaasila (2018), in this study, the term mathematics-related teacher identity is used to emphasise the context (mathematics) in which teacher identity is discussed. Teacher identity is understood as a dynamic construct that changes over time. It is influenced by several factors, such as prior experiences, beliefs, attitudes, emotions, work environment and colleagues, and it develops through social interactions in different contexts.

Although identity is seen as a social construct that is developed in, and influenced by different communities of practice (Wenger, 1998), identity in this paper is studied from an individual perspective (cf. Lutovac & Kaasila, 2018). This means that the discussion about Ashley's mathematics-related teacher identity is mostly guided by Ashley's thoughts and feelings about who she is as a mathematics teacher, how she describes her professional development over time, and how her affective trait (Hannula, 2012) influences her mathematics-related teacher identity.

Teachers' mathematics-related teacher identity is also influenced by tensions between experienced and ideal mathematics teaching, and between view of oneself as a mathematics teacher and view of a good mathematics teacher (cf. Beijaard, Meijer & Verloop, 2004). In this study, tensions are considered as "pairs of contrasting forces that pull a teacher in two different directions" (Andrá et al., 2019, s. 3). These tensions are used to recognise the (conscious or unconscious) needs for the professional learning within the project, and together with Ashley's experiences from the project, evaluate the opportunities that the problem-solving intervention offers for professional development.

The problem-solving intervention

Together with four of her colleagues, Ashley takes part in a professional development project that, by integrating collaborative problem solving into everyday mathematics activities, aims at increasing pupil thinking and engagement in mathematics classrooms. To reach sustainable change in these mathematics classrooms, the traditional teaching and learning practices as well as the physical learning environments are challenged from several fronts, and the mathematics classrooms are treated as systems (Stigler & Hiebert, 1999).

The project utilised a teaching method called building thinking classrooms (Liljedahl, 2020). The teachers implement the new teaching method in their everyday practices in mathematics classrooms. The core of the method constitutes of three activities: Every lesson starts with a problem, the pupils work in visibly random groups, and they work standing on vertical non-permanent surfaces (Liljedahl, 2020). These core activities also resonate with the Finnish curriculum, which emphasises for instance collaborative learning and physical activities as opposed to sedentary lifestyle (see Finnish National Board of Education, FNBE, 2016).

The teachers in the Finnish problem-solving project implement these three core activities in their lower secondary mathematics classrooms from the beginning of the school year. The rest of the 14 teaching practices they implement into their teaching gradually throughout the school year. For this, they receive intensive support through workshops and informal meetings with the researcher.

Methods

Participant

The teacher, Ashley, is a mathematics, chemistry, and physics teacher at a lower secondary school in Finland. She has 3 years of teaching experience after graduating from a university, where she majored in mathematics. Ashley takes part in the project with two mathematics groups, one group from 8th grade and one group from 9th grade (13-16 years old pupils).

Data collection

The data were collected during the first semester of the intervention through two interviews, classroom observations and informal discussions with Ashley between the lessons. The interviews were audio-recorded, while other data supports on field notes.

To answer the first two research questions about Ashley’s teacher identity and view of mathematics, the data were collected from the first interview that took place in the beginning of the intervention. The interview was about Ashley’s educational background, previous professional development projects, her prior and current teaching, insights into her possible future teaching, and about her hopes and needs for the intervention (cf. view of mathematics in Op’t Eynde et al., 2002). She was also asked to explain how certain she is about her knowledge and skills in mathematics.

The data for the third research question about Ashley’s professional development were collected through the second interview about two months after the start of the project, classroom observations and informal discussions over the time of the first intervention semester. These data focused on the experiences from using the new teaching method in Ashley’s mathematics classrooms.

Alongside with implementing the new teaching method into her teaching, Ashley took part in workshops that were built around the building thinking classroom–method. She was introduced to the main ideas and prior results of utilising the method in mathematics classrooms and given hints on how to deal with challenging classroom situations that might occur during the intervention. It is important to recognise the possible influence of the workshops on Ashley's professional learning.

Data analysis

The data were analysed through data-driven content analysis. The first part of the analysis focused on the first research question about the growth of Ashley's teacher identity. The analysis followed the professional developmental path that Ashley describes in the interviews from university studies to the beginning of the problem-solving intervention. Ashley's narrative made it possible study the affective factors that are central for her (Di Martino & Zan, 2015). Moreover, the issues that she highlighted from her past were interpreted as instances relevant to the development of her mathematics-related teacher identity (Lutovac & Kaasila, 2018).

To answer the second research question about tensions, Ashley's mathematics-related teacher identity was contrasted with the view of herself as a mathematics teacher and how she experiences her own mathematics teaching (cf. Op't Eynde et al., 2002). Tensions between the experienced and ideal mathematics teaching, as well as experienced teacher self and ideal mathematics teacher, were interpreted as (perhaps unconscious) needs for professional learning (cf. Andrá et al., 2019).

To answer the third research question, Ashley's expressed goals for professional learning together with the needs arising from tensions are discussed in the light of the opportunities that the problem-solving intervention offers for professional learning, and what changes in her mathematics-related teacher identity Ashley experiences during the first semester of the intervention.

Results

Developing mathematics-related teacher identity over time

Ashley is a young mathematics teacher with a strong need to find a teaching style that feels her own. She has been pursuing towards this goal since being a mathematics teacher student at university. While the university failed to give her enough opportunities to rehearse her mathematics teaching in practice (she reports only having two practice lessons in mathematics), and thus help her to develop a strong mathematics-related teacher identity, she has been testing different teaching methods systematically in her own secondary mathematics classrooms.

By the time of the problem-solving intervention, Ashley has been teaching in this specific lower secondary school for two years. During this time, she has pursued towards more pupil-led teaching practices. She has tried different methods, such as task cards, to support pupil autonomy in learning. She has been guiding pupils to take more responsibility of their own learning and to study mathematics at their own pace. The pursued changes resonate well with the current national curriculum (see FNBE, 2016). She has also tried to differentiate learning especially upwards to create challenges also to high achievers. In Finnish lower secondary school, extensive learning support is given for low-achievers by law, but whether and how the high-achievers receive suitable challenges is dependent on the individual mathematics teachers.

After the first year of working individually towards developing her teaching, Ashely started to collaborate more with two other teachers in her school. This community of practice (cf. Wenger, 1998) has become an important resource for her. The teachers share ideas as well as plan and develop their mathematics teaching systematically together. On the classroom level, their goal has been to engage pupils more in learning mathematics. The three teachers also participate in the reported problem-solving intervention together.

Despite the many professional development projects, implemented individually or with colleagues, and even though she has found methods that engage pupils more in mathematics lessons, Ashley feels that these attempts have not been successful in the sense of finding a teaching method that ‘feels her own’ (her own words).

Tensions in mathematics-related teacher identity

There are many tensions in Ashley’s experienced and ideal mathematics teaching. She is aware of these tensions when she talks about them but, at the same time, it seems that despite the many attempts she has not been able to find tools to answer these needs in her mathematics teaching.

The first tension is between the teacher-led and pupil-led teaching methods. Ashley pursues towards pupil-led learning where pupils take a bigger responsibility in their own learning. In some groups, using the task cards is a step in this direction. However, she finds herself talking a lot in the lessons and explaining mathematical content to the pupils instead of guiding them towards more self-regulated learning.

The second tension is between the processes and the outcomes of solving tasks in mathematics lessons. Ashley explains how she tries to emphasise the solution processes over the correct answers. However, what she experiences in classrooms is that pupils concentrate heavily on the correct answer. Even a small miscalculation can lead to the pupil thinking that the whole task was incorrectly solved.

The third tension is about the number and quality of tasks solved in mathematics lessons. At the university, she realised that mathematics is more about the thinking processes and having a small number of good tasks, rather than solving a big number of routine tasks. As a mathematics teacher, however, she feels that she has moved back to teaching through calculations, as she was taught self in school. Even if all pupils have the freedom to select tasks, the emphasis is on calculating and not on thinking.

Ashley’s view of herself as a mathematics teacher is very close to her view of a good mathematics teacher. She explains that, similarly as a good mathematics teacher, she is easily approachable, she is genuinely interested in pupils’ learning, she is fair, and treats all pupils equally. Additionally, she likes mathematics, but is highly self-critical towards her teaching. The researcher’s notes from mathematics lessons and after-lesson discussions support these self-reflections from the interviews.

In the interview, Ashley emphasises that a good teacher also masters the content, adapts to different situations, is up to date, and can revise her own teaching. These are all elements that Ashley can be related to through her self-efficacy beliefs of mastering the mathematical content to the purposeful development of her own teaching. Hence, even though not explicitly said, my interpretation is that Ashley sees herself as a good mathematics teacher.

Learning from the problem-solving project

When asked explicitly, Ashley's goal for the problem-solving project is (free translation):

> To find a way to teach mathematics that motivates pupils, so that it would be nice to come to the classes, it would be nice to be there, I would enjoy being there, and that we get things done. And that everyone is included, everyone gets some kind of support even if not originating from the teacher, and everyone gets experiences of success.

While the explicit goal for the project is more on the affective level, similarly as the need to find a teaching method that feels a natural part of herself, the tensions stemming from the interview data highlight more concrete needs; Ashley wants her teaching to be more pupil-centred, tasks to concentrate more on thinking rather than calculations as well as to the processes rather than the answers, and learning to be more qualitative instead of rushing through a long list of tasks.

The goals reflecting the tensions in Ashley's mathematics teaching are well in line with the building thinking classrooms–method (see Liljedahl, 2020). Already after two months of implementing the building thinking classrooms–method into her mathematics classrooms, Ashley starts every lesson with a problem (pupil-centred learning that fosters thinking), divides pupils visibly into random groups using playing cards (social gains, among other things), and have pupils work standing on vertical non-permanent surfaces (blackboard, whiteboard tape and windows). She has also paid attention to answering pupils' questions, creating tasks that support group discussion and the processes of learning, how to level learning in classrooms, and how to organise the physical classroom environment to support the desired classroom activities.

The changes in Ashley's classroom practices have been rapid. Only after two months, Ashley explains that she has found the basic idea behind the building thinking classrooms–method, and she has been able to adapt the method into a natural part of her teaching. The building thinking classrooms–method has answered to her needs, especially those viewed through tensions. She also feels that the intervention has had a positive impact on pupils' learning and on classroom climate. Whether the change is sustained over time, we will see after the problem-solving intervention is over (delayed interview and classroom observations).

Discussion

The purpose of the paper was to explore Ashley's mathematics-related teacher identity through view of mathematics and changes in her teacher identity, as well as through the link between identity and teaching practices (see Lutovac & Kaasila, 2018). These issues were studied through affective lenses with an individual emphasis.

The first research question drew attention to the development of Ashley's teacher identity. This question revealed a severe deficiency in Ashley's teacher education that led her to systematically search for teaching methods that would fit to her view of good teaching. The question also revealed the importance of the social aspect in creating a mathematics-related teacher identity. When Ashley talked about her previous professional development projects, she highlighted the importance of other mathematics teachers at her school. This community of practice (Wenger, 1998) has been a great resource for her in developing teaching and mathematics-related teacher identity. As a result, Ashley has high self-efficacy beliefs and confidence towards classroom inquiries.

The second research question focused on the tensions between Ashley's experienced teacher identity and her view of good mathematics teaching. There were no tensions recognised between Ashley's view of herself as a mathematics teacher and a description of a good mathematics teacher. This indicates a quite well-established teacher identity. Ashley was very aware of her strengths and weaknesses in mathematics, and she recognised many tension in her mathematics teaching (cf. Pillen, Beijaard & Brok, 2013). However, what was not recognised was the tension between the verbalised goals for the intervention and the tensions in Ashley's mathematics teaching. This realisation takes us to the third research question about Ashley's needs for professional development.

While novice teachers traditionally are willing to rethink their teaching practices (Liljedahl, 2014), Ashley was ready to reject bigger parts of her teaching. Ashley's needs for professional learning were connected to the teaching and learning activities rather than to mathematical content (Lutovac & Kaasila, 2018). As a result, the problem-solving intervention seemed to have a very positive impact on Ashley's identity building and professional development. After a short period of implementing the new teaching method into her mathematics teaching, Ashley started to see changes in the classroom practices (addressing tensions) and in the emotional atmosphere in the classroom (addressing goals), resulting in a method that 'feels her own'. While these results are encouraging for the success of the intervention, they also confirm some previous research results and raise questions.

First, it seems that the tensions Ashley recognised were at least partly solved. This confirms prior research about the nature of tensions, that is, previously incompatible tensions can be solved (Andrá et al., 2019). Second, teacher identity is a social construct (Wenger, 1998) that is influenced not only by colleagues but also by pupils in the classroom. The positive impact that the intervention had on Ashley's teacher identity was highly influenced by the pupils' actions and reactions in the classroom.

The questions that raised from the study are connected to the interrelation between tensions (needs) and goals (wants) in novice teachers' identity building and professional development. Ashley reported being successful in terms of pupils' learning and motivation also in her previous interventions. What seems to be different this time is, that the intervention also addressed the tensions in her teaching positively. Indeed, what seemed to be a challenge for Ashley was to identify the tensions as concrete goals for her professional development. So, are solving tensions more powerful tool for professional development than fulfilling teacher's goals? There is a need for further studies on the interrelation between tensions and goals in professional development projects that aim to improve classroom practices and teacher identity.

Cooperative learning in game theory activities

Giada Viola[1] and Alessandro Gambini[2]

[1] Sapienza University of Rome, Department of Mathematics, Italy; viola.1744430@studenti.uniroma1.it

[2] Sapienza University of Rome, Department of Mathematics, Italy; alessandro.gambini@uniroma1.it

The purpose of our paper is to analyse the effectiveness of group work and the role of the emotions in game theory activities. Such a setting, unfamiliar to most of the students, allows to build activities with more than one solution and more than one solving strategy. In particular, the activity concerning a cooperative game is reported and, following Kagel and Cooper's studies, it is highlighted how students involving in groups activities have a more strategic and successful approach than those who tackle them individually. One of the aims of this paper is to study the change of the vision of the mathematics after these activities, using the lenses of the Di Martino and Zan framework. Furthermore, this research looks at the metacognitive activities that are stimulated during the resolution and how they lead to the construction of shared knowledge.

Keywords: Cooperative learning, metacognition, game theory.

Introduction and theoretical framework

Problem solving and argumentation are essential skills, and they are one of the objectives of many educational systems (i.e., OECD PISA, 2021). These processes can be supported by collective work, that if it is done correctly, it triggers the process of collective metacognition that leads to the construction of shared knowledge. This study was carried out on game theory activities because this context allows us to analyse the students' ability to apply the knowledge acquired during their studies in unfamiliar situations (Antonini, 2019). This choice is justified by the desire to create a conducive environment to the development of the problem solving and the argumentation processes (Cramer, 2014).

Schoenfeld’s research shows that in order to solve a mathematical task correctly, there is a need to apply control processes. These processes involve understanding the text of the task, planning a strategy, controlling the situation, and managing one’s resources. Schoenfeld highlights the importance to be aware of one’s resources to be able to manage them. Furthermore, he analyses causes of failure or successful in activities of problem solving. The central elements are the beliefs and the individual’s perception of themselves. The beliefs depend on previous experiences with mathematics, and they influence the individual’s ability to use his or her knowledges (Schoenfeld, 1983). Beliefs, emotions, and attitude are very important elements in approaching mathematics; in fact, they are also essential in decision-making process. Emotional experiences are given by the combination of a cognitive and a psychological insight: the interruption of actions or a difference between facts and expectations can lead to an arousal (a general state of activation of the nervous system in response to internal or external stimuli). The emotional experience of the individual is given by the arousal and the formative evaluation of the experience. It is therefore clear that it is not the experience itself that arouses emotions, but the subject's interpretation of the situation, which depends on the individual's beliefs.

Di Martino and Zan highlight the importance of emotional component of the beliefs, in fact, the same belief can arouse different emotions in different individuals. They underline the need to use tools able to investigate the structure of the beliefs' system and to bring out the link between cognitive and emotional component. To analyse the data that emerged from their research, a model consisting of three dimensions was used (Di Martino & Zan, 2011): emotional disposition towards mathematics, perception of one's abilities and vision of mathematics.

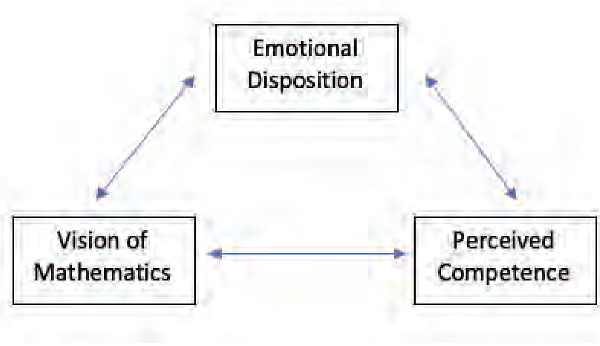

Figure 1: Di Martino-Zan three dimensional model for attitude (Di Martino & Zan, 2011)

It is possible to focus on the link between beliefs and emotions, in particular, negative emotional disposition, due to a negative approach with mathematics. A negative emotional disposition may be due to many characteristics that students assign to mathematics. This implies that there is a link between emotional disposition and vision of mathematics. The perception of one's abilities in mathematics influences the emotional disposition: in fact, the idea of successful in mathematics affects emotional disposition and thus the perception of one's competences.

There are many conceptions about idea of successful:

- successful identified with perception of the knowledge of rules and their correct application;
- successful identified with perceived knowledge of the meaning of the rules and their connection;
- successful identified with scholar successful.

The failure is often due to the link between negative emotional disposition and low perceived competence. Weiner classified the causes of the failure into (Weiner, 1986):

- local inside/local external: inside local causes depend on the subject, while external local causes depend on exterior features;
- stable/instable: whether or not it is possible to change them over time;
- controllable/uncontrollable: whether depend on the beliefs of subject.

Negative emotional disposition is a cause of failure in mathematics for some students. Low perceived competence and negative emotional disposition may be two independent dimensions: some students have a high perceived competence, but a negative emotional disposition and vice versa.

The development of activities in the game theory makes it possible to highlight how a collective performance promotes the activation of metacognitive processes to a greater extent. According to Kagel and Cooper (2005), those who tackle tasks in groups act more strategically than those who carry out them individually. Kagel and Cooper (2005) state that communication between individuals is a possible explanation for the more strategic approach taken by groups. Therefore, through confrontation with others, more ways to resolution were explored.

Cooperative learning is an approach in which small groups are created with students of different ability levels. The members of each group work together to achieve a common goal. The positive aspects of cooperative learning are group goals or positive interdependence, in which students must work together to achieve group success, and individual accountability. In other words, we mean the responsibility of everyone for the success of the group, which involves the motivation of each student to help to achieve the success of the whole group (Slavin, 1990). Efficient group work maximises the learning of each student.

Furthermore, organisational, cognitive, and metacognitive factors must be present for a group to successfully tackle problem solving activities. (Chalmers, 2009). Tuckman and Jensen's model of organisational factors consists of five phases that should be developed in the group activity: forming, storming, norming, performing and adjourning (Tuckman & Jensen, 1977). The first phase involves the setting up of the group work; in the second phase there is a comparison between the group members and the third phase is reached when a meeting point is found between the various ideas proposed. In the fourth phase the group members work together and in the last phase the work is reviewed. On a cognitive level, students need to develop shared knowledge in order to successfully complete the group work. Metacognition is defined as the student's awareness of her or his learning process; in the case of collective metacognition, each participant must be aware of his or her own and other group members mental processes through discussion and comparison. Collective metacognition requires that strategies of orientation, planning, monitoring, evaluation, reflection and elaboration are developed. Orientation is carried out before the problem occurs. Planning, monitoring and evaluation take place during the resolution of the task, while reflection and elaboration take place at the end of the task. These actions allow students to structure a solution strategy, monitor the processes involved, evaluate and interpret the results obtained and express the solution (Van der Stel et al., 2010). Comparison, along with the presentation of different points of view and questions from the group members help the construction of shared knowledge, allowing any individual difficulties to be identified and overcome. Each group member has their own solution strategy before determining the joint one, but previous studies have shown that groups perform better than they would have done individually (Frith, 2012).

By comparing with other group members, it is possible to produce different solution strategies to reach the final goal. Cooperative work, therefore, makes it possible to develop interaction between students, integration and to improve self-esteem (Slavin, 1990). Collective metacognition, moreover, helps to reduce the individual anxiety of failure by distributing it among all group members. The existence of a shared solution increases motivation to carry out such activities. Difficulties that may be encountered during a group activity are communication between individuals and cultural differences, aspects that may compromise collective metacognition (Chiu & Kuo, 2009).

Furthermore, one purpose of this research is to analyse, through two questionnaires, students' emotions and beliefs regarding mathematics and their vision about this discipline. It is important to understand the presence of a change about the student's vision on mathematics after carrying out activities.

Methodology

This experiment consists of two activities carried out within the game theory. One of the objectives of this research is to stimulate problem solving and argumentation processes, to make people take on different points of view, and to promote group activity and comparison between peers. At the end of each activity, an interview was conducted in order to capture the difficulties encountered during the task and some impressions regarding the group work. In addition, two questionnaires were proposed to the students: one at the beginning of the first task and one at the end of the second task. One of the purposes of the two questionnaires was to investigate the students' emotions and their vision on mathematics, and the second questionnaire also asked questions focused on the tasks carried out. The second questionnaire, moreover, analyses the change about student's vision on mathematics. Two questionnaires were created following Di Martino and Zan's researches (Di Martino & Zan, 2011): there were open questions to leave students free to express their emotions and closed ones to analyse specific aspects. Two questionnaires were compilated individually, while the interview was conducted during the final discussion about the activities' results.

Participants who took part in the experiment were 81 secondary school students, grade 9, 11 and 13, of the Italian education system (14-, 16- and 18-years old students). Three classrooms participated to experiment:

- classroom of grade 13 is composed by 29 students. In this classroom half of the students solved tasks individually;
- classroom of grade 11 is composed by 25 students;
- classroom of grade 9 is composed by 27 students.

In addition to these, the two activities were submitted to a "control group" consisting of mathematicians and non-mathematicians, to investigate the similarities and differences between the approaches adopted by high school students, mathematicians, and those with no specific mathematical skills. The control group was composed by people with different ages. In the control group there were 16 individuals, 10 students of master's degree in mathematics and 6 students of no mathematical course.

The experiment was carried out entirely remotely using platforms such as Zoom and Google Meet due to Covid-19 pandemic. Thanks to these, it was possible to create virtual rooms in which students could work in groups. The class of grade 13, due to classroom attendance regulations, was half in the classroom and half at home, so the task was carried out individually by those in the classroom and in groups by those remotely located. These roles were reversed in the second task. The control group took the task individually.

Each task took about two hours to complete. One hour was left for the students to solve the task in groups or individually. The remaining time was devoted to a collective discussion in which the students were able to compare and share the solutions they had arrived at and the reasoning for applying a particular strategy. During the discussion we noted students' statements to analyse their process of problem solving. In the following section we report some students' statements taken by interview's notes and answers to the questionnaires.

Analysis of the collected data

In this paper we focus on the data collected on the first task. The text is the following:

"In a shopping centre there are three shops, AltaModa, BlueJeans and CookLover, which need a new lighting contract. They have been offered several alternatives: if they take out the contract individually, they will pay €250, €200 and €350 per month respectively; if they decide to take out an overall contract, they will pay €600; alternatively, if they agree in pairs, the prices will be €350 per month for AltaModa and BlueJeans, €450 per month for AltaModa and CookLover and €420 per month for BlueJeans and CookLover.

Try to explain the offer and how the three shops could agree on the best offer. Give reasons for your answers."

The table below shows the solutions proposed by the test takers.

Table 1: Proposed solutions. A, B and C indicate expenses for A, expenses for B and expenses for C. % groups and % individuals represent the percentual of students' solutions.

Proposed solutions	**A**	**B**	**C**	**% groups**	**% individuals**
Equal division of the total contract	200	200	200	47%	65,5%
Proportional division of the total contract	187,50	150	262,50	31,5%	24%
Other solutions				21,5%	10,5%

The data comparison of this experiment shows, as argued by Kagel and Cooper (2005), that groups act more strategically than individuals. Students who took the test individually were unlikely to go beyond the first interpretation, namely the equal division of the overall contract. Analysing the response frequencies of both the students and the "control group", it emerges that less than 50% of the groups gave as their solution the equal division of the overall contract. On the contrary, among those who took the test individually, more than 60% supported this solution.

Equal division of the total contract is the most intuitive answer, to which everyone approaches at first stage; some individual students and most groups manage to move away from this first idea, planning other solution strategies.

Some students believed that the equal division was fairer because everyone pays less than or equal to the single contract, while others wondered if there was a division that provided savings for everyone, and this led to the formulation of new hypotheses for solving this task. In this way, those who reflected on these aspects showed that they implemented metacognitive actions such as monitoring and evaluation, as they were able to analyse and interpret the proposed strategies in the context of the problem. These considerations were more frequent in those who worked in groups. Groups that worked efficiently went through all the stages of Tuckman and Jensen model. The groups also took longer to reach a conclusion due to a more thorough analysis of the proposed strategies.

Kagel and Cooper research suggest that the groups should be able to arrive at an appropriate solution if it is proposed by at least one member of the group. The analysis of the group discussions shows that most of the times when a member proposed a strategy different from the first interpretation, the group was able to come up with a solution that deviated from the instinctive response, i.e., dividing the total contract equally. From the discussions in the groups, it is evident that the confrontation with others allowed the emergence of different points of view that led to various solution strategies. Sometimes some members of the group disagreed with the solution proposed by the team, on which occasions the students defended their ideas. At the end of the time allotted for solving the activity, most groups proposed an agreed solution.

Thanks to the interviews and questionnaires, it was possible to ask the students about their impressions of the interaction between groups. In the class in which the two activities were carried out by both individuals and groups, it was also possible to compare the two ways of carrying them out. For example, one request of questionnaires regarded the students' vision on mathematics. This question is proposed before and after the tasks. The why of this choice is justified by the needful to investigate the change of mathematics vision after carrying out the tasks. By students' responses emerged that their mathematics vision is changed thanks to this experience.

Some students stated:

Student 1: “I think my approach is changed: greater depth and focus on different strategies, without stopping at the first insights”;

Student 2: “We often think that mathematics is a strict science with certain rules, but in this activity, we were able to observe the existence of different points of view and different solutions”.

Moreover, in questionnaires, we asked them their impressions about interaction between groups.

Some students stated:

Student 3: “Group work helps, by exchanging ideas and thoughts you eventually reach the choice that is closest to the correct one”;

Student 4: “Every idea was made explicit to the whole group”;

Student 5: “initially I did not understand the problem very well, then the other members helped me to understand it”;

Student 6: “some ideas we had thought individually were changed by the analysis of the whole group, and others emerged thanks to the collective activity”;

Student 7: “it was a good confrontation, it was a ‘thinking together’ rather than a union of individual ideas: we perfected each other intuitions by helping each other.”

From the students own words, the comparison with others was useful for a better understanding of the problem: “...they helped me to understand it”. It also emerges that working together helped them to consider more strategies “...more emerged from the collective activity”. As Frith reports in his research (Frith, 2012), each student hypothesises his or her own solving strategy, but thanks to the collective activity, a better performance is achieved, by placing each proposed strategy under collective analysis. In some groups, the pupils advised their peers to identify with the situations or to consider the activities in a real context. This approach made it possible to concretely analyse the planned strategies and consider their possible implementation in real life.

Conclusion

In this paper we analysed capacity of students to act exploration of the problem, planning of strategies to be implemented, identifying objectives to be achieved. In particular, we focused the attention on the problem solving and the argumentation process and their implementation in group activity. In most cases, the collective performance of such tests ensured, the planning of a greater number of solution strategies and a more in-depth analysis of the procedures implemented and the results obtained. Each participant observed the work of the others, which made it possible to assess the effectiveness of the strategy. Through the exposition of different points of view and the analysis carried out by each component, almost all the groups managed to build a shared knowledge. Difficult students put their doubts to their peers and thanks to the explanations, sometimes repeated, of the other group members, they overcame their critical points. From the previous statements, moreover, we can see the implementation of metacognitive activities that led to the construction of shared knowledge. In fact, thanks to the support and the analysis of each group member, they were able to refine their initial ideas and make their peers understand things that were not clear.

The students themselves acknowledged that working efficiently in a group is better than working individually:

> Student 8: "I think that by working well in groups you can do more than you would do alone".

Those who had the opportunity to work on the activities once individually and once in a group stated that they enjoyed better working collectively. The development of individual metacognition, therefore, was supported by collective metacognition. In this way, thanks the collective work to achieve a shared solution, the motivation to carry out tasks was increased. In a few groups, the work was not conducted fruitfully, with little participation by some members. In such situations, however, collective metacognition was compromised, as students did not compare, preventing the construction of shared knowledge. The data collected through questionnaires allow to analyse subjects' emotional approach in these activities. From responses to the first questionnaire, some students stated that they had a good emotion regarding mathematics, but more than 60% of the students stated: "I like mathematics because I obtain good results". This highlights a strong link between emotional disposition and the idea of successful on mathematics (Di Martino & Zan, 2011). An interesting fact, obtained by responses to the second questionnaire, is the change of the students regarding the vision on mathematics. After these activities the students have more perception about the usefulness of the mathematics in the real life and they have had the opportunity to do mathematics in a different way.

As the tasks were solved, many groups stated that they were satisfied with the work done. Collective activity, in fact, helps to reduce the individual anxiety and fear of failure, distributing it among all the components. In fact, the answers given in the first questionnaire show that many students have contrasting emotions regard mathematical activities, but these students stated, in the second questionnaire, that they valued the group work positively. These results underline how cooperative learning is a positive element for a better approach with mathematics, but also for improving the emotional disposition towards mathematics. Observing the work and discussions of the groups, it emerged that in the classes where students are used to working in groups, there was more interaction and better organisation.

Development of math anxiety in prospective elementary teachers

Thorsten Weber, Elisabeth Rathgeb-Schnierer and Andreas Eichler

University of Kassel, Department of mathematics, Kassel, Germany;
Thorsten.Weber@uni-kassel.de

Some people develop math anxiety whenever they are confronted with tasks that require mathematical skills. Math anxiety influences learners and their performance negatively. Furthermore, the math anxiety of teachers has an impact on their students. Therefore, one challenge of elementary teacher education is preventing and reducing math anxiety, especially at the beginning of the teacher training program. In this study, we investigate the development of math anxiety in prospective elementary teachers in Germany during the first semester at university. We provide the first results regarding the influence of math anxiety on dropouts at the beginning of the teacher training program. Finally, we describe differences regarding the development of math anxiety of prospective elementary teachers at three universities.

Keywords: Math anxiety, first-semester changes, transition, teacher training.

Introduction

Research on math anxiety covers a large field of work with different directions and focuses (Hembree, 1990; Zhang et al., 2019). Math anxiety is defined as "*a feeling of tension and anxiety that interferes with the manipulation of numbers and the solving of mathematical problems in a wide variety of ordinary life and academic situations*" (Suinn & Winston, 2003; Visscher & White, 2020). The math anxiety of a prospective teacher not only affects her/his performance at university (Hembree, 1990; Pekrun et al., 2006; Zhang et al., 2019) but also as an elementary school teacher. Therefore, teachers' math anxiety affects learning situations (Visscher & White, 2020) and the performance of their students (Beilock et al., 2010). Whereas math anxiety and math teaching anxiety are two separate constructs, both are related (Brown et al., 2011). Math anxiety can lead to anxiety about teaching mathematics (Brown et al., 2011; Hadley & Dorward, 2011; Zhang et al., 2019). Because of the influence of math anxiety on teaching, elementary teacher training in mathematics is a big challenge for universities. Particularly at the beginning of the teacher training program since first-year students often exhibit a transition shock (Gueudet, 2008) which may increase the math anxiety.

Elementary teacher training in mathematics is supposed to substantially educate prospective elementary teachers and simultaneously prevent or even reduce their math anxiety. According to the definition, there are various dimensions of math anxiety, and the question arises which dimensions are crucial for elementary teachers. Based on the national curriculum in Germany, math education in elementary school is supposed to promote problem-solving, argumentation, and communication (KMK, 2004). Accordingly, elementary teacher education targets to qualify prospective teachers for problem-oriented teaching (Eichler et al., 2022). From this perspective, two dimensions of math anxiety are relevant for teacher training: problem-solving and explanation anxiety (Visscher & White, 2020). Hence, we focus on the development of both dimensions in our study.

In Germany, there are specific training programs for elementary teachers. Mathematics is a compulsory subject in most of those programs, and prospective elementary teachers are obliged to attend courses in math education. In our study, we focus on the teacher education of prospective elementary teachers and analyze the development of their math anxiety in the first semester.

Aims and questions

The presented study targets to answer three questions on math anxiety of prospective elementary teachers. Based on the negative influence of math anxiety we investigate the transition from school to university by examining those in their first semester at three German universities.

RQ1: Does the math anxiety of prospective elementary teachers change in the first semester?

RQ2: Does the development of math anxiety of prospective elementary teachers differ at different universities in the first semester?

RQ3: Do prospective elementary teachers who dropped out of the math course show a different level of math anxiety at the beginning of the study than those who passed the course?

The third question refers to those prospective elementary teachers who filled out the questionnaire at the beginning of the semester but not at the end. We do not know the exact reasons for these dropouts, but we assume most of these prospective elementary teachers did not complete the math course in their first semester. The question arises if there is a different level of math anxiety at the beginning of the semester in prospective elementary teachers who completed the course and those who dropped out.

Methodology

Instruments

For measuring math anxiety, it is relevant to use scales of math anxiety that align well with the kind of math we are asking teachers to teach mathematics in the classroom. Therefore, we collected data with the math anxiety scales from Visscher and White (2020) that include Likert scales for answers: ”Not at all”; ”A little”; ”A fair amount”; ”Much”; ”Very much”. Table 1 shows the original scales. For collecting data in German universities, we translated these scales into German. Table 1: Math anxiety items (Visscher & White, 2020).

Table 1: Items of math anxiety constructs

Factor 1 – Problem-solving anxiety		
1	Working on a math problem for which you are not sure where to start.	*Items pertaining to difficulty of problem*
2	Being given a math problem that does not look like any problem you have seen before.	
3	Being asked to solve a math problem when you are not sure which formulas to use.	
4	Working on a math homework problem and not making any progress for 5 minutes.	
5	Being assigned an extra-long math homework set.	*Items pertaining to length of problem set*
6	Beginning to work on a multi-page math worksheet.	

Factor 2 – Explanation anxiety		
7	When you are partway through figuring out a math problem, being asked to share your thinking with a classmate.	*Items involving internal doubt*
8	Sharing your solution with a small group of classmates when you are not sure it is	
9	Explaining your attempt at a math problem to a classmate, even though you are not very convinced that it is right.	
10	Describing to a small group of classmates how you went about a homework problem on which you received a perfect score.	*Items involving external validation*
11	After reaching an “aha!” moment on a problem on your math worksheet, being asked to explain your solution to a small group of classmates.	
12	Being asked by a classmate to go through your correct solution more slowly.	
13	Being asked to further justify why your mathematical solution is correct to a classmate who is not yet convinced.	*Items involving external doubt*
14	Having to convince a classmate that your different way of solving a math problem is equally valid.	
15	Continuing to explain your mathematical solution, even though a classmate doubts it is correct.	

Procedure

The study followed a pre-post design. Data collection took place in the winter semester 2019/2020 in math courses for prospective elementary teachers in their first semester (in the first and the twelfth lecture). We created a pseudonym for each participant to merge the paper-based questionnaires from the pre-and the post-test. Figure 1 shows the design and the differences between the three universities.

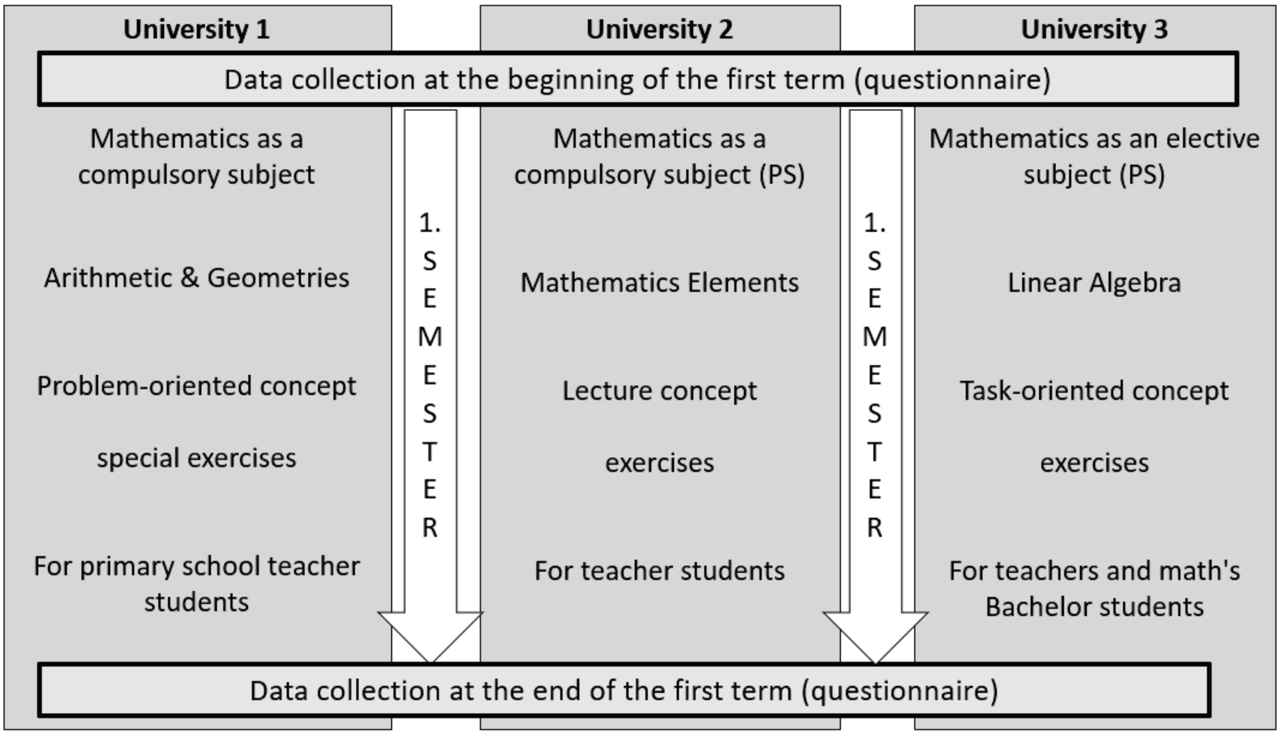

Figure 1: Design of the study and university differences

Sample

We decided to include prospective elementary teachers from three universities with three different math courses for beginners. The sample comprises 583 prospective elementary teachers; 400 participated in both surveys (University 1: 183; University 2: 150; University 3: 67); 183 only participated in the first survey, and we assume these are dropouts.

Analysis

There are several missing values in this data set which we excluded. If values are not randomly missed, deletion of cases with missing values biased the data. Despite a non-significant Little-Test (Little, 1988) (χ^2=*454,418, p = 0,251*) for item-nonresponse data, we assume the data is biased because of several unit-nonresponse data. We compared the scores of math anxiety of dropouts (missing data at the second survey time) with the complete data sets. The goal was to disclose differences between both groups and detect whether math anxiety at the beginning of the term can increasingly lead to the termination of the math course.

To check the quality of the data on an empirical basis (because we translated the items into the German language), we perform factor analysis. The Kaiser-Meyer-Olkin measure was *.823* and showed a relatively good factor analysis. Bartlett´s test of Sphericity was significant *(p < .001)*, indicating that correlations between items were sufficiently large for performing factor analysis. Based on the five dimensions of the scales of Visscher and White (2020), we used the maximum likelihood method and a varimax-rotated five-factor solution. Kaiser´s criteria and the scree-plot justified the extraction of five factors. One of the five factors has an eigenvalue just below *1*; four factors have eigenvalues *>1*. In total, these five factors explain *55,91%* of the total variance. Most of the items loaded highly on one factor. Only item 4 loaded on two of the five factors: comparably low on both. Therefore, it was excluded from the subscale about the difficulty of problems.

For reliability analysis, we calculated Cronbach’s alpha to assess the internal consistency (Table 2):

Table 2: Internal consistency of the math anxiety scales

	Problem solving anxiety			***Explanation anxiety***			
	Whole scale	*Difficulty of problem*	*Length of problem set*	*Whole scale*	*internal doubt*	*external validation*	*external doubt*
First survey Time	.80	.79	.75	.83	.84	.68	.78
Second survey time	.85	.82	.82	.87	.82	.70	.82

The first question was answered with a repeated measure t-test for contiguous samplings. To answer the second question, we use the data from prospective elementary teachers who participated in both surveys and perform a variance analysis with repeated measures. Regarding the third question, we assume all prospective elementary teachers who participated in both survey times completed the course regularly; all those who did not participate in the second survey terminated before the end of the semester. Therefore, we use the data of the first survey time and compare dropouts and prospective elementary teachers who complete the first semester in full. We consider this a limitation of our study since there are several reasons for not taking part in the post-test. Since the Levene-Test was not significant, we can assume variance homogeneity and perform the t-test for unpaired samples.

Results

Table 3: Development of math anxiety

	df	*t(df)*	*p*	*Cohen´s d*
Problem solving anxiety	399	- 2.82	.005**	0.14
Difficulty of problem	399	- 2.10	.036*	0.11
Length of problem set	399	- 1.53	.127	
Explanation anxiety	399	- 3.94	< .001**	0.20
internal doubt	399	- 3.02	.003**	0.15
external validation	399	- 1.93	.054	
external doubt	399	- 3.84	< .001**	0.19

Table 3 illustrates that the problem-solving anxiety decreased significantly over the first semester with weak Cohen's d effect sizes. Looking at the results of the problem-solving anxiety subscales, we see two opposing developments: a significant decrease within the difficulty of the problem but no significant development within the length of the problem set. The explanation anxiety decreased significantly over the semester, too. For the subscales, we can see that the internal and external doubts decreased highly significantly over the semester, while the external validation subscale barely reached statistical significance. The effect size of all significant developments of the subscales is weak, too. Therefore, we can speak of a weakly decreasing math anxiety in the first semester.

Table 4: Differences in the development of math anxiety

	df	*F*	*p*	*partial* η^2	*Cohen´s f*
Problem solving anxiety	2; 397	2.40	.092		
Difficulty of problem	2; 397	7.47	.010*	.036	.19
Length of problem set	2; 397	.21	.809		
Explanation anxiety	2; 397	.01	.986		
internal doubt	2; 397	.31	.388		
external validation	2; 397	.05	.952		
external doubt	2; 397	.81	.443		

Table 4 illustrates the differences in the development of math anxiety in prospective elementary teachers at several universities. While we found no statistical evidence of differences regarding the development of problem-solving and explanation anxiety among prospective elementary teachers from different universities and no differences in 4 of 5 subscales, we found significant differences in the development of the subscale difficulty of a problem. The Cohen's f effect size is *.19*, and therefore a weak effect. Bonferroni-adjusted post-hoc analysis revealed no significant difference between the universities in a pairwise comparison (University 1 vs University 2: *-0.001, 95%-CI[-0.17, 0.17]*)

(University 1 vs University 3: *0.127, 95%-CI[-0.0917, 0.35]*) (University 2 vs University 3: *0.128, 95%-CI[-0.10, 0.35]*). This determined the interaction effect, but the post-hoc test does not clarify which universities are different. Figure 2 illustrates that subscales about the difficulty of a problem increased at university two, whereas they decreased in universities one and three. For these differences in development, we did not find statistically significant results. However, the development of this subscale may not always be the same.

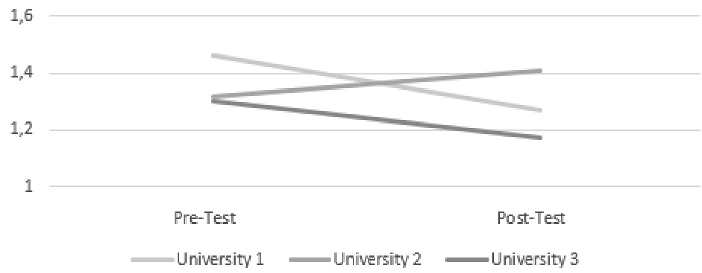

Figure 2: Problem-solving changes regarding the difficulty of a problem

Table 5: Dropouts

	Mean difference	*df*	*t(df)*	*p*
Problem solving anxiety	.013 95%-CI [-0.10, 0.13]	581	.22	.829
Difficulty of problem	- .025 95%-CI [-0.16, 0.10]	581	.39	.699
Length of problem set	.028 95%-CI [-0.13, 0.18]	581	- .35	.723
Explanation anxiety	.003 95%-CI [-0.09, 0.09]	581	.07	.947
internal doubt	– .047 95%-CI [-0.19, 0.10]	581	- .65	.515
external validation	.018 95%-CI [-0.06, 0.10]	581	.44	.661
external doubt	.021 95%-CI [-0.09, 0.13]	581	.36	.721

In summary, results reveal no differences in problem-solving and explanation anxiety at the beginning of the semester of prospective elementary teachers who terminated and those who completed the math course (see Table 5).

Discussion

The results show that math anxiety decreased over the first semester, despite the transition shock (Gueudet, 2008). We conclude that math courses in the first semester can help to reduce the problem-solving and explanation anxiety of prospective elementary teachers. In addition, results suggest that the directions of the developments are similar. Regarding the development of explanation anxiety, first-semester training helps to reduce both internal and external doubts, but explanatory anxiety does not decrease significantly after external validation. To summarize, the first semester can have various impacts on problem-solving and explanatory anxiety. Teachers generally avoid situations in the classroom that could cause anxiety for themselves or their students (Visscher & White, 2020). In this respect, our results are promising because lower problem-solving anxiety of teachers might lead to more problem-solving activities in school, and lower explanation anxiety might lead to more and better explanations in classrooms. Moreover, the transition between school and university, also called transition shock (Gueudet, 2008), does not impair the math anxiety of the prospective elementary teachers at the three universities. In this respect, it is possible the transition is either not perceived as a shock or has been mitigated and does not affect the math anxiety of prospective elementary teachers. However, reducing math anxiety in the first semester is desirable since it may indirectly support problem-oriented teaching.

We predominately see similar patterns in the development of problem-solving and explanation anxiety at the three universities. All three math courses similarly influence the problem-solving and explanation anxiety, despite the differences in content, learning concept, structure, lecturer, and participants. There is only a significant difference with a weak effect in the subscale of the problem-solving anxiety regarding the aspect difficulty of a problem.

In general, our results suggest the math course during the first semester influences the development of math anxiety in prospective elementary teachers, and it is possible to reduce math anxiety in this period. Due to the design of our study, the results only allow general statements about the development of math anxiety of prospective teachers, but no conclusion regarding the impact of a specific approach. However, the significant differences in the subscale "difficulty of a problem" might indicate that the different concepts of the math courses (see Figure 1) influence prospective elementary teachers' development of math anxiety differently. Since math anxiety can lead to anxiety to teach mathematics (Brown et al., 2011; Hadley & Dorward, 2011; Zhang et al., 2019), there is further research required to get detailed information about the effect of specific teaching approaches for university math courses.

Finally, the problem-solving and the explanation anxiety at the beginning of the math course has no influence on the progression during the first semester. Our results suggest the degree of math anxiety prospective elementary teachers exhibit at the beginning of the teacher training program is no crucial factor for passing the math course. Instead, the development of math anxiety within the first semester might have a higher impact on dropouts. However, based on our results, we only can draft this assumption but not empirically prove it. We do not know whether the participants who missed the second survey were dropouts or had other reasons, such as illness, individual problems, other appointments, delays, or refusal to answer the questions. This missing knowledge is a limitation of our study. To investigate the influence of math anxiety on dropouts, we need a study design for future research that measures math anxiety several times: at the beginning, in the middle, at the end of the semester, and one measure parallel to the final assessment. Possibly, this allows us to conclude the development of math anxiety and its influence on dropouts.

The purpose of this study is to analyse relations between students' attitude towards mathematics, prior knowledge, self-efficacy, expected grades, and performance in mathematics among 115 first-year engineering students. We combine two statistical techniques to analyse the data we generated by questionnaires and two tests. First, item-level modeling, in terms of confirmatory factor analysis, which we use to compute the factor scores of construct-validated measures, and to control for measurement errors. Second, composite modeling, in terms of path analysis, which we use to test the research hypotheses. The findings show that both self-efficacy and expected grades have substantial effects on students' performance. Prior knowledge has a non-trivial effect on self-efficacy which, in turn, plays a significant role in students' grade expectations. All other hypothesised relations are not significant. We argue that these findings confirm some basic tenets of social cognitive theory.

Keywords: Affect, higher education, item-level modeling, path analysis, self-efficacy.

Introduction

Affect in mathematics education

Students' affect is critical not only to their well-being but also to their performance in mathematics. Following the lines of thought proposed by Hannula (2012), we define affect in mathematics education research as a general concept that encapsulates factors, other than purely cognitive ones, such as attitude, beliefs, emotions, feelings, goals, moods, motivation, norms, values, and self-efficacy. Thus, each factor that constitutes a unit of mathematics-related affect is regarded as an overlap between cognition, emotion, and motivation of varying stability with psychological, physiological, and social dimensions (Hannula, 2012). Prominent among the mathematics-related affect factors are attitude towards mathematics and self-efficacy. It is arguable that the former is prominent for its incoherent conceptualisations within mathematics research community (Di Martino & Zan, 2010) while the latter is prominent for its high predictive power of performance and its causal relation with students' mathematics performance (Roick & Ringeisen, 2018; Zakariya, 2021a).

Attitude towards mathematics

In line with the theoretical framework proposed by Hannula (2012), attitude of students towards mathematics (henceforth, attitude) shares a boundary between cognition (e.g., knowledge), emotion (e.g., likes and dislikes), and motivation (e.g., internal and external drives to approach or refrain from mathematics activities). It can be operationalised and measured using self-report psychometric research measures. Empirical evidence shows attitude is predicted by prior mathematics knowledge (henceforth, prior knowledge) and it predicts students' subsequent performance on mathematics tasks (Chen et al., 2018; Lipnevich et al., 2016). Students that belief in their mathematics ability, those that like mathematics, and those that approach mathematics with its pre-conceived utility for future aspirations are usually successful in mathematics tasks. On the flip side, students that do not belief in their mathematics knowledge, those that dislike mathematics, and approach mathematics with ill-conceived utility of mathematics for future aspirations are usually unsuccessful in mathematics tasks. Some researchers (e.g., Kiwanuka et al., 2020) have also shown that there is a reciprocal effect between attitude and performance in mathematics. That is, high achievers tend to develop positive attitude. In return, students with positive attitude tend perform well on mathematics tasks. Thus, attitude plays a crucial role in students' success on mathematics tasks.

Mathematics self-efficacy

Self-efficacy has its roots in social cognitive theory as propagated in decades of work by Albert Bandura. It entails "beliefs in one's capabilities to organize and execute the courses of action required to produce given attainments" (Bandura, 1997, p. 3). As it relates to mathematics learning, self-efficacy is students' self-evaluation of competence to proffer correct solutions to mathematics tasks (Zakariya, Nilsen, et al., 2020b). It is a combination of confidence in ones' capacity and an estimation of outcome that follows ones' effort. There are four sources of self-efficacy – mastery experience, vicarious experience, social persuasion, and affective states – among which mastery experience i.e., self-interpretation of previous attainment has the highest influence on self-efficacy (Zientek et al., 2019). An accumulation of evidence suggests that self-efficacy is one of the best predictors of mathematics performance. Students with high sense of self-efficacy have low mathematics anxiety, adopt deep approaches to learning, and perform well on mathematics tasks (Rozgonjuk et al., 2020; Zakariya, Nilsen, et al., 2020b). Evidence supports consistency of a model of reciprocal effect between self-efficacy and mathematics performance with generated data across 24 countries (Williams & Williams, 2010). Moreover, Zakariya (2021a) provides a tentative evidence for causal effect of self-efficacy and performance in mathematics. Thus, self-efficacy is a critical factor for students' success in mathematics.

Relations between attitude and self-efficacy

The relationship between attitude and self-efficacy coupled with their combined effect on performance has been sparingly studied. Yet, the results of the available studies are promising. Randhawa et al. (1993) using structural equation modeling show that attitude significantly predicts self-efficacy which in turn predicts students' performance in mathematics. More so, the effect of attitude on performance is partially mediated by self-efficacy in a non-trivial way. However, the study by Randhawa et al. (1993) is relatively old and focuses on high school students whose findings may not be of direct relevance to undergraduate students. In a more recent study involving seventh graders, Recber et al. (2018) show that there is a non-trivial positive correlation between attitude and self-efficacy. Further, both constructs are significant predictors of performance in mathematics (Recber et al., 2018). Regrettably, correlation between two variables has limited value in terms of inferential deductions and tangible conclusions. A similar limitation can also be ascribed to the study by Öztürk et al. (2019) who report a correlational analysis between attitude and self-efficacy, and their predictive effect on performance of middle school students in mathematics.

The present study

The intention of the present study is to provide an evidence-based model of relationship between attitude, self-efficacy, prior knowledge, and undergraduate students' performance (expected and actual) in mathematics. This study differs from the previous attempts in many ways. First, we approach the analysis from structural equation modeling (SEM) perspective, instead of correctional analysis, which avails us the opportunity to test theory-based hypotheses. Second, we focus on undergraduate engineering students, who have mathematics as a core subject but whose affect (i.e., relations between attitude and self-efficacy) appears not to be given much attention. The inclusion of other factors such as prior knowledge and expected grades in our model constitutes another difference from the previous attempts. In specific terms, the present study addresses the following research question: To what extent do attitude, self-efficacy, prior knowledge, and expected grades predict each other and undergraduate students' performance in mathematics?

To address the research question, we draw on theoretical foundations and some insights from literature to hypothesise that attitude, expected grades, and self-efficacy predict performance and are predicted by prior knowledge. We admit that there is a possibility of reciprocal effect between attitude and self-efficacy. However, we ensure temporary precedence by collecting attitude data eight weeks before collecting data on self-efficacy. As such, we hypothesise that attitude has a non-trivial positive effect on self-efficacy. Given that outcome expectancy is an integral part of self-efficacy, we hypothesise positive effect of self-efficacy on students' expected grades.

Methods

Participants and measures

One hundred and fifteen undergraduate students (90 males) voluntarily gave consent and took part in the study that lasted for a semester. These students, average age between 21 – 25 years, followed a first-year calculus course in a Norwegian university. They completed attitude towards mathematics questionnaire (AtMQ) and sat for a test of prior mathematics knowledge (TPMK) in the third week of the semester. On the one hand, the AtMQ is a five-item measure (sample item: I'm interested in what I learn in math) designed to expose a single construct on a four-point Likert scale from strongly disagree to strongly agree. On the other hand, TPMK is a 16 – item (22 subitems) test of basic algebra, functions, and geometry. Previous studies show that both AtMQ and TPMK demonstrate appropriate validity and have acceptable indices of reliability of .92 and .78, respectively (Zakariya, Nilsen, Bjørkestøl, et al., 2020; Zakariya, Nilsen, et al., 2020a). Further, we administered calculus self-efficacy questionnaire (CSEI) at the end of the semester. The CSEI is 13-item measure on which students are to rate their competence to solving presented exam-like first-year calculus tasks on a scale of 100 points, whose validity and reliability indices have been previously studied with promising results (Zakariya et al., 2019). As a measure of expected grades, an item was appended to CSEI that asks students to report their expected grades in forthcoming calculus exam, at the time. The students' final exam scores in the calculus course serve as a measure of performance in mathematics. The full measures are available as appendices in the referenced validation studies.

Data analysis

We analysed the generated data using some techniques of SEM in two stages. Stage one involves evaluating measurement models for AtMQ, CSEI and TPMK, using confirmatory factor analysis. The rationale for this analysis is to detect and correct misspecification errors in the measurement models prior to hypothesis testing. Simultaneously, we confirm construct validity of each of the measures and compute the factor scores. The second stage of the analysis involves testing the hypothesised relations between the research constructs. We evaluate the structural models using robust maximum likelihood (MLR) estimator. The models are assessed for their global fits of the generated data using a combination of criteria. The model exhibits an exact global fit of the data if the chi-square value is not significant. There is an excellent fit of the data if the comparative fit index (CFI), Tucker-Lewis index (TLI) are greater than or equal to .95, and root mean square error of approximation (RMSEA) is either ≤ .06 or its 90% confidence interval (C.I.) contains 0.06 (Chen, 2007). The model exhibits an appropriate global fit of the data if the ratio of chi-square value to the degree of freedom is less than 3, CFI and TLI are close to or greater than .90, and RMSEA is less than .08 (Bentler, 1990; MacCallum et al., 1996). Significant parameter estimates show that the model exhibits a local fit of the data. We run all the analyses in Mplus 8.5 software.

Results and discussions

Measurement models

The first set of results concern evaluations of measurement models for each of the measures. For both AtMQ and CSEI, we evaluated a one-factor model each using MLR estimator. Following the recommendation by Zakariya (2021b), we correlated disturbances of item 2 and item 4 of AtMQ to improve the model fit. In a similar manner, we correlated disturbances of item 9 with item 11 and of item 12 with item 13 to achieve a model fit as recommended by Zakariya (2021a). Further, we evaluated a one-factor model of TPMK using robust unweighted least squares (ULSMV) estimator. This estimator takes care of the categorical scoring of the TPMK. The best 17 out of the 22 subitems of the TPMK are used for this analysis as recommended by Zakariya, Nilsen, et al. (2020a). The results are presented in Table 1.

Table 1: Goodness of fit statistics of measurement models of the research measures

Global fit indices	AtMQ model	CSEI model	TPMK model
Chi-square estimate (χ^2)	7.846	99.151	129.769
Degrees of freedom (df)	4	63	119
p – value	.097	.003	.236
χ^2 / df	1.962	1.574	1.090
RMSEA [90% C. I.]	.091 [<.001 - .186]	.071 [.042 - .096]	.028 [.042 - .056]
CFI	.982	.905	.968
TLI	.954	.882	.964

The presented results in Table 1 show that there are exact fits of both AtMQ and TPMK models with the generated data. The non-significant chi-square values coupled with RMSEA, CFI, and TLI values that are within recommended ranges support the claim of exact fits of both AtMQ and TPMK models. That is, both AtMQ and TPMK measure the constructs (attitude and prior knowledge, respectively) they are purported to measure. More so, Table 1 reveals that CSEI model exhibits an appropriate model fit of the generated data. The chi-square value is significant but its ratio to the degree of freedom is less than 3. More so, the RMSEA value is less than 0.08 and both CFI and TLI are close to .90. These values support the appropriate fit of the CSEI model. That is, the CSEI measures the calculus self-efficacy of students it is supposed to measure.

Hypothesis testing (Addressing the research question)

After the evaluation of the measurement models of all the measures, we compute the factor scores of both AtMQ and CSEI using the default maximum of the posteriori distribution in Mplus because of the continuous nature of their datasets. On the other hand, Mplus uses maximum a posteriori method to compute the factor scores of TPMK because of the categorical nature of the dataset. Then, we saved the scores and use them to evaluate the hypothesised structural model of relationships between the research constructs. This evaluation avails the opportunity to test the research hypotheses and address the research questions. Figure 1 presents the goodness of fits statistics and the final evaluated model.

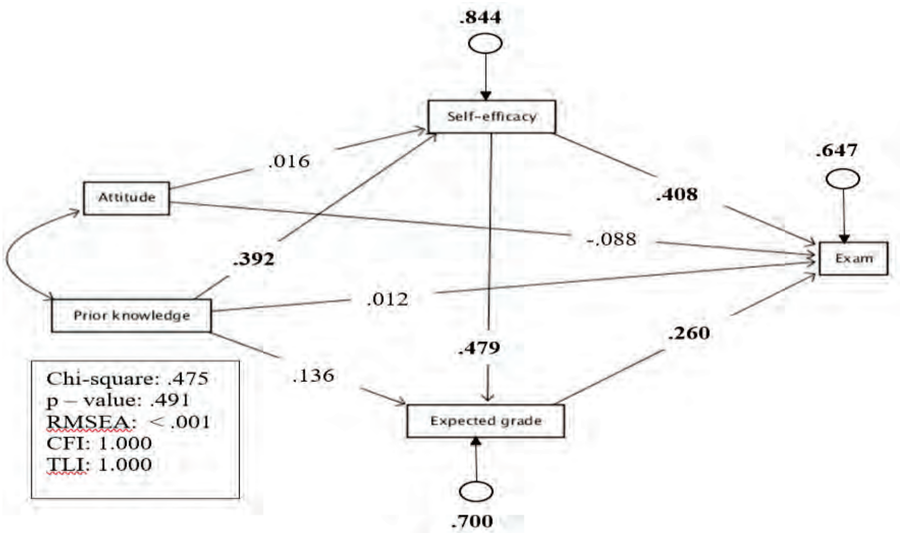

Figure 1: Evaluated hypothesised model of relationships between the research constructs with significant parameter estimates in bold faces

The presented results in Figure 1 shows some interesting findings. From the model fit perspective, Figure 1 shows that there is an exact model fit. That is, there is consistency between the hypothesised relationships and the generated data. In line with the postulations of the present study, Figure 1 confirms that self-efficacy and expected grades are significant predictors of students' performance in mathematics. That is, both high sense of self-efficacy and high students' expectations in the exams lead to high performance in mathematics. These findings corroborate previous studies (Rozgonjuk et al., 2020; Zakariya, 2021a) that have shown non-trivial relationships between self-efficacy and performance in mathematics. In support of the hypothesis of the present study, prior mathematics knowledge significantly predicts self-efficacy. This finding confirms a tenet of social cognitive theory that says that mastery experience (students' prior attainments) is an integral source of self-efficacy (Bandura, 1997). Figure 1 also provide empirical support for the non-trivial effect of self-efficacy on students' expected grades. This finding confirms the postulation of social cognitive theory that theorised outcome expectation as an integral part of self-efficacy (Bandura, 2012). Admittedly, it is logical that expected grade has a reverse effect on self-efficacy. However, we acknowledge this fact and take care of it by ensuring temporary presence with self-efficacy measure coming before the item on expected grade during the questionnaire administration. We recommend that future studies should be designed with this intention.

Contrary to the postulations of the present study, attitude fails to predict both self-efficacy and students' performance in mathematics. This assertion is deduced from Figure 1 that shows that the path coefficients (.016 and -.088) between attitude and the two variables (self-efficacy and exam) are not statistically significant. This finding that attitude does not predict mathematics achievement is aligned with some previous studies (e.g., Fernández-Cézar et al., 2021) although it does not support other studies that have reported substantial relationships between attitude and both self-efficacy and performance (Chen et al., 2018; Öztürk et al., 2019). It is possible that the findings of previous studies are not generalisable to our context. Another explanation for these unexpected findings could be a defect from the measure of attitude. Perhaps, the students had a different interpretation of AtMQ items from what the researchers intended. A future study may be designed to explore students' interpretations of these items. More so, Figure 1 shows that there is no evidence in the present study to substantiate non-trivial effects of prior knowledge on both the students' expected grades and performance in mathematics because the path coefficients (.012 and .136) are not significant. These findings are unexpected as well. A possible explanation could be a lack alignment between the knowledge assessed by PKMT and that of the current course. This observation requires further investigation. In sum, the results of the hypothesis testing address the research question by showing the extent to which attitude, self-efficacy, prior knowledge, and expected grades predict each other and undergraduate students' performance in mathematics.

Conclusion

We made some attempts in the present study to disentangle the complex relations between attitude, prior knowledge, self-efficacy, expected grades, and performance in mathematics among engineering first-year students. We combined item-level structural equation modeling techniques with composite modeling by using confirmatory factor analysis to compute factor scores which we further used in path analysis. This combined analytical procedure offers two advantages. First, we minimize biases from measurement errors by incorporating them in the item-level analysis. Second, we evaluate a complex model using a relatively small sample which would not have been possible, otherwise. The findings provide empirical support for substantial effect of self-efficacy and expected grades on students' performance in mathematics. They also confirm some theoretical postulations such as the crucial role of self-efficacy in students' outcome expectations on mathematics tasks. By implication, the findings support interventions on self-efficacy as a proxy to improve students' performance in mathematics.

TWG09: Mathematics and Language

Introduction to the work of TWG09: Mathematics and language

Jenni Ingram[1], Kirstin Erath[2] and Ingólfur Gíslason[3]

This paper is a summary of the work and discussions of Thematic Working Group (TWG) on Mathematics and Language. In this paper we provide an overview of both the presentations within the working group and of the main themes arising through the discussions. We highlight the diversity and richness of theoretical approaches, methodologies and research foci that lead to the rich discussions we have at CERME conferences. This richness also arose through a joint working session with TWG01 on argumentation and proof that brought different perspectives to the analysis of argumentation in interaction. We also consider the impact of the global pandemic on our data collection but also on the focus of our research within TWG09.

Keywords: Language, interaction, gestures, semiotics, written texts.

Introduction

The thematic working group 9 (TWG09) in CERME focuses on all aspects of language and mathematics, drawing on a diverse range of theories, methodologies and contexts. The importance of researching the role of language in mathematics is firmly established (Barwell et al., 2019; Erath et al., 2021; Morgan et al., 2021) and the working group contributions focus both on the mathematical content and the social, cultural or interactional context when researching the nature of this role. Over time the discussions of the working group have evolved and continue to evolve in line with developments in the field, and advance the work from previous ERME conferences. There is a great deal of richness and diversity in the range of methodological approaches, research foci, and contributions from the members of TWG09. This is partly as a consequence of the significant overlap the research included within the theme has with other working groups within the conference. Common connections include a focus on specific mathematical topics and practices such as multiplication, argumentation, or functions, as well as contexts of teacher professional development or mathematics teaching and learning in diverse and multilingual contexts.

Language is more than the medium through which the concepts and techniques of mathematics are taught and learnt, and this is widely illustrated in the work of TWG09. Research in this group is often characterised by the role that language can have in the learning of mathematics, in developing students' understanding of what it means to do mathematics, but also in terms of the barriers and obstacles it can raise for groups of learners. The research within TWG09 pays attention to how language, interaction and communication influences these processes of learning and teaching mathematics.

This diversity of perspectives, methodologies and connections both enriches the work of TWG09 but also poses a challenge for the group. This was already pointed out by Planas et al. (2019) with respect to the challenges related to presenting language-sensitive mathematics education research both during a conference and in papers and posters. CERME12 saw changes to the template that have made it easier to share transcripts in a way that respects the language of the participants, respects the theoretical approach used by the researchers, and made members of this working group able to more effectively share their data. However, research within this group relies heavily on the analysis of interactions; interactions between teachers and students, interactions within groups of students, and interactions between students and tasks. The global pandemic has seen huge changes in the nature of these interactions with large scale school closures, a move to online synchronous and asynchronous forms of interaction, alongside greater concerns over privacy and data protection. These changes pose challenges to both the collection of interactional data and the presentation of data to illustrate findings from the work within this group.

The relevance of language in the various domains of mathematics education research has also been previously highlighted (Planas et al., 2019). During the 2022 conference, the methodological domains of descriptive and interpretive research for understanding teaching-learning processes in more detail, design research studies aiming at both theoretical insights and teaching-learning arrangements, and intervention studies were addressed. In TWG09 on mathematics and language, there is often a clear focus on qualitative studies with only Quabeck and Erath reporting from a larger-scale quantitative study and Kortüm et al. giving an outlook on planned quantitative research in their poster. Looking at the presented research at the conference from the perspective of the age of the participants, we gain insights moving across primary and secondary schools, across studies in Higher Education, towards studies with teachers with varying degrees of classroom experience. This shows how language and interaction matter for the learning of mathematics right from early years to the point of learning to teach mathematics that continues throughout a career. This diversity of perspectives and foci is illustrated through the keywords of the papers as illustrated in Table 1.

Table 1: Keywords from the papers and posters in TWG09

Language theories, constructs and approaches	Communication, Dialogism, Discourse analysis, Discourse, Gestures, Interaction (analysis), (Interactional) Quality, Language as resource, Language diversity, Language, Lexicalization, Linguistic complexity, Literacy, Participation, Register, Revoicing, Semiotic mediation, Semiotic representations, Social semiotics, Syntax, Teacher talk, Verbal tools,
General Theories, constructs and approaches	Abduction theory, Conceptual learning, Diagnostic, Epistemology/Epistemics, Images of mathematics, Interpretive research (paradigm), Learning opportunities, Literature reviews, Operationalization, Professional Identity, Professional knowing, Progression, Qualitative research, Responsiveness, Video study
Mathematical content	Argument/Argumentation, Combinatorics, Diagrammatic reasoning, Dynamic Geometry, Explanations, Generalisation, Geometry, Graphs, Inquiry-based/inquiry-oriented learning, Multiplication/multiplicative structures, Problem-solving, Reasoning, Time telling, Word problems, Writing

Contexts	Artifacts, Bilingual education, Classroom/teaching practice, CLIC, Educational television, Learning disabilities, Multilingualism/ Multilingual classrooms/ Multilingual teachers, Pandemic, Pluriliteracy, Primary school/elementary school, Prospective/preservice teachers, Reading, Teachers, Textbooks, Web-based/Digital tools

The richness and diversity of research within TWG09 is not only visible in relation to contexts as well as the age and role of participants (see the Contexts in Table 1). It is also represented in the theoretical backgrounds of the presented studies as researchers drew from semiotic, dialogic, epistemological, pedagogic, sociological and interactionist perspectives (as shown in the range of theories, constructs and approaches in Table 1).and in some cases also connected different perspectives These theories and approaches have also been used to focus on different aspects of mathematics, with many focusing on specific mathematical topics and others focusing on mathematical processes and skills.

Organisation of TWG09's work

The working group included presentations of 18 papers and 6 posters, with a total of 47 participants from 11 countries. The contributions are characterised by a strong and fruitful diversity in the contexts explored, research questions considered, and the theoretical and methodological approaches taken.

In the 7 sessions the papers and posters were discussed and organised around some common themes, although some of the papers could have been included in more than one of the identified themes. In organising the themes, we strived to enable connections and thus to foster possible future collaborations. Furthermore, as the groups' diversity can also be a challenge for discussing each paper in depth (Planas et al., 2019), the organisation around common themes was intended to help the audience focus and think deeply on one (maybe not so familiar) aspect of language and interaction in mathematics education.

In each of these 7 sessions, emphasis was placed on the time for discussion for each paper individually with depth. This was realised with a short 5 minutes to highlight the key features of a paper by authors followed by a 10-minute reaction focused on raising questions and generating discussions. The in-depth discussion of the individual papers within each session was made possible through the breakout discussions enabled by the technology. However, this also resulted in the group splitting into four smaller groups and each member of the group choosing which one paper to discuss with the authors in more depth.

Furthermore, one session was dedicated to discussing larger themes across the specific papers or posters for identifying new trends, common challenges, ideas for future collaborations, etc.

Contributions and themes

We first present a brief summary of each of the contributions presented in the TWG during the conference. The themes running through the contributions include the multimodality of language, topic-specific language demands including argumentation, interactional perspectives, written and textual features of mathematics, and teacher education informed by language and mathematics research. We then conclude with some remarks on future challenges and directions highlighted during the discussions.

We opened with a paper from Huth that focused on the different functions of gestures in diagrammatic reasoning in primary school children's interactions. This was complemented with a poster presentation from Kimber and Smith on the relationship between speech and gestures in online teaching videos. Both these contributions focused on the different roles gestures can take in interaction in ways that both support mathematics learning, but also in ways that can constrain it. These different roles were also visible in the paper from Moutsios-Rentzos on multimodal argumentation in the joint session with TWG01 (Argumentation and Proof).

Several contributions from TWG09 focused on topic-specific language demands and semiotic representations that learners draw upon. Pacelli, Pellegrino, Carotenuto and Coppola reported on a project focusing on primary school learner's explanations when working with multiplication algorithms and the accompanying artefacts, presenting the specific case of Napier's bones. Also focusing on multiplicative reasoning in primary schools, Rønning distinguished between the multiplicative reasoning involved when working on different combinatorial problems that depended upon the semiotic representations used. The poster presentation by Şahin-Gür shifted the focus to calculus and learners aged 14 to 16 years by describing a design-research study to foster conceptual understanding in mathematical and language integrated learning-arrangements for qualitative calculus (i.e., understanding based on informal meanings of amount and change). Later contributions in the TWG sessions also included a focus on geometry in combination with digital technologies such as dynamic geometry software as discussed below.

The papers by Palm, Kapland and Bergvall and Planas focused on linguistic features and their role in the learning of mathematics. Palm et al. analysed how the changes in referents in textbooks for the final year in Swedish primary schools constructed opportunities for mathematical generalising. Planas drew on the notion of language as resource to argue for lexicalization as a potential resource for communicating mathematical meanings by reporting on her work with secondary school teachers. The papers in this session and the one that followed all focused on mathematics and language in interaction but in different ways. Bräuning and Feskorn focused on supporting interactional and communicative development of young learners in elementary school. Using an epistemological approach to the analysis of teacher-student interactions they illustrated how one teacher nurtured the students' development of mathematical interaction skills. Beck and Vogler continue this theme by examining responsiveness in interactions and the restrictions on primary school students' opportunities to participate resulting from particular teacher moves. Gíslason's focus on internally persuasive discourses also highlights the often restrictive nature of mathematical interaction, in that it often centres around visual or superficial features of a task rather than mathematical forms of argumentation and justification, this time arising from the students' interaction with dynamic geometry tasks.

Some contributions particularly focus on working with teachers with different levels of experience. Coppola, Ferrari and Miranda analysed student teachers' assessments of the written arguments made by undergraduate students which revealed a lack of attention to argumentative structures and a focus instead on precise use of language and the mathematical content. The poster presentation of Perlander offered a different lens focusing on newly graduated teachers use of mathematical reasoning demonstrated in classroom interactions. In a later session, this focus on teachers and teacher education was continued in a poster presentation from Dafnopoulou who looked at how teachers' professional identities are developed in multilingual mathematics contexts.

Quabeck and Erath shifted the focus to look at how quantitative approaches have been used to capture the quality of mathematics classroom interaction. Their analysis reveals that only a focus on discourse practices, that many of the qualitative studies in TWG09 had, is sufficient to capture the relevant differences in classroom interaction rather than a focus on teacher moves or analysis at the task level that are commonly focused on in larger-scale studies. Ingram also examines differences in approaches to the analysis of classroom interactions, illustrating differences in the use of the term revoicing depending upon the theoretical perspective taken that have consequences on how we understand the relationship between teaching and learning of mathematics.

ETC7 on Language in the Mathematics Classroom already highlighted that the inclusion of digital learning environments and tools is an upcoming theme in the international research on language, interaction and learning mathematics (Ingram et al., 2020). In addition to the paper from Gíslason above, two other papers considered the role of digital technologies in the relationship between language and mathematics. Meaney and Rangnes focused on digital tools including programming and the importance of how teachers use them with multilingual learners. They made a distinction between tools that acted as translators and tools that were used more broadly and consequently were more supportive in developing multilingual learners' mathematics and their language in mathematics. Baschek explored the use of PrimarWebQuests in Content- and Language-Integrated Learning (CLIL) settings in primary school illustrating the motivation of authentic contexts for students to use different working languages and offering an illustration of one such context in the webquests. This focus on CLIL was continued in the paper by Schüler-Meyer who suggested the notion of pluriliteracy as an alternative in CLIL with a shift in emphasis on learners becoming proficient in mathematics using multiple languages, rather than the common target language in focus in the CLIL settings.

In the final session the focus shifted to written mathematics continuing the development of this work across several ERME conferences. Malik and Rezat's paper focused on identifying specific linguistic features that cause learners difficulties in word problems by presenting a literature review. Teledahl, Ahl, Helenius and Kilhamn also analysed several research frameworks for assessing students' writing and illustrated by their literature review that further research is needed to develop research that attends to the different dimensions of students' writing. Kortüm, Meininghaus, Mentrop, Hußmann A., Hußmann St. and Nührenbörger also shared their work on developing a supportive diagnostic tool to assess reading and mathematical competencies and their interconnections. The TWG09 sessions ended with a final presentation from Tatsis and Maj-Tatsis that focused on the public discourses around educational television programs in Poland during the pandemic.

Argumentation and a joint session with TWG01

There was a joint session between TWG09 and TWG01 to bring together the overlapping focus of argumentation that often features in the papers of TWG09. During the virtual pre-CERME12 event, members of TWG09 discussed the idea of a joint session with another TWG at CERME12 as well as which other TWGs to approach. In this way, the members of TWG09 wanted to further embrace the CERME spirit and promote communication, cooperation and collaboration. Fortunately, the leaders and members of TWG01 on Argumentation and Proof were as enthusiastic about this idea as TWG09. Even though, there was always exchange between different TWGs, we are proud to be part of the first official joint session in CERME history and hope that there will be many more at upcoming conferences.

The joint session included two papers from TWG01 focusing on theoretical debates around the conceptualisation of argumentations and two papers from TWG09 focusing on examples of argumentation in practice. The paper of Moutsios-Rentzos began by challenging us to consider the multimodal aspects of argumentation and offering a tool to support the identification of specific ways in which verbal and non-verbal semiotic systems are both explicitly and implicitly used in mathematical argumentation. This paper drew on Toulmin's scheme of argumentation which is widely used by researchers in both working groups. In the next paper Cramer and Kempen challenged the extent to which this scheme can reveal all aspects of structures of argumentation, highlighting the limitations of the scheme as revealed through recent work within TWG01. The two papers from TWG09 focused on discourses of argumentation with Körner and Meyer illustrating the generalising process over time focusing on addition with zero and tracing one learner's development of argumentation during an interview. Toro and Castro then shifted our focus to mathematics teachers' argumentation during class discussions and how features and purposes of argumentation can be recognised through an interactional and communicative theoretical perspective.

The joint discussion in this session highlighted the different theoretical perspectives and approaches to the analysis of mathematical argumentation, and the nature of mathematical argumentation itself, yet with a common focus on identifying and recognising features of argumentation used by both teachers and learners.

Themes and challenges going forward

One session during the conference was organised without the presentation and discussion of particular contributions. Instead, it was organised as a collaborative working session with a focus on identifying and discussing themes and challenges going forward. The group members split in three smaller groups to focus on 1) how different theoretical perspectives can complement each other, 2) research issues challenging the field at the moment, and 3) implications for the professional development of mathematics teachers.

Over several CERMEs and ERME topic conferences there has been continuing focus on the use of different theoretical perspectives to research mathematics and language (e.g. Planas et al., 2019; Ingram et al., 2021). This is partly as a consequence of the range of fields research in mathematics and language draws from but also theoretical diversity is needed to address the complexity of the relationship between mathematics and language, particularly in the messiness of interactions.

Susanne Prediger illustrated this in her plenary presentation where she illustrated the range of theoretical perspectives and methodologies she has used in her work over a research agenda across several years (Prediger, 2022). Furthermore, as discussed in the joint session, since mathematics communication includes writing, talking, pictures, formulas, gestures, we need more refined theoretical tools than existing models (such as Toulmin's model) to capture its nature.

As already indicated at the beginning, one research issue challenging the field at the moment is that many researchers were not able to collect new data of language use and interaction in classrooms or even of small groups in schools due to school closures and restrictions. For researchers whose analysis often depend on video-taped interaction or who are interested in data from the same classroom in a more longitudinal perspective, this poses a huge challenge. Whereas more senior researchers may go back to “old but still rich” data, early career researchers and researchers starting new projects particularly struggle. In this context, it was also reported from different contexts, that (as schools are more and more challenged by the pandemic and other factors) access to schools becomes increasingly difficult, particularly in contexts in which, for example, teachers cannot be rewarded for their participation in research efforts. A third discussed point is that after a period of some political awareness for language and learning mathematics, other aspects are highlighted (as for example distance learning or digital tools) and more and more funding is directed towards subfields of mathematics education research without explicit connection to language and interaction.

The topic of teacher education has become particularly prominent in several recent CERMEs and topic conferences (e.g. Planas et al., 2019; Ingram et al., 2021), and is growing in importance as a focus of much of the research within this working group. Many of the participants are teacher educators and recognise the complexity of supporting teachers to recognise, identify and adopt linguistic features, teacher moves or interactional practices that support mathematics learning. Furthermore, it can be noticed that some projects on the classroom level reported in earlier conferences are now developed into a basis for the design of professional development programs focusing on language, interaction and learning mathematics.

Concluding remarks

The themes addressed by TWG09 show the variety of research questions, theoretical perspectives and methodologies that the papers and posters dealt with. Whilst this conference maintained this richness in the research and data shared, we have shifts in the focus of the research included. This may be a consequence of the nature of data it has been possible to collect and work on during the global pandemic, with fewer studies focusing on interactions within classrooms. In addition, there might be a general increase of attention to digital communication settings. It may also illustrate the interactions and connections with other working groups where many members welcome discussions that result from connections with these other groups. The joint session with TWG01 highlights how connections between working groups can add to this richness by offering different perspectives at the intersections of our research.

Acknowledgment

We want to thank all the participants of TWG09 who contributed through presentations and thoughtful discussions. We would also like to thank the participants of TWG01 who contributed to

the joint session leading to fruitful discussions around conceptualisations and illustrations of argumentation that cut across the two working groups. A special thanks goes to Alexander Schüler-Meyer who supported us during the conference and Aurélie Chesnais who supported as in the preparation of the conference.

WebQuests in Content and Language Integrated Learning Classes on Primary Level

Eileen Baschek

Justus-Liebig-University Giessen, Germany; eileen.baschek@math.uni-giessen.de

In a research project on Information and Communication Technology usage in bilingual settings, pupils were observed by video recording while working with a bilingual PrimarWebQuest. The main research project focuses on the mathematical knowledge as well as linguistic aspects which pupils might acquire in CLIL-settings while using PrimarWebQuests. In this paper the pilot study is presented which focused on the interactions in such learning settings. It will be explained what Content and Language Integrated Learning (CLIL) means in a European context and to which components attention should be paid while planning the use of PrimarWebQuests in CLIL lessons. The fitting of CLIL and PrimarWebQuests will be described to outline the potentials of this approach. Its basic idea and its implementation in bilingual settings will be defined. Afterwards, the framework of the pilot study and first results will be described to conclude next steps of the main study.

Keywords: Bilingual education, primary schools, inquiry-oriented, web-based, time telling.

Research Aim

The advancing language competence of bilingually taught pupils has been proven, for example by Bechler (2014) or Kersten et al. (2010) and is caused by the higher frequency of language contact. In addition to *Basic Interpersonal Communication Skills* being in the front of traditional foreign language classes, bilingual classes deal with a *Cognitive/ Academic Language Proficiency* (Cummins, 1979). In a Canadian research project Bournot-Trites and Reeder (2001) could show that there are positive effects on mathematical learning when students are taught in two languages. Schubnel (2009), who investigated German-French speaking bilingual mathematics classes, suspects the additional linguistic access, which the pupils receive, as a reason for this phenomenon. Moschkovich (2002) describes a multiple-meanings perspective as one of three perspectives for describing bilingual students learning mathematics which seems to underline Schubnel's theory. The multiple-meanings perspective expands the complex role of language for learning mathematics as it highlights the idea of pupils developing and negotiating meanings of mathematical terms in bilingual settings.

As the pupils' everyday use of ICT, specifically the Internet, offers various possibilities to experience foreign areas, the research project investigates the combination of ICT and CLIL. Using ICT allows access to multilingual sources, which enables the pupils to work with authentic and multi-media material, including linguistic reality (Schmidt, 2013). The aim of the research project is to find out about the contribution of the PrimarWebQuest approach regarding the pupils' learning of a mathematical topic as well as the academic expressions which go with each topic. But for this pilot study the main goal was to describe and analyze the interactions between pupils, teachers and the material in a bilingual and digital learning setting for exploring the chances for CLIL lessons offered by PrimarWebQuests.

Bilingual Learning

Bilingual teaching and learning in Germany refer to educational situations in which a subject or even just a selected topic is taught in a different language for a fixed or an enduring time. The term *Content and Language Integrated Learning (CLIL)* is used as a generic term for bilingual learning models in Europe which can be implemented in different ways. It is the core philosophy of the European Union that each citizen of the EU should be able to functionally use at least two more European languages in addition to their mother tongue. This approach aims to connect content learning and language learning in an integrated way. It is seen as an effective method for learning a foreign language with the aid of authentic topics. The language abilities of bilingually taught pupils go beyond everyday speech, the so called *Basic Interpersonal Communication Skills (BICS)*. In bilingual classes pupils should acquire a more technical terminology, the so called *Cognitive/ Academic Language Proficiency (CALP)* which is necessary for demanding topics (Cummins, 1979).

Most studies about CLIL have been conducted at the secondary level. First results about CLIL at primary schools have been published (Elsner & Keßler, 2013). In Germany, the idea of CLIL-classes in mathematics has not been greatly accepted (Viebrock, 2013). There are only a few conceptual ideas in secondary schools as well as at primary level. There are even fewer teaching materials why it is necessary to fill this gap. One possibility for having access to more material seems to be the Internet.

In this pilot study, Coyles (2006) *4Cs Framework* was used for creating PrimarWebQuests for CLIL classes. In her framework she describes the four components *Content*, *Communication*, *Cognition* and *Culture* for planning CLIL lessons (see Figure 1). The *Content* of bilingual classes should be geared toward curricular guidelines of the subject, in this case Mathematics. The aim is a double and profound knowledge acquisition as well as the pupils' understanding with regard to the content. In Germany, the pupils' subject-based knowledge is defined by a curriculum. It describes mathematical skills and specific content areas pupils are supposed to achieve. In this study the pupils should deepen and expand their knowledge about times. *Communication* refers to extending pupils' language knowledge and abilities to qualify them for an academic interaction in class, like using the right expressions for talking about different parts of a day during mathematics classes. The component *Cognition* contains all cognitive abilities which can be established, such as strategy learning or metalinguistic knowledge which could be developed in discussions about different time telling expressions or during calculating activities of different time spans. Particularly in bilingual settings, pupils have to develop a reflexive attitude vis-à-vis their own and other *Cultures*. For behaving in an empathic way, it is important to think about various perspectives, opinions or feelings and to switch between them. The cultural component of the framework is touched by the task to help two people from another country by comparing German and English times for describing the differences to them.

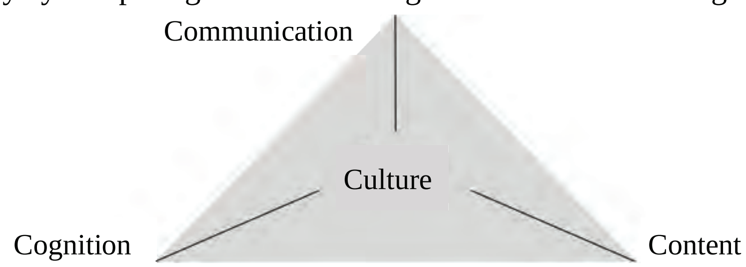

Figure 1: Curricular Framework for CLIL Classes according to Coyle (2006, p. 10)

PrimarWebQuests in Bilingual Classes

The method WebQuest, invented by Dodge and March in 1995, is an inquiry-oriented and web-based learning approach for using internet sources (Dodge, 1997). Even though it is offered on the Internet, the pupils can use online as well as offline sources which have to be chosen by the teacher in advance. WebQuests should give a structure for using the internet sources in an efficient and target-oriented way (Baschek & Schreiber, 2020). Schreiber adapted the method for primary school children in Germany. He called it *PrimarWebQuest*. A PrimarWebQuest contains various sources in order to deal with mathematical concepts and issues. It can set a focus on important aspects and reduce the complexity of available information which can be found on the Internet. The pupils learn in small groups how to conduct their research with online resources themselves (Baschek & Schreiber, 2020). Media competences like searching for, selecting and using online information as well as cooperating, presenting and reflecting can be trained with the small version of the original World Wide Web which is designed by a PrimarWebQuest. The requirements of a PrimarWebQuest should be made transparent for the pupils before beginning. They must be able to self-evaluate their learning process and the learning product (Schreiber & Kromm, 2020).

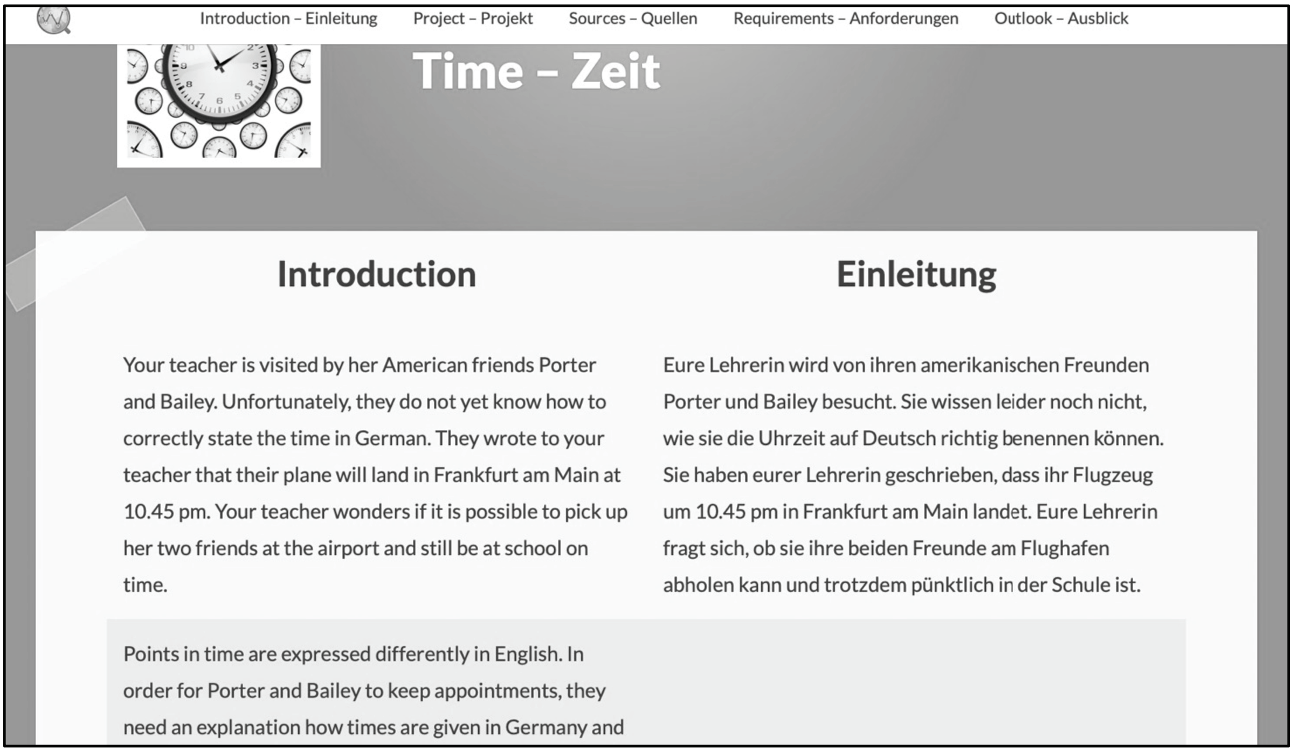

Figure 2: Part of the introduction of the bilingual PrimarWebQuest with the topic of times

Before starting their work, the pupils are split into small groups and get an introduction for using PrimarWebQuests. In the following sequence, the pupils look for more detailed information of their topic independently in their small groups. The teacher only supports them when she or he is asked to do so by the pupils. After the first working phases, there is a sequence for reflecting the working process up to this point. This sequence also offers the possibility to talk about crucial mathematical aspects. The pupils start to prepare their solution for the task and present their results at the end of the unit. When all presentations are done, the teacher reflects with everyone about their group work.

Generally, bilingual PrimarWebQuests (German/English) and monolingual German ones follow the same structure. On the web pages of bilingual PrimarWebQuests, pupils can read all information and instruction in both languages, despite the chosen sources. Because of two different language columns, they can choose the working language independently in every group. When opening one of the sites, the pupils only see the English text in the beginning. By clicking on an English paragraph, the German translation appears (see Figure 2). There are sources in both languages as well, so every group, regardless of which working language they choose, has the possibility to use both languages for research. The sources are mostly realistic web pages made by native speakers (Baschek & Schreiber, 2020). Bilingually designed PrimarWebQuests can motivate the pupils to switch between the languages. When the pupils are motivated to do so by the PrimarWebQuest or the teacher, they practice to work language-sensitively while switching. Additionally, the pupils can get into a collaborative dialogue because of the open-ended nature of the task. Discussing new terms with their classmates offers them the possibility to check their understanding of mathematical terms. Nevertheless, an adaption to the pupils' linguistic knowledge is necessary for a beneficial use of bilingual PrimarWebQuests and to ensure a successful learning experience for all (Baschek, 2020).

Pilot Study

The pilot study was undertaken for describing interactions in a bilingual and digital learning setting to discover chances for CLIL lessons offered by PrimarWebQuests. The group activities were video and audio recorded. Transcripts are and will be generated out of crucial sequences of the collected data, such as discussions about mathematical facts or language-sensitive activities, and will provide the foundation for the processes of analysis and interpretation. By using the interaction analysis (Krummheuer, 2002), the way, in which individuals create and negotiate taken-as-shared meaning, is reconstructed. The aim is to reconstruct any interactions in situations that are meaningful for the participants and to construct as many interpretations of these actions as possible. Every utterance is closely examined and analyzed in small groups for providing multiperspectivity. The utterances need to be kept in chronological order. Interpretations can only be justified and linked backwards as they can only be based on utterances made previously. These initial interpretations are then reinforced or rejected in order to ensure the most convincing interpretation of the episode.

A bilingual PrimarWebQuests[1] about *time telling* was tested with six third graders of a German private primary school offering bilingual classes (German/English) in multiple subjects. Mathematics is taught part-time in English and in German. The school follows the German curriculum and uses German and Irish textbooks. Most of the participants' mother tongue is German, one participant was raised bilingual. As not all pupils of the class were involved, the six participating pupils worked in two groups of three while their classmates did the regular tasks in their classroom. The two groups worked in one room at the same time and were supported by an English-speaking as well as a German-speaking teacher which were the researcher and an assistant. The pupils did not know this method before but were asked to use the bilingual PrimarWebQuest while the working language was chosen freely by them. The explanation for Porter and Bailey, who need the pupils' help for arrival and

[1] The bilingual PrimarWebQuest can be found here: https://math-primwq-bilingual.sd.uni-frankfurt.de

departure times in the PrimarWebQuest, had to be in English (see Figure 2). As the topic of time telling is dealt with mainly in second grade of German schools, on the one hand, this PrimarWebQuest should activate the previous knowledge of the pupils for deepening it. For instance, the difference of points in time and time spans turns calculating into a complex activity which needs to be practiced multiple times. Additionally, fractions, which are no topic of German primary schools, are used for time telling expressions. Instead of only learning the right expressions by heart, the pupils need enough time to think and talk about their conceptual meaning of those expressions for developing an understanding of fractions. On the other hand, using the shown task indented the pupils to learn the differences of time telling in the languages as an intercultural aspect. For example, using am and pm does not only mean to learn the right vocabulary. It also needs the pupils to think about the different time spans of every day and how times can be located in those parts of a day as this phenomenon does not exist in German time telling.

The different sequences of PrimarWebQuest usage offer several possibilities for supporting the mathematical language skills of bilingually taught pupils. To highlight possible learning opportunities of a PrimarWebQuest, pupil interactions are described and analyzed. During a group working sequence, the pupils discuss English and German vocabulary they will need for talking about different points of time. In the following example, the pupils know a German term and try to find the English translation together. Originally English utterances are typed in SMALL CAPITALS, whereas originally German utterances are typed in normal style. Gestures, activities and additional information are typed in *italics*.

Person	**Translated utterance**
Teacher:	OKAY. THE NEXT WORD IS THE BACKGROUND OF THE CLOCK WHICH IS WHITE. DO YOU KNOW HOW IT IS CALLED? IN GERMAN OR IN ENGLISH? GIOVANNA.
Giovanna:	Ziffernblatt?
Teacher:	Ziffernblatt IS THE GERMAN WORD. RIGHT *(attaches the word card to the black board)*. AND DO YOU KNOW THE TRANSLATION MAYBE? LUKAS.
Lukas:	NUMBER PAPER.
Teacher:	NO IT'S NOT THE DIRECT TRANSLATION. LAURA?
Laura:	FACE.
Teacher:	FACE IS RIGHT AND ONE WORD IS MISSING. LUKAS?
Lukas:	NUMBER FACE?
Teacher:	NOO.
Laura:	*(puts her hand in front of her face and whispers)* HAND FACE.
Teacher:	NO IT'S NOT A HAND FACE. WHOSE FACE IS IT *(points at the clock which is attached to the black board)*? LAURA?
Laura:	EH NUMBER NO EH CLOCK FACE?
Teacher:	*(nods)* CLOCK FACE. RIGHT. WELL DONE *(attaches the word card to the black board)*.

In this sequence it is possible to see how the pupils use both languages. Knowing the German term and supported by the teacher, they try to figure out the English translation. Lukas who was raised bilingual starts with an almost direct translation of the German term. Laura remembers *face* as a part of the translation. She could have gotten this information from the informational texts of the PrimarWebQuest. Listening to the teacher's hint, Lukas tries to build a word with *number* again and puts the two words together, calling it *number face*. The discourse seems to motivate him to use his metalinguistic knowledge. Laura instead thinks of further vocabulary by using the term *hand face* which probably refers to the hour and the minute hand and can be an expression she learned from the informational texts. Supported by the teacher, Laura finds the right translation *clock face*. As the specific terms of this topic are similar to everyday language, the main goal for the pupils to learn is using the right expressions. All pupils show a proper use of the terminology in both languages. In fact, they speak more German than English, but they think of the English expressions when writing down notes for their explanations. During the working sequences, the pupils read and interpret the given authentic sources and they need to gather and check suitable information details. It was possible to observe a subject-based discourse in both groups motivated by the PrimarWebQuest. Specifically, the pupils discussed a lot about the difference between am and pm because they developed an idea which parts of the day are addressed.

The following sequence shows how the pupils work together and discuss in a group spurred on by the PrimarWebQuest. They are divided over pm being the morning or the evening of a day and try to find an answer together. For solving their problem, they think of the information which the given texts contain and use a graphic which they copied from a text. The group work helps them to communicate successfully about new information and to get to a mutual solution.

Person	**Translated utterance**
Teacher:	YOU ALSO READ THE INFORMATION ABOUT AM AND PM, SO YOU CAN THINK ABOUT IT. WHETHER IT IS IN THE MORNING OR THE EVENING.
Julia:	IT'S IN THE EVENING. EH MORNING.
Laura:	So that means…Where is this piece of paper *(unintelligible)* it is here.
Julia:	Why was it there?
Laura:	We are, so PM IS IN THE MORNING *(points at the afternoon of a plan of a day with its times)*.
Julia:	No, PM IS EVENING.
Laura:	I see, right.
Julia:	IT'S IN THE EVENING.
Laura:	IT'S IN THE EVENING.
Teacher:	RIGHT.
Julia:	What is two o'clock in the evening?
Laura:	They could, she can come to school.
Eva:	Two o 'clock is in the morning.
Julia:	Two o 'clock can also be in the evening. Namely after one. At one o 'clock you eat and at two…
Laura:	But it is PM.
Julia:	Two o 'clock is fourteen o 'clock.
Eva:	Yes.
Laura:	Yes, but it also can be PM. It is PM anyway.
Julia:	It says PM, so it is fourteen o 'clock.
Laura:	Noo, PM is in the evening *(uses the wrong German article)*.
Julia:	Yes, therefore fourteen o 'clock.
Laura:	*(hits her head with her hands)*
Julia:	But it says, noo, fourteen.
Laura:	Yes okay, do what you want.
Julia:	Yes have a look Laura. Two o 'clock is fourteen o 'clock.
Laura:	Yes I understood that. Yes I understood that.

In the beginning, the three girls think that a pm time belongs to the mornings. The teacher needs to suggest to check their assumption. During the conversation with the teacher a change from one language to another can be observed. After the switch Julia does when the teacher comes to help the group, a multiple switching between the two languages can be observed. This shows that the pupils use their languages in a flexible way and adapted to their communicative intention as well as the task of the PrimarWebQuest. Set off by the group work, they need to describe their own thinking processes while comparing their assumptions and they can learn to verbalize their understanding of the informational texts on their own. In this sequence two different opinions can be observed, but the girls don't seem to be able to explain their assumptions. By naming examples, Julia tries to convince Laura and Eva. Working together, they seem to find out that 2 o'clock pm means 14 o'clock. The open-ended task of the PrimarWebQuest supports their subject-based discourse while preparing the explanation for Porter and Bailey because the pupils need to come to a mutual result.

Conclusion

To begin with, the pupils seem to feel safe because of the open choice of working language. They use the English language when talking to the English-speaking teacher or when preparing their explanation for Porter and Bailey. Therefore, the setting motivates the pupils to work with both languages in an authentic way. In retrospect, it can be considered the pupils learned some new vocabulary or rather time telling expressions and could deepen their existing knowledge. Both groups had the opportunity to improve their strategies in mediation, as most of their discussions are German and their explanation for Porter and Bailey has to be in English. Especially in the working sessions with both groups, most of the pupils showed advanced metalinguistic skills (*Cognition*).

The open-ended task allows an individual main focus during the working sequences. If the content of the sources is too complex for the pupils, the PrimarWebQuest can purposefully guide their work on the task by helping them structure their working steps. Specifically, the intercultural topic of using am and pm encourages them to think about the informational texts and to use their copied graphics (*Culture*). This unknown content motivates the pupils to negotiate new terms or knowledge with their working groups for developing new concepts (*Content*). This cooperation can support language learning as well as a proper language use. Additionally, the pupils seem to be able to communicate adequately to mathematics classes as they can explain their calculating of times and use expressions which contain fractions easily (*Communication*). Besides the language and mathematical learning, the pupils also worked on their media competences while multiple internet sources.

To conclude, using the method PrimarWebQuest can be advantageous for CLIL in mathematics classes. For many topics there is not enough material for CLIL lessons in mathematics. The Internet and its diversity can be a support. The method enables dialogues, offering the possibility to investigate the pupils' understanding of mathematical terms either for teachers or for researchers.

Geometry lessons as a catalyst for the participation of all learners in mathematics lessons in primary school? Empirical studies on the responsiveness of interactions in geometric and arithmetic teaching situations

Melanie Beck[1] and Anna-Marietha Vogler[2]

[1]Goethe-University Frankfurt am Main, Germany; mbeck@math.uni-frankfurt.de

[2]Martin Luther University Halle-Wittenberg, Halle, Germany; anna-marietha.vogler@mathematik.uni-halle.de

Based on the thesis that it is easier to support the participation of all learners in classroom interactions in the field of geometry in primary school than in the field of arithmetic, this article focuses on the interactional support of children's participation by teachers in geometric and arithmetic classroom situations in the context of heterogeneous groups. Using the construct of responsiveness, it is worked out to what extent the opportunities of all children to participate in geometrically-oriented interactions can depend decisively on the content-related and linguistic design of the process of interactive negotiation and whether in the domain of geometry - as compared to arithmetic - interactive "moves" of the teachers which have a beneficial effect on the participation opportunities of the children can be reconstructed to a particular extent.

Keywords: Primary schools, geometry, responsiveness, participation, interaction process analysis.

Introduction

Geometry, after arithmetic, is the second domain in the curriculum of primary school mathematics both in Germany and in many countries (KMK, 2005; NCTM, 2000). In this area, orientation in space, the recognition, naming, and representation of plane geometric figures and illustrations, as well as the measurement and comparison of surface areas and spatial content are formulated. Geometry lessons not only help children to better understand arithmetic, they also address many of the things that interest them, and build on their previous experiences. In this way, geometry can become children's "strongest" mathematical discipline (van den Heuvel-Panhuizen et al., 2008). In geometry lessons, pupils further develop their spatial imaginations and can thus better orient themselves in our three-dimensional world. Probably due to the "accessibility" of geometric content for learners and its strong reference to everyday life, geometry teaching is mostly seen as a particularly suitable area for inclusive mathematics teaching. In a study by Korff (2018), teachers in Germany stated that creating joint learning arrangements in heterogeneous classes is more challenging in arithmetic than in geometric lessons. However, little research has been done on whether teachers actually "succeed" in supporting learners in the area of geometric learning opportunities in everyday mathematics lessons, against the backdrop of a heterogeneous student body, than they do in arithmetic lessons. From a co-constructivist perspective on learning through participation in discourse, this article approaches this research desideratum to make an empirically-based contribution to theory synthesis in this area based on the construct of responsiveness. The central research question is to determine to what extent geometric teaching situations in heterogeneous classes, in comparison to corresponding arithmetic situations, are characterised by a high degree of adaptive or responsive support for all children, to enable them to participate in co-constructive learning processes.

Theoretical background

Teacher support for learner participation in the context of a heterogeneous student groups

In recent years, in response to the UN Convention on the Rights of Persons with Disabilities, Germany and other countries have increasingly included children with special educational needs in mainstream classes at general schools (Sekretariat der Ständigen Konferenz der Kultusminister der Länder in der Bundesrepublik Deutschland, 2021; Westling, 2019). In these inclusive classes, the support of learners' participation is a central concern for enabling joint co-constructive learning processes for all students. In supporting these learning processes, the teacher as the “more competent other person” (Chaiklin, 2003, p. 41) assumes a key role. A common principle in mathematics didactics for supporting learning processes is scaffolding (Wood et al., 1976), in which this more competent other person supports a learner in the form of an interactive structure or interactive scaffolding, so to speak, by providing instructions and assistance in mastering (arithmetic or geometric) tasks. In this way, it is oriented towards the abilities of the learners. Over time, this interactive support, adapted to the progress of the learners, is increasingly “reduced” to enable the learner to participate more and more autonomously: the other person, who is more competent in the subject matter, consequently adapts his/her actions to the actions of learner and thereby “creates” a situation that is conducive to participation or learning. At the level of interaction, a successful scaffolding process and its interactive elements can be described with the construct of responsiveness (Koole & Elbers, 2014; Robertson et al., 2016).

Responsiveness as a construct for analysing (successful) scaffolding processes

Responsiveness is as a coordination process between a child and its person of reference, in which the person of reference orientates itself toward the child’s needs in order to respond to these in a prompt and coherent way. Transferred to teacher-learner interactions, responsiveness is an example of a successful scaffolding process (Beck, Vogler, & Vogel, 2020). For example, a teacher takes up a mathematical idea of a student’s contribution that was not/had not been anticipated. The teacher supports the learner in an adaptive way, e.g. by encouraging him or her to clarify and justify their utterance. So, responsiveness is distinguished by the fact that in the interactive interplay of “initiation, reply and evaluation” (Mehan, 1979, p. 37): the teacher adapts different interactive elements to the learners’ attainment level in terms of (1) mathematical content and (2) interactive discursive skills. In this conversation analytic approach, the aim is to empirically describe the extent to which a teacher’s actions in these asymmetrical learning situations are aligned with the assumed attainment level of a learner, in order to offer them the most productive participation opportunities possible through the appropriate supportive structuring of the interaction process (Robertson et al., 2016; Beck & Vogler, 2021). A high level of responsiveness generates interactional potentials (Vogler, 2019), which opens up possibilities for interpretation and action for the students, in which they can actively recognise or create networks between the different levels of representation (Beck et al., 2020). Both the teachers’ and the students’ subsequent actions are analysed in our observations, as the combination is necessary to reconstruct responsiveness.

Research question

As stated in the theoretical explanations, teachers will be confronted with ever greater heterogeneous learning prerequisites among the pupils in the early lessons, which they must take into account to enable appropriate participation opportunities in the lessons for all children. Teachers must therefore be highly responsive to pupils' expressions, both in terms of content and mathematics, as well as in terms of language and discourse. Geometry lessons seem to be more suitable for this than arithmetic lessons (Korff, 2018). This assumption will be empirically examined in the following under the following question: *To what extent are geometric teaching situations, compared to corresponding arithmetic situations, characterised by a high degree of responsiveness in supporting all children to enable them to participate in co-constructive interaction or learning processes?*

Data and methodology

To address the research questions and clarify the extent to which interactions in primary school arithmetic lessons are responsive, the comparative analyses in this section examine videographic data from the geometry lessons of a 1th and an arithmetic lesson of a 2nd grade class in Germany. The video of the first-grade class was recorded in the project "EVE", which focuses on the professional visions of prospective primary school teachers (Platz et al., 2018). The video sequence from the second-grade class was recorded as part of the project "The Next Level: Lehrkräftebildung vernetzt entwickeln" ("The Next Level: Developing Networked Teacher Training"), which is conducting diverse studies on the professional teaching perceptions of (prospective) teachers in heterogeneous learning groups. Interaction analysis is used to qualitatively analyse the sequences (Krummheuer, 2012) in which the statements are first interpreted individually, in the order in which they occur, to then be able to understand their relationships to each other, following conversation analysis (Sidnell & Stivers, 2010). This makes it possible to work out both the negotiated mathematical meaning and the characteristics of the turn-taking system. The construct of responsivity is used as a sensitising concept (Blumer, 1954) to describe the extent to which arithmetic lessons create opportunities for all children to participate in teaching-learning situations.

Empirical Case 1: Mr. Miller and the change of perspective

The sequence analysed below is from a mathematics lesson in an inclusive 1th grade classroom in Germany. In the following scene, Mr. Miller is interacting with seven children (Denise, Celina, Merve, Joshua, Can, Kostas, and Lars) at a table in a corner of the classroom. Two cuboids are forming an L-shape. Next to the cuboids is a yellow body that also has such an L- shape (Figure 2). Kostas and Can look at the front view of the L-building, and Joshua at the side view. Can and Joshua have described in advance what they can see from their perspectives:

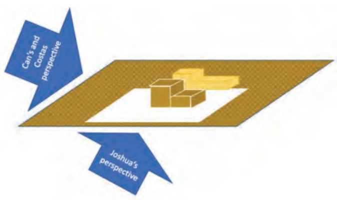

Figure 1: Group situation with Mr. Miller **Figure 2: Wooden cuboids and yellow L-shaped -model**

008	Teacher:	That means you both are right, ne. You have described it from **this** side
009		once.
010		*points at the place in front of Joshua*
011		This has Joshua done. Can has looked from this side.
012		*points at the table in front of Can*
013		that is, building components - #
014	Can	are the same
015	Teacher	are the same. Can but -
016		points at Can
017	Kostas	be the same.
018	Can	be different.
019	Teacher	look **different**. Depending on-(.) What does that depend on/ *shows with his*
020		*finger an arc from Joshua's to Can's place at the table*
021	Can	*raises his finger* row/
022	Teacher	hmm nee. What does that depend on/
(...)		
027		Kostas tell me
028	Kostas	We have just-
029	Teacher	What have you done now/ You are from there- *points at Joshua* to there
030		*points at Can*
031	Kostas	Well we have looked from the edge of the table, what Joshua and Can have
032		done.
033	Teacher	Exactly. That's another side.
034	Kostas	Yes
035	Teacher	Yes, this is another side. That is, the building components depending on
036		which side I look at them from, can look different.

In the selected sequence, the teacher and the students Can and Kostas talk about different views of the L-shaped building (see Figure 2). In line 08, Mr. Miller agrees with both of them and confirms the students' previous statements. In line 13, Mr. Miller begins to sum up: "That is, building components". He leaves his voice suspended for a moment and Can completes the sentence with the attribution: "are the same". Can's statement may refer to the fact that the L-building consists of two identical blocks. The teacher echoes this utterance in line 15 and completes it with a qualification: "can but-". In this turn, Mr. Miller also leaves his sentence hanging. In this way, he creates a universal turn that can theoretically be taken up by all children. This means exerts interactional pressure on the interactants involved to take up the turn. Kostas responds to this pressure and adds "be the same" <17>, again emphasising the equality of the two wooden blocks. Can completes the teacher's sentence with the contrary statement, "be different" <18>. Whether he agrees with the content of this statement or whether, in the interactional flow, he is merely processing the restriction imposed by Mr. Miller's utterance "but" <15> cannot be reconstructed beyond doubt. The teacher again follows Can's utterance and repeats "different" in line <19>. He adds the verb "to look" and thus places the attribution in the context of the appearance of the components. Taking into account all the partial aspects expressed by the interactants, the following content-related statement emerges: "That is, components are the same but can look different". From a mathematical perspective, this sentence has linguistic inaccuracies. In terms of content, however, it could be interpreted as follows: the statement that the same components look different can be interpreted from a spatial-geometric perspective on the situation as a thematisation of different views of the same spatial objects from different spatial perspectives. However, the different perspectives remain unmentioned until line 18. They are only addressed by the teacher following the statement "Depending on-", and the subsequent question.

"What does that depend on?" <19>. The associated gesture (arc) can be interpreted as an illustration of the children's change of perspective: the gesture can suggest that for Joshua, the components look different when he takes Can's perspective. However, Can alternatively interprets the gesture as a "row" <21> and seems unsure of this himself. The teacher evaluates Can's statement negatively <22> and repeats his question from <19>. In <29>, Mr. Miller again addresses the different perspectives by pointing first to Joshua and then to Can, accompanying this with the words, "You are from there- to there". Kostas reacts to these actions of Mr. Miller less regarding perspective than concerning the two boys (Can and Joshua), and expresses that they were looking from the edge of the table. The teacher evaluates this statement positively with "Exactly", and adds, "that's another side" <33>. After Kostas agrees, Mr. Miller finally sums up in line <35–36>: "Yes, that's another side. That is, the building components, depending on which side I look at them from, can look different." In this last statement, Mr. Miller adds the distinction of perspective to the statement from lines up to <18>.

Empirical Case 2: Mrs. Smith and the Number Greater than 90

The second sequence originates from the mathematics lessons of a 2nd grade class in Germany. The children sit in a semicircle in front of the blackboard. The teacher stands to the side of the blackboard. A number line up to 100 as well as seven different coloured balloons are attached to the board. Each balloon hangs above a certain number (see Figure 3). After the teacher has briefly referred to the last lesson, in which the class dealt with the structure of the number line, she begins to pose riddles to the children, e.g. "My number is greater than 90.", and the pupils have to find out what number the teacher is thinking of.

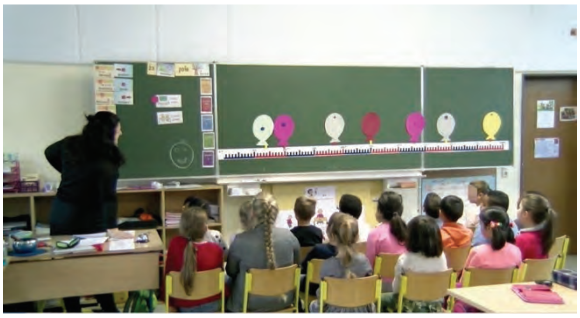

Figure 3: 2nd grade class and number line – Mrs. Smith

001	Teacher:	My number *raises right index finger* is larger than 90 (...)
002	Dennis	*raises the right hand*
003	Laura	*raises the right hand*
004	Teacher	What number is this?
005		*Seven more pupils raise their hand*
006	Teacher	Mhm Dennis please.
007	Dennis	*lowers his hand* Hundred
008	Teacher	Yes, but there the balloon is not pointing at aeh hundred, is it? Alica.
009	Alica	Ninety-five.
010	Teacher	Great Alica, would you please write this number in the balloon? *hands Alica*
011		*a pen*

Mrs. Smith tells the pupils that her number is greater than 90 and supports the relevance of her statement with a gesture <01>. She does not explicitly refer to the balloons or the number line and she has not explained the rules of the game beforehand, so there are potentially several possibilities for solving the task of finding a number greater than 90. On the one hand, any natural number from the number 91 onwards could be a solution. If (1) the number line or (2) the number line in combination with the balloons on the board are taken into account, the set of potential solutions is narrowed down: (1) the numbers 91–100 or (2) the number 95, above which a balloon is attached. After two children, who can either ask a question or name a solution, raise their hands, the teacher asks what the number is. Her question does not provide the pupils with any new insights or possible help. She may be indicating to the students through her question that they should now answer. A total of seven more pupils raise their hands and signal their willingness to participate in the mathematical discourse. The teacher then takes Dennis' answer, whereupon he puts his hand down and says the number "100" <07>. The teacher then voices her objection, "Yes, but there the balloon is not showing at aeh hundred, is it?" <08>, with which she refers to the balloons above the number line for the first time in the lesson. Although the number 100 is greater than 90, this is not the solution she is looking for, as no balloon "points" to this number. The verb "point" is presumably meant to describe the orientation of a balloon above a particular number, since balloons do not have hands or directional elements with which they can point to something. By calling on another pupil, the teacher reinforces her objection, as she can now name another answer or at least complement Dennis' statement <08>. Alica then says the number 95. The teacher positively evaluates this answer in line <11> with the adjective "great", and by requesting that the pupil write the solution in the corresponding balloon on the board.

Empirical Results

Both examples illustrate classroom conversations. In case of Mr. Miller the situation deals with spatial geometric and in case of Mrs. Smith with arithmetic content. In the situation with Mrs. Smith, a task is worked on in which different modes of representation are taken into account, such as the symbolic and iconic modes, which may be supportive for the learners. These modes of representation are supplemented by corresponding verbal impulses from the teacher. The representations on the blackboard and these impulses create different interpretative variations for the pupils that are not taken up. For example, it remains unclear why the mathematically correct answer "100" is rejected by Mrs. Smith. In case of Mr. Miller, similar interactional structures can be reconstructed. This is supported by actions on the material or gestures, in combination with verbal impulses from the teacher. Mr. Miller not only addresses the change of perspective through his statements but also illustrates it twice through different deictic and metaphorical gestures, which he accompanies linguistically. In addition, through his linguistic design, which resembles a cloze text, he repeatedly offers the learners opportunities to take over the turn and thus to participate in the discourse, but only in a fixed way, which was anticipated by Mr. Miller. He does not orient himself to their content-related meanings, such as equality of the two cuboids or Kostas' "row". The mathematical ideas introduced by the pupils and not anticipated by the teachers are devalued by them as undesirable. Based on these reconstructions, **a low level of content-related mathematical responsiveness** can be traced in the classroom conversations of both teachers. In this way, the interactional potential (Vogler, 2019) of the unanticipated contributions is not exploited. The interactive integration of the learners' contributions through the paraphrasing realised by Mr. Miller may initially seem supportive and conducive to participation from a linguistic perspective, but the reconstructed "cloze text" can be identified as a classic funnel pattern according to Bauersfeld (1995): the children's scope for participation is narrowed by Mr. Miller to such an extent that participation is only limited to the children "reciting" the answer anticipated by the teacher. Thus, the analysis has shown that refusing answers, as well as offering participation structures in a very restrictive way, as is the case with a funnel pattern (Bauersfeld, 1995), lead to a low degree of linguistic-discursive responsiveness.

Concluding remarks

This paper aimed to explore how primary school teachers facilitate rich participation opportunities for all pupils in the interactive interplay of arithmetic and geometry lessons. For this purpose, it was to be determined whether geometric teaching situations, in comparison to arithmetic situations, are more strongly characterised by a high degree of responsive support for all children, and therefore whether geometry teaching is possibly better suited for inclusive mathematics teaching. With the help of the reconstruction of responsive structures in two sequences from geometry and arithmetic lessons, it could be shown that the corresponding interactions in the area of geometry as well as in arithmetic show **a low degree of content-related responsiveness**, and that children in these situations are consequently not supported in participating in the content-related mathematical discourse. Likewise, both situations were characterised by a **low level of linguistic discursive** responsiveness. In addition, with the theoretical statements and the findings of Korff (2018), it may be assumed that geometry lessons initially seem to have more potential for the design of teaching-learning situations, but that such potential is possibly only rarely used in instructional discourse, as the analysis in this paper has shown. There seems to be a discrepancy between the perception of the potentials on the one hand and implementation in the classroom on the other. This divergence needs to be further investigated, for example, through collaborative discussion with teachers, or by addressing it in training programs under scientific supervision. Therefore, in the future, teachers will be observed in further arithmetic and geometric lessons to deepen the findings of our first paradigmatic examples.

Learning How to Talk Mathematically: An Epistemological Approach to Teacher-Student-Interactions in Grade 1 and 4

Kerstin Bräuning[1] and Caren Feskorn[2]

[1]Martin-Luther-University Halle-Wittenberg, Germany; kerstin.braeuning@paedagogik.uni-halle.de

[2]Martin-Luther-University Halle-Wittenberg, Germany; caren.feskorn@paedagogik.uni-halle.de

Since mathematics is universally abstract in a sense that other scientific disciplines are not, the teaching and learning of mathematics face major challenges. This is especially true at elementary school level when children start experiencing mathematics in formal instructional settings for the first time. One of these challenges – both for teachers and learners – is the development of mathematical communication skills to share ideas, create meaning, clarify understanding. Looking at two examples from grade 1 and 4 we aim at exemplifying how a teacher responds to this challenge. The epistemological analysis of the teacher-student-interaction reveals that the teacher constantly nurtures the students' development of mathematical interaction skills and that teacher and students undergo a mutual process of mathematical socialization from grade 1 to grade 4.

Keywords: Elementary school, language, epistemology, interaction, problem-solving.

Introduction: Mathematics and classroom discourse

Within the last decades, researchers have come to the conclusion that teaching practices highly influence students' learning opportunities and a paradigm shift in education from teaching to learning was found. This new rationale led to seeing the learning of mathematics beyond the mere acquisition of rote facts and procedures. Instead, a perspective that acknowledges students' mathematical learning processes and outcomes as tied to individual and reciprocal aspects came into being. Evidence shows that language is an integral part of this (Pimm, 1987; Erath et al., 2018) and communicative practices in the teaching of mathematics are required. Looking back at Cobb et al. (1997, p. 258), this idea does not seem to be new: "The current reform movement in mathematics education places considerable emphasis on the role that classroom discourse can play in supporting students' conceptual development." Still, the question remains how to establish ways that will cultivate content-related rich discourses. This appears to be especially challenging for three reasons: First, mathematical objects are abstract concepts that can only be accessed through concrete representations that do not speak for themselves; actual words are needed to interpret meaning. Second, elementary school students are only at the beginning of encountering those abstract concepts and depend on experienced others. Third, (mathematical) communicative skills are only learned by actually communicating (mathematically). These three aspects point out that (mathematical) language is both a goal in itself and a means for attaining the goal. The uniqueness of this manifold situation calls for closer attention and many researchers do so (e.g. Krummheuer, 2011; Erath et al., 2018).

The aim of our research project "PrimaL" (A Longitudinal Study of Problem-Based Mathematics Teaching in Inclusive Learning Environments) in this article is connected to take a more detailed look at teacher-student-interactions in the everyday mathematics inclusive classroom of a public elementary school. A peculiarity of the research project is the fact that the teacher does not undergo any training in planning communicational-sensitive math lessons. Furthermore, the lessons do not take place in a laboratory setting but reflect actual teaching and learning situations. On the theoretical basis of interactional (Krummheuer & Voigt, 1991) and epistemological (Steinbring, 2005) approaches, single case studies are analyzed to pin down the teacher's communicative factors that presumably lead to the construction of mathematical knowledge. For the purpose of this article, two task introduction episodes are chosen to investigate the following research question: What characteristics in teacher-student-interactions can be observed in grade 1 and grade 4 from an interactional and epistemological point of view? Differences between the teacher's communicative actions towards beginning and advanced learners of mathematics become obvious. Furthermore, a student-centered participatory classroom culture seems to emerge as the teacher carefully withdraws from the teacher-student-interaction.

Theoretical and methodical background: Teacher-student-interactions in the mathematics classroom

Generally, mathematical signs and symbols have a dual function: On the one hand, they are the mathematical content that students are required to learn. On the other hand, they constitute the central elements of communication. "In this regard, a learning student cannot be compared with a professional mathematician. The latter has many years of experience in mathematical communication [...]" (Steinbring, 2005, p. 15), while the former is only beginning "to develop and perfect such forms of mathematical communication with his classmates" (Steinbring, 2005, p. 15) and – as will be shown later – her/his teacher. From this point of view, the uniformity that is usually associated with mathematics cannot be taken for granted and learning processes are less uniform, but rather individual, divergent, and heterogeneous. Within those learning processes, (unfamiliar) mathematical signs and symbols need to be both interpreted and constructed. Due to Steinbring (2005), this interpretation and construction takes place in a triad of mathematical content, student, and teacher with communication as their linking element.

The most prevalent interaction pattern that is widely discussed in the field of (mathematics) education is the IRE pattern (teacher's initiation, student's response, teacher's evaluation) (Mehan, 1979). While many researchers describe this pattern as doing only little to enhance students' learning opportunities, some authors point out that a difference needs to be made between the pattern itself and how it is used. Wood (1998), for example, stresses the organizational benefit of the pattern (coining the "term recitation pattern", p. 172) while warning teachers to misuse it as an engrained way to wait for their intended answers to be given by the students. Instead, a series of IRE sequences can be used to orchestrate students' verbal contributions by e.g. highlighting, asking for clarification and reasoning or summarizing. On the surface, this may seem similar to the form of the initially proposed IRE pattern since the sequence teacher – student – teacher remains. However, the content of discourse changes as the students' thinking becomes the focal point of discourse. It is our intention to concretely shed light on this special discursive interplay between a teacher and her students.

Usually, when it comes to interactional research, mathematics teaching is observed and analyzed to describe empirical phenomena with the goal to develop empirically grounded local theories by understanding the actions of individuals (Krummheuer & Voigt, 1991; Krummheuer & Brandt, 2001). However, in these analyses the interactional perspective is the main focus (e.g. Jung, 2019) whereas the mathematical learning content fades into the background. Within this article, we try to include the *mathematical* perspective by considering the interplay of both interactional *and* epistemological aspects by using the analytical instrument "Formal-In" (Forms of teachers' mathematical interaction) (Bräuning & Steinbring, 2011). Within Formal-In, Bräuning & Steinbring (2011) seek to identify particularities in the teacher's verbal behavior that support children's interactive constructions of mathematical knowledge. They propose a methodical grid (see Figure 1) to analyze reciprocal teacher-student-interactions to "better understand how teachers can develop practices that foster mathematical communication" (Bräuning & Steinbring, 2011, p. 929). Although Formal-In was originally provided as a framework to analyze one-to-one teacher-student-interactions it also appears suitable for use on teacher-student-interactions within groups (Bräuning et al., 2020).

ID / ED	Instructive	Intervening	Explorative	Moderating
thing-like concrete use				
symbolic relational use				

Figure 1: The analysis grid Formal-In

The interactive dimension (ID) goes along with a teacher's orchestration of students' verbal contributions and consists of four patterns: instructive, intervening, explorative, and moderating. Interactions of the explorative and instructive type refer explicitly to the mathematical content in question whereas moderating and intervening interactions depict "the form and play" (Bräuning & Steinbring, 2011, p. 929) of communication. Furthermore, explorative and moderating interactions are understood as ways to find out about students' understanding of a mathematical phenomenon. In contrast to that, instructive and intervening interactions happen when interaction is "'transformed' into communication about the information intended by the teacher" (Steinbring, 2005, p. 77).

Because the learning of mathematics at elementary school level is initially bound to concrete material as embodied carriers of the non-perceivable and ideal structures, an epistemological dimension (ED) is included. In dealing with particular objects, both students and teachers can either stick to a thing-like concrete use with a focus on observable properties, which may hinder the interpretation of these objects as representations of something else, or move towards a more appropriate interpretation of symbolic-relational structures that become generalizable (Steinbring, 2015, p. 289).

Research context

The two sample episodes that will be presented in this article are taken from a first-grade and a fourth-grade classroom. Both classrooms are of particular interest as the learners have been taught by the same math teacher (female, in her late 30s, four years of teaching experience) from the beginning of their first day at school so that a look at the teacher-student-interactions in grade 1 compared to grade 4 seems to be possible in the form of a quasi- longitudinal study. The teacher-student-interactions were video- and audio-recorded throughout the school year. Building on the work of many other scholars concerned with the impact of students' language (proficiency) in the learning of mathematics (Prediger et al., 2018), it is important to mention that the school is located in a low-income and socially disadvantaged area. Most children are native German speakers whereas few are German learners. However, both native and non-native speakers deal with lacking vocabulary, limited language skills, and language-induced learning obstacles.

The following interpretative discussion of the chosen examples deals with the interaction that arose between the teacher and her students while approaching the following tasks: *Grade 1:* On a meadow, there are dogs and birds. There are 7 animals. Together they have 18 legs. How many dogs and birds are there? *Grade 4:* In a stable, there are horses and flies. There are 15 animals. Together they have 72 legs. How many horses and how many flies are there? Both tasks are identical in their structure, that is two animal species, the total number of animals, and the total number of legs are given while the exact number of each species is to be found out. Mathematically, the tasks represent Diophantine equations. Didactically, they can be classified as problem-solving tasks (Heinrich et al., 2015).

Analysis of transcript 1[1]: Grade 1 (end of the school year)

The students sit in a semi-circular arrangement in front of the blackboard. The task is visually presented on the blackboard. In addition to that, pictures of seven dogs and seven birds are put up on the blackboard. The teacher presents the task to the students but does not give any instructions[2].

The transcript (l. 1-89) can be divided into the following units of meaning (UM): *UM1* silent impulse and students' initial ideas (l. 1-7), *UM2* teacher reads out task and students come up with first ideas (l. 9-16), *UM3* clarification of total number of animals (l. 17-28), *UM4* total number of animals is seven (l. 28-33), *UM5* clarification of total number of legs (l. 34-45), *UM6* question about possible assignment for group work and summary of preceding task clarifications (l. 46-71), *UM7* teacher proposes a solution (l. 71-85), *UM8* teacher asks students to question her proposed solution (l. 85-89), *UM9* summary of task clarification and transition to group work with clear instructions (l. 89).

Using Formal-In as an analysis tool, the teacher takes a moderating role in UM1 by asking two students to read out the task. On an epistemological level, UM1 cannot be characterized since no mathematical idea is negotiated.

UM2 is characterized by an intervening interaction of the teacher:

9 Teacher: I will read out the task again. So everyone listens.

It can be assumed that she read out the task again to increase the students' attention. One student immediately says she knows the answer (7 birds and 7 dogs). However, it becomes clear that her answer is based on the number of animal illustrations attached to the blackboard. So in UM3, the teacher points out the illustrative function of the pictures but also offers the opportunity to use them as hands-on material to solve the problem. Therefore, UM3 is classified as an instructive interaction.

In UM4, the teacher intensively talks with a student, Zoe, in a one-to-one interaction. She asks Zoe to put seven animals on the blackboard but does not specify the number of dogs and the number of

---

[1] The numbers used here are number lines taken from the original transcript. Full transcripts are available on request from the authors.

[2] We call this a silent impulse. The students (both in grade 1 and grade 4) are used to this way of starting a lesson.

birds. In this respect, the interaction is both instructive and explorative as the Zoe on the one hand is told to do something but on the other hand is not bound to detailed specifications. Zoe takes away all the birds so that seven dogs remain on the blackboard. UM 5 follows in which the teacher points out the discrepancy between the task (18 legs) and the number of legs that seven dogs have. She does not say how many legs seven dogs have. So Zoe points to two dogs and states that together they have eight legs. She moves on to the next picture and adds another four legs by counting in steps of one. She stops when reaching 20:

42	Teacher:	Do you have eighteen legs now?
43	Zoe:	No.
44	Teacher:	So there's something wrong here. There aren't eighteen legs.

In this phase, the teacher takes on a moderating and explorative role. She moderates the discourse but lets Zoe figure out on her own that seven dogs mean more than 18 legs. In the beginning, Zoe uses a symbolic-relational understanding in appointing eight legs to two dogs at once. Since first graders are usually only asked to master numbers up to 10, Zoe then moves on to counting the legs by ones which means that she uses the pictures to concretely represent numbers. However, when stopping at 20 the symbolic-relational mode can be assumed as Zoe seems to refer back to the given task.

In UM6, the teacher asks seven different students what is important about the task and what the task requires the students to find out:

53	Teacher:	What do you have to keep in mind? Fio?
54	Fio:	We are supposed to think about how many legs there are.
55	Teacher:	It's already written on the blackboard. Eighteen legs. Valentina?
56	Valentina:	We are supposed to consider so if we have dogs and birds, consider how many legs there are.
57	Teacher:	The task says eighteen legs. Seven animals with eighteen legs. What are you supposed to find out? Zoe?
58	Zoe:	We are supposed to think to find out how many animals have eighteen legs.

With her frequent questions, the teacher wants the students to set a mutual starting point. She highlights they mathematically relevant aspects (total number of animals, total number of legs) so that her interaction can be classified as instructive, explorative, and moderating. She constantly connects the students' statements to the given task (instructive) while also incorporating their understanding of the task (explorative, moderating).

In UM7, the teacher proposes an idea and puts five birds and four dogs up on the blackboard. One of her students says that there are nine animals now, and the teacher takes away two birds. By giving a concrete solution and asking for the mathematically relevant aspects of the task, an instructive interaction develops in which teacher and students seem to work in the sense of heuristic trial and error. It is followed by UM8:

85	Teacher:	The question for you to answer is how many dogs and how many birds are there. Student1 says that there are three birds and four dogs. Is that right? Is that the answer to the question?

Two students confirm that this is true but Zoe intervenes by saying that the number of legs still is not consistent with the task. The interaction is characterized as explorative because the teacher constantly requests from her students to think about the given solutions.

Finally, in UM9, the teacher transitions a group work. On the epistemological dimension, the teacher implicitly encourages her students to take a symbolic-relational perspective by highlighting again that the total number of animals needs to correspond to the total number of legs.

Analysis of transcript 2: Grade 4 (in the middle of the school year)

The students sit in a circle in the front of the classroom. The task is written twice on two sheets of paper lying in the middle of the circle. Moreover, there are two flies and two horses as illustrations. The teacher presents the task visually but remains silent.

The transcript (l. 1-17) can be divided into the following units of meaning (UM): *UM1* Silent impulse and Nelly's first idea (l. 1-2), *UM2* Jason's solution (l. 3-7), *UM3* Jonas' solution (l. 8-14), *UM4* summary of the task clarification as well as transition to group work with task assignment (l. 15-17).

UM1 begins with the silent impulse. Starting in grade 1, the students are socialized in such a way that one student, here: Nelly, reads out the task and already comes up with a first solution. Since the teacher directly asks Nelly to read out the task and Nelly shares her mathematical ideas with her classmates, this can be seen as an explorative-moderating interaction.

2	Nelly:	I think there are more flies than horses because flies have more legs than horses.

It becomes obvious that Nelly refers to a thing-like-concrete idea of counting the legs at first but then moves on to a symbolic-relational understanding.

In UM2, Jason offers a solution and Jeremy responds. He picks up Jason's idea and elaborates it:

4	Jason:	Fifteen times seventy-two?
7	Jeremy:	I would rather say multiply four until you reach seventy-two.

During the whole process, the teacher does not contribute to the discourse or interfere with the students’ ideas. She only calls the students by name. Therefore, the interaction is characterized as moderating and characterized as explorative since two students' ideas become present.

In UM3, Jonas comes up with a further idea:

8	Teacher:	Jonas
9	Jonas:	We can count the flies or horses first because we always have to calculate because I just did that in my head. Ten times four is forty. That’s just ten horses and there are fifteen animals and there and then I have to calculate the flies. So we still have to calculate the flies.
10	Nelly:	Huh?
11	Teacher:	What’s the matter, Nelly?
12	Nelly:	It just occurred to me if you now have two flies that make twelve and then you just have to add four more flies.
13	Student:	Five flies.
14	Nelly:	I mean five flies.

After 2 minutes, Jonas and Nelly are about to solve the task. Again, the teacher only moderates the interactions and lets the students express their ideas which obviously result in first tries to come up with a solution.

In UM4, the teacher asks the student to start working in groups to finally solve the task. She frequently points out that she expects them to think about the following:

17 Teacher: Can that be true? Why? Why not? Which possible solutions did you find?

This interaction is explorative and shows that thinking about and justifying different solutions are important aspects to the teacher.

Comparison of the two transcripts

When comparing the analysis results, it becomes clear that in grade 1 slightly more instructive and intervening than explorative and moderating interactions occur. This is also evident in the number and frequency of turn-takings: Throughout the transcript, the teacher and one student alternate consistently for the most part, so that the teacher assumes a controlling and focusing function. On the epistemological dimension, only a few phases can be determined. This is probably due to the fact that the first graders still have to get acquainted with the way mathematical tasks are talked about and mathematical meaning is negotiated. In grade 4, explorative or moderating interactions occur and are more dominantly linked to the epistemological dimension. The transcript shows that the teacher only says the students' names in order to orchestrate their verbal contributions whereas the students are responsible for the mathematical content. They work to a large extent independently and thereby almost come up with a final solution of the problem-solving task.

In general, the analysis tool Formal-In allows for comparing the transcripts with regard to the interplay of interactional and epistemological level. With the help of these two transcripts, a change can be shown: From grade 1 to grade 4, the teacher constantly withdraws from the interactions. With her interactive discourse movements, the teacher supports the students to move from the thing-like concrete towards the symbolic-relational understanding of mathematics. It is interesting to note that in the two transcripts the epistemological dimension occurs exclusively in explorative or moderating interactions. This is presumably due to the fact that the examples are the introduction to the lesson.

Conclusion

Our analysis of the two presented episodes and the extensive watching of the video recordings have led us to conclude that the teacher manages to establish a discursive classroom culture in which the students are encouraged to explore mathematical problems independently. Despite methodical limitations (small sample size, restricted contexts), we can outline that an explorative-moderating teacher-student-interaction pattern seems to be fruitful as it is also shown in Bräuning et al. (2020). Our investigations into this area are still ongoing. However, the findings presented in this article are promising to add to the existing body of research in the field of mathematics education. Our future work within the research project PrimaL will focus on finding more evidence for the characteristics of the explorative-moderation interaction pattern.

On prospective teachers' evaluations of freshman students' written arguments

Cristina Coppola[1], Pier Luigi Ferrari[2] and Annamaria Miranda[1]

[1]Università degli Studi di Salerno, Italia; ccoppola@unisa.it, amiranda@unisa.it

[2]Università del Piemonte Orientale, Italia; pierluigi.ferrari@uniupo.it

In this paper we present a qualitative study in which we analyse how a group of prospective mathematics teachers evaluates written arguments produced by freshman students solving a problem involving graphs. The prospective teachers were attending a course of Mathematics Education for the second year of a master degree in Mathematics. In particular we focus on how prospective teachers in their evaluations look at mathematical content, language, and argumentative structure. The outcomes show, on the one hand, a certain attention to some linguistic aspects, on the other hand, a greater attention to the content than to the argumentative structure of the texts. We suggest that prospective teachers' models for linguistic education are often the standard ones, based on conformity to grammar or style rather than on adequacy with respect to goals.

Keywords: Evaluations, language, argument, prospective teachers, mathematical content.

Introduction.

Argumentation processes are growing more and more important in both research and curricula. In Italian curricula for the primary and secondary school level, argumentation is regarded as an interdisciplinary practice, related to mathematics but also to language, history, science and philosophy. Furthermore, it is given the function not only of representing what has already been learned but also of promoting learning. Its interdisciplinary character can be an obstacle to the development of appropriate teaching practices, as some teachers may stick to their subject and disregard the other aspects. Albano et al. (2019) found in an experiment that high school teachers evaluating students' arguments focused on the correctness of mathematical content only, and preferred concise though incomplete rather than more detailed and complete arguments. The goal of our study is to investigate more systematically how mathematics teachers (in this case, prospective teachers) evaluate students' written arguments. In particular, we want to highlight the aspects to which teachers give greater importance, what weight they give to material errors related to mathematical contents, to the lack of explicitation of the premises and logical connections, to the improper use of symbolic notations or verbal language. We expected attention to the argumentative structure, in accordance with school curricula, since prospective teachers have had some opportunities to reflect on argumentation in mathematics education as a teaching goal. The issue addressed in the paper can be seen as part of the more general problem of how teachers can promote students' argumentative competence.

Theoretical framework.

Argumentation in mathematics education has been widely studied in the last years, and a number of theories and models have been proposed, related both to purposes and form of argument. In this regard we assume that the main goal of argumentation in school is making the links between mathematical properties explicit, rather than convincing or warranting. Contrary to some current perspectives, which relate arguments to the application of external rules or constraints (e.g., logical rules), we assume that arguments in mathematics are based not on form but on meaning, and validity is a semantic property, according to Tarski's definition of *logical consequence* (Tarski, 1944). A statement P is a logical consequence of a set X of statements if P is true in all the interpretations that make all the statements of X true. A deep and insightful discussion on these topics has been carried out by Catarina Dutilh Novaes (2020). The idea of logical consequence is the core of classical mathematical logic and thus of mathematics. A good example of the role of meaning in mathematics is given by the way D. Hilbert formulates and comments the first axiom of the book in his Foundations of Geometry (Hilbert, 1909).

> I, 1. Two distinct points A and B always completely determine a straight line a. We write AB = a or BA = a.
>
> Instead of "determine," we may also employ other forms of expression; for example, we may say A "lies upon" a, A "is a point of" a, a "goes through" A "and through" B, a "joins" A "and" or "with" B, etc. If A lies upon a and at the same time upon another straight line b, we make use also of the expression: "The straight lines" a "and" b "have the point A in common," etc. (Hilbert, 1909, p.2)

Here Hilbert is not proposing the application of logical rules or other constraints, but a set of synonymous, interchangeable expressions. Expressions like "A and B lie upon A" and "a joins A and B" have different syntactical structure but the same meaning. So, what relates one expression to another is not form but meaning.

We adopt a semantic approach to argumentation for two main reasons. First, it is much nearer to mathematical practice, as it is impossible to describe any non-trivial argument according to its conformity to logical rules or other. Second, it is more useful in mathematics teaching, as the progressive achievement and refinement of meaning is a common feature of development of arguments at any school level, that any teacher can promote, recognise and evaluate.

Furthermore, an argument is, first of all, a piece of text, as argued by Bermejo-Luque (2011). So, language must be regarded as a relevant factor in the analysis of arguments. In this regard, we adopt a functional-linguistic perspective according to Halliday (1985). In this frame the focus is on the functions of a piece of text rather than on its form. In particular, we regard linguistic competence as the ability to critically and effectively use resources in different contexts rather than as conformity to grammatical or stylistic models. So, in our perspective an argument is the verbal description of the relationship of logical consequence between a set of assumptions and a conclusion. This means showing that in any interpretation where the assumptions are true, the conclusion is also true. Of course, a verbal description cannot be complete, as it is based on the meaning of words, that cannot be all defined. So, the degree of explicitation is never absolute but has to be related to the teaching goals and, possibly, negotiated in the class.

In this frame, we wonder how prospective mathematics teachers evaluate students' written arguments, in particular how much weight they give to the correctness of the contents or to the level of detail in the description of the logical connections.

Methodology.

The experiment.

The first step of our study consisted in collecting (and analysing) a number of written explanations produced by about 150 freshman students enrolled in a 3-year BSc degree in Biology (hereinafter, "students"). They were asked to solve the task in Table 1 and explain their answer. Then we selected some of the answers and we asked a group of prospective mathematics teachers (hereinafter, PTs) to evaluate these arguments. The PTs were attending a course of Mathematics Education for the second year of a master degree in Mathematics. The focus of this paper is on how prospective teachers evaluate the written arguments produced by students, while solving the task in Table 1.

Table 1: The task for the students

Let *f* be defined by: $f(x) = -x^2 + 2\sqrt{-x}$ a) Find the domain of *f*. b) Find *f'(x)* c) One of the following graphs corresponds to *f*. Which one? Explain.	
A) 	B) C) 	D) 
A priori analysis.

Problems of this kind have been presented by some of the authors in other occasions (see for example (Albano et al., 2019). They have proved suitable for triggering arguments because they involve different modes of representation (verbal, figural, symbolic), they require some basic knowledge only but cannot be solved just through the perfunctory application of methods learned at school. The crucial information to solve the problem is in the statement "One of the following graphs corresponds to f". Without it there is no way to give an answer and in any case reasoning by exclusion is necessary, since without further information it is never possible to conclude that a visualization of any graph corresponds to some equation. In some cases (such as here) it is possible to conclude that a graph does not correspond to an equation.

Freshman students' explanations.

Here is the English translation of a selection of five explanations provided by freshman Biology students. We are aware that some features of the text may be lost or distorted in the translation.

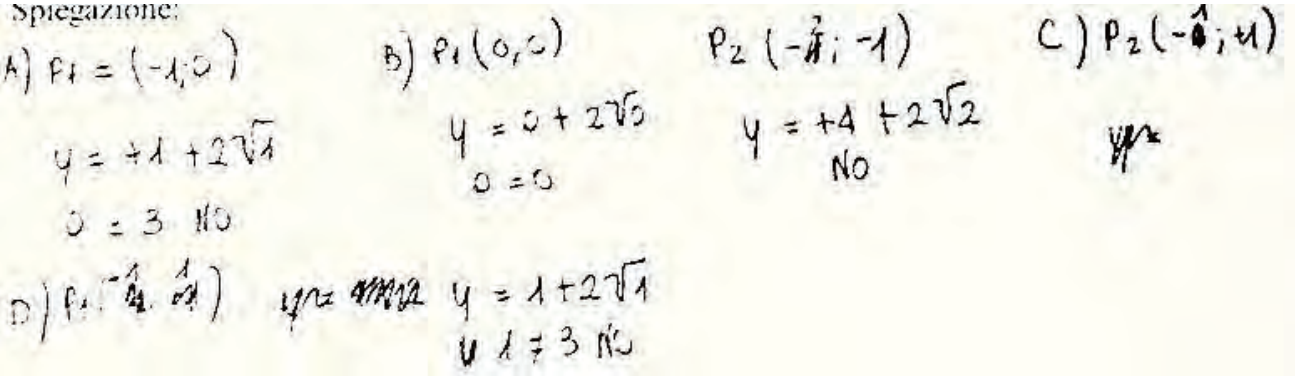
The selection of the arguments was made by taking those that were representative of the most frequent patterns. In particular we chose a detailed one (E1), a couple of concise ones (E2, E3), one without words (E4) and an incoherent one (E5).

E1: From the graphs given, observing the domain of the function f (x) (-∞, 0] we know that the function exists only for values from −∞ to 0, so we do not expect to have the function for positive values from 0, to + ∞; from this observation we can exclude graphs B and D, as they prove that the function exists for positive values (0, + ∞). Substituting in the function f (x) −1, then f (−1) ⇒ = −1, therefore values of x = −1, we obtain that y is equal to 1. The graph A can be excluded because for x = -1 the function in the graph has values y = 0. So by exclusion the graph corresponding to f (x) is graph C, as it satisfies the conditions.

E2: [Checks graph C on the diagram] I exclude the other graphs since B has domain in all R. Graph D has domain in x ≥ 0 and graph A has domain x ≤ 0 but for x = −1 y = 1 so I choose graph C.

E3: Graphs B and D are excluded because the domain is x ≤ 0. Graph A is excluded because f (-1) = 1. By exclusion, the graph corresponding to f(x) is C.

E4: [There is no verbal text, beyond three occurrences of "NO", so we present it as an image]



E5: Graphs B and D can be excluded for the domain. Studying the 1st derivative which is always negative because the domain, the function is always increasing so it is C. [1]

The sample.

The sample considered for our study consists of 50 prospective secondary school mathematics teachers, working in groups of 3 to 5. They were given copies of students' explanations and asked to evaluate them, in accordance with some guidelines, which were intended to make explicit the aspects we wanted to focus on: the weight given to mathematical content, to language, including symbolic notations, and to the argumentative structure. To this end, the guidelines drew the attention of PTs on the clarity of students' explanation, on their length (if they could be shortened or expanded in their opinion), on the mathematical correctness, on the linguistic appropriateness (possibly related to

[1] This is a good example of the drawbacks of the translations of students' excerpts from one language to another. The english translation could be mended by simply adding 'of' after 'because', whereas the Italian original text ("perché il dominio") requires the addition of some verb.

school level) and on the overall acceptability. Moreover, PTs were asked to indicate the critical points and add any comments they believed appropriate. It is worth mentioning that in the course of mathematics education PTs have had the opportunity to reflect on language, and on argumentation in mathematics education and on the importance of developing linguistic and argumentative competencies as a teaching goal.

To analyse the written evaluations provided by the PTs, we observed which elements they took into consideration. More in detail, we searched for finding if there were more references to mathematical content, e.g. material errors, or to the explicitation of the links between the parts of the arguments or to linguistic inaccuracies. We looked at which linguistic aspects the PTs gave weight and how they assessed, for example, improper use of symbols, or of language. For example, comments discussing the mathematical content of poorly formulated explanations without any remarks on language would show a strong focus on the content and a weaker interest in the other aspects. Furthermore, we also found it very interesting to look at the extent to which their attention is paid to other aspects such as completeness and coherence. Finally, we observed also the overall evaluation of each argument and also the models emerging from teachers' comments, in particular if there were expressions showing that they were more concerned about the conformity of arguments to some pattern or about their appropriateness related to some goals.

Data analysis.

We are focusing on the three main aspects outlined in the description of the task:

(1) Mathematical content
(2) Language (including symbolic notations)
(3) Argument (explanation of the steps, coherence, …)

What seems to emerge from the analysis of the protocols is that in most cases PTs, when dealing with the arguments produced by students, evaluate the content rather than the text with which it is communicated. In other words, the texts seem to be considered as carriers of mathematical content rather than as a component of students' productions to be evaluated. Some of them, for example, ascribe the incoherent organization of the text of the 2nd statement of E5 to the wrong calculation of the derivative. An extreme example is given by explanation E4 above: all the groups of the sample gave some interpretation of the procedure adopted by the student and, although there is almost no written text beyond formulas, about half of them describe the (presumed) argument as inadequate or lacking in rigor. According to a couple of groups this procedure shows some understanding of the mathematical ideas involved. Another group claims that this explanation could be appropriate if the student were at level 11. The reference to some school level as a term of comparison is another aspect emerging very often in teachers' evaluations, in most cases related to language. Arguments are considered more or less acceptable according to the (real or hypothetical) level of the student. The following comment, related to argument E1 is an example of this viewpoint.

> Although we reasoned exactly as [the student] did to proceed more quickly, we find this a sufficient but simplistic explanation of the problem for a student starting university. The answer would have been good if the student had been at a lower school level.

As far as language is concerned, most of the teachers who take it into consideration seemingly appreciate the conciseness rather than the completeness of the explanations. Moreover, they are much more focused on the use of mathematical terms or notations rather than on the overall construction of the argument. For example, although some groups appreciated E1 (which is probably the most detailed of the lot), some others claimed it is redundant. Most of the evaluations point out that expressions like ‘even graph’ are wrong, as (they claim) evenness is a property of functions and not of graphs, but on the other side a large part of the teachers was very cooperative (in the sense of Grice, 1975) when interpreting more ambiguous statements.

In general, most groups mainly focused on mathematical content and interpreted students’ productions in a very cooperative way, filling the gaps and neglecting some linguistic inaccuracy. In spite of their sensitivity to content errors, most groups interpreted them as occasional slips, ascribed to distraction or forgetfulness.

We report an evaluation of E2 where special attention is paid to the linguistic aspect.

> The explanation is extremely concise, but by no means incomplete. […] The calculation of the derivative is correct except for one multiplicative factor. We can reasonably conclude that […] the student did not arrive at the correct solution due to a distraction. The explanation […] reveals a fair knowledge of the topics covered […] Expressions such as ‘having domain in’ are not officially recognized nor in common use. The use of mathematical symbology is also poor, as can be seen in ‘for $x = -1$ $y = 1$’. The student omits the use of commas due either to sloppiness or to some difficulty in linking different propositions.

This comment on E2 is a bit different.

> Synthetic and not rigorous explanation, the student has the basic notions and can roughly solve the problem, but cannot adequately motivate it. The description of the domain is informally, but not formally, correct. The calculation of the derivative is incorrect. […] The language is not mathematical, and it is not appropriate for a student who should have mathematics maturity.

Also another group criticizes the use of language in E2 (but their symbolic, ‘meticulous’ representation of the domain is wrong).

> […] For example, a statement like “the graph X has domain Y” is a common error. We are sure that the student has understood the underlying concept but it is not the graph that has that particular domain but the function represented by the graph. There is also an error in the derivative, as a factor ‘2’ is omitted. We assume however, that this is just a simple, not trivial, slip, since the theorem of derivation of compound functions has been correctly applied, which in other answers has not been done. To be meticulous, the domain of the function could have been written more precisely, for example: $\{x \in R \vee x \leq 0\}$, however we believe it is quite a passable thing. As regards the use of Italian, there is a doubt about the phrase “I exclude the other graphs” placed at the beginning of the answer, since it is not clear whether it begins directly in this way (and in this case it would be unjustifiable, especially for one fifth high school or first year university student) or, having marked answer C as correct, she begins by directly motivating why the other graphs cannot be exact (in this case it is justifiable), precisely according to the answer already marked in the diagram. Not only that, we also add that in explaining why graph A could not be the exact one, one could be a little more precise by saying who the $x = -1$ $y = 1$ was referring to and not throw it there without adding any details. We believe that the answer is correct and suggests that the student has quite clear the basic mathematical concepts.

This group points out the improper use of mathematical notation as well.

> Apart from an error in the calculation of the derivative, the answer is mathematically correct and the thinking process is easily interpretable […] we consider it acceptable. The language could be

> improved, for example the student could have formalized the link between 'x = -1' and 'y = 1', however on the whole it is concise and clear and therefore adequate for his school level.

Some groups give a better evaluation to E2. However, all the PTs approved the reasoning in E2.

A fairly large number of PTs criticize reasoning by exclusion as in the next two evaluations.

> In this case an argument stronger than the simple exclusion would have been preferable, even a simple condition of belonging of particular points to the function would have been more adequate and appreciated.
>
> However, since the student has solved the question by exclusion, no certain confirmation can be drawn from it regarding the understanding of the "alternative" concepts which could be referred to for the direct resolution of the problem.

The following evaluation, even bolder than others, contains mathematically wrong suggestions.

> The derivative is wrong and as regards the choice of the graph, even if correct, it goes to the exclusion when it was enough to make the limit to $-\infty$ to identify the correct graph.

Discussion

Mathematical content

Prospective teachers were able to somehow interpret the mathematical content of the explanations, even when they were vague, inconsistent or even missing. In most cases they ascribed mathematical errors to slips or distractions. This is an interpretive pattern rather common among secondary school mathematics teachers and seems to depend on the interpretation of knowledge as separate from performance. The cooperative attitude of teachers is a known phenomenon that affects the attitude of students as well, who are aware of it and sometimes attribute failure in communication to the lack of cooperation of the teacher rather than the inadequacy of their product.

Language

Teachers in some cases did not consider language at all, in others they seemingly evaluated students' productions according to their conformity to some (generally unspecified) pattern rather than to their effectiveness in order to communicate their answers. A clear example of separation between effectiveness and conformity is the comment reported as the first indented citation of the section 'Data analysis': teachers rate the explanation as inappropriate, but admit they had followed the same pattern to proceed faster. Also the comparison between the text produced and the school level suggests a view of language as an (optional) tool to appropriately express already developed concepts rather than a fundamental one to promote learning. The other linguistic remarks are concerned with mathematical vocabulary: most teachers criticize the use of expressions like 'domain of the graph' or 'even graph' in place of 'domain of the function', 'even function'. Also in this case the use of 'graph' may not conform to mathematical vocabulary but is not a great danger for the clarity of the text.

Argument

In general, there have been very few remarks focusing on the structure and the effectiveness of arguments. Teachers have discussed the length of the explanations or the use of particular expressions but have not shown much interest in the explicitation of the relationships between the statements. E1, which is by far the most explicit, has been criticized for being redundant, whereas many groups have praised explanation E2 or E3. Actually, explanations like E3 (but also some of the others) are incomplete and do not give much information about the level of understanding of the student. Some teachers claimed that reasoning by exclusion is not the most appropriate way to solve the problem. We have remarked in the a priori analysis that there is no other way to answer the question. Reasoning by exclusion is based on a well known deductive rule (from 'P or Q' and 'not P' one can infer 'Q') and is perfectly correct from the viewpoint of logic. Most likely some teacher interpreted the explanations as occasions for students to display their mathematical knowledge. Again, there is some separation between knowledge and goals.

Summing up, the PTs involved in this experiment showed some more attention to language compared to the experienced, in-service teachers involved in the experiment discussed by Albano et al. (2019). Trouble is that their models for linguistic education are the standard ones, based on conformity to grammar or style rather than on adequacy related to goals. This suggests that language's evaluation by mathematics teachers is based on different criteria from those adopted by language teachers who follow the national curricula. Also mathematical notations have been considered as warrants for some unspecified rigour, to be applied in accordance with norms rather than semiotic tools capable of expressing meaning in relation to different purposes. This suggests that the semiotic systems of mathematics (verbal language, symbolic notations, figural representations) are to be regarded as such rather than as highways to get some already existing mathematical content not depending on them. So the use of such systems and in particular the conversions between them should be a topic for reflection for prospective teachers. Similar considerations hold for the argumentative aspects: the explicitation of the links among the statements has not been regarded as a relevant factor for evaluation. Apparently, the PTs expected students to write explanations to display their mathematical knowledge rather than to make their thinking process explicit and motivated.

Multilingual mathematics teacher's professional identity in multilingual mathematics contexts

Danai Dafnopoulou

Linnaeus University, Sweden; danai.dafnopoulou@lnu.se

Keywords: Language diversity, multilingual mathematics teachers, professional identity.

Introduction

Language diversity constitutes an overarching notion enclosing terms referring to the multiplicity or variety of language(s) used by teachers or/and learners at the school and societal level, such as multilingualism, bilingualism, second language, or varieties of the same language (Barwell et al., 2017). Multilingualism describes both the teachers and the context, at the current stage of the study, as multiple languages may be present in the school context even though they are not all used.

The need of broadening our understanding of teachers learning processes for teaching in multilingual contexts has recently been posed (Barwell et al., 2019). Even though teachers' teaching dilemmas in multilingual classrooms have been studied (Barwell et al., 2017), scares is the research on identity issues in cases of multilingual teachers in language diverse contexts, especially in Sweden (Delacour, 2020). Multilingualism is recognised in the Swedish educational system, while the role of teachers of all subjects, thus of mathematics, is to use and reinforce students' linguistic repertoires in the learning process (Skolverket, 2021). Therefore, the aim of this project is to provide empirical evidence and develop an understanding of the formation and development of multilingual mathematics teachers' professional identity and of their relation to school and multilingual mathematics classroom contexts. The following leading research questions being posed are: *How does teaching in multilingual mathematics classroom, as well as other past and present experiences influence multilingual mathematics teachers' professional identity? How do multilingual mathematics teachers' professional identities transform over time?*

Theoretical background

Conceptualising identity is viewed as more than self-image or reflection, and its dynamic nature is highlighted as being seen as 'a process of layering of events of participation and reification, in which our experiences and its social interpretation inform each other' (Wenger, 1998, p. 151). The theoretical framework of Patterns of Participation (PoP) (Skott, 2018) will be followed. Incorporating the work of Wenger and Holland and symbolic interactionism, it provides an understanding of teacher's professional identity in cases they are not part of predefined practices, like professional development program. PoP by focusing on teacher's interactions within their profession and in the classroom investigates how prior practices and figured worlds contribute to teacher's experiences of being, becoming and belonging as they engage with others in their profession and what changes may exist in the interplay of those over time (Skott, 2018).

Methodology

Being at the designing process, a multiple case study (Baxter & Jack, 2008) for a longitudinal period of 18-24 months, is proposed, understanding of teachers' professional identities in the long term. The study of three cases of multilingual mathematics teachers in lower secondary mathematics classrooms in Sweden are to be followed. The cases are proposed to be diverse school settings so as possible contrasts may provide multiple insides on those teachers' identities. Multilingual teachers will be selected according to the use of languages other than Swedish or English in different context, rather than their languages proficiency, while mutual linguistic repertoires with some of their students will be looked for. An ethnographic approach will be followed. Regarding the data collection process, multiple sources will provide a holistic view of teachers' identity (Skott, 2018). For that reason, semi-structured interviews and observations will be conducted regularly along the longitudinal period. Interviews will be used for informing about past and present experiences of the teachers about their education, teaching and language, also discussing issues emerging from the observations along the study. Observations will focus on the teacher, specifically teachers' interactions with multilingual students in instances that are related with language and mathematics. Following PoP, analysis will be conducted along with the data collection period, without predefined codes or categories, informing the data collection process.

The poster aims to discuss the contribution of such a project in the field and the methodological decisions for the specific aim, for the data collection process to start following the poster presentation.

Persuasive moments, and interaction between authoritative discourse and internally persuasive discourse when using GeoGebra

Ingólfur Gíslason

University of Iceland, School of Education, Iceland; ingolfug@hi.is

The purpose of this paper is to explore students' discourse when working in small groups on mathematical problems using GeoGebra. Specifically, the interest lies in to what extent the discourses are internally persuasive and to what extent they are alien to the students themselves. The data analysed are drawn from an upper-secondary class of students with histories of low attainment, focusing on functions and the Cartesian connection between algebra and geometry. Discourses of visual appearance were more present than academic mathematical discourse, and discourses of school as compliance counteracted students' appropriation of mathematical discourses into their own internally persuasive discourses.

Keywords: Classroom communication, discourse analysis, inquiry-based learning, dialogism, dynamic geometry software.

Introduction

Mathematics teachers and educators want students to integrate mathematical ways of thinking and communicating into their own thinking and communicating. According to sociocultural theories, the main goals of learning consist in expanding the students' action- and meaning potentials (e. g. Wells, 1999, p. 48), and other researchers have also argued for the motivating satisfaction that people derive from being able to "do something one could not do before" (Papert, 1980, p. 74). Unfortunately, for many students, mathematical ways of thinking and communicating stay alien to a large extent. Mathematics is only ever thought of as the words of authority, to be imitated in order to satisfy the requirements of the teacher, and ultimately, the school system. Many students thus rarely use mathematics studied in school in order to think or communicate about anything except school tasks.

The affordances offered by dynamic geometry software to visually perceive representations of mathematical objects, including the covariation of variables, have the potential to facilitate student's experiences of being able to do something one could not do before. Yet, there is a lot to learn about how students interact with such software in the classroom and the different types of learning made possible by different didactical designs. I therefore explore dynamic geometry problem solving discourses in an upper-secondary mathematics classroom of students with histories of low attainment. Here *discourses* refer to sequences of utterances.

Learning and authoritative and internally persuasive discourse

When we communicate, we are always responding to, and making use of context, which includes social and physical settings. What we assume to be our common ground, our shared assumptions about the world and the situation we are in and what it is we are trying to achieve, is crucial. When a group of people frequently interact in some sphere of shared activity, they develop patterns and types of utterances that are relatively stable. Bakhtin refers to these types as *speech genres* (1986, p. 60).

The goal of learning mathematics, from a dialogical perspective, is that students expand their discursive repertoires to include *mathematical discourse*—the historically established ways of communicating that competent users of mathematics employ (e.g., Sfard 2008). This constitutes the speech genre of mathematical discourse. But not all talk in mathematics class is directly related to mathematics. An important explicit theme as well as background assumption of communication in classrooms are the demands that the school and the teacher make on students. This I refer to as *schoolwork discourse* – utterances that refer to, or seem interpretable only in the context of the school as an institution that makes demands on students to finish certain work to some standard.

I relate learning to Bakhtin's concepts of *authoritative discourse* and *internally persuasive discourse*. The former is a type of discourse that demands acceptance, and derives its power from social authority, "independent of any power it might have to persuade us internally" (Bakhtin, 1981, pp. 110–111). For example, when mathematics functions as prescriptive rules to be followed, without justifications that are convincing to students, it is an authoritative discourse. On the other hand, a discourse is internally persuasive when it becomes tightly interwoven with "one's own word" (Bakhtin, 1981, p. 345). It is discourse that enters into an interaction and struggle with other internally persuasive discourses, which are all the other "available verbal and ideological points of view, approaches, directions and values" (Bakhtin, 1981, p. 346). It connects with and has an effect on our own discourses, being partly assimilated, partly modified, and always subject to our own creative intentions. In other words, it expands our discursive repertoires.

While a discourse can be internally persuasive without any observable indicators, some types of behaviour would imply that discourse is internally persuasive: when students explicitly make, test and modify mathematical conjectures themselves, they show that the mathematical discourse is interwoven with their own discourse and that mathematics interacts with their other internally persuasive discourses. In contrast, when students apply rules for calculation, without making sense of the rules themselves, after which they ask the teacher "is this right?", the teacher's (or the textbook) discourse has not become internally persuasive, it is only authoritative and remains alien to the students. The research question guiding this study is: How do everyday, mathematical and schoolwork discourses intertwine and interact in the problem solving discourses and to what extent do mathematical discourses become internally persuasive for students?

Method

This paper builds on my longitudinal case study of the classroom. In prior papers I described whole class discussions on contextual (paper-based) tasks (Gíslason, 2019), and a dynamic geometry task (Gíslason, 2021), while here the focus is on students in interaction with peers, while working on tasks.

The setting of the study is an upper-secondary school classroom in which most of the students have a history of low achievement in mathematics. The teacher of the class did not rely on textbooks available on the market, but rather found, translated, and adapted tasks from various sources, and made working with dynamic geometric software (GeoGebra) a centrepiece of classroom work.

The data analysed in this paper is drawn from two lessons, all involving the solving of tasks that are intended to make students aware of the Cartesian connection between algebra and geometry, more precisely on concepts of functional dependency and the interpretations of graphs. I recorded pairs of students selected at random, with a hand-held video camera that followed my focus of attention. My role was generally passive, but I was not invisible and the students sometimes addressed me, both to chat and to ask about mathematical tasks. All verbal utterances were transcribed verbatim in Icelandic and finally excerpts chosen to be presented in this paper were translated to English.

In analysing the data, I followed a dialogical approach. This means that I interpreted communicative actions (such as an utterance, gesture, or an input to a computer program) in context, as responses to what was said and what happened before and as initiations to further responses. The interpretations are also informed by my experience as a mathematics teacher and researcher and I began the exploration with an a priori theoretical distinction in mind, that of discourse being either closer to *everyday discourse* or closer to *mathematical discourse*. In the iterative process of analysis, it became clear that these often were intertwined, and the third major category became apparent, that of *schoolwork discourse*. Finally, I noticed that sometimes students seemed to be convinced by themselves that they had found an answer to a question, while at other times they sought external confirmations from an authority. I took this difference to correspond well to Bakthin's notions of internally persuasive discourse for the former and authoritative discourse for the latter.

Analyses of episodes

In the following I present two sequences of dialogue, selected to illustrate the three main types of discourse, how they intertwine, and function as internally persuasive and authoritative discourse. The students have all been given unique pseudonyms.

Whether to believe one's eyes: everyday speech and alienated mathematics (episode 1)

Ragna and Drífa have created a straight line using the line-tool in addition to the line that is modelled with the parameters *m* and *b* (which may be changed by moving sliders). The intention of the teacher was that students would use the sliders to change the line in accordance with task-directions. The first question asked the students to make it horizontal and go through a fixed point (that they had chosen freely at (4,2)). In this sequence the students address me, as I am recording them, treating me as an authority on the mathematics. Underlining indicates vocal emphasis.

1	Ragna:	So you want this to go [Addressing me, the researcher.]
2	Drífa:	through? [Ragna moves the slider for *m* back and forth, the line changes slope.]
3	Researcher:	We want this line to go through the point, and be … and be horizontal.
4	Drífa:	Okay. [The line now approximately going trough P but it is not horizontal yet.]
5	Ragna:	It isn't horizontal.
6	Researcher:	Then you must change it so that it will become horizontal.
7	Drífa:	You have to move this one. [Drífa points on the slider for *b* (y-intercept).]
8	Ragna:	Oh, okaaay. [Ragna moves the slider for *m* so that the line goes trough P, and then she moves the slider for b which moves the line in parallel off the point. This way does not work.]
9	Ragna:	"No can do". [In English.] [Ragna now adjusts the slope, until m=0, and the line is horizontal, but does not go through P.]
10	Drífa:	Yes! Yes like this. And then you move, no. [Ragna increases and decreases the slope (m), back and forth. Drífa points her finger to the point P.]

11	Drífa:	I think you should do …
12	Ragna:	Aargh. Difficult to own a mac. [Tinkers with the slope until the line is horizontal.]
13	Drífa:	Woah. [Swiftly moves the line, so that it goes through the point P.]
14	Ragna:	What is up!? [A phrase used to express surprise or joy.] [They open the note where they have copied the task-questions.]
15	Drífa:	Tada! ... And then m gives zero and b gives two. Doesn't it?
16	Ragna:	Yeah [They start typing in the note: m=0] Okay
17	Drífa:	Okay. Isn't that right?
18	Ragna:	Is it correct? Please tell.
19	Researcher:	Is this a horizontal line through the point P?
20	Drífa:	Yes.
21	Ragna:	It lies!
22	Researcher:	Yes.
23	Ragna:	Totally horizontal.
24	Researcher:	So why are you asking me?

At the beginning of episode 1, the students show that they want to comply with what the authority wants. In turn 1, they seem to assume that I, the researcher, is in the same authoritative position as the teacher and that they are responding to the perceived demand of the schooling situation. I respond with the "we" pronoun, as is common for teachers, possibly to try to frame the task as shared, something to be achieved together. I take this to be an example of schoolwork discourse, as the goal of "finishing the job" is an ubiquitous assumption of schoolwork.

In episode 1, students expressed joy when they managed to adjust the sliders to get a horizontal line (turns 13–15). Their first attempt was to move the slider for the variable b (constant term), until the line coincided with the fixed point, and then change the value of m (slope) to make the line horizontal (turns 4–9). They claim that this is impossible, perhaps perceiving that the "center of rotation" of the line is not in the fixed point. They then try the other way around; change m to make the line horizontal and then change the constant term to translate it (turns 10–14). In turn 15 Drífa reads the parameter values, $m = 0$ and $b = 2$, from the algebra window. By doing so, and noting "the answer", they show awareness that the mathematical object has both an algebraic representation and a graphical representation. They both express joy that they have found the solution (turns 16–17). However, as far as can be discerned in their talk and interaction with GeoGebra, they relied solely on slider manipulation and visual appearance, without any use of meaningful links between the algebraic and the graphical representations. For example, they did not mention that the slope should be zero to get a line parallel to the x-axis, nor did they express indications of recognising this after the fact. They achieved their goal using mainly everyday speech, more or less bypassing mathematical vocabulary and reasoning based on properties. Having found an answer, they were not fully persuaded by the visual appearance, and rather than linking their work to mathematical concepts themselves, they asked me, in turn 18, as an authority, to confirm the answer. In turn 19 and 24 I strongly imply that they *should trust* their own eyes, which can be interpreted as validating their visual, trial-and-error approach, rather than challenging them to explain their reasoning. It is possible that their experience with mathematics tells them *not to trust* their senses, and it is indeed important to reason on the basis of properties and not only from appearance. In summary, Drífa and Ragna did not make much use of mathematical discourse and it was not present in their internally persuasive discourses. Their everyday discourses were up to the task, and they produced a solution. At the same time they did not *fully* trust that they had an answer that would satisfy the teacher. Perhaps they had some awareness that appearance can be misleading, and therefore they sought additional confirmation for themselves through an authority.

Internally persuasive mathematical discourse (episode 2)

One main goal of the class was to get students to appropriate the language of variables. An experience of covariation can be made possible by creating a variable (represented by a slider) and linking that variable to a screen object, functionally dependent on the variable. The task text was as follows:

> Draw the following in GeoGebra:
>
> a) Make a square that can be enlarged and shrunk with a slider.
>
> b) Add a new slider that moves the square horizontally.
>
> c) Add another slider that moves the square vertically.

The link between a variable and a screen object is not given in the above task, unlike the task in episode 1. It is expected to be created by the student. The variable will create an interactive visual effect, closely linked to mathematical properties.

The teacher assisted students in constructing a dynamic square with vertices (*a*, *a*), (*a*, -*a*), (-*a*, *a*) and (-*a*, -*a*). In the following episode, two girls, Lilja and Anna, talk to each other and with the teacher, working on the second question, trying to create a slider that can move the square horizontally on the screen. In the first utterance Lilja suggests a modification, making it possible to move the vertex of the square via a slider determining a variable called *b*.

1	Lilja:	Plus x times b. [Might mean “add one unit, b times” to the x-coordinate, although a more streamlined way is to say “add b to the x coordinate”.]
2	Teacher:	Plus x times b? [Neither affirming nor rejecting, opening for further elaboration. He either does not follow or does not want to make the interpretation for the student.]
3	Lilja:	No [Shakes head, looks at the teacher].
4	Anna:	No... oh … I can’t remember which is x and which is y.
5	Teacher:	Okay the first number is always x and the second number is y.
6	Anna:	Okay should I then do .... aaah [Frustration, both hands waving].
7	Lilja:	We just want the x you know. [Referring to her knowledge that horizontal movement is described by a change in the x-coordinate.]
8	Anna:	Yeah the x is here, I am at the x you know. [Referring to the first coordinate as “x”.]
9	Teacher:	Yes.
10	Anna:	Okay, what should I do just ... plus?
11	Teacher:	Yes, yes what.
12	Lilja:	After the brackets. [Points toward the screen of Anna.]
13	Anna:	After the brackets?

14	Teacher:	Na then you add both to the x coordinate and the y coordinate if you do that. [The teacher knows that (a, a) + b in GeoGebra results in (a + b, a + b). It's unclear that this has an impact on the following turn.]
15	Lilja:	Then not, you should do before the second number ... hooo [Breaths in, throws head back, opens arms, visibly excited.] <u>Before the second number do plus b</u>! [Smiles, increased voice volume and much higher pitch.]
16	Teacher:	Okay that's y, then you move it to the y. [The teacher seems to interpret the suggestion as to write something equivalent to (a, b + a).]
17	Lilja:	No, that, before the first number. [She seems to sense what the teacher meant and the need to make it clear that she means (b + a, a) or equivalently, as she tried to express in turn 15, (a + b, a)].
18	Teacher:	Okay by the first number.
19	Anna:	But why plus b?
20	Lilja:	Because, because when.
21	Anna:	But there is an a there you know.
22	Teacher:	Yes, but yes but it…
23	Lilja:	<u>I got it, I got it</u>! [Visibly excited and joyful.]
24	Teacher:	Okay, show me.
25	Lilja:	Wait, wait.
26	Teacher:	You did a plus b.
27	Anna:	I did something wrong ... I first want to see that she can do it right, then I'll trust you ... first learn to do this plus.
28	Lilja:	Gurrrl gurrrl, gurrrl, gurrrl, gurrrl. Look … oh … gurrrl, gurrrl! [Outburst of joy, smiling and using a higher pitch and volume. Lilja now modifies her coordinates, her suggestion finally implemented as she has meant it, in the software.]
29	Anna:	Okay, uhm, how did you do it?
30	Lilja:	Look, gets bigger and smaller. Just do plus b after the second number.
31	Anna:	Plus b?
32	Lilja:	You know.
33	Anna:	Yes a plus b.
34	Lilja:	Just a plus, ... there ... minus you do also plus a, no, plus b. That's always the first number ... plus b. Now you won't flunk this class! ! [This is accompanied by pointing by her finger on the screen of Anna. She is directing Anna to type, first a + b in the first coordinate place and then -a + b in the first coordinate place of the next vertex. Then she gives a generalisation: always the first number (implied: of the first coordinate-place) plus b.]

Lilja now has a square that can be moved via the slider for variable b. Her square consist of the vertices $(a + b, a)$, $(-a + b, a)$, $(-a + b, -a)$ and $(a + b, -a)$. In episode 2 the students do not immediately solve the problem, which indicates that the mathematical symbolic language of variables and coordinates (as represented in the software) was not initially a part of their internally persuasive discourses. In turn 15 Lilja expresses her excitement in having grasped the nature of the connection between the symbolic slider-controlled variable and the visual behaviour of the screen object. She has not yet implemented her idea, which only happens in turn 28 when she modifies her coordinates and sees the results, verifying her solution. It is as if (this aspect of) symbolic algebraic mathematical discourse suddenly makes sense to her, using the Cartesian link to her own intent, incorporating it into her internally persuasive discourse. At first the teacher does not follow her "before the second number, do plus b" (turn 15), an everyday type of utterance, describing spatial arrangement. Lilja wants to replace (a, a) with (a + b, a) using the variable *b* to control a horizontal movement of the point. She uses everyday discourse to orient to the positions of symbols on the screen, "after the brackets", "before the first number", and the screen object "gets bigger and smaller", yet mathematical discourse is internally persuasive for her and is evident in her input to GeoGebra.

Lilja's partner, Anna, seems not to understand Lilja's description, and she seems to be more or less stuck at trying to imitate (Lilja's) authoritative discourse, grasping for step by step instructions. In turns 6, 8, 10, and 13 she seems to be trying to follow instructions (from Lilja and the teacher) as to what she should type into the software, without consideration of meaning. The mathematical symbolic system seems alien to her, it is only authoritative discourse that does not touch her own internally persuasive discourse. In turn 19, she asks "why plus b", which I see as her attempt to bring the authoritative discourse into contact with her own internally persuasive discourse. She wants the words that she has used to give commands to the computer to have meaning for her. Because what she has typed doesn't work, she expresses doubts as to whether Lilja has really "got it" (turn 27). Lilja describes her solution to Anna only on a syntactical level in everyday language (what symbols to type in and where) but never addresses her why-questions. Instead she tries to encourage Anna that she will not "flunk this class" (turn 34), reminding us that we are in school, talking in a voice from the schoolwork genre. Both Lilja and Anna are concerned to pass the course, but in this episode the mathematical content became internally persuasive only to Lilja.

In contrast with Drífa and Ragna in episode 1, Lilja does not need a confirmation from an authority. She is convinced that she has grasped the symbolic language and the link between that language and the visual representation. She communicates to the computer through the input text: "P = (a + b, a)" and experiences directly an expansion of her action potential. Her outburst of joy *preceded* her actual typing in of the command – it was not a response to seeing it work out (perhaps luckily, through trial and error, as was the case in episode 1). Afterwards, she was quick to also add a functional variable for vertical translation, generalising the method for translation of points in the coordinate system.

Conclusion

In the first episode the students were occupied with the task as a piece of schoolwork to be finished. While they expressed pleasure of having a result (achieved by trial and error), they made no explicit connection between the visual result and mathematical concepts, and also requested confirmation of their answer from an authority. Their satisfaction was due to having finished a job, not with having made mathematical discourse their own. Thus, the schoolwork discourse can be interpreted as being in this case not conducive to learning, or worse, actively working against learning.

In the second episode one student, Lilja, suddenly grasped the relationship between the mathematical symbolism and the visual representation. While she confirmed her answer visually, she was convinced that she knew what needed to be done *before* she gave any input to the software. I interpret her satisfaction as stemming from having made mathematical discourse internally persuasive. Her partner, Anna, did not show any indication of having made the discourse internally persuasive. The schoolwork discourse's assumption that students should finish the tasks set by the teacher frustrates Anna as she was concerned that she might fail the course. Lilja tried to help Anna finishing the task, but described only a step-by-step recipe, without reference to meaning. Lilja, therefore, was not hurt by the schoolwork discourse in this case, while Anna's learning suffered.

The two tasks worked on provide different opportunities to use mathematical discourse to achieve goals. In episode 1, the students manipulated ready made sliders to observe covariation of parameters and a visual representation. This did not make the *mathematical* relationship the center of attention. In episode 2 the students were expected to create sliders for variables and then define the mathematical objects themselves, using the variables. This required students to use mathematical discourse as a semantic tool, which means incorporating it into internally persuasive discourse. One of the students did so, while the other did not.

In their problem solving, students drew on everyday discourse to describe visual elements, both the visual representations of geometric objects and strings of symbols. They also assumed the everyday practice that to be persuaded of something, it is both necessary and sufficient to empirically check its appearence. Mathematical discourse was present in their discourses to a much lesser extent, and in a way that focused more on the surface (the syntax), rather than the conceptual meaning. Schoolwork discourse was always in the background if not explicitly apparent in talk about failing the course. Schoolwork discourse seems push students to imitate authoritative discourse, that is, using mathematical discourse without having made it their own. In other words, schoolwork discourse does not bring authoritative mathematical discourse into contact with internally persuasive discourse. Rather, it functions to keep mathematics only authoritative, and alien to the students themselves.

Handmade diagrams – learners doing math by using gestures

Melanie Huth

Goethe-University Frankfurt, Institute of mathematics education, Germany;
huth@math.uni-frankfurt.de

It is a well-investigated fact that human interaction implies a huge range of expressive modes. Unsurprisingly young learners although do so when doing mathematics together. In the last decade, more and more research has been concerned with this so-called multimodality in mathematical situations. Diverse modes and their interrelations were under investigation, like gestures, speech, or written expressions, sometimes actions. A systematic description of potentially mathematically used gestures by young learners as a part of this mix of modes is still missing. The paper is theoretically framed by an interactionist-semiotic approach wherein mathematics is seen as a social activity of using diagrams. The subject-specific role of gestures is to be clarified: Do gestures play a constitutive role in and for mathematical interactions, literally as a handicraft to work diagrammatically? The exemplary analysis reveals different functions of gestures in the diagrammatic work of the learners.

Keywords: Functions and forms of gestures, subject-specific gestures, diagrammatic reasoning.

Introduction

Observing young learners while doing mathematics together reveals the use of different expressions: Speaking, writing, using a tool (digital or analogue), gesturing or using facial expressions are perceivable as a kind of interwoven mix of modes. Theoretically, this mix of modes is often framed by the concept of *multimodality* (Arzarello, 2006; Radford, 2009). Radford (2009) states, "[…] that mathematical cognition is not only mediated by written symbols, but that it is also mediated, in a *genuine sense*, by actions, gestures, and other types of signs." (p. 112). This *genuine sense* of multimodality, and also of gestures for mathematics learning is often seen as given in advance (Huth, 2018, p. 219). A theoretically supported rationale for this assumption is missing, or at least not described in existing approaches to gestures in mathematics education. The present paper opens up a theoretically grounded view on gestures as signs in mathematical interactions by dint of the theoretical concept of *diagrams* and *diagrammatic reasoning* after C. S. Peirce. *Diagrammatic reasoning* in this sense includes the *construction of a diagram*, the *observation of relations* in that diagram and the *formulation of general conclusions*. It potentially leads to mathematical insights and further developed diagrams (Peirce, 1931, CP 1.54). The use of diagrams, which can be of various forms (Schreiber, 2010), is still perceptible at a very early state in the mathematics learning process. The question arises, if the use of modes in mathematical interactions of young learners and their use of diagrams are interwoven as well. For this purpose, the paper will first consider multimodality in mathematics learning, then offer a definition of gestures in mathematical interaction, and describes gesture as a sign after Peirce. Finally, the diagrammatic theory is used to focus the subject specific-role of gestures in the analysis. It should be investigated, whether gestures *represent* or rather (co-)*generate* leaners' diagrammatic reasoning by the following question: *Do gestures play a constitutive role in and for mathematical learner interactions, literally as a handicraft to work diagrammatically?*

Multimodality: A systemic feature of language – and of mathematics learning?

Radford (2013) claims, that thinking is deeply interwoven with bodily acting in the material world. In this sense, thinking in general, especially mathematical thinking, is *shaped and performed* by using different expressive modes. In line with these ideas, Arzarello (2006) advocates his theory of the *semiotic bundle* to describe a bunch of signs which are used by participants in mathematical interaction. This concept unites e.g., speech as a conventionalized, rule-based semiotic system, and also gestures as a more non-conventionalized mode. It intends to break down the rigid boundaries of considering exclusively semiotic systems in mathematical situations. Krause (2016), in line with Azzarello (2006), emphasizes the representativeness of gestures in mathematical interactions. She investigates mathematical occupations of upper school pupils and describes a "multimodal sign" (Krause, 2016, p. 49) of speech, gestures and inscriptions. The representative role of gestures is grounded in the view, that mathematical objects are not directly accessible because of their alleged abstractedness (p. 16) – a different perspective than it is supposed in the present paper. With regard to the concept of multimodality, Radford (2013) and Krause (2016) refer on the psychological theory of *sensuous* respectively *embodied cognition*. It emphasizes a mind-body-embeddedness in thinking, generating and experiencing the world. *Sensuous cognition* breaks down with a dualistic view of mind (internal and external). Body and mind are no longer separated, but related parts of human cognition.

In linguistic approaches, multimodality is grounded in the *system* of spoken language itself. Fricke (2012) proves a *systemic relevance of gesture* in spoken German language. In sentence constructions, gestures can be integrated in speech to fulfil syntactical positions (so-called *code-integration*, p. 75). In addition, gesture reveals features of language in their structural use, like e.g., *recursion*[1] (so-called *code-manifestation*). Some utterances show aspects of content exclusively coded in gesture. Sometimes, gesture is even obligatory e.g., for using some deictic expressions (p. 74). In addition, gestures can lead to conventionalized forms in interaction, using the same gestures for the same meant recurrently. *Multimodality* in this sense is seen as a kind of characteristic of the language system. This idea of a fundamental *grammar of speech and gesture* underlines the constitutive role of gestures for using language in human interaction. In psychological approaches McNeill (2005) admittedly assumes an "'unbreakable bond' of speech and gesture" (p. 24) and coined the idea of an integrative language system. However, he also states a language-gesture dialectic, where gestures can never be part of grammar in his view. In line with Fricke (2012), the present paper locates multimodality in the language-systemic sense, whereas gestures and spoken language construct this system.

Gestures: Definition, and its significance in interaction

To meet the plenty of manifold definitions of gestures, Andrén (2010) summarizes two main perspectives: The first includes nearly every body movement to be a gesture: movements of hands, arms, head, mimic or facial expressions, gaze, action, etc. In the second perspective, the gesture definition is more narrowed (p. 11). It is leaned on Kendon (2004) who investigates how body movements are *interpreted* by interlocuters in interaction and due to the situational context (pp. 14–

[1]With a finite number of elements and well-defined rules of using these elements one can generate an infinite set of language constructions (Chomsky, 1983, quoted after Fricke, 2012, p. 120).

15). He basically describes gestures as “visible actions” (p. 7) and with “features of manifest deliberate expressiveness” (p. 15). The gesturer is ascribed a “voluntary control” of his gestures which are “being done for the purpose of expression” (p. 15). Goldin-Meadow (2003) differentiates gestures from *functional acts at objects or persons* (p. 8), e.g., adjusting the glasses. In her view, such actions are not seen as gestures, even though they can be done parallelly to speech. She defines gestures based on two criteria: (1) Gestures are hand motions uttered while the *communicative act of speaking*, and (2) are *no functional act* on persons or objects (p. 8). The criteria appear to be mutually exclusive and obviously strictly separates actions from gestures. It can be questioned what is meant by *a functional act on an object or person* and if there could be rather such acts which *includes* a communicative act. A simple example is the (maybe wordless) placement of a chair to broaden an ongoing discussion group while a delayed person enters the room. Can’t we assume here a *communicative act*, although a *functional act* is performed on the chair? The placement is *readable* as a communicative act by the participants, e.g., as an invitation to participate in the discussion, the *where* and *how*. Theses interpretations are based on a culturally grounded commonly shared background and the actual situation in which the participants *act with* and *to* each other mutually and interactively. Thus, the *existence* of a communicative act attributed to an action or a gesture is rather the *result* of an interpretation and not independently given, or ascribed from an outer view. In mathematics education Sabena (2008) also focusses a separative definition of gestures while doing mathematic: She claims, they “*are not a significative part of any other action (i.e. writing, using a tool, …)*.” (p. 21). As a distinguishing feature, she constates, that actions are intentional and goal-oriented (p. 35). Gestures in Sabena’s sense obviously cannot be *manifest deliberate* like Kendon (2004) claims. They are to be seen strictly differently than writing or using a tool. However, Arzarello (2006) speaks of gestures that can be *fixed in written signs* in an ongoing mathematical occupation (p. 291). Harrison (2018) emphasizes the communalities of actions and gestures. He claims, that gestures are performed according to the material world and that some actions show comparable structures with gestures in their co-expressiveness with speech. A person sitting next to another person and performs a description of a direction may draw gesturally a kind of map on his or her thigh. The thigh is used as a paper to draw gesturally the map on. It is interpreted as a *part of that gesture* which in turn depends on this thigh-paper-map. With this in mind, it seems less useful to strictly distinguish gestures from actions or body touches. Their interwovenness is also reconstructed by Vogel and Huth (2020). For mathematical learning they found an intersecting action-gesture-use in *chronology*, the *semantic attribution of meaning*, and in *function* (pp. 241–243). Billion (2021) also takes a look at gestures and their intertwining with actions in mathematical situations to reconstruct diagrammatic interpretations of learners. This paper adopts Kendon's (2004) definition of gesture and draws on Harrison's (2018) view of gestures and actions: Gestures are those movements, which are ascribed the “features of manifest deliberate expressiveness” (p. 15) by the interlocutors. Material-use or exclusive body parts are no exclusive criterion. This definition can be linked to the considered interactionist-semiotic perspective on mathematics learning, where the interpretation of the participants is of core interest.

Mathematics learning: Diagrammatic reasoning in interaction

To focus the role of gestures in mathematical interactions of learners, the nature of mathematics learning has to be described in line with an interactionist-semiotic perspective. Krummheuer and

Brandt (2001) claim, that interactions in peers and with an experienced opposite constitute mathematical learning. From a semiotic view, the use of diagrams is the core of doing mathematics (Peirce, 1931). Both approaches combined, mathematical interactions provide a space for experiencing “a social practice with, on, about, and through diagrams” (Dörfler, 2006, p. 105). Accordingly, mathematics learning depends tremendously on being and interacting with others about, on and with diagrams to increase one’s own proficiency in acting mathematically. Learners gain a kind of autonomy in using mathematical signs and argumentations and develop from the role of participant to an autonomous actor (Krummheuer & Brandt, 2001, p. 20–21). In the ongoing process of negotiation, the interlocuters form together the content of interaction and commonly coordinated interpretations. These interpretations can be used as a kind of template to contrast and adopt one’s own insights. The common coordination tends to offer stabilization, and that is, what Schreiber (2010, p. 59) calls the *framing of the situation* in line with Peirce’ *ground of signs* (1932, CP 2.228). Consequently, Krummheuer and Brandt (2001) claim a social responsibility for utterances in interactions, even if one interlocutor produces its perceivable form. It emerges from the social. Utterances in multimodal designed mathematical interactions of learners can be described as *signs* of different kind with a triadic structure (Peirce, 1932): They consist of a *representamen*, an *interpretant* and an *object*. If a gesture is perceived as a *sign*, it can be described as a sign. It has a perceivable outer form – its *representamen*. The gesture sign evokes an interpretation in the mind of the sign reader – the *interpretant* – related to the probably referenced *object* of the sign (Schreiber, 2010, p. 32). The sign interpretation of the sign reader is shaped by his/her *ground* of the sign which can be named as the activated *framing* in the above-explained interactionist view. It includes theories, habits and experiences as an interpretation background. This concept of *framing* assigns a contextual, cultural and social dimension to the interpretation of signs. The interpretant of the sign is describable as the *effect of the sign* in the mind of the sign reader. It can be uttered again, and used as a new representamen. An endless process of semiosis emerges. In the Peircean semiotic, the concept of *diagrammatic reasoning* and the use of *diagrams* is central according to mathematical occupations. This approach shifts the view from supposedly abstract mathematical objects to mathematics as using signs and diagrams that are materially perceptible and manipulable by hands (Dörfler, 2006). Diagrams are rule-based fixations which show particular relations to each other and can be of different kind: written, created on a screen or even developed by material arrangements (Schreiber, 2010, p. 27). The relations and rules of the diagram are not given in advance, but are based on social negotiation (p. 41). They can be seen as a part of the ground of the sign or diagram interpretation.

Empirical example: Gesture use of learners while doing math

In the follwoing extract of analysis the main research question is: *Do gestures play a constitutive role in and for mathematical learner interactions, literally as a handicraft to work diagrammatically?* Two second graders, Maya and Dennis, ought to find all possible permutations of three elements, presented by plastic animal figures (white tiger, brown tiger, elephant). A hugh amount of paper cards with the animal’s faces are available for documentation. An accompanying person B offers the mathematical problem and the material. Maya and Dennis put in total 7 rows of paper cards (one of them twice) in front of them. They are finally sure *‘we found all of them’*. For the analysis, the situation was videotaped and transcribed: First, an interaction analysis (Krummheuer & Brandt, 2001,

p. 90) is applied. Based on this, a semiotic analysis (Schreiber, 2010) is conducted with the multimodal adopted *semiotic process-cards* (SPC) to map graphically the chronological sign process (Huth, 2018). Every utterance is pictured by two sign triads, one for speech and one for gesture respectively with R (representamen), I (interpretant) and O (object). The gesture-speech triads are connected via a common interpretant. Simultaneous utterances are mapped with a and b in one row.

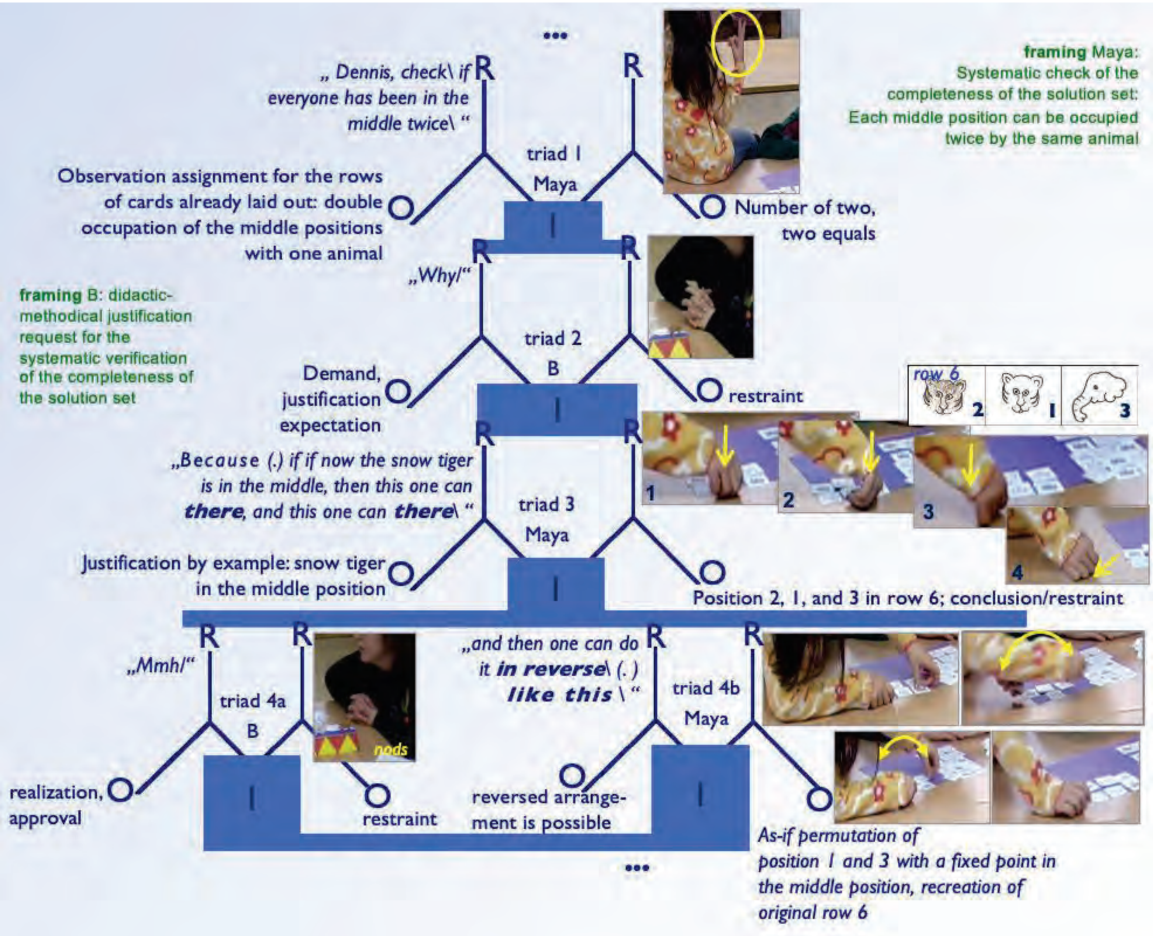

Figure 1: SPC, excerpt 1, Maya's observation instruction to Dennis

Maya starts with an observation order that refers to a first idea of a recognized generalization across all card rows: Dennis should check whether each animal has already been twice in the middle position (triad 1). Maya emphasizes gesturally the number with two similar fingers. She performs this gesture in relation to her speech in front of herself, not to the diagram of card rows, and refers to the mathematical idea of fixing points. In the SPC (Figure 1), it comes to the fore, how strongly gestures and actions are interconnected in the learners' diagrammatic reasoning: After a question of B (triad 2) the explanation of Maya is performed on the diagram of paper cards in both modes (triad 3 & 4b). The fixing point is emphasized gesturally by pressing on the middle position, and in action by leaving this position unaffected. The interchangeable positions are quickly typed or briefly swapped and returned. As activated framings we can assume a systematic review of the card rows based on a mathematical idea of fixed points. B's framing is additionally didactically overdyed. Figure 2 shows a later excerpt of the same SPC. Maya generates a new or more developed diagram mainly in her gestures (triad 23 & 25) after B asked why there are no more rows to find. Maya initially justifies her answer in the quantity of available animals. Then she uses the generated diagram of all rows to expand n to n+1, enriched with her idea of fixed points.

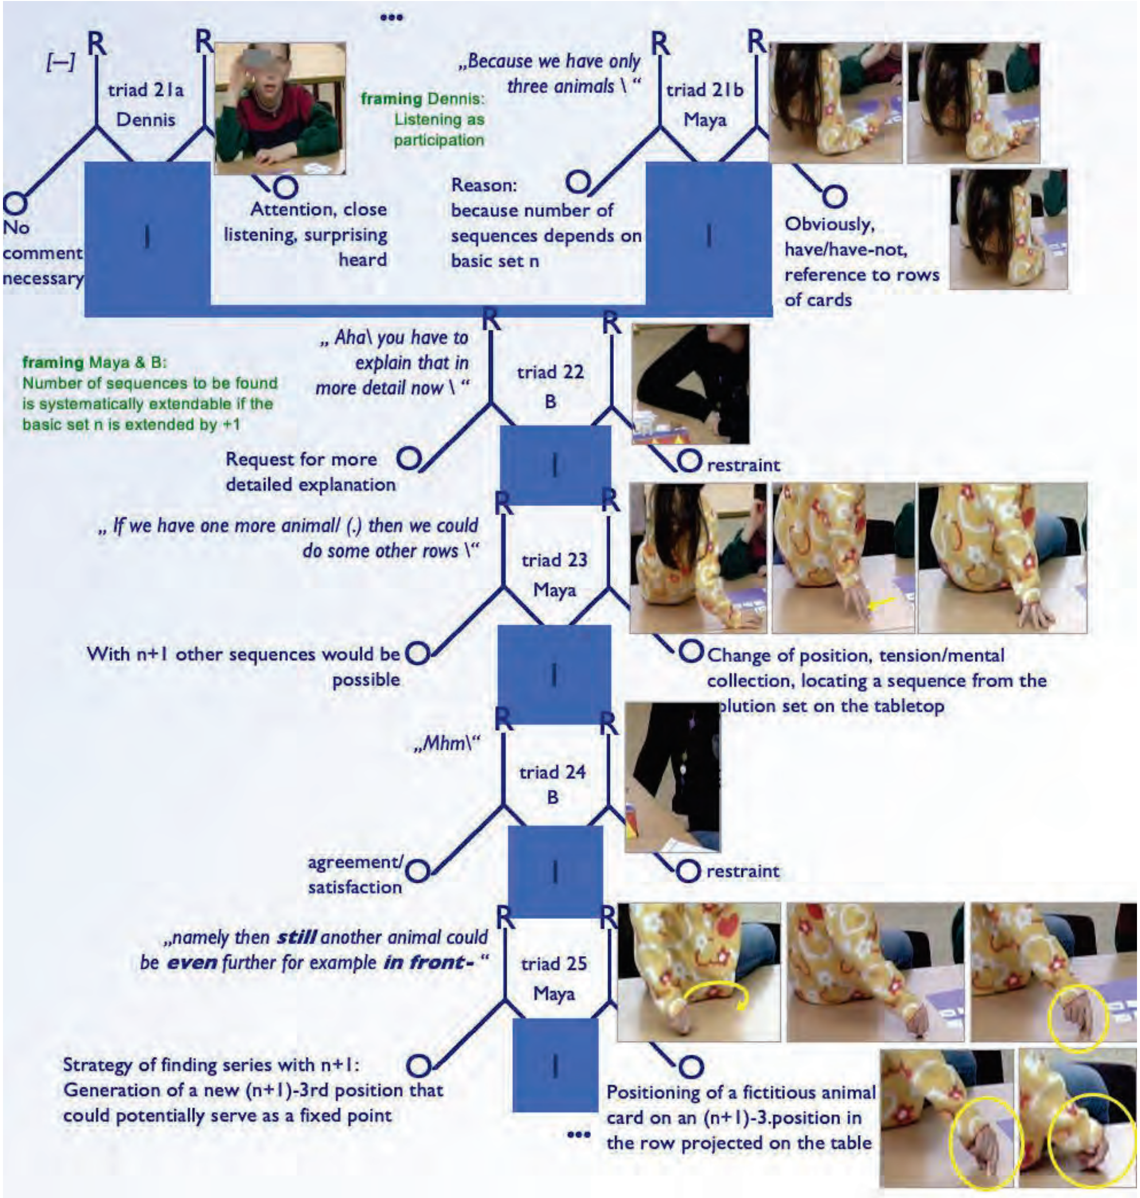

Figure 2: SPC, excerpt 2, Maya's gestural diagram construction and manipulation, rows out of n+1

Maya extracts gesturally one row out of the card-diagram to generate an example of a row (n+1). A new diagram next to the initial diagram is generated. In a Peircean sense, in her gesture she *creates a new diagram* and *generalizes the fixing point idea* to see, if it holds for all comparable diagrams. Maya gesturally outlines the contour of the new row (n+1), starting with an arched sliding gesture from the last to the first position over the table. Then she establishes a new first position in the outlined row, by using a kind of pantomiming action-like gesture with which she lays down exactly an animal card on the new front position (triad 25). With her speech, she indicates how to use the initial rows with n elements to generate rows with n+1 by referring to the concrete animal. Maya relates both diagrams to explain how to generate the second out of the first. Her gestures are used as mathematical signs to build a further developed diagram and to manipulate this gestural diagram again by gesture.

Dennis seems to honor Maya's ideas in a special way and marks it as important due to his ear-pinning listening gesture (triad 21a).

Conclusions

The example shows, that gestures play a constitutive role in and for the mathematical interactions of learners. They can be literally used as a handicraft to work diagrammatically on initially generated diagrams (Dörfler, 2006; Peirce, 1931). With Fricke's (2012) theory of a systemic relevance of gestures for language, one can conclude, that gestures in the Peircean sense have a comparable systemic relevance for acting mathematically: In the learner's diagrammatic reasoning, gestures are an *integral part of mathematical constructions*, like here the idea of fixed pints (mathematical *code-integration*). In addition, perceivable in the diagrammatic reasoning, the commonly negotiated use of *gesturally generated new mathematical diagrams* is observable (mathematical *code-manifestation*). In the shown example, the performed gestures forms range from an explication of speech (triad 1), to gestures, which create links between parts of the diagram (triad 3), until gestures, that are closely related to actions and the material world (triad 3 & 4b). The central mathematical idea is that of *fixing points* in permutations, which is first explained on *one row*, and then *extended* for the gesturally constructed new diagram. In line with Vogel and Huth (2020) gestures and actions are closely interrelated: Both modes are used in a *subject-specific sequence* to expand the generalization of a mathematical idea to n+1. Thus, with regard to the used gestures' functions, one can reconstruct a subject-specificity. They (1) *structure the mathematical interaction* (triad 21a & 21b), (2) which are *used to clarify the framing* (triad 1, 3 & 4b), (3) which *are used to present a mathematical idea* (triad 1), (4) which *manipulate the diagram* (triad 3, 4b, 23 & 25), and, (5) which are *used diagrammatically* to a general idea (triad 25). Considering that gesture mode is flexible due to its functions and forms, these descriptions should not be taken exclusive. In mathematics education research the focus should be shifted on such gesture functions in interaction to apply them to a larger database e.g., in different ages of learners. From this, suitable concepts can be developed to consider and foster the gesture use in mathematics classroom as a constitutive mode for *handmade diagrams* of learners and teachers.

The status and negotiation of knowledge when teachers repeat students' words

Jenni Ingram

University of Oxford, UK; Jenni.Ingram@education.ox.ac.uk

Teachers frequently repeat students' words and in doing so they are doing a wide variety of actions. In the mathematics education literature different names are given and distinctions made to the different types and forms of repetitions. This has led to ambiguity in the meaning and use of terms like revoicing, yet the distinctions made have important consequences for the negotiation of knowledge in mathematics classroom interaction. In this paper two examples are offered to illustrate one such distinction focusing specifically on the use of revoicing in the mathematics education literature, considering specifically the influence these distinctions have on epistemic rights and responsibilities within the interaction.

Keywords: Revoicing, repeating, epistemics, interaction.

Introduction

When teachers repeat students' words they could be doing a wide variety of actions. This repetition is also referred to by many different names in the literature, sometimes synonymously, sometimes drawing distinctions based on the form or the function of the repetition. These terms include for example: repeating, rephrasing, reuttering, reporting, recasting, reformulating, revoicing, rebroadcasting, repairing, and restating. These different terms often reflect the theoretical framing of the research study and are now often used without definition or explanation. Yet the differences between these terms are important when considering the function and role of repetitions in interaction in the management of epistemic access, rights, and responsibilities. In this paper I will offer some illustrations of a few of the distinctions made with a particular focus on revoicing as used by a range of authors within mathematics education, and the impact these distinctions have on the negotiation of knowledge in the mathematics classroom.

Revoicing

O'Connor and Michaels have defined revoicing as "at a minimum, this revoicing involves the teacher repeating or rephrasing some part of the student's utterance, and then opening up the next turn for the student to (tacitly or explicitly) agree or disagree with the teacher's revoicing" (2019, p. 167) building on their initial identification of this teacher move in their 1993 paper (O'Connor & Michaels, 1993). They describe revoicing as involving the teacher drawing an inference from the student's contribution, offering the student and other students the opportunity to validate or challenge this inference. They describe a range of interactional structures of revoicing including the use of discourse markers such as 'so' and turns returning to the students in contrast to the common IRE structure, but the emphasis is on the students' rights to accept or reject the inferences, and thus evaluate them.

Many researchers now use the term revoicing in their own analyses of classroom interactions, without definition or explanation (e.g., Takker & Subramaniam, 2019; Walshaw, 2017) suggesting that it has now become an accepted term within the field, but often to describe moves that only include some of the features originally described by O’Connor and Michaels (1993). The term is also being used synonymously with repeating, reuttering, rephrasing, reporting or reformulating (Forman, et al., 1998; Franke et al., 2007), recasting (Gardner & Forrester, 2010; Moschkovich, 2015), marking and rebroadcasting (Wilson et al., 2019), repairing (da Ponte & Quaresma, 2016; Hintz & Tyson, 2015), restating (Herbel-Eisenmann, et al., 2009) and building on or expanding (Forman et al., 1998; O’Connor & Michaels, 2019), as well as encompassing reformulations that involve moving from one named language to another (Enyedy et al., 2008). Some authors (and teachers (Herbel-Eisenmann et al., 2009)) make a distinction between repeating or reformulating and revoicing (O’Connor & Michaels, 2019; Walkington, et al., 2019) whilst others do not (Barwell, 2016; da Ponte & Quaresma, 2016).

This multiplicity and ambiguity in use can be explained by the different theoretical perspectives and constructs these researchers are drawing upon, including Goffman’s notion of reported speech (Forman et al., 1998; Goffman, 1981; Krummheuer, 2007), Stubb’s notion of meta-commenting developed by Pimm (1987), the notion of positioning as described within positioning theory (Harré & Van Langenhove, 1999; Herbel-Eisenmann, et al., 2015) and the notion of voices from Bakhtin (Bakhtin, 1981; Barwell, 2016). It can also be explained by the fact that when a teacher repeats what a student has said, they can do so in many different ways and achieve many different actions with this move. However, what is important is to consider the implication of these differences on students’ learning and experiences of mathematics.

One way to look at revoicing is to focus on the form of the teachers’ repetition of a student’s contribution. What is said is often not an exact repeat of the student’s contribution. Teachers can select, delete, paraphrase, and otherwise transform what the student said. The repetition can also include other discursive features such as the use of discourse markers like ‘so’, and direct or indirect references to the student whose contribution is being considered e.g., by using their name or using personal pronouns like ‘you’ combined with a laminating verb such as ‘think’ or ‘said’ (Herbel-Eisenmann et al., 2009; O’Connor & Michaels, 1993). Each of these features can alter the epistemic access, rights, and responsibilities within the interaction.

Many definitions or descriptions also consider the function or purpose of revoicing. Many of these include some way of foregrounding or drawing attention to some aspect of the student’s original utterance. These include enabling the idea to be heard (Hintz & Tyson, 2015) or appreciated by the rest of the class (O’Connor & Michaels, 2019), summarising or amplifying the idea (Hintz & Tyson, 2015), supporting mathematical practices such as abstracting, generalising or attending to precision (Enyedy et al., 2008; Moschkovich, 2015) and supporting the use of mathematical language (Battey, et al., 2016; Moschkovich, 2015). Other functions relate to the positioning and ownership of the mathematics under discussion and include giving students credit for the idea (O’Connor & Michaels, 2019), acknowledging a student’s idea (Hintz & Tyson, 2015), attributing authorship (Enyedy et al., 2008), competence or ownership (Battey et al., 2016), asking other students to agree or disagree with an idea (O’Connor & Michaels, 2019), positioning in relation to other students’ ideas or in relation to the academic task being undertaken (Enyedy et al., 2008; O’Connor & Michaels, 1993), facilitating student debate (Enyedy et al., 2008), as well as positioning in relation to accepted mathematics or sociomathematical norms (Alibali et al., 2019; Enyedy et al., 2008). Other descriptions include focusing on misunderstandings, creating a sense of engagement, giving teachers more time to think or make decisions about what to do next (O’Connor & Michaels, 2019), or establishing the role of contributing to the construction of knowledge within the classroom (Forman & Ansell, 2002) and maintaining and demonstrating common ground (Alibali et al., 2019).

Yet the key structural feature emphasised by O’Connor and Michaels (1993, 2019) is that the teacher’s reformulation (or repetition, recasting, etc.) is followed by the opportunity for the student to accept, affirm, reject, refute, deny, or clarify the teacher’s interpretation as evident in their reformulation. Only a few of the examples offered in subsequent literature illustrate this aspect (e.g., Heyd-Metzuyanim, et al., 2019; Ingram & Riser, 2019; Moschkovich, 2015). This diversity in use of the term leads to the question of whether some of the distinctions being made matter with respect to the negotiation of knowledge in mathematics classrooms.

Interactional management of knowledge

In this paper an Ethnomethodological Conversation Analysis (EMCA) approach is taken to examine the negotiation of epistemic status, rights, and responsibilities where teachers repeat students’ words in mathematics lessons. From this perspective, the negotiation of epistemic issues is made visible in interactions between teachers and students. For example, Hellerman (2003) and Macbeth (2004) used EMCA to show how the prosody and modifications of teachers’ repetitions of students’ answers to questions influenced how this repetition was treated in the interaction as accepting the student’s answer or as rejecting the answer.

EMCA examines how actions such as eliciting or access to knowledge are managed in interaction (Heritage, 2012, 2013; Ingram, 2020, 2021). Epistemic asymmetry can be considered to be a defining property of classrooms (Solem, 2016), with teachers usually asking questions to which they already know the answer and also evaluating students’ responses to these questions. The analysis below draws on Stivers et al.’s (2011) three dimensions of epistemic management: epistemic access, epistemic primacy (or rights) and epistemic responsibility. Epistemic access refers to who has access to the information. Epistemic primacy refers to who has the rights to tell, inform, assert, or assess something, and these can vary between classrooms depending upon the norms of interaction within them. Epistemic responsibilities can also vary between classrooms and refer to what information participants have the rights or obligations to know.

Data

The extracts used in this paper are taken from a corpus of videos of secondary mathematics lessons that were naturally occurring. The lessons were recorded by the teachers themselves and shared with the author who transcribed the whole-class interactions using Jefferson transcription (1984) (simplified to adhere to the publication guidelines).

Analysis

In this paper two examples are offered of interactions where the teacher has repeated students’ words. Each of these examples shares some of the structural features of revoicing but not all, and these similarities and differences have interactional implications for the negotiation for epistemic access, rights, and responsibilities.

In the first example the lesson is focused on linear sequences. The students have been asked to find the twelfth term of a sequence that begins 5, 9, 13, 17, 12, ….

Example 1

177	Tanya:	why?
178	Stevie:	you add twenty-eight to it and then that
179	Sid:	what?
180		(1.0)
181	Stevie:	no no, 'cause if you times four by seven, we have seven until we reach like the number at the top, seven ‘til we reach twelve, and then 'cause you're adding four every time, it's four times seven, like that, so that's twenty eight.
182	Tanya:	so four times seven is,
183	Stevie:	twenty-eight
184	Tanya:	so you think the answer is there's twenty-eight sticks, do you
185		(1.9)
186	Stevie:	u:m:=
187	Tanya:	=no, we agreed there was actually forty-nine sticks.

In this first extract we can see two partial repeats of Stevie’s answer by the teacher Tanya. The first of these in turn 182 repeats only a small part of what Stevie said in turn 181 and uses a *designedly incomplete utterance* (Koshik, 2002) which Stevie completes in turn 183. Whilst Tanya’s turn is a partial repeat and includes the initial inference marker ‘so’, it does not invite Stevie to agree or disagree with the repetition, rather it invites Stevie to add the missing part of this repetition. This repetition shows that Tanya has heard what Stevie said, but not necessarily that Tanya has understood in that there is no interpretation or inference drawn as part of this turn (Sacks, 1992; Ingram, 2020). However, the ownership of the contribution remains with Stevie.

The next repetition in turn 184 is doing something different. The twenty-eight is repeated but additional details are added by Tanya including that she has understood Stevie as saying that the answer is twenty-eight and connecting this ‘answer’ to the original question by adding the qualifier ‘sticks’. The inclusion of ‘you think’ means that the ownership of this answer again remains with Stevie, however the addition of ‘do you’ at the end, as well as the prosody of the turn, indicates that there is a problem with this answer. The lengthy pause and Stevie’s hesitation following this turn show that Stevie also treats there as being a problem. Whilst the ‘you think’ attributes the answer to Stevie, this problematisation brings into play the teacher’s expertise and knowledge to make an evaluation of this answer, even though there is no explicit evaluation. The negative evaluation is then made explicit in turn 70, where the use of ‘we agreed’ attributes the knowledge that the answer is 49 sticks to the whole class.

In the first example turn 184 has many of the structural features of revoicing described by O’Connor and Michaels (1993) and can also be described as summarising, enabling the rest of the class to hear what Stevie has said, acknowledging his contribution and giving him authorship of what is being said, and positions Stevie in relation to the academic task. Yet in turn 187 the teacher closes down the potential to build on, facilitate a student debate, or offer the opportunity for other students to agree or disagree with Stevie’s turn. So, whilst turn 184 shares many of these structural features, its actions within the interaction itself treat the students’ contribution as problematic, rather than as an idea to be used and argued with in a way that gives students some agency over the mathematics. It does not give Stevie ‘a voice’ in the ongoing interaction. Later in the interaction it turns out that Steve’s contribution answers one of the questions the class has been working on, but is the answer to how many *more* sticks are needed (28), rather than how many sticks in total are needed (49).

Example 2

In this example the students are analysing a mechanics problem in a revision lesson focusing on moments, where a simple diagram is drawn on the board. The students have already suggested that the question is about taking moments and the teacher is now asking where the students should take moments about.

455	Tess:	…so where do you think would be a good place if this is what I'm trying to find, to decide to consider the moments about that particular place. (.) just pick something and if it's wrong we can talk about
456	Sam:	if you're measuring from A,
457	Tess:	from A, so take moments about A. okay what you think about that Skylar.
458	Skylar:	er would B be easier, as we know the distance is one.
459	Tess:	so you want to take moments about B
460	Skylar:	yeah
461	Tess:	Sian:
462	Sian:	if you take moments about A you can ignore the reaction on A. so it's probably better to take about A
463	Tess:	because what would happen if we do what Skylar says.
464	Sasha:	then you would have another unknown,
465	Tess:	so then you'd have to do a bit more work because then you'd need another equation, and then you'd have to solve them simultaneously. so what are you suggesting, are you agreeing with Sian Sasha.
466	Sasha:	yep

In turn 457 Tess reformulates Sam’s suggestion in a more complete, and mathematically appropriate way within the context of this task and this classroom. The turn includes the discourse marker ‘so’, but the next turn is not offered back to Sam to affirm or deny that they are suggesting that moments should be taken about A. Instead, Tess invites another student to comment on that suggestion. In turn 459, Tess reformulates again into a more mathematically appropriate way and in a way that is consistent with her reformulation in turn 457, again using the discourse marker ‘so’, but this time she returns to the turn to Skylar to affirm her interpretation (turn 460). Sian then offers an argument for why they should take moments about point A. Tess then prompts for a justification for why Sian would not choose Skylar’s suggestion of about point B, which Sasha gives, before adding additional reasons to Sian’s argument, using the discourse marker ‘so’ and the pronoun ‘you’. Tess ends this turn by returning the turn to Sasha to affirm or deny whether they agree with Sian.

In this second example none of the teacher’s turns have all of the structural features of revoicing described by O’Connor and Michaels (1993) but do have many of the functions such as supporting mathematical argumentation, supporting the use of mathematical language, giving students credit for ideas and attributing authorship and ownership, and asking other students to agree or disagree with the idea being revoiced. The teacher also positions students in relation to other students’ ideas and in relation to the academic task being undertaken, as well as positioning in relation to accepted mathematics.

Conclusion

The precise features of teacher repeats of students' words influence the negotiation of epistemic rights and responsibilities within the interaction. Revoicing is different from rephrasing, repeating or reformulating in the epistemic roles and responsibilities teachers and students have. With revoicing the responsibility for the knowledge in interaction remains with the student(s), but also the students have the right and the responsibility to evaluate the knowledge that is being repeated. This is in contrast to rephrasing, repeating or reformulations where the teacher takes on this role and responsibility. There are consequently important differences between revoicing and other terms which have consequences for the status and negotiation of knowledge in mathematics interaction.

Teachers’ talk and gestures in online teaching videos about graphs

Elizabeth Kimber and Cathy Smith

The Open University, UK; elizabeth.kimber@open.ac.uk; cathy.smith@open.ac.uk

Keywords: Language, gestures, graphs.

Study background

Developing understanding of graphs and change involves alteration in students’ mathematical discourse and teachers play a critical role in developing this through their own language and gestures and their responses to students (Schleppegrell, 2007). Prediger and Şahin-Gür (2020) have explored changes in students’ language as they worked on qualitative calculus tasks involving complex situations such as decreasing positive rates. In pre-calculus contexts, research has found persistent difficulties with students confusing high rates with high values and in grasping that a graph represents a relationship between variables (Watson et al., 2013). In this pilot study we combine techniques from Systemic Functional Linguistics (SFL) and gesture analysis to explore teachers’ discourse in online teaching videos about graphs. Our research question is ‘How are graphical concepts constructed through teachers’ choice of language and gestures?’

Theoretical Framework

SFL characterizes written or spoken text as the product of choices in a system of language and practice (Halliday & Martin, 1993). SFL techniques permit analysis of the ideational, interpersonal and textual functions of a text. In our context, these functions tell us, respectively, about the nature of graphs, and how teachers and students interact around that knowledge, via discrete texts. SFL is a way to identify features and functions of the mathematical register, such as characteristic grammatical structures and technical terms (Halliday & Martin, 1993), and to analyze school texts (Morgan, 1998).

Mathematics teaching videos combine language, diagrams, symbolism and gesture and can therefore be viewed as multimodal, dynamic texts. We are interested in how moving between modes supports use of different representations in building mathematical arguments. We are also exploring types of gesture to help analyze mathematical reasoning, particularly pointing, depictive gestures and tracing gestures (Alibali et al., 2013) and how language and gestures together contribute to the ideational, interpersonal and textual functions of these multimodal texts.

Method

Even before the rapid growth in online teaching due to COVID-19, there was a growing phenomenon of online videos published by mathematics teachers and watched by thousands of teachers and students. These videos offer an opportunity for researchers to explore teachers’ language and gestures when introducing particular topics or presenting worked examples in a planned environment. The videos provide information about what the teachers deem important in explanations and may indicate what difficulties they anticipate students might have.

Two teachers gave consent for us to study five of their published videos in pre-calculus and calculus courses. The videos provide simultaneous access to speech, gestures and annotations. We used SFL to analyze transcripts alongside the videos to retain their multisemiotic nature. We then analyzed gestures accompanying each clause and how they related to diagrams or annotations. Here we present our approach to analysis, with examples from a video about estimating the gradient of a curved graph.

Preliminary findings

From the video transcript we identified participants and processes, which contribute to the portrayal of mathematics. The teacher's language choices interweave mathematics as human activity, such as *We want*, *Do you remember…?*, *Let's pick* (in which humans participate in mental or material processes), with mathematical objects participating in material and relational processes: *a line which touches the curve*, *the gradient's becoming quite steep*. We conjecture that changes from human participants to mathematical objects mark shifts from episodes of demonstration to mathematical argument and vice versa. We also found human activity and explanation interjected within relational processes concerning mathematical objects: '***the gradient** // which we sometimes use m to denote // **is going to be the change in y** // so these are the y values //… // **over the change in x** //…*' This may be a feature of a *teaching register*, concerned with connecting what the teacher is doing to the mathematical register, since this episode concludes with a densely-packed nominal group '*So [the gradient at [this particular [point on this curved graph]]] is 3*', which is more typical of the mathematical register.

Gestures can expand the meaning of text. Here we noted their use alongside repeated speech. For example, '*x is 2*' accompanies pointing to an equation and is repeated while pointing at 2 on the *x*-axis and tracing vertically up to the curve. This may emphasize the shift in representation as well as creating a point on the curve from a correspondence perspective, so has textual and ideational functions.

Our poster will elaborate our analysis of teachers' multimodal discourse on graphs.

An interpretative analysis of generalization processes using abduction theory: The case of addition with zero

Christoph Körner[1] and Michael Meyer[2]

[1]University of Cologne, Germany; christoph.koerner@uni-koeln.de

[2]University of Cologne, Germany; michael.meyer@uni-koeln.de

This paper focuses on the reconstruction of generalization processes in interactions. By coordinating different theories, a way to reconstruct these processes by means of interpretative research is presented. This allows the reconstruction of implicit elements beneath explicit language. An interaction revolving around the number zero and addition with zero is analyzed. First, the different types of generalizations are presented and related to the theory of abduction. Second, the interpretative paradigm is detailed to show the procedure of the analysis of an interaction and the spoken language. Last, the results of the analysis are presented, they include reconstructed generalization processes and the tracing of the development of the generality within an interaction.

Keywords: Generalization, abduction theory, qualitative research, interpretative research, interaction analysis.

Introduction

Generalizing is a process that is deeply embedded in mathematics and mathematical thinking. For Dreyfus (1991) generalizing is to infer "from particulars, to identify commonalities, to expand domains of validity" (p. 35). It can also be seen as the application of an argument in a broader context (Harel & Tall, 1991). This paper focuses on the role of generalization in mathematics learning and offers a possibility to reconstruct generalization processes in interactions. Tall's (1991) and Haral & Tall's (1991) considerations of generalization provide the theoretical basis. Coordinated with Meyer's (2010) *theory of abduction*, their theory of generalization can be made accessible for the interpretative research. Therefore, the contribution can also be seen as an example of the connection of different theoretical approaches. Following the networking strategy of coordinating theories (cf. Prediger & Bikner-Ahsbahs, 2014), a conceptual framework is built. Coordinating these theories and following the interpretative research paradigm (Voigt, 1984) allows the explication of implicit elements of spoken or written language concerning processes of generalization. This will be demonstrated in this paper by analyzing an interview of a German first grader that focuses on the number zero and the addition with zero.

Theoretical Framework

Different Types of Generalizations

Harel & Tall (1991) made out three types of generalizations and refer to "schemas" when describing cognitive knowledge of an individual. They propose to distinguish between the following types of generalizations:

1. *Expansive generalization* occurs when the subject expands the applicability range of an existing schema without reconstructing it.

2. *Reconstructive generalization* occurs when the subject reconstructs an existing schema in order to widen its applicability range.

3. *Disjunctive generalization* occurs when, on moving from a familiar context to a new one, the subject constructs a new, disjoint, schema to deal with the new context and adds it to the array of schemas available. (Harel & Tall, 1991, p. 39)

Mitchelmore (1994) considers generalization processes in a comparable way. He does not speak of “applicability range” but of a set of applicable *situations*, which is more fitting for the scope of this paper and pairs better with the *theory of abduction* described in the next section. Therefore, the term *mathematical situation* will be used in the following. In this paper, mathematical situation refers to engagements with enactively, iconically or symbolically (cf. Bruner, 1960) presented mathematical objects of interaction. For example, an action, a material, or even an utterance in a mathematical context can be interpreted as a mathematical situation.

The *expansive generalization* is characterized by the fact that there is no change or reconstruction of the schema. If there is no explicit change, it can be difficult to distinguish expansive generalizations from a renewed confrontation with an already known mathematical situation, i.e., it can be difficult to determine whether the subject is dealing with a known applicable mathematical situation or with a new mathematical situation. However, when interpreting an interaction, this could be clarified, for example, by considering the mathematical situation against the personal background of the subject as well as the context in which they encounter the mathematical situation. Thus, the question whether the learner could have realistically dealt with the mathematical situation before, has to be considered while interpretating.

The *reconstructive generalization*, is characterized by a reconstruction of an existing schema. In this case, a modification of the schema enables the subject to consider situations that were previously not applicable, to be subsequently recognized as applicable. The range of the schema becomes larger, since more mathematical situations can be recognized as applicable. From a purely theoretical point of view, this process can be assumed to be often more cognitively demanding than the process of expansive generalization. Thus, in an interaction, reactions of the subject such as hesitation, pausing, checking, or even inquiring could be interpreted as indicators of reconstructive generalizations. Nevertheless, a deeper interpretative procedure is necessary.

In *disjunctive generalization*, no connection to an already formed schema is recognized. Instead, a new schema is formed. A connection between the different mathematical situations remains unrecognized. A disjunctive generalization may well lead to successful solving of a math problem, but is of little value for the subject (Tall, 1991).

Generalization is often considered an advanced mathematical thinking process (Dreyfus, 1991; Tall, 1991). Nevertheless, generalization plays also a role in learning elementary mathematics (Mitchelmore, 1994), which will be shown further in this paper.

Abduction Theory

Meyer (2010) focused on the analysis of discovery processes and, in doing so, elaborated Charles Sanders Peirce's logical-philosophical modes of inference for use in mathematics didactics. Since then, their use has become established, especially in interpretive research of mathematics education (e.g., Rey, 2021). Since discovering common properties of different mathematical situations is central to generalization processes, this theory lends itself as a further basis for interpreting generalization processes manifested in interactions. Meyer (2010) describes the three logical-philosophical inferences *abduction*, *deduction,* and *induction* as well as their interplay. Central in this context are the terms *case*, *rule*, *result* (resp. *phenomenon*), which are related to each other in different ways depending on the mode of inference.

A deduction is the inference from a concrete case and a general rule to a concrete result. The case and the general rule form the premise, the result is the inferred consequence. The rule is considered general, since it is possible to infer from different cases with the same rule. Deduction plays a crucial role in mathematics, since it is the only inference that guarantees certainty. (Meyer, 2010)

According to Meyer (2010), constructing new knowledge, which is not already implicated in former ones, is only possible by means of *abduction*. The generation of knowledge therefore always presupposes an abduction. It is a discovery process in which an individual generates a rule while exploring and explaining a phenomenon (Meyer, 2010). When confronted with a phenomenon $R(x_0)$ worth explaining, the individual infers a general rule and the specific case $C(x_0)$ that could explain the phenomenon (see Figure 1). The case and the rule go together and are acquired simultaneously; they represent a possible cause of the phenomenon. After the generation of a rule, the phenomenon becomes a *result* of that rule. Thus, the premise of this inference is exclusively the phenomenon; rule and case represent the consequence (Meyer, 2010). This is illustrated by the position of the horizontal line in Figure 1.

Phenomenon (Result):	$R(x_0)$
Rule:	$\forall i: C(x_i) \Rightarrow R(x_i)$
Case:	$C(x_0)$

Figure 1: The general pattern of cognitive abduction (Meyer, 2010)

Abduction is by no means an inference that provides certainty; an abducted rule is only one of many possible rules that could explain a phenomenon with the corresponding cases. Meyer (2010) states that in this context the term *rule* has to be understood in a very broad sense. Rules do not need not be true propositions in the mathematical sense. They might be only plausible or even false. The only conditions that rules must satisfy are that the concrete phenomenon/result can be logically deduced from them (as a consequence of the rule) and that the case forms a concretized antecedent of the rule (Meyer, 2010).

Coordinating the theories: On the role of abductions and rules in generalization

The reconstruction of inferences, especially the consideration of potential rules, offers the possibility to look at generalizing in process. For this purpose, the following section shows how we fitted together elements from the considered theories (cf. Prediger & Bikner-Ahsbahs, 2014). In particular, the concepts *abduction*, *rule*, *mathematical situation*, *schema* as well as (*expansive/reconstructive*) *generalization* are set into relation to each other. Also, these concepts are used for the reconstruction of mathematical communication in order to show the empirical fitting as well as the fruitful use of the concepts that allows to reconstruct also implicit aspects of spoken language.

The theories pointedly compared, following statements suggest themself: The recognition of a connection or the identification of common properties presupposes abductions and the formation or modification of schemas. For Meyer, abducted rules are central at this point; for Harel & Tall, common properties of the mathematical situations under consideration are central. These two considerations are comparable if one interprets the central common properties of the mathematical situations as being made out by abducted rules starting with concrete consequences of the rule (the former phenomena) and therefore sees the schema as being anchored in these rules.

Depending on the reconstructed type of inference, mathematical situations can be compared to the (contents of) phenomena or, after a successful abduction, as (contents of) results of the rule, after the phenomena have been explained. Depending on the generality of the rules in which a schema is anchored, an individual may recognize more or fewer mathematical situations as applicable. These situations can be identified as the x_i in Figure 1. The more general the rule, the larger the set of mathematical situations that can be recognized as applicable by expansive generalization.

If a new mathematical situation cannot yet be recognized as applicable, a reconstructive generalization can take place. The subsequent modification of the schema also presupposes a change of the associated rule. I.e., these rules become more general or the learner grasps the generality of an existing rule. At this point abductions take place, since knowledge is generated (Meyer, 2010).

Methodology

The data analyzed in this paper originates from an interview with a German first grader (age 7) that was conducted as part of the bachelor thesis of Mirjam Jostes. The topic of the interview is the number zero and addition with zero. During the interview a custom board game and other materials were used. The interview was video recorded and transcribed. The transcript is analyzed with regard to generalization processes. Guided by the theoretical framework outlined above, an attempt is made to make statements about generalization processes and their products by analyzing and interpreting the given interaction. The analysis follows the interpretative research paradigm of Voigt (1984), which is widely used in the German mathematics education community. The basis of the interpretative research paradigm is *symbolic interactionism* (see Blumer, 1986) and *ethnomethodology* (see Garfinkel, 1967). Central steps of the Voigt's interpretation method are:

Step 1: At the beginning, the interpreter paraphrases the situation with "his common sense" (Voigt 1984, p. 111, our translation). The goal of the first notation is not to eliminate these previous experiences, but to become aware of them. This pursues the goal of being able to explicitly distinguish oneself from the interpretations in the following; the interpreter thus forces themselves to see more than what was previously clear.

Step 2: Subsequently, the text is divided into episodes and the first utterance is "extensively interpreted" (Voigt, 1984, p. 112, our translation) in order to include as many interpretive hypotheses of the utterance as possible.

Step 3: The interpretation of single turns enables predictions about the further course of the interaction. These are subjected to a test on the subsequent utterance(s): They are either corroborated, when the predictions occur, or the hypotheses have to be falsified.

Step 4: By repeatedly following an extensive interpretation of the subsequent utterance (step 2) as well as a test on the subsequent utterance (step 3) until the end of the episode, the initial variety of interpretations is both expanded and increasingly restricted.

The resulting interpretations are then linked to the corresponding theoretical concepts according to the theoretical framework and checked again on the transcript. The interpretations, which are repeatedly corroborated in the transcript and also enable a maximum gain in knowledge from the point of view of the theory, represent the result of the analysis as interpretive hypotheses. In the following, only corroborated interpretative hypotheses are exemplified. By following the interpretative research paradigm of Voigt (1984) and reconstructing inferences in the interaction, one does not make statements about the cognitive structure of an individuum. One reconstructs inferences that a learner like the individuum, acting in an interaction like this, could make. The interpretation is based on the original German transcript. For this paper, the transcript was translated and adjusted to increase readability.

Analysis and Results

The interview begins with introductory questions. Subsequent to introductory questions, a board game is played. The game board is a path with 10 stepping stones. The first stone is labeled "Start" the subsequent stones are numbered 1 to 10. A custom dice that also has empty faces (represented by in the following, esp. Figure 3) is rolled and a game piece is moved accordingly. Each round Luisa writes down the current position of the game piece, the dice roll, and the new position of the game piece into a table (see Figure 2). The final column of the table is labeled "calculation". It is filled in after the completion of the game. For example, Luisa writes down in row 8 of the table: „current position 6, dice roll 0 ( ), new position 6", when she rolled a zero and did not move the game piece.

In preparation for the game, the interviewer asks the question "What are the special features of doing sums with zero" (T39). Therefore, "addition with zero" is considered the thematic schema, since it is explicitly mentioned by both the interviewer and Luisa and it plays a central role in the interaction.

T40	Luisa	Doing sums with zero. (*4 sec*) if I do one plus zero, it is one.
T41	Int.	mhm-…
T42	Luisa	because the zero, … is actually nothing.
[…]		
T46	Luisa	If I have one stone and add zero stones, it still remains one stone. Because, you can't see the zero.
[…]		
T49	Int.	ok-, and does it work with other numbers as well or only with the one?
T50	Luisa	It also works with other numbers
T51	Int.	why?
T52	Luisa	Because, if I do ten plus zero, it is still 10 (*nodding*) … because the zero actually fits every number.

Luisa responds to the interviewer's question by naming an example (T40), which in turn can be interpreted as the disclosure of a mathematical situation that she recognizes as applicable to the thematic schema. Besides the pure numerical example (T40), she paraphrases an action of adding

(T46). This could indicate that she also recognizes action-bound mathematical situations applicable. In T50, Luisa initially only says that it also works for other numbers. When asked, she gives another example in T52, (10+0=10), and concludes her statement with "because the zero actually fits every number". This linguistic expression suggests that her rule is quite general already.

Luisa's statements can be interpreted in such a way that she sees her schema “addition with zero” applicable to mathematical situations, when a number known to her (n) is the first summand. Thus, her rule allows mathematical situations of the form n+0=n, where n are numbers she knows. Since Luisa seems to already recognize action-bound mathematical situations as applicable, the rule could also admit all mathematical situations of the form nM+0=nM, where nM stands for the quantity n of a material/object M, e.g., one stone. Note that a reference to a material/object M seems to be optional for Luisa. At this point, it can be assumed that she deduces with a rule like “If I calculate nM+0, then the unaltered first summand represents the sum”. The special role of the follow-up question of the interviewer becomes apparent. Without it, it would be impossible to reconstruct the minimal generality of Luisa’s rule as being so developed.

Following the dice game, that took about 10 minutes, the focus is once again directed to the addition with zero. The interviewer asks Luisa to fill in her calculations into the table (see Figure 2). Luisa does not proceed chronologically. She starts by filling in row 4 and row 5 independently without hesitation. In row 6 (position 4, dice roll 0 ( ), new position 4) Luisa stops. This can be seen as a confrontation with a new mathematical situation for Luisa.

Nr.	position	dice roll	new position	calculation
1	Start 0		1	0+1=1
2	1		01	1+0=1
3	1		2X	1+1=2
4	2		3	2+1=3
5	3		4	3+1=4
6	4		4	4+0=4
7	4		6	4+2=6
8	6		6	6+0=6

Figure 2: Luisa’s table and calculations

T80	I	Tell me what you are thinking right now
T81	Luisa	so. (*slowly*) four- (*points at the current position 4*)… hm. plus four (*points at the new position 4*) (*5 sec*) (*faster*) four plus zero. (*begins to write “4”*)
T82	I	mh, you just changed your mind. Why is that?
T83	Luisa	Because the result has to be four. (*continues writing “+0=”*)

Luisa's hesitation and the formulation "four plus four" (T81) can be interpreted in such a way that she does not yet see the row 6 of the table as a mathematical situation that is directly related to “addition with zero”. The five-second pause and subsequent correction “four plus zero” (T81) can be interpreted as an indication of a generalization taking place. Here, a reconstructive generalization could take place, leading to a change of the rule associated with “addition with zero”. The new rule seems to be applicable for calculations of the form nM+0 as well as of the form nM+ . Theoretically, this would lead to a widening of the representational options of the schema “Addition with zero”. The schema Addition with zero can now be linked to more mathematical situations. An abduction that Luisa might have performed is reconstructed in Figure 3. Since a generation of the abduction is hypothetically considered here and not exemplified by Luisa, the inference is made from phenomenon to result and case simultaneously. The inference is therefore indicated by the line directly after the phenomenon (cf. Meyer, 2010). Luisa's expression "Because the result has to be four" (T83) can be interpreted as a *phenomenon in need of explanation*. Following this reconstruction, she would infer from the fact that the first number of the calculation and the result are equal that it has to be an "addition with zero."

Phenomenon:	The result is 4 and 4 appears in the first place of the calculation.
Rule:	If I calculate nM+ or nM+0, then the unaltered first summand represents the sum.
Case:	I calculate 4+ .

Figure 3: Reconstructed Abduction

This interpretative hypothesis is corroborated in the further course of the transcript, especially in Luisa's subsequent confrontations with very similar mathematical situations. For example, Luisa looks at table row 8 (current position 6, dice roll 0 ( ), new position 6) and says "funny" (T88), but then directly states "because I like such calculations with zeros" (T92). Building on the above interpretation, an expansive generalization could be reconstructed here. The rule in which the schema "addition with zero" is anchored would now be general enough so that the new mathematical situation 6+ can be recognized as applicable (see Figure 3). Moreover, in the subsequent discussion of table row 2 (current position 1, dice roll 0 ( ), new position 1), which she had initially skipped, Luisa directly refers to the previous task 6+ , "like down here with the six" (T104), which suggests that it belongs to a common schema. As Luisa seems to determine the order herself and does not want to or could not process row 2, but would be able to do this from a mathematical point of view, further strengthens the interpretation of a completed reconstructive generalization in the course of the interaction that allows subsequent expansive generalizations to take place. Part of the corroborated interpretative hypothesis is, that Luisa's rule depends on the position of zero in the calculation, i.e., zero has to be the second summand. Hypotheses where this was not the case, for example one hypothesis was that Luisa uses the commutativity of addition, were falsified during the course of the analysis, when she was confronted with the first table row.

Discussion and Conclusion

The scene shows how generalization processes can take place in an interaction and how they are built interactively through language. The analysis has shown how the theory of Harel & Tall (1991) can be made accessible to the interpretative research by utilizing the theory of abduction described by Meyer (2010). Without the possibility to reconstruct rules that manifest in a real interaction, statements about the set of mathematical situations an individual's schema applies to, would be empty. On the basis of the theoretical framework, it was possible to trace a conceivable development of the generality of rules and schemas in Luisa's language and actions. This provides insights into generalization processes that students like Luisa could carry out in an interaction like this.

Furthermore, the analysis has shown how challenging it is to make statements about the generality of a rule or the applicability range of a schema. However, the used method allows statements about what mathematical situations could be considered applicable and about possible dimensions of generality of a rule. Mathematical action is based on rules which are generated, applied or tested by abduction, deduction or induction. But they are seldomly made explicit. In classroom reality, a real time reconstruction of rules or of the set of applicable mathematical situations is inconceivable, even in smaller learning groups. This underlines the importance of explicating rules in the classroom and providing students with language means to do so. Asking for explicit formulations of an individual's rules and to explore the applicability range of schema together with the learners can stimulate further generalization processes.

Support-Related Diagnostics in Mathematics Including Reading - FORMULA

Lina Kortüm[1], Anna Meininghaus[1], Maike Mentrop[1], Anke Hußmann[2], Stephan Hußmann[1], Marcus Nührenbörger[1]

Keywords: Diagnostics, learning disabilities, mathematics and reading.

Introduction

The project *Formula* is funded by the German Federal Ministry of Education and Research. It aims to explore the relationship between the mathematical participation of students in inclusive education (in transition from primary to secondary school) as well as their reading skills and how these can be combined. The overall goal is to develop a highly valid, supportive diagnostic tool that can be used to assess reading and mathematical competencies as well as their interconnections. In combination with the associated remediation this is called the *Formula*-Concept. In this way, the project *Formula* responds to a problem of many already existing diagnostic and remediation instruments: They exclusively focus on subject-specific competencies and are neither linguistically appropriate nor linguistically sensitive.

Theoretical Background

Research findings confirm the connection between linguistic and mathematical skills - even for students with learning difficulties and developmental disabilities (Mann Koepke & Miller, 2013; Martin & Mullis, 2013). Students' language competencies are essential for the development of mathematical understanding and are considered as a predictor of learning growth (Prediger et al., 2019). Reading comprehension is regarded as a key skill in all subjects, including mathematics (Borasi & Siegel, 2000; Grimm, 2008). Reading promotion is a necessary component to be taught not only in language lessons but in all subjects. Moreover, this can be important for learners with special needs in particular.

As most recently shown by the empirical studies PIRLS 2016 and TIMSS 2019, a significant proportion of children in Germany at the end of primary school show both below-average mathematical competencies (25% below proficiency level 3; Selter et al., 2020) as well as an insufficient level in hierarchically higher reading processes (19% below proficiency level 3; Hußmann et al., 2017). However, it is unclear how reading skills affect the development of mathematical competencies and which relevance lower- and higher-hierarchical reading processes play in this context.

Research design

In our project we are addressing five research questions using a combination of a research design approach and an intervention study (see Table 1).

Table 1: Connections between research questions, methods and expected results

research questions	methods	expected results
1) How do students' learning processes proceed? What difficulties do they face and what kind of potentials becomes visible? (learning processes) 2) What does a supportive diagnostic concept and design look like? (design) 3) What are the local theories about the relationship between mathematics and reading competencies? (theory)	design-oriented developmental research approach, e.g. cyclic sequential design experiments, eye-tracking	detailed results concerning the correlation between mathematical competencies and reading comprehension
4) How do reading and mathematical competencies influence each other during the mathematical learning process? (relation math + reading)	pre-post interventional study	individual strategies of students, obstacles, potentials
5) How do teachers in elementary and secondary education use the Formula-Concept in their mathematics lessons to integrate reading promotion? (teaching profession)	design-oriented developmental research approach, survey	conditions for a sustainable transfer

The knowledge aims concern the differential evaluation of the competencies of reading and mathematics competencies. However, this is related to the presentation and meaningful context of mathematical tasks. Therefore, appropriate combined support measures for mathematics and reading should be developed, distinguishing between representational and contextual tasks. Tasks from the BASIS-MATH 4-+5 (Moser Opitz et al., 2016) are further developed and specified with regard to the competencies considered in this project. The resulting diagnostic tool will be pre-tested in individual sub-areas on smaller samples first (on average N=60/item), then piloted as an overall diagnostic tool (N=150). Additionally, students' reading comprehension will be assessed at the word, sentence, and text levels with help of the diagnostic test ELFE II (Lenhard et al., 2017).

Linguistic features of word problems that cause difficulties for learners across the curriculum: A literature review

Sara Malik[1] and Sebastian Rezat[2]

[1, 2]Paderborn University, Institute of Mathematics, Germany; [1]smalik@math.upb.de, [2]srezat@math.upb.de

Word problems can be challenging for learners of all ages on different levels. In this paper, specific linguistic requirements and features of word problems contributing to the difficulties for learners will be discussed. For this purpose, first results of a literature review are presented. The literature was analysed according to the model of genre features (Rezat & Rezat, 2017) as a theoretical framework. In the course of the literature review, a system of categories was developed to differentiate the linguistic features addressed in the respective studies. The studies that were assigned to the feature of linguistic complexity are discussed in detail with the aim of identifying specific linguistic features of word problems that cause difficulties for learners. The curricular context and the mathematical content of the studies will also be discussed.

Keywords: Word problems, literature reviews, syntax, linguistic complexity.

Introduction

In the sense of the spiral curriculum, applications are regarded as a topic that should be treated in an appropriate way at different grade levels (Müller & Wittmann, 1984, p. 4193). Word problems are a central type of task of teaching applications of mathematics at all ages. Therefore, they can be seen as a specific genre of mathematics education. A genre is defined as a "pattern of cultural-social interaction in a particular context" (Rezat & Rezat, 2017, p. 4193). In general, language and language use made for didactic purposes is an issue in every subject (Schleppegrell, 2004). Schleppegrell (2004, p. 82) points out that "[s]chool is a culture with its own expectations for particular ways of using language. [Therefore,] students need to learn about genres of schooling and the purpose for which they are useful."

Research has shown that learners at all ages have difficulties with word problems. Daroczy et al. (2015) point out that those features of word problems, which generate difficulties for learners can be at mathematical, factual-semantic, and linguistic-syntactic levels. However, it is unclear which specific challenges these are, in which grades and for which mathematical contents these are relevant, how they develop within the curriculum, and whether difficulties in one mathematical context can also be transferred to other mathematical content areas. Furthermore, Daroczy et al. (2015) highlight that a comparison of previous research results related to word problems is usually not possible. Verschaffel et al. (2020) reinforce this statement. They point out that various (international) research projects on word problems focus on different perspectives about the research topic. Therefore, there is a need for a systematic analysis of pre-existing research results that addresses the requirements and the characteristics of word problems that generate difficulties for learners from a curricular perspective. The systematic analysis of the research findings presented in this paper will focus on the results related to linguistic features of word problems and how they impose difficulties on learners. The following research questions will be addressed:

Q.1: What are linguistic features of word problems that cause difficulties for learners across primary- and secondary[1] level curriculum?

> Q.1.1: What specific linguistic features of word problems have been investigated in previous research?
>
> Q.1.2: Which of these specific linguistic features of word problems affect the learners' solution processes and quality of solutions?

Theoretical framework of the literature review

In order to be able to systematically represent the research results with regard to linguistic task features, the *model of genre features* (Rezat & Rezat, 2017) was used as an instrument. It is grounded in the pragmatic linguistic approach. In the model, a genre is described as a connection between the *type of act* and the *text type*. The authors describe the relationship of both main categories in the model as follows: "The type of act directs the expectation of the text type while features of the text type, especially the formulation patterns, indicate the type of act." (p. 4196). The main category *type of act* was defined based on Halliday's (1985) modelling of the situation of the text, integrating the three social functions of language: field, tenor and mode. Structural features (*structure of the text)* and linguistic features (*language features*) are assigned to the main category *text type.* The main category *text type* is used as a framework in the literature review to systematically identify studies in which linguistic and structural features of word problems are discussed. On basis of the systematic literature review, the genre-specific language features of word problems are determined. Language features that cause difficulties for learners are defined as features that impair learners' solution processes and/or quality of solutions.

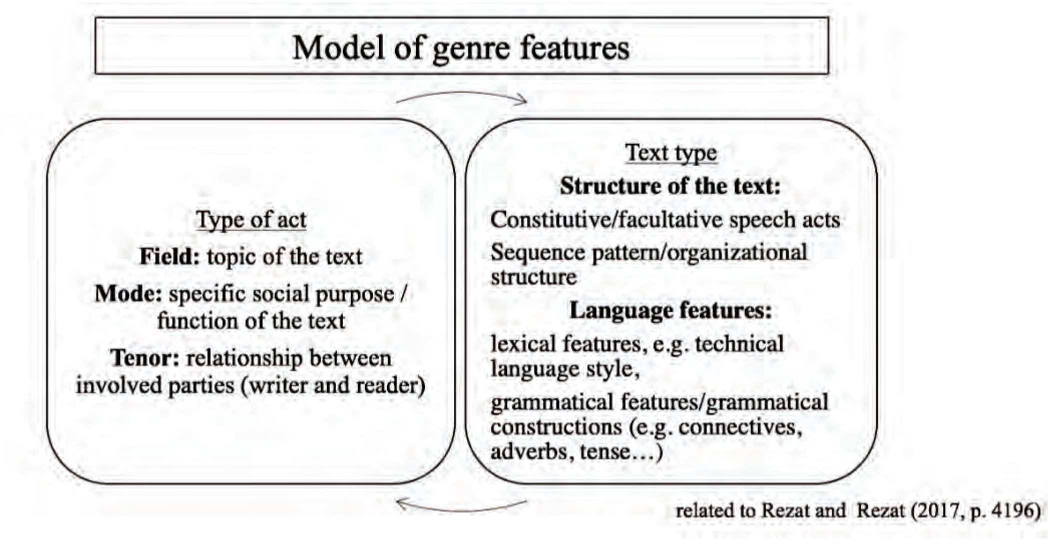

Figure 1: model of genre features

[1] The differentiation between primary and secondary school is based on the international standard. Primary level is understood up to and including grade 6.

Methodology of the literature review

In this section, the procedure of the literature review, which was conducted systematically is presented. Based on a specific literature search via the online literature database ERIC (https://eric.ed.gov)[2] a corpus consisting of 354 scientific articles (peer reviewed) was identified. The identified corpus was analysed based on qualitative content analysis according to Mayring (2015). The main category *text type* of the *model of genre features* with the subcategories *structure of the text* and *language features* was used to systematise the results. The category *language features,* which is the focus of this paper, comprises studies that analyse specific *lexical or grammatical features* of a text. Considering these criteria, a review of scholarly publications was conducted to determine the extent to which structural and language features, especially the *lexical* or *grammatical features* of word problems were addressed. For the review of the whole corpus, exclusion rules were also set and used for the analysis. This led to the removal of contributions that are not relevant in connection with the research questions. Consequently, papers that discuss the performance of learners with word problems (presentation in first and second language) and do not discuss the influence of linguistic features of the task, that analyse teachers' behaviour with word problems, and those that present interventions of teaching methods were excluded. Furthermore, studies that focus on interaction processes between learners, studies that address word problems from preschool or adult education and studies that address language/mathematical difficulties of learners with disabilities are excluded. The remaining corpus was analysed using the deductively developed categories and, if necessary, was extended by inductively formed categories.

Results

By means of the procedure described above, a total of 20 scientific publications were identified in which specific *language* and *structural genre features* of word problems in different grade levels are addressed. Of these 20 papers, 14 papers were assigned to the subcategory *language features*. The following section presents the results related to research question 1.1, followed by the results related to research question 1.2.

Results of the literature review in terms of investigated language features

The categories of language features provided in the model of genre features (Rezat & Rezat, 2017) were too general to allow for a differentiated view of the specific linguistic features of word problems that have been addressed in previous research and how they impose difficulties on learners. Therefore, the 14 scientific publications assigned to the category language features were inductively classified into different subcategories in order to be able to differentiate the particular language features that were investigated in these studies. In total, 5 subcategories could be developed.

Table 1 shows the subcategories describing the *language features* addressed in the respective studies and their definitions as well as the grade levels, in which the language features were investigated.

[2] The following search term was uses: ("Word problems" OR "Story problems") AND (language OR syntax OR "text structure" OR "word order" OR lexicology OR "visual aids" OR "illustrations")

Table 1: Inductively formed category system of the literature review

Inductive category	Definition of the category: Studies, …	Number of studies	Grade
(In-) consistency of language	… in which the influence of (in-)consistent language in the task is addressed in relation to the solution or comprehension processes.	5	1, 2, 3, 4 and 5
Personal pronoun	… in which the influence of personal pronouns in the task is discussed in relation to the solution or comprehension processes.	2	1 and 4
Vocabulary	… in which the influence of the vocabulary of the word problem and the vocabulary of the learners are addressed in relation to the solution or comprehension processes.	3	1, 7 and 8
Linguistic complexity	… in which the influence of lexical and/or grammatical features and/or features of the information structure related to the solution or comprehension processes are addressed.	5	1, 2, 5, 7, 8, 9 and 10
Deictics	… in which the influence of deictic expressions in the task is discussed in relation to the solution or comprehension processes.	1	10

The category syntactic/linguistic complexity comprises studies in which a combination of several individual linguistic features was varied at once in order to determine the influence of this variation on students' solution processes and/or quality of solutions. Since this feature is linguistically conceptualised differently, an overview of which linguistic features were (systematically) varied in the related studies is given to discuss this category in more detail. The linguistic modifications of word problems that were made in the study of Abedi and Lord (2001, p. 221) included: Unknown or rare words were changed, passive verb forms were transformed to active ones, long nominals were shortened, conditions were replaced by separate sentences, or the order of conditional and main clauses was changed, abstract or impersonal utterances were made more specific, complex questions were simplified by using simple question words. Leiss et al. (2019) increased the linguistic challenges of word problems by modifying four features: vocabulary, use of connectives, complexity of grammatical structures and information structure. In another study, a higher linguistic complexity was created by combining three original sentences of the tasks into one complex sentence (Muth, 1984). The following linguistic characteristics were varied individually in the study of Walkington et al. (2019): number of sentences, word hypernymy, pronouns, word concreteness, consistency of sentences, the topic of the task. Ambrose and Molina (2014) see linguistic complexity at the level of syntax and vocabulary.

Summarising this overview, it becomes apparent that on the one hand there are studies that focus on individual linguistic features of word problems, while on the other hand some studies focus on a combination of linguistic features. These studies generally relate to syntactic/linguistic complexity.

However, the notion of syntactic/linguistic complexity is defined differently in the studies and comprises different combinations of individual linguistic features.

Results of the literature review in terms of how language features impose difficulties on learners

In the next step, the results of the studies in the different categories were interpreted in terms of how the language features affect students' solution processes or quality of solutions. The studies that have been assigned to the category *(in-)consistence of language* show controversial indications of the extent to which this feature influences the solution processes and quality of solutions. The two studies assigned to the category *pronouns* show no evidence that this feature influences the solution processes and the quality of solutions by learners. The overall view of the studies that were assigned to the category *vocabulary*, however, suggests that there is a fundamental translation problem on the procedural and conceptual level on the part of the learners and that possible difficulties cannot be explained by the feature *vocabulary* alone. The study that was assigned to the category *deictics* showed evidence that a certain type of error occurs particularly frequently in the field of algebra when the tasks contain indexical expressions. Since only one study was assigned to this category, a more comprehensive view of this language feature is not possible.

This broad overview already suggests that the hypothesis that difficulties of learners working on word problems can not necessarily be attributed to individual linguistic features. This is also supported by the study by Walkington et al. (2019). They analyse the influence of linguistic complexity by varying individual linguistic features of word problems separately and systematically. In this study, in total 451 American students from different school districts from grades 7 to 12 participated. The students were asked to complete different task variations that were presented on a free online homework platform. For this purpose, the word problems from the content area of linear functions were used. The tasks were systematically varied with regard the six different linguistic features mentioned earlier. Each feature was also varied in terms of three levels of difficulty. Students were not given any special instructions that they were taking part in a research study. The accuracy of the solutions and the reaction time were determined with the help of the digital platform. Overall, the authors were able to show that there is little evidence that individual linguistic features have a significant influence on students' performance in solving the word problems in the different grades. Therefore, the results of the studies classified as investigating linguistic complexity will be discussed in a differentiated way with regard to research question 1.2. Table 2 provides a more detailed overview of the studies in which the feature of *linguistic complexity* is discussed.

Table 2: List of studies on linguistic complexity of word problems classified by grade levels

Studies on linguistic complexity of word problems				
Grades 1 and 2	Grades 3 and 4	Grades 5 and 6	Grades 7 und 8	Grades 9 und 10
Ambrose and Molina (2014)		Muth (1984)	Leiss et al. (2019) Abedi and Lord (2001) Walkington et al. (2019)	Walkington et al. (2019)

Abedi and Lord (2001) investigated the influence of language in word problems on learners' performance. For this purpose, the authors conducted two separate field studies. The first study was a perception study. For this reason, in total 36 eighth graders at four school sites in the Los Angeles area were presented original NAEP (National Assessment of Educational Progress) maths items and parallel revised tasks in simplified language. The mathematical requirements were kept constant. In a standardized interview, learners were asked which tasks they would choose in an exam situation. Each learner had to answer this question for four pairs of tasks (original and modified). This study shows that the majority of the learners preferred the modified tasks to the original tasks. In the second study, the Accuracy Test Study, 1174 American students in grade 8 from 39 classes were given a paper-and-pencil math test. The test included 10 original NAEP math items, 10 items with linguistic modifications as described above, and five noncomplex control items. Two different test booklets were developed where the original items are modified were developed comprising original and modified test items. Here, the students' scores on the original and linguistically modified items were compared. In principle, the linguistic modification also led to a significant difference in the mathematical performance of the learners. The modified tasks could be also handled better by the students, certain groups of learners particularly benefited from the linguistic modifications.

Leiss et al. (2019) reconstruct and investigate learners' comprehension processes when solving word problems and, among other things, address the question of what role task characteristics (complexity of the situation, linguistic complexity) play for the comprehension process. In their study, 55 seventh-grade German-speaking students attending three comprehensive schools were asked to complete three reality-based tasks on the topic of linear functions, which were systematically modified in terms of the complexity of the situation model and the linguistic requirements. The sessions took place under laboratory conditions and the students were required to solve the tasks by using the Think Aloud Method (p. 137). In this context, it was shown that the linguistic complexity influences the learners' comprehension more than, for example, the context into which the tasks are embedded.

The studies by Abedi and Lord (2001) and Leiss et al. (2019) showed that English-speaking learners are more likely to work on tasks with lower linguistic complexity. This means that the variations in the linguistic complexity (as defined by the authors) of the tasks resulted in a better understanding of the mathematical requirements by learners. In this context, it was also observed that tasks with lower linguistic complexity yielded higher rates of correct solutions. The results of Leiss et al. (2019) showed that the linguistic complexity of the tasks influences the comprehension of German-speaking learners more than the context of the task. At this point, it can be assumed that higher linguistic complexity (of different linguistic characteristics) can be understood as a feature that creates difficulties for learners.

In the two other studies, the feature of linguistic complexity was investigated using task examples from primary level. The main purpose of the study by Muth (1984) was to determine the relative importance of computational ability and reading ability to the solution of arithmetic word problems. Furthermore, Muth (1984) investigated how learners deal with different requirements imposed on them by different word problems. In this context, 200 sixth graders from two middle schools were asked to solve word problems that were modelled on NAEP tasks. Adding irrelevant information to the word problems forms a computational/problem solving demand in this study (p. 206). The variation of syntax represents a reading-related demand (p. 206). These tasks were used to test learners' skills in addition, subtraction, multiplication, and division. Four versions of the test were created by developing two versions with variations in the additional information and two versions with variations in the complexity of the syntax. The results showed that the variation of syntax had no influence on the accuracy of the solution. Ambrose and Molina (2014) were able to show in a study that it were not so much the superficial linguistic features of the text, including syntax and vocabulary, that hindered the children's successful interpretation, but rather the situations and the limited information provided about them that affected comprehension. The study involved 18 first grade Spanish/English bilingual learners who were asked to retell and solve word problems in their first and second languages. Addition/subtraction and division tasks served as the mathematical content here. This contradicts the above-mentioned results by Leiss et al. (2019). There, the context of the task did not have as strong influence on the understanding of the tasks as the linguistic complexity for learners in seventh grade. A possible interpretation of these contradicting results of the two studies might be that learners in higher grades have more in-depth contextual knowledge than primary grade learners. The latter may need more detailed explanations on the context of the tasks in order to develop an appropriate understanding of the factual situation to be able to solve the task.

In summary, studies that varied single linguistic features show no clear influence on the learners' performance (Ambrose & Molina, 2014; Muth, 1984; Walkington et al., 2019). Studies in which several linguistic parameters were varied show evidence that lowering linguistic complexity leads to higher rates of correct solutions (Abedi & Lord, 2001).

Discussion

Summarising the results of the literature review to answer research question 1.1, it was possible to provide an overview of linguistic features that were investigated in previous research on word problems. Within the framework of this review, the following language features could be found: (*In-) consistency*, *personal pronoun*, *vocabulary*, *syntactic/linguistic complexity* and *deictics*. From these categories, *linguistic complexity* is conceptualized in different ways in the studies.

To answer the research question 1.2, first insights from the review of all studies were summarised and a differentiated review of the studies which were assigned to the category linguistic complexity was conducted. The language features *(in-)consistency*, *personal pronoun*, *vocabulary* and *deictics* appear to be features that are defined and used in the studies in a widely consistent way. Even if the research subjects in the studies differ to some extent, it is possible to draw careful conclusions about features that cause difficulties for learners. Considering the studies on linguistic complexity, which are linked to secondary school content, multiple variations were made (Abedi & Lord, 2001; Leiss et al., 2019). The results of these studies suggest that the features that generate difficulties cannot be attached to individual linguistic features, but rather the language as a whole system controls how mathematical demands of the task need to be perceived and mastered by learners. It has become apparent that learners perform better with reduced linguistic complexity (Abedi & Lord, 2001). The studies in which selected linguistic features were modified seem to confirm this hypothesis (Ambrose & Molina, 2014; Muth, 1984; Walkington et al., 2019). Linguistic complexity as a genre feature seems to be a phenomenon that takes on different forms.

In terms of limitations, it should be noted that only a small number of studies were considered in this paper and the conclusions need to be substantiated by further studies. In the further course of this project, the analysis presented in this paper will be used as a starting point to carry out a task analysis with the aim to describe the connection between the language and the mathematical content in a more differentiated way with a particular focus on how the mathematical and linguistic demands of word problems develop across primary and secondary mathematics curriculum.

Using digital tools in language diverse mathematics classrooms

Tamsin Meaney[1] and Toril Eskeland Rangnes[2]

[1]Western Norway University of Applied Sciences, Bergen, Norway; tme@hvl.no

[2]Østfold University College, Halden, Norway; toril.e.rangnes@hiof.no

In this paper, interviews with teachers and preservice teachers are analysed to understand their views about using digital tools in mathematics classrooms, connected to language-diverse students': communication; potential for learning; and available identities. When digital tools were seen only as providing ways to utilise the home language so that existing mathematical knowledge could be used to complete tasks in the language of instruction, then language-diverse students' available identities were reduced to becoming like their non-immigrant peers. In contrast, when digital tools were considered as providing opportunities for utilising a wider range of their language resources, then preservice teachers broadened their views about language-diverse students' potentials for learning and available identities.

Keywords: Digital tools, multilingual classrooms, teachers, preservice teachers.

Introduction

Researchers have suggested that digital tools, both software and hardware, can facilitate language-diverse students learning mathematics (Le Pichon et al., 2021; Freeman, 2012). However, most research, such as that of Le Pichon et al. (2021) and Freeman (2012), used individualised computer programs, which provided instruction in the home language. The rationale for these studies was often based on teachers needing support in interpreting students' mathematical work, because with the "variety of languages present in the classroom, teachers do not always have the necessary tools and expertise available to appeal to every pupil's home language" (Van Laere et al., 2017, p. 98). These approaches raise two concerns: teachers became almost redundant in the teaching process; and only the student's home language was considered a resource for learning mathematics.

Yet, as Libbrecht and Goosen (2016) stated, "the introduction of ICTs into mathematics teaching brings different ways to express and perceive mathematical activities, concepts, and phenomena" (p. 217). For example, dynamic geometry programs, such as GeoGebra, are considered as providing easy manipulation of multiple representations, "the use of dynamic representations promotes geometric thinking and provides visual, algebraic and conceptual support for the majority of students" (Dockendorff & Solar, 2018, p. 67). Thus, digital tools could utilise language-diverse students' range of resources for learning mathematics, because the different modes, such as graphs and symbolic algebra, contribute to meanings about a mathematical idea being developed. Nonetheless, little is known about how teachers use digital tools to support language-diverse students to activate their repertoire of resources. In this study, we analyse interviews with teachers and preservice teachers about using digital tools to support language-diverse students to learn mathematics.

Knowing what teachers do and the possibilities that they see for using digital tools to teach mathematics in multilingual classrooms is important for designing appropriate teacher education courses and professional development experiences. In Norway, concern has been expressed that teacher education is not providing adequate support for preservice and inservice teachers to incorporate digital tools into their teaching (Søby, 2013). A survey by Guðmundsdottir and Hatlevik (2018) of newly-qualified teachers found that nearly half felt that their professional digital competency was poor because of poor initial teacher education. Yet, in the most recent Norwegian mathematics curriculum "digital skills" are highlighted as one of five "basic skills" for students, with programming being a required part of mathematics education in schools (Kunnskapsdepartementet, 2019). As well, concern has been expressed about mathematics teacher education, in Norway, providing adequate support for preservice teachers to facilitate language-diverse students to utilise their language resources (Rangnes & Meaney, 2021). Therefore, there may be a mismatch between what language-diverse students need from experiences with digital tools, both for learning mathematics and for later life, and with what teachers know how to provide. Thus, designing appropriate courses for preservice and inservice teachers is important based on what they already know as well as what they do not know.

In this paper, we explore how teachers and preservice teachers (PTs) consider digital tools could be used in multilingual mathematics classrooms. As so little research has been done in this area, there is a need to scope the field and identify what kinds of connections can be made between language-diverse students, digital tools and mathematics teaching and learning. The data is from five individual teacher interviews and one focus group interview with five preservice teachers. For the analysis, we use a theoretical model from earlier research (Rangnes & Meaney, 2021) to describe some of the complexity of teachers' views.

Theoretical framework

The "multimodalities, signs and signs-maker in a social context" (MSSM) model was developed as part of a larger project exploring how preservice teachers learn about teaching argumentation for critical mathematics education (LATACME) in multilingual classrooms. This model is designed to understand how respondents, such as teachers, describe the possibilities they see as being available to another group, such as students, when particular resources, such as dynamic geometry and Minecraft, are considered to be vehicles for carrying meaning – semiotic resources.

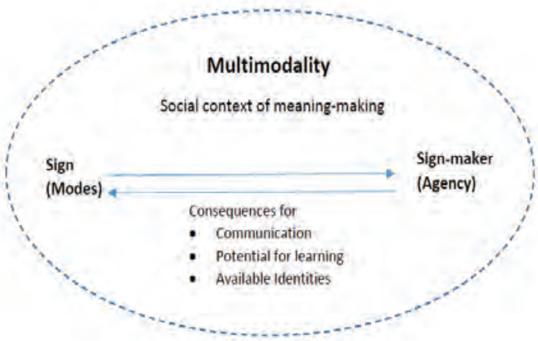

Figure 1: Multimodalities, signs and signs-maker in a social context (Rangnes & Meaney, 2021)

MSSM was built on Bezemer et al.'s (2012) work on multimodal social semiotics. In Figure 1, the oval symbolizes the social context, in which interactions, involving language-diverse students and digital tools, are embedded, as described by the (preservice) teachers. In any interaction, semiotic resources carry meanings. The potential for semiotic resources to be considered as appropriate meanings becomes recognisable, as a result of previous interactions. Therefore, the interaction is not separated from the wider context. Kress and van Leeuwen (2001) described how semiotic resources carry extra meanings, through provenance and connotation. Provenance describes how meanings are imported with the use of signs/semiotic resources from one context (culture, social group, etc.) to another, such as when Minecraft is seen as a play activity in a mathematics classroom, because of students' home experiences. As a result, the kind of meanings that students consider that Minecraft can carry is limited to what is usual in the home situations. The connotations connected to a sign, such as a block house in Minecraft, through the use of a particular mode, the graphic representation, are the socio-cultural values and backgrounds that provide extra information, such as a house being associated with somewhere to live. Participants in an interaction use the meanings from the provenance and connotation of a sign to make interpretations in an interaction, even if the sign maker had not intended for it to be understood as having these extra meanings.

In Rangnes and Meaney (2021), preservice teachers described the sign makers' (the students') choice of modalities, such as spoken or written language, to produce and interpret signs that carried meaning for the students in mathematics lessons. Interpreting PTs' descriptions of the use of different modes in the interactions provided insights into how PTs considered the students' *communication*, *potential for learning* and the *available identities* affected and was affected by the social context of the mathematics lesson. *Communication* occurs in interactions between people and between people and artefacts. Communication is linked to *learning potential* as it is through interactions that there is a potential to meet and engage with new ideas. In our study, we analysed (preservice) teachers' views on how language-diverse students could produce mathematical meaning, using different digital tools as a way of identifying learning potential. Similarly, we consider *available identities* to be the kinds of identities that the teachers implied were available to language-diverse students, when making use of digital tools as semiotic resources.

Methodology

The data was collected as part of larger, Norwegian-wide, research projects that both authors participate in. The focus group interview with preservice teachers was done by project colleagues and the five individual teacher interviews were collected by master students. Both the preservice teachers and the teachers taught grades 5-10 in Norwegian schools. The semi-structured interviews used a similar set of questions about a wider range of topics to do with using digital tools in mathematics classrooms. In this article, we only investigate responses about multilingual classrooms, which came towards the end of both sets of interviews. The format of the interviews and the different interviewers means that although the questions about digital tools and multilingual classrooms were similar in intent, they were not the same. However, as our intention is not to compare the results but to identify issues of interest, we consider that the interviews are sufficiently compatible to do a similar analysis.

In the previous research with this model, the preservice teachers had discussed specific episodes where students engaged with mathematics outdoors (Rangnes & Meaney, 2021). In the interview data, the (preservice) teachers sometimes described specific examples, but often described the potential with digital tools at a general level. Therefore in the analysis, we considered how the (preservice) teachers described aspects of modes, communication, available identities and potential for learning at a general level. The modes were the different kinds of representations that the (preservice) teachers identified as being important in multilingual mathematics classrooms. We identified comments to do with communication as those which talked about the purpose of communication in multilingual mathematics classrooms. Available identities were comments that (preservice) teachers made about language-diverse students as mathematics learners, while learning potential were comments about the kinds of learning that was made available in the mathematics classroom to language-diverse students. By considering how each of the aspects interacted together, we were able to consider how the (preservice) teachers considered the complex relationship between mathematics, digital tools and language-diverse students.

In the next section, we first describe our analysis of the teacher interviews and then the focus group interviews with the preservice teachers, by considering the modalities, the communication, the available identities and in the discussion and conclusion section, we discuss the results across the two data sets and what it means for teacher education programmes.

Teacher interviews

Modalities

The modes that the teachers highlighted in the interviews were mostly spoken and written language, including symbolic mathematics. Generally, mathematics was considered to be universal in these modes, "there are a few other words for things. But otherwise, it is exactly the same mathematics. It is generally valid" (Teacher2). As a result, the teachers focused on digital tools which translated instructions or translations of the students' answers. This would be through audio input or videos in the students' home language, which would enable the students to make sense of instructions illustrations and calculations, presented in Norwegian. T4 summarised that "the strength of the digital is that it is visual and a bit with being able to translate things". The benefit of visualisation was mentioned also by T1 as good for developing students conceptual understanding, but here visualisation seemed to just be referring to watching a replacement teacher on a video, not visualisation as described by Dockendorff and Solar (2018). The focus on these modes may have been because the teachers expected students to learn from listening to a teacher and reading a textbook. These expectations, or provenance (Kress & van Leeuwen, 2001), produced from earlier experiences, of mathematics teaching could lead to the assumption that if the student was unable to understand the teacher or the textbook, then they would be unable to learn mathematics.

Communication

In the interviews, the teachers highlighted the purpose of communication as being to gain access to the mathematical meanings that the students conveyed in their written work, with an assumption that the teachers needed to evaluate it, "it is a pity that one (the student) does not get to show their mathematical competence just because it is the wrong language" (T4). T2, T3 and T5 described how they could talk with students who spoke English as a second language, but, as T2 stated, students who used Polish would be problematic because the teachers would not understand. Consequently, T2, T3, T4 and T5 valued translation programs, such as Google Translate, or the opportunities in Excel, GeoGebra to change the language, because the students were then able to demonstrate their knowledge. For example, in written argumentation, the students could use translation programs to write in Norwegian well enough for the teacher to understand. To achieve this purpose, translation opportunities were highlighted by all the teachers, particularly when the students had limited Norwegian or English, which the teacher could understand.

The teachers also identified the purpose of communication as being for students to understand what was expected of them in class. Translation programs were considered as supporting this to happen, "it's a bit like doing nothing to actually work" (T4). T2 provided a story about a successful mathematics student who used it to understand what he had to do. However, T2 also noted that translation programs were only useful, "if they can then write in their own language, then you have to be good at math, but weak in the language", with "the language" referring to Norwegian.

Potential for learning

The teachers identified potential for learning as occurring when the students could follow the in-class teaching and completing textbook exercises. Digital tools were not discussed as supporting students' mathematics learning except for the access they provided to material provided by the teacher or the textbook. As a result, digital mathematics textbooks were valued because they had less text (in Norwegian) than ordinary textbooks (T3), making them easier to follow for language-diverse students. T2 and T5 described how students could watch YouTube videos on a mathematical topic in their home language, "I do not know if they (on the video) do it right, but they (the student) can see the video and I can see the calculation" (T5). The written calculation allowed the teacher to evaluate the students' learning. However, when language-diverse students had not previously learnt the same topics to the same degree as the other students in the class, then the potential for learning was limited. They considered that language-diverse students who had gaps, in relationship to what they were supposed to do in Norwegian classrooms, were not able to use translations programs or video lessons to bridge into the current mathematics classroom learning.

Available identities

The teachers were focused on bridging language-diverse students into existing classroom practices. Consequently, the students were described as having available identities either of being high achiever in mathematics from their previous countries or being low achievers with gaps in their understandings. As T5 stated, "to learn mathematics you have to have a foundation consisting of concepts and a language, and then be able to build on it". The high-achieving group could benefit from using Google Translate. However, language-diverse students with gaps in their mathematics education and limited Norwegian, were unable to take advantage of translation programs and so digital tools were not considered to provide any possibilities for supporting their meaning making,

> Often they are not necessarily bad in maths, they just have a lot of gaps and have to work with completely different things, things that they should have learned in 5th grade. Some have not got instant recall of basic facts to ten, then it becomes very difficult to add twelve and 18. It takes a long time (T2).

When language-diverse students came with such gaps, then digital tools were not considered as providing possibilities for supporting mathematical learning.

Preservice teachers focus group interview

Modalities

In the focus group interview, although they talked about different digital tools when they came to the questions on multilingual classrooms, the preservice teachers were asked specifically about programming. They described mathematics and programming as types of "language", where language had an implicit taken-for-granted meaning of natural languages. However, there was no details about whether they considered written set of instructions as programming or the modes that were available when the programs were run.

Communication

The preservice teachers' focus on mathematics and programming seemed to be about expressing ideas easily, "But as if there are people with both English and Norwegian, different word choices and in general. So I think it's easier, maybe? With programming because it's so distinctive" (PT2). Yet, what the meaning were that programming could provide were not discussed. Instead, programming was described as more precise and distinctive, making it easier to carry meanings. As well, the receivers of the meanings, expressed through programming, were not identified. It could be the teacher, or it could be other students who were the expected recipients of the communication.

Potential for learning

The preservice teachers discussed very generally what language-diverse students would learn from using programming. The preservice teachers had recently experienced learning programming and recognised that programming languages were unlike English or Norwegian, "so the language they use is also different. So, we became a little more aware of what that might mean" (PT3). As a result, they considered that programming, as another kind of language, was potentially easier for language-diverse students to learn. When they began programming, they used "a lot of trial and error". As well, they had been in a classroom and saw that programming was well received by the students "So that they wanted more challenges, and then programming had to be good" (PT1). As learning programming could be done through trial and error, the preservice teachers considered that the students had agency to control what they were doing, in contrast to "complete all the tasks in class" (PT1). Therefore, the potential for learning could be seen as being on a metalevel, learning about learning strategies rather than about learning specific mathematics or programming skills.

Available identities

As with the teachers, the preservice teachers also considered language-diverse students to be students with "language difficulties" (PT2). Yet, the precision of the programming language meant that students, who were not fluent in Norwegian, or had "language difficulties" could be challenged to learn programming. As well, given that few students had experiences with it, then all students would be learning it on an equal level:

> Yes, and so maybe most students are equal then, in programming. That not everyone has that much experience in it. So, one is in a way on an equal level, or, yes. It is equally unknown, equally known to all. And then you are not so outside. (PT2)

These reflections provided the PTs with the possibility to consider students as wanting to be challenged and not just complete tasks in the textbook and as having equal possibilities to learn programming.

Conclusion

Digital tools have been promoted as supporting students to learn mathematics by being able to convey meanings in a variety of ways (see for example, Dockendorff & Solar 2018). However, when the purpose of communication was to access students' mathematical knowledge, then the possibilities for using digital tools were reduced to having the students use translation programs. These programs provided the students with ways to show what they could do mathematically while they were learning the language of instruction. The use of translation programs provided opportunities to determine whether or not the students could become like the Norwegian students in the class, by showing they were capable mathematics students. On the other hand, using some digital tools, such as programming, allowed language-diverse students to be considered as capable learners, regardless of their fluency in the language of instruction. The features of programming language, although not discussed in any detail, seemed to provide opportunities to see language-diverse students as being similar to their classmates, in that they wanted to be challenged and they had the same capabilities to learn, perhaps more so because they had experiences of learning other languages.

The use of the MSSM to analyse the interviews provided insights into how the purpose of communication was connected to the potential for learning and the available identities for language-diverse students. However, it was more difficult to analyse the focus group interviews than it was to analyse the individual interviews because of the level of details provided by participants.

For teacher education, there are some not-so-simple findings from this research. The teacher interviews suggest that if programming is introduced into all classrooms, as the Norwegian curriculum (Kunnskapsdepartementet, 2019) now demand, and teachers only see the main role of communication in the classroom as interpreting and evaluating students' work, then it is unlikely that language-diverse students would be viewed in alternative ways. The provenance (Kress & van Leeuwen, 2001) connected to mathematics teaching, as being predominantly done through textbooks, would not allow for alternatives to be noticed. Similarly, even if learning programming does provide teachers with ways to see alternative identities for language-diverse students, but connections are not made to students' potential for learning mathematical content then the outcomes for these students will be limited. Unless teachers gain insights into how to make connections to mathematical ideas and value these connections, then programming can take on the connotation (Kress & van Leeuwen, 2001) of being game-like and so not a legitimate way for teaching mathematics to any student, including language-diverse students.

Acknowledgment

This study used data from the Research Council of Norway funded project, Learning about Teaching Argumentation for Critical Mathematics Education in multilingual classrooms (https://prosjekt.hvl.no/latacme/en/), and the project, "Mathematics preservice teachers' understandings about digital technologies" funded by the MatRIC Centre at the University of Agder.

Quality of students' explanations in describing multiplication algorithms: the case of Napier bones

Tiziana Pacelli[1], Cristina Pellegrino[2], Gemma Carotenuto[2] and Cristina Coppola[2]

[1]Università degli studi di Napoli Federico II, Dipartimento di Matematica e Applicazioni "R. Caccioppoli", Italy; tiziana.pacelli@unina.it

[2]Università degli studi di Salerno, Dipartimento di Matematica, Salerno, Italy; cristinapellegrino90@gmail.com; gcarotenuto@unisa.it; ccoppola@unisa.it

We describe a didactic cycle involving the Napier bones algorithm, included in a wider research whose aim is to investigate whether and how the use of different kinds of artifacts can affect students' explanations, supporting the understanding of some aspects of the multiplication. We present and discuss some data regarding group and individual tasks that allowed us to investigate how students' explanations were and what semiotic representations they chose when using Napier bones.

Keywords: Semiotic mediation, explanations, multiplication, artifacts.

Introduction

Algorithms for mathematical operations, which students experience at school, are not the only ones. In particular, for multiplication there are many alternative procedures associated with graphic, symbolic and/or material artifacts. Often, children, after knowing the traditional algorithm (multiplication in column), apply it in a mechanical way, without reflecting on the meaning of the foreseen steps, as a result of the fact that teaching multiplication is frequently based on memorising the multiplication table rather than on a meaningful understanding of the concept and related procedures (Vohra, 2007). Some studies (e.g., Haylock & Cockburn, 2008) suggest that children develop their mathematical understanding through language, symbols, concrete experience, images and manipulatives, which make mathematical concepts and operations more comprehensible to students (Swan & Marshall, 2010). In this sense, we believe that knowledge and use of different algorithms, instead a unique one, could help students to better understand some aspects of the multiplication. Knowledge about algorithms could change from being only instrumental to being also conceptual.

Students also find themselves having to use representations and symbols –typical of each algorithm– that, in addition to everyday language, are interpreted as carrying some meaning. At the same time, however, it should be kept in mind that semiotic mediation may not work. It depends on both the individuals and the characteristics of the tool involved in the mediation (Hasan, 2005). Explanations, produced by students during mathematical activities, could be a useful means for teachers both to see whether the mediation has worked and to observe whether understanding has been achieved.

The aim of our overall research is to investigate whether and how the use of different kinds of artifacts can affect students' explanations, and, therefore, the understanding of some aspects of the multiplication. We conducted a study in a primary school, involving 25 students who participated in mathematical activities focused on 5 different multiplication algorithms (multiplication in column, Chinese multiplication, Arabic multiplication, Napier bones multiplication, Genaille-Lucas rulers multiplication), each characterized by specific symbolic, graphic and/or material artifacts. In this paper we only focus on the Napier bones algorithm, answering to the following research questions: *what are the qualities in the students' explanations and what semiotic representations do the students' explanations draw upon when using Napier bones?*

Theoretical framework.

Our research is framed within the semiotic mediation paradigm, key aspect of the sociocultural theory of cognition, and developed in the work by Hasan (2005) and in that by Bartolini Bussi and Mariotti (2008). For Vygotsky (1978) cognitive development occurs through a *social activity* consisting of a progressive *interiorization* of strategies for using tools and mediation forms, allowing the child to attribute meaning to signs. The interiorization is carried out through *semiotic processes*: the construction of individual knowledge requires shared social experiences involving the production and the interpretation of different systems of signs (such as everyday language, images and symbols). Hasan (2005) refers to *mediation by semiosis*, i.e., mediation through the use of sign systems acting as an abstract tool in changing human activity, and emphasizes the semiotic function performed by language for the development of thought. Bartolini Bussi and Mariotti (2008) elaborated the Theory of Semiotic Mediation (TSM) in order to study links between artifacts, tasks, signs, and the mathematical knowledge to be mediated in the classroom. The teacher assumes the role of *cultural mediator* (Hasan, 2005; Bartolini Bussi & Mariotti, 2008): she mediates mathematical meanings to students through an artifact, exploiting its semiotic potential in relation to the tasks she has designed.

Admitting a link between language and thought, we can hypothesise that the quality of the explanations a student produce is related to the quality of her thinking (Albano et al., 2015; Ferrari, 2017). Within the field of mathematics, the explanation is closely related to 'mathematical understanding' and has to perform different functions: to clarify aspects of one's mathematical thinking; to describe the steps of a procedure used; to tell how one can arrive at a solution; to convince oneself or another person of some claim; to expand students' mathematics learning, as they communicate existing thoughts and can also generate new thought objects. In this way, explanations can be considered as constituent elements of the arguments (Levenson & Barkai, 2013) and, in our view, it is essential to analyse them in order to understand the development of knowledge that occurred during a semiotic activity involving artifacts.

Methodology.

The research is qualitative with an exploratory and descriptive aim: it is limited to collecting, analysing and interpreting data emerging from the specific context under investigation. In this study a single-group *pre-experimental research design* (Campbell & Stanley, 1963) was used, i.e., only the experimental group was considered, without a control group.

Context and overall research design.

The investigation involved 25 students from a fourth primary class of the Istituto Comprensivo 'Calcedonia' in Salerno (Italy), aged between 8 and 10 years.

The overall research design reflected the approach of the TSM (Bartolini Bussi & Mariotti, 2008). Researchers designed group and individual tasks, implemented in 5 didactic cycles, each one lasted about 1 hour, focused on a particular multiplication algorithm. In the first didactic cycle the work groups were formed and they remained the same for each cycle: the class teacher gave the role of ‘captain’ to five students with a good basic level and, then, four children were randomly assigned to each of them. Teacher was always present in the classroom, but her role was that of an external observer. The activities were conducted by one of the authors, a pre-service teacher who was doing her internship at that school. Each cycle was articulated in 3 phases: a *group activity* by means of tasks designed with the aim of exploring the artifact; a *collective discussion* on the structure and the way of using the artifact, based on the explanations produced by the students in the first phase; an *individual activity* by means of tasks designed to verify the understanding of the algorithm.

The didactic cycle n°4: Napier bones multiplication algorithm.

Napier bones multiplication algorithm is based on a material graphic artifact (Figure 1) consisting of 10 strips numbered from 0 to 9 and a further strip, called ruler, marked with the symbol ×. Each strip is divided into 9 squares, each—except the ruler—cut by a diagonal line running from top right to bottom left, in which are shown the multiples of the number marked at the top. In each of the 9 squares of the ruler there is a number from 0 to 9. To calculate the product between two multi-digit numbers, the bones of the digits of the first factor are placed side by side with the ruler on the right, creating a table with nine lines. Then, you have to consider the lines corresponding to the digits of the second factor, one after the other, starting from the units one. Each line will correspond to a partial product, obtained by summing along the diagonals. The desired product will be obtained as the sum of the partial products (Figure 1).

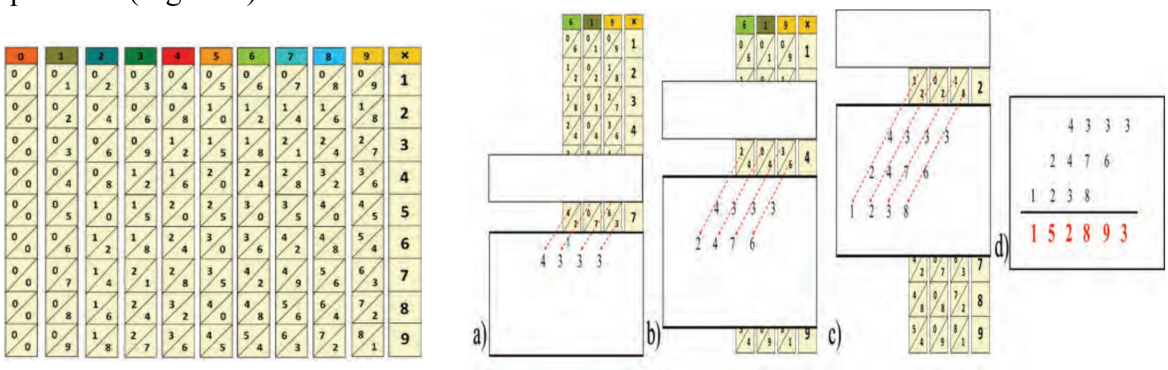

Figure 1: Napier bones (on the left) and four steps calculation of 619×247 (on the right)

The students were not familiar with this artifact, but it was introduced after they had already experienced multiplication in column, Chinese and Arabic algorithms, as part of the educational path. We expected not too many difficulties with the Napier bones, since some algorithm features are similar to those of Arabic multiplication. In the following we focus only on group and individual activities.

Group activity consisted of two tasks: Task 1 and Task 2. Each group was given a paper on which Napier bones were illustrated, without saying what they were. **Task 1** consisted of 3 questions (Bartolini Bussi & Mariotti, 2008): 1) What are they?; 2) What do they look like? You can use not only text, but also drawings to describe the objects; 3) What can they do? Justify your answer. The first two questions were strictly aimed at exploring the artifact and bringing out the students’ prior knowledge, on which the new mathematical content would be anchored; the third question involved highlighting the utilization schemes of the artifact, which would then become a tool[1].

Then the students were told that the strips were named Napier bones and were asked to cut out the paper strips so that they could manipulate and use them for **Task 2**, which consisted of 3 questions:

1. Imagine you only have Napier bones available to carry out multiplication. Describe how you could execute the operation 123×6.
2. Describe how you could execute 436×72 multiplication using Napier bones.
3. What similarities and what differences do you notice between Napier bones multiplication and Arabic multiplication?

Starting from the assumption that Napier bones derive from Arabic multiplication, Question 1 aimed to investigate whether students, in exploring and using the artifact, were able to explain how to calculate a multiplication with a one-digit factor; it also aimed to observe what kind of semiotic resource the students used in their explanations. Question 2 had the same aim, but in the case of multiplication with a non-consecutive two-digit factor, which involves adding the two partial products, as in the traditional algorithm. The aim of Question 3 was to investigate whether the students were able to make a comparison between Napier bones algorithm and Arabic multiplication.

For *individual activity* was designed and implemented only **Task 3** consisted of 4 questions:

1. In a third-year class, the math teacher gives each child Napier bones without explaining what they are or what they are used for. Luca can't quite understand how to use them. Explain what they are and show him a few examples, describing step by step how to use them.
2. Luca still shows some difficulty. Execute the same multiplications as in your examples using multiplication in column and explain to him the differences between the two methods.
3. What are the advantages of using Napier bones? And what disadvantages?
4. In your opinion, does the use of Napier bones make multiplication easier than traditional calculus? Justify your answer.

In Question 1, by asking for examples, we wanted to find out if the students were able to explain how to do multiplication using the bones—highlighting algorithm features—and what representation they used to support their answers. The aim of Question 2 was to further investigate whether the students were able to explain the mathematical properties underlying both the traditional algorithm and the Napier bones. The Questions 3 and 4 were aimed at understanding how they perceived a possible use of bones in daily school practice.

Data collection and analysis.

The data were collected by means of *observation* during each phase of the didactic cycle, *structured group/individual tasks*; *field notes* regarding the collective discussions based on students' production.

---

[1] According to the instrumental approach (Béguin & Rabardel, 2000) a subject, engaged in a goal-directed activity, can build schemes of instrumented action for an artifact. Thanks to the visible signs elaborated by the solver (e.g., text, words, representation), we can make inferences about the schemes she is developing for the tasks.

In this paper we consider only the explanations provided by the students in *structured group/individual tasks*. As we have just described, for each structured task, students were asked to explain their answers and to use different types of representation. In each group/ individual task, requests such as “Justify your answer”, “Explain how you arrived at the solution” or “What differences do you notice?”, “What are the advantages/disadvantages?” were included in order to stimulate explanations and continuous comparison. Once the data collection was completed, the name chosen by each group (Fulmine, Vento, Tempesta, Pioggia and Neve) was recorded for all group activity protocols. The protocols of the individual activities were numbered from 1 to 25, assigning the same number to each student in the different activities.

For the analysis of the explanations the attention was focused on the different types of representation used by the students: *graphic, verbal*. In addition, for analysing their qualities we were inspired by the criteria as used in the work by Cusi et al. (2017), namely *correctness*, which refers to the absence in the explanation of mathematical errors; *clarity*, which refers to the comprehensibility of the explanation by an interlocutor ; *completeness* refers to the description of all the steps of the algorithm, including the final step leading to the solution. As an example “12 and 17 are 29” can be considered *correct*, *no clear* and *no complete* because the description of the procedure is missing and a classmate might not understand that ‘and’ refers to an addition. Thus, if an explanation is correct, clear, and complete, it is able to perform the functions that Levenson and Barkai (2013) attributed to it.

Results.

In this paper we present only some results from data concerning Question 1 and Question 2 of Task 2 carried out in the group activity and Question 1 of Task 3 carried out in the individual activity.

Task 2 - Group activity.

Concerning **Task 2,** all groups provided an answer to **Question 1**. The analysis has revealed that all of them used *verbal representation* to explain their answer. Almost all of the explanations, however, was not qualitatively adequate, in relation to the chosen criteria.

In fact only one group (Fulmine) produced a *correct, clear and complete* explanation in that, even though it made use of a colloquial register, it explained with care the procedure to be used to do multiplication, showing that the group identified some similarity between the calculation of multiplication with Napier bones and Arabic algorithm.

Fulmine: We took the 1-2-3-X sticks (the one that contains the numbers up to 9) then we did 6+1=7, 2+1=3 and then 8+0=8, and came up with 738 using Arabic multiplication.

The other 4 groups, even though they did not describe the correct procedure and did not specify the various steps to be taken, still provided an explanation that, for 2 groups (Tempesta and Pioggia) was quite *clear*, while for the other 2 (Vento and Neve) was difficult to understand (*no correct, no clear, no complete*). We propose, as examples, the answers given by Pioggia and Neve.

Pioggia: To solve with Napier bones you have to put them in a row, counting only the numbers that you have to multiply. We put a 1-stick, a 2-stick, and another, 3-stick, then put sheets on the other numbers and add up the results of each number. The result is 18.

Neve: To do the 123×6 multiplication we have to put the 6 in the 3, then the 6 in the 2 and finally the 6 in the 1 then we do the result and at the end the result is 7938.

The data regarding **Question 2** show that all groups provided the answer but the quality of the explanations worsened. None of the groups gave a *complete* answer and 3 out of 5 groups described the use of bones in a *no correct, no clear, no complete* way. As an example, the quality of the explanation provided by Fulmine seems to worsen with respect to the Question 1: the group described the procedure in a fairly *clear* way, but made an error in the sum of the partial products and, consequently, in the final result and they skipped some steps of the whole process.

Fulmine: We took the 4-3-6-X sticks (the one that holds the numbers 1-9) then we did 436×7 first and then we did 436×2 and finally we added up the two results and it came out 30520.

More *clear and correct* (even if the final result is missing) is the explanation produced by Tempesta, as the group did not explain how to arrange the sticks, nor how to calculate the two partial products.

Tempesta: First we looked at the numbers coming up in the 2's line and then the 7's line and finally we added up.

Task 3 - Individual activity.

Question 1 was completed by 21 out of 25 students and only 12 of these answered to the first part of it (e*xplain what they are*). As for the second part of the question (*show him a few examples, describing step by step how to use them*) only 16 out of 21 students provided explanations (Figure 2).

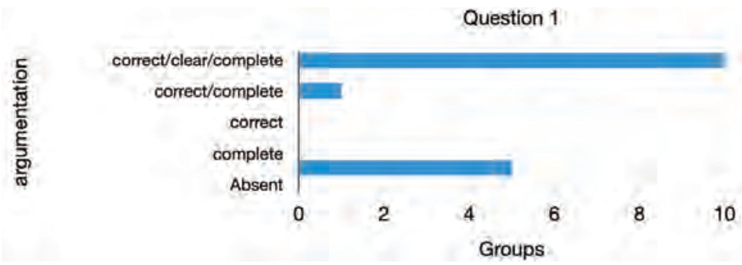

Figure 2: Task 3 - quality of the explanations in Question 1

Each one reported a single example and, 6 students used *verbal representation* to explain*,* describing in a more or less *correct and clear* way the various steps to be performed; 10 students, instead, used only the *graphic representation* by drawing the sticks they had to use to do the multiplication chosen as an example (Figure 2).

	Prot. n°12: I'll give you an example, 54×5; take the ruler and the 5-stick and 4-stick. Take a sheet of paper and divide it in half, you will come out with two equal sized sheets. Put the 5, 4 and ruler next to each other, take one half of the sheet and put it (ruler part) on 1-2-3-4 and the other on 6-7-8-9 and count the numbers in the diagonals that are created, like in Arabic multiplication.
Figure 3: A *correct/clear/complete*	

explanation (Prot. n°11) with graphic representation	

Regarding the quality, more than half of the sample (10 out of 16 students) provided *correct, clear, and complete* explanations, with some students using *verbal representation* (e.g. Prot. n° 12) and the majority using *graphic representation* (Prot. n°11 in Figure 3).

5 students out of 16 provided *no correct, no clear, no complete* explanations, using, often, a convoluted syntax. Only Protocol n°25 explained in a *correct and complete* way: using *verbal representation*, she explained all the steps to arrive at the result of the chosen multiplication, but, as for most of the class, she used a not very clear colloquial register. In addition, she was the only one to specify that it is important to move the second partial product one place to the left, because it is the product of the tens of the multiplier by the digits of the multiplicand.

Prot. n°25: Luca first you need to add up the numbers in the diagonals to get the result. If the multiplication is 172×47, to get the result you have to isolate first the second number i.e. 7 and then the first number i.e. 4. Finally you add it all up and the result will come out. But we must remember that the product of the tens must be under the other tens.

Discussion and Conclusions.

In this study we explored the qualities of students' explanations and what semiotic representations students draw upon in their explanations when using Napier's bones, in two different situations. Although this algorithm derives from Arabic multiplication, previously experienced, the analysis of the responses to Question 1 and Question 2 of Task 2 highlighted that the quality of students' explanations did not meet the chosen criteria. In addition they are all based on verbal representations. For the former only one group explained in a correct, clear, and complete way; for the latter only one group described the procedure of Napier bones algorithm in a correct and clear way. From the data analysis regarding Question 1 of Task 3 the quality of the explanations, with prevailing graphic representations, even if in colloquial register, seems to be improved according to the chosen criteria: 10 students provided correct, clear, and complete explanations and one student explained in a correct and complete way. This may also be a consequence of the collective discussion—not analysed in this paper—orchestrated by the preservice teacher (Vygotsky, 1978; Hasan, 2005; Bartolini & Mariotti, 2008) and based on the students' explanations collected in Task 2. In this way, students began to make sense of what they were doing and improved the quality of their explanations. Furthermore, the data seemed to suggest us that the use of graphic representations of Napier bones, in students' explanations in the individual activity, had helped them to perform multiplication correctly, to make connections with previous knowledge (Prot. n°. 12) and to understand some operation properties (Prot. n°. 25) (Swan & Marshall, 2010).

The study is at an early stage: data from other tasks, from other didactic cycles on different algorithms, and from collective discussions, still need to be analyzed. Nevertheless, we believe that it can be a starting point to reflect on artifacts mediation of a meaningful understanding of some aspects of the multiplication (Haylock & Cockburn, 2008).

Generalizing mathematically through changes in referents

Kristina Palm Kaplan[1,3] and Ida Bergvall[2]

[1]University of Gävle, Department of Electrical Engineering, Mathematics and Science, Gävle, Sweden; kristina.palm.kaplan@hig.se , [3]Karlstad University, Department of Mathematics, Karlstad, Sweden; kristina.palm-kaplan@kau.se

[2]Uppsala University, Department of Education, Sweden; ida.bergvall@edu.uu.se

In this pilot, opportunities to engage in mathematical generalization were identified in a section of a textbook from year 6. From a social-semiotic perspective, we explored how these opportunities were constructed linguistically. While passive verb forms and nominalizations constructed an independent character of mathematics, logic expansions constructed limitations for the generalizations. Changes in referents constructed opportunities for generalizing actions.

Keywords: Mathematical generalization, social semiotics, transduction, textbooks, primary school.

Background

Mathematical generalization (henceforth MG) has been raised as a big idea in mathematics, for example through scaffolding algebraic reasoning, functional thinking and many other mathematical activities (e.g., Dörfler, 1991). It is also known that students often have difficulties with, among other things, expressing generality and using generalized language (Mason, 1996). Generalized language may here be interpreted as a part of disciplinary literacy (Shanahan & Shanahan, 2008), as specialized texts and literacy skills are expected of students at more advanced levels of studies. However, big ideas are also a part of primary school mathematics (Madej, 2021). Therefore, the expected literacy skills and specialization are important to scrutinize also in texts for primary school.

Despite its importance MG is not in focus in the 2011 Swedish steering documents. The course plans hardly mention aspects of generalization (Hemmi, Lepik & Viholainen, 2013), and it has been shown that Swedish primary school textbooks after 2011 contain very low proportions of generalized arithmetic (Bråting, Madej & Hemmi, 2019). Still, textbooks largely seem to organize the teaching in Swedish primary school classrooms (Koljonen, 2020). This makes Swedish textbooks an interesting starting point for understanding opportunities to engage in MG.

Different aspects of language have been compared for various school years in Swedish textbooks in various subjects (e.g., Österholm & Bergqvist, 2013). Aspects of language have also been studied in textbooks in other countries (e.g., Alshwaikh, 2016). While the degree of abstraction and generalization has been studied in Swedish educational texts for social science, natural science and literature (Edling, 2006), to our knowledge so far, the ways in which MG is presented have not been investigated from a linguistic point of view. Therefore, this pilot study aims to explore and describe linguistic aspects of MG in a section of a textbook. The research questions are:

- What opportunities for mathematical generalization can be identified in the textbook section?
- In what ways are linguistic resources used to construct the mathematical generalization?

Mathematical generalization and a social semiotic perspective on mathematics

MG entails both generalization as an object or conclusion, and generalizing as an act or process (Ellis, 2007; Harel & Tall, 1991; Mason, 1996). It has been regarded as e.g., mental processes or social interaction across agents and within specific contexts, and may be expressed through gestures, images and other semiotic resources, as well as formal symbols or words (Dörfler, 1991; Harel & Tall, 1991; Radford, 2018). Ellis (2007) takes an actor-oriented perspective and empirically identifies different ways that a learner may engage in MG. In her taxonomy, these ways are described as the *generalizing actions* of relating, searching and extending, and the *reflection generalizations* of identification or statement, definition and influence. Generalizing actions are inferred through activity and talk, while reflection generalizations are inferred through statements or the use of a result of a generalization. Since textbooks are always oriented towards the students using them, Ellis' actor-oriented perspective seems useful for the present study. However, it is not what students actually do, say or write when using textbooks, or students' mental processes, which are in focus here. Adapting Ellis (2007), we look at explicit opportunities in the textbooks to engage in generalizing actions, to read or state reflection generalizations or to read or use a result of such a generalization.

To understand how MG is constructed through written language and other semiotic resources in textbooks, we build on a social semiotic perspective and Systemic Functional Linguistics, SFL (e.g. O´Halloran, 2005). Central in this perspective is that in any act of communication we make choices of language in order to construct a certain meaning (e.g. Halliday & Matthiessen, 2004). This is also the case for semiotic resources such as mathematical notation and images (O´Halloran, 2005). Further, a change in the semiotic mode, the process of *transduction*, includes ontological shifts (Kress, 2010). Through the "re-articulation of meaning from the entities from one mode into the entities of the new mode" (Kress, 2010, p. 125), we believe such shifts may be important for the ontological construction of MG. In this paper, various semiotic resources are analysed with SFL to understand opportunities to read and write MG in a primary school textbook section.

Methods

A textbook for year 6, the final year of Swedish primary school, was considered suitable since MG is often considered rather difficult for students to master (Mason, 1996), and therefore, it can be expected that a book for older students will contain the largest proportion of opportunities for MG. The text analysed in this study is taken from a year 6 book translated from Finnish into Swedish. This particular book seemed to include a large variety of opportunities for MG, compared to others.

In this pilot, we test the methods of analysis. We do not identify all textbook sections where MG is offered. Therefore, we selected an initial section on patterns, which was spontaneously deemed to offer MG. The selection is small, but we do not seek to generalize the findings in this pilot to a larger body of texts. To answer the research questions, two analyses were conducted. Both analyses were conducted by one of the researchers, checked by the other, and then discussed until agreed.

The analysis of mathematical generalization

To identify the opportunities to engage in MG, we used a taxonomy of mathematical generalization (Ellis, 2007). It is presented in our version adapted to textbooks in Table 1.

Table 1: Questions for identifying opportunities to mathematical generalization

MG (Ellis, 2007)	Questions posed to the text
Generalizing action	*Do the students have the opportunity to …*
Relating	• relate situations through the formation of an association between two or more problems or situations? • relate objects through the formation of a similarity between two or more present objects?
Searching	• detect a stable relationship between two or more objects. • test if a procedure remains valid for all cases? • check whether a detected pattern remains stable across all cases? • determine if the outcome of the action is identical every time?
Extending	• expand to a larger range of cases than that from which the phenomenon originated? • remove particulars to develop a global case? • operate on an object to generate new cases? • repeat an existing pattern to generate new cases?
Reflection generalization	*Do the students have the opportunity to write (in tasks) or read (in introductory text) …*
Identification or statement	• the identification of a property? • a statement of commonality or similarity, or of a general phenomenon?
Definition	• a definition of a class of objects all satisfying a given relationship, pattern or other phenomena?
Influence	• an implementation of a previously developed generalization or an adaption of an existing generalization to apply to a new problem or situation?

The SFL-analysis

Linguistic generalizations may be constructed through choices of referents and nominalizations (Halliday & Matthiessen, 2004). These are the main features explored in this analysis.

Referents are experiential elements in the text. Different types of noun phrases, and how they change, indicate different ways of using language (Halliday & Matthiessen, 2004). Referents can have an everyday character or be technical, and they may be presented in a variety of semiotic modes (Kress & Van Leeuwen, 2006). They may also be placed on scales between physical and abstract, specific and general (Edling, 2006). A move in the text from a specific to a general referent may realize a linguistic generalization in the text, whereas a move from a concrete to an abstract referent instead may realize a linguistic abstraction in the text (Figure 1). When a referent is changed into a different semiotic resource it is called a transduction which at the same time re-articulates the ontological meaning of the referent (Kress, 2010). For instance, a picture of 5 apples which then is followed by the number 5 entails an ontological shift from concrete to abstract meaning. Linguistic changes of referents including transduction may thus indicate opportunities in the textbook for MG. This will be explored in the analysis.

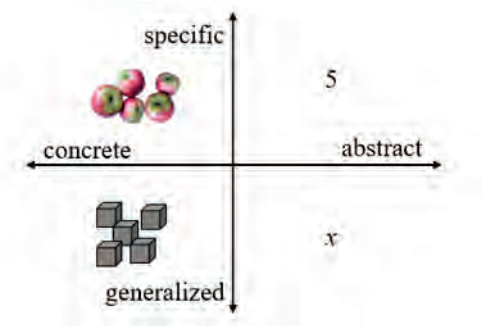

Figure 1: Abstraction and generalization in different referents, adapted from Edling (2006)

A *nominalization* is an incongruent expression, or grammatical metaphor (Halliday & Matthiessen, 2004), where a noun (e.g. *subtraction*) is used instead of the corresponding verb or adjective form (e.g. *subtract*). Nominalization is a means of constructing generalization because an operational process, expressed by a verb, is reified into a general concept by the nominal form. Operational processes are mostly tied to specific situations where calculations are needed, whilst general concepts describe mathematical relations without necessarily linking to specific situations. Nominalization also hides human participation, since there is no explicit human agent carrying out the action. This downplaying of human agents further accentuates generalization. Therefore, generalization may also be indicated through a *passive verb form*, e.g. in the phrase “can be used” instead of “you can use”. Our analysis explores in what respect nominalizations and passive verb forms contribute to MG. To avoid overlooking other important linguistic features, the instances of MG in the textbook section were read, reread and discussed with respect to the semiotic resources used in them. For instance, expansions of clause complexes show in what ways a text may be developed (Halliday & Matthiessen, 2004); this might contribute to MG. However, the analysed text mostly consists of main clauses.

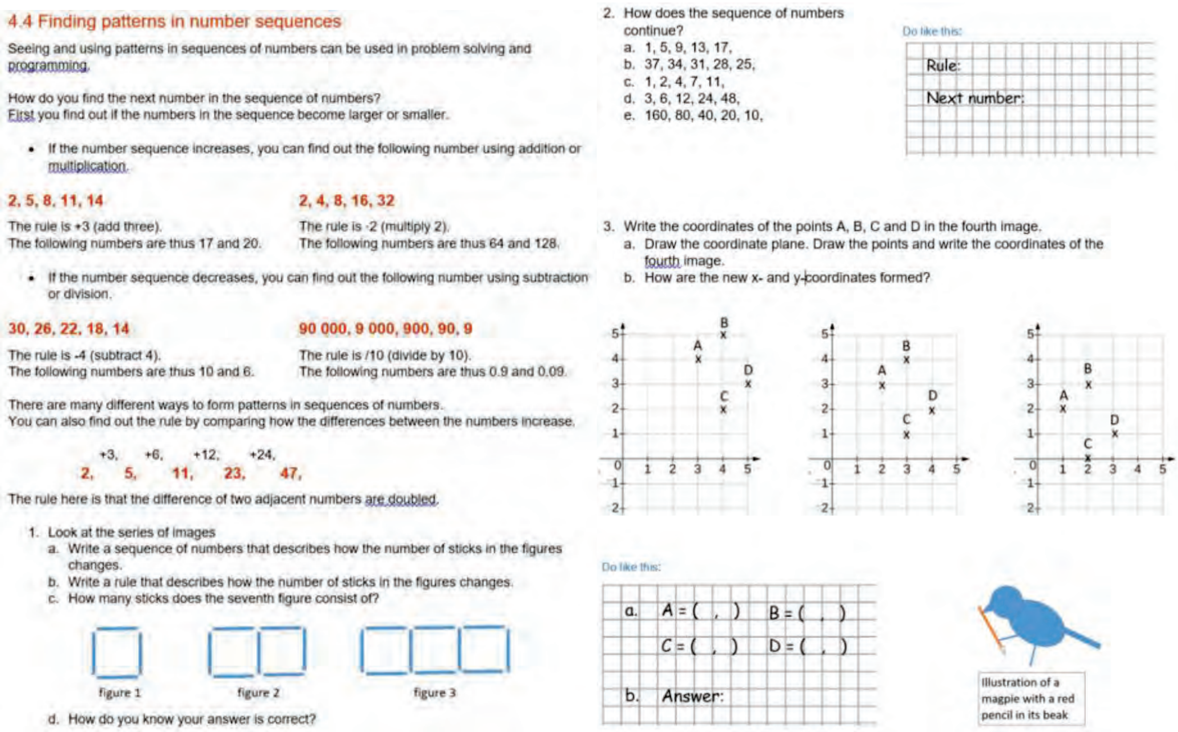
Finally: In a certain sense, textbook tasks comprise one half of a dialogue where the textbook author asks questions and the students answer. We acknowledge that in such a dialogue, any feasible reflection generalization will be constructed in the answer and not the question. Since this study does not look at actual answers, opportunities for reflection generalization are therefore not linguistically analysed in the tasks, only in the introductory text.

Results

Opportunities to engage in mathematical generalization, MG, are given in the form of generalizing actions and to some extent in the form of reflection generalization. To answer the research questions, the results are structured by what is identified in introductory text and tasks respectively. All translations from the textbook section are ours.

Nominalizations and passive verb forms constructing an independent character

The introductory text provides opportunities to engage in *generalizing actions* and read *reflection generalizations*. The top of the page question and the two following sentences (Fig.2) constitute a prompt to search for relationships, and thus models *searching* in the form of detecting a stable relationship between objects. A similar statement is made for decreasing number sequences using subtraction and division. Finally, "You can also find out the rule …" models *extending* to other ways of investigating number sequences. All three statements "If the number sequence [increases/ decreases] …" and "You can also ..." are descriptions of general strategies for investigating patterns and therefore examples of *reflection generalization* as *identification or statement*. Hence, in the introductory text, the generalizing actions and reflection generalizations seem to coincide



4.4 Finding patterns in number sequences

Seeing and using patterns in sequences of numbers can be used in problem solving and programming.

How do you find the next number in the sequence of numbers?
First you find out if the numbers in the sequence become larger or smaller.

- If the number sequence increases, you can find out the following number using addition or multiplication.

2, 5, 8, 11, 14
The rule is +3 (add three).
The following numbers are thus 17 and 20.

2, 4, 8, 16, 32
The rule is ·2 (multiply 2).
The following numbers are thus 64 and 128.

- If the number sequence decreases, you can find out the following number using subtraction or division.

30, 26, 22, 18, 14
The rule is -4 (subtract 4).
The following numbers are thus 10 and 6.

90 000, 9 000, 900, 90, 9
The rule is /10 (divide by 10).
The following numbers are thus 0.9 and 0.09.

There are many different ways to form patterns in sequences of numbers.
You can also find out the rule by comparing how the differences between the numbers increase.

+3, +6, +12, +24,
2, 5, 11, 23, 47,

The rule here is that the difference of two adjacent numbers are doubled.

1. Look at the series of images
   a. Write a sequence of numbers that describes how the number of sticks in the figures changes.
   b. Write a rule that describes how the number of sticks in the figures changes.
   c. How many sticks does the seventh figure consist of?

   figure 1 figure 2 figure 3

   d. How do you know your answer is correct?

2. How does the sequence of numbers continue?
   a. 1, 5, 9, 13, 17,
   b. 37, 34, 31, 28, 25,
   c. 1, 2, 4, 7, 11,
   d. 3, 6, 12, 24, 48,
   e. 160, 80, 40, 20, 10,

Do like this:
Rule:
Next number:

3. Write the coordinates of the points A, B, C and D in the fourth image.
   a. Draw the coordinate plane. Draw the points and write the coordinates of the fourth image.
   b. How are the new x- and y-coordinates formed?

Do like this:
a. A = (,) B = (,)
C = (,) D = (,)
b. Answer:

Illustration of a magpie with a red pencil in its beak

Figure 2: The textbook section Find patterns in number sequences

The written referents in the three statements in the introductory text mentioned above, e.g. "patterns in number sequences" and "the following number" change to the specific numbers e.g. "2, 5, 8, 11, 14". The ontological meaning in this transduction shifts from generalized to specific. The specific number sequences in the introduction thus function to explain and unpack the *reflection generalizations*. The nominalizations in the four arithmetic operations in these statements construct the number sequences as structures: it does not matter which specific numbers are added, multiplied, subtracted or divided, because it is the operations in general which are relevant, not their results. The passive verb form "are doubled" constructs *searching* as something independent from human beings: the activity does not render different results (e.g. as tripling instead of doubling), depending on who performed the investigation. This independent character is a quite fundamental aspect of MG. Finally, the introductory text is expanded logically in the reflection generalizations "If the number sequence [increases/decreases] …” constructing a condition for when the procedure described in the main clause is valid. These expansions thus limit the range of the generalizations.

Generalizing actions in tasks constructed through changes in referents

Task 1 prompts a re-articulation of the number of sticks in a given pattern into a number sequence. Through forming a similarity between the two objects, an opportunity to *relating* is constructed. The ontological meaning is re-articulated through a transduction from the generalized-concrete sticks to specific-abstract numbers. An opportunity to engage in *searching* is given through writing the rule for how the pattern changes. Here, the ontological meaning shifts from the specific-abstract numbers to the generalized-abstract rule, formulated as “+3 (add three)”. 1c prompts to continue the number sequence and generate a new case, the “seventh figure”. Here, the transduction re-articulates the generalized-abstract “a rule”, to the specific-abstract number of sticks which is supposed to be calculated. In this way, the ontological shift supports a control of the identified rule and the test for new cases, thus *extending* by continuing the pattern. The last part of task 1 gives the opportunity to write an *identification or statement*. However, this opportunity could not be analysed linguistically.

Task 2 is fairly similar to task 1. It prompts to re-articulate specific-abstract number sequences as generalized-abstract rules for the sequences and thus gives an opportunity to *searching*. The prompt in the last part is to re-articulate new cases of specific-abstract numbers, which gives an opportunity to extending. Since no concrete figures are given, this task does not comprise *relating*. The picture of the checkered piece of paper in the task and what is written on it, explicitly models how to engage in searching and extending the number sequences. In task 1 and 2, *searching* is then constructed through transduction from specific-abstract to generalized-abstract, whereas *extending* is constructed through the ontological shift back from generalized-abstract to specific-abstract meaning.

Task 3 gives the opportunity to a *reflection generalization* as an *influence* since the previously developed generalization of how to work with patterns is adapted to a new situation, consisting of coordinates which constitute successive sets of ordered pairs. The first step prompts to “[w]rite the coordinates … in the fourth image”, so focus is on extending through continuing the pattern, to generate a new case. *Relating* and *searching* are thus not supported ahead of extending, as in the previous tasks. 3a prompts “draw” and “write”. It could be argued that these requests include relating the points A, B, C and D in the sequence of graphs to their more abstract re-articulations as sets of ordered pairs of numbers. However, it is only the points and “coordinates of the fourth image” which are explicitly asked for. In 3b, the question “How are the new x- and y-coordinate formed?” could include searching for a stable relationship between the points A, B, C and D in the sequence of graphs. Just as in 3a, only the “new” coordinates are asked for. The picture of the checkered piece of paper in task 3 is different from in task 2. It supports writing down the coordinates for one set of points A, B, C and D, and to write the “Answer”.

To solve task 3, learners thus need to recognize the steps of relating and searching the pattern in the first three graphs without a prompt to do so. *Extending* to the fourth picture is the only explicit request. The steps include transductions from the graphical mode to numbers (3a), and from the numbers to formulating the rule of the pattern (3b), respectively. As in task 1 and 2, *searching* seems to be constructed through an ontological shift from the specific-abstract to the generalized-abstract. The graphs are interpreted as concrete referents in this study since they have a spatial extension. *Relating* in task 3 is thus constructed through an ontological shift from concrete to generalized meaning.

Concluding remarks

This pilot analysis of a section of a mathematics textbook has revealed opportunities to engage in *generalizing actions*, as well as reading and writing *reflection generalizations*. However, no opportunities to read or write *definitions* are given, nor to read a reflection generalization as *influence*. Swedish textbooks have low proportions of generalized arithmetic (Bråting et al, 2019) and mathematical generalization, MG, include many aspects (Ellis, 2007). We therefore believe that a forthcoming comparative study of textbooks would reveal differences in opportunities for MG. Further, different proportions of *searching* might be a distinguishing feature since searching has been prominent in the textbook example analysed in this study. A study of students' solutions or work with the textbook section may contribute to the understanding of what MG actually takes place.

In the introductory text, opportunities for reading *identification or statement* are constructed through nominalizations of the four arithmetic operations. The range of two *statements* about patterns are constructed through logical expansions in the text. Moreover, passive verb forms and nominalizations construct patterns as structures, independent of human agents. In this sense, the *identification or statement* does not only model reflection generalization, but also expresses the general character of mathematics. These linguistic features may be interpreted as a part of the disciplinary literacy (Shanahan & Shanahan, 2008) which is expected of students, in order to understand MG. Finally, the reflection generalizations in the introductory text are unpacked and explained through the ontological shift which occurs in the transduction from written text to number sequences. In this way we can see that various semiotic resources are used to express MG.

Opportunities for generalizing actions in the analysed tasks are mainly constructed through different transductions, i.e. changes in the referents' semiotic mode. When *relating*, the ontological meaning shifts from concrete to more abstract; when *searching*, it shifts from specific-abstract to general-abstract. When *extending*, the ontological meaning shifts back from generalized-abstract to specific-abstract referents. Therefore, for a textbook to support opportunities for learning *generalizing action*, we believe that transduction may be a key feature. Further, to enhance opportunities for MG attention should be paid not only to the change between concrete and abstract referents, but also between referents which are specific and generalized, and referents presented in different semiotic modes.

Communicative projects about mathematical reasoning

Annika Perlander

University of South-Eastern Norway, Norway; annika.perlander@usn.no

Keywords: Mathematical reasoning, dialogism, classroom practice.

Background

Mathematical reasoning as concept in education research comes in various shapes and is used with different purposes (Jeannotte & Kieran, 2017). Regardless of definition, mathematical reasoning is included in many curricula as part of being mathematically competent. Now, in Norway, after the curriculum renewal in 2020, (Norwegian Directorate for Education and Training, 2020), mathematical reasoning is linked to students' capability of using mathematical language, of engaging in posing and answering questions and of using mathematical concepts in different situations. The responsibility for creating opportunities for students to develop an understanding of and ability to carry out mathematical reasoning lies with the teacher. However, creating and maintaining a discourse that promotes the development of these competencies, seems to be challenging for teachers (Højgaard et al., 2010).

As part of my PhD work, the study presented here focuses on the interactions in the classrooms of newly graduated teachers when communicating mathematical reasoning. The study contributes to the understanding of what participation in mathematical reasoning activities looks like as well as aspects of how learning experiences influence each other over different timescales. The research questions are: What kind of communicative projects are established in the classroom when the new teacher and students are communicating mathematical reasoning? How do these projects evolve over time?

Theoretical framework

For this research I have chosen a dialogical approach. Dialogical aspects of students becoming active members of the mathematical discourse in the classroom have been addressed in several research studies. For example, studies have shown how participating in conversations about mathematics promotes students' understanding of mathematical concepts or a development of formal mathematical language (Barwell, 2016; Schleppegrell, 2007). Following Linell, dialogism is a theory of sense-making where "action, communication and cognition are thoroughly relational (or inter-relational) and interactional in nature" (Linell, 2009, p. 14). This relational aspect of communication puts focus on both sense-making as a situated joint construction and on communicative acts as sequentially ordered. In the negotiation of meaning there is a flow of initiatives and responses forming a dialogical interdependent relation between single acts and more overarching activities. Similarly, activities form larger units of communication, "communicative projects", interrelated to other goals or doings in, and across situations. This interdependence connects acts in the present to dialogical contributions prior in time and to future contributions (Lemke, 2000). Analysis of what happens in communicative projects, how they are organized or on what timescale they are carried out can be a way to understand a locally produced discourse (Linell, 2009). The dialogical principles of sequentiality, joint construction and act-activity interdependence also imply that contexts and discourses are constantly shifting, interdependent with what others do, have done and potentially could be doing in the future.

Methodology

The study focuses on communicative projects about mathematical reasoning and how they evolve over time. To identify communicative projects, I will do observations of a sequence of 10-12 consecutive lessons. This enables analysis of interactions both within a lesson and between lessons (Lemke, 2000). The observations will be done in three to four classrooms at upper secondary level using video recording. Also, the teachers of those classes will be interviewed. The teachers will have up to three years of experience teaching mathematics since graduating from teacher education. Video recordings and interviews enable analysis of how communicative projects evolve. Capturing actions such as gestures, the use of physical objects or use of words can connect different timescales. Interviews will give information about how the teacher planned and adjusted activities. Both methods can be used for finding shifts in organizational aspects (Linell, 2009) such as the use of time and space in the classroom or the function of reasoning activities. I will use the mathematical reasoning framework presented by Jeannotte and Kieran (2017) for identifying topic activities on mathematical reasoning. Although there are challenges in finding communicative projects and connecting interactions to a relevant timescale, the dialogical approach makes it possible to discuss how teachers handle shifting learning opportunities connected to mathematical reasoning. For the poster I hope to have some initial data and I want to discuss using dialogism as theoretical framework for the analysis.

Elaboration and use of sentences for specialized mathematical meanings in classroom teaching talk

Núria Planas

Universitat Autònoma de Barcelona, Catalonia-Spain; Nuria.Planas@uab.cat

Language as resource is a challenging research approach in mathematics education because it examines whether, how and why language can function to support mathematics learning and teaching. The approach originally started to develop in response to discourses of non-mainstream languages and cultures as problems or obstacles to mathematics teaching and learning. While in the past language as resource has been mostly examined with respect to the languages and cultures of school learners of mathematics and more recently to the orchestration of mathematical discourse practices, a mathematical-linguistic focus is proposed for extending the notion/approach in the study of and work with mathematics teaching talk. For this, a verbal tool in language –lexicalization or giving sentences with specific meaning potential into a content register– is presented and discussed in relation to school teaching and developmental work with mathematics teachers.

Keywords: Language as resource, mathematics teaching talk, developmental work, lexicalization.

Introduction

Planas (2018) built on two related arguments to explain the complexity and importance of the language as resource approach, namely: 1) all languages of learners own the potential of producing mathematical meanings; and 2) obstacles and supports to the realization of such a potential are critical to the generation of mathematics learning opportunities in classroom interaction. The view of the language complexity of mathematics learning was not specifically linked to the view of the language complexity of mathematics teaching. The current widening to include the languages of mathematics teachers in teaching talk represents substantial progress. The communication of mathematical meaning in classroom teaching talk is not always sufficiently explicit or precise. Communication in the mathematics classroom, as in all other language contexts, is made up of communicative intent and intended meaning on the one hand, and communicative function and interpreted meaning on the other. Mathematics teaching and teachers need to support learners in their communication of the intended mathematical meaning, but also need themselves to successfully resolve their communicative intents of mathematical meaning. Given the challenge with mathematics teaching talk that the intended content meaning be always communicated as clearly as expected, a question is: *How a focus on language at the sentence level can support research and work on mathematics teaching?*

Language in/for the study of mathematics teaching

In this first part, I address the critical accomplishment of content communication of mathematical meanings in classroom teaching talk. In Planas (2019, 2021), I initiated this discussion for algebraic contents through the examination of instances of two teachers' talk. That discussion was built on the identification of specialized meanings within the algebra of equations and of their communication in classroom teacher talk. In the teaching of the equation concept, explicitness of specialized meanings for algebraic equivalence and equal sign was particularly revealed as crucial and critical, and some tools in language were preliminarily explored. With inspiration in the Mathematics Discourse in Instruction frame (MDI; Adler, 2017, 2021) and in the Systemic Functional Grammar theory (SFG; Halliday, 1978, 1985), the next section offers some progress on the theorization of the verbal tool in language called lexicalization. The mathematical-linguistic focus in this report is not to say, however, that the study of content mathematics teaching can be limited to the study of vocabulary and grammar. Words and sentences are tools interacting between them, within the large system of tools and modes in language, and with the many discourse practices ongoing in any social setting. The selection of a mathematical-linguistic focus to illustrate an extended interpretation of language as resource is part of a more general attempt to rectify the imbalance I see in recent classroom research on mathematics teaching and language, where varied interests in discourse practices or strict interests in vocabulary and word names, have led to a certain disregard of what is linguistically said and how in mathematics teacher talk. Even though learners and teachers listen to and talk to each other in the classroom, and hence teaching is discourse in interactional practice (Erath & Prediger, 2021; Ingram, 2021), words and sentences in teacher talk mediate mathematical discourse practices with and between learners. Figure 1 puts together, not in opposition, content-specific verbal language of the teacher and mathematical discourse practices in the talk with learners. I see these two dimensions as made of related nodes and itemised into diverse discourse practices and verbal tools.

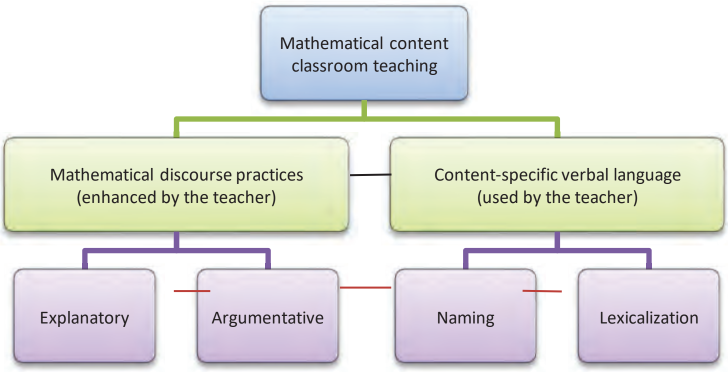

Figure 1: Elements for/in content-specific school mathematics teaching

Content teaching talk at the sentence level

With forms that have become lexical units or words and sometimes names in a language, we can produce combinations which, in turn, can be grammatically correct and at the same time semantically open. ‘Raining cats and dogs’ is grammatical and meaningful (i.e. ‘raining heavily’) in English; nonetheless, when beginning learners of English first listen to this sentence, they can find the form familiar but semantically open or even absent of meaning because its use in the English language system has not been learned yet. The form remains only a group of words as long as nothing more is known about it. Lexicalization is then the reductive process, from a semantic point of view, in which a grammatical form or sentence becomes lexical or with meaning into a precise language or register. In brief, grammaticalization is about structured forms (i.e. combination of words according to established rules or operations in a language system), and lexicalization is about specialized meanings (i.e. combination of words in a grammatical way and with precise meanings attached beyond those embedded into individual units or words) (Halliday, 1978, 1985; Lehmann, 2002).

Rather than a ‘defect’ in mathematics teaching talk, semantic openness is a consequence of the ubiquitous plurality in language, as well as an opportunity for the exploration and realization of mathematical meaning potentials. Here, lexicalization is the reductive process for the communication of precise mathematical meaning within languages of mathematics. Like the learning of word names and of specialized meanings behind them in naming, lexicalization involves more than learning the forms of grammar in a language. In Planas (2019, 2021), the frequent naming of the word name in Catalan for the equation concept without talking mathematical qualities and connections behind the name revealed a number of hidden conceptual meanings in lessons from the participant teachers. Paying now attention to the angle concept and given the option in language of producing grammatical forms with the word name for angle that are semantically open, lexicalization into geometry for conceptual teaching of angles is an issue. There are always sentences in teacher talk not intended to support conceptual understanding, with unfocused or implicit specialized meanings behind word names, functioning to promote pedagogic issues (e.g. ‘Look at the angles in the table’) or routine procedures (‘Always add the angle type’). There must be, however, teacher talk aimed at providing specialized (newer) meanings for mathematical objects encoded in (un)known words and sentences.

Just as how the MDI frame refers to naming in instructional research and to word use in developmental work with teachers, lexicalization –or lexicalizing to emphasize the process over the result– can be seen as the verbal tool available in language interpreted, in the work with teachers, as the elaboration and use of sentences with the potential to make mathematical meaning explicit and precise in classroom content talk. That is, work oriented to discuss how particular sentences function or not for content teaching, and how they might more ideally function to do so. ‘Angles made of a vertex and two rays’ is grammatically correct and it encodes specialized meanings into static plane geometry for the angle concept, but it could more ideally function to do so. While it is not a linguistic or grammatical obligation, the additional choice of the complement ‘… and the space between them’ would function to communicate the relevance of the region contained. More complements would still support meanings for ‘between them’ in relation to the two regions in principle delimited by the two rays. In ‘Angles from which the view is good’, for example, verbal complements for elaborating on angle view would function to encode language accounts of meaning into spatial geometry.

Table 1 summarizes the thinking of lexicalization from the use of meaning-focused sentences in languages for communication to its more ideal use in languages for communication of specialized mathematical meanings in classroom talk. There are bigger lexical unities above words and sentences in talk as well as multimodal accounts of meaning in communication; content communication cannot thus be theorized by the linguistics of words and sentences only without considering the wider communicational multimodal system and the representations of the contents at play. At the same time, the macro analyses of lesson teaching talk in search of communicational patterns do not tend to provide the grain detail of instances of lexicalization of content meaning. Words and sentences totally conforming talk, and accounts of meaning conformed at the expense of verbal representations made of words and sentences are both illusions. The intricacies and limitations of underestimating the effects of these illusions will require more study. For now, the current stage of theorization of the function of lexicalization orient the second part of the report on the function of language as resource in developmental work on mathematics content teaching with teachers.

Table 1: Lexicalization in mathematics content teaching

MATHEMATICAL LEXICALIZATION – SENTENCE USE	
General function *What does lexicalization do …* *in language for communication?*	Specific function *What does lexicalization do …* *in language for mathematics content communication?*
It encodes **- more or less complex clusters of meanings** for words and forms of grammar	It encodes - **specialized mathematical meanings** for words and forms of grammar within content-based mathematical languages

Language in/for work on mathematics teaching

Over the last decade, in order to improve the impact of mathematics professional development on classroom practice, increasing attention has been given to work with teachers guided by their teaching needs (e.g. Kazima, Jakobsen & Kasoka, 2016). It is an assumption that work with teachers on teaching is especially productive in terms of professional learning when the teachers take responsibility for the identification and interpretation of challenges. The four teachers (Jana, Maia, Anna and Roc) in the second round of the research and developmental project partially reported in Planas (2019, 2021) expressed various concerns with the teaching of the angle concept. They all had several years of mathematics teaching experience, and worked in the same secondary school at the time of the collaboration. Their professional knowledge and my mathematical-linguistic view of the MDI and the SFG frames were the points from which we explored angle-specific teaching. Although they were very much focused on their individual classrooms, had prepared lesson plans together and experimental tasks with dynamic geometry software. The results of the learners in the tests, however, had continued to show views of angles as static only, in disconnection with space, openness and inclination and as means for classifying figures. Anna especially linked the poor learning of specialized meanings for angle to common difficulties in the later understanding of classes of triangles with equal values for trigonometric functions, and of the slope of functions in calculus.

My response to the demand of the teachers was to interrogate their talk in the school lessons on angles. In most of my experiences of work with teachers, they do not normally feel that the mathematical richness of the classroom practices can be hampered by under specificity in talk. My response, though, was not a surprise, at least for Jana and Maia since they had participated in the first round of workshops about noticing choices in talk for teaching the equation concept (Planas, 2019, 2021). We agreed on exploring the improvement of angle teaching through improving angle teaching talk. Four of the 90-minute five sessions (S1 to S5) were task-driven workshops. Even though the four teachers graduated in mathematics, S1 was for revising mathematical knowledge on polysemous meanings for angle as: 1) static shape and dynamic turn; 2) object and means; and 3) region or sector and inclination or openness. S2 and S3 were for work on the language-based tasks, and S4 and S5 for work on explanatory tasks (Adler, 2017, 2021) of comparing angles, and of expanding the Pythagoras theorem to the obtuse/acute triangle. Developmental work thus supported mathematical knowledge, more ideal ways of choosing and using words and sentences for specialized communication, and mathematical discourse practices. Given the focus in this report, I present one of the language-based tasks. Task 1 was designed on the thinking of word names and sentences as related resources for mathematically situating the angle concept in teaching talk. The goal was to compare and eventually give sentences with angle-related word names, forms of grammar and meanings. Each workshop was organized to include the presentation of the task, the discussion of the teachers in group, and the final reflection with me. The pandemic circumstances recommended the synchronic online mode for all sessions. In the next section, the illustration of Task 1 is exemplary towards the argument that the realization of content teaching talk can be revised and practised throughout participation in workshops on mathematically and linguistically informed choices and uses of words and sentences.

A developmental task for discussion of angle-focused sentences

In S2, the participant teachers were given Task 1. An English version is offered in Table 2, with word names in the geometry of angles and pairs of related sentences written to represent those in Catalan, the source language, without pretending to be word-to-word translations or exactly equal in meaning. In the preparation of Task 1, I particularly drew on my knowledge of mathematics and of students' challenges in learning angles (for this, I built on my past experience as school teacher of mathematics, but also on Devichi & Munier, 2013), as well as on conversations with the teachers about their teaching needs and the local curriculum for low secondary mathematics specific to angles. On this basis, I considered emphases on dynamic turn vs. static object, object vs. means, and inclination or openness vs. region or sector, as well as angle-related word names that low secondary school learners usually know (e.g. point, vertex, orientation, measure) and which have extremely rich meaning potential in Catalan everyday languages. The original sentences came from talk of the teachers (T) in online recorded lessons at the pandemic time in 2021, and were chosen to illustrate instances with the potential of encoding specialized meanings for the concept. In all of them, the word for angle was named but important angle-related specialized meanings remained implicit or unclear. I invented the paired sentences to offer alternative sentences in the sense of more ideal, amongst many other possible, for the communication of specialized (newer) meanings for angle and related word names.

Alongside the centrality of the mathematical content in the design of Task 1, the linguistic particularities of Catalan, the language of instruction in school at my place and of the participant teachers, were also central. This is in line with what Halliday tells us (1978, 1985), as well as mathematics education research (e.g. Kazima & Adler, 2006) on the centrality of the form-meaning relationship in meaning making. When looking for angle-related word names that had been said by the teachers in the online lessons, I selected ten name words (first column, Table 2) in Catalan whose meaning inside and outside languages of mathematics was shaped by the words as put in interaction with other words. Triangle was one of these names. In a lesson in which Roc had asked his learners to draw an example of angle, some learners drew a triangle and then indicated with an arrow an internal angle of the figure. The view for angle as measure and means for describing triangles, and as part of a whole, was present in lessons from the other teachers, too. Since the name of triangle was common in the lessons aimed at the conceptual teaching of angles, I looked for opportunities in the languages of the teachers to relate triangles and angles in mathematically meaningful ways through a number of possible verbal complements. For this, I selected "A triangle contains one hundred and eighty degrees." I can imagine other word names and candidate sentences in an English version of the task and the study. As far as I know, in this language and regardless of being or not common in teacher talk, the choice of angle as verb is available, and specialized meanings for angle as action can be encoded through sentences about placing an object at an angle or about changing its direction.

Table 2: English version of the worksheet with Task 1

Task 1. Word use into angle-focused sentences Which are the meanings behind the word names and the sentences?		
Words	*What does T say?*	*What could T say?*
Angle	The angle rotated around the point.	The segment line rotated around the point makes the angle.
Turn	One turn of an angle is the circle.	One complete turn of a segment line around a point draws a circle.
Point	An angle is an angle at a point.	An angle is a rotation of a segment line around a fixed point in a plane or in space.
Vertex	Angles are made of a vertex and two rays.	Angles are made of a vertex, two rays, and the space between them.
Sides	Sides are not important in angles.	The length of the sides is not a characteristic of angles.
Orientation	The angle is different because of the orientation.	The angle is different because its rotation has opposite orientation.
Measure	The angle is different because of the measure.	The angle is different because the measure of the rotation is different.
Right	Perpendiculars intersect at a right angle.	Perpendicular lines intersect at four right angles.
Straight	Straight angles look like zero.	Straight angles and zero angles look similar but the turn implied is different.
Triangle	A triangle contains one hundred and eighty degrees.	The three internal angles in a triangle add to one hundred and eighty degrees.

Since the four teachers accepted recording the working sessions, I could take notes at different moments in time. They were given the document with the task and were asked to comment on each word name and the sentences two by two, and to reflect on encoded specialized mathematical meanings possibly different to those already known by the school learners. On the one hand, the teachers noted that many words could be assumed to be known by learners although not necessarily in relation to the angle concept. The Catalan word name for ‘right’, *recte*, was particularly discussed. *Recte* is used in the everyday language to qualify objects with no curvature; the angle-related meanings for *recte* cannot thus be understood through the meanings behind the word that may have been learned and, in addition, the word is mathematically polysemous in the geometry of angles as it can function to encode the ninety-degree measure and the notions of inclination and perpendicularity. On the other hand, the teachers noted that any of them could have said the original sentences (second column, Table 2) in their teaching. They became engaged in distinguishing what was said from what was possibly intended, and so in assessing these aspects separately. Regarding “Sides are not important in angles”, for example, Anna said to miss some explanation of the reasons for why they are not important, and hence found the alternative sentence more ideal. We all agreed on the need to produce teacher talk aligned with mathematical discourse practices of content explanation.

Two of the teachers had referred to, “The angle rotated around the point” (first column, Table 2) in their lessons. This sentence was selected for Task 1 to pay attention to the specialized meaning as dynamic turn encoded in the name for angle. Attention to meanings behind some preposition words, however, soon led to enhanced talk about the choice of spatial prepositions such as at/around (a point) and on/around (a segment line) as words with implications on the communication of angle-related meanings. The four teachers knew that the Catalan compound word *al voltant de* (of which the English one-word ‘around’ might be a feasible counterpart) can express spatial or plane relationships, or relative location and directional motion of the subject object. The Catalan version of “The angle rotated around the point” is then grammatically correct and mathematically meaningful but the basic meanings implied are not about the angle as dynamic turn as in the Catalan version of ‘The segment line rotated around the point.’ In the former sentence, we work with angle as means to produce in the plane or in space other mathematical objects included the solid angle (which is not a curricular content of low secondary mathematics); in the latter, we work with segment lines to produce Euclidean plane angles. At the end of the developmental session, the mathematical meanings encoded behind prepositions in interaction with other word meanings had been discussed intensively, and related to the choice of words and sentences in content teaching. Anna, for example, introduced the discussion of how differently it was ‘around the point’ from ‘rotated around the point’ in that the two expressions encoded two different sets of paths or sequences of positions enclosing the point.

Language accounts of meaning matter but so do other accounts

The interpretation of ‘more ideal’ in Task 1 is not independent of the circumstances in which the sentence might be said in the school classroom, of the discourse practices ongoing, and of the broader talk and modes of communication accompanying the teaching. The inseparability of all these aspects was addressed in S4 and S5, in the discussion of promoting the communication of angle-related meanings more largely across mathematical discourse practices resourced by languages of content teaching. The fact that these are classrooms with multilingual learners is not insignificant although it was hardly brought up by the teachers in their comments over the workshops. Like the efforts here to reproduce in English word names and meaning-focused sentences originated in Catalan without missing the mathematical-linguistic points intended, Jana, Maia, Roc and Anna teach angles, equations… by moving across forms of academic and everyday Spanish and Catalan in ways that may favor the communication of some specialized mathematical meanings in one language only at a time. These teachers flexibly use their languages as resources in their content teaching of mathematics with the possibility of encoding different mathematical meanings in each language.

Behind the arguments of improving the clarity and coherence of teaching at the sentence level of language, there is the Vygotskian assumption that opportunities of mathematics learning are generated through exposition and attention to specialized mathematical talk and texts, or by active listening to others who are more knowledgeable. Making available specialized mathematical ways of talking is critical for school learning, and hence there are consequences of opening and of closing opportunities for mathematics learning through teaching talk, be it an ever present and highly visible or almost a disappearing feature of classroom communication. These arguments also apply to multilingual mathematics teaching with multilingual learners and those belonging to cultures that have developed non-verbal ways of communication. The nodes and tools in Figure 1 fall short if teachers are confronted with the communication of specialized mathematical meanings for names and grammars to learners who are learning some of the words and sentences as used in the language of instruction, and who can well recognize some of the specialized meanings when encoded in other linguistic forms or semiotic modes. Teachers cannot assume that multilingual learners who are learning the (sign) language of instruction do not know some of the mathematical meanings involved in classroom interaction, and teaching thus needs to facilitate their participation and sharing through mathematical discourse practices entailing the use of the various semiotic modes in language.

Measuring quality interaction: how much detail is necessary? Results from a quantitative video study on the conceptual dimension

Kim Quabeck[1] and Kirstin Erath[2]

Quantitative video-based investigations of quality interaction raise challenges due to their complexity. In this paper, three different operationalizations for measuring mathematically rich interaction are derived from larger teaching quality studies that vary in detail. Those heterogeneous operationalizations are task-, move-, and practice-based. We apply all three operationalizations to video data from 49 small group interventions (210 students, age 10-14 years) that aim at fostering students' conceptual understanding of fractions. Qualitative and quantitative results indicate that when capturing interaction quality, measuring the quality by task- and move-based operationalizations is not sufficient to capture all relevant differences in classroom interaction.

Keywords: Interaction quality, video study, operationalization, conceptual learning.

Introduction

Qualitative studies repeatedly provide empirical evidence that quality interaction is crucial for students' access to mathematical learning opportunities (e.g., Walshaw & Anthony, 2008). The transition towards quantitatively researching quality interaction, as every quantitative research, entails considering *how* to transfer theoretical conceptualizations into measurable operationalizations (Praetorius & Charalambous, 2018). However, operationalization is a major challenge in time and effort, especially when assessing the quality of classroom discourse as part of quality interaction (Pauli & Reusser, 2015). Therefore, in this paper, operationalizations for quality interaction that differ in their operationalization bases (i.e., the way to simplify the measurement based on tasks, moves, or practices) are derived from larger teaching quality studies (e.g., Charalambous & Litke, 2018; Pauli & Reusser, 2015). They are applied to video data from a language-responsive intervention study (Prediger et al., in press) to investigate empirically in how far the ways to simplify measurements when operationalizing quality interaction matters.

Background: Quantitatively measuring the quality of interaction

There is strong empirical evidence that underlines the importance of quality interaction for students' access to rich mathematical learning opportunities (Cai et al., 2020; Walshaw & Anthony, 2008). At the same time, qualitative studies show that quality interaction that aims at students' conceptual understanding (rather than procedures and facts) is strongly intertwined with teachers' initiating and continuously supporting students' rich discourse practices such as explanations, argumentations, or justifications (e.g., Erath et al., 2018). However, quantitative evidence with a focus on this relation is still too rare (see overview in Erath et al., 2021).

For conceptualizing quality interaction, Erath and Prediger (2021) suggest disentangling the talk-related, discursive, conceptual, and lexical quality dimensions for teachers' activation and students' individual participation. Because the teachers are particularly responsible for the quality of interaction

(Walshaw & Anthony, 2008) and mathematically rich learning opportunities consist of teachers' addressing and supporting students' conceptual understanding (Hiebert & Grouws, 2007), this paper concentrates on the teachers' enacted *conceptual activation*. Conceptual activation means the degree to which teachers engage the students in rich mathematical (e.g., conceptual instead of procedural) activities in classroom interaction. Other quality dimensions are excluded here due to space limitations.

For operationalizing conceptual activation, researchers use heterogeneous operationalizations in video studies that all vary in the level of detail. As our literature review will show, capturing *conceptual activation* is addressed by *task-, move-, or practice-based operationalizations* and differs with regard to measurement decisions (counting time, turns, or rating highly inferential).

High or low demanding tasks that intend challenging or less challenging mathematical activities might serve as a precondition for conceptual activation but are not necessarily identical to their enactment (Cai et al., 2020). Larger teaching quality studies therefore entail both, task demand and their enactment. In PYTHAGORAS, a *task-based operationalization* (rating the quality of demands and supports posed by tasks) is capturing the length of teachers' enacting more or less demanding tasks (Hugener et al., 2006, p. 165). Repeatedly, *task-based operationalizations* capture the quality of classroom interaction together *with move-based operationalizations*. *Move-based operationalizations* are all teacher actions in classroom interactions, for instance, if teachers' moves address mathematically more or less demanding types of knowledge or students' activities (TIMSS video, Stigler et al., 1999). We often identified *move-* and *practice-based operationalizations* that jointly assess the quality co-constructed in the teacher-student interaction. For instance, the classes' conceptual activation can be assessed by rating to what extent teachers' moves and enacted practices explicitly address and support the connection of representations and mathematical concepts (MQI, Charalambous & Litke, 2018, p. 447). Further, we identified approaches to capture conceptual activation that are based on task-, move-, and practice-based operationalizations, for example, the level of task enactment (e.g., TALIS, OECD, 2020, p.10). However, especially for the highly inferential ratings, it often remains unclear to what extent which operationalization is decisive for rating high or low quality (in conceptual activation). A major challenge for all studies is measuring aspects of teachers' and students' discourse in the enacted classroom practices, as it necessitates time and effort due to its complexity, interactivity, and multidimensionality (Pauli & Reusser, 2015). Therefore, researchers utilize *practice-based operationalizations* that focus solely on the teachers' contributions (e.g., TIMSS, Stigler et al., 1999), turn-related assessments of whether contributions contain reasoning but omit the length or the contribution's aim (e.g., PYTHAGORAS, Hugener et al., 2006), or by rating the quality of discourse in less details on scales like in MQI or TALIS video (Charalambous & Litke, 2018; OECD, 2020). To sum up, researchers use different approaches *how* to operationalize conceptual activation, based on *tasks, moves, or practices.* Given the immense workload, the assessment of practice-based operationalizations capturing teachers' and students' discourse must always be simplified in a certain way.

Following the results from this short literature review, we derive the need to compare more systematically how the simplification to task-, move-, or practice-based operationalizations for capturing conceptual activation matters. Therefore, we use operationalizations according to the three different bases systematized from existing quantitative studies (see columns of Table 1). Also, we decided to assess conceptual activation in a high level of detail by capturing the amount of time descriptively first and not mixing quality and amount (which is criticized by Praetorius & Charalambous, 2018). For increasing the comparability of the different operationalizations, we relate all to the total time on task of the group (including times of writing or silence). Thus, in our framework, the quality dimension *conceptual activation* is operationalized in three ways (Table 1).

Table 1: Operationalizing conceptual activation by three different operationalizations

	Task-based operationalization	**Move-based operationalization**	**Practice-based operationalization**
Conceptual activation	Relative length of group time spent on conceptual tasks	Relative length of group time spent on conceptual moves	Relative length of group talk spent on conceptual practices (incl. teacher)

The entries of Table 1 show the operationalizations that are applied: *The task-based operationalization* is measured by the relative length of group time spent on conceptual tasks; the move-based operationalization is captured by the relative length of group time spent on conceptual moves; *the practice-based operationalization* is measured by the relative length of group talk spent on conceptual practices (incl. teacher). Contrary to other studies' operationalizations, the practice-based operationalization entails the teachers' and students' discursive realization with rich discourse practices (i.e. the length of an individual student's explanation) and not only what teachers intend for students' contributions.

By operationalizing conceptual activation systematically with different operationalizations, it becomes possible to quantitatively investigate their relation. We contribute to the question of whether *task-based operationalizations* (with much less coding effort and complexity) can already capture relevant aspects of conceptual activation or must be extended to more complex and detailed measurements of *move-,* or *practice-based operationalizations*. By applying three *operationalizations* to video data from 49 small groups working on developing a conceptual understanding of fractions, the relation can be empirically investigated. Hence, the pursued research question is *how are the different task-, move-, and practice-based operationalizations of conceptual activation related?*

Methods: Research context and data analysis of types of operationalizations

Research context. The research question is pursued in the larger mixed-methods intervention study MuM-MESUT 2 (pre-post-follow-up design, see Prediger et al., in press). Instruction aiming at developing a conceptual understanding of fractions was organized in small groups of 3 to 6 students (10-14 years old) and one teacher per group (pre-service teachers or PhD-students). It spans over 5 sessions of 90 minutes each. All small groups' teaching is based on identical curriculum resources, although some small groups received additional integrated lexical support.

Data corpus. The analysis presented in this paper is based on all sequences of small groups' interaction in phases of knowledge inquiry, consolidation, and organization for reinventing the concept of equivalence of fractions (49 small groups, 210 students, ~30 hours of video).

Data analysis. The analysis of the three *operationalizations* was conducted in five steps. First, five descriptive low and high inferent basic codings were conducted on the curriculum resources, transcripts, and video recordings. Basic codings entail (1) time-on-task (time spent on selected tasks, excluding breaks and off-topic time); (2) individual length of students' as well as teachers' utterances; (3) *task-based operationalization* (time spent on conceptual tasks, task demand categorized by their intention in a previous study); (4) *move-based operationalization* (length of the sense-making units when teachers' moves aim at the construction of conceptual knowledge, see Wessel & Erath, 2018), and (5) *practice-based operationalization* (person-related, second-specific length of engaging in rich discourse practices like explaining of mathematical concepts). (3)-(5) were coded in sense-making units that start with teachers or students initiating a problem or question and end when the problem or question is marked as being finished. Second, interrater reliability for the high inferent basic codings was controlled in R and shows good results with an overall $\kappa = 0.87$. Third, according to the entries in Table 1, operationalized criteria were calculated as the *percentage of time of enacted task demand in time-on-task, percentage of time in enacted move demand in time-on-task,* and *percentage of time in enacted discursive realization in time-on-task*. Forth, descriptive statistics were calculated for determining the means, standard derivations, and Pearson's correlations.

Empirical results: Conceptual activation assessed by tasks, moves, and practices

This section provides an example for large differences of conceptual activation assessed by different *operationalizations* in two small groups with comparable conditions (students from higher-tracked schools and the same curriculum material). This example motivates the analysis of correlations between task-, move, and practice-based operationalizations.

Comparing the assessment of conceptual activation in two small groups

Table 2 shows the scores for conceptual activation in all small groups as well as in the two small groups Q and U chosen for the illustrations, here.

Table 2: Distribution of teachers' conceptual activation relative to the time-on-task

Conceptual activation	Relative length of group time spent on conceptual tasks	Relative length of group time spent on conceptual moves	Relative length of group talk spent on conceptual practices (incl. teacher)
Mean (SD) of all small groups	77.4% (10.9%)	35.3% (12.9%)	23.5% (12.3%)
Mean of small group Q	80.2%	52.7%	18.0%
Mean of small group U	82.0%	61.1%	35.4%

Concerning *the task-based operationalization,* Teacher Q and Teacher U both invest a similar relative length of group time on conceptual tasks (both >80%). This high proportion might seem surprising but can be explained by the intervention design that aims at developing students' conceptual understanding (of fractions) and therefore contains more conceptual and less procedural tasks. With respect to *the move-based operationalization,* Teachers Q und U also engage students in conceptual moves for (jointly) constructing conceptual knowledge in more than half of the time-on-task (Teacher U slightly more), which is distinctively above all groups' mean. However, assessment of quality varies *considerably* in the two small groups' *practice-based operationalization*, despite the similar task-based and move-based assessment. While in group Q teacher's and students' contributions are in 18% of the time-on-task talk on conceptual practices, group U has almost double as much enacted, rich discursive realization. Thereby group Q falls below all groups' mean and U exceeds all groups' mean.

Qualitatively analyzing exemplary situations from these two groups' teacher-student interactions illustrates what these different proportions in *the practice-based operationalization,* thus discursive realization, mean for students' engagement in conceptual practices. The comparison takes place when Teacher Q and U work on the same tasks with their small groups: Switching and connecting symbolic, contextual, and graphical representation of equivalent fractions in the bar board (for details on tasks see Wessel & Erath, 2018). When orally discussing results, Teacher Q and Teacher U at first use similar moves to intend an explanation of why the drawing in the bar board fits the respective contextual and symbolic representations, thus intending group talk on conceptual practices. However, Teacher Q's moderation quickly switches to less demanding discourse practices or even non-discursive practices (like one-word answers or half-sentences) when asking her students questions like "How much do you have to color for the teachers' share?", "How often did the teachers hit the goal?" or "How many pieces do you have to colour?". It becomes apparent that she does not succeed in engaging students in conceptual practices like explaining-why that are necessary for developing conceptual understanding and meaning. Contrary, Teacher U holds up the enactment of demanding *conceptual practices* by asking the students to explain "Why did you chose this bar" or jointly creating explanations like "This bar fits this group because …" in orally discussing the results. The students in group U take up the discursively demanding talk on conceptual practices and jointly construct explanations which meet the discursive needs for developing conceptual understanding.

Summarizing, the varying quality in conceptual activation in small group Q and U was only visible in the *practice-based operationalization*, i.e., when also considering the quality of teachers' and students' contributions, not only *task- and move-based operationalizations.* Hence, it is essential to operationalizing the enacted discursive realization by *practice-based operationalization* also with respect to teachers' and students' rich discourse practices.

Quantitative dependencies between assessments by three operationalizations

The last section qualitatively underlines that it is necessary to distinguish operationalizations for assessing conceptual activation. In the following, we generalize this idea by quantitatively investigating the association between assessing conceptual activation in *task-, move-, and practice-based operationalizations* in the whole data corpus. Table 3 shows Pearson's correlation coefficients for all small groups' coded data.

The correlations between three *operationalizations* of conceptual activation show that there is a relation that is low to moderate (0.204-0.448).

- Contrary to expectations, the association between *task- and move-based operationalization* is low (0.204). This implies that the teachers' enacted relative length of group time spent on conceptual moves is only weakly associated with the relative length of group time spent on conceptual tasks (in our data). Two interpretations are possible for the data corpus in which all teachers use the same tasks: Either (some) teachers facilitate conceptual tasks with (several) procedural moves and thus do not meet the aim (like Teacher Q) or (some) teachers' enacted moves also address conceptual knowledge in non-conceptual task demands. This finding must be interpreted carefully and might not apply when teachers use their own tasks with more varying demands. The *move-based quality assessment* might then be closer connected to the *task-based quality assessment*.

- The association between *task-* and *practice-based operationalization* (0.151) is similarly low. This means, how much time teachers spent on *conceptual tasks in time on task* is almost hardly related to a rich practice-based enactment concerning the talk within conceptual practices in time on task (in our data).
- The association between *move-based and practice-based operationalization* (0.448) was anticipated from existing research since initiating conceptually demanding discussion (by *moves*) requires teachers' and students' explanations, argumentations, or justifications. This shows that what teachers ask is more closely connected to the groups' actual *practice-based realization.* However, Teacher Q's *discursive realization* that partly fails to meet the *enacted move demand* serves as an example for explaining that the association is much lower than 1: Not every conceptually demanding situation is also *enacted* discursively rich.

Table 3: Pearson's correlation coefficients between operationalizations in all 49 small groups, * for significant correlations ($p < 0.05$)

Conceptual activation (relative to the time-on-task)	Task-based operationalization	Move-based operationalization	Practice-based operationalization
Task-based operationalization	1	0.204*	0.151*
Move-based operationalization		1	0.448*
Practice-based operationalization			1

Discussion

By including tasks, moves, and practices as operationalization bases for assessing conceptual activation, we were able to investigate their relationship empirically. We show quantitatively that quality assessments of conceptual activation based on *task-, move-, and practice-based operationalizations* are low to moderately associated with *move- and practice-based operationalization* in closer connection. This is in line with researchers emphasizing that the teachers enact cognitively demanding tasks in varying quality (Cai et al., 2020; Walshaw & Anthony, 2008). Also, the qualitative example of Teacher Q and U underlines the great importance of operationalizing practice-based: Teacher U's moderation leads to a substantially more challenging and sophisticated group talk on conceptual practices, even though both teachers enact similar quality of interaction when assessing with task- and move-based operationalization. Thus, it seems insufficient to capture the conceptual activation by task- and move-based operationalizations only. Beyond this, assessing the *enacted discursive realization by practice-based operationalizations* can better capture students' access to and engagement in rich mathematics.

The presented empirical results point to the importance of methodological considerations for future quantitative studies aiming at investigating quality interaction in the dimension of conceptual activation. *How* to turn theoretical conceptualizations into measurable *operationalizations* must be discussed carefully. This is a major challenge and at the same time a huge gap in research on teaching quality, as many researchers mix measurements of amount, quality, and frequency (as criticized in the survey by Praetorius & Charalambous, 2018).

The empirical results presented in this paper are limited due to the specific data collected and analyzed: Because of comparable conditions in the intervention and identical curriculum resources, the findings cannot be immediately transferred to whole-class settings and everyday mathematics classrooms. Also, we cannot conclude which type of operationalization is more valid to capture classroom interaction. However, our next step in the larger project is to investigate the predictive power of the three *operationalizations* for the growth in students' conceptual understanding of fractions in the dimension of conceptual activation, but also in the other quality dimensions (Erath & Prediger, 2021) as this is identified as research gap in mathematics education research (Cai et al., 2020; Praetorius & Charalambous, 2018). We especially aim at generating quantitative empirical evidence of the relation between discourse quality and student learning (Erath et al., 2021, Pauli & Reusser, 2015).

Choice of representations in combinatorial problems

Frode Rønning

Norwegian University of Science and Technology, Trondheim, Norway; frode.ronning@ntnu.no

This paper is based on classroom sessions where Norwegian 9-year-old (Grade 4) children work on combinatorial problems. The classroom sessions are part of a four-year long research project where the topic of multiplicative structures was central. I will investigate to what extent the pupils recognise the combinatorial problems as multiplicative and identify possible connections between the semiotic representations chosen in the solutions and in the formulation of the problems.

Keywords: Combinatorics, multiplicative structures, register, semiotic representations.

Introduction

This paper is based on data from the project Language Use and Development in the Mathematics Classroom (LaUDiM)—a four-year collaboration project between researchers at the Norwegian University of Science and Technology and two primary schools. In this project, a central theme was multiplicative structures, and a recurring question was to investigate connections between the formulation of a problem, the pupils' choice of semiotic representations to solve the problem, and to what extent they recognised a given situation as multiplicative.

In this paper, I study pupils in Grade 4 (nine-year-olds) working with two combinatorial problems (see Figures 1 and 2). The problems were presented with no previous instruction that could give an indication about what mathematical knowledge and techniques that would be helpful for solving the problems. Pupils worked in pairs, and work in selected pairs as well as in whole-class sessions were video recorded. I pose the following research question: *In what ways can the context of a situation be seen to influence the choice of registers in the solution, and how can the chosen registers provide evidence about the extent to which the situations are perceived as multiplicative?*

Theoretical framework

The concept of *register* is used in somewhat different ways by different authors. Duval uses the term register to mean a semiotic representation system (e.g., natural language, symbolic systems, graphics) and emphasises that "[c]hanging representation register is the threshold of mathematical comprehension for learners at each stage of the curriculum" (Duval, 2006, p. 128). I follow Duval's usage of the term, which is also in accordance with the usage by Prediger and Wessel (2013) in their model concerning changing and relating registers. This model entails a transition between different registers - a concrete representational register, a graphical representational register, different verbal registers and a symbolic-algebraic or symbolic-numeric register (Prediger & Wessel, 2013, Fig. 1, p. 437). This resembles the process described by O'Halloran when she writes that language is used to introduce and describe a mathematical problem, later to visualise the problem, and then the problem is solved using mathematical symbolism (O'Halloran, 2005, p. 94).

Before discussing the classroom situations, I will define what is meant by *a multiplicative structure*, or *a multiplicative situation*. Steffe defines a multiplicative situation as a counting situation where "it is necessary to at least coordinate two composite units in such a way that one of the composite units is distributed over the elements of the other composite unit” (Steffe, 1994, p. 19). This is the basis for my discussion of multiplicative structures. There are several different classifications of multiplicative structures to be found in the literature (see e.g., Greer, 1992). I will rely on the classification given by Vergnaud who splits multiplicative structures in three classes: *Isomorphy of Measures*, *Product of Measures*, and *Multiple Proportions* (Vergnaud, 1983, p. 128). The latter will not be discussed here. *Isomorphy of Measures* is defined as a structure involving a direct proportion between two measure spaces, M_1 and M_2 (Vergnaud, 1983, p. 129). Situations like equivalent groups and multiplicative comparison (Greer, 1992) fall into this category. Further, *Product of Measures* is defined as a structure involving a mapping from a product of two measure spaces into a third measure space, $M_1 \times M_2 \rightarrow M_3$ (Vergnaud, 1983, p. 134). Combinatorial problems (Cartesian products) and rectangular area problems fall into this category. Rectangular *array* problems (Fosnot & Dolk, 2001), to find the total number of items laid out in a row-column pattern with a certain number of items in each row and each column, may look similar to area problems but they actually belong to the class *Isomorphy of Measures*, with M_1 = [number of rows (columns)] and M_2 = [number of items in each row (column)]. Unlike many other Isomorphy of Measures-problems, these are *symmetric* (Rønning, 2012). In combinatorial problems, the measure space M_3 may not be initially present. M_3 is where the counting unit is situated, and that this space may initially be unknown, represents a challenge when solving such problems. This is also connected to the phenomenon that the counting unit is of indefinite quantity and that there is not always a clear strategy to determine when the problem is actually solved (English, 1991; Shin & Steffe, 2009).

The tasks given to the pupils

The first task given to the pupils is presented, in its simplest version, in Figure 1, the second task in Figure 2. The tasks were given on two different days of the same week. No instructions were given on how to solve the tasks, and what strategies that might be helpful could also not be inferred from what the class had worked with immediately before the sessions where these tasks were presented.

> How many different gingerbread biscuits can we make if we have cutters in these four shapes ☆ ◇ ○ ♡ and we have white, green and red icing?

Figure 1: Task 1

> Ms. Hall has 3 pairs of trousers and 5 sweaters. The trousers are in the colours blue, black, and grey. The sweaters are in the colours blue, red, black, green and purple. She will use one pair of trousers and one sweater each day, and she will combine different pairs of trousers with different sweaters. How many days in a row can Ms. Hall wear different outfits?

Figure 2: Task 2 (Ms. Hall is the teacher in the class)

After agreeing on a solution, each pupil in the pair was asked to produce a written account of the method used. Both tasks induce a mapping $M_1 \times M_2 \rightarrow M_3$, with M_1 containing shapes in Task 1 and trousers in Task 2. M_2 contains colours in Task 1 and sweaters in Task 2. In Task 1, M_3 contains coloured shapes (biscuits). It could be argued that since M_3 in Task 1 contains coloured shapes, the measure space M_3 is not really new, it is a variation of M_1. A more precise representation of the mapping in Task 1 could therefore be $M_1 \times M_2 \to M_1^*$, where M_1^* denotes *coloured shapes*. In Task 2 one may think of a mapping $M_1 \times M_2 \to M_3 \to M_4$, where M_3 contains outfits and M_4 contains days of the week. M_3 and M_4 are isomorphic, so this transition would be expected not to be challenging.

In the language of Steffe (1994), one can say that it makes sense to distribute the composite unit from M_1 over the elements of M_2, or the other way around, which means that the situation is symmetric (Rønning, 2012). Both problems can be seen as a matrix product **c** of two vectors, **a** and **b**, where **a** and **b** represent the composite units from M_1 and M_2, respectively, and $\mathbf{c} \in M_3$ (see Figure 3).

$$\mathbf{a} = \begin{bmatrix} a_1 \\ \vdots \\ a_n \end{bmatrix}, \mathbf{b} = [b_1 \quad \dots \quad b_m] \text{ and } \mathbf{c} = \begin{bmatrix} a_1 \\ \vdots \\ a_n \end{bmatrix} [b_1 \quad \dots \quad b_m] = \begin{bmatrix} a_1 b_1 & \dots & a_1 b_m \\ \vdots & & \vdots \\ a_n b_1 & \dots & a_n b_m \end{bmatrix}.$$

Figure 3: Matrix structure of a combinatorial problem

Each element, $a_i b_j$, of the product matrix **c** represents one possible combination (composition). This representation shows that the dimension of M_3 equals the product of the dimensions of M_1 and M_2.

The discussion above shows that although the problems in the two tasks are computationally equivalent, the mappings between measure spaces are somewhat different.

Design and method

The project LaUDiM was based on interventions consisting of two-three classroom sessions dealing with the same mathematical topic, preceded by planning meetings where teachers and researchers met. Between and after the sessions, reflection sessions were held. The design of the classroom sessions was based on the Theory of Didactical Situations (Brousseau, 1997).

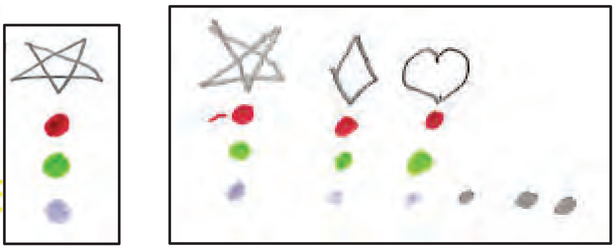
The classroom sessions contained whole-class activities and activities where pupils worked in pairs with given tasks. For each session, the work of two pairs was video-recorded, as were all whole-class activities. Attempts were made to choose pairs to be recorded differently for each session, so that the pupils should not feel that only a few participated in the project. The pairs were determined by the teacher, based on her expectations of who would collaborate and communicate well. The school from which data for this paper come, lies in a well-established, middle-class neighbourhood. The pupils all have Norwegian as their first language. Data consist of video-recordings from the sessions, as well as pupils' written work, collected from all pupils, not only those who were video-recorded.

The analysis is based on the thematic development of the dialogue in the pairs, as well as the written work, including work from the pupils not video-recorded, in order to identify statements that show the choice of the representational registers and also serve as evidence for the pupils' possible perception of the situation as multiplicative. Parts of the video-recorded discussions have been transcribed and translated into English. In the analysis I will follow Naomi and Roger in Task 1 and Naomi and Filipa in Task 2. This means that I present data from one pupil (Naomi) in her work with both tasks. Therefore, I will pay most attention to her work in the pairs.

Analysis of the work in pairs

Task 1 (Naomi and Roger)

Naomi and Roger start looking at the task and Roger's first suggestion is that there will be seven different possibilities since there are four shapes and three colours. Then Naomi starts drawing the four shapes in one row and she colours the heart red. She indicates that she can continue to draw new rows with the same shapes and change the colour for each row. She does not complete the drawing in detail but on the video recording it can be seen that she indicates three rows with four shapes in each row (a matrix structure). Then she counts, one-two-three, four-five-six, seven-eight-nine, ten-eleven-twelve, tapping on the drawing column by column as she is counting. I interpret from her gestures and utterances that she has identified a countable unit. She indicates groups of three, but still she counts the shapes one by one. She now considers herself finished with the task and Roger does not object. Since Naomi and Roger solved the first task so quickly, I challenged them to find out what would happen if they had eight shapes and seven colours. They cannot really think of eight different shapes, so Naomi just draws eight circles in a row and fills in with more circles below these. They start to colour each row in one colour (purple, blue, red, …), until they have used all seven colours and hence got seven rows. The result is shown in Figure 4[1]. To the right is shown the calculation the pupils wrote on their worksheet. The drawing shows that they have marked four groups of 14 circles (dots). In the calculation I interpret the first line (14 14) to represent the first two groups, added to get 28 (second line). Then another 14 is added to get 42 and finally another 14 (not written) to get 56.



a) b)

Figure 4: Naomi and Roger's solution **Figure 5: From Naomi's solution in "Our method"**

As part of the task, each pupil should fill in a sheet with the heading "Our method for the biscuits task". Naomi wrote (referring to a version of the task with three colours and six shapes):

> We thought that we took a star like this with the three colours beneath [indicated by an arrow pointing to Figure 5 a)]. Then we did the same with all shapes, like this [indicated by an arrow pointing to Figure 5 b)]. Finally, we counted all the dots. We could also take them in small groups like this 3+3+3+3+3+3=6+6+6=18.

In Figure 5 b), Naomi has not drawn all the shapes. Based on her text quoted above, I assume that she has imagined the last three shapes, without a need for drawing them.

[1] They did not colour the first row of circles, so they put in eight green dots at the bottom. The three encircled shapes at the bottom of the drawing do not belong to this solution.

The representational register used in the formulation of Task 1 consisted of a text and the iconic representation ☆ ◇ ○ ♡. This drawing, endowed with colours, formed the starting point for the work in all the pairs. The pairs worked more or less systematically but the solutions shown in Figures 4 and 5 are representative for many of the pairs, as evidenced by the worksheets. The preferred representations show a matrix structure where each entry consists of one particular shape and one particular colour, mimicking the matrix product in Figure 3. Each entry has the form $a_i b_j$ where a_i represents a shape and b_j represents a colour. An emerging multiplicative structure can be seen, represented graphically as well as numerically. In the solution shown in Figure 4, Naomi and Roger have made groups of two and two columns, and in her description, Naomi writes "[w]e could also make them in small groups like this 3+3+3+3+3+3=6+6+6=18", indicating six groups of three or three groups of six. It is not clear what reasoning lies behind the representation "3+3+3+3+3+3=6+6+6=18", since the only evidence is what Naomi has written. It could be that she groups each 3+3 into 6 and then gets three groups of six. Another possibility is that she sees 3+3+3+3+3+3 by counting on the columns and 6+6+6 by counting on the rows (Figure 5).

Task 2 (Naomi and Filipa)

The two girls start by drawing five sweaters and three pairs of trousers and then they colour each piece, using different colours for each piece in the same category. On the video can be seen that Naomi draws a line from the red sweater to the grey pair of trousers and writes "man" (Monday) above this line. Filipa connects the red sweater with the brown pair of trousers and writes "tir" (Tuesday). The girls continue in the same way, ascertaining that for each new combination they find, it is not already taken. After having written Tuesday for the second time, a break can be observed on the video, and it seems that they struggle to find new combinations. Gradually, they find new combinations and when they have found 14, they think they are done.

1	Naomi:	All the trousers on this [points to the brown sweater] because this has three lines. [Looks at the sheet] I think we have made it.
	Filipa gets a new sheet. Naomi looks further at the drawing.	
2	Naomi:	Oh, we can have one more. [draws a line between the green sweater and the blue pair of trousers]
	Naomi writes 2 weeks and 1 day.	
3	Naomi:	I will ask if it is correct.
	One of the researchers comes to the table and asks if the pupils have found a solution.	
4	Naomi:	We think we have figured it out. We *think* it is two weeks and one day

Naomi puts emphasis on 'think', which I take to mean that they are not sure, and they ask the researcher for confirmation. When the researcher is reluctant to give an answer, the girls call upon one of the other researchers, and the following conversation takes place.

5	Researcher:	Is that what you found? How did you find that out?
6	Naomi:	We took everything together. So there are three lines for each outfit.
7	Researcher:	Three lines for each outfit? On each sweater and each pair of trousers?
8	Naomi:	No, for each sweater and each pair of trousers … For the trousers, it will be … five lines.
9	Researcher:	Are you sure you have drawn lines between all? Have you found all the outfits?
10	Naomi:	I think so. Is it correct?
11	Researcher:	You have to try to convince me. How are you thinking to make sure you have found absolutely all? It can be easy to forget to draw a line, right?

12	Filipa:	Yes.
13	Researcher:	Have you found a strategy to be sure that you really have taken all the sweaters with all the trousers?
14	Naomi:	It is not so easy to see if we have taken all.

The result of Naomi and Filipa's work can be seen in Figure 6. The lines are marked with abbreviations of the weekdays and to the right is written "2 weeks and 1 day" (2 uker og 1 dag).

Figure 6: Naomi and Filipa's solution

Figure 7. One of Frances' five groups

What appears from the pupils' discussion of Task 2 is a less systematic approach, uncertainty about whether they have identified all possible outfits, and a solution based on counting one by one. There is some evidence of grouping when Naomi says "three lines for each outfit" (#6) and later adjusts to three lines for each sweater and five lines for the trousers, after being questioned by the researcher. Still, there is no evidence of seeing the problem as a situation of five groups of three or three groups of five. The representation chosen by Naomi and Filipa in Task 2 (Figure 6) is much further away from a matrix structure than Naomi's representation in the solution of Task 1 (Figure 5). As an example of a grouping emerging also in Task 2, I show a solution produced by Frances (Figure 7). She made five groups, each group containing one coloured circle representing a sweater and three coloured circles representing three pairs of trousers. One of these groups is showed in Figure 7. Inside each group she had written "tre dager" (three days). She also wrote "take three times 3 times 3 times 3 times 3, which is 15". Hence, she got the correct answer but wrote "times" instead of "plus". Other indications of an emerging multiplicative structure are shown by Roger and Nora, when they say that they have "five lines for each pair of trousers" and "three lines from each sweater", and then they say that they take "all the sweaters with all the trousers and all the trousers with all the sweaters".

Discussion

Prediger and Wessel's (2013, p. 437) model shows a relation between a concrete representational register, a graphical representational register, different verbal registers and a symbolic-algebraic or symbolic-numeric register. Both tasks start with a verbal representation, in Task 1 also a graphical representation. In both tasks, all the pupils made use of a graphical register in the solution process, (evidenced by the worksheets), but also other registers could be identified.

The formulation of Task 1 used a verbal register and an iconic graphical register (Duval, 2006, p. 110), the picture of the shapes. This picture turned out to be instrumental in the pupils' solutions. All pupils started by copying the picture of the shapes and then they started to colour the shapes. Almost all pupils ended up with a matrix structure similar to what is shown in Figures 4 and 5. Most pupils got several examples to work on, with different number of shapes and colours, and the representations developed into being more systematic and refined for each new example. I described Task 1 as involving a mapping $M_1 \times M_2 \to M_1^*$, with M_1 containing shapes, M_2 containing colours, and M_1^* containing coloured shapes. The elements of M_1^* are, in a concrete sense, a product (combination) of the elements of M_1 and M_2: "shapes times colours gives coloured shapes". For combinatorial problems, an issue is that the target measure space may not be present from the beginning, and that it is not clear when to stop counting (English, 1991; Shin & Steffe, 2009). The strong relation between the measure spaces in Task 1 may have reduced this challenge.

Task 2 involves a mapping $M_1 \times M_2 \to M_3 \to M_4$, where M_3 contains outfits and M_4 contains days of the week. Here, the connection between the measure spaces is weaker than in Task 1. Task 2 was formulated purely in a verbal register, but the dominating register used in solving the task was an iconic graphical register. The solutions were heavily based on drawings of the clothing items. The lack of a stopping strategy was evident in Task 2, as exemplified by Naomi and Filipa: "We *think* it is two weeks and one day" (#4) and "It is not so easy to see if we have taken all" (#14). They stopped because they were not able to find more possibilities, not because they were convinced that the solution was correct. There are some occurrences of statements "three times five" in the data material, but with no clear reasoning about *why* three times five is a representation of the given situation.

Although a graphical register was used in both tasks, the representation chosen for Task 1 was much closer to a symbolic-algebraic representation (matrix) than was the case with Task 2. In Task 1, Naomi also introduced a symbolic-numerical representation by writing 3+3+3+3+3+3=6+6+6=18. A similar representation as in Figure 6 could be found in many of the pupils' worksheets, and some indications of grouping could be found in the graphical representations (Figure 7) as well as in the discussions. However, there is a significant difference in the chosen representations and in the extent to which the situations are perceived as multiplicative. Despite utterances like "three lines for each sweater" and "five lines for each pair of trousers" in Task 2, there are very few indications of grouping and counting of composite units. The counting is done one by one, sometimes using tally marks when a new connection between a sweater and a pair of trousers was discovered. I interpret this difference to be due to two aspects: The difference between the representations in the formulation of the tasks, and the nature of the target measure space. It turned out that in Task 1, many of the pupils could generalise to other numbers, whereas no such generalisation was observed in the work with Task 2. Mathematical symbolism, seen by O'Halloran (2005) as the final stage in a solution process, is generally used to a very limited extent.

In Task 1 the target measure space M_1^* is a variation of the measure space M_1. This makes the situation close to a rectangular array situation (Fosnot & Dolk, 2001), with shapes (biscuits) laid out in a row-column pattern. Therefore, Task 1 is not a genuine *Product of Measures* situation, but more like an *Isomorphy of Measures* situation, and hence less challenging (Vergnaud, 1983).

In this paper, I have shown how the choice of representations and the difference between the measure spaces can influence pupils' solution strategies. In Task 1, the pupils found a systematic solution strategy, which they also could generalise to larger numbers. The nature of the measure spaces in Task 1 made this situation closer to a rectangular array problem than was the case with Task 2.

Content-specific teaching practices to enhance learners’ concise language use while dealing with amount and change

Dilan Şahin-Gür

Keywords: Teaching practice, content-specific, explicit language use.

Content-specific teaching practices to increase conciseness

In their research survey on language-responsive approaches, Erath et al., (2021) observe that so far, planning and interaction dimensions of scaffolding have been investigated separately and call for investigating the mutual relationship: “Future research should strengthen the efforts to combine the analysis of dimensions that have formerly been researched separately” (p. 258). In particular, little is known about how macro-scaffolding is supported by micro-scaffolding strategies as Pöhler (2018) outlined while addressing this question to some extent by investigating the impact of micro-scaffolding prompts on intended teaching-learning processes. Even if a few studies already show that students’ language development can be enriched by teaching practices (e.g., Smit et al., 2013), further studies are requested (Erath et al., 2021).

One part of my PhD thesis will contribute to reducing this research gap by showing the impact of spontaneous support through adaptive micro-scaffolding practices on students’ language use while dealing with amount and change and their relationship.

In previous empirical studies we have already shown that conceptual challenges in dealing with amount and change, e.g., confusing the levels f, f', f'' (Nemirovsky & Rubin, 1992), can be overcome successfully when a concise meaning-related language is developed (Prediger and Şahin-Gür (2020) differentiated conciseness topic-specifically into explicitness of level references and preciseness of change process comparisons). In addition, we have observed that teachers' prompts for making references explicit are crucial for developing conciseness of language. These have given us important hints for the further development of the teaching-learning arrangement. At the same time these insights emphasize the need to provide opportunities for enhancing students’ explicit and concise language while dealing with deep mathematical concepts such as amount and change.

So far much is known about students’ processes of extending their individual lexicon, but too little is known about explication and preciseness and even less is known about the effective support of more and more explicit and precise language expansion. This allows me to present a poster sketching the research on the following research questions:

What teaching practices repeatedly emerge in relation to learners' increasing explicitness of language use while dealing with amount and change? And how are these teaching practices related to varying degrees of explicitness and particular concepts of amount and change?

Methods

Data collection. The data collection for the complete PhD study comprised design experiments with 16 pairs of 10 and 11th graders (14-16 years old), and the author as the design experiment leader. The research reported in the poster focuses on data from design experiments in laboratory settings with nine pairs of 11th graders. Two sessions of 45-60 minutes each were completely video-recorded for each pair (around 1000 minutes of video material).

Data analysis. In order to analyze the connection between teachers' practices and students' topic-specific explicitness and preciseness of their language use, the qualitative data analysis proceeds in three steps needs to coordinate two theory-driven deductive codings:

Step 1. Locating students' and teachers' utterances in the topic-specific degree model for conceptual conciseness (explicitness and preciseness) (Prediger & Şahin-Gür, 2020)

Step 2. Depicting the chain of utterances (Prediger et al., 2020), marking and connecting the pathways

Step 3. Based on these coordinated, theory-driven codings, the teachers' questions and prompts are coded and typical recurring practices are identified in sequences or questions and prompts, following the analytic procedure suggested by Prediger et al. (2020).

Conclusion

The necessity to elaborate vague student language has already been identified in other transcripts from qualitative calculus (Prediger & Şahin-Gür, 2020). The poster will reveal first content-specific insights on what is crucial to pick up and connect in students' thinking (e.g., identifying and explicating the levels) by identifying relevant teaching practices.

Outlook for the physical poster. The poster will list in bullet points the theoretical approaches and show the research question. I would like to spend a large part of the poster on empirical findings, illustrated in an exemplary transcript and the related analytic scheme of the identified practices.

Pluriliteracy as a framework to conceptualize CLIL mathematics classrooms

Alexander Schüler-Meyer

Eindhoven University of Technology, The Netherlands; a.k.schuelermeyer@tue.nl

In an increasingly globalized world, European politics pushes for schools to accommodate multilingualism and to facilitate students in becoming proficient in the subjects in multiple languages. As a result, many schools in the Netherlands begin to offer mathematics in a Content- and Language-Integrated Learning (CLIL) English framework. However, CLIL is often realized in ways that limit students' use of their home languages in favor of maximizing students' exposure to English, which does not support students in becoming proficient in mathematics in multiple languages. To establish alternative didactical approaches to CLIL, this theoretical paper introduces the notion of pluriliteracy to mathematics. Pluriliteracy emphasizes students agentic use of representations during practices of reading and writing mathematically. The notion of pluriliteracy is illustrated with examples.

Keywords: Multilingualism, pluriliteracy, literacy, CLIL.

Introduction

Traditional Content- and Language-Integrated Learning (CLIL) classrooms follow an ideology of maximizing exposure to the target language and minimizing students' use of their home language(s), with the idea that such maximized exposure would benefit students' learning of the subject-specific target language. This traditional approach to CLIL education is prevalent in the Netherlands. However, translanguaging questions this ideology, as it highlights that students' multiple languages are tightly intertwined and form one shared resource for cognition and communication (García et al., 2017). In fact, there is convincing evidence that translanguaging is most beneficial for multilingual students' mathematics learning (Schüler-Meyer et al., 2019b; Uribe & Prediger, 2021). Hence, the old ideology of maximum exposure to the target language needs to be replaced with new principles for conceptualizing CLIL in mathematics classrooms in terms of translanguaging.

Beyond addressing recent research in multilingual mathematics education, innovative CLIL classrooms also need to address contemporary issues of digitalization and globalization. With respect to digitization and its associated increase in textual communication, there is a need to prepare students for reading and writing a wide range of multimodal mathematical texts (website or newspapers, enriched with diagrams or tables). With respect to globalization, there is a need to prepare students for accessing their mathematical knowledge in multiple languages. Inside school, globalization is already reflected in the superdiversity of classrooms (Vertovec, 2007). To address these two developments as well as recent findings of the relevance of translanguaging, CLIL classrooms should focus on facilitating students' pluriliteracy (Coyle & Meyer, 2021). In this theoretical paper, I introduce pluriliteracy in mathematics and discuss its benefits for conceptualizing CLIL mathematics classrooms, with the research question of how to conceptualize discourse practices of translingual textual communication in terms of pluriliteracy.

A model of pluriliteracy in mathematics classrooms

Pluriliteracy in mathematics can be defined as the agentive engagement in multilingual discourse practices of textual communication of mathematics across languages, genres and representational registers. Figure 1 represents this definition in the form of a three-dimensional model of mathematical pluriliteracy, with the central assumptions that languaging, literacy (conceptualized as proficiency with mathematical genres) and representational registers are intertwined elements of pluriliteracy. Hence, pluriliterate practices can be considered as points in this three-dimensional space, and particularly, the cubes in the model denote such practices on different levels of proficiency.

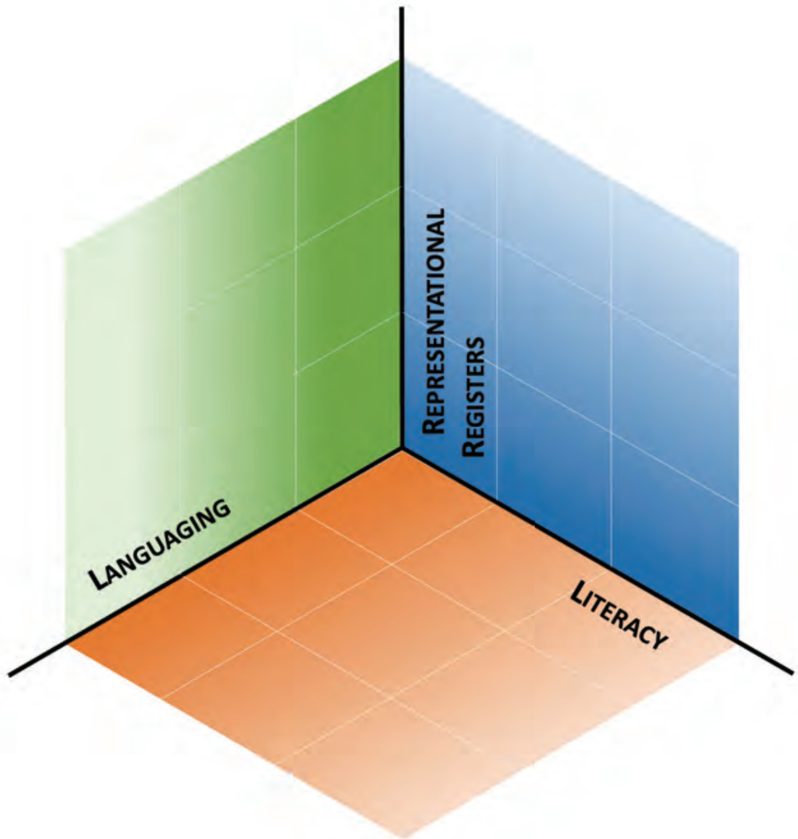

Figure 1: three-dimensional model of pluriliteracy in mathematics

The model of mathematical pluriliteracy builds on a monolingual definition of mathematical literacy which conceptualizes mathematical literacy as the proficiency to agentively "create, use and interpret representations of mathematics concepts, utilizing a variety of verbal, visual, gestural and multimodal 'texts'" (Way & Bobis, 2017, p. 1). Texts in mathematics education can be recursively conceptualized as linguistic artifacts that initiate a subject's meaning-making through inviting specific relations to previous text (Rojano et al., 2014, p. 390). Agency is a crucial element in this definition, as students should be able to be literate outside of and after school, so they need to be able to initiate, for instance, the use of representations to make sense of a multimodal text.

While the definition of literacy does not consider multilinguality, it can be extended into a definition of mathematical pluriliteracy based on the notion of multilingual discourses. Moschkovich (2015) argues that the notion of discourse is central for literacy in a multilingual context, as it provides a broader view of proficiency that “not only [involves] oral and written text, but also multiple modes, representations (gestures, objects, drawings, tables, graphs, symbols, etc.), and registers (school mathematical language, home languages and the everyday register).” (p. 44). While pluriliteracy adopts this broader view of proficiency, it focuses on a specific element of discourse, namely textual mathematical communication (Fig. 1, text as communication). Accordingly, pluriliteracy emphasizes mathematical practices that are particularly concerned with producing and interpreting mathematical texts (Fig. 1, reading, writing and using representations).

Pluriliteracy in mathematics classrooms

In the following, I will give examples of pluriliteracy in mathematics classrooms, highlighting the specific pluriliterate discourse practices students might need to engage in when developing their pluriliteracy. The examples from the students Joris and John are from a bilingual Dutch-English 8th-grade CLIL classroom in an urban middle school in The Netherlands, where pluriliteracy practices were implemented for the topic of percentages and diagrams (van der Aalst et al., 2021). In this classroom, master students designed learning activities to promote pluriliterate practices to support students who aim for a lower degree, to democratize access to CLIL mathematics education.

Example 1: Reading as pluriliterate discourse practice

Reading a text with mathematical information across languages and across academic and everyday registers is an example of a pluriliterate mathematical discourse practice. Many multilingual students will be confronted with a multimodal mathematical text in their home language outside of school, requiring them to interpret mathematical information by utilizing both, their home language and the language of instruction. Outside of school, mathematics often appears in multimodal texts, possibly in another language, such as websites or advertisements. For instance, deciding where to buy an electronic product – when visiting family in Mexico or Turkey or at home in the US or Germany/Netherlands – involves comparing prices and discounts as well as customs rates on websites in different languages. Hence, reading as pluriliterate discourse practice requires all, work with texts (literacy), representations (representational register) and languaging in multiple languages.

Reading a multimodal text with mathematical information across languages, genres and registers is demanding and involves actively asking questions to the texts, on both the academic and colloquial level. These reading demands become evident when considering how students who learn mathematics in English might read an advertisement of a Dutch supermarket (Figure 2). The advertisement presents a discount that is dependent on the number of pizzas bought. The new prices are presented in orange squares which grow in size, perhaps presenting a growing stack (“stapel”). In an academic reading, the squares could remind of a step function. Furthermore, only the biggest square is labeled with the percentual discount that results from the “stapelkorting”. In a colloquial reading, these 62% are an attractive offer, because in the context of other frequent advertisements in Dutch supermarkets which advertise 50% discounts (buy one product, get one for free) it can be considered as better. In an academic reading, one could identify that the advertisement refers to pizzas of different price categories, and indeed, the 62% only apply if one buys four of the most expensive pizzas for 3.99€. The advertisement is an example of a multimodal text that integrates language and pictures through a (culture-specific) “visual grammar” (Kress & van Leeuwen, 2006).

Stack discount

Summer weeks

Up to 62% discount.

2 pieces 4.00

3 pieces 5.00

4 pieces 6.00

(Pizza brand)

Deep frozen

All types, combinations possible.

[price] per piece from ~~2.25~~ – ~~3.99~~

Figure 2: Advertisement in a Dutch supermarket, found at https://static.wekelijkse-folders.nl/image/item/albert-heijn/8030/img001.jpg (Accessed at Aug.-31-2021)

Engaging with the multimodal text in the advertisement could elicit and facilitate several further pluriliterate discourse practices. Firstly, *Reading the text from different perspectives:* With respect to a colloquial reading, students have to be able to identify relevant factual information from the advertisement, such as the price and the respective discount ‘model’ for different numbers of pizzas. With respect to an academic reading, particularly, the use of representations, students should find a mathematical model that allows them to calculate the discount in both, percentage, and absolute numbers. If the “stapelkorting” is assumed to continue for arbitrary numbers of pizzas, a step function with an increase of 1 for each step is an interesting model to explore. Secondly, *formulating questions about the advertisement:* To critically read the advertisement in an academic way, students could formulate their own questions, such as: “How much do I save each time when I only buy the cheaper pizzas, which cost 2.25€ per piece, in absolute numbers, but also in percentages?” “Is the advertisement correct or perhaps misleading?” “What should I do if I want to buy 5 pizzas?”. Thirdly, *communicating results across colloquial and academic registers:* To answer their questions, students have to communicate their results in the form of a text (or presentation). For that, students have to use academic mathematical English, for example concepts such as “amount” of “decrease”, but also their colloquial language, for instance as “to buy 5 pizzas with a price of 2.25€, you should buy them as two “stapels” of 3 and 2 pizzas, as well as representational registers and a suitable genre.

Example 2: Using representations as pluriliterate discourse practice

Mathematical representational registers are crucial for multilingual students to make sense of mathematics, as they enable students to activate everyday meanings in their home language (Moschkovich, 2002) or to mediate between their languages (Uribe & Prediger, 2021). Accordingly, representational registers enable pluriliterate discourse practices. For instance, specific representations are better suited to convey a specific message for a specific audience in a suitable format – hence, they support the (trans-)languaging dimension, but at the same time require specific genre choices. Thus, from the perspective of preparing students to communicate mathematical information across languages and across academic and everyday registers, it is key for student to learn to agentively and purposefully use representations.

The use of representations can be conceptualized as practices of translating between a situational ('colloquial') representation and a suitable formal ('academic') representation (Prediger et al., 2016). Such practices of translating between representations are crucial for multilingual students (Moschkovich, 2002; Schüler-Meyer et al., 2019a). However, little is known about how multilingual students become agentive in connecting informal and formal representations to support their mathematical reasoning across multiple languages. To the authors knowledge, there is only circumstantial research on this issue, and only in monolingual contexts. For instance, in Early Algebra, students' informal drawings can be a vehicle for introducing variables (Schliemann et al., 2010).

In a summative self-assessment for the topic of percentages (8th grade), students in a multilingual Dutch-English CLIL-classroom attempted to connect formal and informal representations, supported by links to everyday contexts (Figure 3). Here, students are supposed to link informal contexts with formal representations. The percentage bar acts as model and can support linking informal and formal representation, e.g. linking the situation of how much remains to download (bottom right) with the formula for calculating the file size with the help of the download bar (top right). The following episode highlights how two students, John (Polish and Dutch as home languages) and Joris (Dutch as home language), struggle to make such connections.

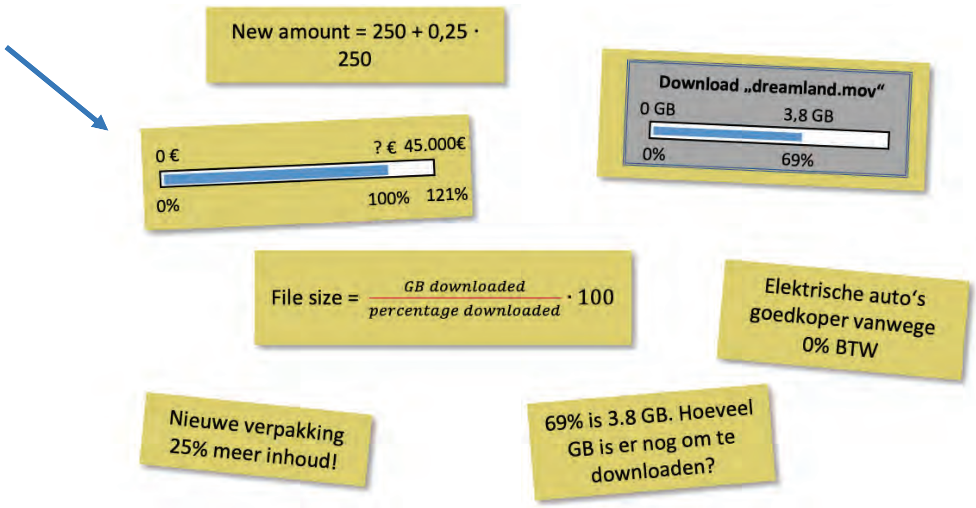

Figure 3: Cards that students have to link to generate tasks, in the context of a self-assessment

Joris: Maybe, maybe this one's belong together then [points at card with arrow]. But I'm not sure.

John: Hm. Ik twijfel. Ik weet niet, is dit increase of decrease zeg maar? *[I doubt that. I don't know, is this increase or decrease, so to say?]*

Joris: I think this is a, I don't know because it is already given the number. It could be increase because 100 percent is normally the max of something so if 21 percent joins it, it would be an increase. I think this is a, I don't know because it is already given the number. It could be increase because 100 percent is normally the max of something so if 21 percent joins it, it would be an increase.

Joris suggests connecting the download bar with the card below that presents a formula for calculating file size. John attempts to interpret the download bar in terms of the concepts decrease and increase. These two concepts have been repeatedly discussed in the previous learning-teaching unit, and they stem from the target repertoire of English terminology. Joris follows this line of reasoning and interprets the card as an increase, but he is conflicted by a "rule of thumb" that percentages cannot be higher than 100%. Hence, students see through the representations towards underlying concepts. For that, they use their multilingual repertoires as communicative resource to express doubt.

Despite regular use of the percentage bar in the preceding teaching unit, the students struggle to make sense of its colloquial meaning, that is, with respect to what situation the percentage bar could re-present (that electric cars do not pay value-added tax /'BTW'). In earlier attempts, students used pattern matching to connect informal and formal representations, that is, searching for cards with the same numbers. These struggles with the percentage bar are in line with the general observation that the students in the unit rarely initiate the use of representations themselves and struggle to connect representations across colloquial and academic registers.

As representations are a crucial tool for multilinguals to connect their multiple languages and representations have been frequently used in the preceding learning-teaching unit, this finding is unexpected. Accordingly, more research is needed on the representation-dimension of pluriliteracy, that is, the agentive creation, use and connection of representations.

Example 3: Pluriliterate writing as example of the literacy dimension

Mathematical writing is a crucial discourse practice for communicating mathematically. In school mathematics, mathematical writing has been shown to be beneficial tool for consolidating and reviewing knowledge but has rarely been investigated as a discourse practice that needs to be explicitly taught. Particularly, the demands of writing in a second or third language, which are quite extensive (Manchón & Matsuda, 2018), have seldomly been explored, so the demands of a pluriliterate practice of mathematical writing are unclear.

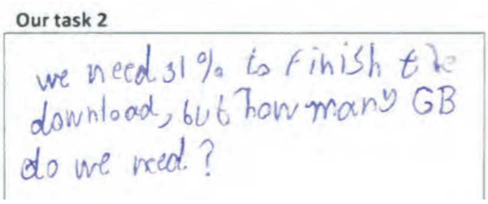

Figure 4: Joris and John's writings in the context of summative assessment

Joris and John’s attempts at mathematical writing in Figure 4 are an example of how students use previous texts to write mathematically, which results in a bricolage of texts from the assessment tasks. When required to formulate a task based on the given cards (Figure 3), students write a task in English (Figure 4). Joris and John’s task resembles the card at the bottom right in Figure 3, which translates into “69% is 3.8 GB. How many GB are there still to download.” Accordingly, the words “download”, “how many” and “GB” are revoiced from the cards. However, to formulate their question students write from their own perspective in terms of “we need”. Hence, the students’ writing practice reminds of the notion of flow (Barwell, 2020) where previous instances of a specific text uses inform students’ later use of these text pieces in their writings.

Discussion and Summary

This article has introduced a three-dimensional model of pluriliteracy as a means to identify discourse practices of textual communication across languages and modes. The model allows to innovate CLIL classrooms with respect to two major developments of the 21st century. Firstly, globalization increasingly requires students to access their knowledge in multiple languages in their future life. Secondly, digitalization makes communication and information increasingly textual and multimodal. Thus, facilitating pluriliterate discourse practices in the CLIL classrooms could enable students to engage with mathematics in their future life in a globalized and digitized world.

The model of pluriliteracy builds on established research in multilingual mathematics education, for instance to substantiate literacy through discourse practices Moschkovich, 2015) and the importance of connecting registers and representations for students to use their multilinguality for epistemic purposes (Uribe & Prediger, 2021). While that allows to identify relevant discourse practices that constitute pluriliteracy, it also points to further research needs to understand translingual discourse practices of textual communication, particularly with respect to interpreting real-live texts in different languages or to produce texts in writings or presentations while activating multiple languages as epistemic and communicative resources. While such discourse practices should be informed by the use of representations, the data presented here suggests that students struggle with an agentive use of representations during reading and writing. Hence, more research is needed to investigate pluriliterate discourse practices.

Images of mathematics: The public's reactions to educational television programs in Poland during the 2020 lockdown

Konstantinos Tatsis[1] and Bozena Maj-Tatsis[2]

[1]University of Ioannina, Greece; ktatsis@uoi.gr

[2]University of Rzeszow, Poland; bmaj@ur.edu.pl

Keywords: Images of mathematics, educational television, pandemic.

During the Covid-19 pandemic, we have experienced the broadcasting of educational television programs in Poland, which were offered as an alternative to classroom teaching in all subjects, especially for the students who did not have access to online courses. "Szkoła z TVP" ("School with TVP") was such a program; a total of 1,600 lessons were broadcasted within this program, with a total duration of 1,440 hours. Concerning mathematics, this program has sparked a lively debate among different agents, including academics, mathematics teachers, journalists, parents, as well as students, who were the target group of these series. The aim of the present study is to analyse the images of mathematics, as they emerged in discussions among the aforementioned agents. The data came from 1202 texts published in educational fora (closed Facebook groups), social media, emails, websites (articles, interviews, and comments) and communication platforms. We view the image of mathematics as consisting of: stated attitudes, feelings, description/metaphor for mathematics, beliefs about the nature of mathematics, views about mathematicians and their activities, beliefs about mathematicians' ways of knowing and warranty of mathematical knowledge, description/metaphor for learning mathematics, aims for school mathematics, memories of best/worst mathematics lessons, beliefs about mathematical ability and beliefs about sex differences in mathematical ability (Lim & Ernest, 2000, p. 195). Based on these, we performed a thematic analysis (Boyatzis, 1998) by assigning codes to the utterances contained in the texts. The codes were then combined, to identify emerging themes, which constituted the different images of mathematics.

Results and selected examples

Our analysis led us to four overarching images of mathematics: a) mathematics is unambiguous, b) mathematics teachers are expected to act as motivators, c) mathematics lessons are expected to be interesting and lively and d) mathematics teaching should not be based on rote memorisation. Due to space limitations, we present examples only of the first two images.

Mathematics is unambiguous

This image emerged from two codes: the first one referred to the teacher-presenter's mathematical errors (ERR), while the second referred to the nature of mathematics (MATH):

> Without a doubt, the content that has reached us contains gross errors. (ERR) Basic mathematical skills and concepts are so clearly defined that there is no doubt that there are no two points of view concerning the correctness of the content contained in the program. (MATH) ("Nauczycielka o lekcjach matematyki w TVP: To jest przestępstwo popełniane na umysłach

naszych dzieci” / “Teacher on mathematics lessons at TVP: This is a crime committed on the minds of our children”, 2020)

Mathematics teachers are expected to act as motivators

This image emerged from codes related to the teachers-presenters’ verbal (QUEST) and non-verbal behaviour:

> The lessons are such that there is a person or two in front of the camera and a whiteboard. Some people act as if they stand/sit in front of a normal class, ask questions to non-existing children (QUEST), listen, and then answer by themselves... (Papuzińska, 2020)

We may relate this to the ‘Teacher as motivator’ role described by Munter (2014): “the teacher must be energetic and captivating so that students will be sufficiently motivated to learn with no mention of what the teacher should do with respect to content” (p. 600).

The images identified in our study are related to images that appear in the literature. It seems that the television programs have enhanced specific images of mathematics teaching, especially those related to rote memorisation. Bakker and Wagner (2020) mention that “Several colleagues worried that quick adoption of new technology will lead to falling back to less favorable pedagogy” (p. 2). Our study’s contribution is twofold: towards the improvement of educational programs (and eventually online courses) and towards the improvement of the public’s images of mathematics.

Quality in students’ writing in mathematics

Anna Teledahl[1], Linda Marie Ahl[2], Ola Helenius[3] and Cecilia Kilhamn[2]

[1]Dalarna University, School of Education, Falun, Sweden; ate@du.se

[2]University of Gothenburg, National Center for Mathematics Education, Sweden; linda.marie.ahl@gmail.com; cecilia.kilhamn@ped.gu.se

[3]University of Gothenburg, Department of Pedagogical, Curricular and Professional Studies, Sweden; ola.helenius@ncm.gu.se

We present a literature review with the aim to identify and characterise research frameworks that propose standards for assessing the quality of students’ mathematical writing. Eleven studies that investigated students’ solutions to problems, journal writing, essays, or instructions, and proposed frameworks for analysing such writing, were identified. The analysis sought to characterise what the frameworks attended to in students’ mathematical writing and whether they described a progression with a reference to quality of the writing. The main result is that the frameworks mainly attend to the content and that there is little attention to form. Further, quality is most often regarded as a question of content, if the text contains for example an explanation, then the explanation is seen as a sign of quality with no reference the form. Our review concludes that research rarely describes levels of quality in students’ mathematical writing, something we believe further research should do.

Keywords: Writing, quality, progression.

Introduction

The universal practice of having students present their solutions to mathematical problems in writing and using this writing to draw conclusions about students’ proficiency, has been common for centuries (Morgan, 1998). Reporting mathematical work in writing requires knowledge on how to represent mathematical investigations, conclusions, justifications, and arguments. In many curricula communication is presented as a competency and as such it can develop so that students over time could exhibit a progression, for example in the quality of their mathematical writing. In this paper we have investigated the question of quality in mathematical writing through a literature review where we set out to answer the questions: Does research provide standards for assessing the quality of students’ mathematical writing (MW) and if so, what are these standards?

A theoretical point of departure is the idea that competence in mathematical communication, in our case in writing, is a skill that can be analytically separated from other skills. This idea is captured by the concept of communicative competence (Hymes, 1972), which suggests that in a particular social situation all things said are not communicated with equal competence (Craig & Muller, 2007; Rickheit et al., 2008). The simplest criteria for what can be considered competent communication are efficiency and appropriateness (Rickheit et al., 2008). Efficiency relates to the idea that communication takes place to fulfil a goal and if you achieve your goal then the communication is effective. Appropriateness connects with the social aspect of communication: to communicate well in a social situation is to be familiar with all the ways of making meaning within that situation. Wittgenstein referred to this social localisation using the metaphor of a language game. He suggested that competent communicators are those who know and abide by the rules of the language game that the social situation constitutes (Wittgenstein, 1953/1986). It can thus be argued that what is considered good communication changes with the situation. This idea is fundamental to the movement labelled Writing Across Disciplines which has advocated the differentiation of writing skills in relation to different academic disciplines of which mathematics is one (Bazerman et al., 2005).

In line with the ideas presented above it can be noted that modern communication in mathematics is a special kind of communication which has developed over two centuries (Solomon & O'Neill, 1998) and is defined by its multi-semiotic nature (O'Halloran, 2005). Because mathematical concepts are often difficult to articulate in ordinary language, mathematical symbolism has developed to express meaning beyond what can be expressed by ordinary language (Schleppegrell, 2007). It has been proposed that MW can be decomposed into a formal logical structure in which we find definitions, theorems and proofs, and a complementary informal structure in which motivation, analogies, examples, and explanations have their place (Steenrod et al., 1973). The logical structure relies on mathematical notation and symbolism which owe their strengths to their universality and independence of context (Sfard et al., 1998). The complementary structure relies on natural language, which owes its strength to its flexibility, offering a nearly endless number of ways of conveying meaning through multiple modes.

Mathematical writing takes place in relation to different objectives and prompts. Students use writing to personally make sense of, record or explore mathematical ideas, but also to document processes, explain, describe, and make arguments in social situations with peers or teachers (Casa et al., 2016; Morgan, 2001; Stylianou, 2011). Within these different categories there is a difference between writing in mathematics and writing about mathematics (Bosse & Faulconer, 2008). Writing to personally make sense of mathematics and writing for others such as teachers and peers represent two very different processes, but commonly, they are concurrent in school mathematics (Morgan, 1998). The definition for MW used in this paper is borrowed from Casa et al (2016) and encompasses both these categories. MW is understood to be writing to reason (personal) and to communicate (with others) in an educational and mathematical context. We assume that standards for assessing the quality of students' mathematical writing apply to either one specific form of writing or several forms.

Review methodology

We conducted a literature search in ERIC (EBSCO) where we searched abstracts using the following search words: [writing AND (mathematical or mathematics) AND (pupil* or student* or children*)]. The search words were chosen with the intent to capture research in which students' mathematical writing is treated as an object separate from communication in general (Schleppegrell, 2007; Steenrod et al., 1973). The search was performed on the 24th of May 2021. We found 806 peer-reviewed articles fitting the inclusion criteria (see table 1).

Using the software *Covidence* to manage our literature review, each paper was screened by two reviewers. The screening was made in two steps. First, we screened the title and abstract to forward relevant studies to full-text review. In cases where we were hesitant, we chose to forward the paper to full-text screening. In the full-text screening, papers were included if they contained frameworks or guidelines on how to write, or explicit descriptions of progression or levels of writing.

Of a total of 141 papers, 50 remained after the full-text screening (see table 1). These were categorized according to what was investigated in the paper in terms of: Studies that compare different frameworks for analysing mathematical writing (1); Studies that create a framework for analysing mathematical writing, but where the research question concerns something else (the framework created is a means to study for example the way digital technologies influence students' writing or how writing affords learning) (26); Studies that use a pre-existing framework for analysing mathematical writing (the framework is a means) (12); and finally, Studies that result in a framework for analysing mathematical writing (11). In this study we have chosen to focus on the latter category to investigate only research that focuses exclusively on students' mathematical writing as an object.

Table 1: Screening process

	Inclusion Criteria	**Exclusion Criteria**	**Excluded**
Title and abstract screening 806 studies imported	Mathematical writing Students Frameworks for assessing writing or identifying aspects of writing	Journal writing without guidance for assessing writing No instruction or identification of aspects of writing or frameworks for assessment	665 studies irrelevant
Full-text screening 141 studies imported 50 remained for data extraction	Frameworks for how to write Guidelines for how to write Explicit ideas for progression Descriptions for progression or levels of writing Meta-reflections on the benefits of writing	Not a research article No criteria for analysing or assessing mathematical writing Full text not available. Not about mathematical writing	57 21 8 5

The literature review is a configurative review (Gough et al., 2012) aimed at identifying, interpreting, and characterising research frameworks that propose standards for assessing the quality of students' mathematical writing. After an initial review of overarching data such as age groups and types of writing (Bosse & Faulconer, 2008; Casa et al., 2016), the analysis focused on the proposed frameworks. The first part of this analysis sought to characterise the frameworks in relation to what they attended to, and the second part was concerned with investigating hierarchies or descriptions of progression in relation to quality, within the identified frameworks.

Results

The types of mathematical writing that was investigated varied across the studies in the sense that the writing samples were collected through different prompts. They were, however, all examples of accounts of writing that *communicated* mathematics, i.e., the texts were created with the understanding that they were supposed to be read by someone other than the student herself. The most common were prompts related to documenting and reporting solutions to mathematical problems. This type of writing was found in six of the eleven studies that were part of the review (Hughes et al., 2019; King et al., 2016; Kosko & Zimmerman, 2019; Morgan, 2006; Pugalee, 2004; Teledahl, 2016). The remaining prompts concerned proofs (Lew & Mejía-Ramos, 2019), journals (Clarke et al., 1993), essays (Stonewater, 2002), and instructions (Kline & Ishii, 2008; Shield & Galbraith, 1998). The writing samples were collected from different age groups, three from students in higher education, two from students aged 17-19 and the remaining from different constellations of students aged 6 - 16.

In our characterisation of what the frameworks attended to, we were originally interested in questions of form and content, inspired by previous research in which content and form in students' MW emerged as contrasting qualities. In our analysis, content and form proved to be useful categories although they failed to capture everything the frameworks attended to. Beyond these categories, we identified attention to the meta-functions of language as the focus of one of the frameworks. Our final characterisation therefore consists of the categories meta-functions of language, content, and form, which will be presented below.

Meta-functions of language

Only one of the proposed frameworks attended to the meta-functions of language and communication (Morgan, 2006). Morgan suggested using tools from systemic functional linguistics (SFL) to analyse students' MW. Such an approach would enable us to understand how students represent their understanding of who does mathematics, what kind of objects are involved in mathematics and what relationships are constructed (the ideational aspect); who the participants are in the written mathematical communication including their relationship to each other and to mathematics (the interpersonal aspect); and what the written text does (the textual aspect).

Content

The most common question that the frameworks attended to was *what?*, i.e., there was a concern with content in all but one of the studies. A typical framework lists several textual elements that should appear in the MW. In the studies investigating problem-solving accounts or solutions, such elements could include recounts of the steps of the problem-solving process, explanations, accounts of reasoning, and referrals to context (Hughes et al., 2019; King et al., 2016; Kosko & Zimmerman, 2019). Mathematical language or the use of mathematical terms can also be viewed as elements of MW that are either present or not in the text, hence it becomes a question of content (King et al., 2016; Kline & Ishii, 2008). One of the studies characterises the content of the MW as descriptions of sub-processes in the problem-solving process (Pugalee, 2004). There is an orientation element, an organizational element, an execution element, and a verification element, all of which correspond to processes in students' problem-solving behaviour. The studies that describe types of writing other than solutions to problems also list content. These include descriptions of context, descriptions of steps, exemplars, kernels, goal statements, justifications, links to prior knowledge, dialogue, summaries, and recounts (Clarke et al., 1993; Kline & Ishii, 2008; Lew & Mejía-Ramos, 2019; Shield & Galbraith, 1998; Stonewater, 2002).

Some of the content elements described in these frameworks are described with a reference to quality. The most common quality articulated is *mathematical.* The term mathematical is attached to textual elements such as steps, descriptions, explanations, language, and reasoning. There are, however, no descriptions of how a textual element qualifies as being mathematical.

Form

Three of the proposed frameworks address the question of mode or form. One of the studies (Teledahl, 2016) lists empirically identified modes of communication in MW together with their apparent function in the MW. Two of the studies investigating proofs (Lew & Mejía-Ramos, 2019) and essay writing (Stonewater, 2002) attend to students' use of mathematical notation and in the case of poofs, and in particular their adherence to rules of academic language and the formality of the proof.

Hierarchies or progression

Only four of the eleven studies address the question of hierarchies or progression in students' MW. The remaining seven either do not mention any differences in quality or treat quality as a question of whether the MW contains a desirable element or not or how often it appears. The two studies that address quality describe three (Clarke et al., 1993) or six (Kosko & Zimmerman, 2019) levels of writing and details the differences between these. In the case of Kosko & Zimmerman the analysis, and subsequently the quality criteria, details the difference in quality between six different ways of expressing an argument in students' MW. Two other studies describe elements of MW that were highly valued by respondents in relation to writing an instruction (Kline & Ishii, 2008) or an essay (Stonewater, 2002). The latter is the only study that mentions form as something that affects the quality of the MW. Stonewater suggest that "*Highest scoring writers use both a greater number of* algebraic, numeric, and graphic representations […] *and a greater variety of these representations to augment their written work than do the lowest scoring writers*" (2002, pp. 330-331).

Discussion

The review aimed to identify research-based frameworks that propose standards for assessing the quality of students' mathematical writing. The results indicate that while there were several frameworks that in different ways describe students' mathematical writing there are very few that do so with a focus on different levels of quality. Of the four frameworks that describe quality beyond the inclusion of different elements in the MW, only one investigated accounts of problem solving. This framework however focused on a specific part of such accounts: the expressing of an argument. The other three studies investigated other types of mathematical writing.

If quality is thought of as something that can be decided based on which elements are included in MW, then there are more examples of frameworks. The choice whether to include specific features in MW can be related to what prompted a student to write the text or to her idea of the discourse in which the text is written. The simplest of the criteria for communicative competence are appropriateness and effectiveness (Rickheit et al., 2008) both of which depend on knowledge about the discourse or, to use Wittgenstein's words, the rules of the language game (1953/1986). Adherence to rules and conventions regarding the form and content of MW is connected to the appropriateness as well as the effectiveness of the communication. If you communicate in ways that let readers recognise the writing as mathematical discourse, then this is appropriate and if readers understand what is communicated then the writing is effective. In the written discourse of mathematics there are conventions and expectations (Schleppegrell, 2007; Sfard et al., 1998) particularly in mathematical domains such as proofs that rely heavily on mathematical notation (Steenrod et al., 1973). The result of this review, however, indicates that in school mathematics such conventions and expectations are, if not missing, then at least not described in research, neither regarding content nor form. It is possible that this is connected to the fact that communication in school mathematics, because the students are young and/or still learning, rely more on natural language than other modes of communication (Sfard et al., 1998).

In preparing for the review, we assumed that we would find research that had taken an interest in how the use of different representations or forms of communication could contribute to an increased quality of MW. Not only did we encounter very few frameworks that addressed the issue of different levels of quality at all, but we only found one that mentioned form. The study that mentioned form, however, proposed that a greater number of different representations together with a greater variety of forms of representations was a sign of high-quality writing without addressing the appropriateness of the representations in relation to the context. How students communicate in writing is, from what we can conclude, not an issue connected to the quality of the writing. If we instead turn to content, we still encounter a lack of agreement on the features that signal quality in accounts of problem solving. The idea that the quality of MW increases if it contains arguments and/or justifications is only visible in frameworks that investigate other types of writing. Considering the small number of papers in our study it is likely that our scope was too narrow and that our study will yield different results when we, in the future as part of our longitudinal study, include also studies that propose frameworks for analysing MW while investigating something other than the quality of the writing itself. But this issue pinpoints our concern regarding the separation of MW as a means from MW as the primary object of interest. Our aim was to identify studies in which the focus was on the MW itself, as an object worth investigating in detail.

Considering that the studies investigated different types of writing from different age groups, one might ask if we should expect agreement or universal ideas on quality in student MW? Is writing not intimately connected to different curricula, different contexts, and different levels of mathematics? We believe there could be universal ideas on some elements of MW, for example the inclusion of arguments and/or justifications in students' accounts of problem solving. It is our hope that future research will attend to such ideas.

Understanding mathematics teacher's argumentation: considerations during classroom tasks discussion

Jorge A. Toro[1] and Walter F. Castro[2]

[1]University of Antioquia, School of Education, Medellin, Colombia; jandres.toro@udea.edu.co

[2]University of Antioquia, School of Education, Medellin, Colombia; walter.castro@udea.edu.co

This paper presents the research results whose aim is to understand the mathematics teacher's argumentation during classroom tasks discussion. Aspects of a theoretical stance are used, on the one hand, to show how the teacher's argumentation can be described in the mathematics classroom and, on the other hand, to specify aspects of the discourse in the mathematics classroom. The analysis is illustrated with one episode in a tenth-grade classroom, where the teacher and her students discuss the solution of a task about trigonometric ratios. The results allow recognizing features of the teacher's argumentation features, purposes, and conditions that activate it.

Keywords: Argumentation in mathematics classroom, discourse in mathematics classroom, learning opportunities, professional knowing.

Introduction

The argumentation of the mathematics teacher during teaching requires specifying aspects about the participation and discussion in mathematics class. On the one hand, it can be observed how research on and with mathematics teachers has grown in the last two decades, which in addition to being multifaceted, has a broad scope for teaching and learning mathematics (Chapman, 2016). On the other hand, interest in discussion and participation in mathematics class, particularly in the discussion of tasks, is associated with the way in which learning is conceived, this is from a participatory perspective (Krummheuer, 2011), where learning is conceptualized as participation in classroom discourse. The interest here is focused on the teacher, in what some authors have called the Teacher's mathematical discourse (e.g., Planas et al., 2016), that is, consider the teacher's communication of mathematical content in his interaction with his students. In addition to investigating the learning opportunities that these pragmatic considerations can promote; it is interesting to recognize links between the teacher's argumentation and student participation.

Given this concern and considering that: (1) argumentation can be used to deepen the decisions and practices of teachers (Metaxas et al., 2016); (2) there are elements or qualities in the communication between teacher and students that are important for learning mathematics (Drageset, 2014); (3) to describe the discourse in the classroom, detailed frameworks with categories and concepts are needed to describe individual turns (Drageset, 2015), and (4) argumentation in the educational field can be conceived as a social space and discursive (Ayalon & Hershkowitz, 2018). This paper proposes to answer the question: how is the argumentation of the mathematics teacher during class task discussion? The data analysis is illustrated through one episode of a mathematics class lesson in a tenth-grade teacher (15-16-year-old students) in the city of Medellín (Colombia).

Theoretical background

This section comprises two sections; the first one presents considerations on argumentation and the second one presents concerns on class discourse.

Considerations on argumentation

Like different authors, the definition of argumentation presented by van Eemeren and his colleagues (2014, p. 7) is taken up:

> Argumentation is a communicative and interactional act complex aimed at resolving a difference of opinion with the addressee by putting forward a constellation of propositions the arguer can be held accountable for to make the standpoint at issue acceptable to a rational judge who judges reasonably

This consideration regarding argumentation seeks to attend to complex interactions in mathematics classroom, where the teacher and his students argue during the development of a lesson regarding a certain task. It also implies that the object of this research, the mathematics teacher's argumentation, tries to isolate itself from the classical position, in which argumentation is assumed as a set of premises and conclusions formulated with the help of formal symbols, to assume a position closer to language and communication. Considering the argumentation under this theoretical assumption, consists of seeing the argumentation as a type of activity with purpose or intention, so that the activity is recognized as a process whose representation is the use of language and, therefore, the structure of the constellation. of propositions must be analyzed as speech acts that are part of the resolution of differences of opinion.

The difference of opinion does not necessarily take the form of a disagreement, dispute, or conflict, but there is one party that has a position and another that doubts whether to accept that position (van Eemeren et al., 2014). In mathematics class, it is possible that there are doubts regarding a statement, indication or explanation of the teacher, doubts about an answer or procedure different from the one presented by the teacher, or different answers to a task in the students' work, where the teacher's argumentation is required.

This position regarding argumentation also requires considering the process and the product of argumentation. In this document, the process is analyzed based on three dimensions, the first is the communicative dimension, which refers to what the teacher says and why he says it, that is, statements, questions and purposes; the second is the interactional dimension, which refers to the place where he says it and to whom he says it; and since the argumentation takes place in an educational context, the epistemic dimension is considered, which refers to how he says it and why he says it. The product includes each of the episodes selected for the analysis, which begins with an argumentative intervention, in which the difference of opinion on the part of the teacher or a student is made explicit and ends with the closing. In the episode, the professor seeks to convince his students from his point of view, for which he draws on his knowledge and professional experience.

Given the purpose and object of research of this study, an adjustment is made to the conditions that should occur in the mathematics class for the development of the argumentation proposed by Solar and Deulofeu (2016). In this way, the following conditions are recognized: (i) Communicative and interactive strategies, (ii) Focus of the lesson, (iii) Task focus, and (iv) Professional knowledge. The indicators for each dimension emerge from the respective analysis.

Considerations on discourse

Given that the argumentation is expressed mainly orally and by a group of participants (Knipping & Reid, 2015), it is pertinent to consider some class discourse elements. Discourse and its terms are frequently used in studies in Mathematics Education (Lim et al., 2020). However, the term discourse is usually related to different approaches and traditions, which implies that no single interpretation is used (Ryve, 2011). However, as other researchers (e.g., Moschkovich, 2003) and given the perspective in which this work is inscribed, we adopted the notion of discourse presented by Gee (2008, p.161):

> A Discourse is a socially accepted association among ways of using language and other symbolic expressions, of thinking, feeling, believing, valuing, and acting, as well as using various tools, technologies, or props that can be used to identify oneself as a member of a socially meaningful group or “social network,” to signal (that one is playing) a socially meaningful “role,” or to signal that one is filling a social niche in a distinctively recognizable fashion

Discourse is considered something more than speaking or writing (Moschkovich, 2003), considered the language in use since it can be interpreted differently depending on the context. Furthermore, discourse refers to multiple processes through which people communicate (Planas et al., 2018), which implies considering it as a means and objective (Gee, 2008). For example, a discursive means of the teacher in class around the discussion and resolution of tasks and a goal is teaching-learning objects (Planas et al., 2018). This position is consistent with the purpose of the research since it is interesting to know what the teacher says and how he says it, the identity he takes when he says it, and the acts accompanying it.

In this paper, mathematical discourse is understood as the interventions by the whole class or in small groups, where the teacher and his students discuss mathematical tasks that take into consideration the understanding of concepts, operations, procedures, and their interrelations (Walshaw & Anthony, 2008). The mathematical discourse also includes “not only ways of speaking, acting, interacting, thinking, believing, reading, writing, but also mathematical values, beliefs and points of view” (Moschkovich, 2003, p. 326).

Likewise, this study explores the teacher’s mathematical discourse, which is considered an essential component of educational mathematics practice. It is understood as the selection, sequencing, explanation, adaptation, and *argumentation* of multiple situations. The teacher communicates with his students during the solution of a task in class to raise generality mathematics [italics added] (Planas et al., 2018).

It is not possible to characterize discourse as a series of individual actions, but rather as a social practice, where each intervention is related to previous interventions (Drageset, 2014). Therefore, the typification of teacher reactions to student intervention proposed by Ruthven and Hofmann (2016) is used, which includes: Approve, Disapprove, Repeat, Restate, Translate, Redirect, Probe, Expand, Revert and Devolve.

Method

This research corresponds to a study with a qualitative interpretive approach, where observation is used as a tool for data collection. It is intended to explore and describe environments and situations in mathematics class and produce in-depth interpretations to analyze the individual and collective actions of the mathematics teacher.

This article reports on Emma's class (pseudonym), a tenth-grade class with 32 students (pseudonyms used) whose ages range from 15 to 17 years (female group). In preparing her lessons, Emma follows the curricular plan designed by the educational institution, which is consistent with the statements of the Colombian National Curriculum Standards. The data correspond to six lessons guided by Emma. The episode presented in this article corresponds to one of these lessons, where Emma and her students discuss the following task: *Finding the value of trigonometric ratios of notable angles*. The task was developed during two lessons. In the first lesson, Emma, together with her students, finds the value of the sine, cosine, and tangent. In the second lesson, there is an autonomous work by the students accompanied by Emma interventions. The episode that is presented take place during the second lesson. Each episode begins with an argumentative intervention and ends with the closure. The argumentative intervention is preceded by turns that contextualize it. Not always, there is an argumentative intervention and a closure. More than one argumentative intervention or more than one closing may occur.

For data analysis, discourse analysis techniques are used in two actions: fragment and connect (Boukafri & Planas, 2018). Fragment to obtain more manageable units and connect to discuss data and results that have been treated separately. According to Boukafri and Planas (2018), the reiterations of fragmenting and connecting lead to three units of analysis: turn, episode, and lesson. At first, the analysis episodes in each of the lessons are identified, for them a tracking is made in each of the turns, both teacher and students, of the argumentative interventions, and of the respective closings, which indicates the beginning and the end of the argumentation. Then, in the unit turn, the reactions to the students' interventions are identified in response to the teachers turn, using the framework of Ruthven and Hofmann (2016). Responses are taken either when the teacher's turn starts the episode or when a student starts it. The turns are analyzed in the three dimensions: communicative, interactional, and epistemic. The actions of the communicative dimension relate to the framework of Ruthven and Hofmann (2016). Regarding the episode unit, argumentative interventions and closings are retaken, to identify purposes of the teacher's argumentation. And in a third moment, in the lesson unit, the adaptation to the proposal of Solar and Deulofeu (2016) is used to identify the conditions that activated the argumentation in the different episodes within a specific lesson.

Data analysis and findings

The analyzes are exemplified from an episode, where Emma is explaining the procedure that allows us to calculate the value of tan30 °. Together with her students they have reached the expression 1 / √3, the students seem to realize that they must rationalize, to which Emma asks them why they do this, marking the beginning of the episode. Given the interventions of the students, it seems that there is a certain level of understanding of the procedure to follow. Then, however, there is an intervention by Sofia and Mia, which reveals difficulties and requires the teacher's attention.

253	Emma:	[...] At what point do we rationalize? Why do we have to rationalize?
254	Students:	Because there is a root below.
255	Emma:	Because the root can't be left below and what is that called below?
256	Students:	Denominator.
257	Emma:	Denominator. Well, then it would be a tangent of 30 ° ... here it would be equal to 1 per root of 3, how much does that give me?
258	Students:	Root of 3.
259	Emma:	Root of 3 over the root of 3 by root of 3.
260	Sofia:	3 root of 3.
261	Mia:	Root of 6, right?
262	Emma:	Well, let's look at what did we say, last class? Turn back in the notebook.
263	Alice:	Root 3 square.
264	Emma:	Root of 3 square, root of 3 by root of 3 gives me root of 3 squared and what happens here?
265	Students:	They are canceled.
266	Emma:	What is canceled?
267	Bianca:	The exponent in the root.
268	Emma:	The exponent in the root? ... The exponent with the root. I have a tangent of 30 ° is equal to the root of 3 over 3

In this episode there are two situations that deserve attention within the teacher's argumentation. The first one, the anticipation of a difference of opinion through Emma's questions in [253], also considered as the first argumentative intervention. The responses of the students in the interventions [254, 256] allow Emma to identify a certain level of appropriation in said procedure, her intervention in [225, 257] consists of supporting the justification of the students and therefore presenting a partial closing. And the second situation, based on the interventions [260, 261] of Sofia and Mia respectively, show a difference of opinion and therefore correspond to the second argumentative intervention, since in addition to presenting different answers, they warn errors, before which Emma does not explicitly declare the error, but directs the justification for the students to realize it and convince themselves of the expected response, presenting the closure in [268].

Regarding the communicative dimension, it is identified as a question from Emma, with which she seeks to probe the appropriation of what it means and implies rationalizing an expression, marks the beginning of the episode. This question is preceded by interventions from the students, before which Emma raises statements with which she approves, translates, restates, or reverts. Even though in a previous episode the notation of irrational expressions seemed to have become clear, a certain procedure takes place in turn [257] before which the students express in [258] $\sqrt{3}$ as an answer. Emma intervenes in [259] to restate it, to which Sofia raises $3\sqrt{3}$ as an answer, and Mia $\sqrt{6}$ as an answer. In the following interventions, Emma uses questions and assertions, with which she takes up procedures that have already been discussed. Also, in the intervention [255] distinguishes another type of reaction: request, which, given the purpose of this research, makes it necessary to continue expanding the table proposed by Ruthven and Hofmann (2016).

In the interactional dimension of this episode, participation, media, and class norms, convincing and discussing, stand out as characteristics. The intervention [262] seems to be interesting, in which Emma refers to previous lessons by inviting the students to review her notebook. In addition to involving them in the answer to a question, she attends to a question of the students in handling with roots, using an indication to be followed by all, because she knows that it is a question that had been discussed.

On the other hand, they are characteristics of the epistemic dimension: treatment of the mathematical object when requesting clarity [255], taking up other lessons to verify the use of a certain procedure [262], error handling [262] and, procedures and answers to verify [253, 255, 257, 264, 266, 268] and validate a given answer [268]. Emma's actions described in this dimension allow us to suggest how her experience in this degree of schooling allows her to justify to the students the use of a certain procedure, insist on when and why it should be done and anticipate possible difficulties with the treatment of the same.

Before describing the purposes of the professor's argumentation in this episode, the particularity of it is highlighted, in it an argumentative intervention is identified [257] during an explanation process, which alludes to the fact that within the professor's mathematical discourse also of explanations there is also argumentation, and it reaffirms the consideration of explanation as a different process from argumentation. Emma seeks to justify the procedure for solving the task, to achieve this, she poses a question [253], considered here as an auxiliary argumentative intervention, which is preceded by interventions by the students, in which answers to the question [255, 257] and therefore a first closure. However, the episode does not end there, it is only until the intervention [268] that the closing of the episode can be recognized, when Emma states the answer to the task. In this way, the purposes in this episode are highlighted: to clarify the properties of the mathematical object, the root, involved in the solution procedure of the task [253, 255, 257, 264, 266], to clarify the solution procedure of the task [255, 257, 262, 264, 266, 268], and dealing with different points of view that do not match the expected response of task [262].

In relation to the conditions that triggered the argumentation, the following are identified: (1) The communicative and interactive strategies, the questions associated with the task solution procedure draw attention, in which Emma seeks to retake procedures, so much so that they were treated in the same lesson or in previous lessons [257, 262, 264], which seems to be related to the statement of the task "Finding the value of the trigonometric ratios". It seems that the students still have difficulties in handling procedures: rationalization, root management, and fractional operations, necessary to respond to the task. (2) The approach to the lesson, the argumentative intervention refers to understanding, that is, Emma observes the work of her students and begins the argument by asking the reason for a procedure [253]. And (3) professional knowledge, Emma seeks to link the work done in previous lessons [262], since she seems to be aware that, to respond to this type of task, the students should be able to handle different concepts and procedures. In addition, it is repetitive the action of inviting students to name mathematical objects in an appropriate way [255, 266].

Conclusions

We can affirm that the argumentation of the mathematics teacher constitutes a complex formed by three articulated dimensions: communicative, interactional, and epistemic, whose objective is to educate students in mathematics. The primary intention of the teacher is for students to understand mathematical objects, and for this she puts into play resources that are in these dimensions. The use of the teacher's reaction typology for the identification of own actions in each characteristic stands out as a success, and the contribution of this research by expanding said typology is worthy of note. It is important to point out how communicative actions allow observing the participatory perspective of learning, to which the research alludes, where not only the teacher's intervention is recognizable, but also that of the students.

We recognized how Emma links her students in answering questions or situations in a class lesson, how she raises justifications to convince students of a certain answer to a task or question, and how they use students' concerns to open the space for discussion and participation, and how she seems to be interested in the students not only correcting an answer but also being participants and aware of the errors when carrying out a procedure for solving a task. The link between the actions of the epistemic dimension with professional knowledge is also evident, since Emma's actions indicate her experience, which is, it can be corroborated in how she raises justifications for certain procedures, insisting on when, how and why they should be made.

The purposes of the argumentation warn how Emma in addition to presenting the solution of a certain task, she is interested in having her students participate in the class lesson. It was useful to recognize the argumentative interventions and the closings in each episode, which in addition to delimiting said episodes, allowed us to recognize situations in math class lessons where the teacher argues. The conditions that activate the argumentation are recognized both in the interventions of the students and of Emma, they account for specific moments of a class lesson where the teacher should be attentive and prepared to face them.

Scope and focus

Thematic Working Group 10 has been active since CERME3 in 2004 and is focused on discussing mathematics education within the realms of *the cultural, the social and the political*. TWG10 builds on the premise that mathematics education is always more than an encounter between an individual and a mathematical object in a classroom setting. Instead it views such encounters as shaped, produced and reproduced in the context of wider cultural and societal contexts that are inherently social and political (Black et al, 2021). At the same time such encounters are viewed as contributing and constituting the contexts in which they are embedded in ways that reproduce, challenge or disrupt power relations. Research in this group is characterized by multiple efforts to reflect its own double-role in analyzing, shaping and reconfiguring mathematics education practices.

The group is specifically interested in research that investigates how diversity and difference is produced through mathematics education and how this process affects the possibilities, opportunities, obstacles, privileges and disadvantages associated with mathematics education. This includes issues of gender, race and ethnicity, language, socio-economic status, social class, disability, life opportunities, aspirations, worldviews and ideologies, school systems, governance structures, space, and settings. Additionally, diversity and difference may occur in relation to who is doing the research and who is being researched, posing methodological issues of an ethical, ontological and aesthetic nature. As all these multiple diversities and differences intersect, a reflective approach is expected in reporting what might be the effects of specific mathematics education reforms but also in discussing the effects of particular theoretical frameworks that attempt to frame and discuss mathematics teaching and learning in praxis. The group strives to unravel and contradict power relations between fields and how research depends on both theoretical and empirical assumptions in practice. Hence, to decenter oneself as a researcher is a strategy and joint endeavor in the team's collaborative work during the conference.

Organisation of TWG 10's work

Understanding research as a practice that is situated within diverse cultural, social, and political contexts has implications for practicing research *in situ*. During the conference, we organized the group to work in a way that 1) cultivated a change of perspective and fostered reflexivity and 2) created awareness about the effects of power relations that are always embedded in efforts to understand, theorise and research diverse practices in mathematics education. Hence, we began our work in the group by posing core questions that are ongoing and have been a theme throughout the years in TWG10:

- What forms of exclusion or inequality are being created through mathematics education and how their visibility or invisibility becomes framed or narrated?
- What possibilities or opportunities are there for disrupting inequalities or exclusion in mathematics education?

Due to the rapidly changing landscape in education following from the pandemic, we added the questions:

- What new forms of exclusion or inequality has the COVID 19 pandemic created or made visible for mathematics education? Or are existing inequalities merely amplified?
- What possibilities or opportunities has the COVID 19 pandemic created for disrupting inequalities or exclusion in mathematics education?

In an attempt to make poster contributions visible to the whole group, they were also presented in the first session. This potentially stabilized the hierarchical distinction between papers and posters by ensuring they were reported and discussed by the group.

The development of reflexivity was sought by following the principle of *peer presentation*, namely that authors do not present their own paper, but give a short (5 minutes) presentation of a colleague's paper. This peer presentation included a description of the main ideas from the perspectives adopted in the paper and the formulation of questions from the presenter's own perspective. This was followed by a discussion in smaller break-out rooms between the author and reader - but also other TWG participants joined and added their reflections to the discussion. We finally held a joint discussion on interesting, important and challenging topics to put forward. In this way we sought to recognize research as a collective assignment that takes place in a network of social practices of dissemination, reflection, writing and problematizing as we shared and developed ideas, methodology and theory.

In order to encourage and also facilitate drawing connections between papers, they were grouped in sessions that were broadly thematic in some way. A number of papers focused on mathematics in a range of out-of-school settings provoking us to think about how localized mathematical practices relate to the mathematics curriculum. Ferrarello et al. presented findings from their project on Mathem-ethics in a prison setting in Italy, Solares-Rojas & Goizueta looked at the embedded mathematics utilized by Hñañu women embroiderers in Valle del Mezquital, Mexico and Francois & Vandendriessche reported on their ethnographic study of local activities described as string figure making in Northern Ambrymese society, Vanuatu. These papers raised debate regarding the paradox of validating mathematical knowledge from marginalized communities using academic mathematics and whether this really legitimates embedded mathematics or simply marginalizes in a different way.

Another common focus across the papers was teachers' understandings and experiences of marginalization and diversity. Gildehaus & Liebendorfer highlighted how a group of pre-service teachers often experience being positioned as less valued in comparison to mathematics majors on university mathematics courses. Xenofontos et al. explored teachers' perceptions of the causes of marginalization in school mathematics in Scotland highlighting the dominance of social class in teachers' perceptions. Hummel & Bohlmann reported on pre-service teachers' understandings of diversity and their desire to acknowledge diversity in their future mathematics teaching but with limited knowledge of how to do so.

A third commonality between some of the papers was the recognition of diversity between students and how this might be both a challenge and a resource within classroom practices. In relation to gender, Foyn & Solomon focused on the challenges faced by a high performing girl, Sarah, whose experiences in the mathematics classroom are dominated by male performances of 'smartness'. The paper by Tiedke et al. focused on factors that influence the construct of low attainment prescribed by teachers - also highlighting the role of gender, in addition to self-concept and the quality of classroom management. A third paper by Ay highlighted differences between privileged and non-privileged students in their approach to modelling tasks outlining how more privileged students are able to unpack real world assumptions more readily when engaging with such tasks. Two papers also focused on recognizing differences between students as a resource for generating social transformation and change. Carrijo identified racial differences as a resource for investigation in the mathematics classrooms so that students may see their own lived realities in their mathematics activities. The paper by Ryan et al. focused on multilingual students' relocating of academic school mathematics across the home-school boundary - which, they argue, is a useful focus for pedagogic approaches that try to recognize home and community practices as a resource for learning mathematics.

Assessment was another theme that was addressed in two papers. Makrakis looked at how time and speed in national high stakes mathematics tests in Greece produces exclusion from mathematics. By contrast, Nieminen focused on an alternative framework that emphasizes students as co-designers of assessment (Universal Design for Learning), and explored how assessment frameworks may be designed to increase rather than hinder participation in mathematics and open up access for students with disabilities.

A larger group of papers investigated how research in mathematics education can produce social transformation both within the classroom and in society. Steflisch discussed teachers' perceptions of innovation in the mathematics classroom and categorized their responses into three types. The paper argues that those who struggle to stick to their pedagogic ideals rather than reverting to traditional pedagogic strategies may offer the most potential in terms of bringing about change. Lo Sopia et al. also focus on teachers' perceptions - but in relation to creativity in problem solving activities in the context of schools where there are high levels of student drop out. In addressing resistance to pedagogic change at a local level, Reinholz et al. discuss EQUiP - an observation tool which offers teachers/mathematics faculty with data on the link between social demographics and student participation in their own classroom as a tool for professional development. Plunger highlighted the necessity of learners' reflective processes for using mathematics to critique society - particularly, in relation to context orientated reflection. Buttitta & Di Paola discussed the concept of cultural transposition as a means to decentralise a didactic practice from a specific social and cultural context. Finally, Wright introduced the concept of socio-mathematical agency to critical mathematics education, which he defines as "the ability to use mathematics effectively to argue collectively for social change".

Another theme focused on developing critical thinking through mathematics education in ways that question socio-political bias and inequalities. Steffensen et al. presented findings on students' views of the pandemic that demonstrate their ability to identify and use mathematics-based argumentation as a means to question a range of social inequalities. Andersson et al. highlight the challenge in doing this, outlining how discourses regarding the necessity of mathematics to democracy and citizenship make the development of critical thinking with mathematics difficult. Kollosche focused on questions regarding the epistemic status of mathematical knowledge itself. He proposed the ‘styles of reasoning’ framework as useful to critical mathematics education since it can help highlight the socio-political bias of mathematical knowledge without dismissing its objectivity altogether.

Finally, several papers discussed the COVID 19 pandemic and the way it has made visible hidden inequalities produced and reproduced through mathematics education. Vosbergen highlighted how the pandemic created a mathematics teacher shortage in the Netherlands which manifests a break down or blurring of the distinction of public and private education leading to questions regarding the quality of teaching and de-professionalization. Abtahi et al discussed the ethical issues made visible by the pandemic in doing mathematics education research. Lastly, Applebaum et al. pinpointed the pandemic as an example of a dystopic crisis that should be embraced by critical mathematics education suggesting the need to appropriate the tools of dystopia for local and indigenous struggles.

Common conclusions and open questions

TWG10 historically is orientated towards perspectives and methods that are more visibly located in other related disciplines of reference but not yet established within the field of mathematics (Abreu et al.). There is a strong emphasis on critical social theories and the questioning and deconstruction of concepts that are often taken for granted in mathematics education more broadly. CERME 12 was no different in this respect - group discussions on the above papers led to questions around the epistemic status of what we might term as ‘academic mathematical knowledge’ and how mathematics circulates across institutional boundaries with everyday practice. What are the power hierarchies at work here? This led us to consider whether the pandemic has created further in/out relations in mathematics education which linked back to the first session and indeed the conversations held within TWG10 in the CERME11 ¼ pre-conference meeting.

Additionally, a key tension in the group was around modelling and its function in critical mathematics education. Clearly, global crises such as the COVID 19 pandemic and climate change are generating more interest in modelling as a way to develop awareness and action for social justice. But the group also questioned how far modelling a role plays in the hegemonic reproduction of injustice and inequality and how we might prepare teachers to discuss this with students. This leads to a broader question: are we, as mathematics educators creating the problems of injustice that we are trying to solve?

Ethics is an important aspect of any mathematics education research. The two projects referred to in this report were designed to explore the experiences of migrant and/or Indigenous students and teachers in mathematics classrooms. Both were disrupted by the COVID-19 pandemic's shift from in-person to online data collection. The disruption led us to become aware of ethical aspects of the research that were not previously evident to us. We present and discuss several such moments of awareness, including the "shielding" role of school making some injustices invisible, and challenges of participatory online interaction.

Keywords: Research ethics, migration, ethical awareness, mathematics learning, mathematics teaching

Introduction

The presence of migrant or Indigenous pupils in mathematics classrooms can create educational and cultural vulnerabilities, as well as opportunities for transformation and adaptation. Generations of Indigenous students may have experiences of tensions in classrooms through acts of assimilation and colonization. Students and teachers can experience tensions of transformation and adaptation as they engage in classroom practices on the basis of what they know about their own and the community's history and culture (Gutiérrez & Rogoff, 2003). Within mathematics education, there is a long history of research focusing on challenges and possibilities experienced by migrating pupils (e.g., Planas & Civil, 2013) and Indigenous pupils (e.g., Meaney et al., 2012). In our two projects, in Canada and in Norway, we study the impact of migration and the history of colonialization on mathematics learning from the perspectives of students and teachers. Each project aims to examine potential richness afforded by students' multiple cultural, linguistic, and educational experiences of mathematics (education): e.g., different ways of doing, learning, and thinking about mathematics. The aim of the Canadian project is to promote intercultural dialogue. The Norwegian project aims to develop strength-based pedagogies. We will describe the projects and then elaborate on the data collection methods and how they changed as a response to the pandemic. Finally, we discuss some of the ethical issues which emerged in relation to this transition.

The Canadian project: Migration in Mathematics Classrooms (MMC)

More than 500,000 children in Canada come from migrant backgrounds (Statistics Canada, 2011). The Canadian study defines migrant students as those who, as a result of a change of residence, experience differences of culture and language in school. Thus, migrant students include those whose families have moved for economic or employment reasons, refugees, and Indigenous students whose families have moved between Indigenous settings and an urban school. We ask: how does migration affect students' and teachers' experiences of school mathematics? We designed the study to create multivocal, intercultural dialogue among families, children, teachers, and school systems, in relation to the learning and teaching of mathematics, by highlighting "unfamiliar" mathematics for teachers and for students following Tobin (e.g., 1989). Initially there were to be two phases of data collection. In the first phase, our research group would visit ten schools and work with five students in each school. These students would take the role of co-researchers, gathering accounts of their prior and current experiences of mathematics, from their parents, and in their mathematics classes. Near the end of our meetings, students would synthesize their collective experiences in the form of collages to communicate students' experiences with teachers. At the end of the group meetings, a round of interviews with each individual student would take place. The second phase would focus on teachers' experiences. We would share each collage with teachers from the school, to understand their responses to students' experiences of migration. Teachers, as co-researchers, would collect observations of their own practice, noting shifts arising from their new understanding of their migrant students' experiences. At the end of this phase, teachers from the ten participating classes would compare the collages created in their schools, their responses to them, and resulting shifts in practice.

The project was interrupted by school closures from the COVID-19 pandemic. We redesigned our data collection, shifting it online, but continued with a multivocal, dialogic, layered approach. In the redesigned project, the two data collection phases are maintained but their character has changed. In the first phase, we planned ten virtual math clubs, each with six children in, meeting. virtually for five sessions and engaging in both synchronous tasks and "take home" activities to work on with parents/siblings to share at the next session. At the end of each math club, we hold interviews with each student and, if they wish, a family member. The second phase will include six virtual groups of mathematics teachers who will meet twice. We will share and discuss the student participant profiles with teachers, as well as examples illustrating children's cultural-historical repertoires with respect to mathematics. Teachers will be asked to reflect on information shared, their reactions, and implications for practice. So far, we have collected data from two groups of children: 11 sessions of online mathematics activities with 7 children ages 8 to 12.

The Norwegian project: Mathematics Education in Indigenous and Migrational contexts (MIM)

The Norwegian project investigates challenges in mathematics education in times of societal changes and movements. The aim is to promote education responsiveness to diversity, and through participatory research methodologies develop and evaluate strengthening pedagogies. These are research-based pedagogies building upon participants' strengths and assets. They may be identified by examining past positive experiences; encouragement of hope and optimism and development of emotional satisfaction with the present (Seligman &

Csikszentmihalyi, 2000) moves away from cultural-deficit orientations and instead promotes achievement for all students. We address how different languages and cultures may either challenge or support the mathematics learning of two groups in Norway, Indigenous and migrated students.

Migrated students perform lower than their Norwegian peers on national tests in mathematics (SSB, 2019), as do Sami (Indigenous) students (Udir, 2018). Sámi mathematics teachers are decolonizing their school mathematics through developing culturally based examinations (Fyhn et al., 2016), interdisciplinary teaching (Nutti, 2013) and activities building identity and pride based on cultural heritage combined and language revitalization (Huru, Räisänen & Simensen, 2018).

We had planned to collect data in four rounds including: (a) conversational interviews, (b) video- and audio- recordings of planning and enacting of various practices and pedagogies, (c) collection of artefacts from discussions and classrooms (e.g., student work), and (d) collective discussions to reflect on the work together. Starting with the students, then teachers, and if required, school leaders, community members, we would start with the “core” and work our way out to the periphery. Moreover, because history and context are central to this work and to shed light on the other findings, the final phase of the project would include collection of relevant policy documents and media analysis.

This plan was interrupted by school closures in the pandemic. Our researchers were not allowed to visit schools for at least the first year of the project. Thus we flipped the order of data collection to start with a larger media analysis and online interviews with school leaders and community members. Participatory work features a democratic model that challenges traditional ideas of who can produce, own and use knowledge. It honours and grapples with tensions from bringing together ways of knowing and generates new forms of knowing (and being) (Morales, 2016). The pandemic interfered with this important principle for data and analysis.

Ethics in mathematics education

In each project, the research team grappled with the disruption of the pandemic and became aware of moments of interactions that led to ethical perplexity. A conversation among the teams emerged, focusing on ethics. Varela (1999) explains that acquiring ethical know-how is a:

> skillful approach to living […] based on the pragmatics of transformation that demand nothing less than a moment-to-moment awareness of the virtual nature of our selves. In its full unfolding, it opens up openness as authentic caring. These are radical ideas and strong measures for the troubled times we have at hand, and the even more troubled ones we are likely to have. (p. 75)

In the troubled time of the pandemic, we made changes to our practices. To remain ethical demanded ‘nothing less than our moment-to-moment awareness’ of ourselves as researchers and of our practices. In doing research, our approach to ethics is pragmatic and relational and promotes equity. It is pragmatic because we understand that rules and standardized procedures can lead to inequity and can even be unethical. As researchers, being ethical as we conduct research involves working to develop an ethical awareness and to make decisions with this awareness (Varela, 1999). The ethics are relational because our research involves relationships with participating students and teachers. Moreover, we understand that our practices as researchers are produced in relation to our understanding of our participants, and their responses are similarly in relation to us. In this sense, research ethics are dialogic.

Some ethical awarenesses

In this section, we report on some ethical awarenesses about relationships that arose as a result of the pandemic's disruption—in some cases, relating to new approaches to data collection, but in other cases, relating to broader aspects of the research. By nature, crises are unique. Thus, the ethical dilemmas arising for mathematics education researchers in this pandemic are unprecedented in many ways. Nevertheless, there has been some discussion (probably not enough) considering research in contexts of social conflict. Vithal & Valero (2003) pointed to the impact of conflicts on research questions and the theories that relate to the questions. So far, the pandemic has not changed the fundamental research questions in either of our studies, though it is changing the order in which questions are addressed in Norway. Further, we know that when we write papers we often adjust the research questions from the ones we foresaw. Thus, we expect some adjustment to our questions. Nevertheless, Vithal and Valero suggested a move toward critical theories and participatory research in conflict situations, and both of our projects already take these approaches.

Relationships with children and their families no longer mediated by school

In any research project, relationships are built between researchers and participants. We hope that these relationships extend beyond what is necessary to obtain data. The transition to online data collection made visible schools' roles in facilitating such relationship-building. If we had been visiting schools, the schools would mediate the relationship between researchers and students and their families. In Canada, we are now attempting an online approach that reaches out to families directly using the connections we have in the group—at least one participant school had an established relationship. The Norwegian project started later and has not been able to establish such relationships.

Given that the children are minors, it is appropriate that researcher interaction with them is mediated. Schools are well-positioned to do this normally because the system has experts who are at least somewhat familiar with educational research. The families and children may trust the researchers on the basis of their trust in the teachers who invited the researchers into their classrooms. When the mediation of the school is removed, then who plays this important role? Community organizations may feel ill-equipped to mediate in this way due to their unfamiliarity with this kind of research. In Canada, participating students have joined the project through their parents. What if students were not as interested in the math club as their parents?

Questions arise when schools do not mediate research relationship: What is the nature of a school's mediating role in relationships between researchers and children/families? If the school is not there (e.g., in this pandemic) how can/should researchers manage relationships with families and children?

Different mathematical knowledges are valued differently

Whose mathematical knowledge is highlighted? The Canadian data collection methods entail doing mathematical activities with students with a migration background. The Norwegian research addresses minoritized students which includes Norwegian Indigenous children whose voices rarely, if ever, are heard. While designing, conducting, and reflecting on mathematical exchanges, a tension emerges about whose mathematics is highlighted.

In the original Canadian project, the goal was to get insight into migrant students' experiences of the 'standard' mathematics taught in school. By participating as researchers in their own classes, their account of these experiences would be important data (rather than our own observations of the class). In the revised project, the mathematics activities are facilitated by members of the research team. The distance in the original design is lost. We acknowledge that these tensions cannot be resolved. We all bring our ideas and experiences of mathematics (our repertoires) to the project, and we 'see' participants' repertoires through our own. In the revised project, we are now more entangled in the interaction between different mathematical repertoires.

In the Norwegian project, the plan was for participatory research with schools in northern and southern Norway. We planned for close collaborations with students, practicing and becoming teachers and school leaders. We had planned to start the participatory work as the heart of the research, in close partnerships with students and teachers in their classrooms. However, the pandemic forced us to reconsider. Instead of being present in the classrooms: noticing, interviewing and observing for positioning and storyline analysis (e.g., Andersson & Wagner, 2019), we changed our plans and started from the periphery. We decided to analyze the societal discourses first through a media analysis, and second, zoom-interviews with all school leaders and some some of the teachers. Through the media analysis we identified positionings that were made available to migrated and Indigenous mathematics students in this public discourse through seven prominent storylines about youth from minoritized cultures and/or languages in Norwegian news media (Andersson et al., 2021). The ethical question we ask ourselves is, how will our knowledge about these storylines in the public discourse influence our data collection and analysis when we as researchers now move from the periphery towards the center, into these schools in the post-pandemic Norway? Careful ethical considerations are needed in every stage of the research to make it possible for us to avoid reproducing the public storylines in our analysis and research texts.

Relationships online

In both projects, we became aware of how the online environment has the potential to change relationships. In the Canadian project, as the location of data collection changed from school to the virtual space (as students and researchers are physically at their home), aspects of the role of school are made visible to us. School conceals differences among students; the four walls of the school appear to be shielding students from these differences and to offer a sense of security. Inspired by Fasheh's (1998) question, "Which is more fundamental? Outward peace or being true to our humanity?", we ask: What sort of an "outward peace" is created by schools and what becomes invisible by this portrayal of peace? What deeply rooted inequalities are given permission to be ignored in an "equal school"?

In Norway, zoom-interviews also show this approach. Some of our researchers are insiders, or at least known, in some of the northern and Indigenous communities where we do our research, getting interviews has been relatively easy. In (most) Indigenous communities where we do not have those types of connections this has been harder. This reminds us of the importance of establishing trust in research in tight communities. Experiences of colonization enhances the need for members of the communities to know where we as researchers are coming from and understand at least some of the underlying history and storylines (see Battiste, 2007). Our research is based on participatory practices, and we wonder how we can be truly participatory online? Are we able to establish partnerships and trust in the schools and communities during a pandemic and in post-pandemic periods? We also wonder to what extent the research incorporates the insider's perspective online, especially in the participatory context and with participants as co-researchers. How do we build trust in a video-conference medium?

We note that answers to this question will help us think about how we build trust, incorporate insiders' perspectives and take care of those participating in face-to-face interaction too. But now, we are interested in trust-building in the new mediums. How do we as researchers understand the context of participants if we cannot physically observe the context? As both projects' original plans were interrupted and we do not know the extent of online and virtual data collection in the new 'normal', we need to be concerned with how our understanding is impacted. We are becoming more aware of the impact of our observations outside the formal data collection on our interpretation Practices.

Concluding thoughts

Through this presentation, we have described some of the ethical awarenesses that have arisen for us as we reworked two research projects in the context of the pandemic. We have focused on awarenesses about relationships in mathematics education research, focusing on the role of the (absence of) schools, the impact on how different knowledges are valued, and the effect of the online environment on relationships. We hope that the conversations with the CERME12 community will not only help us reflect on the ethical dilemmas that we are facing, but will also open up a discussion about ethical issues related to data collection in cyberspace and beyond.

Mathematics curriculum discourses on democracy: critical thinking in the age of digital traces

Christian H. Andersson[1,], Lisa Björklund Boistrup[1] and Helena Roos[1]

[1]Malmö University, Sweden; christian.hans.andersson@mau.se

The use of people's online digital traces has given rise to concerns for democracy. The digital traces may affect the individual's life in unexpected and negative ways. Such traces may also be of importance for understanding the spread of disinformation and the like. This paper reports on a Foucault inspired discourse analysis of the Swedish upper secondary mathematics curriculum. Two discourses are construed in the intersection of critical thinking, democracy, and this new technology. Skovsmose's concept of mathemacy is used to identify what is critical knowledge and what is not. The first construed discourse is, "With knowledge in formal mathematics, critical thinking on democracy will follow." The second is, "Rather a personal career than a critical citizenship." Neither of the discourses promotes a need for mathematics education to change due to new technology with regards to critical thinking.

Keywords: Critical mathematics education, digital traces, democracy, discourse, curriculum.

Introduction

We leave digital traces of our actions online. They are used in algorithms that update the feed in social media and provide us with search engine results. This enhances experiences and makes them more personalized. However, most users do not know the exact mechanisms behind what is seen on the screen. In conjunction with research across various fields, this gives rise to concerns about citizens' ability to critically assess mechanics of democratic elections, economic exploitation of vulnerable social groups, and the flow of (mis)information, etc. Our interest in this paper is in how this critical gaze is highlighted in school and in governing school documents, especially in mathematics education.

This paper reports on a discourse analysis of the current Swedish mathematics curriculum for upper secondary school, adopted in July 2021. The analysis is inspired by the viewpoint that teaching mathematics is a political activity due to its contingency and sociological impact (Gutiérrez, 2013; Valero & Orlander, 2018). Since society is in a state of constant change, there is always a need to assess whether the curriculum is in tune with contemporary societal challenges. The analysis takes a particular interest in potential issues for democracy related to the new technology of collecting and mining people's digital traces. By democracy, we mean a way of living together in a society with a shared belief in values such as equality and equity, and where different opinions can meet in debate without any hampering interference from misinformation. One incentive for writing this paper is to contribute to an exploration of how critical thinking for democracy can be nurtured within mathematics education, as in e.g., critical mathematics education (Skovsmose, 2005). The specific aim of the paper is to investigate curriculum aspects of the current situation of critical thinking in relation to democracy and this new technology. This could inform future explorations of what can be improved (C. H. Andersson, 2021). The research question is: what discourses can be construed in the intersection of critical thinking in relation to democracy and the changing role of mathematics in society due to the new digital technology?

Digital traces and democracy

The following examples are intended to illuminate some topics that we view as possible to draw on in a version of mathematics education which includes a focus on critical thinking in relation to digital traces and democracy.

Digital trace data is processed in algorithms to extract information that was never explicitly there. This fuels the new technologies of machine learning and artificial intelligence that are increasingly becoming a driving force in the economy (Villani et al., 2018). Data can be, and is, used to prey on vulnerable social groups with targeted advertising (O'Neal, 2016). If the workings of the new economy are opaque to most citizens, democracy has few regulatory controls to alleviate such ramifications. With knowledge of how targeted advertising works, citizens could also start to think critically about it in new ways. When machines learn from human behaviour, there is a risk that undesirable attributes flaws such as racism and sexism may be embedded in the algorithms and lead to discrimination (Villani et. al., 2018). If this happens to the algorithms that steer and select information online, these algorithms could become a structure that reproduces social injustice. The risk is exacerbated if the algorithms are believed to be neutral.

Social media can be used to change voting behavior (Bond et. al., 2010), which has been attempted on a large scale to support a particular candidate through the use of digital traces (Sabbagh, 2020). This means that the digital trace you leave can act as someone else's tool without your knowledge, and furthermore be used against your interests. It is debatable to what extent this is successful, nevertheless the strategic use of digital traces has become an integral part of election campaigning. Attempts to swing public opinion can also operate through personal digital traces since they cluster people into groups with similar interests. Such groups are used as levers in disinformation campaigns where group members' views are cultivated and directed (Starbird et al., 2019), demonstrating another way for the digital traces to act as tools for others.

Digital traces are relevant to take into consideration when understanding search engines. One example is how these attributes more relevance to clicked links (Shah, 2021). When sensational (mis)information is uploaded, the resulting clicks out of users' curiosity increase its visibility in new searches, which then result in even more clicks, and a relevance feedback loop that changes further search results. The interaction between human behavior and the algorithms can propel the visibility of the sensational, rather than the relevant. This knowledge may be the basis of a new perspective and critical thinking in relation to news found with search engines, for example.

Previous research in mathematics education

Critical Mathematics Education (CME) has a long history through the work of Freire, Frankenstein, Skovsmose, and others, of engagement in how mathematics education could support democracy (e.g., Skovsmose, 2005). There is research addressing topics around new technology and democracy, for instance how people meet new technology albeit being unaware of how mathematics operates in it (e.g., Straehler-Pohl, 2017), the need for mathematics education to address computer science (e.g., Borovik, 2017), and students' ethical reasoning when data science is discussed in mathematics education (Register et al., 2021). However, we have been unable to locate any research with a specific interest in mathematics in relation to critical thinking on the ramifications for democracy of digital traces, the specific interest of this paper.

Democratic values aimed at in governmental documents in Sweden

Democracy occupies a salient position in the Swedish Education act (Sveriges Riksdag, 2021), stipulating that education shall convey and anchor the "fundamental democratic values "on which Swedish society rests" (4 §, chapter 1, our translation). It is not specified, however, if this means merely conveying democratic values as such, for example how education is organized, or whether students furthermore should attain *specific knowledge* that supports the sustainability of democracy, such as through developing argumentative speech skills. Other steering documents and government agencies have the option to add such levels of detail. Concerning search engines, Sundin (2015) showed that the Swedish primary and lower secondary school curriculum treated them as neutral, and thereby hindered critical media literacy. More recently though, the Agency of Education has in different ways started to express the need for compulsory school pupils to be informed on how the algorithms of search engines work (C. Andersson, 2021). The mathematics curriculum subject to analysis in this paper is thus enacted in a time of increasing awareness of the importance of online algorithms, and is a part of a collection of documents that have the overarching of aim of conveying and anchoring democratic values.

Theory

This paper takes a dynamic view of theory, meaning that theory adapts to the questions asked. The paper coordinates (Prediger et al., 2008) Foucault's (e.g., 1995) framework with CME (e.g., Skovsmose, 2005). Coordination is achieved through using Foucault's framework for how knowledge, practice, and the dynamics of structure and agency are intertwined within institutions; while CME is used to pinpoint the characteristics of mathematical knowledge from mathematics education that, if the discourse allows, could benefit the development of critical thinking. Coordination of the two frameworks takes place only within the frames of this paper's research question.

Foucault's (2002) framework defines discourse as language use, norms, habits, artifacts, institutional praxis, etc. A discourse is a collection of such matters together with the discourse's rules of formation that act as gatekeeper for the creation of objects (including abstract) that can be a part of the discourse. There is also an enunciative function of statements which is the action performed by them (Foucault, 2002). Through the limits of what is said and acted, including what cannot be said within the discourse, discourses portray structure-agency dynamics and how knowledge and power are produced and linked. This can be related to agency in educational institutions or within an educational system (Boistrup, 2017).

The second theoretical framework has a CME perspective, since we draw on Skovsmose (2005) to introduce *mathemacy* as a competence that is a "reference to mathematics, in the broad sense of the term, but also reference to a notion like democracy interpreted as a way of living … [and] a capacity to modulate, and to see a situation as open to change" (pp. 187). Critical thinking is similarly defined in this paper as the *competence to think beyond the most common practice of the local milieu, realize the contingency of situations and evaluate alternatives*. The similarity enables us to use characteristics of mathemacy for critical thinking. Skovsmose (2005) addresses three distinct types of knowledge related to mathematics, rephrased by us as (1) mathematics knowing itself; i.e., dealing with mathematics notions (2) pragmatic knowledge; i.e., applying mathematics notions in different situations, and (3) critically reflecting on such applications including the consequences of different mathematical decisions in people's lives. The third knowledge type, reflective knowledge, is an important characteristic for the development of mathemacy, whereas the other two are not always required. This has affected the analysis, which is described below.

Methodology and Process

Data

The 27-page national mathematics curriculum for upper secondary school in Sweden begins with a preamble followed by the general aim of the subject. Then follow 11 course titles, each of which is described by two sections: *central content* to be taught and the *knowledge requirements* for each grade (The National Agency for Education, 2021). The 11^{th}, and last, course's central content does not stipulate any specific content but just give examples of possible content, and is excluded from our analysis. The ten remaining courses are divided into three parallel tracks, vocational education, social sciences and art, and science and technology. Many words and phrases in the central content are repeated across courses, or in the descriptions of grades within or between courses. The document is in Swedish. Quotes in this paper are translated to English by the authors.

Method of analysis

The analytic procedure was a back-and-forth process between three steps, though, for clarity, they are described as three steps following each other. The first step was to formulate codes. Codes were allowed to be intersectional to encompass interplay between concepts. The code *individual* was used throughout the analysis corresponding to when students were mentioned separately and in subgroups. Two codes were related to the first two knowledge types identified by Skovsmose (2005), i.e., (1) mathematical knowing itself and (2) applying mathematics. The code *to-do* encompasses limited and specific tasks within the realms of either of the knowledge types (1) or (2). The code *to-know* concerns mathematical knowing, either in (1) mathematics itself, or (2) in relation to applications of mathematics. Two codes were needed to pinpoint Skovsmose's third knowledge type, critical reflections of mathematical applications (called reflexive knowing). One of these codes is *to-judge*, which concerns all instances where there is a judgment of mathematical methods or other mathematical acts. The other code needed for fulfilling the reflexive knowing is *society*, which concerns instances where mathematics is connected to the wider context beyond school.

The second step was to use the analysis program Nvivo. Using the program's tool *cases*, the document was divided into overlapping sections: preamble, aim of the subject, central content, knowledge requirements, and the different educational tracks. Every piece of coding was thereby labeled with at least one case referring to its locality in the document. The outcome was analyzed by both quantification and interpretation. An example of the former is statistics on the simultaneous appearance of codes. An example of the latter is investigating whether codes tend to appear close to each other, e.g. in the same sections of the text. Another example of the latter is reinterpretation of statistics due to the repetitive nature of the text.

The third step was discourse analysis inspired by Foucault. This analysis was based on the first two steps of analysis, which gave information about patterns of what is written and what is not. This informed us about what the rules of formation of objects for a construed discourse could be. At this stage there were many alternatives for such rules and, consequently, for possible construed discourses. To reduce this complexity, we followed Foucault's (2002) suggestion to start with what appear to be tensions in relation to our research question. Discourses are broad and general in the sense that both sides in a conflict within an institution or a discipline can use them, or they can remain invariant across other kinds of tensions. Consistency was achieved by identifying an enunciative function for the statements, so that what first appeared to be a tension or contradiction was dissolved in light of how the rules of the particular discourse work. Each such consistent view on the research question, based on rules of formation of objects and specified enunciate functions for statements, became a construed discourse named with a phrase capturing its central theme.

Main findings and construed discourses

The construed discourses in this paper are (1) *with knowledge in formal mathematics, critical thinking on democracy will follow*, (2) *rather a personal career than a critical citizenship*, and (3) *society as an aim but not to be assessed.* Since the third discourse differs from the others with its focus on assessment, it is outside the scope of this paper and will not be described in the findings.

The first discourse, *with knowledge in formal mathematics, critical thinking on democracy will follow*, has formal mathematics as a vehicle to have mathematics education updated to the new digital technology and any related issues with democracy. The curriculum's preamble posits, "as society is digitized, mathematics is used in increasingly complex situations" (The National Agency for Education, 2021, pp. 1). However, the document never explicitly follows up on what this change means for mathematics education, nor does the curriculum make any statements that can be construed as being about critical thinking. One of the codes for critical thinking is *to-judge*, and it has a textual separation from the other codes. For instance, it has few simultaneous appearances with other codes, and it is separated by punctuation from other codes in a way that is not typical of the rest of the text. A similar textual separation of codes exists for the code *society*. This does not only mean that *to-judge* and *society* are separated from other codes, but it also means that they are separated from each other. Hence, the text does not connect the markers whose simultaneous appearance could have indicated critical thinking on a societal level. There is only one instance of a simultaneous appearance of *to-judge* and *society*: "[f]urthermore, the teaching must contribute to the students developing knowledge about the significance and use of mathematics in other subjects as well as in a professional, social and historical context" (The National Agency for Education, 2021, pp. 1). The coding of *to-judge* is too weak here for critical thinking, and derives only from the word "significance" (Sw. betydelse) as a value-laden word. Instead of explicitly describing critical thinking, or how the new digital technology is affecting mathematics education, the curriculum describes mathematics education in other ways. It is described as something that the students shall be able *to-do* (307 occurrences) and *to-know* (145), and to a lesser degree *to-judge* (57). When "judging" occurs, it is typically found in students assessing the plausibility of their answers in problem solving, which further emphasizes *to-do* as the most prominent since it concerns the outcome of students doing. The closest the text ever comes to students questioning, not only answers but also methods, is in the central content: "[e]valuation of properties and limitations of mathematical models" (pp. 3). However, there is no discussion of alternative models or any arguments for choosing between them. Overall, the text mainly describes mathematics education as something that concerns separate individuals and their ability to perform tasks. This can be seen as situated within Skovsmose's description of mathematical and pragmatic knowledge, with little reflective knowledge. This is underpinned by the analysis of the tandem appearance of codes, which clearly shows a strong link between *to-do* and *individual*. The occurrence of this pair is most common in the knowledge requirements. The absence of any explicit statements on critical thinking in relation to democracy, and the absence of anything on new technology after its mention in the preamble, have the same root in this discourse. They are interpreted as redundant by the in lieu salient position of performing mathematical tasks. In this discourse, it is sufficient for students to know formal mathematics. This knowledge will provide them with a sufficient toolbox, and since formal mathematics does not change, no further pointers on how to use it in the context of democracy or new uses of digital traces in society are needed. The rules of formation do not allow the creation of the object *student's mathematically guided critical thinking on democracy*, because that object is subsumed into the object *student's knowing mathematics*. The discourse does not in any way dispute the need for mathematics education to engage in critical thinking or democracy; on the contrary, the enunciative function for statements on mathematical tasks is to show how to do this. Formal mathematics resolves the issue!

The second discourse, *rather a personal career than a critical citizenship*, is orientated around tensions within the text. One tension from the viewpoint that steering documents may concretize overall aims, is that the code *society* first has a clear presence in the preamble, is reduced in the aim of the subject, only mentioned sparsely in the central content, and is non-existent in the knowledge requirements. Navigating through the steering documents from the overarching aim in the educational act down to individual students' learning goals seems to leave a trace of diminishing pronounced societal aims. The only other topic in the text that goes beyond the classroom setting is in mathematics for professional life. In contrast to the societal aim, however, the notion of mathematics to support a career is still clearly present in the central content. There is even a separate subsection only for this in the courses for vocational education; for other tracks there is specific content included that resonates with their education track, such as geometric sums (useable for calculations on loans) for economically oriented study-programs, and vectors (for physics) for science and technology. In relation to our research interest, this discourse *does not* promote the need for mathematics education to engage in critical thinking related to democracy, including in relation to any new technology such as use of digital traces. When the text mentions society these functions as lip service to the overarching aim in the education act. The enunciative function in this discourse for society thereby creating a hindrance to any actual engagement with it.

The two discourses described above can both be connected to previous research. The discourse, *with knowledge in formal mathematics, critical thinking on democracy will follow*, has similarities with Valero and Orlander's (2018) description of an implicit assumption in mathematics education of the intrinsic power of mathematics that automatically gives students access to powerful and universal reasoning. They describe it as an often dominant view in curricula formulation, and note that a tension has been identified in research between this view and views that center more on uses and applications of mathematics. The discourse, *rather a personal career than a critical citizenship*, resonates with Jablonka's (2003) description of mathematical literacy for developing human capital, which emphasizes economic growth for both the student and society.

Discourse analysis is an interpretive process that can take different routes. The analysis in this paper provides merely one way of viewing the mathematics curriculum. In this case, the construed discourses challenge the notion of a curriculum that is regularly updated due to new uses of mathematics in society. Taking the (self)regulation induced by discourses into account, a change towards a more vivid ambition to nurture critical thinking for the benefit of democracy in a rapidly changing society would therefore be held back by the inertia of these discourses. Therefore, it would be interesting to investigate if teachers and students also engage in these or similar discourses when reflecting on digital traces, and critical mathematics education, vis-à-vis democracy. In that case, it might be possible to identify if, and how, they engage in other discourses which may alleviate some of the official resistance to change.

Actionable Mathematics Education Via Dystopia

Peter Appelbaum[1], Charoula Stathopoulou[2] and Constantinos Xenofontos[3]

We suggest that Mathematics Education theory and practice can find new directions through recognizing their dystopic characteristics, and embracing them as both the source of challenges and method of response. This contrasts with the generally utopic approach of most scholarship. We offer critical ethnomathematics education as a model for such an approach, since it has its own origins in lingering dystopic legacies of colonialism. A perpetual hopelessness and disempowerment is one implicit curriculum of contemporary mathematics education, where the mathematics once learns might help to describe things, yet hardly assists in transforming the reification of power and agency in society. Embracing dystopia rather than trying to circumvent it helps us see that it is more crucial to re-think curriculum than pedagogy.

Keywords: Critical ethnomathematics, curriculum studies, ethnomathematics.

An Introduction

We began our study with the recognition that school mathematics does not necessarily prepare society to respond to the most pressing crises of our epoch: severe weather and climate change, refugees from war and climate change, human trafficking and global economic injustice, etc. In early 2019, the world seemed unprepared for the COVID-19 pandemic, whether individually or via social policy. In particular, the situation created by the pandemic transformed many aspects of social reality globally (Możgin, 2020), as well as school reality (Bond, 2020; Niemi & Kousa, 2020), spreading fear and insecurity, and making people feel unprotected. In general, we live in a time of acceleration (Virilio, 2012; Rosa, 2013), with precarious scenarios of evolution; yet the daily experience of the COVID-19 pandemic, in and out of school, leapfrogged doomsday pronouncements away from mythology or Revelation, and into a visceral idea of the end of the world. The focus on the pandemic can also be understood as a primarily "first world problem," in the sense that there were and continue to be far more urgent crises outside of the highly industrialized nations, in what is sometimes referred to as the "global south." This aspect of crises helps us to think simultaneously about whether school mathematics prepares humanity for anticipating and responding to global crises, and at the same time whether it enables humanity to recognize the legacies of colonialism that influence what is even appreciated as a crisis in the first place.

We apply strategies from "critical ethnomathematics education" for understanding parallel concerns of equity (opportunity and outcome) and curricular content choices. We do this because critical ethnomathematics has already demonstrated techniques for educators to theorize paradoxes of global crisis. "Critical ethnomathematics education" makes sense of mathematics education, both for preparing people to anticipate and respond to global crises, and for practicing pedagogies that address seemingly insurmountable, “dystopic,” crises in our environment, geopolitics, and the future of our planet as ever-present yet necessarily livable.

Social and Political Mathematics Education as Context

Ole Skovsmose (2021) proposes three types of relationship between mathematics and crises: Mathematics can (a) picture a crisis, (b) constitute a crisis, or (c) format a crisis. Are there parallels for mathematics *education*? Even as numerous mathematics educators would agree that significant cultural, historical, and political knowledge is needed to make sense of complex global issues (e.g., population movements of refugees and migrants (Xenofontos, 2015; Planas & Gorgorió, 2004), climate change (Barwell, 2013; Appelbaum & Stathopoulou, 2020), species extinction (Radakovic, et. al, 2018), local community problems (Gutstein, 2006; Hunter & Sawatzki, 2019)), typical school curricula worldwide is primarily formal, decontextualized (academic) mathematics, a manifestation of Western thought, Cartesian logic and ‘rationality’ rooted in a logic of domination and human-centric thinking, sometimes termed a logic of domination (Warren 1990). In this conception, purpose lies in generalizability, wide applicability to decontextualized concepts/methods, and in structures that manipulate variables across specific cases. This bird’s-eye view of human experience and deeply-rooted cultural patterns undergirded by Western assumptions of domination over nature are increasingly recognized as creating interrelated challenges of climate change, extreme weather, food production, and species extinction, demanding new directions of relation centred in social justice and alter-global social movements (Warren 1990, Appelbaum, 2018). Persistent dichotomies (e.g., people of Western culture(s) and Others) project one of the pair as the epitome of progress (despite its ignorance of other knowledge traditions and practices): mathematics education is seen in this was as a tool of power, oblivious of its failings (Gerofsky, 2010). Educational experiences curate forms of knowledge and exclusion, function as processes of normalization and epistemicide (Santos, 2007; Paraskeva, 2020), and structure the identification of differences across teacher, student, family and community cultures.

The catastrophic COVID-19 emergency demonstrated these processes of normalization and epistemicide more clearly than pre-COVID mathematics simply because it placed ongoing learning and teaching practices in a new context. Initial discussions -- politicians, media, medical experts, educators -- often amplified feelings of confusion and disempowerment. Some well-intending mathematics educators seized on the “teachable moment.” Remote education simplifies some aspects of instruction, complicates others. Some mathematicians and mathematics teachers used the virus to make mathematical concepts and skills accessible (Sullivan et al., 2020). An unprecedented number of blogs, websites, news articles, Tik-Tok videos, Instagram feeds, etc., used visual representations and analogies to explain exponential growth, the nature of meaningful evidence, model mathematical inquiry, or demonstrate the importance of mathematics in the study of a global pandemic. That is, we lived through parallel experiences: for school mathematics, the questions mostly became a matter of how teaching will be continued through distance learning, not a moment of curricular reconsideration; for public pedagogy, this was an explosive moment of graphs, metaphors, and a contestation of knowledge, demonstrating the superiority of social media over school in making mathematics relevant. Although public pedagogues successfully provided resources, and although there are many ways in which they created examples of how mathematics can help the public to understand their situation, feel informed and to witness themselves as in control of knowledge, we ask whether this was nothing more than a shifting of focus from school to popular culture of a more insipid and disempowering form of education, constructing a dystopian version of knowledge and knowing. We claim most of our many resources on using mathematics to solve real-world problems are caught in the trap of social and cultural reproduction, despite their claims to a certain overarching 'natural goodness' (Swanson, 2017). COVID-19 is an example: the majority of school and public pedagogy mathematical lessons focused on mathematical models of the behaviour of the epidemic, and not on a broader framework for interpreting the models of the world, or our experience of it (regarding modelling and problem solving, see English & Watson 2018; Kaiser & Brand 2015; Houston et al. 2010; Lingefjärd & Meiter 2010). Such public pedagogy (Appelbaum, 1995) mirrored standard textbook approaches –simplified, artificial models, glossing over details, confounding variables -- even as it dressed up key concepts and relationships in engaging video and animation. The more general observation is that the focus on the pandemic distracted from the enormous crises around the world that existed pre-pandemic, and continue to this day, inadequately addressed. This latter point indicates one more way in which mathematics education and its impact on problem generation and solving can have far-reaching consequences for what becomes the focus of attention, reproducing and amplifying global legacies of power, as well as related assumptions about what is a universally agreed-upon "urgent need."

Embracing Dystopia

Critical mathematics education embraces coloniality as both the problem and the method of social change; mathematics education can embrace coloniality and dystopia as its problem and method. Rather than searching for solutions to the legacy of colonialism, critical mathematics education recognizes the dystopia of coloniality as here to stay, and appropriates both western mathematics and the coloniality of school mathematics as its own tool, not for "dismantling the master's house," but for accomplishing local and indigenous goals of dignity and reconciliation (Appelbaum & Stathopoulou, 2020). This contrasts with the pursuit of utopian dreams. Those working to implement curricular reform imagine a post-dystopic vision; they try to overcome dystopia, and are doomed to failure no matter what gestural leaps they attempt. As Stein, et al. (2020) argue, "decolonization is increasingly treated as a site and subject of consumption and accumulation, not only of material benefits, but also of knowledges, relationships, experiences, and even critique itself" (p.44). This is why we urge avoidance of "decolonial critiques,' as is fashionable academic currency, arguing instead against solutions and alternatives to colonization within existing paradigms, regimes of property, and comfort zones. We understand "colonial patterns of relationship and colonial habits of being are reproduced at the very moment they supposedly become unsettled … when efforts made under the umbrella of decolonization are re-routed back into the same desires and entitlements that produce colonization in the first place," so that "the transformative possibilities and ethical responsibilities of decolonization are eclipsed, and decolonization itself becomes weaponized as an alibi to continue colonial business as usual." Fantasizing a possibility of decolonization is a fallacy, as is curricular reform. It is better to appropriate methods and resources of dystopia for alternative, local goals. In has sometimes been coined 'creolization' (Appelbaum, 1995, 2008).

This approach critiques reform efforts in general as typically enacting a utopian-fueled fantasy of leaping out of the current dystopia (see Popkewitz 2018, Lim & Apple 2016). A caricature of reform efforts would describe policy-makers as saying, “Oh, this didn’t work. Let’s try something else, which would be so great!” Instead of imagining utopias, designing them and promoting new curricula, teachers, and students to act as utopian characters, we urge the following: start with acknowledging that the current curricula, teachers, students, and policy-makers are currently actors in a dystopia. Instead of trying to escape that dystopia, we could appropriate tools of the dystopia for local and indigenous struggles. The dystopia is both the problem and the method. Even as we pursue local and indigenous appropriation of tools and practices of coloniality for locally-identified purposes, we recognize the problematic term “indigenous” as preserving and maintaining distinctions of colonialism. One might say that we are perpetuating the dystopia. A ‘composite’ definition of both terms, utopia and dystopia, understands how most utopias are linked by their commitment to a form of enhanced sociability, or a more communal form of living, sometimes associated with ideals of friendship, while their dystopian counterparts are substantively connected by the predominance of fear, and the destruction of ‘society’, as a polar opposite of friendship. Perhaps we can reframe indigenous in this sense of an ‘enhanced sociability;’ where enhanced sociability has been maintained for some period, “utopia” has been lived to some extent (Claeys 2013); and where the opposite occurs, “dystopia” is the relevant descriptor. Fundamentally, utopia and dystopia are mutually determining.

Mathematics Education in the time of war in Ukraine, in the time of COVID, in the time of mass migration from severe weather and famine … are here to stay, as is mathematics education in the time economic inequality, the breakdown of democracies ... Mathematics and mathematics education are at the heart of each crisis, serving at once as forms of knowledge with which we describe and come to know each aspect of the global crises together, and in erasing alternative forms of knowing and coming to know about our world and its future. Inherited from critical mathematics education is the key concept, “abyssal gap of coloniality” (Santos 2007) -- that separation literally and epistemologically between metropolitan and colonial societies. Even today, people who live in or whose origins are in former colonial countries -- and women, refugees, etc. -- are framed as inferior by structures of coloniality. This distinction also concerns people’s knowledge, a distinction that ignores the intrinsic value of various bodies of knowledge in favor of dominant social, political and economic structures. This knowledge is excluded and essentially erased, because the people who produce this knowledge are excluded as creators and finders of knowledge. Epistemological clashes between different kinds of knowledge, in particular, between scientific and non-scientific forms of truth, are only recognized once one takes a critical stance. One kind of knowledge—counting as true—is on the one side, while the ‘other side’ is relegated to mere “beliefs, opinions, intuitive or subjective understandings” that at best are issues for scientific inquiry. In this way “abyssal thinking” consists of distinctions and dichotomies that construct a divided world (Santos 2007, p. 45). It is supposed that people stay in a static situation – the dystopia does not change placement relative to the abyssal line. Yet people are also different, even if they share elements that define them on one side or the other (López, 2019; Benson, 2019). “Kinds of people are cemented through research and administrative apparati, but also through uprising and revolt" (p. 164). People are constructed in these kinds of ways for governmentality's purposes, but at the same time, since people are not just the object of static nominalism (Hacking, 2006), and not merely "passive receivers of imperial administration and control," they react in resistant ways.

Mathematics education expresses coloniality and other characteristics of power relationships through languages of accountability and global economic competition. Mathematics education is both experience and cause of this dystopia. We can explore ways to open imagination, giving learners spaces for creativity and knowledge of self, and in using problems posed by the students themselves; such a utopian imaginary of mathematics education can challenge the perspective of globalization, exploring for example alter-globalization (Appelbaum, 2018)–where there is space for solidarity, participation, self-determination, dignity, and reconciliation. However, there is no magic in pursuing utopia, as in contemporary rhetoric and its dreams of "Mathematics for All", "Life skills", "Citizenship", "Problem Solving," and "Mindsets." Language such as deregulation, climate, and inequality, relegated to those ways in which people "solve problems," establishes the abyssal gap between politics and life (Latour 2018). a language of culture, survival, justice, existence, land, and land reform might describe what is at stake with necessary clarity. Such language is central to critical ethnomathematics. What would mathematics education look like if culture, survival, justice, existence, land and land reform replaced numeracy, life skills, problem solving and mindsets in our rhetoric, framing of research and practice, policy documents, to dwell in dystopia rather than fantasies of various utopias?

Latour (2020) proposed a within-dystopia response to the pandemic: "Let us take advantage of the forced suspension of most activities to take stock of those we would like to see discontinued and those, on the contrary, that we would like to see developed." We advocate an analogous approach for mathematics education through the following questions, paraphrased from Latour.

What are the mathematics education activities, in and out of school and remote school learning, now suspended, that you would like to see not resumed?

Describe why you think those activities are harmful/ superfluous/ dangerous/inconsistent, and how their disappearance/suspension/substitution would make the activities you favour easier/ more consistent. (Make a separate paragraph for each of the activities listed in the first question).

What measures do you recommend to ensure that the workers/employees/agents/entrepreneurs who will no longer be able to continue in the activities you are removing find support for their transition toward other activities?

Which of the now-suspended activities would you like to develop/resume or even create from scratch?

Describe why your newly developed or resumed activities seem positive to you, and how they make it easier/ more harmonious/ consistent with other activities that you favour, helping to combat those that you consider unfavourable. (Make a separate paragraph for each of the activities you list).

What measures do you recommend to help workers/ employees/ agents/ entrepreneurs acquire the capacities/ means/ income/ instruments to take over/ develop/ create these favoured activities?

In those places in the world where COVID-19 was experienced as the most urgent crisis, there were three main mathematics-related trends: (a) The greater need than we might have previously realized for the wider public to comprehend and interpret the mathematics behind models, graphs, etc., related to the pandemic, and in general as preparation for any crisis. (b) Perpetuating the same curriculum that did not prepare people for understanding the crisis in the first place even as schools focused during the pandemic on how to make (mathematics) teaching more accessible. (c) Inconsistencies between what the public needs and what schools are doing. To understand why these trends unfolded, we analysed school mathematics and mathematics education as dystopia. Critical ethnomathematics is a model of how to embrace dystopia rather than to try to overcome it or avoid it. Critical ethnomathematics education is an approach that addresses dystopic elements of contemporary mathematics education practice while centering attention on coloniality and the need to exploit traditional school mathematics in ways that serve local cultural, political, and environmental needs, in a broader, ethnomathematical commitment to local and indigenous mathematical practices.

Social (in)equality through mathematical modelling? – Results of a case study

Ilja Ay

University of Münster, Germany; i.ay@wwu.de

Solving realistic mathematical tasks with multiple possible solutions can require many competencies. At the same time, they can allow students to engage with a situation mathematically according to their own preferences. Previous studies seem to indicate that – through socialisation – socio-economically privileged students are more likely to acquire skills dealing with such tasks. This paper approaches the described issue qualitatively by comparing modelling processes of privileged and unprivileged student pairs. It turns out that privileged pairs, on average, spend more time on making real-world assumptions and they show a broader spectrum of assumptions compared to unprivileged pairs. Thus, it is discussed to what extent differences and similarities can be traced back to students' habitus and how modelling tasks may thus increase both social inequality and social equality.

Keywords: Social (in)equality, mathematical modelling, qualitative content analysis, Bourdieu.

Introduction

In a variety of studies social background is associated with school success (e. g., OECD, 2019). This can be explained, among other things, by parents who are more or less likely to support their children's learning financially, culturally, socially and psychologically (OECD, 2019). Moreover, certain characteristics tend to be taught in socio-economically privileged households, such as argumentation and communication, discussing learning strategies or perseverance in problem solving (e. g., Weininger & Lareau, 2009). In the German educational standards for mathematics (KMK, 2004) such characteristics are described as competencies students are meant to develop. It seems that privileged students internalise a habitus through socialisation (Bourdieu, 1994/1998), which rather finds acceptance in school. Furthermore, in mathematics class students should apply their knowledge in real-world situations in order to be able to view natural, social and cultural phenomena from a mathematical perspective (KMK, 2004). The role of the social background when dealing with real-world tasks is, thereby, controversially discussed. While, for example, Piel and Schuchart (2014) show social class differences to be more likely to occur for reality-based tasks than for purely mathematical tasks, Ay et al. (2021) find socio-economic status to be less strongly related to the solving of modelling tasks compared to other tasks. This paper focuses on this field of research from a modelling perspective, by analysing and comparing modelling processes of privileged and unprivileged student pairs qualitatively (Schreier, 2012). Using Bourdieu's habitus, it thereby shall be discussed to what extent differences can be explained by students' socialisation and in what way results from other fields of research can be confirmed.

Theoretical framework

This raises the question of why socio-economic status can be related to certain school behaviours. For instance, the number of books on the shelf cannot yet explain how social inequality occurs.

According to the sociologist Pierre Bourdieu, there is a connection between one's socio-cultural position and the individual lifestyles. A mediator, Bourdieu calls *habitus*, stands between social position and individual patterns of thought and action. Hereby, one's habitus represents the disposition towards the world, such as habits, ways of life, attitudes, values, aesthetic standards, etc. According to the habitus-theory, most actions of individuals do not pursue an intention, but are an expression of their acquired dispositions (Bourdieu, 1994/1998). The habitus creates a scheme that individuals use to classify and judge other situations, objects, persons, actions etc. – and ultimately themselves. However, individuals usually do not consciously activate these schemes. Clearly, people from the same social class do not completely match in their habitus. Nevertheless, they are most likely to have had more similar experiences and, thus, match more in their behaviour than people from other classes (Bourdieu, 1972/1977). Thereby, a person's habitus can often be detected in little things.[1]

Social (in)equality and the processing of tasks

When addressing social (in)equality, a variety of factors such as migration background, language, gender and school systems, can be relevant. In this study, socio-economic status is considered as a central distinguishing characteristic since it measures family resources and their social position and thus aligns with Bourdieu's concepts. For some time now, empirical studies based on sociological theories regard how children process tasks. In one study, children are given 24 pictures showing food. They are asked to group the pictures so that they fit together well. It turns out that the unprivileged children sort the pictures more often according to their own experience, such as 'tastes good', while the privileged children are more likely to sort the pictures according to more abstract criteria such as 'vegetables' (Holland, 1981). Similar results can be found in other studies. Students are shown sketches of two tables showing pizzas and seats. On one of the tables, there is one more pizza, but also two more people can be seated here. Students are asked which table they would join and why (Lubienski, 2000). In her study, the unprivileged students are more likely to focus on real-world concerns (e. g., arriving late) instead of using the task to learn generalizable methods (using relations to make comparisons). The author states that this experience-based orientation could hinder unprivileged students in understanding the mathematical ideas behind the situation. On the other hand, the author finds several instances of unprivileged students being concerned with getting the algorithm that solves the task, getting frustrated and giving up more quickly when facing barriers.

However, looking at social diversity in a fruitful way also entails considering the needs and strengths of unprivileged students. Previous research suggests that it might just be topics that are problematic, communicative and relevant to students' real world that enables them, regardless of social background, to participate in the classroom according to their own abilities and experiences (Nasir & Cobb, 2007).

[1] Bourdieu's habitus-theory is often accused of determinism. Bourdieu argues that individuals can be free and creative within a certain frame. According to him, certain life courses are not predetermined, but more or less likely.

Mathematical modelling

Mathematical modelling can be defined "as the solving of a realistic problem" (Maaß, 2010, p. 288). Modelling problems are often accompanied by authentic situations, missing relevant information and multiple possible approaches. During a modelling process students need to identify and collect relevant information, translate a respective situation into mathematical terms, structures and relations, work within the mathematical model, interpret and check results with respect to the corresponding situation (KMK, 2004). This distinguishes modelling from embedded tasks, as embedded tasks use contexts from the real-world, but "have no real relation to reality. The factual context is of no importance regarding the solution" (Greefrath et al., 2017, p. 933). Following the rules of the game of embedded tasks, students can usually be successful in the mathematics classroom if they ignore the context of a situation, use recently learned formulas and don't question the motivation as well as the action of involved persons (Verschaffel et al., 2000). When approaching modelling tasks, these rules hardly apply. Instead, real-world~~s~~ assumptions and everyday knowledge are crucial for modelling.

Synthesis and research questions

Now, why should one draw on Bourdieu's concepts of habitus when discussing social (in)equality in mathematical modelling? The metaphor of a game might clarify this. When playing a game, players need a practical sense or a *feel for the game*. That is the "mastery of the logic or of the immanent necessity of a game – a mastery acquired by experience of the game, and one which works outside conscious control and discourse" (Bourdieu, 1987/1990, p. 61). This construct coincides to some extent with the game in mathematics classroom (Verschaffel et al., 2000). Both have rules to be followed in order to be successful, have an inherent logic that is not revealed and are acquired through experience. Looking at previous empirical findings, it seems that many unprivileged students lack a feel for the game when they draw tasks with (seemingly) multiple possible solutions on everyday experiences rather than more abstract constructs such as the mathematics beyond (Cooper, 2007). According to the "habitus as the feel for the game" (Bourdieu, 1987/1990, p. 63), different immanent rules apply in different fields so that habitual behaviours are manifested in social classes. Bourdieu (1984) describes the habitus of lower social classes as a *taste of necessity*, focusing in everyday life on practical, functional and technically necessary things, on conformity and on immediate satisfaction of needs. Such taste may thus become apparent when observing students organising food according to their desires (Holland, 1981) or discuss planning to meet their friends (Lubienski, 2000).

It remains unclear, to what extent these concepts can be applied to mathematical modelling. While the inclusion of reality-based experiences is highlighted in other studies as being disadvantageous for task processing, it might just be seen as an advantage in modelling. For example, assumptions are essential and, thus, a real-world model is still being developed. Therefore, characteristics attributed to unprivileged students might be advantageous here. Still, a wide set of competencies which can be seen as useful for modelling has been attributed to privileged households in various studies (e. g., Weininger & Lareau, 2009). This leads to the following research questions:

To what extent do socio-economically privileged and unprivileged pairs differ in making assumptions in the modelling process? To what extent can conclusions be drawn about students' habitual behaviour?

Methodology

A qualitative approach is chosen with the aim of understanding, reconstructing and interpreting contexts and processes. 24 tenth-grade students (around age 15) from two urban secondary schools in western Germany belonging to four different classes partake in this study. The student body of both schools is considered culturally diverse and heterogeneous in performance due to schools' locations and concepts. Pairs of students are shown a picture of a giant pizza (www.bit.ly/2WRXOSU) and get the information that they are planning a party for 80 people and the task to figure out how many pizzas to order. The context comprises a realistic situation and the giant pizza can be ordered in the students' home region and, thus, may have a connection to their everyday life. To enable drawing conclusions, the pairs are put together according to their socio-economic status. Therefore, student and parent questionnaires are carried out for measuring students' HISEI (*Highest International Socio-Economic Index of Occupational Status of both parents*). The HISEI is determined by the professions of the parents and takes income and educational level into account (Ganzeboom et al., 1992). Students who fall into the upper quartile of the nationwide comparison of the HISEI are considered socio-economically privileged. Reversely, students from the lower quartile are considered unprivileged. The survey is divided into the three phases of observation, stimulated recall and interview. A qualitative content analysis (Schreier, 2012) serves as foundation for the data evaluation. Therefore, all phases are being recorded, transcribed, and coded. The evaluation follows a quantitative-qualitative approach by comparing categories quantitatively, identifying qualitative differences and supporting concise differences by means of transcript excerpts. To ensure coding quality, codings were carried out and compared by two independent persons. In addition, inductive subcategories were developed based on the research interest. For example, processes that serve to develop a real-world model are divided into subcategories like *simplifying*, *organising* and *assuming*. Simplifying contains e. g. repeatedly reading text segments or identifying missing information. Organising is often reflected by students drawing or measuring, and assuming entails that assumptions and premises are set or estimated using everyday knowledge. Whereas simplifying represents a surface-level processing strategy, organising and assuming represent deep-level processing strategies (Schukajlow et al., 2021). This paper will present some results on these subcategories. For readability and recognition, privileged students are assigned a three-syllable name and unprivileged students a two-syllable name.

Results

The modelling task Giant Pizza allows multiple possible approaches and solutions. The students can decide individually, which meaning they attach to the photo, to what extent they estimate using everyday knowledge and objects of comparison and to what extent they use mathematics to solve the task. Accordingly, a wide variety of approaches are found. Firstly, there are five pairs (Dominik & Krystian, Vivien & Oliver, Tobias & Benedikt, Samuel & Nathalie, Dawid & Leon) who choose a mathematical approach by estimating the diameter of both the giant and an ordinary pizza, determining their areas, comparing them and generating a real result. Secondly, some pairs (Julia & Florian, Samuel & Nathalie, Michael & Paulina, Kaia & Mila, Ronja & Hürrem) choose an extra-mathematical procedure by dividing the giant pizza visually and concluding the number of giant pizzas to be ordered. Thirdly, there are pairs (Amba & Bahar, Lena & Pia, partly Sofi & Aram) where the result is rather guessed. Regardless of their approach, all couples come to a final solution.

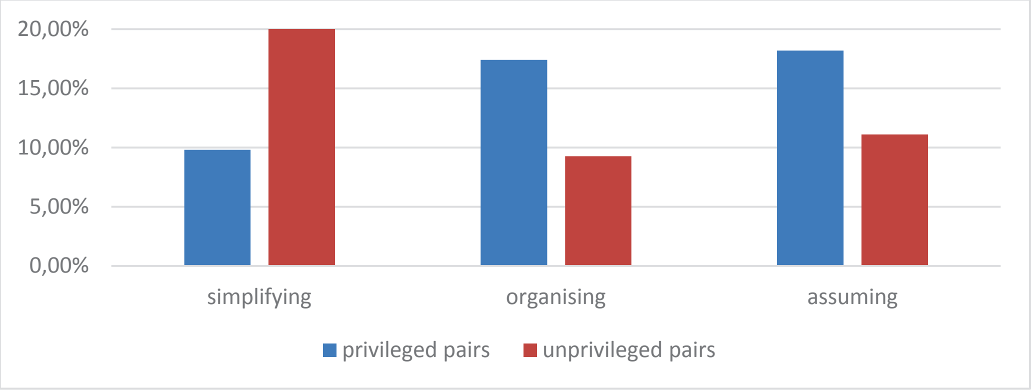

Figure 1: Contribution of the categories

Figure 1 shows that privileged and unprivileged pairs differ regarding their processes. On average, the unprivileged pairs deal more extensive with simplifying processes, whereas privileged pairs put a stronger focus on organising and assuming. In many processes, estimations play an important role, although not all students use them as part of a solution approach. Only the five initially mentioned pairs use everyday knowledge to estimate the diameter of the giant pizza. As objects of comparison, they use parameters such as the height of people or the dimensions of trailers. Additionally, there is a variety of other estimates and premises that pairs consider relevant (see Table 1).

Table 1: pairs' everyday knowledge and objects of comparison

… observed only in unprivileged pairs	… observed in both groups	… observed only in privileged pairs
size of the angle of a pizza slice	diameter of an ordinary pizza; pizza per guest; width of a person; gender / age of the guests; comparison with the school class	height of a person; size of a family pizza; size of a salami slice; length and span of a hand; length of a forearm; size of a pizza plate; dimensions of a trailer; size of a bun; thickness of the giant pizza; duration of a party; other foods at the party

On average, the privileged pairs do not only spend more time on assuming, they also show a broader spectrum of assumptions. Some are used to compare sizes, others for visualisation and others for validating the results. Five pairs use visualisations to generate a real result. Two of them (Julia & Florian, Michael & Paulina) thereby express objects of comparison, such as the hand of the women and the size of a pizza plate, to develop their model. Taking a look at the process of Kaia & Mila shows that they also use visualisation as basis for their approach. "How many pizzas do you think you can fit in here, normal ones? […] 1, 2, 3, ((tracing circles)) 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, shall we just say 20?" (Kaia, 04:42) As other students, Kaia carries out the visualisation without sketching. The pair does not estimate the diameter of the giant pizza and does not express objects of comparison to find out the number of ordinary pizzas that match the giant pizza. In the interview Kaia explains: "And there's the picture, then I have a rough idea of it and can put a guess in there accordingly.” (01:18) Even though she does not include any objects of comparison explicitly, she seems to have a sense of the size. Instead, she expresses other assumptions:

02:40	Kaia:	[...] if you're planning a party […] you have to assume that people are our age.
02:54	Mila:	Okay.
02:55	Kaia:	[…] if I we’re planning a party (.) I would do about half boys, half girls, right? […]
03:07		Let's say then that women usually eat a little less than men […]

Kaia thus relates the task to a situation that is close to her life: “It says YOU and a party with 80 people. […] people at a young age, they certainly invite people from their grade or from some hobby area, football or something else.” (03:07, stimulated recall) Other pairs are rather guessing a result. Amba & Bahar, for example, keep discussing what the intention of the task might be. Bahar explains what to do instead of calculating. “I don’t think we’re supposed to calculate anything there [...] we’re just supposed to say how many pizzas, whether that’s enough.” (03:22) Asking Amba about this during the stimulated recall she explains: “it’s a task where you just have to estimate and not really calculate. You can tell by feeling how much you need or don’t need. […] You don’t have to think much.” (01:16) Although they make a few assumptions and visualise to some extent, they mostly go back to repeatedly reading the task to find some hidden information. In the end, they guess a result.

Discussion

The aim of this paper is to uncover differences and similarities in the modelling processes of socio-economically privileged and unprivileged students as well as to draw conclusions about habitual behaviour. For this, 12 pairs of students work on the modelling task Giant Pizza. All pairs are organising or assuming in some way, for example sketching or using everyday knowledge. Nevertheless, the pairs differ noticeably in how deeply they engage with these processes and whether those lead to a further development of their models. The work assignment of the modelling task does not indicate that estimation is to be done using everyday knowledge or that mathematisation should be carried out. It stays hidden, to what extent reality is to be considered. Five pairs choose to calculate and compare the areas of the giant pizza to an ordinary one using estimation and everyday knowledge. Four of those pairs are assigned to the socio-economically privileged group. Five pairs divide the giant pizza visually and conclude the number of pizzas to be ordered. Here, all of those who expressed objects of comparison for their visualisation are socio-economically privileged. This is also reflected in the quantitative comparison. The unprivileged pairs engage more in reading repeatedly and talking about the relevance of the text elements, whereas the privileged pairs spend more time organising and assuming. Further, the processes of privileged pairs are characterised by a wider range of estimates and objects of comparison, which they use to develop their models and verify their results. It seems like surface-level processing strategies (Schukajlow et al., 2021) are rather used by unprivileged pairs while the privileged pairs tend to focus more on deep-level strategies. Relating these results to Bourdieu's game (1990), there are inherent necessities or logics in the modelling task. It seems that the privileged pairs are more likely to recognise them (as stated by Cooper, 2007). These necessities are contrary to the rules that usually apply for embedded mathematical problems (Verschaffel et al., 2000), where the situation has no relevance for processing. Those school socialised routines do not apply here, and thus habitual differences may be meaningful in explaining the observed differences.

With regard to the taste of necessity of lower social classes (Bourdieu, 1979/1984), the process of Kaia & Mila in particular stands out as one of the few unprivileged pairs who intensively deal with assumptions and everyday knowledge. While most privileged pairs estimate measurements and use objects of comparison, Kaia & Mila make assumptions regarding the organisation of their own party, for example the gender balance, the age of the guests and the leisure activities people are invited from. In accordance with the findings of Bourdieu (1984), Holland (1981) and Lubienski (2000) one could say, that the approach of Kaia & Mila conforms to everyday useful purposes. A notable difference to Lubienski's study however is that she considers it less appropriate when students refer to everyday experiences. Here, using everyday knowledge is not inadequate, but conversely, of central importance. Yet, differences are apparent in the use of everyday experiences.

Nevertheless, socio-economically unprivileged pairs appear across all described approaches. Besides, even though they are less likely to bring in estimates, a few seem to have a sense of dimensions of objects of comparison. Also, all pairs still achieve a final result, although the approaches vary in depth and adequacy. Unprivileged students who are more likely to give up (Lubienski, 2000), cannot be observed – despite frustration. Further, three unprivileged pairs use adequate mathematical or visual approaches to find a result. In addition, also pairs who follow a guessing approach show organising and assuming to some extent. Due to mathematical errors or misconceptions, such processes remain partly infertile or get stuck.

At this point, some aspects should be discussed critically. Bourdieu does not operationalise his constructs essentially, and his empirical findings refer to France in the 1960s. Thus, his constructs run the risk of being overinterpreted and his work can hardly consider more recent phenomena such as educational expansion. Nonetheless, current empirical studies can confirm Bourdieu's findings to some extent and, thereby, make his constructs more tangible. Bourdieu's theories and constructs are primarily sociological in nature and not directly designed for application in didactic research. Other factors that may be relevant here but are not (or can't be) controlled include other characteristics of social background and the individual school context in which the students find themselves. Moreover, it could also be fruitful to analyse this data through the lens of Bernstein's work on realisation rules and language codes. For methodological reasons, a dichotomization of socio-economic status is carried out into privileged and unprivileged pairs. This represents a simplification of reality, as socio-economic background is a complex construct that entails individual pathways in specific cases (Weininger & Lareau, 2009). In addition, more cases need to be studied to confirm the results.

In this paper, systematic differences and similarities between socio-economically privileged and unprivileged pairs of students in mathematical modelling can be identified. Thereby, behavioural patterns become apparent which may be attributed to students' socio-economic background, be it in relation to Bourdieu's habitus or to more recent empirical studies. At the same time, many fertile approaches are evident regardless of socio-economic status. Overall, mathematical modelling tasks seem to contain aspects that are rather difficult for unprivileged students. At the same time, the case analysis provides evidence that all students in some way can engage in the context and achieve a result (for a quantitative comparison see Ay et al., 2021). This paper, thus, provides indications that mathematical modelling contains aspects that may increase social inequality as well as social equality. In addition to investigating these findings further, it needs to be discussed what must be done so that all students can benefit from mathematical modelling regardless of their background.

Learning together with immigrant students: differences as resources in mathematics classes to fight racism

Manuella Carrijo

São Paulo State University, Brazil /University of Klagenfurt, Austria; manuellaheloisal@gmail.com

Several situations of racism and xenophobia indicate the need for the school to consider means to promote the recognition of diversity and foster inclusive learning practices considering immigrant students. Racism fosters prejudice and intolerance based on stereotypes that can limit the foreground of the students. Fighting racism requires recognizing differences. Meeting amongst Differences in mathematics classes call immigrant students to collaborate, and differences can be resources for investigation in mathematics classes. They can choose themes referring to their own realities. This is related to students' motives for learning mathematics for social transformation.

Keywords: Foregrounds, Racism, Mathematics education, Immigrant student.

Introduction

According to the United Nations International Migration Inventory, in 2019, around 3.5% of the population on the planet are migrant people[1]. Education systems across the world are becoming increasingly more diversified and are being called upon to rethink their policies and structures in the understanding that migration is a human right that includes the right to education.

The debate on immigration and its impact on education are not new. However, it is a relevant and complex theme that demands constant reflection. Several situations of racism and xenophobia indicate the need for the school to consider means to promote the recognition of diversity and foster inclusive learning practices considering immigrant students.

Education is a political act because it is at the service of certain proposals (Freire, 1972; 1998). It is therefore not disjointed, disinterested and neutral and can take a democratic or authoritarian position. Education can consider the demands of subordinate groups such as people with disabilities, women, LGBTQIA+ people, black people, immigrants, and other members of marginalized groups. It can be exercised in the sense of anti-racist practices.

Skovsmose (2020) argues that mathematics can shape society, and this requires considering an ethical dimension in the face of a series of social implications. Mathematics education has a political and social dimension and must propose reflections that express concerns about oppression and exploitation, poverty and economic inequalities, racism, democracy, and ecological crises.

Consequently, mathematics education is also not neutral and apolitical. It can give power to a group of people by making them more accepted in society's decision-making abilities. This fact is directly related to racism, not only in relation to access to mathematical knowledge, but also to the different types of knowledge that are considered or not in school. Also because of the misuses of

[1] Retrieved April 4, 2021, from https://nacoesunidas.org/estudo-da-onu-aponta-aumento-da-populacao-de-migrantes-internacionais/

mathematical knowledge and skills in the hands of exploiters to keep privileges of certain groups according to racist assumptions.

This essay is a result of doctoral research reflections. It is in the process of qualitative research in the phase of data production through interviews with immigrants and teachers who teach mathematics. The research is structured around understanding the possibilities of mathematics education for the inclusion of immigrant students (Carrijo, in progress—a).

This essay aims to foster the debate on the possibilities and challenges that contemporary migratory processes present to the field of mathematics education. Therefore, it seeks to problematize, reflect, and signal the learning possibilities that migrations and cultural diversity provide.

For presenting a theoretical discussion on themes addressed in my doctoral research, I will, in the first section, discuss racism and how it can shape the *foregrounds* of immigrant students. Next, I discuss *meeting amongst differences* as a learning opportunity for mathematics classes. Then, I address the necessity to include *themes with political and social implications* in the process to consider immigrant students' differences as a resource for mathematics education with antiracism proposes.

Immigrant students and racism

Racism is part of a larger, structurally based racial system and it is constantly being brought up to date. It is a systematic form of discrimination through practices that produce disadvantages or privileges for individuals, depending on the racial group to which they belong. Not only black people are victims of oppression of a racialized system. Latinos, Arabs, Persians, Gipsies, Jews, Asians are included in this system (Bonilla-Silva, 1997; Marinucci, 2018; Romero, 2008).

In terms of a globalised world, the inequalities are intense and based on ideas of belonging and not belonging, and of favouring and disfavouring. This includes precarious public services, social and political instability, and social and economic vulnerability. In this context, populations in migratory movements experience several forms of exclusion and violence centred on racialisation. In other words, racism fosters prejudice and intolerance based on stereotypes and produces xenophobic practices that perpetuate the oppression and subordination of migrant populations. In the social context of exclusion, differences can be used to degrade, a variant that combines fear and contempt.

Racialized societies reflect the ways in which the school reflects privileges and exclusions. Thus, racism permeates the way diversity can be understood as a problem and is often ignored or fought. In culturally diverse environments with the presence of students of different nationalities, this may be even more evident.

The denial of diversity in the educational context can mean barriers to learning. Vandenbroeck (2013) points to the following misconceptions: *Believing that all students should all be treated the same way*: This can put the teacher in a position to consider the criteria of a “standard” student, an ideal student. In this case, this “standard” student may be in the teacher's imagination a student who corresponds to a white, middle-class child who lives in a traditional family. *Reduce the student to a nationality or a cultural group*: it denies the enormous diversity present in cultures. There is a risk of having the stereotyped idea that the child of African origin will be a good dancer or that they will eat with their hands, for instance.

Because of stereotypes, students can be excluded from mathematics opportunities. Barros (in progress) has noticed that social stereotypes might shape and limit the *foregrounds* of groups of people. A *foreground* is constituted by the person's hopes, priorities, perspectives, aspirations, and possibilities in life (Skovsmose, 2014). In this sense, racism can limit the *foregrounds* of immigrant students by belittling and oppressing them.

About schools in the USA, Danny Martin (2019) states that black children routinely experience different forms of systemic violence in mathematics education. For Black students, teacher evaluation was nearly as powerful a predictor as math performance. The white frames and white imaginations of Black children's intellectual inferiority also emerge to produce injurious intellectual violence against Black children.

Also, for Carneiro (2005), the epistemicide acts beyond the annulment and disqualification of the knowledge of the subjugated peoples, but also by the restriction of access to quality education, by the processes of intellectual inferiority, underestimation of the cognitive capacity and discrimination present in the educational processes.

Fighting racism requires recognizing differences. And this demands educational processes that challenge and deconstruct homogenizing practices that do not recognize differences. For this, it is necessary to create spaces, actions and activities that encourage the overcoming of exclusion and social injustice.

In this context, the challenge for mathematics education is to mobilize inclusive ways of connecting to diversities. This includes seeking forms of understanding them as a learning possibility. That is, transforming differences into a pedagogical advantage and creating spaces, actions and activities that encourage overcoming exclusion and social injustice.

Meeting amongst differences for learning together

Racism is a narrative based on the oppressor-oppressed power relationship. The oppressed are transformed into almost a "thing" and subjected to domination, alienation, or marginalization. The dehumanization of non-white people guaranteed white supremacy and justified exploitation and social inequalities.

In this sense, the humanization process through education must raise awareness of people who are capable to reflect, analyse, critically position themselves and make ethical decisions in society. Mathematics can bring possibilities to understand the world critically, pointing out that situations of social inequalities need to be transformed.

According to Skovsmose (2019), the *Meeting amongst Differences* in mathematics classes highlights the meeting between people with different life experiences, cultural backgrounds, different fulfilled and frustrated dreams. Also, with different hopes, priorities, opportunities, perspectives, and aspirations. It is about the meeting between students with different *backgrounds* and *foregrounds.*

The meeting between immigrants and nationals in school and non-school environments demands respect for diversity. It requires valuing all the knowledge and experiences involved. This meeting is a possibility to learn about cultural, linguistic, religious, physical multiplicities, and so on, through mathematics.

Gutstein (2006) points to the possibility of *reading and writing the world with mathematics*. It means involving students in issues related to social justice. This can help to create space for human rights reflections and students can discuss reality and engage in social change. In this sense, immigrant students, through mathematics, can interpret their life contexts. Furthermore, they can recognize themselves as agents of change and use mathematics to change their realities into a sense of belonging. When writing about the world, the students can use mathematics to find solutions. When students want to understand, for example, the situation of labour market, they can identify themselves or members of their communities, schools, or churches as potential victims of work analogous to slavery. They can engage in denunciation and understanding the needs to combat precarious work circumstances, for example.

In a social racialized system mathematics can be used as a tool for oppression and dehumanization. Also, the access to mathematics, and hence to economic opportunities, is selective in protecting white and male privilege rather than being truly democratic in nature (Martin, 2013).

But on the other hand, the *Meeting amongst Differences* in the mathematics classroom together with *reading and writing the world with mathematics* can create an environment in mathematics classrooms to learn collaboratively. It is a possibility for students who are culturally and linguistically different, poor students, students with disabilities, and immigrant students or children of immigrants, for example, to have mathematics learning opportunities. This space is invited for *Dialogue Across Differences*.

Dialogue Across Differences supports place across differences by establishing dialogues between different worldviews. The participation of students in the educational process takes place in a dialogic educational process in which each student can express their worldview, can be heard, and be considered. Any kind of differences with respect to cultural backgrounds, religions, nationalities, economic conditions, or abilities is considered to provide learning environments where all students can learn together (Skovsmose, in progress).

Moura (2020) reports in his research the possibility of meeting between deaf and hearing students in mathematics classes. This context provides to students the movement to see the other, to wanting to be together with each other and to learn from each other, promoting cooperation and building equity.

Considering diversity at school goes through valuing and using student diversity as a resource for education and taking responsibility in the search for social justice and equity (Akkari, 2018). In this process of being together and being able to see the other as possibilities to learn together, the differences that students bring to the mathematics classroom are considered an important contribution to the construction of knowledge.

Immigrant students need to be considered in mathematics classes. Respect for diversity goes through recognition. This is the way to combat racism that mutually feeds practices in society and at school. The themes addressed in mathematics classes are also important bridges between differences.

Political and social implications issues in mathematics classes

Thinking about the issues that can create barriers in the mathematics learning of immigrant students goes through many issues. A widely debated point involves mathematics classes in linguistically diverse contexts. Barwell et al. (2016) point out that diversity in language can create hierarchies and exclusion since not speaking according to a standard form of the local language can put students in the position of "less educated". One must consider that each participant in a mathematics classroom, including the teacher, brings their own combination of languages, varieties and modes of speech that must be considered to strengthen dialogue.

On the other hand, speaking the local language is essential in the learning process context but does not guarantee that immigrant students are considered as equals in mathematics classes. Although the immigrant students speak the local language without any indication of foreign accent, it does not prevent them from exclusion and to be labelled as "foreigners" (Baber, 2007).

I consider it is also important to include *themes with political and social implications* in mathematics classes to support an inclusive environment. These themes can involve issues of interest of the students and mathematics can help in understanding and reflecting on different realities. Themes such as distribution of wages and wealth; racism and xenophobia; migratory contexts; housing and living conditions; or about representation in social media, are some examples of real contexts that can be explored. Immigrant students are called to collaborate, and differences can be resources for mathematics classes.

Skovsmose (in progress) proposes the landscape of investigation *Erosions of Democracy* focused on some specific issues. Students can imagine the functioning democracy of many countries with extreme differences between rich and poor, investigate the distribution of welfare and share particular interests. Also, Britto (2013) planned mathematics lessons that relied on the investigation into the visibility of black people in Brazil. Through a landscape of investigation, he proposed an investigation to some students about the presence of black people in magazines. Students had to look for pictures of children and consider whether these children were being registered in positive or negative contexts and reflect the visibility of black people.

These two examples illustrate the possibility of proposing investigation in mathematics classes focused on themes with political and social implications. Students can look and reflect on these questions and understand the reality in a broader way. Mathematics is a tool to understand society's injustices and adopt a critical stance towards inequalities. In classes with immigrant students, these themes can refer to their own realities.

However, considering social and political issues goes beyond simply bringing certain issues into the planning of mathematics classes. It is crucial when considering topics referring to the context of immigrant students, not put them in the place of "folklorization", of exotics. Also, the mistaken perception of “foreigners” as inferior intellectually and culturally, would contribute to the exclusion process.

According to Akkari and Maleq (2020), citizenship refers to belonging to a global community. Education must include demands for local and global challenges. In this sense, it is important to consider the global context in the themes addressed in the classes. In the landscape of investigation *Global Visibility Matters* (Carrijo, in progress—b), I consider Global Citizenship and the necessity to enable students to understand global issues in mathematics classes. It includes an awareness of other perspectives, a perception of oneself as part of the global community. It can help to develop a sense of social responsibility and solidarity towards less privileged groups of people. This perception is also part of the process to fight against racism.

Such an education demands a critical and transformative approach. It means considering and respecting diversity in mathematics classrooms, ensuring inclusive and equitable quality education, and promoting learning opportunities for all. Such an education must also value diversities in mathematical knowledge, which means considering and learning together with others, and acquiring different kinds of mathematics knowledge.

Concern about how racism can create exclusions within and outside the school context must be part of the teaching and learning process with immigrant students reflecting on their expectations for the future. I see the concerns of mathematics education moving towards combating racism by using social-political themes as tools to *read the world with mathematics*. But beyond that, you must *write the world with mathematics*. And this is related to students' motives for learning mathematics as it relates to their own future possibilities for life and social transformation.

Concluding Remarks

In a society strongly marked by great inequalities, the coexistence of differences in the same educational space has been a challenge in building education systems that truly consider everyone.

Only the access of immigrant students to school, supported by legislation, does not guarantee support to immigrant students in the process of belonging that is crucial to immigrant people.

Racism can create a learning barrier for immigrant students because of stereotypes that can limit their *foreground*. They can feel excluded in the mathematical learning process, or they don't see that mathematics plays any significant role in their futures.

Mathematics education has a political and social dimension and must propose reflections that express concerns about racism. It is necessary to embrace differences and consider the contexts and knowledge that students bring to school, developing actions that can impact the inclusion of immigrant students.

Meeting amongst differences for *reading and writing the world with mathematics* together makes it necessary to address political and social issues. These themes can refer to the immigrants’ reality and by investigation, students can learn together.

The next steps of the doctoral research will bring an analysis of reports of experiences lived by immigrants and also discussions with teachers who teach mathematics in Brazil about possibilities in mathematics classes with immigrant students.

Problems with variation in teaching/learning Geometry: an example of Chinese Cultural Transposition

Benedetto Di Paola[1] and Giulia Buttitta[1]

[1]University of Palermo, Italy; giulia.buttitta@unipa.it, benedetto.dipaola@unipa.it

This paper discusses some theoretical/methodological observation and some qualitative results coming from a Cultural Transposition experience, implemented in the Italian school context (grade 8), according to the methodology of variation, as one of the most significant problem solving approach in Chinese schools. The framework of the Cultural Transposition and the methodology of variation are presented as an important condition for "decentralizing" the didactic practice from a specific social and cultural context. We argue that looking at different teaching/learning mathematics strategies coming from East-Asia cultures can favor some cultural contaminations at school and allow students to a significant and unusual thought about "inclusion" and "diversity" in mathematics. Our variation problems are designed on 3D Geometry and are aimed to guide students in discovering the relationship between pyramid and cone areas/volumes.

Keywords: Cultural Transposition, Chinese problems with variation, Teaching Geometry.

Introduction

In a society dominated by cognitive zapping (Veen & van Staalduinen, 2009), which is constantly changing due to socio-cultural transformations, school is also changing. Learning and teaching trajectories are in fact, in many cases, varying in all countries. Looking at the new scenarios that the school is experiencing in recent years, the classroom realities that teachers and students observe are in fact nowadays changing, enriched by new approaches, new stimuli, new routines, new didactical processes that come from inside and outside social and cultural classroom contexts. These scenarios are in many cases complex and difficult to study for the mathematics education Communities. One pioneering work (Bishop, 1988) highlighted the importance of recognizing mathematics practices as social phenomena that are embedded in those cultures and those societies that generated them. D'Ambrosio (2010) pointed out that taking care about cultural and social issues into mathematical practices contributes to the understanding of cultures and the mathematics itself. Nowadays the awareness of taking into account cultural and historical contextualization in Math classroom teaching practices and the crucial assumption that culture permeates mathematics education practices is well known by all the mathematics education Communities. As Radford underlined, it has to be clear for teachers that the "configuration and the content of mathematical knowledge is properly and intimately defined by the culture in which it develops and in which it is subsumed". (Radford, 1997). Barton's research (Barton, 2008) reinforced the importance of a cultural perspective to study mathematics education phenomena, looking for example at different languages, and cultural manners. Agreeing to this perspective, we argue that culture gives students an opportunity to engage in mathematics focusing on concepts of inclusion, integration … to discover diversity as a resource! In some cases, the participation of many countries in international student competence tests (such as PISA) gives also the opportunity not only to compare different counties obtained results (Schleicher, 2019), but also to reflect on the educational practices, social, political and cultural environments that determined these performances. The last good results (as the previous ones) obtained by students from East Asia, especially those from Hong Kong and Shanghai, have prompted comparisons to reflect on the "reasons" for this educational success. It is well known (Spagnolo & Di Paola, 2010) that in these countries some learning approaches that compared to those of their Western peers produce different mathematical skills, in many cases more useful. According to Di Paola (2016) and Mellone et al. (2019; 2021) in these learning/teaching approaches there are many cultural factors linked to different cultural assumptions, educational practices and related cognitive styles (Bartolini Bussi & Martignone, 2013; Mellone et al., 2019). The same feeling is nowadays claimed by many teachers and researchers around the world: they in fact confirm how, in many cases, East Asian students, already educated in their own country, show more developed knowledge and skills in many mathematics subjects.

Theoretical framework

Bartolini Bussi & Martignone (2013), studying didactical phenomena discussed in the previous paragraph, emphasized the possible correlation between mathematical knowledge and the cultural context, cultural beliefs, in which they are and have been inserted and in which, therefore, mathematical knowledge is elaborated, assimilated and transmitted. In recent years, some other research works, through qualitative and/or quantitative approaches (Bartolini Bussi et al. 2017; Di Paola 2016; Mellone et al., 2019) pointed out how the *cultural diversity* could become, in this sense, an opportunity in mathematics Education (Kaiser, 2018). Researchers and teachers, coming into contact with educational practices adopted in other cultural contexts, are able to *deconstruct* (Derrida, 1967) them, reconsidering the themes of educational intentionality defined as background of their educational practices. Mellone at al. (2019), inspired by the Skovsmose's (1994) approach, defined the framework *Cultural Transposition* as "a condition for decentralizing the didactic practice of a specific cultural context through contact with the didactic practices of different cultural contexts". *Cultural Transposition* (CT) is a perspective that can allow the meeting between different mathematics education school practices/approaches, coming out from different cultural contexts, and define a potential space for reflection and awareness, and also development for researchers, educators, teachers, students (Mellone et al., 2021). CT involves those who implement/observe math teaching practices, coming from other cultures, to a "*deconstruction*" process useful to a re-interpretation of their own thought and consequently a possibility to change/improve personal (cultural) beliefs, values, and didactical principles. As Derrida stated defining the deconstruction, "*an analysis of the different levels in which a culture is stratified*" (Derrida, 1967). According to this perspective it is possible to recognize, valorize and include possible differences coming from "other" cultural Communities, linked to different values, principles, beliefs systems, happens, for example, in schools Communities (Mellone et al. 2021). To "get in touch" with different educational practices, coming out from different social and cultural contexts, can help researcher and teachers not only to become more aware of their social and cultural paradigm in regards to the classroom teaching practices but also to deconstruct their thought decentralizing their cultural expectation and assumptions and rethinking mathematics educational practices (Bartolini Bussi et al, 2013) in terms of "inclusion" and significant us of possible social, cultural "diversities". Of course this "changing process" is complex and needs more and more opportunities for reflection and *contamination* (Bartolini Bussi et al., 2017; Jullien, 2006). From the school student's perspective, *diversity and difference* in learning mathematics strategies appears, in this sense, a great opportunity, a good chance for something that maybe should not be favored without this "revolution" of prospective and without this change in the cultural system of reference. This could permit us to look at diversity and difference in mathematics and in mathematics teaching within the realms of the cultural, the social and the political. Spagnolo & Di Paola (2010), a pioneer of this kind of subject, presented this approach as a continuous open dialogue between cultures, societies, histories … useful to *cross* the didactics of mathematics. In the last years several researches (e.g. Bartolini Bussi et al., 2013; Di Paola, 2016; Mellone et al., 2021; Spagnolo & Di Paola 2010) discussed different CT experiences in Western school contexts. Several of them look to Chinese culture and in particular the use of Chinese practices of "*problem with variation*" for an early approach to Algebra in Primary school. What is a rather new (Leung, 2003), research subject discussed in this paper, is the use of this methodology in teaching/learning mathematics in Middle school and, in particular, in teaching/learning Geometry.

"*Problems with variation*" is considered one of the most significant mathematics education tools used in Chinese Primary school (e.g. Bartolini Bussi et al. 2017; Fan et al., 2004; Mellone et al., 2019; Sun, 2011). In the last twenty years, many researchers underlined the importance of the variation approach as a necessary condition for deep learning (e.g. Marton & Booth, 1997; Sun, 2011) and in particular for the learning of mathematics. variation is typically expressed by Rowland (2008) as a practice in structured exercises which varies considerably from country to country and from text to text. Sun (2011) underlines the use of variation problems as a tool "to discern and compare the invariant features of the relationship among concepts, solutions and contexts, and provide opportunities for making connections, since comparison is considered the pre-condition to perceive the structures, dependencies, and relationships that may lead to mathematical abstraction." (p.107). In Chinese language it is *Bianshi* (變式,) where *bian* stands for "*changing*" and *shi* means "form.". Yakes and Star (2009) looked to variation as a critical means for comparing and developing flexibility for learning mathematics already from the first school years. In China, the variation approach to problem solving is linked to many disciplines and used in all school levels from the first grades. The issue of variations in problems perfectly reproduces one of a Chinese proverb: "*no clarification, without comparison*", and it is "*in contrast*" to the assumption used in many textbook in different countries: "to consolidate one topic, or skill, before moving on to another" (Rowland, 2008). According to Rowland, comparing this problem solving approach with the one used, in many cases, in the Italian school (textbooks and/or practice), it is in fact possible to point out a strong difference, in some cases, common in several Western countries and related to the use of isolated problems/exercises, organized in progressive steps, strongly partitioned between them and so not very useful to define a possible abstract thinking looking relationships between concepts, strategies, algorithms (Cai & Nie 2008; Spagnolo & Di Paola, 2010). These considerations can be useful to underline the significant opportunity to proceed with *contamination experiments* (Jullien, 2006) aimed to get in touch with different "good practices", coming from different cultural contexts and linked to different language; different historical tradition; ideologies; school systems; governance structures… In this sense, the *contamination* appears as an important condition for teachers to "decentralize" their own didactic practice of a specific cultural context to something more wild, different, and in many cases more useful for their own mathematics students and could be included. Bartolini Bussi et al. (2013), Di Paola et al. (2016), Mellone et al. (2021) discussed this approach in Italian schools for an early approach to Algebra in Primary school. As we already discussed, very few research papers refer instead to the inclusion and the use of "*problem with variation*" in teaching/learning mathematics in Western Middle school (grade 8) and, in particular, in Geometry. The CT discussed in this paper is aimed to look at a different teaching/learning mathematics practice, coming from East-Asia cultures, as an important opportunity for a significant and unusual (for the Western culture) 3D Geometry problem solving. In particular the proposed variation problems are aimed to guide Italian students in discovering, almost autonomously, the relationship between pyramids and cones area/volume. According to the declared aim, our lens was focused on students' reaction to this approach and, in particular, the research question to which we tried to answer was: *What kind of process do grade 8 students of Italian (Western) culture show in variation geometric problem solving?*

Methodology

In this section we discuss our CT in teaching/learning Geometry, implemented in the Italian school context (four classrooms of grade 8), according to the methodology of variation. It is important to underline that our intention was not an attempt to *translate*, or even worse *import* a Chinese practice/teaching strategy into the Italian culture and more in general in the Western one. On the contrary, the educational path we analyze, developed by the author of this paper and the group of teachers and researchers with whom we have collaborated for some years, is aimed to create a real CT, with an interesting inclusion of the different Chinese model into the Italian didactical practice in grade 8. With the aim to reply to the research question expressed before, our CT was particularly focused to help students to transfer their mathematics knowledge from a well-known context to another apparently different context, using the variation approach. The two contexts refer to 3D Geometry and in particular to the concepts of pyramid, cone and their area and volume. Authors of this paper were involved in all phases of the education path, the design, the implementation of it with school teachers and the analysis of the collected data. The grade 8 students (around 100) were engaged for almost 20 hours. All of them were conscious about experimenting with a pedagogical method from another culture; during the CT path they explored it, initially by themselves, after being guided by the Authors of this paper.

According to the declared aim and what the literature discusses about educational practices based on the same research subject (e.g. Bartolini Bussi e al., 2017, Mellone et. al., 2019), the sections of the CT path referred to the proposed mathematical subject were designed following this frame:

1. Pre/Post-questionnaire about 3D solids knowledge (pyramid and cone and their area/volumes),
2. Single students resolution of different variation problems about pyramid and cone solids.
3. Students interview about their own variation problem solutions (difficulties and mistakes personally implemented CT).

Before to start the first phase, with the aim to propose useful tasks in all research phases of the implemented educational path, we provided a structured and very fine *a-priori* analysis of Chinese and Italian textbooks (schemes, images, writing, task …) and of methodological implicit assumptions that variation approach could have had on the involved students about the inclusion of this didactic methodologies in the one commonly adopted by Italian teachers. All research phases were video and audio recorded. These collected data were qualitatively and quantitatively analyzed (with cluster and implicative analysis). Researchers and teachers studied these data step by step during all CT path phases in order to eventually redefine and redesign the path frames. According to the contamination theory, protocols and interviews were examined with a specific focus on possible interesting used of different sings (words, pictures, arrows, colors, …) useful to describe students approach to variation and, in particular, to underline possible difficulties or readiness to define relationship and among concepts, solutions and contexts. Cluster and implicative analysis gave us the possibility to put in evidence possible stable behaviors in the analyzed students sample. In this paper we don't present these data; we are referring only to some qualitative findings.

An example of an implemented variation problem task (the first triplet) is shown in Figure 1. Starting from a problem concerning only the pyramid solid and its area (first problem on the left), we asked the students to solve two more problems on the cone solid (regarding its area and volume). According the variation problems theory and the contamination one, discussed before, the defined triplet was structured in order to favor the possibility to find, independently, the relationships (similarities and differences) between the two proposed texts and the images of geometric solids, without an explicit "presentation" by the teacher of the second one (about the cone).

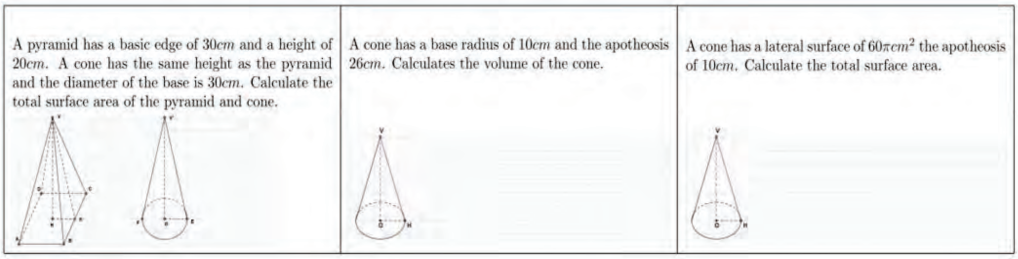

Figure 1. Our CT: an example of a first triplet of variation problem

As we also mentioned before, all students knew the concept of pyramid and its area and volume calculation and properties; none of them knew (we formally tested it) the cone solid. Students, to solve this task needed to autonomously "transfer" (using variation approach) knowledge and skills acquired on the pyramid solid, to the cone. In the three problems the graphical representation has been also inserted in order to help students to better focus on the relationships and possible links in area and volume calculation. This choice retraces what Chinese textbooks and Chinese teachers commonly propose in classrooms.

Empirical findings and first conclusion

In order to give an overview of the obtained results and related discussion, in this section, we briefly present some finding, come from the analysis of students protocols referred to the phase 2 of the implemented CT path and some data coming from a qualitative analysis of the same two students interview (phase 3 of the CT) about their own variation problem solutions.

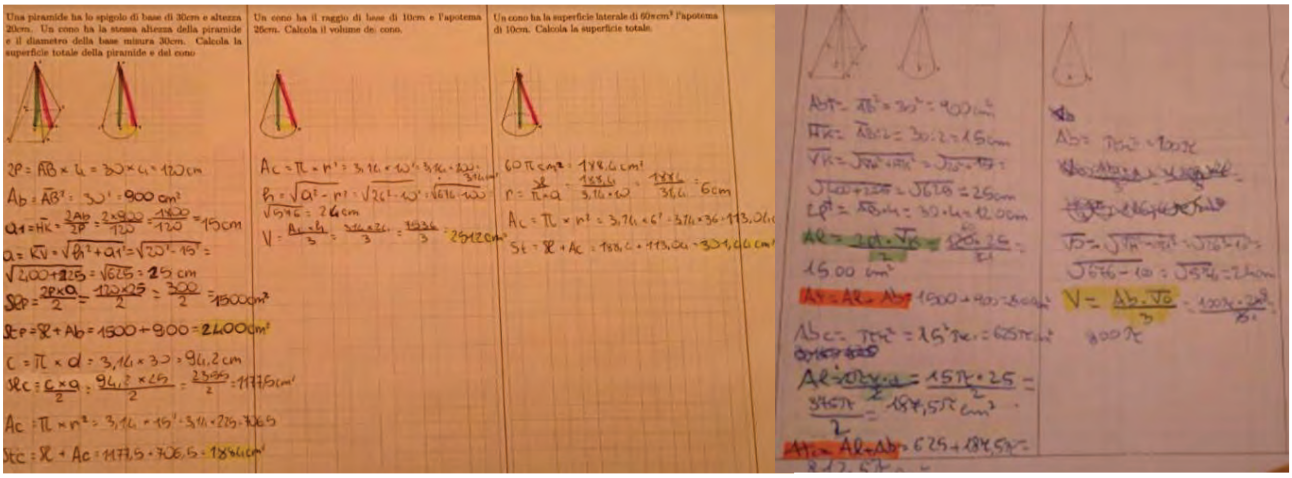

Figure 2. Maria's and Valentina's variation problem protocols

Maria's and Valentina's protocols appear interesting for replying to our research question. In both students sheets it is, in fact, possible to observe an noteworthy and autonomous use of the colors in the proposed variation problems. Maria used colors to highlight analogies and relationships between part of solid. A solid that she knows and a solid that she doesn't know. Valentina did the same but taking into account the solving strategies and the formulas, instead of the graphic solid representation. Thanks to the Chinese variation approach, she autonomously discovers a relationship between two used formulas. In both cases (we found similar approaches in many student protocols) the opportunity to be *contaminated* by the Chinese variation methodology (Mellone et al., 2019, 2021) guided them in discovering in the problem solving activities something new as the relationship between pyramids and cones area/volume. Their approach to variation problems and their "surprise" to the possibility to autonomously learn "new mathematics' ' (Maria used these terms during her interview), clearly emerged also during their subsequent interview. The following part of the dialogue between Maria and her teacher, appears interesting:

Teacher: Could you better explain to me what you mean?
Maria: I highlighted with the same color what behaves in the same way.
…
Maria: Here I have something that I know and something unknown into the same problem. I tried to look, to search for analogies and relationships. It's a interesting problem. I like it.
Teacher: What did you find?
Maria: All are right triangles, the first two are just the same ... same numbers! So I highlighted them the same way.
…
Maria: Prof., could we do the same argumentation between Prisms and Cylinders? We studied them… We could find a general "rule", we could use less memory and more variation. Problem solving can become more "simple".
Teacher: You can try, …
Maria: It is great. I didn't know anything before today about it. We have to look also to other countries (smiling) …

As Maria, almost all students benefited from the Chinese contamination of variation problems. they declared that working with this methodology, they became more aware of their knowledge and they were able to construct step by step a general solving approach to this kind of problems (the same finding in Cai & Nie, 2008). Of course a few of them (Giovanni, Marco and Francesca speeches are some examples) didn't immediately reach up to this expertise.

Giovanni: We haven't studied the cone solid, the teacher was wrong … that's why I only solved the pyramid problem.

Marco: I don't know the cone and I don't remember the pyramid, sorry.

Francesca: We have not studied the cone, but the teacher gave us a task with the pyramid and the cone; we don't know anything about the cone ... I tried to use what I knew about the pyramid but I couldn't find the way.. why did the teacher put the pyramid next to the cone? I will try to think about it. We didn't do this same kind of problems before

As we said before, this "changing process" is complex and long (Bartolini Bussi et al., 2014); Giovanni, Marco and Francesca need more and more opportunities for reflection and *contamination*.

According to Spagnolo & Di Paola (2010), Sun (2011) and Mellone et al. (2021) findings, our students approach underlines how the implemented CT path gave them a good chance to stimulate and improve a possible abstract thinking, finding relationships between concepts, strategies, algorithms in variation problems. The defined variation problems gave them an important opportunity to deepen abstract geometrical thinking - structure, strategies, relationship, concepts … - (Leung, 2003) than does typical isolated problems on the two investigated solids as, in many cases, happens in Italian (but also in other Western countries) school context. They discovered a "new", "diverse" culture and different related problems solving approaches that enrich their teaching practices and, according to our finding, their mathematics learning (Barton, 2008). Thanks to the CT path they had the opportunity to engage in mathematics through a cultural lens, helpful to discover and use diversities as resources for their future teaching. This gave us, as researchers, the chance to rethink our own cultural expectations and assumptions about possible important cultural, social and political issues in Mathematics Education research.

Mathem-Ethics in prison: how mathematics can enhance social skills

Daniela Ferrarello[1] and Maria Flavia Mammana[2]

[2]University of Catania, Department of Mathematics and Computer Science, Catania, Italy; mariaflavia.mammana@unict.it

The aim of this paper is to investigate the potential power of mathematics in a socially difficult environment, as a high-security prison. More, we ask whether mathematics can enhance social skills (ethic skills, in particular), not only in prisoners: we present a mathematical experimentation involving prisoners, as those who, by means of mathematics, first learn ethic skills and then teach ethic skills to people from outside the prison, with a methodology we call "Mathem-Ethics". The theoretical framework we work with is Horizontal Teaching, which provides a way to learn for both learners and teachers. We briefly discuss some results of the experimentation, in terms of its efficacy on people from inside and outside the prison.

Keywords: Mathematics education, ethics, social change, horizontal teaching.

Introduction.

"Mathematics is bad for society", said Arvid, an 11 years old student, in a challenging tone (Ryan et al., 2021). What Arvid was brave to say, is perhaps, shared by many students of different ages. As Wright (2019) highlighted, quite often mathematics is reduced to a set of rules and procedures to memorize and apply (OFSTED, 2012; Foster, 2013), resulting in many children (and adults) continuing to exhibit alienation from mathematics (Nardi & Steward, 2003). Nowadays education aims more and more towards functional mathematical literacy, that refers to the capacity of creating and applying mathematical knowledge when required in real life (Jablonka, 2003), and many efforts are taken from researchers and teachers to enhance mathematical skills in students that are useful for developing citizens able to solve real life problems that require mathematical literacy. But still, it is a common idea among students that these mathematical skills are only technical, and are not useful in social life. If mathematics is not bad for society, at least it is seen as useless for society, not connected to ethics and not useful to contribute to a life change. "Discussions about the connections between mathematics and democracy amongst the general populace have not been explicitly well rehearsed, other than to either assume that mathematics has nothing to do with anything political, being neutral in form and practice, so it has nothing to do with democracy, which is something political; or that it is implicitly democratic." (Swanson, & Appelbaum, 2012, p.1). However, mathematical literacy is relevant to both social and economic needs and to an individual's participation in today's democratic society (Jablonka, 2003; Skovsmose, 2007). If there are those who think mathematics is a tool to obtain social training in obedience, an industrial trainer (Ernest, 2019), Swanson and Appelbaum ask whether disobedience to the evocative power of mathematics could be itself a democratic action. Democratic teaching practices may have a positive influence on students' learning outcomes in the mathematics classroom. This may be because successful democratic teaching and learning is conceived as situations where "individuals are able to think for themselves, judge independently, and discriminate between good and bad information" (Dewey as in Orrill, 2001, p. xiv). Therefore, there is a need to rethink teaching, taking into account the social dimension. Both Vithal (1999) and Aguilar and Zavaleta (2012) pointed to the need for empirical studies to experiment with existing theoretical ideas on the connection between mathematics education and democracy. Daher (2019), for instance, presents a study to assess four democratic practices (freedom, equality, engagement and justice) in the mathematics classroom. If mathematics education can be used to develop citizens' skills to sustain a democratic society (Aguilar and Zavaleta, 2012), it should be even more important to develop it in a context where the students are prisoners. This has not been investigated so much and it is the focus of this paper. Several mathematical activities with students that are inmates have been successfully carried out in Swedish prisons (Helenius and Ahl, 2017; Ahl and Helenius, 2020). The authors highlight that successful mathematics education in prison can play a role in producing identity change increasing opportunities for re-entry in the society. In this paper we present a project, called *Vietato non toccare (Don't not touch)*, carried out in a high-school in a high-security prison in Sicily (Italy). This project aimed to enhance mathematical skills in inmate students through a laboratorial approach, in order to improve motivation of students and their sense of self-efficacy, i.e. confidence of success in handling a problem (Bandura, 1997). More, we aimed to use mathematical education for ethical purposes, with a methodology that we call *Mathem-Ethics*, experimenting with a way to use mathematics to achieve a change of life. We call Mathem-Ethics a methodology to teach/learn mathematics, giving precise ethical meanings to mathematical concepts. It is possible to design mathem-ethical activities, with the precise target of enhancing both mathematical and social skills. Our research questions are: "Is it possible for inmate adults to acquire ethical skills by means of a mathem-ethical path that will help them with a real life change?" (RQ_1), "Is it possible to enhance social skills in people by means of a mathem-ethic path in prison?" (RQ_2). In this paper, we first present the theoretical framework as the basis of our activity, Horizontal Teaching. Afterwards, we briefly describe the whole project and the methodology. Then we present the mathem-ethic path that was carried out. We end with some discussion and conclusions regarding the efficacy of the experimentation for those involved.

Theoretical framework.

Ethics or moral philosophy is defined as that branch of philosophy that involves systematizing, defending, and recommending concepts of right and wrong behaviour. Ethics is born, already with Socrates and many Greek philosophers, to answer questions of human morality by defining concepts such as good and evil, right and wrong, virtue and vice, justice and crime. It is a common opinion that social sciences, like literature, art, history, are didactically useful for ethics investigations in students. It is our opinion that mathematics too can be used to learn concepts useful for students' lives, in general, and to ethics, in particular. The theoretical framework we use to achieve ethical goals is based on Horizontal Teaching (HT) (Ferrarello et al., 2013). In teaching/learning environments, the actors are the one who teaches, the teacher, and the one who learns, the student. These two figures generally have distinct roles and, in traditional environments, the teacher transfers his/her knowledge to the student, we might say in a "vertical way", top-down. In HT, on the other hand, there is a teacher's awareness: the teacher is willing to challenge him/herself and expand his/her knowledge by entering the sphere of the student's knowledge. In fact, in HT, the two sets of knowledge, the one of the student and the one of the teacher, are placed at the same level and initially have an intersection (Figure 1a); the teacher must be able to enter into this intersection and expand it, so that the knowledge shared is greater than at the beginning of the process, expanding not only the student's knowledge, but also his/her own (Figure 1b). The expansion of the teacher's knowledge takes place not only in terms of content, but also with respect to the students' experiences, their interests, their learning styles. The expansion of students' knowledge is not only about content, but also about the way they learn, contributing to enhance their mathematical literacy (Jablonka, 2003). So it is not only the student who absorbs from the teacher's knowledge but also the teacher expands his/her knowledge: this is the fundamental characteristic of Horizontal Teaching.

Figure 1: Horizontal Teaching

In the HT model, learners are seen in relationship with themselves, but also with the other learners and the world, just as in Maheux & Roth (2011), where the authors describe a way of thinking about knowing, namely relationality, starting from the biological theory of cognition, (Maturana & Verden Zöller, 2008). Human beings are theorized as complex biological "learning systems" that coordinate with the co-emerging environment that they "bring forth" (Maturana & Varela, 1998) and in knowing mathematically, the learner and the knowledge are not independent entities. The novelty of HT, with respect to this model, is the role of the teacher, who becomes a learner too, sharing with the other learners (the students) their participation in creating a new world of knowledge.

Description of the project and Methodology.

Vietato non toccare (*Don't Not touch*), https://sites.google.com/view/dontnottouch/home, is a project conceived in 2017, when one of the authors won the *Italian Teacher Prize*, promoted from the Italian Ministry of Education. It was carried out with adult inmates in the high-security prison of Bicocca, within the high-school "K. Wojtyla" of Catania. It aimed to create an exhibition of mathematical objects in prison, and it consisted of three steps: 3D-printing of some objects, (Step 1); mathematical training of inmate students on the created objects (Step 2); guided tours of the exhibition (Step 3). The exhibition consisted of four sections (see Table 1).

Table 1: Sections of the exhibition

Section 1	**Not orientable surfaces**: Möbius strip; Klein Bottle.
Section 2	**Pantographs for geometric transformations**: Pantograph for homothethy; Pantograph for axial symmetry; Pantograph for central symmetry.
Section 3	**Conicographs**: Cone with conics' sections; Ellipsograph with antiparallelogram; Ellipsograph with rhombus; Hyperbolograph with rhombus; Parabolograph.
Section 4	**Archimedes' machines**: Parabolic mirror; Coclea; Lever.

Most of the objects of the exhibition are mathematical machines (Bartolini Bussi & Maschietto, 2006). The authors led the training course for the inmate students (Step 2), to help them understand the functioning of all the objects: 15 students were enrolled, just 3 became guides of the exhibition, because the others were moved to other prisons or got out of the prison. The training consisted of 20 meetings, held according to the methodology of the *Mathematics' Laboratory* (ML) (Anichini et al., 2004). In the ML, students are guided to discover and construct the concepts, supported by the teacher and their peers, in a collaborative and/or cooperative way. In fact, the ML is a set of activities carried out by students and teachers aimed at the construction of meanings of mathematical objects. In the ML, students do not study mathematics, but rather do mathematics, dealing with a problem, exploring, conjecturing, proving, applying. During the training (Step 2), every object was introduced by means of a problem, typically: "What does it do? And why?". The object was manipulated by students working together and under the guide of the teachers they developed an understanding of what the object does and why and they constructed the mathematical meaning lying within the mathematical object. At the same time, they were introduced to the ethical meaning of each section (see next paragraph). Learners are not only invited to touch, but rather they have to do it, in order to make visible and comprehensible the mysterious operating forces of mathematics, often remaining *unrevealed* (Roth & Maheux, 2015). Once the students finished the training course, they became guides of the exhibition and the gates of the prison were opened (Step 3). Visitors were students from school and university, teachers of all school grades, both mathematics teachers and not, university professors, both mathematics professors and not. Also the exhibition was organized as a mathematical laboratory: visitors were invited to touch the objects and manipulate them in order to understand their functioning. Together with the guides, visitors were assisted by the authors of the paper, who explained the ethical part of the various exhibition sections. Being in a high-security prison, we could not videotape the students or the visitors. We conducted a qualitative analysis, based on the spontaneous comments of students. They did not gain any kind of advantage in taking part in the project and they were not forced to write those comments. As for visitors, we administered a questionnaire with two questions. The first one differs according to whether the visitor was a student (question Q_S) or a teacher (question Q_T). Q_S: "Has your visit to the exhibition had or do you think it will have an *impact on the way you conceive mathematics*? (e.g. in relation to the social role that mathematics can play)"; Q_T: "Did your visit to the exhibition have or do you think it will have an *impact on the way you teach*? (e.g. with regard to methodologies, attitude towards students, topics etc.)". The second question was the same for both (Q_{ST}): "Did or do you think the visit will have an *impact on the way you behave in society*?"

The Mathem-Ethic path.

At the guided tours of the exhibition, all sections were presented according to their mathematical meanings and ethical meanings (Ferrarello et al., 2021) that we briefly describe here. Section 1- "Not-orientable surfaces: when *inside* and *outside* merge together": The objects we see every day have generally orientable surfaces, i.e. they have an inside and an outside, separated by a boundary, which we are forced to cross whenever we want to pass from inside to outside or vice versa. In life, we often classify things and people, by placing them inside or outside a certain set, with a very clear boundary. What we discovered, working with 'bad-by-definition' people in prison, is that, indeed, these boundaries are not as clear as we paint them, but rather blurred. Objects in this section were symbols of the meeting among people from inside (the prisoners) and from outside (the visitors) in the neutral field of mathematics. Section 2 - "Pantographs for *transformations*: transform yourself by remaining true to yourself": In geometry, it is possible to transform a figure into another one, maintaining certain properties. A task of education should be to make students grow and evolve, by changing some things about them (transform yourself) and maintaining some of their features (remaining true to yourself). The school does not replace the students with new people, but rather transforms them. Objects of this section were symbols of the transformation of students and visitors. Section 3 - "Conicographs: Conditions for being in a *locus*". Conic sections are curves that can be described as geometric loci, i.e. we can describe a mathematical condition for a point, satisfied if and only if the point belongs to the curve. Being in a locus (a geometric one or, in a metaphor, in a real place) therefore depends on the conditions that one sets. Our behaviors (the conditions, in the mathematical metaphor) determine the effects on our life (the geometric locus, in the mathematical metaphor). If you really want to change the locus, then you have to start by changing the conditions. The ethical meaning of this section is the importance of self-determination to encourage students and visitors to own their own lives, taking them in hand and setting new conditions, to achieve new loci. Section 4 - "Archimedes' machines: Sicily, land of mathematics!". The place where the project has been carried out, Sicily, is often covered by prejudices associated with facts, people and ideas, which are not universal in Sicily: it is also the land of a millenary culture. Our exhibition is pleased to host a section of machines attributed to the Sicilian genius of Archimedes. In this section we want to remember Sicily for other facts, people, ideas and those that have contributed to our scientific culture: it is not only the land of mafia, but also the land of mathematics: like a person is not only a prisoner, but also, in this case, a guide of a mathematics exhibition (and much more).

Brief discussion and conclusions.

In this paragraph we briefly discuss the efficacy of the HT in the third step of the project: the guided tours of the exhibition, hosting people from outside the prison. In the following, we report in Italics some parts of the spontaneous comments from prisoners and answers from visitors. We underline where, as per the HT framework, students (blue set in Figure 1) can be also teachers (let us recall that visitors were teachers and students from outside), while teachers (pink set in Figure 1) are inmate students after becoming guides of the exhibition. In order to answer our first research question, RQ_1 ("Is it possible for inmates adults to acquire ethical skills by means of a mathem-ethic path to help them in a real life change?") we take into consideration the teachers' expansion, i.e. what the inmates, as guides of the exhibition, learned. We report some of their spontaneous comments. *This project brought into my life something unique and unimaginable. I didn't believe I could reach so much, and this makes me understand that also I have the skills and possibility to yearn for a future rich of occasions, and to give a turning point to my life*; and more. *This project involved a cultural change for us, but above all a personal one. At the beginning we were very enthusiastic but not very motivated, just because we gave limits to our potentialities, to our knowledge and intelligence. But by attending classes with commitment and passion we managed to get great results, making calculations, conjectures and evaluations. Until a few years ago, we would never have imagined debating on mathematical concepts. …* [We thank the teachers who succeeded] *to illuminate the way of our journey to a better future, believing from the beginning in* *us, teaching us that in life we must look beyond our expectations. But above all, thanks to mathematics, we know who we are and who we will be. Remembering that mathematics is not only made of numbers and sums, but also of much more! Thanks again for believing in us, and that we believed that the only thing you can't do in life is to divide by zero!*. We underline that the inmates we worked with are all incriminated for mafia association (n. 416 bis of the Italian criminal code). Some of them are, by "family tradition" involved in crime and also did not have school education until they entered prison. Some, even if they are Italians, had difficulty also in speaking proper Italian, because they used to speak dialect. Moreover, inmates did not gain anything in taking part in the project. Little by little, they made *our* project *their* project and felt proud of being part of it. It is too early to see long term effects of this adventure, but for sure, from their word, we can say that a change already started. The 3 guides just finished high-school in prison and they are planning their future, even enrolling to university. In order to answer our second research question, RQ_2 ("Is it possible to enhance social skills in people by means of a mathem-ethic pathin prison?") we take into account the answers to the questionnaire by the visitors. As for Q_S, students visiting the exhibition expanded their knowledge seeing mathematics in a different way: they recognize that *it is possible to make mathematics also with a social role, a role of unity and education* because it can be a *tool for educating, growing, learning,* not *only for well-educated students,* but for all. *The myth of the social role entrusted mostly to social sciences has been dispelled*. As for Q_T, teachers visiting the exhibition had the opportunity to test the efficacy of the ML, whether they were math teachers or not. *Only those who play an active role in the learning process really learn: it is fundamental to let students having the pleasure of discovery. Asking the right questions, leaving space for silence, listening, observing together, providing tools, stimulating curiosity, are much more important activities than simply providing data and ready-made answers. Student as actors and not audience are happier and more effective* (from A. and P., not math-teachers that already work in a laboratorial way: the visit confirms their belief). We want to underline the position of N., a math teacher, who is revising his teaching practice, and he claims that the visit *has accelerated this revision process*. The teacher learned that *you cannot set a standard model to which the students must adapt, but the reverse process is needed: the teacher must adapt to the students.* Then all teachers benefit from visiting the exhibition expanding their knowledge in terms of teaching methodology. Let us move to Q_{ST}. Teacher P. wrote that *the way of behaving towards society has become more conscious*. The project *breaks down many commonplaces about prisons and prisoners* because the project shows that *the polarity of reality is a scam: true/false, good/bad, ignorant/knowledgeable, right/wrong, the polar view of reality is limiting, reductive, excluding* (target of Section 1 of the exhibition). Visitors (students and teachers) *discover wonderful people with a great desire for redemption*, and they found that *everyone needs to be recognized: trust, sincere appreciation, a smile, kindness, can help everyone grow much more than through disapproval and punishment* (target of Section 2 of the exhibition). Thanks to education, and also to math education *not always those who have committed a crime are bad people and can never change, [*they*] improve or try to take a new and better path* (target of Section 3 of the exhibition). Visitors *saw in their eyes* (the prisoners) *the desire to escape from a past that, now thanks to the experience made with the project, was "narrow"* (target of Section 4 of the exhibition). This led them *not to be prejudiced and do not judge too quickly, because the social, economic, cultural* *situation of each person varies according to the society in which they are born and grow up and they cannot choose that. While it is all of us who together can do something different and we can benefit from it all together!* Visitors are inspired to do their best in a view of *I care*. A last consideration is the reciprocal relation amongst the people involved in the project. At every tour, the discourse always started with mathematics, and became more and more mathem-ethic. During the flow of the tour visitors and guides entered more and more into a confidential conversation. Usually, at the end, there was no more distinction between "inside people" and "outside people". One of the guides said that he *succeded to enter in to a relation with people, this was always my flaw*. The same happened to visitors. In the intersection of blue and pink sets (Figure 1), we find no difference between teachers and learners: a full Professor, visiting the exhibition, said "*I have had the pleasure of feeling ignorant in a singular place, where the last prove to be the first*". We hope that future mathem-ethics paths taken in prisons could open the doors to the development of social skills both in prisoners and in math educators. More to come!

Surprising everyone but herself with her good results: the twin dynamic of invisibility and failure to see

Trine Foyn[1] and Yvette Solomon[1,2]

[1]Oslo Metropolitan University, Norway, trine.foyn@oslomet.no

[2]Manchester Metropolitan University, UK, y.solomon@mmu.ac.uk

In this paper we explore the co-construction of identity in a Norwegian lower secondary school mathematics classroom. Focusing on one high-performing girl, Sarah, we analyse the role of male-dominated performance of "smartness" in her positionality in the figured world of Class A. While Sarah can be simply understood as making herself "invisible" in this dynamic, her teacher's account draws our attention to the impact of gender performance on what she sees and values in her students. We argue that Sarah's positionality is the result of a twin dynamic between girls' cultural invisibility and her teacher's failure to see, indicating a need for greater awareness of girls' situation in mathematics classrooms, particularly where - as in Norway - gender is seen as "no longer an issue".

Keywords: Classroom dynamics, gender performance, invisibility, equity.

Background and literature

Although Scandinavian countries are often seen as a "beacon" of gender equity, women's participation in science, technology, engineering and mathematics (STEM) lags behind other countries (Talks et al., 2018), particularly in Norway: only 1 in 3 STEM graduates are women (Confederation of Norwegian Enterprise NHO, 2018). Talks et al. (2018) suggest that part of the problem is the common perception that Scandinavian countries have "fixed" the problem of gender inequity. In this paper, we explore girls' experiences of mathematics in the crucial years before they choose their final educational pathway, in a setting where gender equity in the sense of a level playing field is assumed to follow from an emphasis on equal opportunities. We find that, on the contrary, being a successful student is marked by a highly gendered performance within a classroom dynamic that goes unquestioned by all participants, including the teacher. Focusing on the case of Sarah, a consistently successful girl, we argue that the gendered performance of "smartness" in the classroom renders her invisible, and contributes to her teacher's failure to see her achievement: everyone is surprised by her marks except Sarah herself.

The link between classroom culture and students' mathematical identities is well established. Black (2004a, 2004b) notes the role of interaction between teacher and students in the construction of mathematics knowledge in a British primary school, with particular implications for girls. Rather than engaging with the girls about mathematics, the teacher "somehow negotiated with these girls a coping mechanism where they stayed silent on the periphery of the classroom in whole-class discussions, but were praised for neatness and presentation elsewhere" (Black, 2004a, p.49). Girls who laid claim to a higher profile were "positioned out" as in the case of Sian, a girl whose ability was publicly acknowledged, but was exploited by the teacher to work as a "pace-maker", contributing minimal responses which enabled the boys to continue in more productive dialogue with the teacher: "it is because of Sian's compliance with the teacher's agenda ... that the [high performing] boys … were able to engage in more dialogic talk .... it involves using the right kind of input (or response from the teacher) to signal and be recognised as 'high ability'" (Black & Radovic, 2018, pp. 280-281).

Similarly, Foyn (2021) investigates how being good at mathematics is performed in a Norwegian lower secondary school. She argues that gender is refracted through a cultural model of "smartness" signified by "effortless" work, interrupting the teacher or challenging her mathematical competence, leading to a collectively held claim that there are no gender differences, but that the best students are boys (since they act in this way). Hence the gendered nature of high achieving girls' self-censorship away from activities that are connected to the performance of smartness goes unchallenged. In an earlier study, Foyn et al. (2018) focused on "clever' girls" positionality in an upper secondary school classroom in Norway, finding that they subtly positioned themselves as clever without performing in the same way as the boys in the classroom. However, their performance was restricted by a gendered discourse in which they both "policed" each other and "self-policed" in order to (re)enforce particular rules for combining being female and being good at mathematics: performing in terms of visible "natural ability", flair and competitiveness was unacceptable as "feminine" behavior, and indicators of ability (e.g. ability group membership, marks) were expected to be noticed but not commented on. The case of girls' visibility in mathematics is also elaborated on by Walls (2009), who identifies gender differences in the way students express their response to mathematics. She argues that, in order to survive, girls and women in mathematics "are required to don a cloak of invisibility that affords them temporary status as honorary males in a male domain" (Walls, 2009, p.47).

The teacher's role in how students develop their positionality is illuminated by Jaremus et al. (2020). They found that teachers assumed three main categories of students: the gifted, characterized by their perceived natural ability, speed and achievement; the "dedicated", characterized as hard working; and the utilitarian, having specific career goals (mostly "masculine") which required mathematics. These subject positions "were not equally available to girls and boys" (p. 226): the utilitarian and gifted groups were predominantly male, while the dedicated group was mostly female. Jaremus et al. argue that the "naturalization" of mathematics as masculine excludes girls from the "gifted" subject position, whereas the normalization of effort makes the dedicated position available to them; the utilitarian position is available only if they can subscribe to the normalized aspirations to male-dominated careers. Both Walls' and Jaremus' research took place in Australia, while Black worked in Britain. As noted above, Scandinavian countries, Norway included, lay a strong claim to gender equity, yet Foyn's earlier work questions this. In this paper we explore the twin dynamics of girls' (self-) imposed invisibility and teachers' assumptions about their capability in the Norwegian context further. Hence our research question is: What are the dynamics of gender (in)visibility in a Norwegian classroom?

Theoretical framework – positionality in a figured world

In this paper we draw on Holland et al.'s (1998) theoretical framework to see the mathematics classrooms as a figured world, a "socially and culturally constructed realm of interpretation in which particular characters and actors are recognized, significance is assigned to certain acts, and particular outcomes are valued over others" (Holland et al., 1998, p. 52). A figured world is "a social reality that lives within dispositions mediated by relations of power", where actors see themselves as having "more or less influence, more or less privilege, and more or less power" (p. 60). Importantly, though, figured worlds are not independent of other worlds, and the structuring effects of major discursive forces such as class, gender and ethnicity which underpin power and privilege in surrounding worlds impact on local worlds too. Thus,

> social categories also can have meaning across many figured worlds. [...They] separate those who are routinely privileged from those who are not. Cross-cutting markers tend to become stereotypically associated with these social categories, if not actually demanded (p. 130).

In the Western world at least, gender as a positional force may lead some female students to see themselves as not having access to significant acts in the classroom such as participating in discussion about mathematics: "gendered dispositions to participate, or not, in given activities, develop in places where gender participation in activities is treated as a claim of gender specificity" (Holland et al., 1998, p. 143). Actors in a figured world get to know "their" position in relation to others as they participate in its everyday practices; in a mathematics class, students (and the teacher) learn to live out the figured world in terms of what they are "allowed" to say or do, what is expected of them, and what is valued. To understand girls' positionality in a mathematics classroom, we need to notice the mundane activities of the classroom, its norms, rules and habitual acts:

> They come to have relational identities in their most rudimentary form: a set of dispositions toward themselves in relation to where they can enter, what they can say, what emotions they can have, and what they can do in a given situation (Holland et al., 1998, p.142–143).

Thus students' acts in the classroom are based on a blend of figurative identity - "signs that evoke storylines or plots among generic characters" - and positional identity - "acts that constitute relations of hierarchy, distance, or perhaps affiliation" (Holland et al., 1998, p. 128). Hence being a female "clever student" or a male "clever student" is "normally" played out differently in the same figured world, and position becomes disposition, ways of being that are frequently unconscious and "out of awareness" (p. 139). Habitual acts may thus lead towards situations of exclusion and inclusion of which actors in the figured world are unaware. As Holland et al. point out,

> even in situations where all students are admitted to the arena of learning, learning is likely to become unevenly distributed .... Teachers will take some students' groping claims to knowledge seriously. … Others, whom they regard as unlikely or even improper students of a particular subject … are less likely to receive their serious response (p. 135).

The mundanity and ordinariness of acts of exclusion or inclusion mean that noticing, resisting and countering these norms is unlikely or difficult, because "the everyday aspects of lived identities . . . may be relatively unremarked, unfigured, out of awareness" (p. 140). In this paper, we focus on the ordinariness of acts of inclusion/exclusion in the mathematics classroom on the basis of gender, and how this mundanity appears to prevent such acts from becoming visible.

Methodology

The data for this paper derive from a larger ethnographic study tracking a Norwegian lower secondary school mathematics class (“Class A”) from grade 8 to grade 10 (Foyn, 2021). Just outside Oslo, the school is in a high socio-economic status area with a fairly homogenous population mostly comprising native Norwegians and native Norwegian speakers. The school prides itself on its high grades. Students are assessed in the national system with grades from 1-6, where grade 6 is the best. Grades 5 and 6 are considered to be at a “high level”. Grades awarded correspond with the goals set for each grade, so achieving grade 5 in two consecutive years requires making the improvement required to meet the higher goals of the later year. All students follow the same curriculum. We draw on a variety of data collected by the first author in this ethnographic study: fieldnotes from participant observation; focus group interviews with the students in 8th and 9th grade; individual narrative interviews at the end of 10th grade; interviews with the teacher, Miss A, at the end of 8th and 9th grade; and copies of the teacher’s assessment record and students’ diary notes.

In this paper, we focus on one case study student, Sarah, whose 10th grade interview about her grades and performance, work effort and experience of mathematics is of particular interest because of her comments on her marks. However, the ontological implication of taking a figured world approach means that it is not possible to investigate any act, event, or statement in isolation, because it occurs between people in a context over time. Thus analysis focuses on story structure, collective storying and their connection with collectively spoken and enacted norms and values.

Sarah’s and the other students’ stories were analyzed in terms of narrative structure. Operationalisation of important concepts are exemplified in Table 1.

Table 1: Operationalization of narrative concepts

Concept	Definition	About	Operationalization
Positional utterances	About relations to groups or actors	Positionality	Describing/explaining oneself in relation to subgroups/persons
Flow	Narrative structure, choice of incidents, combination of ideas	Style of authorship	Sequencing of events, connections
Contradictions	Conflicting/contradictory issues in the talk	Ruptures	Contradictory claims/voices

Interviews with Miss A and the students take place within the figured world of Class A. Table 2 illustrates the operationalization of the central concepts of norms/rules and values in the figured world.

Table 2: Operationalization of central concepts of figured worlds

Concept	Definition	About	Operationalization
Norms/Rules	Expected actions or moves	Habitual events	**Observations** - what is repeatedly observed? Expected actions based on previous experiences in observations **Narratives** - descriptions of characteristic actions in the class **Co-constructions** in focus group interviews

Values	Perceived importance of actions or objects	How artefacts are employed, positional acts	**Observations** –acts that seem to give credit to the actor **Narratives** – description of what is important to do in order to claim status **Co-constructions** in focus group interviews

In addition, the analysis draws on fieldnotes and observations of student movement within the classroom to gain a broad access to the figured world of Class A. Interviews were transcribed in Norwegian and translated into English. In our translations we have aimed to keep as close as possible to our understanding of intended meaning in the original Norwegian. This study followed the research ethics practices of the Norwegian Centre for Research Data, and all names are pseudonyms.

Analysis: Sarah in Class A

> *SARAH: Is seen as mediocre by the teacher. She keeps on working. Enjoyed maths in primary school**. I think she is overlooked by the teacher**, because when I talk to Sarah in the classroom, I get the feeling that she is getting the concepts and does understand the connections. Easygoing, natural way of acting. Is improving her grades, got a rock solid 5 in the final test this year.*

(Fieldnotes, end 9th grade)

This summary impression of Sarah remained unchanged through 10th grade, with reference to both the way she acted in the classroom and her assessment record: she performed steadily at grade 5 throughout the year. Not being noticed seemed to be her "destiny" in this mathematics classroom, and her interview at the end of 10th grade revealed that Sarah was aware that this was the case.

Sarah's story – everyone is surprised by her good results, except herself

A typical feature of Sarah's story is her straightforward attitude when she describes her work in mathematics. Even though she is ambivalent about the way they work with mathematics, she just gets on with it: *"In 10th grade we kind of had to learn it quickly and then it wasn't as much fun because I didn't quite get it, but I learned it"*. It seems that Sarah tends not to like the fast pace, but she accepts the situation and goes along with it. However, this doesn't affect her performance, because her marks indicate improvement in Miss A's assessment protocol and Sarah says that this will continue: *"I think it might go upwards if I'm working to make it go up"*. Despite this confidence, she hesitates to position herself among the students who are doing well in mathematics, instead positioning herself as ordinary: *"I guess I've always been somewhere in the middle in maths, really. I find something difficult while something is very easy, surely like most of the other students, so like many or most of them, actually"*. Furthermore, she declines to query her marks: "*I don't often dare to say that I deserve a higher or lower grade, I'm more that what she gives me is what I get*".

Given this apparent acceptance of the situation, the most striking moment in Sarah's story is her account of her teacher's excited response to her final test score. Mid-sentence, she suddenly mimics Miss A: [Excited voice, imitating the teacher's bright tone] "*Wow! This is really good, aren't you surprised?* [Continues in her own tone, with indignant emphasis] *I was just like, 'no thanks!'* ***I** wasn't surprised"*. Her rejection of Miss A's storying of her results as a surprise returns when she is asked how she thinks the others in the class, including the teacher, see her: *"I think she [the teacher]is a bit like the others in the class, who think I'm a bit dumber or not as good as I am"*. She continues; *"people might think I'm going to get slightly worse grades than I get, or they go like* [parodying puzzlement]*'are you smart?'"* Clearly aware of her positioning by others, Sarah's resistance goes no further than parody. To understand further, we turn to an analysis of the figured world of Class A.

The figured world of Class A - Sarah's position within the performance of smartness

Although the students describe Class A as a unit storied with a 'we' in which everybody does their best and works together despite differences, this image cracks the moment achievement is mentioned. Eva admits that *"There are some who get 6s in every single test, also there are quite a few who are average, and also some who can't do it, the special group"*, while Elias says "*There's a group that is quite a lot better than the others, at a higher level than the others ... They do more difficult tasks, help others a bit more, give explanations and discuss a bit more with Miss A"*. Sarah is aware of this group as well. Asked who is very good at mathematics in Class A, she replies, "*I feel boys or people think that. At least in our class, the guys are the smart ones good at maths, but I think that it differs from class to class"* She adds: *"We have a lot of very extraordinarily smart boys, at least, who are doing maths for upper secondary school and things like that, so I think a lot of people think they're smart"*. She describes the boys as smart, but it is notable that she doesn't accept this argument unreservedly - twice she says this is "what people think". She goes on, perhaps reflecting her own experience: "*But I think the girls are keen to do well, maybe, more than the boys too"*.

Miss A's account adds to this complex picture of how things are seen in Class A. In her interview at the end of 8th grade she is asked if there is any subject the students connect to status. She replies: *"In this class we have a whole bunch of special boys …, who are very interested in mathematics and science. And getting good grades in mathematics is high status"*. As for the girls, she says: *"I have the impression that they like to do well, but I haven't picked up any indication that mathematics is particularly significant.* She goes on: *I think maybe they are thinking a bit more in the direction of language, for those who like to write"*. She repeats this account of the boys in her 9th grade story of Class A: "*I have to mention this group of boys, "the smart boys"; they are a driving-force, academically. They easily affect others in a positive way"*. Miss A's comments on the girls' assumed favoring of language over mathematics are by her own admission speculative, and appear to be based on the fact that the girls do not *act like* the boys. Both teacher and students described how this group of boys performed smartness through acts which have particular significance in Class A: acting as "assistant teachers", engaging in discussion with Miss A and so on. Miss A stories the girls very differently. Only two high performing girls are presented as high achievers in mathematics alongside the "smart boys" in Miss A's narrative of the class, but they have a less prominent position than the boys, being mentioned in either the 8th or the 9th grade, but not both. Neither are described as particularly interested in or focused on mathematics, and they appear in Miss A's narrative as stereotypical girls in mathematics While the "smart boys" are presented as enjoying discussion of a subject they are interested in -*"Erik and Ross, they are the same, they think that the subject is interesting and like to enjoy it and discuss"*, Emilia is presented as hard working - *"I have to say Emilia works extremely hard and tackles challenges head on and wants to stretch herself"*. Equally successful, Kine is portrayed as lacking in confidence: *"Kine can feel a bit of performance pressure … when she really trusts herself and comes up with something it's really great"*.

Although Sarah is also a consistent high performer, she is not mentioned alongside the "smart boys". In 8th grade Miss A describes her as being in the group of students who are in the middle, both in terms of achievement and how they work in mathematics. She comments that some of the girls, including Sarah, are doing better in other subjects: *"I think I can say that Sophie, Maya, Kine, Josephine and Sarah are all typically better in social science and religion"*. At the end of 9th grade, Sarah is still not mentioned among the best students, even though we know that her achievement has improved. Instead, repeating her emphasis on hard working girls, Miss A places her among a group of girls she labels "the sporty hard-working girls", characterized as *"just chatting girls, laughing […] they spend a lot of time together in their spare time. Also, they are sporty girls"*. Sarah, whose results in mathematics are improving all the time, is barely mentioned in Miss A's storying of Class A, even though achievement is clearly important in this classroom culture. It seems that good marks are not enough for Sarah to be recognized as a good student in mathematics, since she is positioned outside of the highly gendered performance of "smartness".

Discussion: the twin dynamics of invisibility and failure to see

In this paper we have focused on just one girl, who interested us because of her critical parody of her teacher's surprise at how well she had performed on a test. Our analysis is not intended as a basis for generalization about girls' experiences – other girls in Class A have different experiences. However, Holland et al.'s (1998) framework emphasizes that Sarah's positionality cannot be understood in isolation from her context; it takes place within the dynamics of the classroom as a figured world, hence our research question: "What are the dynamics of gender (in)visibility in a Norwegian classroom?". We have seen how Miss A fails to see her achievement as worthy of the label "good at mathematics", but Sarah herself doesn't resist her positioning as a mediocre student beyond a private parodying of the teacher and the other students, even though she is aware and resents the fact that her competence in mathematics is not recognized. For us, Sarah's positionality is a double bind: she is caught between others' failure to see - students and teacher are blinded by the "smart boys" performance of smartness - and her invisibility in that she is unable or unwilling to perform smartness.

Holland et al's (1998) theory provides tools which enable us to understand the dynamics behind this double bind. We argue that Sarah's positionality and the fact that her mathematical competence goes unrecognized in Class A are two sides of the same coin. Miss A and Sarah both act within the norms and values of the figured world of Class A, caught by the same dynamics of power and privilege in connection to the smart boys' performance of smartness. It is as though this performance is a significant marker of being good at mathematics which goes beyond results. As Holland et al. (1998) point out, actors in a figured world get to know "their" position in relation to others as they participate in its everyday practices; they learn to know what they are "allowed" to say or do, what is expected of them, and what is valued. These relations take place within the mundanity of the classroom, its rules, norms and habitual acts. In Class A, the performance of smartness is inextricably linked to gender – we see that not just from Sarah's account but from the other students and Miss A herself. Its habitual nature means that exclusion is hidden in plain sight, since Sarah can only make herself visible by her good results, and these go unnoticed, remarked on only with surprise as though this was an unusual event. Without access to those acts which signify smartness - interest, discussion, helping the teacher, Sarah is invisible, and described at best as "hard working", echoing Jaremus et al.'s (2020) finding that female students are excluded from the position of "good at mathematics". We argue that in fact she has no means for countering these norms in Class A - Foyn et al. (2018) drew attention to how difficult and even risky it can be to break out of gender dynamics, or challenge gendered norms in the classrooms, since "discourse border guards" ensure that gender lines are not permeable.

As Holland et al. (1998) emphasize, the mundanity of everyday lived identities makes them difficult to challenge. It might be argued that Sarah could change her behavior in order to publicly resist her positionality, but Sarah's double bind means that this isn't easy. This is not to say that change is impossible, but making Sarah's situation visible goes beyond Sarah's and Miss A's acts alone - it requires a collective recognition and action. The implications of Sarah's story in the figured world of Class A are that gender dynamics in mathematics classrooms need to be discussed in classrooms, school departments, and teacher education; arguably this is particularly so in a country such as Norway where gender inequity is assumed to be in the past, and mundane classroom practices go questioned.

A philosophical investigation of local mathematical practices

Karen François[1] and Eric Vandendriessche[2]

In this article we explore the possibility of implementing local mathematical practices in the current mathematics curriculum of the studied area. This research relies on two theoretical frameworks that focus on the value of culture in relation to the study of science and scientific practices in relation to the learning process. The analysis is based on an empirical long-term ethnographical investigation in the Northern Ambrymese society (Ambrym Island, Vanuatu, South Pacific). The local activities investigated in this empirical research can be described as string figure-making. By improving our understanding of the implementation of local mathematical practices in the current mathematics curriculum, we will show the added value and provide a guideline for best practices.

Keywords: Ethnography, local mathematics curriculum, practical turn, social turn, learning theory.

Introduction

Research on local mathematical practices and the implementation of these practices in the main school mathematics curriculum relies on two theoretical traditions. The first of which is the practical turn within the philosophy of sciences; the second, the social turn in learning theory. Both traditions share a similar concern for the fusion of both scientific practices and learning processes in a given sociocultural environment. In the theoretical section, we shall conduct a brief overview of the way in which both traditions evolved over the past decades and how the research we are reporting on is a continuation of these traditions. In the empirical part, we report on the ethnographical investigations of the local mathematical practice of “string figure-making” and its historical, cultural, social and political connections to argue for the value of implementing these practices in the current school curriculum of mathematics.

A practical turn in philosophy of science

The relation between mathematics and culture was one of the first investigations (Powell & Frankenstein, 1997) undertaken, mainly in non-western culture. The topic also became of interest in the study of western mathematical practices (Larvor, 2016a, 2016b) with a large research community (e.g. Association of the Philosophy of Mathematical Practice (APMP) founded in 2010). The practical turn was further developed in situating knowledge related to the body. Haraway (1991) speaks in this context about situated knowledge as knowledge that is constructed from a particular and specific embodiment. It is based on these partial perspectives that an “objective” vision can be constructed. Specifically related to mathematics, Lakoff and Núñez (2000) set the paradigm of the embodied mind holding that mathematics results from the human cognitive apparatus. It was further investigated by de Freitas & Sinclair (2014) by emphasizing a non-reductionist role of the body in constructing knowledge, as we elaborated on in François (2017). The body is part of a mathematical practice that produces mathematical knowledge as specific kinds of “transmaterial assemblages”. This way of building knowledge, as a co-

construction based on an embodied practice can have an important implication when it comes to the teaching of mathematics.

A social turn in learning theory

The second aspect of our article focuses on the implementation of local mathematical practices in the school mathematics curriculum. The theoretical background of this research topic relies on the social turn within learning theory and the emphasis on the fusion of the learning process into a sociocultural environment. Social sciences have developed during the last decades three main learning theories, each of them with a specific focus on the learning process (François & Pinxten, 2017). Whereas (i) behaviorism focuses on the input-output mechanisms ignoring the black box in between (ii) genetic psychology mainly focuses on the black box and what is going on in the student's mind. The (iii) sociocultural theory considers the environment in which the learning process is taking place. The social turn within the learning theory became of interest in the field of mathematics education (Bishop, 1985) mostly as a reaction to the huge dropping out of pupils from a specific socio-cultural background. Even in countries with high scores in international comparative research (which doesn't imply our support of these tests) one can easily conclude that migration and language backgrounds are an important determinant of failure in mathematics (OECD, 2014). Sociocultural theory elaborates on the learning theory of the Russian Lew Vygotsky (1978) and his concept of a *zone of proximal learning* (ZPL). The concept can be understood as the cognitive field of the pupil, which can be spotted at the fringe of the background knowledge and the out-of-school worldview. It is the zone of learning where the pupil will be able to connect insightfully to new knowledge because of the intrinsic relation between background knowledge and new inputs. Background and out-of-school knowledge are integrated in formal learning as a stepping-stone for acquiring new knowledge, new meanings and new mental frames. The concept of ZPL was an inspiration for later developments of socio-cultural learning theory and such central concepts as the pupils' background and foreground (Vithal & Skovsmose, 1997; Skovsmose, 2005). Lave & Wenger (1993) elaborated on the ZPL concept and developed a more specific notion of *legitimated peripheral participation* (LPP). They emphasize that the learning process is always a situated learning that considers the student holistically. The student is an agent who is active within a specific world context and all these aspects are mutually constitutive for the learning process. Learning is not perceived as the reception of factual knowledge or robust information. It is a social activity that takes place within a community, at first legitimately peripheral. Later, it increases gradually in engagement and complexity. Participation in social practices is the fundamental form of learning. It implies more than connecting the immediate context to the instruction. It is even more important "to consider how shared cultural systems of meaning and political-economic structuring are interrelated, in general and that they help to constitute meaning within communities of practice." (Lave & Wenger, 1993, p. 54). This concept of LPP will be an important tool to analyze our data on informal learning practices in the local communities and to understand the importance of implementing them into the formal schooling and learning environment. François & Pinxten (2017) state that we have to consider out-of-school knowledge and skills the child possesses and uses when first coming into contact with mathematics education. We have to investigate the background knowledge that children actually bring to school and how we can introduce their learning context in the teaching of mathematics at school. Blindness and ignorance concerning the local culture, local practices and knowledge may well explain the gap between success and failure, in a formal mathematics classroom. In the following section we will examine the possibilities of implementing local practices within the school curriculum.

String figure making as a local mathematical practice

For over a century, string figure-making practices have been observed by anthropologists in many regions of the world, especially within "oral tradition" societies (Paterson, 1949; Maude, 1978; Braunstein, 1992). Some mathematicians have also regarded string figure making as a worthy topic within their discipline. At the beginning of the 20th century, Cambridge mathematician W. W. Rouse Ball (1850-1925) devoted a chapter to string figures in his popular book on mathematical recreations (1911) which is—to our knowledge—the first attempt made by a mathematician to demonstrate the connection between mathematics and string figure-making (Vandendriessche, 2014a). Thereafter, a few mathematicians have developed mathematical and modeling tools in order to formalize this practice (Amir-Moez, 1965; Storer, 1988).

In the Vanuatu Archipelago (southwestern Pacific), string figure making was first documented in the 1920s by anthropologist L. A. Dickey (1928). Called the New Hebrides by the British navigator James Cook in the 1770s, this archipelago—consisting in a chain of 80 inhabited islands, located 1,750 kilometers east of northern Australia—was managed through a Colonial French & English Condominium from 1906, until its independence in 1980 and the foundation of the Republic of Vanuatu. Consequently, this country has been engaged in a (long and difficult) process of decolonization, and particularly in the field of Education. For about a decade, the Republic of Vanuatu has undertaken a reform of the National Curriculum (inherited from the colonial period), with the goal of taking more into account the various local cultures *i.e.* the various vernacular languages as well as traditional knowledge and practices.

Conducted in Northern Ambrym (Central Vanuatu), since 2006, Vandendriessche's ethnomathematical project is devoted to the study of different practices with a mathematical character such as the making of string figures. It is based on a long-term ethnography (around the village of Fona) and carried out in collaboration with both local people (practitioners and local educators in particular), and actors of the "Vanuatu Cultural Centre" (national institution working for the preservation and the promotion of different aspects of Vanuatu's culture). In François, Fantinato, Vandendriessche & Mafra (in press) we investigated the specific topic of "The researcher as the 'other'" as well as the ethical issues raised while conducting ethnomathematical field research, and collaborating with local people and institutions. We will therefore not elaborate further on these fundamental issues here.

In Vanuatu, making a string figure requires creating a loop by knotting the ends of an approximately two-meter-long string—which is made with a thin slice of a pandanus tree leaf. The activity then consists in applying a succession of operations to the string, using mostly the fingers, and sometimes the wrists, mouth, or feet. This succession of operations, which is generally performed by an individual and sometimes by two individuals working together, is intended to generate a final figure, whose name refers to a particular being or thing. Our ongoing ethnomathematical project aims at collecting various types of data: 1) the procedures leading to the various figures (using an original symbolic writing system for noting/recording them) 2) the vernacular (technical) terminology linked with the studied practices 3) the oral texts and/or discourses which are sometimes associated with the latter. At a second stage, the collected data are analyzed—and put in perspective with other ethnographical sources—to comparatively analyze the mathematical dimension of the latter procedural activity in their relationships with other forms of knowledge (Vandendriessche, 2014b). Indeed, a string figure can be seen as the result of a "procedure" (or "algorithm") consisting of a succession of "elementary operations". Most of these operations can be defined as "geometric" operations whose purpose is to modify one configuration/state of the string to transform it into another (see database in progress http://emergences.huma-num.fr/items/show/13, Vandendriessche, 2015).

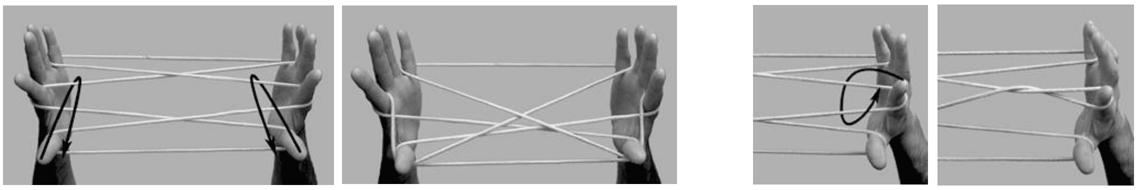

Figure 1: Elementary operations. Left: "picking up" a string. Right: "twisting" a loop

The activity of creating new string figure procedures can be regarded as mathematical at different levels. Their production very likely required an intellectual task of selecting the elementary operations and organizing them in procedures and "sub-procedures" (*i.e.* ordered sets of elementary operations either iterated within a given procedure or repeated identically within several different string figure algorithms of the same corpus). Based on an algorithmic practice, the production of string figure algorithms is also of a "geometrical" and "topological" order, insofar as it is based on investigations into complex spatial configurations, aiming at displaying either a 2-dimensional or a 3-dimensional figure. Several recurrent phenomena confirm this point: the concept of "iteration" (iteration of a pattern or a sub-procedure) and the concept of transformation (of the final figure "geometry" *i.e.* combination of motifs) are ubiquitous in this practice. Finally, some Ambrymese string figures suggest that practitioners have elaborated some procedures by altering one or several operations involved in the making of another string figure.

Local mathematical practice as knowledge transmission

In Vanuatu, there are no less than 120 different vernacular languages, corresponding to different cultural areas in the archipelago. A large number of string figures can be found in various linguistic areas, whereas a few string figures seem to be more locally practiced. However, there are significant linguistic variations (from one area to another) related to string figure making, in the names given to the activity as well as to the final figures, and in the use of technical expressions. In Northern Ambrymese society, string figure making is locally termed using the vernacular expression "*tu en awa*" (literally "to write with a string"), suggesting that this activity is perceived in this society as an encoding of information. Some other vernacular expressions are used by practitioners to refer to the (basic) movements involved in string figure making. In particular, the (elementary) operations implemented to the string are designated through action verbs; the subjects being the finger names (for instance, *pokolam hu pokokiki*, the thumb picks up the little finger *i.e.* implicitly a string running from the little finger). A few (short) "sub-procedures" (ordered sequences of a small number of elementary operations) are also named. These technical expressions are used in instances of transmission from one person to another, although not consistently. The "*tu en awa*" procedures are indeed taught or shown most often without any technical comments. However, the existence of these expressions is an indicator of the perception by the actors of orderly sequences of operations, suggesting a local perception of the notion of "elementary operations" and "sub-procedures" revealed by ethnomathematical analysis. Furthermore, vernacular terms explicitly express the property of "symmetry" (shared by a number of these figures) and the "iteration" of a pattern or a sub-procedure. It seems that string figure making is mostly transmitted to children by their mother and/or grandmother. The long "sub-procedures" (made with more than three elementary operations) are nameless for the Ambrymese practitioners. However, they spontaneously relate one string figure procedure with another when both "*tu en awa*" procedures share an "ordered set of basic movements". The practitioners do so by pointing out that from a given stage of a string figure procedure, "You do it in the same manner as you do it in another procedure". While working with Ambrymese children, we often noticed their ability in making such links between string figure procedures. This suggests that "sub-procedures" play—for these practitioners—a major role in the process of memorizing the making of string figures. In Ambrym (and more generally in Vanuatu, and even in Melanesia), the practice of string figure making is—or was—meant to record, memorize and/or express a particular knowledge of mythology, cosmology, geography, social rules, and ritual prescriptions (Vandendriessche, 2014b, 2015). For instance, the Ambrymese string figure named *bulbul algon* (literally "canoe lizard") is related to the story of Yaulon, one this society's mythical heroes. *Bulbul* designates this hero's canoe, while *algon* (lizard) recalls the symbol of one of the seven grades of the chieftainship system, whose conception is attributed to this local mythological hero. In this society, string figures are preferably performed during the yam harvest (from February to July), while their usage is prohibited outside this period, the making of such figures being perceived as having a negative impact on the growth of the plant's stem winding around the stake: it would favor the entanglement of the stem, slowing down the plant's growth. The practice of string figure-making can thus be analyzed as a method for the organization and the transmission of knowledge (mythological, cosmological, etc.), involving the use of (ethno-) mathematical concepts. When learning how to make string figures, Ambrymese children become acquainted with a technical activity (with a geometric and algorithmic character), requiring dexterity and concentration, and, at the same time, they develop their knowledge of their cultural environment.

A pedagogical application

Based on social learning theory and more specifically on the concepts of ZPL as developed by Vygotsky (1978) and later on elaborated on by Lave & Wenger (1993) as outlined in the theoretical sections, we can now analyze the added value of implementing local mathematical practices in the school curriculum. From social learning theory, we have evidence that pertains to the pupil's background information (Vithal & Skovsmose, 1997; Skovsmose, 2005), which is essential for the learning process. Pupils attending classes need to be apprehended in their entirety, as agents who develop extracurricular skills, and who live and interact in a complex environment (Lave & Wenger, 1993), where they share common cultural systems and social rules. Most of which are handed down through informal learning systems by the community. The Vanuatu National Curriculum (VNCS, 2010) is a good example of what we mean with the integration of local practices into the formal curriculum. It recognizes the value of traditional knowledge and practices—such as string figure-making, mat making, and sand drawing in particular—for calling upon the latter practices in formal education. Teachers should begin with the children's background before introducing unfamiliar knowledge, skills and attitudes. The VNCS (2010, p. 52) claims that "Teachers need to breathe life into the curriculum and demonstrate its relevance to children and students by using local examples whenever possible". It is implicitly recognized that some of these traditional practices are sometimes in decline and prompt the members of each community to "assist the children in learning about these art forms and make simple mats and other objects". Therefore, the Vanuatu Cultural Centre has given its (mandatory) assent for our project in ethnomathematics providing it leads to pedagogical applications. Beyond this institutional incentive, another motivation for undertaking such educational research is that Northern Ambrymese people generally welcome with interest the idea of using their traditional practices in the curriculum. Whereas the purpose of ethnomathematical (theoretical) research is clearly not perceived as vital as we think it is, indeed, its educational valorization makes sense for these people because they consider it as a way of preserving their local culture. Aware of these practices' decline in their community and asserting that young people are no longer interested in traditional knowledge, they consider this valorization as a way of preserving their local culture. In this context, pedagogical materials will be elaborated in an attempt to help local teachers in experimenting with the use of culturally related mathematical string figure-making practices "as such", in and of themselves. A pedagogical mathematical sequence (say in Northern Ambrymese 6th year classrooms) related to string figure-making could start by the collection of the string figures (and their vernacular names) that the pupils do remember. They should be prompted to use their local vernacular language for expressing the various operations involved in the making of these figures, as well as the symmetries and the iteration of patterns. The set of string figures thus collected could be then completed with other "*tu en awa*" procedures known to the elders of the community. Previous studies on string figures' value in mathematics education suggest that practicing string figure making may develop vital skills necessary for practicing mathematics—such as concentration, self-evaluation, spatial relation consciousness, or conducting step by step ordered sequences of instructions (Moore 1988; Murphy 1998). Beyond this analogy between string figure-making and mathematical practice, the pedagogical sequence might continue through an in-depth analysis of a set of procedures, bringing to light the (elementary) operations involved, their impact on the string configurations and their organization in sub-procedures. The teacher might induce pupils to reflect on how a string figure has sometimes been transformed into another, and how the iteration of an ordered set of operations may allow the iteration of a given motif. Ambrymese string figures sometimes differ on one—and only one—elementary operation. This remarkable property implies a methodology to create new string figures (Ball, 1911; Murphy, 1998) by altering a few operations within some "*tu en awa*" procedures, the pupils would become creators of new string figures themselves. This pedagogical (ethno-) mathematical sequence on string figure-making will not be isolated from the other forms of local knowledge imbedded within this activity. One way to do so, would be to include this sequence in an interdisciplinary pedagogical project, bringing into the classroom the cultural and cognitive complexity of this practice.

Concluding remark

In this concluding remark, we will emphasis the added value and we will offer a guideline to implement local practices in the school curriculum. As we could see from the empirical example, local mathematical practices are embedded in the social and cultural environment. They take part in the communities' social networks, their histories and their languages. They enmeshed with their natural environment and have a deep connection with nature, with a circular timeline, and with seasons, e.g. string figures are performed during the yam harvest (February–July). The idea of sustainability is implicit. Local practices are also part of the social interactions, social relations and of the informal learning processes in these communities, outside of school. String figure making is practiced by children of the Ambrymese community to play without any deeper meaning given to this practice. Connections to the broader cultural tradition are analyzed in the case of string figure making, e.g. knowledge transfer, storytelling–related to mythical heroes of that society, and encoding information. Out-of-school practices can be of interest in the formal mathematics curriculum. String figure making, with an emphasis on the mathematical analyses of the procedures (e.g. symmetry, iteration) shows how a local practice can be analyzed as a method for the organization and the transmission of knowledge. Implementing these practices in mathematics and school curriculum acquaint pupils with a mathematical (e.g. geometric, algorithmic character) activity. At the same time, pupils develop knowledge of their own cultural environment and they learn to value local traditional practices and knowledge as a means of preserving their culture. This way we create a continuum between informal and formal learning which relates to the socio-cultural learning theory, the concept of a *zone of proximal learning* (ZPL) and the concept of *legitimated peripheral participation* (LPP). The local practice we studied is performed in a situated context, it is connected to the daily life experiences and related to broader cultural traditions and transmission of knowledge. The guideline we take from this analysis is that local practices can serve as a tool to connect to pupils. When implemented in a formal school curriculum, they remain connected to the pupils' background and their out-of-school worldview. Pupils will be able to connect insightfully to new (mathematical) knowledge because of the intrinsic relation between local practices and the mathematical procedures that underlie the local practices. Even new pedagogical materials shall never be isolated from the other forms of local knowledge they are imbedded in. This clears a path for interdisciplinary activities and the integration of mathematical knowledge in a lively and meaningful context. A situated learning process considers the student as a whole person as is the case in the out-of-school transmission of the local practices we studied. The challenge for further research will be the application of this study to a variety of cultural environments and how the implementation of local practices in formal (mathematics) curricula should work.

How to educate preservice mathematics teachers? - Identity perspectives in a mixed concurrent setting

Lara Gildehaus[1] and Michael Liebendörfer[1]

[1]Paderborn University, Institute of mathematics, Germany; gildehaus@khdm.de; liebendoerfer@khdm.de

Different systems (e.g. concurrent and consecutive), knowledge (e.g. CK, PCK, SRCK, PK) and interventions (e.g. bridging courses) in teacher education are widely discussed. Facing a loss of interest in mathematics and often claimed irrelevance of subject specific content, we investigate preservice teachers' participation in university mathematics from an identity perspective, taking their social context into account. Three group interviews of 14 preservice teachers in a mixed concurrent setting (one course specific to preservice teachers, one general mathematics course for major students as well) were analyzed, showing that they experienced a position of being less valued in the mixed course. We identify different ways of students' self-authoring, which partly explain their disaffection and consequent learning behavior. Consequences for institutional settings are discussed.

Keywords: Preservice teachers' education, university mathematics, identity, participation.

Educating preservice mathematics teachers

Although there are many different school and training systems internationally, the discourse about content or pedagogical knowledge, pedagogic content knowledge or school related content knowledge (Dreher et al., 2018), scientifically or practically oriented teacher training is evident in almost every context – especially for preservice higher secondary teachers. While there are additional or dual training programs in some countries, the main form of teacher education in most countries remains the preservice education at universities (Durand-Guerrier et al., 2010). These trainings can be organized differently, mainly in an either concurrent or consecutive way. The concurrent model of initial teacher training involves a study program that combines general, theoretical, and practical training from the outset. Students gain a teaching specific degree, mainly with two different subjects. This is the case for example in Austria, Poland, Sweden, or Turkey. In the consecutive model, preservice teachers first obtain a general qualification (e.g. a university degree in mathematics) followed by further studies to gain an additional qualification for teaching. They often (but not always) study one single subject. Examples for consecutive systems are France, Georgia, Italy, Malaysia, or Singapore (see Tatto et al., 2012 for details).

Largely independent from the concrete organization, the often-challenging transition from school to university mathematics and the overall faced double discontinuity (Klein, 1932) reveal further challenges for preservice mathematics teachers. It seems, that many students worldwide question the relevance of their studies, being dissatisfied and feeling treated as second-class students which are no "real mathematicians" (Tatto et al., 2012; Bauer & Hefendehl-Hebeker, 2019).

In this paper, we focus on the mainly concurrent system for preservice higher secondary teachers in Germany with its rather mixed setting: In contrast to the consecutive system, preservice teachers enroll in specific teacher training programs at the beginning of their studies and have to choose two subjects. However, they usually attend some subject specific courses together with major students of the respective subject – sometimes also subject-specific courses designed specifically for preservice teachers. Additionally they have, courses on subject-specific pedagogical content knowledge as well as general teacher training courses on pedagogical content knowledge together with preservice teachers of other subjects. Hence, preservice mathematics teachers share part of their courses with mathematics major students.

Differences in cognitive prerequisites between mathematics majors and preservice teachers are rather small at the beginning of their studies (Bauer & Hefendehl-Hebeker, 2019). However, an overall disaffection and different participation, based on a perceived exclusion and lack of relevance, can be seen for some preservice teachers, after the first semester: they lose interest in university mathematics more than the major students do, describe themselves as being excluded from the mathematics community, especially in courses that are shared with mathematics major students (Ufer et al., 2017; Liebendörfer, 2014), they think about dropping out more often, report to both copy homework and use surface learning strategies more often. They report to be very disaffected with their study content, criticize university mathematics as being irrelevant for their future profession, and demand more practice-related content (Gildehaus & Liebendörfer, 2021 with further references).

To better cater to preservice teachers' demand for more practically relevant content, many universities adapt or supplement their teaching, e.g. with specific tasks connecting university mathematics with school mathematics. However, the main critique often sustains, right after specific tasks are finished (Bauer & Hefendehl-Hebeker, 2019). Making the relations to school content more visible may raise students' utility value but not their interest or personal relevance (Rach, 2020).

To better understand preservice teachers' disaffection with and perceived exclusion from mathematics, we suppose to broaden the perspective by including the social context: Preservice teachers need to negotiate and integrate their own competing interests and self-images between their subjects and pedagogy facing competing subject cultures and corresponding attributions. This may explain specific values and motivation that could explain different participation, as well as an overall rejection of university mathematics content (Gildehaus & Liebendörfer, 2021). We therefore take identity as a theoretical perspective to examine preservice teachers more closely within the social context of university mathematics (Graven & Heyd-Metzuyanim, 2021). Investigating their sometimes-perceived exclusion from university mathematics in line with different participation, we focus students' positioning and authoring.

Identity in figured worlds of university mathematics

"Identity is a concept that figuratively combines the intimate or personal world with the collective space of cultural forms and social relations" (Holland et al. 1998, p. 5). Hence, identity covers specific career aspirations and interests of preservice teachers as well as the social context of university mathematics and the exclusion mentioned above.

According to Holland et al. (1998), identity is mainly produced and developed in figured worlds which are “socially and culturally constructed realms of interpretation in which particular characters and actors are recognized, significance is assigned to certain acts, and particular outcomes are valued over others” (p. 52). University mathematics as a figured world possibly includes major students, preservice teachers, professors, and tutors as relevant actors, where specific outcomes (e.g. knowledge, solutions of tasks) would be valued.

The transition from school to university mathematics can be seen as a phase of identity development, a situation where a new figured world is entered and orientation of specific actors, roles, positions, and practices are sought. Students may search for “new guidelines” (Hatt, 2007) within this new world of university mathematics. Certain roles within this figured world help to define who one is. The so called “positional identity is a person’s apprehension of her social position in a lived world: that is, depending on the others present, of her greater or lesser access to spaces, activities, genres, and, through genres, authoritative voices, or any voice at all” (Holland et al., 1998, p. 151). Along with day- to-day social interactions, one claims position and positions others by social interaction and on the ground relations of power (Hatt, 2007). In terms of the experienced exclusion that some preservice teachers described and the feeling of being perceived as “less valued”, it may thus be a question of their position and positioning within the figured university mathematics world.

Based on Bakhtin’s thoughts on dialogism, the concept of “authoring” refers to how individuals construct their own identities (Urrieta, 2007). Since one’s positioning within a world may also determine one’s space of answering and negotiating one’s own identity, Holland et al. (1998) introduce the “space of authoring”. Hereby, authorship is not a choice, because within social situations every action or inaction would be a reaction and response to the situation (Urrieta, 2007). Thus, the interactions between characters and actors (e.g. preservice teachers, major students, professors, and tutors) of the figured world, might indicate insights of the individual’s space of authoring and negotiating of their perceived position. E.g., the described position of preservice teachers feeling “less valued” may be integrated or negotiated within students self-authoring process.

Research questions

Facing the disaffection of preservice teachers in mathematics from an identity perspective, we aim to examine their position and authoring within the social context of a mixed concurrent model:

RQ1: How do preservice mathematics teachers describe and experience their perceived position and positional identity in a mixed concurrent teacher training system?

RQ2: How do preservice mathematics teachers author their own spaces and voices in this situation?

Method

Our study is located at a German university where in their first semester, preservice higher mathematics students attend one course (linear algebra, LA) together with mathematics majors and one course specific for preservice teachers (introduction to mathematical thinking and working, IC). This latter course is designed as a bridging course, which aims to facilitate the transition from high school mathematics to abstract, formal mathematics at university. Thus, its overall content requirements are lower than the ones in the LA.

Three semi-structured group interviews with four to five preservice mathematics teachers each (n=14; 8 female, 18 to 23 years old) were conducted in winter term 2019/20 at the University of Paderborn two months after the first semester had started. The interviews took place in person, after students answered an open call voluntarily. The call addressed groups of students already e.g. they had been working together on homework before. This was chosen to comfort them to freely discuss their perceived position and limit the influence and power of the interviewer. It also gave the chance to directly contrast different authoring between the students. They were guaranteed anonymity and in no further contact or relation with the interviewer. The participants represented diverse second subjects (e.g. sciences, foreign languages, sports or social science).

The interviews focused on the students' experiences and their identity. The guide included questions like: "To what extent do you identify yourself with university life here? How much do you feel as mathematicians? How would you describe to your parents what mathematicians are and do?" Students were not explicitly asked whether they perceived differences between the two courses. Only during data analysis, this occurred to be a dominant theme and was therefore included.

For data analysis the interviews were coded deductively and inductively (Saldana, 2016), firstly identifying passages along students perceived positions (e.g. their scope of action, their ways of participation), as well as their authoring (e.g. their reasoning narrating themselves). The different themes that emerged within these categories (e.g. writing to the board, asking questions) were then combined into broader categories (e.g. being valued, being competent, and access to spaces) and later analyzed with the specific focus on the different courses. Keeping and gaining different perspectives in the interpretation, themes were frequently discussed with researchers from different backgrounds (e.g. mathematicians and preservice teachers, males and females). In the following, all presented quotes were translated from German by the first author.

Results

RQ1: In line with the separate study programs, the perceived position of preservice teachers was described as "different" and divided from the mathematics major students. This difference was present in all spaces, e.g. during the mixed courses, but also during general learning at university:

> Student 3: So, computer scientists and mathematicians always sit together and preservice teachers always sit together somehow. And I think that it just doesn't come together at all.

Consistent with their further career aspirations, large differences were reported concerning the value of explaining and teaching mathematics to other people:

> Student 4: So, math is fun to me, as a teacher. It's not that I'm happy in my math world like a mathematician, but I would like to teach it to someone.

Within the two courses, they described differences how these attributes were valued in the different courses:

Student 3: In IC, I think, there are only people who are really teachers and you can say that they (…) really try to explain things to you (…). In LA there is just less, yes, somehow motivation to explain.

In line with this, they felt relatively respected and accepted in their position in the IC, even though they were mainly passive receivers of knowledge and realized that the content was "far from what is done in school already":

Student 3: Well, I think it works to a certain extent in IC. So, you can still keep up well.
Student 2: IC gives a good feeling, especially in contrast to LA.

Within their LA course, however, and in general in comparison with the major students, they described to feel less valued and as second-class students. Mainly they referred to other students:

Student 1: I think it's always a pity when people come and say, oh yeah, you're only doing a teaching degree.

Similarly, they referred to the lecturer of the LA course:

Student 6: But you always have the feeling that he doesn't really think much of teachers either. // He doesn't say that precisely, but always
Student 4: So, you always notice that you're talked down to.
Student 6: Like: "Yes, we do that so that the future teachers sitting here can teach their students that, so they can then solve the math problems of tomorrow." And then you think to yourself: "are we too stupid for that or what?"

Preservice teachers' access to activities and spaces was also limited in comparison to mathematics majors, who were remarkably more present in terms of what "counted" in this figured world, hence in relation to the specific power of knowledge (even though they were fewer people): They were for example using the whiteboards in the university, visibly discussing mathematical problems. They were described as "asking questions in the lecture" and "making jokes with the professor", while the interviewed students did not see such voice for them:

Student 5: They [mathematics majors] are more on the professor's level than on ours.
Student 6: Well, they always get along really well with him, and he also makes jokes with them.
Student 4: But we just don't understand it.

Their institutionally different and divided positioning became also clear, as they were not attending the second course for major students "Analysis I":

Student 3: And then he says yeah, you might know that from Analysis (…).
Student 4: Then you sit there and think to yourself, well, I'm studying to be a teacher, I don't have Analysis in parallel (…). How am I supposed to know that?

Hence, some described feeling misplaced, since they felt not addressed or valued by the professor in the LA course:

Student 5: I think it's true that you sometimes have the feeling that you really notice that the lecture is tailored to mathematicians. So that he always addresses them, the mathematicians rather, and you as a preservice teacher are just like (…) okay, somehow I'm a bit out of place here.

RQ2: The most dominant topic in students' ways of authoring was to find a voice at all, since they all felt more or less overwhelmed in their current situations. However, we found remarkable differences between some students:

One way of authoring was that of quickly accepting the perceived position of being less valued and use this image of “just a teacher” to legitimize less participation and lower performance in the LA course, including the acceptance of being perceived as less competent in mathematics:

Student 1: I would never call myself a mathematician, for that I also see more and more in the homework that it’s just not like that (…) I’m just a freshly started teacher student.

Student 1: So, my entire first half of LA [referring to necessary point in exercises] is not based on my own knowledge, but that is just sometimes a thing.

This was underlined with the idea, that the LA course would not be very relevant, and one would somehow do the same in the IC course anyways. Hence, the IC course was seen as very relevant and useful and perceived competence was taken out of this:

Student 1: I now have at least one lecture where I can still follow (…) and once you have that in a somewhat weakened form, it really doesn’t hurt, I think.

Other students, in contrast, struggled with their perceived position and tried to renegotiate it, mainly referring to their self-image of “always been good in mathematics”. These students tried to find a voice and participate, but realized that their actions were not valued:

Student 6: When they [tutors in the LA course] roll their eyes when you ask something.

Student 5: There you already don’t dare to ask a question.

What followed this failed participation was a rejection of the mathematical content of the LA course, as being irrelevant and major students and tutors of this course being unsocial (see Gildehaus & Liebendörfer, 2021 for details). While those students participated successfully in the IC course, they used it to legitimize the irrelevance of the LA course. They authored themselves as mathematics teachers, who are just not competent in the LA course, because it did not suit their specific needs as preservice teachers.

In addition to these two ways of authoring, there was one more way presented by a rather exceptional student: She agreed on being positioned as a (less valued) preservice teacher but tried to renegotiate her position to be recognized as full mathematics student as well. She valued both courses for their individual strengths and reported to participate successfully in both courses (e.g. she was asking questions in the tutorials for both courses and sometimes chatting with the tutors). Thus, this student was also exceptional in that she was mathematically able to participate in both courses. At the same time, she clearly distanced herself from the teaching profession:

Student 2: A lot of people here are like, yes, teacher is my dream job, but I’m not like that. (…) I don’t know yet if I’ll eventually be a computer scientist instead of a teacher, I don’t know. Why can you only be one thing, // why can’t you be everything?

Discussion

Preservice mathematics teachers are often disaffected with their studies, question the relevance of the content, and aim for more practical relevance. Using an identity framework, we expanded the theoretical perspective from the individual to the social context of university mathematics. We analyzed group interviews of first-year preservice teachers in a mixed concurrent setting in Germany, where they attend one specific preservice teachers’ mathematics course and one mathematics course together with major students.

RQ1 investigated the perceived position of preservice teacher within the social space. Even though preservice teachers were the vast majority in the mixed course, they felt positioned as a marginalized minority: they described exclusion (insider jokes, mismatching addressing) and being less valued and perceived less competent by professors, tutors, and major students. RQ2 focused students' different ways of self-authoring along this perceived position. One way of negotiation was to accept the position including lower performance and less participation in the LA course. Another way was to reject being less valued despite finding no voice in the LA course, followed by a rejection of the content and staff of this course. A third way was finding an exceptional position claiming to be both a preservice teacher and a mathematician.

The first two presented ways of authoring eventually lead to accepting and integrating the perceived position of "just being a teacher" legitimating students' minor engagement (e.g. copying homework, as Student 1 describes) with university mathematics contents, as they consider the contents as not relevant for them. Yet, students following the second way were clearly seeking participation in university mathematics. Their rejection and claimed irrelevance followed after not finding a voice.

Despite initially small differences (Bauer & Hefendehl-Hebeker, 2019) preservice teachers are soon positioned as less competent than mathematics majors. Their performance might in fact be lower as they study a second subject and miss synergies with the Analysis course. However, within the mixed setting preservice teachers are so strongly positioned as less valued group that even exceptionally able students can hardly escape attribution to the teachers' group only. The positioning as preservice teacher builds on very visible categories like attending the Analysis lecture and students' physical positions in the LA lecture and thus becomes very dominant. Our research also confirms that almost only high-performing students may legitimately participate in the university mathematics discourse (Solomon, 2007). In concurrent teacher education with mixed settings, preservice teachers may then have severe trouble participating equally. This calls for a new pedagogy that allows legitimate participation like asking "stupid" questions without tutors rolling their eyes.

Specific bridging courses seem double-edged: They help students participating in a discourse. However, the courses may also be used to legitimize the irrelevance of lectures like LA, since they are not "real teaching lectures" and thus not important for "just teacher students". Thus, an intervention to accommodate students in their transition to university mathematics, can also lead to additional distancing.

We conclude that if we want to address the dissatisfaction and alleged content-irrelevance reported by preservice teachers, we should not focus (only) on the usefulness of the content for the profession but find ways for students to participate mathematically on an equal level with any other group attending the same courses. Taking these results into the wider context of concurrent and consecutive teacher training systems, the consecutive model, not having an institutional distinction, could reduce the perceived differentiation between the major and teacher students. At the same time, individually (as well as systemically) different values and images of "becoming a teacher", "valuing explaining" remain and might not prevent from similar positioning and related self-authoring.

Limitations and further research implications

The presented results mirror one specific institutional system, with the data highly pending on their specific social context. Future research should include different institutional systems in an international perspective to draw conclusions on preservice teachers' identity formation if they have only shared courses with mathematics majors or only their own courses. Including the perspective of mathematics major students and teaching staff would also help depicting preservice teachers' identity formation in the shared social space. It remains unclear how major students, that might struggle with the contents could find a voice to participate, as the "just teaching" image is obviously not available for them.

Diversity-aware teaching of mathematics: an explorative study on pre-service teachers' views

Anna Hummel[1] and Nina Bohlmann[2]

[1]Leipzig University, Faculty of Education, Leipzig, Germany; anna.hummel@uni-leipzig.de

[2]Leipzig University, Faculty of Education, Leipzig, Germany; nina.bohlmann@uni-leipzig.de

Preparing future teachers to be aware of students' diversity and enabling them to teach responsively in order to create equal opportunities is considered an important part of teacher education. Realizing this for mathematics education is commonly associated to various approaches to promote equity. In this contribution, we focus on the innate views of pre-service teachers on diversity-aware teaching of mathematics to investigate their initial understanding. We present an explorative study that surveyed the views of 105 primary school pre-service teachers by means of a questionnaire. Those views were categorized by a qualitative content analysis. The results show that pre-service teachers most likely want to be and act aware of diversity when teaching, but rarely show sensitivity or knowledge of the particularities of school mathematics.

Keywords: Pre-service teachers, diversity-aware teaching, mathematics teacher education.

Introduction

Notions like 'diversity' or 'equity' have gained in significance in the last twenty years in the realm of education as well as in other discourses and society in general. Despite conceptual and terminological vagueness around these terms, in education they are commonly linked to the idea of creating an *education for all,* i.e. overcoming socio-economic inequalities and providing all students with equal opportunities to participate and succeed in the education system. This idea results in certain demands for teacher education as well as research attempts to conquer the lack of theoretical and practical knowledge how to reach this goal. Responding to students' diversity is associated with knowledge, awareness and acceptance of other cultures (including demographic factors such as race, gender and age) and results in responsive teaching to and through students' personal and cultural strengths and experiences (Gay, 2010). Considering that within the German education system the term of 'cultural awareness' is highly associated with intercultural learning – which does not necessarily provide an intersectional perspective on all markers of difference in students – we used the terms 'diversity awareness' and 'diversity-aware teaching' to represent the associated meanings as stated above.

Preparing future teachers for diverse classrooms is a complex issue which includes, among others, practical, theoretical, philosophical, ethical and affective aspects. In this paper we want to focus on the aspect of *diversity-aware teaching*, which (for us) combines being aware of differences among students, appreciating those differences as well as taking actions to promote equity. These aspects play into the perception what teaching a diverse classroom could look like and are tangent to reflecting on the relation between teaching and (structural) learning disadvantages. This process can be labelled as 'doing pupil' and is highly normative (Schönknecht & de Boer, 2008, p. 255).

Apart from certain general characteristics of diversity awareness, every school subject has specific peculiarities that result in subject-related attributes of diversity-aware teaching. Since mathematics education is widely known as a gatekeeper to successful participation in school and society, it is attributed with a significant role in creating equal opportunities (e.g., Stinson, 2004). We regard diversity-aware teaching as central to a pedagogy that seeks to overcome social inequalities and see special importance in investigating diversity-aware teaching in the realm of mathematics education. However, there is no consistent concept for diversity-aware teaching of mathematics and there is still little known about how to develop according dispositions. Considering these two aspects of unclarity we seek to investigate pre-service teachers' innate views on diversity-aware teaching for mathematics. This, in turn, should give us information about how to improve mathematics teacher education in order to enable pre-service teachers to reflect on their own view on diversity-aware teaching before engaging with a certain approach and eventually develop responsive dispositions.

In our study we surveyed the views of 105 primary school pre-service teachers by means of a questionnaire. We will first discuss the state of research on pre-service teachers' views on diversity-aware teaching of mathematics, before we present our empirical study on the pre-service teachers' views.

Literature review

Terminological and conceptual aspects of diversity awareness and diversity-aware teaching of mathematics

Although the concept *diversity awareness* is considered as central for teaching (Mason, 2008; Turner et al., 2012), it is rarely defined or described explicitly. Notions that are used as synonyms or underlie a similar understanding are *diversity sensitivity* or *cultural awareness.* Furthermore, there are parallels to the concept of *culturally responsive teaching*. Besides the fact that there is no common understanding or widely accepted definition, we find a terminological inconsistency whether diversity awareness is an attitude, a set of attitudes, a competence, or a belief. Despite the terminological inconsistency and conceptual ambiguity, there is consensus that diversity awareness is not a passive mindset of being tolerant. It moves beyond merely tolerating differences and is rather about appreciating, understanding and valuing personal differences. This includes perceiving differences as normal and reflecting on standards and norms (such as heterosexuality, Christian socialization or whiteness) as well as developing agency to promote equity. All of these aspects of diversity awareness feed into potential conceptualizations of diversity-aware teaching. In accordance with Eickhoff and Schmitt (2016) diversity-aware teaching requires

- to recognize differences (and commonalities) between individuals,
- to accord everybody equal rights,
- to recognize unintentional attributions, stereotyping, stigmatization or discrimination and work against them,
- to perceive existing inequalities, to name them and finally to reduce them.

Due to its historical development and its special attributes, school mathematics inheres structures and practices that result in inequitable access to achievement and participation for certain groups of students. It is in particular non-native speakers, female students, students with disabilities, immigrant students, students of colour and socially or economically disadvantaged students who face difficulties in school mathematics. Diversity-aware teaching in the realm of mathematics education requires knowledge and reflectivity about discriminating structures that are specifically inherent in school mathematics. This includes, among others, the fact that mathematics is primarily an abstract science, which is hierarchically organized and requires prior knowledge. Mathematical knowledge is often framed as intellectual with little integration of the body and of physical learning. Furthermore, high school mathematics is often characterized by problem solving activities which is difficult to reconcile with the desire of female students who tend to prefer clearly structured activities (Budde, 2009).

Conceptual frameworks for mathematics education referring to, and thus being aware of students' diversity in international literature are often presented as 'equity in mathematics education' (e.g., Civil, 2007; Gutiérrez, 2012; Turner et al., 2012), 'culturally responsive mathematics education' (e.g., Parker et al., 2017) or 'teaching mathematics for social justice' (e.g., Gutstein, 2006). Implementing those concepts in teacher education as well as addressing the contradictions within researching social injustice and mathematics education (e.g., Aguirre et al., 2017; Bartell et al., 2017; Hauk et al., 2021) are vivid contributions. However, although significant contributions around equity in mathematics have been done (see, e.g., Atweh et al., 2011 for a compilation of international work on that topic), there is a need of more research on how to achieve equity and social justice in mathematics education.

Studies on pre-service teachers' views on diversity-aware teaching of mathematics

In our study we investigate pre-service teachers' innate views on diversity-aware teaching of mathematics in order to provide a reference for the development of mathematics teacher education. Following Felton-Koestler (2017), we focus on and use the term 'view' for a number of reasons. First, encouraging pre-service teachers in unpacking their views about teaching is a key component to developing reflective practitioners. Second, our data consists of written responses to a questionnaire, with a small number of selected questions. The answers might enable us to capture students' views, but not something like beliefs, which are often framed as relatively stable and difficult to access (Felton-Koestler, 2017). For the same reason we did not focus on the interplay of pre-service teachers' identity and their views, even though views on diversity as well as on diversity-aware teaching are always connected to the perception of oneself and personal schooling experience (e.g., White et al., 2020). We perceive 'view' as a manifold influenced mode of looking at or regarding something and/or as an opinion or judgment.

To our knowledge there are no studies that focus on pre-service teachers' innate understanding of, or views on diversity-aware teaching of mathematics. Bitterlich and Jung (2019) found that pre-service teachers see major challenges in responding to students' diversity, especially in mathematics, and that they are missing concrete positive experiences they could associate to this diversity (p. 620). These findings deliver further evidence that diversity-aware teaching of mathematics is seen as very difficult, which highlights pre-service teachers' valid concerns and feelings of unpreparedness, but do not present how pre-service teachers view diversity-aware teaching of mathematics initially.

In line with these findings, the need to prepare pre-service teachers for diverse classrooms is a focal point in related research, whereas most studies discuss pre-service teachers' development of views or skills before and after attending a certain course. These pre-post-study designs are based on specific conceptualizations or approaches for equitable mathematics education, instead of determining pre-service teachers' innate views.

Connecting children's mathematical thinking and their cultural funds of knowledge can be seen as one approach of diversity-aware teaching which works towards equitable mathematics teaching. Turner et al. (2012) focused on the development of pre-service teachers' learning trajectories for engaging with children's *multiple mathematical knowledge bases*, considering and including the diversity in community or culture-based experiences and knowledge. Pre-service teachers framed drawing on community-based knowledge for mathematics learning as a possibility to position "children, their families, and communities as valuable knowledge resources" (p. 74). This proposes a view on diversity-aware teaching which purposefully incorporates multiple mathematical knowledge bases in instruction and was thereby consistent with the learning trajectories goal to promote equity. But other comments of pre-service teachers showed deficit-based views of children's families or communities, e.g., by framing certain characteristics of some families as detrimental to children's learning. Those results picture diversity-aware teaching more as an approach that has to compensate for collectivized deficits. These findings highlight an important notion to diversity awareness, since *being aware* does not necessarily equal *appreciating* diversity.

White et al. (2016) implemented a cultural awareness unit for pre-service teachers aiming to develop awareness of the role of culture in the teaching and learning of mathematics. One goal of the unit was for pre-service teachers to explore strategies to teach mathematics to all students (and therefore to reflect on their own view of diversity-aware teaching). They were assigned to search for journal articles that discussed the teaching and learning of mathematics with students that were culturally different from themselves. Stating that most pre-service teachers were drawn to a "particular culture or strategy for teaching diverse students" (p. 167) when choosing an article, the findings suggest that pre-service teachers' tend to break down diversity-aware teaching into specific or even isolated perspectives on diversity. These findings relate to the importance of acknowledging how difficult the conceptualization of diversity-aware teaching of mathematics is and was taken into consideration while attending to the pre-service teachers' answers in our study. The approach to elicit pre-service teachers' perspective of teaching mathematics for equity through literature-based reflective tasks can also be seen in Jackson and Jong (2017). They stated that even though students were aware of "the necessity to incorporate students' backgrounds in the classroom […] they did not realize the importance of doing this in a mathematics class" (p. 76). 35% of participating pre-service teachers had not thought about how to connect culture with mathematics education.

Summarizing, these findings led us to our research interest to what extent pre-service teachers view diversity-aware teaching of mathematics as linked to social constructs and socio-political context.

Methodology: data collection and analysis

The aim of our qualitative study was to examine pre-service teachers' views on diversity and diversity-aware teaching of mathematics. For this purpose, we designed an online questionnaire with a small number of open questions on diversity and inclusion in the context of mathematics education. The study was conducted in April 2021 with a group of pre-service teachers from Saxony (a federal state in the eastern part of Germany and former GDR) who were in the third year of their academic teacher training. The student population in Saxony is predominantly white, middle class and without confession or of Christian denomination. 105 students finished the questionnaire (gender identity: 1 diverse, 11 male, 93 female; average age: 23,5 years). Our investigation is to be seen as an explorative study, which serves as a starting point for further research, and additionally as impetus to modify the ways and contents of our own teaching. In this paper we focus on two questions of the questionnaire: 1) What is your understanding of diversity? and 2) What is your understanding of diversity-aware teaching of mathematics? The data consists of written responses to each question which differ in length between single words up to several paragraphs (approx. 160 words).

As a tool to analyse the data, we used a qualitative content analysis. This approach aims at the establishment of categories that are supposed to be developed while doing the text analysis. In our study we deployed an inductive category formation as there is no specific theoretical background that could be used and as we wanted to analyse the data as open as possible. The inductive ongoing "aims at a true description without bias owing to the preconceptions of the researcher, an understanding of the material in terms of the material" (Mayring, 2014, p. 79). We applied an open coding procedure, formulated and revised the categories while working through the text.

Results

First, we will focus on the pre-service teachers' views on diversity. The analysis showed differences in the conceptual understanding of diversity. We could identify a large number of vague and descriptive answers, simply pointing to differences (among students) or mentioning supposed synonyms (such as heterogeneity or variety) (88 out of 105 responses). Some of the pre-service teachers specified those differences in terms of individual characteristics (special skills, appearance, needs, interests etc., stressing the individuality of every single person) or in terms of group-related characteristics (social or cultural background, first language, race, gender, religion, etc.). Some of the answers mentioned that the notion *diversity* implies valuing differences, mutual respect or seeing it as a chance and enrichment for a classroom and/or society (26 responses). Only few students additionally pointed to a reflective mindset, e.g., considering diversity as normal or desirable or questioning structural inequalities as result of a constructed norm (13 responses).

Second, we will look on the pre-service teachers' view on diversity-aware teaching of mathematics. Here, a large number of the answers referred to a teacher's mindset towards diversity. Most of the participants stated the need to be aware of differences and/or students' individuality as well as to react to it (63 responses). Segments we coded accordingly can be seen as unspecific (e.g., not suggesting any implications for adapting the teaching), and do not allow a deeper analysis of the (conceptual) understanding of the awareness for differences or how it could affect teaching. About 10 % of the answers showed a positive reference to diversity for teaching/learning interactions, e.g., claiming appreciation or promotion of diversity as well as valuing individuality. Here we could clearly recognize links to the pre-service teachers' conceptual understanding of diversity.

Another 20 % suggested a reflection on what is perceived as diverse or as normal (referring to students' characteristics, identity or learning pathways) as part of diversity-aware teaching. Some of the pre-service teachers also mentioned the need for teachers to reflect on their own perceptions and pointed to the influence of attitudes or of normative assumptions for classroom interaction. Almost a third of the answers were coded as *socio-political perspective*. Here we found reflections on internalized stereotypes within teachers, reproduced stereotypes in narratives or teaching material or on structural relations between educational disparities and social/societal disadvantages.

44 responses referred to certain methods, specific tasks or organizational adjustments for teaching a (however defined) diverse group of learners in order to respond to students' diversity. We summarized these answers as *teaching strategies*. Most of the strategies aimed at reducing inequalities or at valuing diversity within teaching/learning interactions. If specific methods, tasks or organizational adjustments could be identified as typical or specific for mathematics teaching, we coded them as *specific structural aspects of mathematics education*. Here we found references to the negatively attributed reproduction of stereotypes or discrimination within certain materials, narratives or organizational aspects that are characteristic for mathematics education. For instance, some of the pre-service teachers mentioned the particularities of word problems whose narratives run danger to reproduce stereotypes or do not represent the lifeworld experiences of certain groups of students. Others were concerned with gender-related differences and called for methods, activities and contexts that enable especially girls to successfully participate in the mathematics classroom. We could also find references to mathematical tasks that allow for different approaches and/or different results (such as natural differentiation), or to linguistic challenges and necessary support in teaching and learning mathematics. Some mentioned specifically 'fast calculators' or students 'with poor counting skills'. However, only 19 % of the answers showed such references to specific structural aspects of mathematics education.

Discussion

The majority of the pre-service teachers in our study presented a view on diversity-aware teaching which simply put *being aware of differences in and individualities of students* as an essential part of teaching. Most of them presented themselves as well aware of the diversity in current and future classrooms. Significantly less answers framed diversity-aware teaching within a view that explicitly valued or mentioned the promotion of diversity. The transfer of being aware of diversity into teaching strategies seems to be a major obstacle, since not even half of the pre-service teachers mentioned any strategies or approaches to do so. This tendency becomes even more apparent when focusing on the elicited views on diversity-aware teaching which could specifically be related to mathematics teaching and learning: Only 20 out of 105 pre-service teachers linked diversity-aware teaching to specific structures or characteristics of mathematics education. Within those subject-related answers most stated some sort of appreciation of diversity and referred to (responsive) teaching strategies specifically for mathematics. This highlights that pre-service teachers most likely want to be and act aware of diversity when teaching mathematics (whether due to an appreciative attitude or due to the sheer necessity to do so), but rarely show sensitivity or knowledge of the particularities of school mathematics. This also points out another tendency within the study: If a connection between diversity and mathematics education was made, it predominantly referred to tangible interactions or strategies of teaching rather than to structural contingencies. None of the given answers reflected on mathematics as a gatekeeper or on the influence of mathematics education for paving educational pathways. These findings are well in line with current research reflecting on mathematics teacher education (e.g., Jackson & Jong, 2017) and deliver implications for our own further teaching.

Within the stated tangible strategies for diversity-aware teaching of mathematics, the expressed connections between mathematics teaching and diversity awareness mainly referred to the very apparent level of representation. More than half of the elicited views on diversity-aware teaching that specifically referred to teaching mathematics emphasized the need for the representation of diversity in teaching materials (e.g., illustrations in textbooks or chosen contexts for word problems) or they stated the need to avoid stereotypes or discriminating language when phrasing tasks. Making a deeper connection between diversity-aware teaching and structural disadvantages in mathematics education could only be identified in four answers. These answers presented a view on diversity in students (cultural, community or family) backgrounds and experiences as relevant for mathematics education. This view can be interpreted as a first step to recognizing the complex interdependencies of mathematics education and socio-politics. For us, these conceptions represent a higher reflective level when debating diversity-aware teaching of mathematics.

Addressing mathematics pre-service teachers views on diversity can be seen as a key component in preparing them for diversity-aware teaching. Eliciting those initial views was one of the goals in our study. To us, the results highlight the importance of referring diversity-aware teaching explicitly to mathematics education and emphasize the need to discuss the role of (school) mathematics as a gatekeeper in teacher education – despite or even because of the vagueness when pinning it down. Even though there are numerous significant contributions in mathematics education research on equity (e.g., Atweh et al. 2011; Gutiérrez, 2012; Aguirre et al., 2017), there is no shared or well-defined understanding of ‘equity’ and how it can be achieved in mathematics education. Following the call of Gutstein and colleagues (2005), that each of us “has a responsibility to both think about and act on issues of equity” (p. 98), we consider becoming aware of one’s own understanding of diversity and diversity-aware teaching as one of many steps to deepen the understanding of equity in mathematics education. In addition, according to the identified categories in this study, a theoretical framework combining socio-political and subject-specific aspects for diversity-aware teaching of mathematics seems to be a necessity in future research.

Study guidance in Arabic in mathematics – tutor resources

Petra S Källberg[1] and Ulrika Ryan[1]

[1]Malmö university, Faculty of Education and Society, Malmö, Sweden; petra.svensson@mau.se
ulrika.ryan@mau.se

Keywords: language as resource, mathematics, epistemology, study guidance in mother tongue.

Background

Due to migration many students attend classrooms where they cannot learn mathematics in their home languages because of prevailing monolingual curricula and classrooms norms. This is the case in mainstream mathematics classrooms in Sweden where Swedish is the language of instruction and where this study was conducted. It is regulated in Skolförordningen [the Swedish School Ordinance] (SFS 2011:185 chapter 5 §4), that a student can receive study guidance in the mother tongue (SGMT), if the student needs it. Thus, SGMT in mathematics is grounded in the idea of the home language as a resource for multilingual students' mathematics learning. SGMT is provided by SGMT tutors. There are no formal educational requirements for tutors. According to Skolverket [Swedish National Agency for Education] (2015) it is desirable that tutors have subject knowledge, knowledge about the students' prior and current educational systems and pedagogical practices, and a developed linguistic awareness about differences and similarities between Swedish and the mother tongue. This places special demands on tutors' resources. Further, it means that they need to handle epistemological dimensions of language and mathematics in their everyday work as SGMT tutors in mathematics. Thus, it is of interest to explore, with an epistemological focus: How are a mother tongue study guidance tutor's languages and knowledges employed (or not) as resources for multilingual students' mathematics learning in a mainstream school?

Theoretical approach: The Language as resource model

To explore how SGMT tutors' resources can be employed as resources in mathematics activities from an epistemological perspective we use "The Language as resource model" (The model) (Ryan, et al., 2021). It builds on previous research concerning the language-as-resource idea, more specifically the epistemological potentials of multilingual language use and mathematics identified in this research (see Ryan & Parra, 2019). The model has two axes that make up an interface, which holds epistemological language-as-resource potentials that move from separating to synthesizing languages and mathematics (see Figure 1). For example, potentials of translation activities are activities in which languages are used in a separated manner, as separating first- and second languages, whereas *translanguaging* (García & Wei, 2014) activities are examples of activities in which languages are used in a synthesized manner. That is languages are used without clear boundaries and students use their full range of language resources, that is all words, grammatical structures, idioms *etc*. that are available to a speaker. Actualizations of language-as-resource potentials in multilingual mathematics activities move dynamically over this surface, that is among the language-as-resource ideas' epistemological potentials for language use and mathematics. The *x*-axis displays a continuum of epistemological potentials of mathematics that move from separating ways of knowing mathematics to synthesizing plural ways of knowing mathematics, for example from separating informal and formal mathematics to synthesizing a plurality of mathematics acknowledging mathematics as cultural activity. The *y*-axis displays the continuum of epistemological potentials of multilingual language use that move from separating named languages to synthesizing new language practices. The surface holds two named potentials; *the 'lever' potential* that can move students from informal mathematics talk in their mother tongue to formal mathematics talk in Swedish, and the *'one-new-whole' potential* that constitute prerequisites to produce new ways of languaging and knowing mathematics which requires interknowledge among the languages and plural mathematics. These two potentials are implicit in Rosén et al.'s (2020) conclusion that SGMT can be viewed as support through the student's mother tongue but rather should be regarded as a translanguaging practice that challenges linguistic and cultural boundaries.

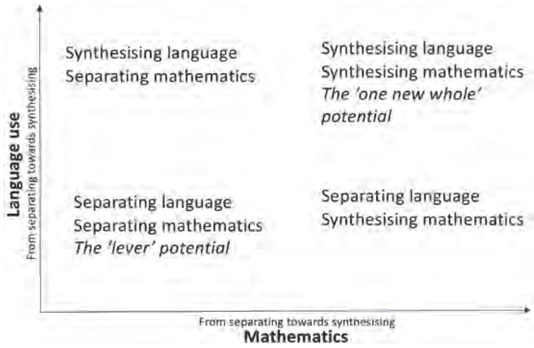

Figure 1: Framework for epistemological potentials in multilingual mathematics activities based on the language-as-resource idea.

The poster presentation

In the poster we present an example of an analysis of an excerpt from an interview with a SGMT tutor (in Arabic) to illustrate how the model can be used for analysing how SGMT tutors' resources can be employed as resources in mathematics activities from an epistemological perspective.

2+2=4? Mathematics lost between the pitfalls of essentialism and alternative truths

David Kollosche

University of Klagenfurt, Klagenfurt am Wörthersee, Austria, david.kollosche@aau.at

This essay problematises the epistemic status of mathematical knowledge. It is based on the observation that essentialist epistemologies provide no solid basis while relativist epistemologies have not yet convincingly succeeded to explain the objectivity of mathematical knowledge. I will start with three examples from popular media which illustrate that awareness for the problem discussed here has already reached the interested public. I will shortly address popular answers to the problem, only to refute them. I will end the essay by discussions which stay close to the example of 2+2=4, ending with the presentation of possible directions for further understanding and research.

Keywords: Mathematical reasoning, epistemology, relativism, alternative truth, styles of reasoning.

Debates on 2+2=4

Surprising as it may seem, the question whether 2+2=4, which so prominently demarcated the border between 'truth' and 'doublethink' in George Orwell's novel *Nineteen Eighty-Four*, has recently become the object of public attention. One example is the award-winning short film *Alternative Math* (Maddox, 2017), which is an alternative-facts parody, where the mathematics teacher's rejection of a student's claim that 2+2=22 kicks off a chain of events in which the teacher has to face outraged parents, a public mob and undiscerning officials. It begins with the teacher showing the primary school student his test with 2+2=22 marked wrong and with the teacher explaining 2+2=4 with markers to the disavowing child. In the next scene, we see the teacher and the boy's parents discussing the issue. When the parents ask the teacher who says that 2+2=22 is 'not the right answer', the teacher replies 'says maths', whereupon the father asks 'Who are you to say that your answer is right and his is wrong?' Later, when a board of officials asks the teacher to proclaim that she is 'open to the possibility there might be multiple correct answers', the teacher replies 'there is only one correct answer'. In the end, the teacher is fired but manages to demonstrate the consequences of allowing 2+2=22, at least for the school's finances. While the comedy of the short film builds on applying the logic of alternative facts to something as consensual as mathematical facts, the irony is that the teacher offers little more than authority and dogmatism to legitimise the epistemological claim made, which eventually does not dispel but invite further scepticism. Why does 2 plus 2 equal 4 and nothing else?

A different episode was brought to us by James Lindsay, a graduated mathematician, blogger and critic of post-structuralism. As a parody of the logic of post-structural narratives, Lindsay had posted the following on Twitter: '2+2=4: A perspective in white, Western mathematics that marginalizes other possible values.' What followed were intense debates on social networking services whether 2+2=4 had to be accepted as a true statement and if 2+2 could equal 5. Lindsay (2020) provided an (obviously factionary) overview of the discussions and rejected different proposals for 2+2 not equalling 4. The proposals included non-trivial mathematical interpretations of the expression 2+2 (e.g., in a ternary numeral system, where we might note 2+2=11, or in the residue system modulo 3, where we might note 2+2=1), as well as peculiar contextualisations, for example, interpretations of addition as the bringing together of animal populations which might result in procreation or in the consumption of some specimen. Such proposals may be useful philosophical exercises that help us to explain what we mean by 2+2=4, but in all cases the expression 2+2 has been changed to mean something different than intended, thus losing its relation to the original problem.

A last example comes from the United States and even made it into the newspaper and television news in Germany and Austria. In early 2021, the Oregon Department of Education offered a course for in-service teachers based on the materials provided by the project ‘A pathway to equitable math instruction’ (Cintron et al., 2000). Most uproar was caused by the question whether mathematics was racist, but debates also kindled over the question whether or not mathematics provides unambiguous knowledge. Cintron et al. stated that ‘the concept of mathematics being purely objective is unequivocally false, and teaching it is even much less so’, that ‘upholding the idea that there are always right and wrong answers perpetuate objectivity as well as fear of open conflict’, that focussing ‘on getting the “right” answer’ is an instance of ‘white supremacy’, and that teachers should instead encourage students to ‘come up with at least two answers that might solve this problem’ (p. 65). Consequently, the material was interpreted by many by claiming that mathematics does not produce unambiguous knowledge, and that claims that it would were establishing mathematics as a racist endeavour. Meanwhile, the project leaders clarified on their homepage that this is not what they meant and changed their material, avoiding the problematic passages. The echo in the media with many rather emotional than epistemologically educated responses however indicates that there is a growing fear that the objectivity of mathematical knowledge may be called into question sooner or later.

Two popular explanations and their problems

Lindsay (2020) presented himself as a mathematical realist and argued that mathematics deduces propositions such as 2+2=4 from fundamental premises (axioms) which are ‘relatively simple and connect to the real world in a very obvious way’. Considering the axiom of induction from Peano’s axiomatisation of natural numbers, such fundamental premises do not at all appear to be ‘relatively simply’, nor do they ‘connect to the real world in a very obvious way’. But there is a more fundamental problem: Axioms for arithmetic were provided by Peano only at the end of the nineteenth century. Before that, it was impossible to prove the statement 2+2=4 in the way described by Lindsay. So, does the validity of the statement 2+2=4 really depend on mathematics as a deductive discipline? In fact, we could argue that we constructed mathematical theories in a way that provides for the truth of 2+2=4 (and Lindsay implicitly does so as well when arguing ‘if we chose to start with different fundamental assump¬tions, we’d have a different mathematics that doesn’t seem remotely interested in reality at all’).

A different explanation is that 2+2=4 is abstracted from experience. (Remember the teacher explaining 2+2=4 with markers in the above-mentioned short film.) We see that two and two apples make four apples, that two and two cows make four cows, that two and two fingers make four fingers, and by induction we presume that 2+2=4 holds true in general. But even if induction was the reason that we hold 2+2=4 to be true, how about 74+26=100? Surely, we would not claim that we saw 74 of something and 26 of that same thing make 100 so often that we hold the abstract 74+26=100 to be true in general. Even worse, Greer (2005) made a strong point that 'whether a situation is appropriately modeled, or not, by the equation 2+2=4 [is] a matter of complex interpretation' (p. 297). Already Frege (1884) had established that the use of arithmetic presupposes a specific interpretation of one's perception, and Bishop (1988) informed us that the corresponding epistemology of what he calls 'objectism' has to be understood as a Western particularity. Consequently, it is not convincing either to establish the truth of basic arithmetic through induction.

The epistemological problem in more general terms

The discussion whether or why 2+2=4 holds true is intimately (although often not explicitly) connected to an unresolved struggle in epistemological enquiry between essentialism and relativism, which can only be presented here in a brutally abridged version: Robertson & Atkins (2019) proposed that 'essentialism is the doctrine that (at least some) objects *have independently of how they are referred to* (at least some) essential properties'. They add that such views have been fundamentally objected lately. In this sense, Lindsay (2020) argued that 2+2=4 is a truth that exists independently of humans and can only be discovered. In contrast, relativism supposes that 'things have the properties they have […] only relative to a given framework of assessment' (Baghramian & Carter, 2019).

In the philosophy of mathematics, the most prominent essentialist position is Platonism, where it is assumed that mathematical objects have a mind-independent and unalterable existence, that they provide shapes for the composition of our perceivable world, and that their properties can be discovered by the human mind. Linnebo (2018) reported that 'platonism has been among the most hotly debated topics in the philosophy of mathematics over the past few decades' and that 'a variety of objections to mathematical platonism' includes that 'abstract mathematical objects are claimed to be epistemologically inaccessible and metaphysically problematic' (p. 1).

In mathematics education research, the best-known objections against essentialism come from radical constructivism and post-structuralism. While the former stressed that humans lack the sensual apparatus to create an unbiased understanding of the world, and that knowledge is therefore necessarily relative to the limits of perception and interpretation (Glasersfeld, 1995), the latter was more interested in the refutability of truth claims and the historical deconstruction of their relations to power. For example, I discussed elsewhere how the laws of logic are far from natural or necessary but cultural products, which allied with specific social interests (Kollosche, 2014). So, is 2+2=4 a 'perspective in white, Western mathematics that marginalizes other possible values' after all?

Interestingly, scepticism based on post-structuralism is not only guiding progressive research on equity in mathematics education and beyond, it also laid the epistemological ground for the phenomenon of alternative truth. As McIntyre (2018) documented in much detail, the intellectual pioneers of alternative truth explicitly adapted the post-structural claim that every discourse is necessarily constructed and socio-politically biased to a technique that then allows to refute any truth claim. The very real effects of this development can be observed in the course of the denial of anthropogenic climate change or the COVID-19 pandemic by leading politicians. MacMullen (2020) argued that this epistemological scepticism is no longer only the academic background of the alternative truth phenomenon but an explicitly held position of some citizens. Elsewhere, I claim that this problem is not appropriately addressed in mathematics education research (Kollosche, 2021a).

Koertge (2017) regarded the phenomenon as a result of fundamental problems of relativism. She agreed that ‘all observations are laden with theory’ but questioned whether this means ‘that there is no objective/impartial perspective from which we can appraise and compare the truth-value of claims’ (p. 809). She warned that, ‘if it really were true that scientific assessments of truth and falsity could never be objective and could never be more than warring opinions, then we would be left with nothing but a clash of civilizations’ (p. 810). Indeed, it is one of the central problems of relativist epistemologies that they cannot sufficiently explain how we can avoid a situation where anybody can claim anything, how some sort of epistemic commitment can be guaranteed, and how specific ‘frameworks of assessment’ become accepted as scientific while others do not.

Skovsmose (2012) was early in warning the community of mathematics education researchers that post-structural deconstruction might be insightful but not productive in legitimising knowledge. In the light of the spread of alternative truths in public debate, Marcone et al. (2019) recently wondered if the fight of some scholars in our discipline against ‘the uncritical faith in mathematics’ and ‘the ideology of certainty’ has played a part in the post-factual ignorance of scientific facts (p. 186). They felt that ‘our arguments against universality and neutrality [of mathematics] have been trivialized and turned back against its original intention’ (p. 187). But have they? The fact that relativist arguments have been adopted by post-fact politics neither solves nor disvalues the original philosophical problem. It invites us to rearticulate it with greater urgency. Thus, we may ask: How can we explain the objectivity of mathematical knowledge without falling back to essentialist epistemologies?

Getting back to 2+2=4

In a way, the above question is typical for Wittgenstein’s *Remarks on the Foundations of Mathematics* (1956), which I cannot address any further in the limits of this contribution. Recently, I have only seen the question further discussed by Azzouni (2006). I recommend to read his chapter, but this is not the place for me to discuss his sometimes fruitful and sometimes problematic ideas. Instead, I want to return to my initial example of 2+2=4. Staying with such a basic example allows us to ground our complex philosophical thoughts in a matter that stays somewhat simple.

Let me shortly present my own understanding of why 2+2=4 or 74+26=100 holds true in a non-essentialist epistemology: We experience that there are several situations in which two of something and two of that same thing make four of that thing. There may also be situations in which this addition does not make sense. In the course of abstracting our experiences to the statement 2+2=4, we also learn in which situation it makes sense to see 2+2, and in which it does not. However, we do not arrive at the knowledge of 74+26=100 this way. Instead, we arrive at the knowledge of 74+26=100 through a line of algorithmic argumentation. From our empirically-based handling of small numbers, we abstract a certain logic of calculation, which is suitable to inhabit our most simple and inductively true calculations and can be extended to quantities well beyond our experience. The study of the teaching and learning of arithmetic is a prominent field in mathematics education research and investigates such processes, in which the handling of large numbers is again and again made sense of through our handling of small numbers. We could say that calculation is a kind of reasoning that allows us to establish 74+26=100 as a true claim, even though it is no longer directly connected to experience, nor are its truths established deductively.

A more sophisticated description of such an understanding has been provided by Piaget (1971) through the distinction of empirical and reflecting abstraction. Lensing (2018) discussed the importance of this distinction for mathematics education research and provides a good introduction. In short, empirical abstractions abstract from observables, while reflecting abstractions abstract from human action. In this sense, 2+2=4 might be an abstraction from empirical cases of counting and adding, but the logic that lets us arrive at 74+26=100 has been gained through an abstraction from our actions with numbers in easier cases. Piaget’s distinction and its application to mathematics education shed light on the complex interplay of different epistemic processes that lead to the justification of knowledge. I will end this paper by a presentation of a more complex description of such processes and their interplay not from a psychological but from an epistemological perspective.

Styles of reasoning as a way out of the epistemological dead end

Here, we might pause and wonder whether there are fundamentally different ways to establish the result of an addition of natural numbers as a true claim. Such results might be abstractions from empirical observations, they may we won through the manipulation of material models such as markers, they might be products of an algorithmic technique, and they might be theorems proven in axiomatic theories. These ways to establish a truth claim such as 2+2=4 reach the same judgement, but it is interesting that they arrive there by very different activities, which, each for itself, has the power to establish a claim as true. If we do not want to allow ourselves to fall back to essentialist explanations, this power and the consensus reached here are curiosa that demand an explanation.

Elsewhere, I have proposed to elaborate on Hacking’s (1992) framework of *styles of reasoning* in order to arrive at a possible explanation (Kollosche, 2021b). A style of reasoning includes methods of argumentation for reaching truth claims, therewith also a set of statements whose truth-or-falsity can be decided scientifically, therewith also a set of objects that enter the scientific discourse in the first place. Hacking (1992) drew on the work of science historian Crombie (1994) who described the historical development of six distinct styles of reasoning: the postulation style, the experimental style, the modelling style, the taxonomic styles, the statistical style, and the genetic style.

It is already interesting that nearly all styles (maybe not so much the genetic style) are used in mathematics or use mathematics themselves: postulation in the axiomatic-deductive theories of mathematics, experimentation in experimental approaches to mathematics and in experiments on the suitability of mathematical models for specific applications, modelling for the understanding of our world through mathematics but also for gaining knowledge of mathematics objects through models such as diagrams, taxonomy as a principle for concept development in mathematics, and statistics as a mathematical technique itself. Further, Hacking (1992) proposed to add ‘algorismic’ reasoning to Crombie’s list (p. 8), and was open to further additions or changes. We can recognise the postulation, the experimental, the modelling, and the algorismic styles of reasoning in our above-mentioned explanations of why 2+2=4, which already shows the potential of this framework.

Here, I want to return to more general philosophical considerations one last time. Hacking’s (1992) framework of styles of reasoning clearly proposes a relativist epistemological position. However, it does not appear completely defenceless against the objections issued against epistemological relativism. Let us address Koertge’s (2017) concern that, in relativist epistemologies, ‘truth and falsity could never be objective and could never be more than warring opinions’ (p. 810). Note that opinions are individual views that do not require any justification (although opinions can be elaborated upon). I may hold the opinion that twelve is the most beautiful number, and may even present my thoughts associated with this opinion, but this does not establish ‘twelve is the most beautiful number’ as any kind of justified knowledge. When Koertge warns that relativism would degrade truth claims to opinions, she fears that we would be lost in opinions and that shared and accepted knowledge would no longer be possible. In the styles-of-reasoning framework, this is not the case. Here, we have a limited number of historically established frameworks of assessment, which are shared amongst people and used to justify knowledge on an interpersonal level. Especially, styles of reasoning do not allow to present just any opinion as knowledge, just as a mathematical theory does not allow to proof any statement whatsoever.

Admittedly, one might not be completely satisfied with the merely historical explanation of why Hacking’s (1992) styles of reasoning are accepted as truth-makers in science. Should there not be reasons specific to the respective styles which explain why they are acceptable for scientific inquiry and why other frameworks of assessment such as astrology are not? It is not easy to give an answer here. Hacking underlines that relativism implies that there is no objective ground from which the suitability of a framework of assessment for scientific enquiry can be decided. This means that answers can only be found in the styles and their interplay. He furthermore stresses that the acceptability of frameworks does underly historical changes, that all styles have appeared sooner or later in history, the statistical style being the most recent, that once-accepted styles such as the logic of resemblance as described by Foucault (1966) appear utterly ridiculous to us today, and that we cannot foreclose that new styles may emerge and gain acceptance. It may be productive to focus on the interplay of different styles of reasoning. Ruphy (2011) introduced the concept of ‘ontological enrichment’ to capture that styles of reasoning do not only create new objects of scientific inquiry (in the way that Peano’s axiom system created numbers as axiomatic-deductive entities), but that these new objects mirror already-known objects (such as numbers as algorismic entities). Despite these ontic differences, we act ‘as if’ we were speaking about the same object in both styles, which allows us to gain understanding by studying this object in the various styles. Is it a fruitful hypothesis that new styles of reasoning gain acceptance through reproducing the knowledge gained by already-accepted styles while adding some new possibilities for understanding? For example, see how the postulation style mathematics of Ancient Greece as documented in Euclid’s *Elements* reproduced the already existing algorismic and diagrammatic mathematical knowledge of the time while adding new possibilities of expressing, justifying, ordering and interrelating knowledge – at least until incommensurability problems provoked serious doubts concerning the suitablity of this acting ‘as if’. I assume that the history of mathematics would be a good field to study the fruitfulness of this hypothesis, not only for the philosophy of mathematics itself but for epistemology in general.

Back to mathematics education

While the above considerations have been very philosophical and theoretical in nature, the mathematics classroom demands specific action. I cannot claim that I have thought-through recommen¬da-tions for the mathematics classroom, but I have pressing questions, which mathematics education research might want to consider:

- While the styles-of-reasoning framework proposes that mathematics is an integral part of many styles of reasoning, the public image of mathematics and research in mathematics education focuses on one specific style of reasoning, namely on mathematical proof (Kollosche, 2021b). In how far does this bias hinder us to study mathematical reasoning more broadly in research and to address different forms of mathematical reasoning in the classroom? In how far is this bias socio-politically functional, for example for upholding an ‘ideology of certainty’ around mathematics?
- As the styles-of-reasoning framework allows to preserve both the ideas of relativism and of justified knowledge, may it be helpful, for example in the context of studies on what US-Americans call ‘race’ and mathematics, to articulate a critique of the socio-political bias of mathematics without questioning its objectivity altogether?
- In how far would a differentiated understanding of mathematical reasoning in the framework of styles of reasoning allow to deconstruct exactly which epistemic practices may interact with the preferred styles of knowing of possibly disadvantaged social groups without questioning the epistemic value of mathematical reasoning in general?
- Assuming that the growing public scepticism towards scientific knowledge leads to demands that schools should provide some sort of an epistemological education, that is education about the justification of knowledge, then would mathematics education not be a privileged place, given that mathematics is intimately connected to nearly all styles of reasoning? What would such an epistemological education in the mathematics classroom look like?

Eventually, answers to be above problems might also help to articulate in how far mathematics education helps adolescents to develop their reasoning skills – a claim that reoccurs in mathematics education research and educational policy in connection to mathematical argumentation, mathematical modelling, and problem solving in mathematics. Rethinking these fields from the perspective of a relativist epistemology can allow to articulate their theories more clearly, while the relativist framing would allow to more easily include a socio-political perspective in these fields of research.

Mathematics teachers' creativity for fostering inclusion and preventing early school leaving

Rosalia Maria Lo Sapio[1], Gemma Carotenuto[1], Cristina Coppola[1] and Maria Mellone[2]

[1]University of Salerno, Salerno, Italy; rlosapio@unisa.it; gcarotenuto@unisa.it; ccoppola@unisa.it

[2]University Federico II, Naples, Italy; maria.mellone@unina.it

In this paper we investigate mathematics teachers' creativity in offering problematising activities and promoting inclusion and positive attitude toward school in territories with worrying dropout rates. This is an initial study in which we interviewed four teachers working in this kind of territories and very active in designing and implementing inclusive and visionary mathematics activities. From the analysis of the answers to two particular questions, we outline the perceptions of these teachers on the sources of their educational creative work, identifying peculiarities and communalities. In particular, a common intention to achieve citizenship education objectives emerges.

Keywords: Mathematics teacher, creative teaching, inclusion, problematising education.

Introduction

Equity, inclusion, and fair opportunities were felt as crucial issues by researchers in mathematics education already before the pandemic and have become even more urgent issues during it (Bakker et al., 2021). In particular, the pandemic, as "a magnifying glass on issues that were already known" (p. 1), revealed even more clearly the inability of the school education to properly include pupils in disadvantaged contexts and its responsibility in creating several unacceptable phenomena of social marginalization and exclusion. Indeed, nowadays, the educational outcomes of younger generations are still determined to a large extent by the socio-economic background of their parents rather than by their own potential. Promoting inclusion[1] and equity in education and training is thus fundamental in breaking these patterns. In the suburbs of many cities, school lacks resources to properly include children and teenagers experiencing socio-cultural disadvantage and ends up losing its institutional value in the eyes of pupils and their families. Hence, there is risk of early school leaving and, in some particular contexts, also the consequent serious danger for children and teenagers to be approached by gangs and organized crime. For this reason, it is of fundamental importance that educational research reflects on the endogenous factors of early school leaving (Morgagni, 1998), i.e. factors that are internal to the educational system. An effective struggle against this phenomenon should aim to create the conditions for every student to create her own identity within the school. In particular, this possibly implies the need that the mathematical activities proposed at school should (re-) build a positive attitude towards mathematics (Di Martino

[1] Here, the term "inclusion" is used in a general sense, as in the Italian educational system. By inclusive educational environment we refer to the participation in mathematical activities both by students with claimed disabilities and by students with special educational needs. The latter group also includes students with very critical cultural disadvantages, such as limited Italian language proficiency or lack of cooperation, if not hostility towards the school, by their families.

& Zan, 2011) for the students which are most in difficulty. In socially disadvantaged contexts, this means proposing to pupils tasks which are meaningful in their eyes and improving their perceived competence in mathematics.

For several years our research group has been engaged in educational projects in collaboration with schools to implement highly inclusive mathematics education environments, aimed at preventing the phenomena of early school leaving. In these contexts, inspired by the vision of active pedagogy, we have tried to design mathematics education activities as engaging and captivating as possible, for example by activating students body movement inside schools, but and also in outdoor environments; by creating narrative frames that allow students to link the exploration of the mathematics worlds to the exploration of cultural and naturalistic city sites (such as museums, art galleries, parks, site of urbanistic interest and so on) and critically connect pupils to the territory in which they live. The theoretical background of reference for these mathematics education activities design has been the informal mathematics education (Nemirovsky et al., 2017), which concerns non-compulsory activities, with very fluid boundaries between disciplines and with no formal grading.

Working on these educational projects, we have also tried to involve the school teachers in the design and implementation of these visionary informal mathematical activities. Indeed, our main research interest in informal mathematics education projects is to investigate how to create an intertwining between the highly engaging approach of mathematical activities implemented within them and curricular teaching. We recognize the centrality of school teachers in these transformation projects: they are called to be guides capable of creative inclusive mathematics education activities, in a continuous dialogue with the territories in which they work. With this gaze, in this paper we present a first research attempt to capture and describe the kind of mathematics education creativity needed for teaching in socio-cultural disadvantaged contexts, and elsewhere. Our research aims to investigate teachers' creativity, both in design and implementation of mathematics activities responsive to students' interests, in order to foster inclusion and thus prevent early school leaving.

Theoretical framework

Our research is framed in active pedagogy, born at the end of the 19th century, that considers the student as the active protagonist of the educational process and the relationship between the subject and the environment as central. Therefore, according to this point of view, it is essential to organise educational and school contexts in such a way that the environment can foster creativity, plurality of opinions and the freedom of pupils to experiment on their own. Moreover, the educational experience cannot disregard the everyday life in which the subject lives.

In this scenario, the educational proposal of Paulo Freire was to create an emancipatory pedagogical process aimed above all at that part of society that lives in a situation of oppression (Freire, 1970). According to Freire, the action of the educator is characterised by two essential moments: the preparation of the lessons and the meeting with the students; it is by analysing these two practices that it is possible to distinguish a *depositary education* from a *problematising education*. In the first case, the educator, during the preparation of her lessons performs an act of knowledge in relation to the knowable object. Then, during the meeting with the students, she narrates and discusses the object on which she has performed her act of knowledge. The task of the students, in this perspective, is to know or learn by heart what is narrated and delivered by the educator (student seen as a patient or a docile recipient of content). Depository education does not allow the students to perform a true act of knowledge, since what is delivered or deposited to them is a possession of the educator and not a mediator of the critical reflection of both (Freire, 1970). In the case of problematising education, on the other hand, there is not a clear distinction between the moment of preparing the lessons and the moment of meeting the students. The latter is characterised by dialogue, which is fundamental for the educator in order to review – through the re-visioning of the students – what was objectified in the preparation of the lesson. Problematising education becomes an act of knowledge: both when preparing the lesson and when meeting the students, the educator is a *knowing subject*. With the problematising practice, the educator makes the students become *critical researchers*, in a permanent dialogue with the educator, who is a critical researcher herself. According to Freire (1970), it is only through a problematising education that it is possible to carry out an emancipatory pedagogical process that pushes the students for learning to face their world by putting knowledge into play, developing creativity and constant reflective critical capacities. The educator, therefore, has to reflect on what to propose to her students and, from the constant dialogue with them, imagine original themes to be returned as concrete problematic situations, challenging and motivating for the students, which allow them to reflect on significant dimensions of reality, promoting a critical understanding.

In this frame, our research aims to explore teachers' creativity in the strictly intertwined processes of designing and implementing mathematical problematising education activities (Freire, 1970) in socio-cultural disadvantaged contexts. In literature, there are several studies on the mathematical creativity of professional mathematicians. For example, Hadamard (1945) in his seminal work collected the perceptions of contemporary mathematicians on the mechanisms by which they produce new mathematics. He outlined the existence of unconscious mental processes and tried to capture the phenomenon of illumination in doing mathematics. Later, Liljedahl (2004) updated Hadamard's work, focusing on the specific context of mathematical problem solving. In particular, he confirmed the experience of mathematical illumination, perceived as caused by a sudden coming to mind of an idea. He analysed preservice teachers' logbooks, together with reflective anecdotal accounting from undergraduate mathematics students and prominent mathematicians of our times. Here our focus is on mathematics teachers' creativity and very few studies can be found about it (see for example Levenson, 2021).

Methodology

Participants

In order to investigate the particular kind of creativity of the mathematics teachers we are interested in, we identified two Italian informal education projects that offered very innovative mathematical problematising education activities (Freire, 1970) to primary and secondary students from socio-culturally disadvantaged areas of two different cities, Naples and Turin. Within these projects, we involved four teacher-researchers, as they are responsible for educational design: Perla, Nadia, Riccardo and Claudia (pseudonyms). The first two are high secondary school math teachers in

Naples (Italy) and partners of the cultural association “Matematici per la Città” (MPC). The association was born in 2013 with the aim of realising urban math walks through the suggestive and fascinating streets of Naples, bringing mathematics out of the classroom, in a less formal, more comfortable and enveloping scenario. Currently, MPC collaborates with several primary and secondary schools in Naples, often located in disadvantaged districts of the city. It promotes extra-curricular educational paths with the aim of stimulating and encouraging children and teenagers to observe reality with curiosity and critical sense. In all its activities mathematics is strongly intertwined with other disciplines, such as art, music, history, chemistry, and above all with citizenship education. The other two teachers, Riccardo and Claudia, are lower secondary school math teachers in Turin (Italy) and both took part in the design of the educational activities of the “Next-Land” project. The project, promoted by the cultural association Next-Level, started in 2020 and is still underway. So far, it has involved lower secondary school students from the most disadvantaged Turin’s neighborhoods. Next-Land offers educational paths on STEM disciplines, which are intertwined with the arts. It is characterised by a widespread, laboratorial educational action, which is hosted in the city’s museums, open spaces, research places and in digital environments. Among the transversal aims of the project there is the fight against the gender gap in study and work contexts.

Data collection and analysis

Data collection consisted of oral and semi-structured interviews, inspired by the Explicitation Interview method[2] (Vermersch, 1994), audio-recorded and transcribed. Due to space constraints, in this paper we present only the analysis of the responses to two particular questions, which we consider to be the most interesting in the context of an exploratory study of teacher creativity. Here we refer to the selected two questions as Question 1 (Q1) and Question 2 (Q2):

> Q1. In designing a teaching activity, do you feel more like ideas emerge all of a sudden or that they originate from a process of investigation?
>
> Q2. Referring to your design choices, do you think that, in general, they also consider your personal background and the social and cultural dimension? If so, to what extent do you think that the personal, social and cultural dimension can influence the creation of educational activities? Could you refer to a specific anecdote or a particular moment to support your thinking?

Q1 is inspired by a particular question used by Hadamard (1945) and later by Liljedahl’s (2004). This question refers to the dichotomy, already emerged in the community of mathematicians at the beginning of the 20th century, between a vision of mathematical activity that emphasizes intuition and another one that tends to emphasize the rigour and formalism of deductive reasoning. In our context, in which we are not reflecting on mathematical activity but on the design of teaching activities in mathematics, we ask teachers whether they attribute their creative acts to a spontaneous arising of ideas or to a work of reflection that we might consider more methodical and goal-

[2] The Explicitation Interview is a method based on techniques for the formulations of the re-launchings aimed at facilitating and attending the a posteriori verbalization (in the sense of putting into words) of a particular experience (Vermersch, 1994).

oriented. By this question we want to collect the teachers' perceptions on how the creative acts at the basis of their educational work originate.

Q2 aims to investigate teachers' perceptions about the causes behind such creative acts, and in particular whether and how they would connect them to the social and cultural dimension of their lived lives. The answers to this question could provide some information about the teacher's personal and professional experience, which she relates to her work in instructional design. Therefore, with this question we expect to outline some aspects that are at the origin of the creativity of the interviewed teacher, which determine her uniqueness.

At this stage of the research, we have analysed the answers, highlighting commonalities and peculiarities. Next, we will move on to enlarge the sample of teachers and, alongside this type of analysis, we will analyse the recurring themes.

Findings

Answers to Question 1

Q1 asked to choose between two alternatives: the teacher could attribute her creative acts to a spontaneous arising of ideas or to a more methodical process of investigation. All four teachers chose the first alternative and all shared, as an argument to their answer, what they believe to be the sources behind what is currently a spontaneous arising of ideas in their design activity. As we will show shortly, the reasons that the teachers identified are all different from each other. We draw attention to the fact that the other question, Q2, was formulated precisely for the purpose of investigating the origin of the creativity of the interviewed teacher. However, in the analysis we preferred to keep the answers to Q2 distinct from the argumentations accompanying the answers given to Q1, because of the characteristic of spontaneity of the latter

> Perla: So look, I'll tell you that I usually get ideas all of a sudden [...] with an association, which is often instinctive, of elements that are apparently very far away. [...] I am quite convinced that this fact, which is quite easy for me, more than anything else I find it instinctive to put together apparently distant worlds, is a consequence of my mathematical education, in the sense that it is a bit like when you have the data of a problem or the hypothesis of a theorem and you have to put them together and arrive at the final result or proof of the theorem, I have the feeling that when I come up with a project idea, in the end, I actually think in this way [...]

Perla attributes what she considers a "sudden" and "instinctive" emergence of ideas in her design work to her mathematical education, which taught her to put seemingly distant elements into communication with each other, as when from the data of a problem one seeks a solution or from the hypotheses of a theorem one arrives at its thesis.

> Nadia: [...] Some conditions have been created, even with the association I belong to [MPC], to design together, to reflect together, so when I find myself alone in designing an activity, I don't know how much it is accidental or how much it is actually the result of this continuous process of sharing and building together and so, sometimes, I say: "Is it mine? Did it come to me spontaneously?" and maybe, even this approach of building activities in this way, in my opinion, leads me to think spontaneously about things, but it is a spontaneous in some way conditioned.

Nadia talks about a "conditioned" spontaneity. This conditioning leads her back to the experiences of collective reflection and shared planning, within the association MPC. Moreover, in the interview, Nadia links her design choices also to post-university education. In particular, she refers to courses for teachers or conferences on mathematics education that over the years she has carefully selected because they gave space to collective design activities and because they promised to provide first-hand experience of laboratories.

> Riccardo: Most of the ideas that come to me come out of the blue while I'm doing something else. [...] while I'm shopping, while I'm jogging, while I'm reading a book that has nothing to do with anything, I get ideas and then I try to develop them later. So, I can't tell you whether actually, I mean whether to classify them as ideas that come out of the blue or that are the result of a process. They are certainly, in some way, the result of a process of which, however, I am not always aware here. It seems to me that they happen suddenly, but I also wonder how much this suddenness is due to the stimulations I had, to the thoughts I had [...].

Riccardo relates the spontaneous arising of ideas, during the preparation of the lesson or the meeting with the students, with a process of which he is not always aware, but which he recognizes as being conditioned by external stimuli and previous reflections.

> Claudia: It depends! Maybe we need to distinguish between the planning of the mathematical activity itself (a longer process of investigation, which leads me to search among books, websites, ideas from notes taken during conferences...) and the [laboratory] methodology to be used (more improvised creative ideas).

Finally, Claudia prefers to distinguish between the spontaneity of some ideas, which initiate the planning – which at the beginning of the interview she recognizes to be connected with the places or the artefacts she has available – and the work of defining the activities, which she considers a work of investigation for which she uses different sources.

Answers to Question 2

In reference to Q2, the answers of the teachers interviewed return some salient aspects of their personal and professional experience.

> Perla: [...] my dimension of life has a profound influence on the creation of the activities, that is, in those activities there is really me! This is a certain fact and often, I try to put in what I think is important for children to discover, to know, that is, that can form them in some way as citizens. [...] the example of the project on the enlargement of the map of municipalities, where did that come from? It came from the fact that over the last ten years, for personal reasons, I have interfaced a great deal with the administrative bodies of my city [...] and I have realized how important it is for a citizen to know how the administrative machine works [...]

In answering Q2, Perla asserts that what she proposes to students is strongly determined by personal interests and curiosities – the books and articles she reads or the movies she watches – but also by a range of social and cultural experiences that she has collected over time. The excerpt contains one of the examples she gave us, in which she recounts how her political commitment led her to instructional designs in which mathematical goals were intertwined with goals of citizenship education she recognized to be of crucial importance for her students.

> Nadia: All the activities that we realize with the association [MPC] always try to work on breaking distances in some way: breaking distances within the city, within a territory, within a class, this is a climate that I feel I always carry inside. I experience it externally in the places I frequent and it also influences the type of activity.

Nadia, as in her answer to Q1, refers first of all to her activity within the association MPC. She claims that the sharing of “educational responsibility” and the possibility of experiencing it as a “collective process” offered by the association influences the way she relates to her students and the dialogue she strives to create in the classroom. She also finds that her teaching choices have been influenced by her movement from a small town to a big city like Naples, where she currently lives and works. Naples gave her the opportunity to relate to a broader cultural environment and meet people from different cultures, drawing her attention to issues such as migrant rights, gender equality, or what it means to be a citizen. As shown by the excerpt, this influenced her goals as an educator and in particular her desire to educate to “break the distances” among individuals.

> Riccardo: Certainly, personal background comes up a lot in the design of activities. [...] To make students feel good in school, to make them feel good together with others and to make them feel free to express their opinion [...] is something that I, in some way, trace back to my personal background, to my life experience, to my school experience as a student, [...] but maybe also to the very motivation for which I decided that I would be a teacher in life. More than teaching math, really more about having the opportunity to interact with students to help them bring out their potential to interact with others.

Riccardo believes that his personal experience as a student and his own motivation in wanting to become a teacher- which is characterized by the desire to educate students in comparison with others and in collective living – greatly influences his design choices.

> Claudia: I have been a researcher in the history of mathematics, and most of the activities created by me take cues from my knowledge in this discipline and my passions. I love history! And I really enjoy doing activities that can leave my students surprised, because I myself love finding myself fascinated by mathematical content when it has been presented to me in a “creative” way!

As shown in the excerpt, Claudia believes that her previous experience as a researcher in the history of mathematics and her personal tastes as a student, fascinated by creative and surprising didactic actions, have influenced her design work the most. Moreover, answering to Q2, Claudia recognized that her creative attitude in didactical design was influenced by the successful professional experience in a particular school, situated in a poor neighbourhood of the city of Turin, which is characterized by the presence of many families of recent immigration. She said: “Once I figured out how to ‘catch’ these guys (each in their own way, of course), my creative streak increased, because I could see how much my effort paid off.” Finally, she noted that the presence of students from different countries motivated her to design mathematical activities involving different cultures, such as one on number-words to reflect on the decimal number system.

Although in different ways, all four teachers believe that their personal backgrounds and their social and cultural dimensions influence the work of creating teaching activities.

Discussion

In this first study we tried to inquire the way in which these four mathematics teachers, which are responsible for the educational design inside two very innovative informal mathematics projects, tell about their experience of creating mathematical activities and how they link it with their personal and cultural background. Looking at the interviews, in particular at the answers to Q1, it is possible to recognize in their description that the way in which the design of the mathematics activities emerges is characterized by illuminating moments, but also by a “conditioned” spontaneity, as Nadia says. Moreover, the answers to Q2 helped to catch how the different teachers’ personal, professional and cultural experiences play a key-role in the realization of the very innovative mathematical activities they propose, both during the preparation of the lessons and during the meeting with the students (Freire, 1970). Perla referred to her personal interests and to her experience of collaboration in the administrative bodies of her city. Nadia told about the influence of her social commitment, through the militant activity in the association MPC, and beyond. Again, Riccardo referred to his school experience as a student and his educational objective of educating for collective living, which he sees as a priority. Finally, Claudia told about her research experience in the history of mathematics field and about her professional experience in a challenging reality, which required great effort on her part to engage the students. The answers to Q1 and Q2 show a very varied picture on these teachers’ perceptions regarding the sources of their creative educational work. Nevertheless, the same answers reveal a point of contact in the teachers’ pedagogical goals. All of them aim at educating at democratic citizenship through mathematics. Perla spoke about a project exploring with students the administrative bodies of the cities; Nadia referred to her (and her association) action of breaking distances, at all social levels; Riccardo declared his desire to educate at a collective living; finally, Claudia told how she used mathematics to create meeting among different cultures. In this sense it is worth to emphasize how Freire’s ideas were of great inspiration for the field of critical mathematics education (see, e.g., Skovsmose, 1994). One of the most recognized pedagogical aims in this field is the intertwined development of critical citizenship consciousness and mathematical competencies:

> […] mathematics should be a vehicle for students to deepen their grasp of the sociopolitical contexts of their lives, and through the process of studying their realities -using mathematics- they should strengthen their conceptual understanding and procedural proficiencies in mathematics. (Gutstein, 2007, p. 109).

Students’ thoughts on time and speed in high-stakes mathematics tests

Nikos Makrakis

University of Klagenfurt, Greece; nimakrakis@edu.aau.at

Time and speed are important aspects of mathematics education and assessment. Students are expected to produce results in prescribed time frames, which means that they have to perform at a specific pace. How does this affect students’ engagement with a mathematics test? How can a high-stakes strictly-timed mathematics test increase the focus on speed? How can these conditions produce exclusion in mathematics assessment? We discuss these questions through an interview with a student a few weeks after she took the mathematics test of the Greek national exams of June 2021, which is a nation-wide, high-stakes and strictly-timed mathematics test.

Keywords: Time in education, speed in mathematics, time in assessment, mathematics assessment.

Time and speed in mathematics assessment

Time is an important dimension of education and affects every aspect of it. There are very specific time frames for every school activity and there is a predefined pace at which students and teachers are expected to work. In assessment, students are expected to work within very specific time limits and also at a specific pace (Adam, 1990).

In mathematics assessment, research has studied the effect of speed on students’ performances. Some results show that students who are more mathematically anxious (Boaler, 2014) may be affected by the time limits of mathematics tests more than students who are less anxious (e.g. Hembree, 1987; Tsui & Mazzocco, 2006). There are conflicting reports on this issue and it has not been studied enough.

Boistrup (2010) studied mathematics assessment through the analysis of assessment acts. One assessment discourse which she analyses is “Do it quick and do it right” (p. 166), which describes emphasis on a quick and correct final result of the student’s work in an assessment task rather than on the thinking process that produces this result.

For high-stakes mathematics tests with strict time limits, the issue of the effect of time on students can be more complicated. High-stakes tests influence teaching, students’ preparation and learning very much. Teaching shifts from issues that focus on knowledge and meaningful skills towards a narrower focus on the tasks which are regularly included in a specific test, a phenomenon that is described in research as “teaching to the test” (Cankoy & Tut, 2005, p. 235). This also affects learning as

> more time spent focusing on procedural skills such as drills, test taking, or practice with tests from prior years, with little connection with conceptual understanding and qualitative reasoning, can distract students and encourage them to memorize procedures and to search for a single path to a single answer (Cankoy & Tut, 2005, p. 242).

Research on mathematics assessments suggests there are important non-content factors that affect students’ performances, for example, test familiarity (Hembree, 1987). Furthermore, high-stakes testing increases the phenomenon of shadow education or private tutoring, which increases inequalities, because low-income families cannot afford it (NESSE, 2011).

These high-stakes tests are, often, nation-wide mathematics tests that states need for assessing and ranking masses of students with the minimum cost and in a manageable time frame. But, mathematics tests which focus on the mathematical content and not on other factors, usually, have to be longer, and require more time to design and to score, and more time from the students to complete (Suurtamm et. al, 2016). This potentially creates a tension. Firstly, time limits are imposed that, sometimes, can be very strict and, secondly, speed is imposed as an important skill in mathematics literacy. Students may be interpellated by this double imposition and form themselves as governable (Kollosche, 2018) subjects who are supposed to find speed with mathematics important and act accordingly. Thus, speed becomes a characteristic of informal social norms or rituals (Lundin & Christensen, 2017) of mathematics education. It, also, may be related to the value of efficiency that is highlighted in contemporary society and economy (Chronaki, 2017). These impositions provide forms of exclusion which everyone agrees on without consciously knowing and which, ultimately, are necessary for the economic and ideological function of mathematics education (Pais, 2014).

There are questions raised by these issues about the position of the students in this framing (Makrakis, 2021). How are students affected by time limits in high-stakes mathematics tests? How do time limits of mathematics tests affect students' preparation for them? How do students view the fact that speed is expected of them in a strictly-timed mathematics test? How are these issues connected to the sociopolitical character of mathematics education?

Methodology: Data collection and framework of analysis

I will discuss these questions presenting preliminary results of interview data from a broader study that I am carrying out. I focus on one interview of a student that had just participated in the mathematics test of the Greek national exams of June 2021. Greek national exams are taken just after high school graduation and largely determine a student's admission to higher education after students' performances are compared to each other. Their grade in mathematics may contribute even more to their final score. Greek national exams in mathematics present some general regularities and trends as far as the preferable tasks are concerned (Thomaidis, 2021). The Greek national mathematics exam has a three-hour time limit, which is often insufficient (Mavrogiannis, 2017). The test always contains four tasks, task A asks about theory and the other tasks B, Γ and Δ are mathematical problems.

This semi-structured interview was taken, recorded and transcribed a few weeks after the exam through Skype (for COVID-19 safety) and a whiteboard was screen-shared. I interviewed a 17-year-old student, Litsa (name changed), who performed well at the test. I have taken interviews with 13 students for my general project and Litsa was one of the typical cases. The interview questions were about time, speed, anxiety, and her decisions during the test in relation to the time limit. The interview was conducted and transcribed in Greek and translated by me for the needs of this paper.

I will briefly discuss excerpts of the interview. In my comments I will include some elements of discourse analysis particularly, from approaches that are derived from Lacanian Discourse Analysis, which view discourse not as a closed structure but study of the emergence of elements from the Real (Lacan, 2006) behind the signifying structure, which may, also, act retrospectively. They view discourse in reference to the issue of the agency of the split subject and they study not only what is being said, but, also, latent elements, which are present through their absence (Frosh, 2014) and, also, nonsensical elements of discourse (Parker, 2014).

Results

Nikos: You said "concerning your preparation". Did you mean (…) Did you have tests of prior years in order to prepare for the time limit?

Litsa: Yes, yes, I did have tests of prior years. I, also, took mock tests held by the tutoring school which I attended and I timed my completing the test, uhm, in order for me to use less than 3 hours for sure.

Litsa thinks that completing the test in time needs special preparation. She did past exam papers in order for her to be more familiar with the circumstances of the actual test. Tutoring schools organize mock tests (which they call "simulation tests") which simulate the test of the Greek national exams. Litsa evaluates the fact that she took such a test as important for feeling prepared for the time limit. Apart from the timing of the test which the tutoring school held, she says that she also timed herself, imposing a limit of her own for less than 3 hours, in order for her to be sure that, when she takes the actual test, then the three-hour limit will be enough. Taking the initiative to time yourself is a different experience than having a time limit imposed on you, because it means that you have internalized the need for synchronization and performance in the expected time frame and you posit yourself as the one who regulates it. She tries to fit herself to the standards expected of her, synchronize herself and become the one who delivers the expected performance on time.

Nikos: How anxious did you feel before and when you were taking the test?

Litsa: All in all, before taking the test I was feeling only a bit anxious. I am not anxious in general. I knew that I had done the appropriate preparation. OK, I knew that it is mathematics – you can get stuck somewhere. But that didn't make me feel anxious. When taking the test, I wasn't anxious, I just kept writing, I didn't even have the time to feel anxious. So OK.

Litsa evaluates the fact that she had done the "appropriate" preparation as important for feeling not too anxious. Preparation for the test is somewhat specific. Every student is expected to have done past exam papers and to have solved most of the tasks that are included in the official school textbook and one of the 3-4 most popular books which are written to prepare for the Greek national mathematics exams. So, Litsa, having done this expected preparation, feels not too anxious. She, also, recognizes that, in mathematics, having done what is expected may not be enough, as you may get "stuck somewhere". That is, in a task you may not think of something to do in a given time, which you cannot predict beforehand. She, also, says that this did not make her feel anxious as she "kept writing" and "didn't, even, have the time to feel anxious". She, maybe, recognizes that she has reasons to feel anxiety, she recognizes that she cannot do anything about those reasons, and then she just has to perform. She knows that time may not be enough if you think too much, or if you feel too unsecure. She can cover those reasons by "just writing". She, also, identifies herself as someone who is not anxious "in general". So, she acts and poses as a person who is not one of those that get anxious, but one that just keeps writing, because she is supposed to and prepared to do so.

Litsa: Surely, I tried to prepare to complete the test at least half an hour earlier. So, I started with huge rush, let's say, to complete as soon as possible task A and B, in order to have time for Γ and Δ.

Nikos: OK. What do you mean by saying "huge rush"?

Litsa: As quick as possible. I wasn't thinking much during tasks A and B. I did them (…), I tried to do them mechanically. That is, for them to be something I had already seen, so as not to waste time on this.

Litsa says that she set a personal limit of 2-and-a-half hours to complete the test and half-an-hour to check again her answers. She evaluates different tasks as needing different amount of time to be spent on. Task A on theory needing the least along with task B which is considered the easiest problem and tasks Γ and Δ, which are considered the most difficult, needing the most time. So, Litsa thinks that she had to work at different paces during the test.

Litsa says that she has to be quick, especially at some tasks. When asked to explain her "rush", she says that she has to do them "mechanically". She is describing herself as having to work very quickly on something so familiar that she does not even have to think about it, because she must do so in order to be on time and because she is prepared to do exactly that. She makes the sentence "to be something I had already seen, so as not to waste time on this" which is a syntactically incorrect collation of two phrases in order to just show that they are connected in her mind. She evaluates having seen similar tasks as very important in order for her not to spend time thinking how to solve them, because this would have been a "waste" for her, as it would result in her spending less time at tasks Γ and Δ, as they, actually, require thought. She evaluates writing as the only thing that she is expected to do at tasks A and B, instead of both writing *and* thinking.

Nikos: Task B3 asked you to compute the asymptote line and compute a limit. Do you maybe remember which of the ways a., b. or c. did you try in order to compute it?

Litsa: Huh, I don't remember. I think, huh, just a minute, because I remember nothing. I think b., I'm not sure. I moved (…) I wanted to get rid of this the fact that this expression is indefinite. I moved one of those to the denominator, so (…) I don't remember how I thought of it (…)

Nikos: Did you do it on the first or the second try?

Litsa: On the second. I think. I'm not sure.

Nikos: (…) If you tried it with way b, then it couldn't be computed. It could be computed with ways a. and c. So, you began with way b, and then moved on to a.

Litsa: I did it for sure. For this kind of tasks I begin using one way or the other and then I see if it can be computed. If not, then I do the other way.

Nikos: OK. Do you think that there is a way to think which of those two ways can produce the outcome? Or do you choose by luck?

Litsa: By luck mostly, but… because e^{1-x} (…), I don't remember now, when you compute the derivative, I think that it cannot produce the outcome, right? Do you move that to the denominator? I did this mostly by luck, I didn't think about this with enough (…) mechanically. I didn't remember.

Nikos: So, then, you choose a way by luck, but you knew that it may not be able to produce the outcome, and then you would try another way, right?

Litsa: Yes, yes, yes. That's what I do usually.

Here Litsa was asked which way she chose in order to try and compute the limit $\lim\limits_{x\to+\infty} xe^{1-x}$. The three possible ways were: a. $\lim\limits_{x\to+\infty} \frac{x}{\frac{1}{e^{1-x}}}$ b. $\lim\limits_{x\to+\infty} \frac{e^{1-x}}{\frac{1}{x}}$ and c. $\lim\limits_{x\to+\infty} \frac{xe}{e^{x}}$. Only ways a. and c. can produce the required outcome. She remembered that she tried way b. and then moved on to try way a. and finally did manage to produce the required outcome. When asked if she chose this specific way by luck, she agreed. She is aware that for this task she could not know which way would produce the required outcome before making the necessary computations. So, she says that she had to choose by luck and if the way she had chosen failed, then she had to try another one and not think about this any further. Here, she makes a syntactical error just to squeeze the word “mechanically” into her sentence. She thinks she is not supposed to think about this point, but just to choose a way, and if she hits a dead-end, she tries again, in an automated process, in order for her to be on time. She says that she usually does so. She expects this to happen and she isn’t surprised by it. She shares no thought that this approach may make her lose time.

Nikos: Do you think that in order for someone to succeed at the mathematics national exam it is required of them to be quick at doing mathematics, and why?

Litsa: Uhm (…), I would say yes. Because national exams tests have a narrow time frame and if you get stuck somewhere (…) uhm (…) and you do not move on quickly to the next tasks, you won’t be able to spend the time that you want on it. So, generally, yes. To be fast to complete the first tasks quickly, because the next ones really require to put thought on. So, if you don’t have this time, then you can’t solve it.

Here Litsa evaluates speed as important and relates it to the “narrow time frame”. Since you are expected to operate in this narrow time frame, you really have to be quick and not “get stuck somewhere”. For her, being quick means not getting stuck, because if you do get stuck, then you spend more time than what you are supposed to. And this is not the same for each task, as she repeats that she feels that the first tasks require more time than later ones. So, if you do not do the first ones quickly, then you will not have the time “you want” on the later ones. She says “you want”, but who is the one that wants? Is it herself? Is it what is wanted of her by others or, maybe, what she thinks is wanted of her?

She says that the last tasks are the ones where you are required to “put thought on”. For the first ones you are not, you just have to complete them as fast as possible and this means without thinking. Therefore, no thought somewhere is described as the precondition for thought elsewhere, with time being the key here.

The tasks where you do not have to think, tasks A and B, assess theory and basic problems. If you complete them without mistake, then you get half marks and you score about average. But Litsa is a good student who expects and is expected to perform very well. So, she may not have to “put thought on” the tasks that get you just average performance. She may think that it is almost self-evident for her to do them without thinking. And just to do them quickly in order for her to “put thought on” the tasks that really matter for a student of her expected performance, tasks Γ and Δ, which are always more difficult.

Nikos: Do you think that in order for someone to be good at mathematics, they have to be, also, quick at doing mathematics and why?

Litsa: OK, maybe. In the sense that (…) I don’t know, actually. Yes, I usually correlate it with quickness, so OK, someone can be good and solve a task for many hours and so on, but I find better someone who solves them fast. Uhm (…), it comes to their mind automatically. It doesn’t require much time and so on. Which means that they have done more practice. They have worked on them more, so, consequently, they can solve more complex problems faster.

Nikos: Uhm, so you are saying that being good relates to speed at doing math in your opinion.

Litsa: Yes, it relates to a point, in my opinion.

Nikos: And you say that displaying speed, they show that they have practiced enough on what they are solving and this is an element which you say that it shows that they are good. Is that what you mean?

Litsa: Yes. Of course, this doesn’t go for every case. There are people who find it more difficult and need more time. Or people who have not practiced at all and they solve the tasks quickly. But, on average, I think that the one that solves the tasks quickly is the one that has practiced a little, just a bit more than the rest.

Nikos: You said that [the one that] has practiced more, but, also, the one that shows that they have practiced more. Right? So you believe that it matters to be shown that they have practiced more. Is that what you mean?

Litsa: What do you mean? In quickness? To show that they have practiced more?

Nikos: For them to show their familiarity with what they are dealing at that moment.

Litsa: Yes, certainly. When someone is solving a problem fast and so on, yes, it is shown that they are pretty familiar with it. They go qui (…), their mind is inside this process. It works mathematically. So, reasonably, they are more familiar.

Nikos: OK. What do you mean by saying "their mind works mathematically"?

Litsa: Generally, every mathematics problem has a certain process to be solved. So, a deductive (…), a deductive way of thinking. You begin. You draw conclusions. You analyze them. Then, you connect them in order to find the solution to the problem. Surely, it is something that you can acquire very difficultly, let's say. And it is the most difficult part in mathematics, for you to get in the process of thinking in this way and analyzing every piece of data that you are given and drawing conclusions. So, this particular part is that which need the most work and which shows who has acquired a mathematical way of thinking.

Nikos: And for you, do you believe that this is shown when they do it faster, also? That this is something that helps you do that?

Litsa: Yes, this is an indication, yes.

Here, Litsa says that she considers someone is better at doing mathematics when they solve something faster than someone who actually solves it but takes many hours. She says that the reason for this is that the first solves it automatically and it comes to their mind "automatically". Automatically, like mechanically, means that they do not have to do something, they do not have to think or process something, they just solve it. Here, in her descriptions of the difference between someone who is and is not good at mathematics, we can find a gap. She repeats that being faster at solving a task means being better at doing mathematics, because this shows that you have spent more time practicing. Having practiced shows as familiarity and quickness, and this allows you to be considered better at mathematics. Is there a possibility that someone has practiced a lot, but this doesn't show as quickness? She says yes, but "on average" no. "On average" is a statistical measure, but in common speech it can mean other things, too, like "normally". It may be used as a manifestation of a norm, which may have exceptions, but still counts.

She, then says that the person who does mathematics quickly and shows being familiar with the test indicates that "their mind is inside this process" and "works mathematically". She explains this as having deductive thought. She uses the Greek word "Παραγωγική", which, apart from "deductive", also means "productive". When she describes it, of course she does not describe deductive reasoning, but another process. She describes that a student facing a task may start by making some initial results that can be drawn firstly by the data. After that, they have to find ways to connect these results in order to achieve the requested outcome of the test. In order to do that the student has to have experience and also to try out different things which may fail. The process of course takes time, so this is in contrast with what she says earlier. Students who take less time, are those who actually take the time to do what is asked. Here she appears to describe a situation in which the students that are supposed to solve it, are the ones to actually solve it. She says that "this particular part is that which need the most work and which shows who has acquired a mathematical way of thinking". So, she thinks that there are students that have acquired this "mathematical way of thinking" and others that have not. And speed at doing mathematics is an "indication" of that.

Discussion

The timed conditions of high-stakes, strictly-timed mathematics tests shape the way students view and prepare for them. Students may feel that the performance expected of them requires very specific preparation according to time. Students may feel that they have to fit the pace by which they solve tasks to a required time frame. They may view this as fitting a norm which is considered familiar and relevant to mathematics a type of social synchronization in doing mathematics. Students may view their speed at doing mathematics as a characteristic that defines their identity as students of mathematics, i.e. as those who perform in the required time frames or as those who do not. Students are interpellated by this framing.

This, maybe, produces a fantasy of the ideal student of mathematics assessment, who does not only know mathematics, but also preforms mathematics in a quick and automated way, in a minimal time frame, and this is reflected directly and objectively in their assessment score. Students who do not fulfill this fantasy may be excluded, and this fantasy itself retrospectively justifies their exclusion. That is, mathematics assessment tests are supposed to assess if you are good at mathematics. But if there is a latent belief that being good at mathematics also means fast, then some mathematics tests assess speed, too. So fast students will, mostly, succeed and then the fantasy of the ideal quick mathematics student will be fulfilled retrospectively. This fantasy acts as one of the ideological presumptions, which normalize the exclusion produced by mathematics education and assessment and, also, make possible its reproduction in the future.

If doing mathematics is described as a ritual influenced by social and discursive norms, then this ritual is, also, a ritual that happens in time. In mathematics assessment tests with strict time limits, the line that shows what is mathematical and what is social is even more difficult to recognize. This affects the identifications that students make in relation to mathematics. And this produces exclusions which have less to do with mathematics than we commonly think.

Lessons learnt from history: Socio-cultural perspectives on mathematics education reform in Egypt

Mariam Makramalla

University of Cambridge, United Kingdom; mmmm2@cam.ac.uk

Keywords: socio-cultural capital, power dynamics, reform, memorisation, history.

Introduction

The study of educational reform initiatives is not a neutral enterprise. It needs to take into consideration – among other factors- the social and cultural heritage in which the given reform is situated (Ball & Lewis, 2008). In other words, for a reform in mathematics education to be socially accepted and practically effective, it needs to be bought into by the actual stakeholders in closest relation to learners and by the learners themselves. Hence, we can consider these social stakeholders as pillars of capital that make or break the reform initiative enactment. Building on this contextual view of educational reform, this poster is underpinned by a historical investigation of reform patterns in Egypt. It utilises a widened perspective on forms of capital, in an attempt to analyse patterns of societal buy in that have evolved over the years and that can be traced as part of the recent reform initiative in mathematics education in Egypt.

Theoretical Underpinning

This poster is based on the forms of capital theory, in which Bourdieu (1986) distinguishes between three types of capital; namely: economic, social and cultural capital. The latter two refer to the power of societal buy in and cultural heritage to contextually determine how a given initiative gets received and practiced. These three forms of capital are underpinned by what Bourdieu (1986, p.256) refers to as "the historical baggage" of a given context. "The historical baggage" is marked by eras that have shaped the cultural and societal topology of power dynamics. For the scope of this poster, based on the historical inquiry process (Hicks & Doolittle, 2008), I present a work-in-progress literature review covering three main eras of educational reform along the modern Egypt educational historiography, namely the post-colonial era (1914-1922), the republican era (starting 1967) and the era of global and open economy (1971 onwards). Patterns noted in these times serve as a lens for better investigate the current social tension around the current educational reformation, which aims to move away from a longstanding tradition of memorisation based instruction (Megahed, 2018).

Three eras of mathematics education in Egypt

Centered around the depiction of a historical baggage, the poster uses the historical inquiry process to illustrate the aforementioned three selected eras of societal transition in educational policy in Egypt, which show a repeating trend of societal power dynamics, presented more elaborately below.

Mathematics education in post-colonial Egypt: Two-tier structure

During the British colonisation, the modern Egypt was exposed, over an extended period of time, to a westernised education system in mathematics, which focused on creation and problem solving. This philosophy was socially foreign to the local eastern educational culture at the time. The westernised curriculum was only available to the elite, which resulted in the mainstay of a societal and cultural divide. This divide in educational ethos triggered the first, so called two-tier structure of education in Egypt which was largely sustained even after the colonisation (Heyworth-Dunne, 1968).

Mathematics education in the Republic of Egypt: Centralised Governance Model

In an attempt to offer equal opportunities for all, the government of Egypt, in 1967 took the radical step of unifying the curriculum across contextual affordances. The curriculum was centrally controlled by the government. The idea was to ensure the same curricular enactment is replicated irrespective of educational context, thereby closing the longstanding socio-cultural gap, which was created by the two-tier structure and safeguarding the system against extremist stimuli (Sayed,2006).

Mathematics education in the open economy of Egypt: Back to two-tier structure

President Sadat practiced a relaxed policy of open economy, which in turn gave rise to western investment in national education. Despite being heavily controlled by the national agenda for education, the elite had the opportunity to be educated differently; a societal trend that again gave rise to the return of the two-tier structure. Memorisation based instruction was again the ethos of the mainstream channels for education, while problem solving was taught selectively (Sayed, 2006).

Discussion

With this toggling trend of access, the mainstream of educational stakeholders have over the years solely been exposed to memorisation based instruction. This explains the reality which fostered the mainstay of the socio-cultural divide. Shifting suddenly to a different mathematics instructional model is understandably perceived as foreign to the mainstream and unwelcomed by the elite. The growing need to include Egyptian students, often refugees, at European schools gives rise to the importance of understanding the contextual reality that these learners come from and how they relate to western educational practices. This makes this poster relevant beyond the case of Egypt.

Universal Design for Assessment in mathematics

Juuso Henrik Nieminen

The University of Hong Kong, juuso@hku.hk

Universal Design for Learning (UDL) is a commonly used framework for designing accessible learning environments. While UDL has been reportedly applied to testing situations, much less is known about how classroom assessment (e.g., formative assessment) could be designed accessible to support the learning of all students. In this conceptual study, the previously introduced idea of Universal Design for Assessment (UDA) is reformulated in the context of mathematics. It is argued that in the test-driven assessment culture of mathematics, UDA holds specific promise; recent studies have noted that mathematics assessment does not enable students with disabilities to participate fully due to inaccessible practices. The proposed framework discussed how UDA could promote the following guidelines in mathematics assessment: i) partnership, ii) diversity, and iii) dialogue.

Keywords: Mathematics assessment, Universal Design, accessibility, diversity, ableism.

Introduction

It is a publicly known secret that classroom assessment has been unable to meet the needs of students with disabilities. In assessment, disabilities are not seen as something to be celebrated but as something to be overcome. Assessment with both its summative and formative purposes largely draws on individualised assessment accommodations rather than on inclusive practices; students with disabilities are seen as the problem to be fixed, not assessment itself (Nieminen, 2021).

While recent contributions have critically examined how mathematics education constructs disabilities through inaccessible teaching practices (e.g., Lambert, 2015; Nardi et al., 2016; Tan et al., 2019), much less attention has been given to assessment. This is surprising given how test-driven the assessment culture of mathematics is. As shown by Nieminen (2020), mathematics assessment plays a crucial role in *disabling* students. The test-driven culture of mathematics does not only create barriers for learning but for inclusion and participation by excluding students with disabilities from other mathematics learners both physically and socially (Bagger, 2022).

In this conceptual study, the commonly used framework of Universal Design for Learning is used to rethink mathematics assessment as an inclusive endeavour. This study draws on earlier critical work to understand ableism in mathematics education (Padilla & Tan, 2019): how assessment produces an ideal of certain normality and then excludes students who do not fit this ideal of a *normal, able* student (Nieminen, 2022). Rather than focusing on the pitfalls of current assessment practices, this study reaches further by formulating a framework for Universal Design for Assessment to guide future research and practice in mathematics education. First, Universal Design is introduced.

Universal Design for Learning

Overall, Universal Design refers to accessible design for everyone, originating from the field of architecture. In education, Universal Design has been largely promoted through the pedagogical framework of Universal Design for Learning (UDL). UDL refers to accessible pedagogical design that "proactively builds in features to accommodate the range of human diversity" (McGuire et al., 2006, p. 173). Due to such underpinnings, UDL is often connected with the social model of disability that does not understand disabilities as a deficit to be cured but instead sheds light on educational practice that actively *disable* students. While UDL has been most commonly used to design accessible practices with disabilities in mind, recent contributions have expanded the notion to address, for example, racism (Waitoller & Thorius, 2016). The UDL model encompasses three main principles, as formulated by CAST (2011):

- **Engagement** (the 'why' of learning): Multiple ways for stimulating interest.
- **Representation** (the 'what' of learning): Multiple ways for representing knowledge.
- **Action & Expression** (the 'how' of learning): Multiple ways to express knowledge.

UDL builds specifically on the very idea of design: rather than drawing on retrospective, individual adjustments it instead shifts our gaze to careful design of learning before the learning process itself. While UDL has been largely promoted in educational policies and practices, thus far such designs have been rarely reported in mathematics education.

Universal Design for Assessment

While UDL has been widely promoted in education, its implementation in assessment has received less attention. Accessible design in *test item design* has been noted, and indeed Universal Design for Assessment (UDA) has so far focused on how to design accessible large-scale exams (see Ketterlin-Geller et al., 2015). It is fitting that the seminal study by McGuire and colleagues (2006) only referred to UDL in assessment in terms of large-scale national testing.

Some more holistic conceptualizations have been offered. Ketterlin-Geller (2005) defined UDA as "an integrated system with a broad spectrum of possible supports so as to provide the best environment in which to capture student knowledge and skills" (p. 5). Ketterlin-Geller and colleagues (2015) discussed UDA in terms of target and access skills in assessment. According to the authors, assessment is intended to 'measure' certain skills and abilities (*target skills*), while other skills might also influence students' performance while demonstrating their mastery (*access skills*). Through careful pedagogical design, the interference of access skills can be minimized (e.g., a large font size ensures accessibility in a test so that the test item measures the intended mathematical skill).

However, to date, earlier studies have not built a critical framework to guide the design of classroom assessment in all its diversity beyond test design (e.g., self- and peer assessment) (Nieminen, 2022). Moreover, there is a need for a mathematics-specific UDA framework to address the ableism and inequity related specifically to mathematics assessment.

A socio-political, mathematics-specific framework for UDA

In this conceptual study, UDA is reformulated in the context of mathematics education. Recently, there has been a call for critical approaches to challenge ableism in mathematics education regarding students with disabilities (Tan et al., 2019). This is exactly the approach taken in this study. In fact, the UDL framework has been criticised for its focus on pedagogical design over challenging ableism and injustice, trading disability activism into an 'activation of neural networks'

(Nieminen & Pesonen, 2020). In the words of Hamraie (2016), UDL has become “emblematic of a depoliticized orientation toward disability” while largely ignoring “systems of oppression such as racism, sexism, or ableism” (p. 302). Following Hamraie, this study uses UDA as an inspiration but ties it with a critical approach. The UDL framework is reformulated as a novel UDA framework for mathematics assessment (Table 1). While introducing the UDA guidelines in the following sections, the main issues in mathematics assessment are introduced from the viewpoint of equity and disability rights. The study mainly focuses on the viewpoint of students with disabilities, but the framework holds promise for intersectional work too (Nieminen, 2022; Waitoller & Thorius, 2016).

Table 1: The reformulated framework for Universal Design for Assessment in mathematics

Original UDL principle	Engagement	Representation	Action & Expression
Revised UDA principle in mathematics	Partnership	Representation & Diversity	Dialogue

UDA principle 1: Partnership

The issue: In test-driven assessment cultures, students are merely the targets of assessment rather than active agents. In other words, students are *objects* in assessment, not *subjects*. Even when ideas such as Assessment for Learning are promoted, the process tends to be dominated by teachers’ actions and choices. As students are not enabled opportunities to co-design assessment practices, they might learn to be dependent on teachers’ actions rather than to truly ‘own their own learning’. The effects of such unilateral idea of assessment might be more prevalent for students with disabilities who have historically been dependent on teachers’ actions (Nieminen, 2021) and in mathematics education (Lambert, 2015; Tan et al., 2019). As the medical model of disability dominates in assessment, students are dominantly seen as the objects of support services determined by others.

The first UDA principle draws on the ideal of democratic education that understands learners’ rights to take part in actions and decisions that concern themselves. This is achieved through the principle of *partnership* that provides students with opportunities to act as co-designers of educational practices (Cook-Sather et al., 2018). Matthews and colleagued (2021) noted that while co-design practices has been reported widely in educational literature, such approaches have been rare in assessment. This highlights the urgency of the first UDA principle, especially in the test-driven context of mathematics assessment. The first UDA principle taps into the design-based roots of UDL (McGuire et al., 2006). Traditionally, UDL has emphasised that accessible educational design benefits everyone. The design process should hear the voice of the end users: designing *for* students with disabilities is not enough as assessment needs to be designed *with* them. This was noted by Nieminen and Pesonen (2020) who reported a university mathematics course whose design drew on UDA. As the design process only heard students’ perspectives after the course design, the process was certainly not inclusive; a worthwhile lesson for both the authors and the readers! Importantly, the first UDA principle emphasises that all students need to be heard in assessment design processes, but marginalized students in particular to enable accessibility (Cooker-Sather et al., 2018; Matthews et al., 2021).

In practice, the first UDA principle means that students are enabled possibilities to design the mechanisms of assessment. The principle disrupts the individualizing nature of assessment by rendering the mathematics assessment design process as a collaborative, communal project (see Matthews et al., 2021). Traditionally, it is the teacher who determines the learning goals and then designs assessment accordingly. While seeing students as partners, they need to have their voice heard in terms of which assessment practices are used and how. Experiences of co-design might be especially powerful for students with disabilities as this way they could feel sense of agency in how their mathematical skills are assessed: they indeed become subjects in assessment.

Students might co-construct a rubric with the teacher and, in the process, engage in a discussion about the relational standards regarding mathematical skills and knowledge. Students could design novel assessment practices, perhaps drawing on accessible digital technologies. Students with disabilities have been shown not to be able to fully participate in mathematics tests (Bagger, 2022; Nieminen, 2020); students could co-design other, more accessible forms of both summative and formative assessment. Even tests can be communally co-designed as reported by Rapke (2016) in the context of university mathematics. In Rapke's study, students have an opportunity to co-design a mathematics exam, as sitting an exam was required by the regulations of the university. This way this summative practice became a communal process instead of an individualised practice in one given time.

Assessment co-design processes (e.g., students taking part in constructing digital assessment forms) could promote students' understanding of mathematical knowledge and how this could be validly assessed: this is *assessment literacy* in action. As students learn the 'hidden mechanisms' of mathematics assessment, they also learn to examine their own assessment actions reflexively. For example, Nieminen and Lahdenperä (2021) discussed how mathematics students' preference for traditional assessment practices resulted from an assessment culture that undermines students' assessment literacies. Instead, students could be trained to critically examine how mathematics *is* and *should be* assessed, and what their active role in the process could be. Fostering assessment literacy is especially important for students with disabilities. This way students can learn not to only determine themselves as mathematical learners through the assessment information provided by others.

UDA principle 2: Representation & Diversity

The issue: Mathematical knowledge is most often presented in the form of text. While graphs and graphical illustrations are an important part of presenting mathematical knowledge, in the end, what is considered as the most powerful form of representation is abstract mathematical text and notations. In mathematics assessment, *time* has been another crucial determinator of mathematical knowledge. This is most imminent in controlled testing situations. These very boundaries of text and time are not accessible for all learners (Bagger, 2022; Thomas et al., 2015). While inaccessible representation of knowledge can exclude learners from mathematical communities in overt forms (e.g., by dividing students with hearing and vision impairments to segregated classrooms), covert forms are also present. For example, students with dyslexia might feel they do not belong in mathematical communities due to the dominance of visual text format (Nieminen, 2020).

Much like the original UDL principle, the second UDA principle promotes the idea that mathematical knowledge can be represented through a variety of ways. This UDA principle promotes multiple forms of media in presenting mathematics. For example, mathematical knowledge could be presented in the forms of images, videos, and embodied ways such as dance, gestures, signs and movements. In assessment situations, and especially in summative assessment tasks, enough time should be provided for students for whom time management itself might be an access skill (see Ketterlin-Geller et al., 2015). Mathematical concepts are often presented in unnecessarily complex ways, especially in high schools and universities. The UDA principle reminds about the ableist underpinnings of abstract mathematical text and the preferred fast pace of mathematical learning and assessment. Sometimes it is simply colors and images that are enough to provide accessibility; even such simple ideas might disrupt the ableist norms of mathematical representation. This UDA principle ensures that the need for individual assessment accommodations is lowered, supporting not only students with disabilities but also, for example, those needing extra support with language (Thomas et al., 2015).

In order to be successful, UDA needs to disrupt the ableist norms of mathematics assessment (cf. Nardi et al., 2016; Padilla & Tan, 2019). Nieminen and Lahdenperä (2021) showed how mathematics assessment sets boundaries for what counts as mathematical knowledge, thus setting epistemic boundaries for who can *know* mathematics and how. Even if teaching practices would promote conceptual understanding of mathematics through multimodal ways, assessment might override such representations by reminding what is truly important: individual performance textual summative assessment. Indeed, students in Nieminen and Lahdenperä's (2021) study expressed that the knowledge produced through self- and peer-assessment is *invalid*. According to the students, such formative assessment practices could be used, but exams show what one's *real* mathematical skills are. Such a hegemonic role of tests is ableist, as students with disabilities are excluded not only socially but epistemically. They are taught to understand themselves as the 'others' who are not able to fully participate in one of the most sacred rituals in mathematics education: the exam.

The second UDA principle holds promise for many marginalised forms of knowledge. Mathematics assessment always privileges certain forms of knowledge over others. What students with disabilities learn in mathematics assessment is that their personal epistemologies – the knowledge about themselves, their very personhood through which they operate as mathematical thinkers and doers – are something to be overcome, not celebrated. This of course aligns with the harmful idea of disabilities as deficits (Lambert, 2015). Thus, this UDA principle calls for assessment practices that allow students to inclusively use their "cultural repertoires, identities and out-of-school activities" in assessment (Waitoller & Thorius, 2016, p. 384). In this way, marginalized forms of knowledge can be valued in assessment by offering students various ways to understand themselves as mathematicians. For example, both formative and summative assessment tasks could draw on the language (in its both verbal and nonverbal forms) and cultural knowledge of students themselves.

UDA principle 3: Dialogue

The issue: As noted, mathematics assessment is globally built around testing. Even when other forms of assessment are introduced, tests still remain in the very centre of assessment and grading mechanisms of mathematics. Yet it is tests in particular that causes barriers for students with disabilities (Bagger, 2022). To foster inclusivity, mathematics assessment needs to diversify its practices to enable all learners to show their skills and capabilities.

The UDL principle of Action & Expression promotes various actions through which students can demonstrate their skills and knowledge. The second UDA principle is built on this premise: it reminds that all students have the right to be assessed through a diverse menu of practices (e.g., self- and peer-assessment, portfolios, group assessment…). Such practices should also be provided through multiple forms of media (cf. UDA principle 2). UDA principle 2 focused on the presentation of knowledge, but the third principle emphasises that diverse assessment should be used to widen the very idea of what it is to do mathematics. The principle draws on earlier work that has promoted very similar ideas in terms of mathematical tasks (e.g., Nardi et al., 2016).

This UDA principle promotes *dialogue* as the main purpose of assessment. When assessment draws strongly on summative practices, assessment becomes a monologue. The concepts of 'dialogic assessment' and 'dialogic feedback' have been used to emphasise how the learning potential of assessment is best achieved when students have an opportunity to *use* feedback (Steen-Utheim & Wittek, 2017). This means that assessment is not primarily used as the last word but that students could utilise feedback to enhance their mathematical work and understanding further. Importantly, such feedback could be produced in a dialogue not only with the teacher but with other students as well – or even with non-human actors such as computers (e.g., through automatic digital feedback).

The learning benefits of dialogic feedback and assessment are discussed elsewhere (Steen-Utheim & Wittek, 2017), but here the focus is on how such practices promote inclusivity and accessibility. As summative and formative assessment are both understood as forms of dialogue, focus can be shifted from only discussing the 'validity' and 'reliability' of assessment (as is often the case in mathematics assessment). Just as in any dialogue, the importance of content should surely not be neglected: for example, inaccurate feedback does not promote learning nor inclusion. Viewing assessment as a dialogue it becomes possible to notice all aspects of interaction and dialogue, such as expression of mathematical language (Thomas et al., 2015) and bodily expressions such as gestures and signs. In a dialogue, students with disabilities need to have their voice heard: what novel assessment innovations are yet to be discovered (cf. UDA principle 1)? Could mathematical knowledge be demonstrated through a dance? Tests might have their place in mathematics assessment, but only as a part of dialogue. For example, perhaps students might wish to back up their test results with a digital portfolio where they could save evidence of their learning in various forms (video, images, social media posts…).

Dialogue in mathematics classrooms rarely happens only between the teacher and a student. The third UDA principle also includes the idea of communal interaction within the whole learning community in the classroom and beyond, extending to families and school communities. In mathematics assessment, students often produce artefacts only for the purposes of assessment (e.g., tests or essays). However, through communal assessment it is possible to challenge the epistemic idea that mathematical abilities are purely *individual* (Nieminen & Lahdenperä, 2021) by producing something concrete and *useful* as a part of the assessment task (Nieminen, 2022). For example, it is possible to conduct assessment in the form of a communal real-life project. Perhaps students might want to demonstrate their statistics skills by conducting a survey about inequities in their school context. In such communal projects, all students can participate through their personal ways of communication and interaction, everyone working inclusively toward a communal goal.

Just as any dialogue could take multiple and sometimes even surprising turns, mathematics assessment now becomes a risky business. As students with disabilities learn to use assessment and feedback for their own purposes (call it 'assessment literacy' or 'critical thinking'), the results might not be what educators wanted it to be in the first place (students might even decide they do *not* want to engage with mathematics at all!). This is the beautiful risk of democratic education. A sustainable dialogue cannot be dominated by any actor, which also holds true for mathematics assessment.

Conclusion

UDA offers a valuable framework for mathematics education to strive for accessible ways to assess students' mathematical skills. While offering practical tools, UDA is, above all, a way to examine mathematics assessment through a critical lens. It offers mathematics educators a way to render assessment – traditionally a major source for inequity (Bagger, 2022; Nieminen, 2020, 2021) – as a tool for inclusion. Thus far disabilities have been understood as deficits in assessment: if we wish to celebrate diversity in mathematics classrooms, assessment simply must be rethought.

Mathematics, ethics and climate change- ethical awareness in mathematical education.

Magnus Ödmo

Malmö University, Sweden; magnus.odmo@mau.se

Keywords: Mathematics, Ethics, Climate change, Critical math.

Background

The overall goal of the research project presented here is to investigate and produce knowledge about how students and teachers are learning mathematics when presented with mathematics in the context of climate change. Climate change offers a timely and to many people relevant problem, and this problem consists of amongst other things ethical considerations. There are no easy technical solutions to the problem of climate change and the norms and values to address the problem differs around the world (Block, 2019). These norms and values are based on ethical standpoints. It is these that will be discussed and exemplified in mathematical examples in a series of lessons in school-based research.

School-based research

For my coming school-based research, a series of lessons will be created to exemplify how ethics and mathematics are intertwined and, in the classroom, there will be discussions about ethical considerations concerning climate change. Different ethical standpoints and perspectives will be presented to the students, illustrating the complexity of the problem of climate change. Articles dealing with the ethical implications concerning climate change are multiple in the research community. Gardiner (2011) argues that climate change plays a fundamental role due to decision making, which affect animal and future generations. Gardiner (2011) also point out some reasons why it is hard to be ethically sound. Local emissions have a global effect. A decision in one place may have implications in a totally different place in the world. Raymond (2004) argues for an ethics of commons. The atmosphere is a global common good and he proposes that the emissions should be allocated between nations. It could be done by using the principle of equal burden. Meaning that nations should reduce their emissions based on the burden of this reduction. Another approach based on equal human rights would be to allow an emission level per capita. Shue (1999) concludes that "whatever needs to be done by wealthy industrialized states or by poor non-industrialized states about global environmental problems, the costs should initially be borne by the wealthy industrialized states" (p.111). He then describes the reasoning behind this conclusion and how proportional and progressive burden can be explained. All these suggestions mentioned above are based on different ethical assumptions, and are examples of what can be presented and discussed in a mathematics classroom regarding ethics and climate change. They also deal with mathematical concepts, for instance proportionality and progression, that can be used as examples. The mathematical examples the teacher make to illustrate climate change, through graphs, diagrams and tables influences how the discourse is formed and has implications on the finding of possible solutions to climate change. These choices and implications are something both the students and the teachers must be made aware of.

Methodology and analysis

In the upcoming project, data will be collected through interviews with the students and the teachers. The analysis of the data will be performed using *actor-network-theory* (ANT). It is a methodological approach to study social phenomena where everything exists in a continuously changing network of relationships (Latour, 2005). As Latour (2005) describes, everything that happens in a social situation takes place on the same level. So, for instance, humans as well as objects have agency, and both play a role in creating a social situation. In ANT there are two central concepts, *mediators* and *intermedieries*. *Mediators* "transform, translate, distort, and modify the meaning or the elements they are supposed to carry". (Latour, 2005, p.39). *Intermedieries* on the other hand, is what transports meaning without transformation: "defining its inputs is enough to define its outputs" (p.39). But how do we distinguish between mediators and intermediaries? Latour mentions that to learn ANT is nothing more than to "become sensitive to the differences in the literary, scientific, moral, political, and empirical dimensions of the two types of accounts" (p.109). I will look at the student as an actor and mathematics as an actor and how the two-trough translation is changed into a mathematician - an actor-network - a new entity with new agency. What are the necessary interactions for this translation to be successful?

Discussion questions

- What are suitable mathematical examples based on ethical standpoints that can be useful when teaching and learning mathematics in a climate change context?
- What should be the main focus when using ANT as methodology in this research, is it the students, teachers as actors or maybe Climate Change as a token, and how these are changed by the interaction in the classroom?

Acknowledgement

I would like to express my special thanks of gratitude to Anna Chronaki and Lisa Björklund Boistrup, for their support in writing this poster.

Mathematics' learners engaging in context-oriented reflection. An exploratory investigation to promote more differentiated views on mathematical concepts.

Cornelia Plunger

Universität Klagenfurt, Austria; cornelia.plunger@aau.at

This paper presents an investigation in which eight-grade students (14 to 15 year olds) are encouraged to engage in context-oriented reflection related to the mathematical measurement of geometric shapes. The contribution of such reflections to societal and socio-political challenges is not primarily aimed at critiquing society or mathematics. Rather, the objective of this study ends one step earlier by providing students with a better grounding for such critique (be it positive or negative). By means of interviews, data are produced to provide a deeper look into the students' reflective processes. Evaluation results show that, in their work, students address the context of buildings and their furnishings. This and other aspects are used to analyze reflection processes and results of varying profundity.

Keywords: Reflection, mathematical literacy, geometric shapes, calculative measurement of sizes.

Introduction

Context-oriented reflection is advocated by various authors (e.g. Skovsmose, 1998; Schneider, 2019). For the present investigation, the definition of context-oriented reflection is based on that of Schneider (2019), in whose research project I am involved. Here, context-oriented reflection means reflecting on mathematical concepts and the effects that arise from using them in different contexts of our world and society. Thereby, reflecting means thinking about the characteristics, connections and relationships that cannot be read off by the given fact (Schneider, 2019; Plunger, 2021). What can be read off by given facts or not depends on the prior knowledge of the reflecting individual. Context-oriented reflection thus has to be an individual process or experience which focuses on new insights related to effects, characteristics and connections of mathematical concepts in their application to different contexts. The product of this process should be a fund of knowledge, which might simply be communicated. However, the mere repetition of such knowledge cannot be a sign of reflection. For different perceptions of mathematical literacy, several types of reflection seem to be an essential contribution to a mathematical education for societal participation and the development of society (Plunger, 2021). Context-oriented reflection enables diversity in access to mathematics learning, especially as a contribution to societal and socio-political challenges. First, it is about examining mathematical content for its effects and functions in society and characterizing this activity itself as relevant content for mathematics education. Second, the activity of reflecting forms a counterpart to the widespread calculus-oriented, repetitive activities in learning mathematics: insights into characteristics, connections and effects which initially seem to be hidden in the given facts, are generated through independent reflection. Third, learners are given the opportunity to make reflections related to society on the basis of personal, subject-related experiences of learning mathematics and supra-subject-related experiences from their lifeworld (including school) with the thematized mathematical concept. The reflection process should provide insights into the extent to which the mathematical concept contributes to our life together, or what would change without it.

In this paper, I will rely on data collected within the framework of my PhD project. The intention was to use special tasks to encourage students aged 14-15 to engage in specific types of reflection on different mathematical contents. Here, the results of the task that aimed at context-oriented reflection related to the mathematical measurement of geometric shapes are discussed. In this regard, three questions will be addressed in the following sections. (1) What contribution can context-oriented reflection make to mathematics learning from a theoretical perspective? (2) How can students be encouraged to engage in context-oriented reflection? (3) What context-oriented reflections do students engage in when they are encouraged to do so through specific tasks and settings?

Theoretical Perspective

In this section question (1) is addressed. In 2012, Fischer presented his ideas about (mathematics) teaching in our society based on the division of labour, where it is not possible to be an expert in every discipline. Thus, according to him, the goal of general education should be to enable learners to make independent evaluations and to be able to form appropriate judgments for themselves, relating to mathematical content. Calculus-oriented mathematics education, as described by Kollosche (2019, p.105), seems to work against such a purpose, because it seems to prepare students “to repeat the same procedure again and again, also following rules which are set by others and whose purpose might not be fully understood” (Kollosche, 2019, p.107). The challenges facing our societies today require an education that empowers critique (Steflitsch, 2021). Critical awareness involves the ability to perceive multiple facets, both positive and negative. Skovsmose (2011) contrasted the modern, very positive conception of mathematics with a critical one (p.60). In order to give students access to such a critique, he made them take a closer look at applications. In doing so, he encouraged a series of reflections that focus on the effect of mathematics in this concrete application (e.g. ibid., pp. 72-75). Fischer’s approach to mathematics is a more neutral one. In 2005, he stated that mathematics is indispensable in modern society “because it materialises abstract things and thus makes them accessible to individual thought as well as to communication” (p. 293). Furthermore, he argued that such materialisations offer a dialectical potential in the sense that they can be used to hold on to what is described as well as to overcome it (Fischer, 2005, p. 24). In both cases mathematics is seen as a tool. According to Skovsmose such a tool brings with it very specific effects in a certain situation, which should be analysed. According to Fischer mathematical concepts provide the chance to materialise certain aspects of a situation to make them accessible for discussion.

In my conception of context-oriented reflection, mathematical concepts are also interpreted as tools, but they are dissociated from one specific context insofar as different contexts of application for one of these tools are taken into consideration. The comparison between these different contexts should help to compare the distinct characteristics of this tool and might provide an insight into what is gained through mathematization, but also into its limitations. This ultimately should enable one to make a more informed judgement about the use of this tool on the one hand, in relation to other concrete situations, but also in general to better estimate how and when this tool can be used. With this type of reflection, the reflective activity ends before there is the concrete occasion to engage in criticism related to the subject or society. Rather, the mathematical concept is seen as a kind of tool and an awareness is created that its use can bring along a range of effects. This raises the following questions: Which of these effects are grounded in the concrete materialisation (mathematization through the tool of the mathematical concept)? Moreover, which ones are grounded in interpretations of this mathematization? Thus, through context-oriented reflection deeper insights may emerge related to the mathematical concept and to the contexts under consideration. However, the essential interest of context-oriented reflection lies in the effects that are made possible by the mathematical concepts. Thinking about such effects should afford a differentiated stance between the two poles of an exclusively positive and an unreflectively negative conception of mathematics. This creates a basis that contributes to more well-founded subject and social criticism.

Data production by means of interviews

This section discusses the methodology used to produce the data in response to question (2) How can students be encouraged to engage in context-oriented reflection? In my PhD-project I focused on model- and context-oriented reflection and decided to investigate this question by means of interviews with pairs of students aged 14 to 15 years; I conducted interviews with eleven pairs of students who participated voluntarily and from three different schools (four different classes) in Carinthia. Each pair participated in three interview sessions focusing on varying mathematical contents (arithmetic, statistics, geometry). It was ensured that the required content was already addressed through school lessons, but the concrete lessons of the different classes were not further analyzed. On each interview date students were asked to deal with two tasks in partner-work, the first task aiming at model-oriented reflection, the second task aiming at context-oriented reflection. At the end of each interview a short discussion followed about affective issues related to the processing of the task. The interviews are documented by audio recording and its transcripts. The task for the context-oriented reflection on the content of geometry is reported in Figure 1; It was presented to the students on the first or third interview date, after a task that was intended to stimulate model-oriented reflection which dealt with the determination of the air volume in a classroom by means of a cuboid.

Geometric Shapes

In mathematics lessons you have learned to calculate lengths, areas or volumes of different geometric shapes.

What are the advantages of being able to calculate lengths, areas or volumes of different geometric shapes?

Figure 1: Task, headed "Geometrische Figuren und Körper", translated by C.P.

The intention of the task in Figure 1 is that students think about the consequences that (can) result from the mathematical determination of various geometric shapes. Possible lines of thought are (a) that geometric shapes have the potential to be seen in many objects of our environment, and the possibility of calculating certain sizes from such objects can be helpful. (b) Geometric shapes can be used as models for buildings, e.g. a swimming pool, which can facilitate planning since necessary material for the construction can be calculated in advance, as well as the water capacity. (c) If geometric shapes are used as models for buildings, there is the possibility of testing different solutions, e.g. with regard to material consumption: a cube-shaped-house offers more space with less material consumption than one with an elongated base. (d) Lengths can easily be measured physically, but this is not true for areas and volumes. (e) Computational methods can provide more exact numbers for lengths than physical measurement methods in selected cases (e.g. for the diagonal of a unit square).

The task itself may stimulate reflection, but reflection also needs an environment that invites it. In conducting the interviews, it was important to me to create such an atmosphere. The students should understand that it is their thoughts, their reflections that matter. By noticing and feeling that there is real interest in their personal thoughts, they should be encouraged to reflect. Additionally, I tried to apply some reflection-inviting features, but they seem to be dialectically related to each other. *Working in pairs vs. individual work:* communication seems to be essential for reflection because through communication new perspectives and ideas can be exchanged and further developed. On the other hand, individual reflection is also a prerequisite for successful reflection in communication, and reflection is also possible individually, for example, when one enters into an inner dialog. In the interviews individual work is scheduled to grasp the task and first deal with it for the first 2-5 minutes. This also should increase the likelihood that both partners have individual ideas that can be exchanged and discussed. Working in pairs additionally provides the possibility to get closer to the thoughts of the students, because a conversation with a classmate should favour a natural and spontaneous exchange about the results and thoughts that led to them. A one-to-one dialogue between student and scholar seems to inhibit such natural exchange. *Speaking vs. writing:* aiming for a predefined written product may inhibit reflection, on the other side writing would demand more clarity and thus deeper reflections. During the work with the tasks, the students were given paper and pencil for notes but were not required to create a written product. *Free conversation vs. interventions:* the interest in the thoughts and pair-working processes was emphasised in the introductory phase of the interview and a conversation between the two students was encouraged above all in the beginning of the working process. Yet, interventions provide the opportunity to ask for more detailed explanations of statements or to stimulate alternative directions of reflection. As an Interviewer I used guided and free interventions focusing on general or content-related aspects. The first interventions usually consisted of general questions such as *Look at the question again - did you answer it? Is it possible to approach the question in a different way? Try to explain how you came up with the different ideas/aspects.* Only in a second step, interventions should become more content-specific in order to obtain a scale for the evaluations. Content-specific interventions for the task discussed here were, e.g. *Try to consider this question separately for lengths, areas and volumes. What possible alternatives are there to mathematical calculation? Try to address this task in the sense of what would be the consequences if there were no way to calculate lengths, areas or volumes.* Such interventions were chosen freely during the interview, depending on what I as interviewer considered the students' processing required. This allowed me to ask for more detailed explanations or review the processing as well as stimulating alternative ways of reflection where this seemed appropriate. Nevertheless, it remains a challenge to maintain the balance between interventions for the purpose of focusing the core of the given task and a natural exchange of thoughts in a conversation between students.

Reflection processes of learners

This section addresses question (3), What context-oriented reflections do students engage in when they are encouraged to do so through specific tasks and settings? In general, in the interview-parts that refer to different tasks on content-oriented reflection it became evident that students found it very unfamiliar to engage in such reflections. They were able to draw on appropriate contexts, nevertheless they had difficulties to concentrate on the core of the question. Depending on the mathematical concepts on which the task focuses, positive but also negative effects of the mathematical tool are observed by the students. Across the different tasks it can be noticed, that the students do not take a critical look at their results, hardly putting them into perspective or considering the possibility of differentiation. Such attitudes might hinder the understanding of mathematical concepts but especially deeper-founded critique towards mathematics or society.

Regarding the task presented in this paper, three characteristics that are consistently observable in the corresponding interviews are described in more detail. For their reflections, learners draw on the context of buildings, especially houses, and their furnishings. In doing so they have difficulty differentiating where length measures and where area measures are required. An effort to find positive examples is recognizable, while negative aspects are not illuminated. In the following, the reflection processes of one interview pair, Klara and Joelle (all names changed) are examined in more detail and accompanied by spotlights from other couples. This allows an insight into how these three characteristics develop and how differentiated the underlying statements are.

Klara and Joelle initially had different approaches to the task. Joelle saw the geometric shapes and their calculability as personally relevant to her because she wants to become an interior designer. She justified this importance for interior designers with the fact that one must know the surface area in order to know what fits into this space, Joelle's first comment on the task (all transcripts translated from German by CP) was:

Joelle: […] So, what is important for me, for example, because I want to become an interior designer, is exactly this kind of thing, because if you have to put something in a room, you also have to know the surface area and everything, so that it really FITS in the room, because well, you can't, I don't know. [Into] a three meter long room you can't put a four meter long bed, ok that's maybe a bit exaggerated, but that would just be an example, you can't put it in, because. For that it is once practical.

This indicates one aspect of thought line (a), that it can be helpful in a situation to determine the area of a particular object. Implicitly, it must be assumed that (a) geometric figure(s) can be seen in this area. However, the further description of such a situation (does the bed fit into the room?) reveals that even more differentiated considerations would be possible here, Joelle herself indicated that this is not a well-suited example. In the ongoing conversation, the importance of the computational determination of geometric shapes for furnishing was put into perspective, presumably from personal experience with furnishing (Klara mentioned that sizes like length, width, height are usually indicated), but not explicitly related to what these measurements can and cannot contribute (e.g. that a number that expresses the area of a room is not helpful to determine whether an object like a bed fits well in it). Later in the conversation, Klara justified the area calculation of a house or apartment by knowing “how much living space a person has in the house”. Klara’s first contribution to the task addressed precision as an important element of calculating, but together they failed to come to a coherent justification for themselves.

Joelle: And if you just calculate it could be even more exact, because you have, for example, decimal numbers or something, because that’s what you have when you measure normally, yes, ok, it could be, but. Yes, hmh. That was not so now, smart {Both laugh}.

In this conversation it is repeatedly recognizable that the two had difficulties in differentiating where mathematical measurement methods are possible and where physical measurement methods are necessary:

Klara: Yes, such a house is something that should be beautiful. Especially because people are going to live inside it and

Joelle: Yes. And.

Klara: It is perhaps simply important that one can calculate all the areas and so, hmm, because I would not go to a house now, the tape measure from one corner to the other and then perhaps even in the height. It is perhaps intelligent if you know the dimensions and can then calculate how many rooms will fit into the house and.

Even in other interviews, for example with Chris and Vedran, problems with differentiating the need for physical measurements and possible calculations of sizes arose. Following a statement that the benefits of calculating are being more precise, taking less time and effort I requested them to explain in more detail what this means through a dialogical conversation. Vedran told Chris to start by gauging a length, a width and a height. Taking these sizes would take about 30 minutes, while these few numbers could be calculated much faster using mathematical calculations. Then the volume of the room could also be calculated to know how much space there would be for a cupboard and find something that would fit in the room. Chris did not contradict this, on the contrary, he affirmed several times throughout these remarks and anticipated Vedran’s statement that afterwards furnishings that fit the room have to be found. In this case again, we see that the two do not take into account that a number expressing volume is not suitable for finding fitting furnishings. Further, like other pairs, they do not recognize that a physical determination of lengths is a prerequisite for being able to determine concrete numbers for areas and volumes in which geometric bodies are seen. In any case, Chris and Vedran do not relate these facts to the example they outline. Mark and Nicolo, on the other hand, recognized that when they thought of the need to determine lengths, only examples where lengths can be determined physically came to their mind. This is probably based on the fact that lengths are easier to measure physically than areas and volumes – an approach to line of thought (d). Nevertheless, an intervention from my part with the question of how areas or volumes can be determined without calculating, and their adequate response to it, did not help to address aspect (d) explicitly. They continued to look for situations in different contexts where a computational determination of lengths seems necessary. They mentioned very complicated constructed situations where different lengths had to be added and geometric figures played only a secondary role. Other examples referred to the fact that desired areas or volumes were given and suitable lengths had to be found.

For other students the fact (d) that areas and volumes cannot easily be determined by other means was a starting point:

Gina:	But I think that you might not be able to estimate a volume very well, if you could not
Hannah:	No.
Gina:	determine it mathematically like that, because or at least I can't.
Hannah:	(Uncomprehensible.)
Gina:	And that this is indeed helpful.
Hannah:	It is indeed very helpful, yes.

Almost all pairs took up the context of buildings and their furnishings for their reflections without noticing that the specification of a number for the area is not very helpful. As can be seen from excerpts of the interview with Klara and Joelle, both tenable examples and those that require a closer examination are mentioned together during one interview. An explicit evaluation of such examples is rather not done by the students and occasionally these examples are kept until the end of the interview. All in all, critical aspects are rather faded out, whereas benefits are often mentioned with emphasis, without backing up them by reasonable statements.

Discussion

The interview results show that although the students take up similar contexts on the one hand, they come to different depths with different approaches and at different points. What all pairs of interviews have in common is that they have difficulties in keeping their focus on the core of the question, which is the *calculative determination* of sizes of *geometric shapes*. Nevertheless, they make a great effort in the interview to engage with the question and to work on it with their reflections. It is remarkable that the students only look for positive aspects and tend to ignore critical aspects or at least do not examine them in detail (e.g. suitability of an area measurement for the equipment of a room). On the one hand, this may be due to the task, which explicitly only asks for advantages, but in the interview I did ask for more precise explanations at such points. On the other hand, it may also be due to the selection of the participants for the interview, who were willing to engage in such interviews to reflect on the use of mathematics. Such student might have a more positive attitude towards mathematics in general.

According to the theoretical perspective context-oriented reflections should contribute to independent evaluations, appropriate judgements and the analysis of effects emerging from the use of mathematical concepts. At the same time, these aspects provide a kind of solid groundwork for a well-founded subject and social criticism, because they seem to facilitate the ability to adopt a critical stance. This would also include differentiating considerations or careful examination of arguments, which regrettably could not be largely observed in this study. However, it must be recognised that this is only a first step in the demand for more reflection in learning mathematics. It investigates the reflection processes of students who had little experience with this in their mathematics classrooms. The students are not involved in a systematic classification and differentiated consideration of their reflections outside the interviews. This is not possible within the framework of my PhD project. The students themselves see a need for further processing insofar as some of them ask for feedback in the follow-up conversation or express an interest in exchanging results with other pairs. From a teacher's perspective, the students' reflections would offer potential to look at the results on this question even more deeply and to develop a more differentiated picture of the collected "advantages". This seems to be significant in relation to this one mathematical concept of the calculability of geometric figures and solids, but it would also promote a further development of the ability to reflect and a transfer of this ability to other contents.

In the follow-up conversations to the interviews, almost all participating pairs described their processing of the tasks as being meaningful. This indicates that the students are willing to engage in the analysis of the use of mathematics in contexts they are familiar with - what seems to be a very important prerequisite in the development of a critical attitude. The positive effect of reflection for the students should be used as a potential in learning mathematics in order to draw a more differentiated picture for the use of mathematical concepts, especially as a basis for a well-founded and if necessary differentiating critique towards society or mathematics.

Moving beyond gatekeeping: Using data analytics to overcome resistance to pedagogical change

Daniel L. Reinholz[1], Chris Curtis[1], and Niral Shah[2]

Postsecondary mathematics education often plays a gatekeeping role in STEM higher education. Accordingly, research highlights the need for pedagogical change to promote more equitable mathematics classrooms. However, mathematics faculty often resist change, grounded in rationalizations such as "math is just hard." In this manuscript, we offer a concrete approach to overcoming such resistance. The approach uses classroom data generated by the observation tool EQUIP. We provide reflections from one participating mathematics faculty member on his experiences engaging in this process. We discuss implications for using this approach at scale.

Keywords: Change, classroom observation, data, instructional change, pedagogy, reflection.

Introduction

Mathematics is widely recognized as a gatekeeper to higher education, especially within STEM fields (Martin et al., 2010). Cultural narratives position mathematics as largely white, masculine, and able-bodied (Reinholz, 2021). As a result, mathematics plays an integral role in the persistent marginalization of students based on race, gender, disability, and other identities (National Center for Science and Engineering Statistics, 2021). Mathematics instruction is typically guided by a number of purportedly neutral logics, which in fact disproportionately impact students based on their identities (Leyva et al., 2021). Logics include, "mathematics as universal and objective," "math is challenging," "some people are simply not math people," and that the role of mathematics instruction is to "weed out incapable students so the best ones remain" (Reinholz & Dounas-Frazer, 2017; Seymour & Hewitt, 1997). Given that such logics are regularly deployed in mathematics instruction, how can the field make progress towards more equitable and anti-racist teaching practices?

In this manuscript, we offer an approach for making progress despite this seemingly intractable problem (cf. NCSES, 2021). Our approach is organized around classroom observation and data analytics. First, we document concrete events in a context that is relevant to an instructor – their own classroom. Next, we use these as grist for interrogating taken-for-granted cultural logics. To do so, we use the classroom observation tool EQUIP (Reinholz & Shah, 2018), which provides data analytics describing patterns of inequity in classroom participation, disaggregated by social marker identities. By providing such data to an instructor, we first demonstrate concretely how inequities arise in everyday classroom interactions. Next, we work with instructors to change their teaching practices, and accordingly, demonstrate that changing such participation patterns is within an instructor's locus of control. This serves for the basis for discussions of why such inequities existed in the first place, and why they align with what one would expect based on historical patterns of marginalization in mathematics. To illustrate this approach and learning process, we provide reflections from a single mathematics faculty member who participated in an EQUIP learning community in Spring 2020. Our goal is to spur conversations on how this approach can be scaled up and used across contexts.

Background

Participation in classroom discussion is highly valued across mathematics education (Hufferd-Ackles et al., 2004). The reason for this focus is that participation in discussion contributes both to learning and identity development for students (Reinholz & Shah, 2018). It follows then, that students who participate are more likely to succeed and persist in mathematics. Yet, simultaneously, research shows that these patterns of participation are inequitable across identities such as race and gender (Ernest et al., 2019; McAfee, 2014). Thus, participation is one concrete site within which inequities arise in the mathematics classroom. Moreover, patterns of participation are relatively easy to capture through classroom observation, and once captured, changing such patterns is within an instructor's control.

We used EQUIP to capture participation (Reinholz & Shah, 2018). To efficiently facilitate the use of the EQUIP protocol, we used the free, open source and customizable EQUIP web app (https://www.equip.ninja). EQUIP describes classroom participation at multiple levels – individuals, groups, and the whole class – through a variety of data visualizations. The unit of analysis in EQUIP is a contribution, which consists of a sequence of talk from a single student. Each time a new student talks, a new contribution begins. For each contribution, a coder (in this study, a graduate student observer who was trained to use EQUIP) codes several aspects of the contribution, such as the length (1-4 words, 5-20 words, or 21+ words) and type of student talk (why, how, what, or other), and an instructor's questions (why, how, what, other, or N/A). Because all these facets of classroom practice are attached to specific students, analytics can be disaggregated at a student level. By including demographic information, a user can then generate analytics about particular student groups (e.g., Black women, Latinx men). The specific demographic categories and codes used can be customized according to the local context. In this way, EQUIP represents a particular methodology for tracking classroom participation, which is instantiated according to local needs.

Method

Participants and Context. We report on work that took place at a large, research intensive Hispanic Serving Institution (HSI) in the US.[1] Participants were recruited through an open call to the university. The second author of this manuscript (Professor C) participated in a cross-disciplinary learning community during the Spring 2020 semester. During Spring 2020, instruction began in a face-to-face modality, and transitioned online mid-semester in response to the global coronavirus pandemic.

[1] HSI is a federal designation that denotes at least 25% of the student population is classified as Hispanic.

The second author is a member of the Mathematics Division, whereas the first author is a member of the Mathematics Education division. This difference in affiliation manifests in a strong difference in professional obligations between the two authors, with the second author expected to publish regularly in highly specialized technical journals, pursue external funding, supervise theses in mathematics research, and promote an overall culture of “competitive” mathematical ability within the department with an eye towards maintaining standing in the larger international research community. This role directly reflects the second author’s educational background and acculturation within mathematics. In large part, the role of the second author then is to find and select the “best” students to follow the same professional trajectory at the second author. This institutional pressure differs from an approach that would instead focus on helping all students succeed as much as possible.

Focal Course. Professor C taught *Introductory Real Analysis* (also called *Advanced Calculus*, in the US), which met three times weekly during 50-minute sessions. The student population in this course is diverse in terms of race, gender, and mathematical focus. Some students are focused primarily on becoming mathematics teachers, whereas others are working towards STEM-intensive careers. In either case, Real Analysis is a critical course for all mathematics majors and is seen a difficult course. Students enroll in this course during their 3rd or 4th year, after completing three pre-requisite courses. For students transferring from local community colleges, this may be their first mathematics course in a new learning environment. Given all these factors, the student population is very heterogeneous.

There were 33 students in the course (22 women, 11 men). The racial demographics were: 12 White (36%), 5 Asian (15%), 9 Latinx (27%), 1 Pacific Islander (3%), and 6 Unknown (18%). These data were collected from a survey of students, and missing information was filled in based on the instructor’s perceptions (which is the reason for unknown results in the race category). The racial demographics are somewhat less diverse than the campus as a whole. We recognize that instructor perceptions may not always align with student self-identification, but we note that an instructor’s biases are most likely to align with their own perceptions, so they were still useful for an intervention to reduce bias and promote equitable teaching. The gender demographics were notable because 3rd/4th year math courses tend to skew heavily towards men but did not in this case.

On the target campus, the deadline to withdraw from classes is two weeks after the semester begins. Given that this date is so early in the semester, students may realize that the course does not fit into their schedule or work/life balance only after this deadline. As a result, there are sizable populations of students that essentially “drop” the class by ceasing to participate for the majority of the semester. These students can be become especially frustrated at their lack of success and finding effective strategies to keep them engaged or get them reengaged in the course is nontrivial.

Design. The six faculty participants in the learning community met on a regular basis (typically every few weeks) to work collaboratively to improve equity in their classrooms. The learning community was organized around iterative reflection cycles. In each cycle: 1) instructors were observed teaching (through a video recording), 2) the teaching was coded and feedback was provided, and 3) there was a feedback meeting to debrief and plan next steps. By including multiple reflection cycles over the course of a semester, instructors had multiple opportunities to reflect, change practices, and observe changes in the data. There were five debrief meetings throughout the semester. In this manuscript, we focus on a Professor C, who was the only mathematics faculty member in the learning community.

A total of four lessons were video recorded and coded by a graduate student who was trained in the EQUIP protocol. In the beginning of the semester, instruction was recorded in the classroom using a video camera, which was later coded. In the second half of the semester, Zoom virtual meetings were recorded and coded. In the classroom recordings we could only capture whole-class discussions (due to data collection limitations), whereas in the Zoom recordings we captured both whole-class discussions and breakout rooms. Instructional practices were coded along several dimensions, including the length and quality of student talk, and the type of instructor question. The coded data from each observation were provided to Professor C in a written report, which outlined key highlights in the data, as well as possible suggestions for revision to practice. Detailed notes from each meeting and well as records of feedback were retained to support data analysis and interpretation.

Analyses. In this brief manuscript, our analyses focus primarily on the Professor C's reflections (the second author), with some reference to the analytics generated in the process. Prior work has documented changes to instructional practices through EQUIP communities (Reinholz et al., 2019, 2020). Here, our goal is different. We are focused on longer-term changes to an instructor's logics, and how EQUIP could support such self-reflection.

Results and Reflections

Initial Approaches. Even though Professor C was a member of the mathematics division, he had a personal commitment to do his own studies of feminist and anti-racist literature. This is somewhat unusual for core mathematics faculty. The impetus for this reading was grounded in his general worldview and attention to equity. This background work provided him with a foundation to start thinking about students' intersecting identities with varying degrees of existing privilege. However, most of this reading was in more general settings and not specific to mathematics. This also meant that he did not have specific instructional moves that he could apply to mathematics teaching. This was a primary motivation for joining the learning community. While he was aware of issues, he was not sure how to approach solving them. Moreover, he was less aware of how his own demeanor and particularly privileged identity (white, hetero-passing, cis-male) influenced the nature of discussions in his classrooms.

There is a general perception within the department that students should be "mathematically mature" by the time they enrolled in *Advanced Calculus*. Given these broader narratives within the department (and mathematics writ large), Professor C initially felt that if a student was not "ready" by the time they enrolled, then there was little chance of them doing well. Professor C reflected on this bias of his and its origins in his own educational experience. Even as he questioned his own assumptions, there was still the larger issue of developing effective strategies and alternate pedagogical approaches to help enhance participation and success for all students in his class. One strategy that Professor C did use from the beginning of the semester was breaking students into groups of 3-4 students who would work collaboratively on problems. A rationale was that "stronger" students would serve as the de facto liaisons with Professor C, providing a kind of cover for students less willing to engage in what had been described as a "coldness", "lack of patience", or "condescending attitude" from Professor C (quotes taken from prior student reviews). As we note below, Professor C later came to question this idea of stronger students being the ones to support their peers, and he looked for ways to engage more students directly in the class.

Data Analytics. We begin with data from two of the four EQUIP observations that focused on in-person teaching. Across the two observations, what is perhaps most notable is that 23/33 (70%) of students logged no interaction at all. This issue of such a marked absence of classroom participation then became a topic of focus during the learning community meetings lead by Professor R, which occurred after observations. In addition, of the 35 interactions logged, they were disaggregated by the following racial demographics: 18 White, 14 Unknown, 2 Latinx, and 1 Asian. Thus, while only 36% of the class was White (12/33), 51% of contributions were from White students (18/35). By gender, they were: 11 by men, and 24 by women, which largely matched the class demographics of 11 men and 22 women. This shows that there were clear patterns based on race, but not so much based on gender. Largely underlying these patterns was the fact that 18 of the contributions belonged to just three students (a white man, a white woman, and a woman of unknown race, with 6 contributions each). The fact that a few individual students could dominate the discussion became a focal point of discussion within the learning community. Notably, the presence of a dominant subset of students was consistent with the notion of "de facto liaisons" to the professor. What is important from the perspective of anti-racist teaching, is recognizing that this small subset of dominant students often belongs to privileged racial groups in the discipline, and thus better distributing their participation would be a move towards racial equity.

The final two observations were conducted during virtual teaching. Whereas the initial observations focused on whole-class discussions, the primary teaching method in the online setting was through breakouts, which were easy to code using the virtual medium. Across these observations, there were 61 contributions logged, from 18/33 students (55%). The breakdown of contributions by race was: 18 White, 27 Unknown, 11 Latinx, and 5 Asian. By gender, it was 13 by men, and 48 by women. It's notable that the patterns of participation were more equitably distributed by race, with far more contributions from Latinx and Asian students than in the original two observations. This may partially be explained by the closer interactions between instructor and student being documented in breakout rooms. In addition, we suspect that strategies developed (e.g., using student names directly) provided Professor C with tools to engage more students and increase racial equity. This allowed him to shift the patterns that were present in the first two observations.

Transformed Practices. By the end of the semester, through looking at the EQUIP data and interacting and receiving feedback from the other faculty and classroom monitors in the discussion group, Professor C began to develop a better sense of the need to use more personally identifying features of students, such as first names, when engaging in classroom/Zoom discussions. These was particularly profound in a subject matter like mathematics, which is typically seen as objective and depersonalized. Likewise, he developed an emerging sense of trying to ask questions related to tasks at hand that were not only directed towards getting the answer, such as "What were some difficulties that came up while trying to solve problems?” or “What was the most interesting part of the discussion for you?” to give more students an opportunity to participate and thereby integrate themselves into the classroom dynamic. This was important because mathematics is usually seen as right or wrong, and the goal is to get the right answer as quickly as possible. Changes in questions can be seen in Table 1.

	Why	How	What	Other	N/A	Total
Face-to-Face	3 (8.6%)	1 (3%)	3 (8.6%)	7 (20%)	21 (60%)	35
Zoom	2 (3%)	0	10 (16%)	38 (62%)	11 (18%)	61

Table 1: Transformation of teacher question types

There are two notable shifts. In the first two sessions, 60% of questions were coded as N/A, which meant students shouted out answers without a specific question from the instructor. This decreased dramatically in the Zoom sessions, reflecting the instructor's increased role in managing the discussion. This is important, because prior EQUIP work has shown that when students simply shout out answers, dominant students tend to dominate the discussion. Also, there was a larger increase in "other" questions (from 20% to 62%), reflecting the alternative types of process questions the instructor was asking.

Overall, Professor C developed a much greater sense of and strategies for addressing the need to keep as many students as possible actively engaged in classroom dynamics as a means towards enhancing equity in the classroom. He recognized that without such strategies, students who were from dominant racial and gender groups were most likely to dominate. Thus, these general strategies of involving students who may not be participating are an important step towards being able to monitor racial and gender equity in an ongoing way. In future classes, if similar patterns become visible, Professor C was now equipped to utilize strategies to engage individual students within particular identity groups to better bring them into the classroom discussions.

Reflecting One Year Later. Since the time Professor C participated, he taught *Calculus 2* via Zoom to 130 students. Admittedly, the online environment did not readily facilitate implementation of the techniques explored and cultivated in the Spring 2020 EQUIP discussion group. However, he will soon take over the role of coordinator for the course and will be responsible for the educational experience of approximately 450 students. This involves Professor C coordinating across two to three Instructors as well as seven to eight Teaching Assistants. Having seen the inadequacies of online instruction for what is for many students an especially demanding and stressful course (e.g., in limiting meaningful interactions between instructors and their students), from his experience with EQUIP, he is keenly aware of the need for implementing strategies to keep students engaged in as equitable of a fashion as possible, and that doing so is critical to student success. This will include

1. Engaging in discussion with Teaching Assistants and Instructors about the need to encourage different groups of students to participate in class and to find novel strategies to facilitate that participation. Such strategies include soliciting replies to questions which do not directly deal with the mathematical problems at hand, or explicitly finding ways to elevate the voices of students that otherwise might be quiet.
2. Developing the capacity for Teaching Assistants and Instructors to personalize interactions using names or other means of identification to reinforce students' personal involvement and investment in the classroom environment. For students who might not feel as though they belong "by default," instructors need mechanisms to explicitly create a sense of belonging.

3. Facilitating conversations among Teaching Assistants and Instructors about the role implicit bias may be playing in their teaching and ways in which they could work to address said bias. This is especially salient with regards to social markers such as race and gender, which are visible in the classroom and are also known sites of inequity in mathematics education.

These implications for practice and coordinating the learning experiences of students were informed by Professor C's opportunity to reflect on his data and his own biases in teaching with EQUIP data. Outside of the classroom, Professor C also reflects on the role of larger movements. For example, in response to the Black Lives Matter movement as well several other social justice movements involving Latinx, Asian, and Native American peoples, Professor C views part of his role as a tenured member of his department and as a course coordinator as involving anti-racist work, which he views as essential to ensuring equitable access to success in STEM. His participation with EQUIP provided invaluable tools and insights for performing this kind of action in concrete ways in the classroom. It helped bridge the gap from theory to practice. In this way, although the EQUIP community was ostensibly focused on classroom teaching, it provided impetus, support, and strategies that could be transferred to other venues such as course coordinating, departmental policy, and civic engagement.

Discussion

Mathematics long has a history of gatekeeping and weeding out students. There is also a history of divide between Mathematics and Mathematics Education faculty within mathematics departments. In this paper, we share preliminary work that aims to bridge both divides, by applying mathematics education techniques to teaching mathematics, and by building a meaningful partnership from faculty in both branches of the department. The approach is grounded in data. Especially for faculty working in Applied Mathematics, there is a facility and disposition towards using data that makes the approach particularly appealing.

Here we illustrate how the data were helpful in overcoming inertia associated with the weed-out culture of mathematics. Initially, Professor C was coming from the perspective that some students simply would not succeed, so it was important to center efforts on those who would most likely succeed. Working with concrete data and a supportive community, this shifted over time to building greater awareness of the sociological aspects of teaching and how to develop concrete strategies for bringing more students meaningfully into the mathematical discussions.

This preliminary work has the potential to scale. Given that EQUIP is a fully customizable tool, it can be used to consider equity issues relevant to any context. While some of the issues related to race are specific to the US context, racial dynamics can play out differently in other places, and there are other forms of hierarchy (e.g., language, immigration status). Another issue to consider in scaling is the process of observing and facilitating professional learning. As the work continues, we will explore further models for self-study and self-reflection, which provide a greater variety of opportunities.

Multilingual students' talk about their work to relocate school academic mathematics in home-school transitions

Ulrika Ryan[1] and Petra S Källberg[1]

[1]Malmö University, Faculty of Education, Malmö, Sweden; ulrika.ryan@mau.se, petra.svensson@mau.se

We interviewed groups of students in a language diverse school, where the prevailing language norm was Swedish only, to answer the question; What do students say about relocating school academic mathematics in transitions between home and school? The students mentioned relocating school academic mathematical concepts, problem solving and arithmetical methods from home to school and vice versa. The relocating work provided resources for mathematics learning and feelings of being smart and mathematically knowledgeable and the opposite. We conclude that pedagogical designs that enhance students' first languages and home cultures as resources may benefit from considering students' work with relocating school academic mathematics to enhance opportunities for mathematics learning.

Keywords: multilingualism, mathematics, transitions, home, school.

Introduction

Multilingual students are far from a homogeneous group either in, or across contexts. However, multilingual students are often from marginalized groups whose home languages and cultures may not be acknowledged in mainstream society in general or in mathematics learning in particular (see for example Källberg, 2018). First-language-as-resource and culturally responsive and relevant pedagogics are pedagogies that have been advocated for some time. They are designed to enhance mathematics learning opportunities that recognize non-dominant languages and cultures as resources for mathematics learning. The latter approach often emphasizes colloquial, non-academic mathematics as part of non-dominant languages and cultures. Experiences with out of school academic mathematics may also be significant resources for multilingual students' mathematics learning (Abreu et al., 2002). However, for multilingual students to use school academic mathematics experiences as learning resources, transitions between in and out of school may require work to relocate school academic mathematics in conversations outside of school and vice versa (Abreu, 2008). We are interested in what students say about relocating school academic mathematics in conversations about mathematics in and out of school since relocating school academic mathematics influences multilingual students' relations with and expectations of mathematics education (Meaney & Lange, 2013). This influences their opportunities for mathematics learning and ultimately their future prospects. Therefore, in this paper we investigate the question; What do students say about the work they do to relocate school academic mathematics between school and home and vice versa? We use the metaphor work because to re-locate something in the physical world requires work. In the same vein we think that relocating school academic mathematics requires work.

Transitions between different cultures of school academic mathematics

In Sweden and elsewhere, language and cultural diversity is rapidly becoming the demographic norm in society and hence also in mathematics classrooms (Meyer et al., 2016). In most places it is possible to identify a dominant language and culture to which non-dominant cultures and languages often are positioned as subordinated. This connects to asymmetric power relations which motivates us to investigate multilingual students' work with relocating school academic mathematics in transitions between home and school. Mathematics learning is often perceived of as trajectories from informal, colloquial cultures of mathematics articulated in home languages to formal school academic cultures of mathematics articulated in the dominant language (see for example Webb & Webb, 2016). In this paper we consider cultures of formal mathematics as cultures of school academic mathematics. Cultures of informal mathematics we think of as colloquial every-day mathematics. In processes of transitions between informal and formal mathematics, students may find some of their everyday out of school experiences and languages valued and useful while they may find other experiences and languages not valued or even rejected (Crafter & Abreu, 2011). Despite that experiences with non-hegemonic cultures and languages (e.g. indigenous, immigrant or working class) can provide rich resources for mathematics learning (Huru, et al., 2018; Planas & Setati-Phakeng, 2014), they are often viewed as deficits (Gutiérrez, 2008; Källberg, 2018) which may stigmatize transitions and ultimately diminish some students' opportunities to learn mathematics. In addition to experiences with informal mathematics, multilingual students may have experiences with school academic mathematics out of school. Consequently, when mobilizing resources for thinking and doing mathematics, multilingual immigrant students may move among language and cultural resources where the dichotomy informal-formal may apply, but they may also move among various cultures of formal school academic mathematics. Albeit still debated, the notion of mathematics (as a plural noun) as cultural products is widely accepted. Different cultures have developed mathematical practices that share resemblance, but hold distinct features (Ryan & Parra, 2019). School academic mathematics could be considered one type of cultures of mathematics among other mathematical cultures. Transitions between cultures of school academic mathematics is not a straightforward matter. To relocate school academic mathematics as resources among sites require intellectual work (Prediger et al., 2019). Multilingual students often need social and pedagogical support to successfully conduct such intellectual work (Abreu, 2008; Meaney & Lange, 2013). Moves among different school academic mathematics are not neutral. Rather, they signify values of normative appropriateness (Abreu et al., 2002). Consequently, who is appreciated as mathematically knowledgeably may shift among such moves. This means that multilingual students may find themselves positioned as mathematically knowledgeable in one location while being positioned as less knowledgeable in a different location when for instance using the same algorithm. Such experiences may evoke stigmatization and is ultimately an issue of social justice (Meaney & Lange, 2013).

Theoretical framing: migration and re-location work

To capture the work that students do to relocate school academic mathematics we recognize that in migrational contexts, motion and mobility are metaphors to think about identities, cultures and societies. Mobility suggests discontinuous states of being and knowing that dialogue with where one came from (Keating, 2009). This means that issues of dislocation and re-location that pertain to here-and-now and there-and-then are present in conversations for instance when multilingual students talk about mathematics in and out of school. People speak in and from spaces and times that project particular values, social orders, authorities, and affective attributes (Dong & Blommeart, 2009). As people move in spaces (physically or metaphorically) of for instance school academic mathematics, they may find themselves or others as highly capably to think and do mathematics in some spaces, while they may find themselves as incapable in other spaces. This is not because of lack of competences, but because the values and norms that organize the spaces in particular ways have changed (Dong & Blommeart, 2009). Therefore, time and space are constitutive because they shape how people connect to each other and to mathematics. When mathematics is discussed in families with migrational experiences, family members may speak about mathematics from times and spaces that are located prior to migration. Their talk may project values and norms that connect to times and spaces prior to migration that relate to for example curricula content, social classroom norms, methods, and to what is valued as mathematical knowledge. In conversations for example about homework these values are relocated and experienced against the values and social orders that organize the time and space of the student's experiences with mathematics at school. Simultaneously, the student's experiences with mathematics at school that project the values of the dominant societies' school mathematics are relocated and experienced against times and spaces before the family's migration. We use the expression "experienced against" to echo Garcia and Wei (2014) who discuss multilingual translanguaging as a re/production of language, in which the "enaction of language practices that use different histories … are experienced against each other in [multilingual] speakers' interactions" (p. 21) because we see the enaction of different mathematics practises in the same vein. Paying attention to what language and mathematics norms are experienced against each other; who is positioned as knowledgeable; and what affective attributes are present in acts of relocation allow us to illuminate some work that multilingual students do to relocate school academic mathematics in and out of school.

Methodology

Three mathematics teachers at a school located in a city center in south Sweden invited the authors to participate in a project about enhancing multilingualism and language responsiveness as resources for mathematics learning. As part of the project the authors conducted three group interviews to learn what students themselves say about thinking, doing and talking about mathematics in multilingual contexts in and out of school. At the school most students were multilingual but quite a few students spoke only Swedish, the language of instruction. The three teachers selected students who were willing to share their experiences for the interviews, while at the same time aiming for as diverse groups as possible with respect to gender, languages, experience of migration and mathematics achievements. When asked, most students in the interviewed groups claimed that their school was a good school and that they learnt a lot. We asked about languages that were part of the students' everyday life. The students in the three groups mentioned Arabic, Bosnian, Kurdish, Polish, Spanish, Swedish, and Turkish. The Grade 4 group (aged 10-11) consisted of one boy and three girls. The Grade 7 (aged 13-14) group consisted of one girl and four boys. The Grade 8 (aged 14-15) consisted of three girls and two boys. Most of the students in the groups were multilingual. In the groups some students had experiences of attending school in other countries, some were born in Sweden by immigrant parents. The interviews that lasted about one hour were semi-structured (Patton, 2002). We (the researchers) had a battery of issues that we wanted to talk about, but we were sensitive to peruse issues that appeared to be crucial to the students during the interviews. School academic mathematics transitions between home and school were one of the salient issues that the students wished to discuss. We started by discerning excerpts that comprised talk of transitions of school academic mathematics between home and school. We found 26 excerpts, 9 of them were selected for in depth analysis based on that they focused students' intellectual and/or affective work to relocate school academic mathematics in transitions between home and school in conversations with others. By intellectual work we mean for example work to move among languages or mathematical methods. By affective work we mean moving among different kinds of emotions. Each of the 9 excerpts were analyzed with respect to *norms and values*, who is *positioned as knowledgeable* and to *affective attributes*.

Multilingual students' work to relocate school academic mathematics

We present findings on transitions from school to home and then from school to home.

Transitions from school to home

One student says[1]:

Student 1: If you learn math in Turkish, but Swedish math, it may be difficult for Turks, because they are not used to it. They do not have the same mathematics as us.

This student of Turkish descent talks about moving between two spaces of school academic mathematics (the Swedish and Turkish) in connection to internet conversations with his Turkish cousins. The quote shows that it is the different kinds of mathematics (problem solving methods in this case) that are at heart. When this student experiences Swedish and Turkish school academic norms against each other he finds that:

Student 1: I do not know Turkish mathematics. I have not studied their mathematics. I have only seen it [Turkish mathematics] when my cousin does it. When he read [a textbook problem] I did not get a thing. They have a whole different way of solving the problem.

This student seems to be aware of how moving between spaces means encountering different school academic values and norms. He appears to experience that because he doesn't know the norms and values of Turkish school academic mathematics, he cannot engage in the problem solving. By saying "I did not get a thing" it seems as if he finds himself unknowledgeable in the Turkish school academic space. Although that he does not explicitly mention affect, experiences of not understanding mathematics are usually not positive ones.

Another student shares that:

[1] To recognize the equal value of all languages we wanted to provide readers with quotes in the original language together with English translations. This was not possible for space reasons.

Student 2: Here in Sweden you learn in one way, but in our home country we learnt in a different way. Sometimes there are faster ways than those that you find in the textbook, so then I have a plus that he [the student's father] wants to help me. He says "Yes but you could just do this".

To move among different spaces of school academic mathematics norms seem to be a resource for this student. The relocation of at-school mathematics to home allows her to add the methods that her father shows her to her mathematical repertoire. Here both the father and the daughter appear to be positioned as mathematically knowledgeable. The daughter positions her father as a knower of mathematical methods that she grasps. The affective attributes in the excerpt shows that she is positive about the situation and finds her father's mathematical knowing beneficial (a plus) to her learning.

One of the students talks about using mathematical concepts in Arabic at home. Her parents encourage her to speak about mathematics in Arabic at home to maintain her Arabic language skills. In a sense, norms and values that relate to spaces and times prior to the family's migration are relocated to the here and now space and time. On the one hand this student seems to be positive about that and mentions for example that knowing several languages is a plus when applying for jobs in the future. On the other hand, she says that she speaks Arabic with her parents "because I have to":

Student 3: I speak Arabic with my parents because I have to. They want me to improve and extend my [Arabic] vocabulary. When I do it [talk about school academic mathematics] in Arabic then I feel a bit less smart. I always use some Swedish words to be able to do it [talk about school academic mathematics] in a good way.

This student works intellectually to relocate school academic mathematical concepts to the Arabic language that her parents want her to use. She explains that since she learns mathematics in Swedish, she does not know all the mathematical concepts that she knows in Swedish in Arabic. This influences how she sees herself as mathematically knowledgeable. When she talks about school academic mathematics in Arabic, she says that she feels less smart. To appear more knowledgeable in conversations about mathematics with her parents she "always use some Swedish". It is not because of lack of knowledge but because of moving between different (language/conceptual) norms and values that this student finds herself positioned as mathematically less knowledgeable (than at school) in conversations with her parents.

Transitions from home to school

Some students share experiences with school academic mathematics transitions from home to school. In the quote below the student talks about methods for problem solving that her parents taught her which they learnt in their home country. When she brings those methods to school the teacher seems to reject the student's work to relocate school academic mathematics methods that she brought from home:

Student 3: And when I show it [the methods that his parents taught him] [the teacher's name] says that it is wrong. He says "It is this way that you should count. It [the student's method] is not wrong but it is this way not that.

Here to appear mathematically knowledgeable in the classroom space, the student's work to relocate school academic mathematics from spaces and times prior to migration, to school requires that she ignores the mathematical methods that she learnt at home. It seems like the teacher indirectly positions the parents' mathematical knowing and the school academic mathematical norms of their home culture as subordinated to those of the majority society. To show that both methods could be appreciated the interviewer comments that it is good that the student knows both methods. The student replies in a downhearted tone:

Student 3: Yes, but that will not help me.

In contrast, another student reports positive feelings with relocating school academic mathematics methods from the home country to school. He says:

Student 4: It is always a plus because then you show that you have different methods for calculating. The teacher might ask a question, and then you can say several different ways to calculate it.

This teacher seems to welcome different methods in the classroom and appears to consider knowing a variety of methods as an indicator of mathematical knowledgeableness. Hence, the teacher's approach seems to position the student's home school academic mathematics as equally important and appreciated as those of the majority society. This appears to support the student's cognitive work with relocating school academic mathematics. Potentially the relocation work is a resource for his learning and a source for positive feelings about himself as mathematically knowledgeable.

Implications and closing remarks

In this paper we investigated what students say about the work they do to relocate school academic mathematics in transitions between home and school and vice versa. One reason for that is that the students that we interviewed were interested in sharing their experiences with relocating school academic mathematics. This may be because some of the students had experiences of schooling in countries where they were born. We noted, in line with the findings of for example Prediger et al. (2019), that students with migrational experiences in their families need to conduct intellectual work to relocate school academic mathematics among sites. We found that the students needed to do affective work because school academic norms and values change when they talk about and do school academic mathematics in mathematics spaces that connects to times and spaces before and after migration. For some students this meant that they felt mathematically knowledgeable in one school academic space while at the same time finding themselves unknowledgeable in another school academic space. Although that the notion of transitions and the dichotomy informal-formal mathematics consider students' out of school experiences with colloquial home cultures and languages (Abreu, 2008; Webb & Webb, 2016), it does not fully grasp the intellectual and affective work that multilingual students engage with when relocating school academic mathematics in transitions between home and school. Language as resource and culture responsive teaching approaches may benefit from including attention to students' work with relocating school academic mathematics. Lessons could include discussions in small language homogenous groups about the mathematical concepts that are at stake. In such discussions the home language is both a resource for mathematics learning in the language of instruction and a learning object in its own right. The discussions could be summarized on the board in a table that shows the concepts in the languages present in the classroom. In the same vein different arithmetic or problem-solving methods could be focused. In this way the intellectual work that students do with relocating school academic mathematics may be a resource for learning rather than evoking stigmatization as for example discussed by Meaney and Lange (2013). In addition, it would give a broader range of students the opportunity to perform and be viewed as mathematically knowing subjects in the classroom (see for example Ryan et al., 2021). It could mitigate experiences of being positioned as unknowledgeable at school and/or at home. This is important because as Crafter and Abreu (2011) mentioned, multilingual students' mathematics learning transcend the physical school building. Ultimately attention to students' work with relocating school academic mathematics is a sociopolitical issue because it revolves around encounters between dominant and non-dominant languages and cultures (Planas & Setati-Phakeng, 2014). Pedagogical designs that appreciate and make explicit both dominant and non-dominant school academic mathematics norms recognize that multilingual students need access to the dominant language and mathematics to be recognized as mathematically knowledgeable in the dominant society where they may conduct future studies and compete on the labor market. However, to merely ask multilingual students to (re)produce dominant mathematics may cause harm (Le Roux & Rughubar-Reddy, 2021) because their relocating work is then ignored or rejected. This may cause stigmatizing feelings which diminish multilingual students' opportunities to learn mathematics.

We are grateful to the Research Programme LIT (https://litresearch.se/) at Malmö University.

Mathematically significant knowledge of Hñañu women embroiderers from the Valle del Mezquital: a possibility for an encounter and dialogue

Armando Solares-Rojas[1] and Manuel Goizueta[2]

[1]Mathematics Education Department, Cinvestav, Mexico; asolares@cinvestav.mx

[2]Pontificia Universidad Católica de Valparaíso, Chile; mgoizueta@gmail.com

We present some results of an ethnographic perspective-based study of mathematically significant knowledge of Hñañu women embroiderers from Valle del Mezquital (Mexico). In this contribution, we focus on an interview throughout where one embroiderer and the researchers encounter and dialogue about the realization of embroideries ordered by the clients (the researchers). This encounter (Radford, 2021) gave rise to a joint discourse built through the discourses from the culture of the embroiderers and that of the researchers. Based on these results, we reflect on the possibility of constructing encounter opportunities in classrooms between school mathematical knowledge and knowledge about embroidery. We consider that the construction of such encounters requires the active participation of members of the – historically marginalized - indigenous communities so that the school will not be a space for the domination and homogenization of people and their knowledge.

Keywords: sociocultural studies, indigenous knowledge, ethnomathematics, cultural education.

Introduction

The discussion we propose takes place in the diverse context of studies regarding the knowledge of cultural groups and how they relate to mathematics and school. These studies are plagued with encounters and ruptures between the Western mathematical tradition and knowledges from other cultures and peoples (D'Ambrosio, 2014, 1985). The Western mathematical tradition is often presented as a parameter, setting out development levels and promoting a deficiency-based approach to other cultures' knowledge (Albanese et al., 2017; Bishop, 1991; D'Ambrosio, 1985; Radford, 2020).

The need to overcome this deficiency-based approach has led several authors to reconceptualize the idea of mathematical knowledge (Ascher, 1991; Bishop, 1991; D'Ambrosio,1985). In turn, mathematics education research has developed several proposals seeking to integrate these forms of knowledge into schools (D'Ambrosio, 1985; Kisker et al., 2012; Lipka et al., 2019; Stathopoulou, 2020; Pradhan, 2020; Sharma & Orey, 2020; Albanese et al., 2017; Gracas & Marinho, 2015; Verner, 2019). However, integration processes into school practices are not simple; they are entangled in a complex mesh of continuity and discontinuity between the activities and knowledge of cultural groups and those specific to schools (Solares et al., 2016; Trinick et al., 2017).

We based our study on critical approaches to cultural-centric positions to widen our understanding of mathematical knowledge and to include, among others, forms of knowledge involved in practical activities recognizable from the Western mathematical tradition (Bishop, 1991; D'Ambrosio, 1985, 2014), which we have named *mathematically significant knowledge.*

This contribution gives an account of local expressions of mathematically significant knowledge of Hñañu women embroiderers from Valle del Mezquital (Mexico). Through the analysis of interviews, we give an account of the dialogue between the embroiderers and the researchers in which they negotiate and discuss meanings related to embroidery and mathematics knowledge. We have named this polyphonic and incipient dialogue as a *discourse-for-us* (Venegas-Thayer, 2019), a jointly built discourse that emerges from the discourses of the cultures of the embroiderers and the researchers.

Theoretical framework

We chose to articulate complementary theoretical notions from the Ethnomathematics Program (D'Ambrosio, 2014) and the Theory of Objectification (Radford, 2021). According to D'Ambrosio (2014), we understand *mathematical knowledge* in a broad sense as the "bodies of knowledge elaborated based on qualitative and quantitative practices, such as making comparisons, ordering, classifying, inferring, and the code systems of measure, weight, and quantity [numbers], which have been accumulated through generations, in certain natural and cultural environments" (p. 102). Thus, when we speak of Western mathematical knowledge, we mean that which has been developed – and is still being developed – in what today we call the Western culture.

This broad conception of mathematical knowledge allows us to refer to the explanation and practice systems that shape embroidery and are recognizable from the Western mathematical culture. Thus, for example, we say that an embroiderer counts, adds, or subtracts stitches, reflects a motif according to a symmetry axis, etc. In other words, we associate the knowledge mobilized by the embroiderers to perform specific actions with knowledge that is part of Western mathematical knowledge. It is this knowledge, developed in this specific region and culture and mobilized by the embroiderers, that we call *mathematically significant knowledge*.

Concerning the specific manifestations of these explanatory and procedural systems in a culture, we take up the distinction between *knowledge* and *knowing* proposed by Radford (2021) in his Theory of Objectification. Knowledge is not simply present in a group and transmitted to its new members or something each subject constructs when facing reality. Knowledge is a social, historical, and cultural product. It is accessible and shared by groups of people who use it in recognizable and significant ways inside the group. Knowledge is potentiality, instantiated in specific moments and circumstances through actions performed by particular persons. Following Radford, we call these instantiations knowing. Thus, knowing is not an atemporal construction of the subject but an instance of knowledge that occurs inside the cultural group and activities that give it meaning (Radford, 2021).

Methodology: A Study in Two Phases

The methodological design of the study included two phases. In the first phase, we describe and classify many traditional embroideries of the Hñañu culture of the Valle del Mezquital through plane isometric transformations that allow creating their geometric motifs (Barquera y Solares, 2016). During this first phase, the contact with the embroiderers has allowed us to become conscious of the distance between how we understood the embroidery activity and its products and how the embroiderers do it. This understanding led us to design the second phase, in which we adopted an ethnographic perspective (Lave, 2011) to understand the knowledge the embroiderers mobilize in their activity.

We used the results from the first phase as a starting point for the second; mainly, to design the interviews with a family of embroiderers and field observation guidelines. In this contribution, we focus on the results of our interview with Alejandra.

Interview Design

At the time of the study, Alejandra was 24 years old and had completed high school studies. Her first language is Spanish and, although she understands Hñañu, she does not speak it. The interview with Alejandra took place in two parts: in December 2016 and in March 2017. Here we focus on the second interview, organized around a few embroideries we asked her to do as clients.[1] Figure 1 shows the embroideries we ordered (*el encargo*, in Spanish): a tortilla napkin and a shirt.

Figure 1a

Figure 1b

Figures 1a and 1b: Embroideries ordered in the interview with Alejandra

We chose motifs related to translation, rotation, and proportionality tasks, typical of school mathematics. For each of the ordered embroideries, we performed an *a priori* analysis from the perspective of academic geometry. That is, the mathematical reference knowledge we wished to relate to the mathematically significant knowledge observable in Alejandra´s activity. Table 1 presents the embroidery ordered for the napkin and the task we asked her to perform.

Table 1. Embroidery Task of a Tortilla Napkin with Geometric Motifs

Task: to embroider a tortilla napkin with geometric motifs	
Academic mathematical knowledge involved: axial symmetry, translations, reflections	
Task formulation during the interview:	Vertical direction in which this motif is not usually continued

Horizontal direction in which the motif is usually continued

[1] An important part of the activity of the embroiderers from Valle del Mezquital is selling their embroideries. The order, fabrication and sale of the embroideries guide a significant amount of the activities they perform.

"I want a napkin with this embroidery at the center but repeating it four times, in this direction (pointing horizontally with the hand) and in this direction (pointing vertically)."	

Also, informed by our previous field observations, we anticipated the possible procedures and difficulties Alejandra might find when doing the embroidery as a basis for discussion during the interview.

Interview Analysis.

What follows is an analysis of some of the dialogues we had with Alejandra concerning the napkin embroidery.

Reflection and Little Rows: Embroidery Knowledge Encounters Academic Geometry.

Based on the *a priori* analysis, we believed the task could be solved by reflecting or translating the central motif (Figure 1a). However, when presented with the task, Alejandra immediately noted that "this cannot be continued because it ends in a little flower, it ends in a tip," pointing at the tip of the motif's flower. Alejandra explained that the problem making the embroidery was that the motif's flower tips would end up stuck or joined together. This is not relevant from the – academic and formal – point of view of axial symmetry, and, thus, we did not think it would be so for the task. However, for Alejandra, this aspect was fundamental because the flower tips should not be joined, possibly responding to aesthetic criteria. Thus, we had contradictory ways of understanding the solution for the task – doing the embroidery. Alejandra believed it could not be done. In contrast, we believed it was not only doable but that the "obstacle" Alejandra anticipated was not understandable in terms of our academic knowledge since all geometric objects in the plane can be reflected on an axis.

After several minutes of explaining and despite the anticipated problem, Alejandra agreed to fulfill the order and try to satisfy the clients' petition. First, we must note that this negotiation between the clients' request and the embroiderer's work is common practice in embroidery. As Alejandra put it: "It is like they say, if it is what the client wants, we have to do it."

About one month later, we returned to get the embroidery. Alejandra told us she had managed to do it and then explained how she did it.

Dialogue. The Little Row as a Solution

Alejandra: Yes, because, in fact, I tried once or twice, and I could not do it. Then I undid it again and restarted it, and I said: "You know what? I will leave one thread, a little row". So, I left a strip of thread here, so I could start again, to do it again, repeat the same [motif]. [She pointed out in the napkin one small space she introduced between the motif and its copy].

Interviewer: There is a space here? [Pointing out at the space between the motif and its copy].

Alejandra: Uhuh, that is why it seems like a little hole here in the middle. Because I was trying to join it to the other, but it was going to look weird, it would look ugly. So, I thought: “I had better leave one [space] and then start the other one so that it will look well [...]”.

Alejandra: Now, if you placed a mirror here, it would reflect the same one over here, like this. Also, it is the same thing [using her hand as a make-believe mirror, placing it on the space she left between the motif and its copy; using her right hand to point out the copied motif].

In contrast with the possible reflections and translations we anticipated, Alejandra introduced a novel solution to perform the requested embroidery. It was an unexpected and non-academic response to the task. Furthermore, Alejandra displayed a specific knowing we were not expecting: the introduction of space between the motifs – the *little row* (la *filita*, in Spanish). This allowed her to do this unique embroidery keeping the motifs from being conjoined and, thus, "looking weird, looking ugly". Simultaneously, this solution satisfied the buyer’s request and her aesthetic criteria.

When describing how she performed the task, Alejandra used the *mirror metaphor*[2]. Although we do not know if this metaphor is part of the embroiderers’ knowledge or if they use it in their everyday activities, after its introduction, both Alejandra and the interviewer used it on different occasions to continue talking about the embroidery and how it was done.

These dialogues, together with the words and metaphors – such as *little row* and *mirror* – introduced and negotiated throughout the interview, account for the “voices” of the other. Alejandra and the interviewer gradually established a negotiated discourse that allowed them to talk about embroidery and how it is done, despite the differences between their respective knowledge. This is the discourse we call *discourse-for-us* (Venegas-Thayer, 2019).

In the interview, they continued discussing the motifs that “can be continued and those that cannot.” For Alejandra, it was essential to make it clear to us that some embroideries “can be continued” and some cannot, both materially (i.e., is it feasible to do them with embroidery techniques) and aesthetically (i.e., they do not look ugly or weird). According to her explanation, some motifs “can be [continued] in both directions,” that is, in the direction of the fabric’s both *weave* and *warp*[3] (which, from the point of view of academic geometry, would be equal to a tessellation of the plane).

To explain which motifs can be continued and which can’t, Alejandra resorted to a classification: there are “cut-off” motifs, and there are “finished” motifs.

Dialogue. Cut-off and Finished Motifs

Interviewer: And how do you know it is possible [to continue a motif]?

---

[2] It’s a metaphor commonly used when studying axial geometry in elementary schools in Mexico. You imagine the use of a mirror perpendicular to the plane of the motif you wish to reflect, placed over the reflection axis.

[3] The embroidery is done on a base fabric, created with two perpendicular groups of thread interwoven in a regular pattern. Regarding the embroiderer’s body, the threads that run from the right to the left form the fabric’s weave, while the series of threads that run perpendicular to them form the warp. Thus, *weave* and *warp* shape an orthogonal grid.

Alejandra: Because here you can see one half [Figure 2a]. Pretend we only have one half of this here [she points out half of one of the motif's diamonds; Figure 2a]. It is as if it had been cut-off like this [she points out the halves of the diamonds, in the directions of both the weave and the warp]. Then it can still be continued upwards, downwards, and sideways.

When you see it is cut-off, then it can [be done].

However, for example, these ones are finished. Therefore, they are finished [motifs from Figure 2b].

Figure 2a. Example of a cut-off motif

Figure2b. Examples of (horizontally) finished motifs

According to this explanation, cut-off motifs (*motivos mochados*, in Spanish) are those we can imagine as continuing but have been cut off, like the diamonds in the motif in Figure 2a. These motifs can be continued precisely in the direction in which they were cut off. In contrast, some motifs are already finished and cannot be continued. For example, the motifs in which the figures – flowers, stars, etc. – appear complete or finished, there is no need – or aesthetic possibility – to continue them. In this case, Alejandra uses embroidery knowledge to explain why some can be continued and some cannot, proposing a classification of embroideries.

Discussion and Final Reflections

The interview with Alejandra was designed as a space for an encounter (Radford, 2021) between the knowledge of embroidery and academic geometry. The order had the double purpose of creating a conversation around the act of embroidery and facilitating the emergence of mathematically significant knowledge. This interview's analysis allowed us to showcase some tensions between the knowledge of embroidery and academic geometry concerning the carrying out and the classification of the embroidery motifs. During the conversation, these tensions led the participants to introduce and articulate different semiotic resources (words, gestures, metaphors, etc.), which reflect/refract their knowledge rendering it intelligible.

In this encounter, with its communicational possibilities and limitations, both the embroiderer and the interviewer were able to talk and make progress in their conversation about embroidery categories in a significant way, from the point of view of both embroidery knowledge and Western mathematical knowledge. We observed the interlocuters progressing in their conversation, progressively negotiating and providing common meanings for the terms, which allowed them to bring out their ideas, accepting each other in a joint reflection of the subjects that interest them.

Based on these results, we wonder about the possibility of building bridges between academic mathematical knowledge and embroidery knowledge. For example, is it possible to create in schools encounters between academic mathematical knowledge and embroidery knowledge in a way that benefits educational activities?

Even acknowledging the importance and validity of the knowledge of the embroiderers and other cultural groups, taking it to school is not trivial. Taking the tasks of the embroiderers from Valle del Mezquital to the classrooms would imply many reformulations and adaptations of the conditions and demands characteristic of the educational institutions and communities (Traoré y Bednarz, 2009). From the point of view of school mathematics we wonder, how to acknowledge and dialogue with the mathematically significant knowledge of embroidery? What is it desirable and possible to take to school to create new academic meanings?

We believe these encounters between the school knowledge and the knowledge of other cultural groups require changes in our ways of understanding, teaching, and learning mathematics, changes in the current curricular organizations, teachers' education, and the creation of didactic proposals. To create these proposals, we need active and significant participation from indigenous communities, who have been historically marginalized, so that schools are no more a space for the domination and homogenization of people and knowledge. In this way, these encounters will allow the "the creation of reflexive and ethical subjects who critically position themselves in historically and culturally constituted mathematical discourses and practices, and who ponder new possibilities of action and thought" (Radford, 2021, pp. 15-16).

Students' discussions of cultural, social, economic, and political aspects of the COVID-19 pandemic

Lisa Steffensen[1], Kjellrun Hiis Hauge[1] and Jakob Graave Nakling[2]

[1]Western Norway University of Applied Sciences, Norway; lste@hvl.no and khh@hvl.no

[2]Danielsen Ungdomsskole, Norway; jakob.nakling@gmail.com

Worldwide, students have experienced the impacts of the COVID-19 pandemic. This paper investigates students' reflective discussion of the consequences of measures taken during the pandemic in Norway. Socio-critical mathematics perspectives are used as a theoretical framework when analysing 13–14-year-old students' discussions of the pandemic. The students read, discuss, and present findings from media articles provided by their teacher. We found that the students identify and use mathematics-based argumentation when reflecting on cultural, social, economic, and political aspects from their own real world. They ask questions, investigate, listen to peers' argumentation, show awareness of, and discuss challenging issues such as mental health, increased violence during home-schooling, unemployment, loss of income, and rising inequality in society. We suggest that mathematics education can promote students' reflective discussion of wicked problems.

Keywords: Socio-critical mathematics, mathematical representation, discussion, wicked problems.

Introduction

The ongoing COVID-19 pandemic is an example of complex real-world problems often referred to as wicked problems. Characteristics of wicked problems are that time is running out, no optimal solution, conflicting interest, no central authority, and policies discount the future irrationally (Levin et al., 2012). During the pandemic, citizens worldwide dealt with a highly mathematics-based language and mathematical representations. For instance, the Reproduction (R) number showing how many people one infected person infects on average is central in describing, understanding, and predicting scenarios in Norway. Kollosche and Meyerhöfer (2021) describe the R-number as having "formatted our perception of the status of the pandemic" and "justified specific political measures" (p. 10). They highlight that although substantial measures are taken partly based on this number, the significance of the R-number remains questionable.

In the Norwegian mathematics curriculum (MER, 2019), it is stated as vital that students critically reflect on models, statistical representations, and mathematical argumentations to make justified stands in essential issues in their lives and society. In this paper, we are inspired by Nakling's (the third author) master thesis, involving 13–14-year-old students' mathematical argumentation about risks of infection control measures of COVID-19. The students used media articles to discuss risks and impacts for groups in society. In this paper, we use the empirical data to consider how students can engage in wicked problems. Specifically, we investigate *How do students apply mathematics to critically reflect on the consequences of measures taken during the COVID-19 pandemic?*

Socio-critical perspectives in mathematics education

The use of models in the pandemic is often connected to statistics, for instance, in reporting numbers of infected. Weiland (2017) argued that students should learn “to tackle complex sociopolitical issues in conjunction with learning powerful statistical concepts and practices in an effort to be able to read and write both the word and the world with statistics as critical citizens” (p. 45). Reflecting critically on societal issues in authentic applications of mathematics in real life can involve empowering students in discussions about the consequences of using mathematics, statistics, or mathematical models in society (Barbosa, 2009; Blomhøj, 2009; Gibbs, 2019). Barbosa (2009) emphasised that students’ reflection of the nature, criteria and consequences of mathematical models in society is crucial and should be the primary goal for socio-critical discussions. Relatedly, Blomhøj (2009) described that critical reflection may concern “the societal issues where mathematical modelling and models are used as means for analyses and critique of political decisions or societal phenomena” (p. 13). However, Gibbs (2019) found limited empirical research on students’ socio-critical perspectives and reflexive discourse during modelling. She argues that such discourse is crucial to move from modelling as a school activity to understanding the role of mathematics in society and that reflecting through mathematics can make it clear that a reduced representation can be an incomplete representation of the social phenomenon.

When students engage in socio-critical modelling activities, they “make assumptions about variables and quantities needed for their models” based on their own identity and history (Brunner et al., 2021, p. 139). However, the foundation, variables, and quantities may be invisible when using existing models or statistical representations. Therefore, when working with mathematical representations, it is essential to consider the properties of models or the statistics, what variables are included, and perhaps more importantly, what is not included. For instance, the R-number gives important estimates nationwide of health issues regarding changes in numbers of infected, hospitalised, etc. However, it does not include the impact of the pandemic on variables such as mental health issues.

A democratic society needs to develop competence in the general population “to critique mathematical models and the ways in which they are used in decision making” in society (Blomhøj, 2009, p. 11). The prevalence of mathematical applications in the pandemic, and the use of these in decision-making, call for students’ awareness of consequences of these applications so that they can critically reflect on such as the foundation, who has chosen the variables, what kind of variables are considered as important, and what does the models, statistics, and numbers tell us. Hattori et al. (2021) describe how socio-critically open-ended problems could foster critical mathematical literacy. They emphasise that students should develop abilities to critically perceive mathematics according to the situation and make social decisions based on values using mathematical thinking. They described how students discussed problems related to the pandemic in groups and argued for solutions based on personal values and mathematical argumentation.

Rosa and Orey (2015) highlight mathematical modelling as a teaching methodology to develop students’ social-critical efficiency. They encourage investigating familiar problems to the students so that the content becomes the stimuli for students’ critical reflections on the role of mathematics in society, showing that mathematics applied is not neutral. Cultural, economic, environmental, political, social, and natural aspects of reality are contents they suggest as essential for socio-critical modelling. The COVID-19 pandemic is an issue with multiple aspects, as regulations have a range of impacts. One could say that pandemic regulations are based on a model of reality, where different facts and considerations are taken into account. However, it is only partly mathematical, as sub-models, numbers and statistics, together with some weighting of concerns, as elements of a rather unarticulated model. While Rosa and Orey (2015) emphasize the importance of engaging students in the whole modelling process, it is also of value to critically reflect on their suggested aspects through numbers, statistics and modelling presented in the media together with the role of these numbers. In this paper, we ask how students apply mathematics to critically reflect on the consequences of measures taken during the COVID-19 pandemic. We investigate students' utterances in light of Rosa and Orey's (2015) aspects and pay attention to aspects that may be in conflict with each other.

A Norwegian context during COVID-19 pandemic

The Norwegian Government has various policies to limit and delay COVID-19 outbreaks, such as restrictions on travels and group meetings, prohibiting public events, and closing schools and national borders. In the initial stages of the pandemic, the government designed a strategy based on keeping the R-number below 0.9, the so-called suppress strategy. This strategy was partly based on the capacity of hospitals and uncertainties regarding treatment, potential vaccines, and how the virus would affect people and the nation. Closing schools and borders severely impacted citizens and the national economy, and later, a shift in the policy focused on social consequences such as loneliness and unemployment. The Norwegian population shows significant trust in authorities, e.g. they trust the information provided by the government, and there is an estimate of 90% vaccine coverage.

Teaching in Norway varied between digital home-schooling and physical attendance at school, with varying restrictions on social distancing. The students in the empirical data experienced a long period of home-schooling during their last year of primary school. In their first semester at lower-secondary school, teaching varied much between home and school, and when at school, students were grouped into so-called cohorts. Their mathematics teacher, Nakling, did his master thesis in his class.

Method

To investigate students' discussions, we used empirical data from Nakling's master thesis. Nakling designed the lessons, and Hauge and Steffensen participated in the collection of data. The teaching took place during a two-week project and consisted of four lessons, each lasting 2 x 45 minutes. The students were 13–14 years old, the class consisted of 30 students, and they worked in groups of five, a total of six groups. Their teaching plan can be described in three parts. During the first part, the students worked with graphs to ensure students' understanding of what they represented. For example, the teacher showed a graph that simulated the progression of hospitalised infected individuals over time compared to the capacity of hospitals, with and without societal interventions. The students were prompted to consider potential consequences whether measures were taken too early or too late. In the second part, the student worked in groups. Each group was assigned one role from society: nurses, parents, unemployed, psychologists, university students, and teachers. The teacher had selected 3–4 media articles for each of the groups, who were to present the situation of their assigned role based on mathematics-based content. The third part was a plenary activity. Here, each group first presented their findings orally, followed by a plenary classroom discussion about the pandemic and risk assessment for groups in society.

The students' utterances were video recorded during group work and in the plenary part. Only students who had given consent were recorded, resulting in data from four of the six groups. When analysing students' utterances, we took starting point in the six aspects of reality described by Rosa and Orey (2015). The cultural, social, economic, political, environmental, and natural aspects were used to identify and categorise students' utterances. While some of the utterances overlapped different categories, others did not. The idea behind this categorisation was to get an overview of the width of the student's reflections. The categories are used to structure the discussion part. The theoretical described above are used to understand, interpret, and support the discussions.

Students' discussion on cultural, social, economic, and political aspects

In the following, we analyse excerpts from the students' group work, plenary presentations and plenary discussion to show students' reflexivity related to Rosa and Orey's (2015) aspects of reality. We connect these to mathematical models, here broadened to include applied mathematics and statistics in general. We further discuss this in relation to how their experience with the pandemic possibly has influenced their reflectivity.

Cultural and social aspects

The media articles provided by the teacher included a range of cultural and social aspects as a consequence of the handling of the pandemic, such as increased violence towards children during home-schooling and mental health issues. In the group discussing risks for parents, a researcher asks if they have considered any risks. Chris starts by saying it is relatively easy to handle the pandemic and suggests that laws could regulate people's behaviour and that people who violate these could get punished. He declares: "If you say you get the death penalty if you walk out the door", indicating that if people just stayed at home, the virus would not spread. In Norway, relatively few were fined for violating COVID-19 regulations. On the contrary, many restrictions were encouraged rather than forced, basing restrictions on people's trust in authorities and their wish to contribute to the common good. This reflects a cultural and social aspect of Norwegian society. However, this careful approach was criticised in the media when the number of infected people increased. Chris' only concern seems to be to stop the pandemic without introducing other concerns.

As a response to Chris, Kari says she has read about some of the risks of home-schooling. She argues it will affect children because parents get strained during lock-down:

Kari: Some take the stress out by being violent to their children [...] primary students are less followed up by teachers […] 1 of 3 parents was angrier at their children. It was more violence, and parents had anxiety, depression and stress symptoms.

Kari’s argumentation challenges Chris “simple” solution that everybody should stay at home. She brings forward new perspectives, namely that if you impose people to stay at home, this can have severe consequences. The numbers are taken from one of the media articles her teacher has provided to support her argument. She further reflects on youth managing home-schooling better than children in primary school. Kari connects this to her and her peers’ own reality and identity, as highlighted as relevant by Brunner et al., 2021, when making assumptions about real-world situations. Kari’s critique of Chris’ claim is partly supported by numbers and is related to humans’ well-being and what is considered appropriate behaviour. She thereby draws on cultural and social aspects.

Later in the group discussion, Chris says:

Chris: I now think the problem is that it is hard to justify a choice if we do not have all the facts or know all the risks. If you compare them, which is most important if there is a great danger of many dying if we go for it? But it can have such big consequences. Then we have to find out which one weighs the most. And in that way, we can decide. But if we do not know all the risks, it can be very difficult.

Chris problematises the group discussion, including his previous claim. He critically reflects on decisions based on limited facts and knowledge of risks. Perhaps he still believes in a shut-down and penalties for leaving home without permission, but he realises there are competing concerns that must be weighted and with unknown consequences. Critical reflections on facts and uncertainties are essential in modelling, and when Chris uses his hands to visualise the weight of each risk, he communicates a model for decision-making. The pandemic is surrounded by uncertainty about facts and perceived risks, so Chris points to a highly relevant political aspect: what, how and who to choose.

Ingeborg raises concerns about mental health issues when presenting her group’s findings in the plenary activity (from the psychologist group):

Ingeborg: Almost 40% between 16 and 25 year- olds state they are unhappy with life in the pandemic. About 1 of 3 Norwegians feel lonely during the pandemic. During spring 2020, there is an increase of 45% in pills against anxiety, depression, and insomnia.

Ingeborg uses mathematics-based language, emphasising numbers such as 40%, 45% and 1 of 3 when she presents the magnitude of concerns. Statistics is thereby used to critically reflect on a social issue. Her tone of voice is serious, and she keeps eye contact with her classroom peers. Later, in the plenary discussion, students continued to elaborate on mental health issues. For instance, Anna (from the student group) said: “It was rather lonely, really. They just said ‘don’t be with others, just stay home’, and it came rather suddenly and we didn’t get any information”. She relates to the numbers expressing loneliness and voicing her own experience. Other students expressed it as important to be allowed to visit some friends during lock-down. In the plenary discussions, the teacher asks the students what they would argue as appropriate measures in society if they were decision-makers? Iris (from the nurse group) replies: “It is a bit difficult, but cohorts in schools are good because it keeps people apart, and at the same time, people don’t need to develop anxiety and depression”. When referring to mental health issues, she nodded towards the psychologist group, perhaps as a potential solution to the issues they described. She probably referred to cohort regulation as a way to still have social relationships, basing this on personal experiences and a way of making social decisions based on values and using mathematical thinking as described by Hattori et al. (2021).

Economic and political aspects

In the group discussing risks related to unemployment, Miriam says to her group members: "Many struggle and many borrow money to survive. Many have become unemployed due to the pandemic, and struggle with such strict measures". Miriam uses the word "many" multiple times to emphasise the problem of unemployment. Because she has read articles presenting numbers on unemployment, "many" refers to these numbers and communicate that she is concerned about the economic aspect. The numbers have thereby contributed to pointing at risks as a result of restrictions. Miriam seems to have forgotten the specific numbers when Haavard asks curiously:

Haavard: Can you tell us a little about those who have lost their jobs?
Miriam: Then I will find some numbers.

Miriam starts looking for numbers. In the following discussion, they use phrases such as "8% have difficulties", "1 of 4 households are affected", and "15% have no savings left". There is a distinct move from the less precise "many" towards a mathematical-based langue. They also give a more nuanced picture of what kind of struggles there are. The move to precise numbers is probably due to the task given by their teacher and that they are going to present their findings to the rest of the class. Miriam's use of "many" can be regarded as her interpretation of the situation is severe.

They use both the Internet and the provided articles, which brings up conflicting numbers. In her initial search, Miriam found that 25% of household is economically exposed. A moment later, she exclaims, "Oh, no, sorry. Now I entered another website. This is from October tenth". After examining together with Haavard, she continues: "So, 18%, or about 430 000 households, are still exposed. This is in December". After some discussions, she concludes, "The number of economically exposed households has thus decreased". The conflicting numbers resulted in critical reflections on the relevance and validity of the numbers in play, which are crucial in developing and considering statistics and mathematical modelling. It is also part of reading and writing the world and the world with statistics, as described by Weiland (2017). This focus on relevance related to updated statistics is seen when they later investigate the issue of people's savings.

When asked if they had noticed any risks, Haavard replies: "It may be a bit odd saying this, but they risk starving to death. Honestly. Or, it's unlikely, but they actually can". So far, the discussions have focused on the number of people losing their jobs or struggling without reflecting on how this struggle could manifest. Now, Haavard is bringing up the risk of starving. Miriam adds, "But 5% need to borrow money for food". As previously, she provides numbers to strengthen her argumentation. Although Norway has a fair welfare system, with no cases of extreme poverty, there is an increase in low-income families. Typically, people with low-income jobs took the biggest blow financially in the pandemic. The students' focus on the risks of unemployment brings awareness to these aspects.

The economic consequences were later connected to political aspects. Miriam suggests that in their presentation, they should say that, "It will create inequality in society for a long time". The issue of long-term perspectives of inequality is new, and Haavard struggles to formulate Miriam's utterance on their PowerPoint slide. He asks her about it, and she reformulates: "This crisis can lead to bigger differences. And the economy can be destroyed. It will take a long time to recover". She focuses on inequalities and long-term perspectives. In their critical reflection on the consequences of measures, they do not explicitly connect and critique the nature of the numbers, statistics, or mathematical models themselves, as described by Barbosa (2009) and Blomhøj (2009). The topic of inequality and differences in society can, for some students, have strong proximity and for others be at a more distance. However, an awareness of this aspect is essential for all students. During their investigations and discussions about numbers and statistics of unemployment and people struggling economically in the pandemic, they have started to explore the important issue of inequality in society.

Concluding comments

In this research, we have investigated students' discussion of the consequences of COVID-19 measures. The students develop a critical understanding of real-world problems through mathematics-based information by showing awareness of and discussing the measures' cultural, social, economic, and political aspects. Rosa and Orey's (2015) environmental and natural aspects might have been included in their discussion if other articles had been chosen for the students. For instance, more biological aspects of the virus or reduced CO_2-emission due to less traffic and fewer flights. The cultural and social aspects in the students' discussions involved mental health issues and family violence during home-schooling. The numbers identified by the students represented mental health issues, which Anna, Iris and other students associated with feelings of loneliness. When students reflect on these problems with peers, mental health issues can be normalised and make them less challenging to discuss. The use of numbers showing the extent of people struggling with mental health issues during the pandemic may have contributed to forward discussions on this topic. Undoubtedly, the pandemic severely impacted the economic and political aspects of society. When governments closed restaurants, hotels, etc., and maintained strict travel restrictions, many people lost their jobs and income. Miriam and the other students started to explore some of the statistics and numbers related to loss of income and increasing inequality in society. Social inequality is a concern in critical mathematics education, and inequality seems to have increased during the pandemic (Borba, 2021).

Although students identified and used the numbers to discuss wicked problems and consequences of measures taken, most of the time, they did not critically question statistics or numbers in itself. Thus, implications of this research can be that teachers can have an important role by asking questions leading to such inquiries. They could encourage them to critically examine what is behind the numbers, statistics, and mathematical representation, what they consist of, sources, its use, and the consequences of mathematical application in society. Perhaps students could have made a model themselves to inform decision-making. Such a critical gaze can bring further awareness of the limitation of mathematics, but still how mathematics permeates wicked problems like the pandemic. Engaging students in these issues facilitates their understanding of different perspectives and as critical mathematical citizens. While this research is limited to a few students in a short period, it provides insights into how students relate to mathematical argumentation during a time of crisis.

Other characteristics related to the student's discussions involved questioning, listening, investigating, and changing perspectives due to others' argumentation. They moved from giving simple solutions to wicked problems towards sharing more nuanced reflections like Chris did when reflecting on risk and potential measures. When society deals with wicked problems and decision-making, it is impossible to predict all consequences. At the beginning of the pandemic, concerns were raised about the capacity of health institutions, and mathematical representations heavily informed governments in their decision-making. Later, concerns for young children and mental health issues were given more significance. Other values came into play. When measures are implemented in uncertain times, it is crucial that uncertainty is conveyed and risks are presented openly to give citizens reason to follow given advice, as doubting the science behind COVID-19 can be fatal. However, wicked real-world problems need multi-disciplinary approaches where it is essential to consider cultural, social, economic, and political aspects, to understand the complexity of the problem and avoid misuse of information, mistrust and polarisation in society. Although other school subjects might have added perspectives and depth to the students' discussions, the activity shows that mathematics education has a vital role in involving students in investigating mathematics-based information in times of crisis, discussing aspects of their own reality.

Math teachers’ visions of an ideal math class: What do they tell about bringing innovations into the classroom?

Daniela Steflitsch

University Klagenfurt, Austria; daniela.steflitsch@aau.at

Various social and political factors within the school environment influence how teachers ultimately design their teaching and also their motivation to bring innovation into the classroom. The paper presents results of math teacher interviews about their vision of ideal mathematics teaching. From these answers, conclusions can be drawn about teachers’ potential for bringing innovation into the classroom and the factors that might hinder them. Three different types have been derived, with varying levels of motivation to participate in in-service teacher training and to further develop the teaching. Teachers that like to teach in the way “it has always been done” show the least potential, in contrast to the idealists among teachers, who align their teaching with their high standards to design lessons that they believe best for their students’ learning. To narrow the theory-praxis gap, the focus should be on the third type of teacher – the struggling ones – who need support to stay true to their ideals and to avoid adapting to more traditional patterns.

Keywords: Teacher socialization, mathematics teachers’ beliefs, theory-practice relationship.

Introduction

Working with in-service teachers in professional development courses is not always easy, and participants are often reluctant to acquire new knowledge and develop their teaching. “We do not have time for this” or “I am experienced enough after teaching for 20 years, I don’t need this anymore” are just two statements given at the kick-off event for an in-school professional development course for high school mathematics teachers that aimed to elaborate the concept of “critical mathematics education” and possible implementations in the classroom.[1] These comments were made before the teachers even knew in more detail what the course was supposed to be about. From the very beginning, one could notice a general aversion to any participation in the professional development course. The intended courses at this school were canceled after the kick-off due to the lack of teacher motivation.

Continuing professional development throughout the career is seen as an essential part of the teaching profession. Teachers need to constantly develop their teaching practices to be effective in today’s classrooms. In-service teacher training is a necessary prerequisite for innovations to be implemented in the educational system and the classrooms, as it is not enough to rely on next-generation teachers to bring about changes. It requires the participation of experienced teachers (Mayr & Neuweg, 2009). However, it seems that the awareness that teaching is a life-long learning process is not very pronounced for some teachers. Some of them might feel that they are “conclusively trained teachers” after completing their degrees and do not see a necessity to professionally develop further, which is why they articulate their resistance to development work (Körkkö et al., 2020). Such a mindset has long been fostered in Austria by the political and

[1] All quotes from my interviews are originally in German and have been translated into English by me.

structural requirements placed upon teachers since, until a few years ago, high school teachers had no obligation to undergo further training after completing their studies. Such regulations might therefore influence the image that teachers have of their profession, the demands placed upon them, and ultimately the extent to which innovations find their way into teaching practice. As teacher educators and researchers work to constantly improve teaching and learning and are eager to bring new scientific insights into practice, such attitudes are worrisome. This is especially the case as teachers are the ones who are supposed to engage students to evolve, learn new things, rethink old habits, and keep up with the times to meet future challenges.

The theory-practice gap in teacher education – complex reasons

The issue of the theory-practice gap is an ongoing one and has been discussed intensively in the research community. Reasons why it is especially challenging to bring about changes in the educational system are complex and multifaceted.

Teacher education programs might already cause some trouble in letting pre-service teachers link theory to practice and might not be structured in a way that counteracts eventually unfitting attitudes about the teaching profession. Most of the student teachers start teacher education programs a short time after they leave high school. This means they bring a vast amount of experience into the system they now want to work in and have strong preconceptions about what it means to be a teacher. Changing these preconceptions within teacher education seems to be very hard (Joram & Gabriele, 1998). Research shows that new teachers are often highly influenced by how they learned the subject matter themselves when they start teaching (Stofflett & Stoddart, 1994). This influence seems to go deep as even experienced teachers prefer to use teaching styles they were getting used to as students. Moreover, as they might think they already know what it means to be a teacher (as they have observed teachers more than half of their lives), many do not understand the need and the usefulness of the knowledge and competencies they acquire within teacher education. Their preconceptions influence the way they understand new knowledge (Korthagen, 2010).

Even if pre-service teachers' attitudes shift in the course of the teacher education program, it is not certain that innovations will find their way into the classroom. Different studies across different contexts describe that novice teachers experience a "practice or transition shock" after entering the teaching profession (e.g., Corcoran, 1981). As many do not feel well enough prepared and experience frustration within their beginning years, they are not using the theoretical knowledge and competencies acquired in teacher education. Many then fall back into what they experienced in their school carrier as students. Most new teachers tend to adjust their focus to rules and practices in school rather than on recent scientific insights. Especially young teachers experience the pressure to acquire the school's culture, following old patterns and standards that other teachers are using, which discourages modernization and innovation in teaching. Experienced teachers might pass on their attitude that theoretical knowledge and competencies acquired at university cannot be put into practice and is just something you needed to learn to get your degree. This "teacher socialization" often causes a shift away from initial ideals, as it might seem difficult for an individual to influence these existing patterns (Brouwer & Korthagen, 2005). Within this process, even highly motivated teachers with the will to change classroom practices towards more innovative and research-driven teaching practices might resign and comply with "how it has always been done". Resisting these dynamics and insisting on one’s ideals usually needs more individual effort. Moreover, it often goes hand in hand with resistance from different sides (colleagues, students, parents, principal) as schools often have hidden hierarchies keen on maintaining the self-created power structures. Consequently, efforts to change often encounter the “school system’s immune system” and are either rejected or absorbed and defused (Heintel & Krainz 1998). This already illustrates the complex interrelationships and the wide variety of socio-political influencing factors that affect a teacher and thus also his or her teaching.

Nevertheless, some teachers are still eager to design classroom practice in the best possible way for students, even if this sometimes requires creative ways to not adhere to all the guidelines or get into conflict with more traditionally set colleagues. These are the ones most willing to develop further to meet new demands and are therefore also the ones with the most potential to bring changes into the classroom.

Nowadays, mathematics lessons can be carried out in a variety of ways: they can be very traditional and exercise-oriented or very application-oriented, the focus can be more on individual performance or group work and discussion, the lessons can always be similar or, depending on the topic, always different – in short, teachers have many possibilities to design their mathematics lessons. If you ask mathematics teachers about the “ideal” mathematics lesson in which they think children can best learn mathematics, it becomes apparent that opinions differ widely. Based on the teachers’ answers, one can see whether this ideal teaching is implemented in reality or whether they only have an idea of it and do not carry it out for various reasons. The paper aims to present results of interviews carried out with middle and high school math teachers, who described their view of an ideal mathematics class. Looking more closely at their visions of mathematics teaching can also provide insights into their motivation to bring about changes to their teaching and the factors that might cause resistance.

Data collection and analysis

Twelve Austrian mathematics teachers who take part in the professional development course about implementing critical mathematics education approaches participated in the semi-structured interviews. Ten of them are teaching at a middle school, and two of them are teaching at a high school and a middle school (together, they form the entire mathematics teacher team of a middle school in Klagenfurt).[2] The teacher group ranged from participants with only one year of teaching experience to participants with over 30 years of experience. Five of the participants were male, leading to a nearly balanced gender distribution. The interviews were part of a larger study on how teachers deal with bringing critical mathematics education approaches into their classrooms. One of the questions focused on how the teacher would design mathematics classes to make them the best possible for their students to learn mathematics. Participants were asked to describe their vision of it (or what they would change compared to current practices to make it an ideal math class) without

[2] Pre-service teacher education differed between middle and high school teachers in Austria until some years ago. High school teachers needed to complete at least five years of studies at university level, while middle school teachers participated in a three-year program at the educational college. Therefore, theoretical background about teaching and learning mathematics might differ considerably between these two groups which might also influence their answers.

thinking about school guidelines or other regulations. Audio records of the whole interviews were transcribed and coded, letting themes emerge from the data. Within the process, codes across teachers' answers have been compared in order to find similarities and differences, which led to three different themes regarding the question of an ideal mathematics class.

Findings: The ideal mathematics class – three different approaches

Results indicated that there are three different approaches to answering this question. From the answers given, it can be concluded that depending on which approach the teachers tend to correspond to, they also show different potential to bring innovations into the classroom. In general, it was striking that many of the teachers needed some time to think about the question. Some articulated that they have never thought about it before. Therefore, they had some difficulties answering the question, and it was challenging for them not to think about school regulations. That already indicates that many teachers do not think beyond their usual image of teaching and are quick to comply with the school's guidelines or "hidden" agenda of their school without reflecting on it. As one teacher with 20 years of teaching experience replied after thinking about it for some time:

> Hm… Depends on the children. Maybe I would use more visual materials and maybe more time. I would really like to explain everything in more detail, but that is not possible in the lessons. Perhaps also more examples from real-life… I don't know. It would probably be good to have more math lessons per week… but that is not realistic anyway. We already have four math lessons a week, so from that point of view… I don't really know.

It becomes apparent that she has never really thought about it and also doesn't exactly know what to answer. In between, she keeps thinking and throws in new ideas, which, most of the time, she then discards because the regulations in the school system, in her opinion, don't allow it anyway. She does not elaborate on any of the ideas mentioned but simply lists different approaches. This suggests that she does not exactly know how she envisions an ideal mathematics class and that she might have never reflected about the socio-political agenda of her teaching as well. It appears that this teacher has adapted to the school's culture and teaches within this framework without feeling much need to change or evolve her mathematics lessons. Therefore, it might be assumed that she sees less need for regular in-service teacher training.

That might as well be the case if you as a teacher meet your own standards or ideals of teaching and school guidelines fit you well. A younger teacher (7 years teaching experience) responded very quickly and short: "I wouldn't change anything. It suits me just the way it is." He then explained that for his lessons, he often follows the two school books to structure his teaching, using the one with explanations for elaborating new content and the other one with examples for giving homework. That seems to work well for him and, in his opinion, also for his students. However, as school books often mainly focus on exercises and do not foster reflections about the use of mathematics, it might be assumed that students will mainly acquire operational and procedural skills in such a way of teaching mathematics.

These examples show that some teachers seem to always have had a clear image of what it means to teach mathematics and do not feel that changes or adaptations are needed. As a result, they likely are the ones with less motivation to participate in training courses, and when they do participate (which is obligatory for middle school teachers but not for high school teachers who started teaching before the school year 2019/20), they might make little use of the new knowledge provided in these courses. Therefore, the potential of this group of teachers to bring innovations and new scientific insights into the classroom is rather low. As these teachers do not reflect much about their teaching practice and are quite happy with their traditional form of teaching mathematics it might also be assumed that they will not easily see a necessity for using more critical approaches in their mathematics lessons and might not really be aware of a connection between mathematics and socio-political issues themselves. They might not change their attitudes towards professional development and the teaching and learning of mathematics unless they experience an event that causes them to do so (Pehkonen, 1994).

Other teachers struggle more with meeting their own ideals of teaching mathematics, have a clear idea of how it should look but are unsure how to realize it. They articulated their struggles between meeting the school systems' demands and their standards of teaching as an excerpt of the interview of a young high school teacher (3 years of experience) shows:

> In any case, [my ideal mathematics class would be] very application-oriented, where you can maybe also try things out... That you can touch certain things or you do projects or just always have such small fields of application […] Working in a more open framework, where you can also work across subjects and not be stuck to mathematical content only. But you are a little bit caught in this concept of school, and you need to prepare students for the [standardized] matriculation exam. Nothing has happened in this [more open] direction in the last years. Everything is already so stuck. But for me [the ideal mathematics class is structured so] that the teacher should act more as a coach than a preacher, who stands in front and presents everything. That would be the ideal case... (is thinking) … But there is again the question if and when you can implement that so easily... I am asking myself whether you can do so much as an individual.

It gets clear that she is not genuinely practicing what she would see as an ideal mathematics class, pointing to constricting structures in the school. Her struggles show how much influence the (hidden) structures within the school system and, above all, the school culture itself and the associated expectations placed upon her ultimately have on her teaching practice. She is obviously experiencing a notion of a discrepancy between her ideals developed during teacher education and the pressure of more traditional patterns in school. As Dann et al. (1978) indicated, these "discrepancy experiences" lead to a decline in using more innovative teaching practices with whom teachers got in contact in pre-service teacher education programs. As a result, they rely more on traditional teacher-centered instruction. Others, like Brouwer and Korthagen (2005), indicated that this might also cause these teachers to start to doubt (again) whether it is possible to put the theoretical and research-based knowledge from education programs into practice. Even if you as a teacher are ultimately the one responsible for what happens in your classroom, the guidelines of the principal, the attitudes and practices of your colleagues, the expectations of parents and students (which are often generated by a certain school culture) might ultimately strongly influence how you design your classes.

Even though these struggling teachers experience obstacles, they do show the motivation to change classroom practice. How much of these ideas will find their way to their students might depend on how deep their beliefs are settled and how much support they will get to realize them. This is especially important in the first years of teaching as the answer of a novice teacher, who only started to teach some months before the interview took place, shows:

> I would say that it [the ideal math class] should be a bit experimental, with group work, problem-solving, discussing how you find a solution, and where everyone should be able to benefit from each other. […] But I still have to get more into it, because you also need all the materials, you still have to get everything. But so far, my teaching hasn't been quite the way I imagine it, I was a bit more reserved in the first year, but it should go in that direction if everything is possible.

This young teacher has an idea of how she would like to design her math classes but hasn't really dared to carry that out in her first year, was still "reserved", and doesn't yet exactly know whether it's possible to realize it. This is probably because she first wants to get to know the habits of the school and her colleagues to see how far her ideals are from current practices, which is in line with research on teacher socialization (Brouwer & Korthagen, 2005). It gets clear that novice teachers orient their practices strongly on their colleagues and cannot easily realize their individual visions about teaching, which also underlines the power of the socio-political environment in maintaining the status quo. However, the motivation of this group of teachers to participate in professional development courses might be pretty high (especially at the beginning of their struggles), as these courses can be one way of supporting and strengthening their ideals. Moreover, they might get to know ways to realize them within their teaching and find others who have similar visions. Though, if there is no support from other teachers or from their institution to realize the ideals, these struggling teachers may adapt to prevailing rules and patterns and scale back their initial ideals after a few months or years. At the same time, their beliefs that theoretical knowledge and competencies acquired in teacher education can be useful in practice might fade, and their motivation to participate in professional development courses might decrease. This might be especially the case for teachers whose ideals were not yet firmly established but only began to change in the course of their teacher education.

Others with stronger convictions might find creative ways within the system to realize what they feel is the best possible way to teach mathematics or might otherwise even leave the profession when they are not able to do so.

> I arrange my mathematics lessons within the school system in a way that I think the students can take away the most – otherwise, I simply couldn't work there. […] For example, vocational orientation is, in my opinion, very important, and that also happens in my math classes, just like in other subjects. References to everyday life are always included […]. Because just going in [the classroom] and simply calculating examples, then it's also boring at some point, and then you [as a teacher] are just happy when vacations begin again. And I don't want to be part of that [group of teachers], and I only want to do the job as long as I really like doing it!

For this teacher with about ten years of teaching experience, it seemed natural to always arrange mathematics lessons in a way that he felt would benefit students the most. He includes content that is not demanded by the mathematics curriculum if students are interested in it (e.g., cryptocurrency), setting a focus on building relationships to real-life situations. He clearly distinguishes himself from the group of teachers who, in his opinion, equate mathematics lessons with calculating examples without really thinking about what students are interested in. Moreover, he articulated that he is keen on constantly developing his teaching further and that he would find it a good idea to observe math classes of his colleagues to learn from each other.

It is apparent that these teachers are more eager to participate in professional development courses and are the most likely to bring new ideas and innovations into the classroom. They seem to manage to find ways to deal with organizational struggles as well. As their teaching ideals are strong, they are willing to put more effort into designing lessons that meet those ideals. But even if they are willing to work more on an individual basis, most of them will need support in the school community after some time. If this type of teacher finds that, despite great effort, they cannot make their ideas a reality and nothing in their environment is improving, they may even leave the profession. Therefore, the ones with the greatest innovation potential are also the ones who resign first when they realize that nothing is changing and that they, as individuals, cannot do much about it.

Discussion

In education, there is still a large gap between theory and practice, and as the distribution of types of teachers in this small sample shows, a majority of teachers are within the first two types – so they are either not seeing any reason for changes or are struggling to implement them. Only two of the twelve teachers participating in the study could be categorized into the third, more idealistic type. Even though the three approaches were derived from a small sample of 12 teacher interviews, it can be assumed that most teachers can identify themselves with one of these categories. Besides, these cannot be considered static approaches; instead, teachers can find themselves in several of these within their professional life.

Moreover, it seems that there is a noticeable difference between middle and high school teachers when it comes to openness for development work. The initial excerpts in the introduction came from experiences with high school teachers with whom it was first planned to carry out the professional development course on critical mathematics education. However, as they showed no willingness to participate in any professional development course and even expressed a discouraging attitude towards anyone not directly anchored in the school system, a new school had to be found for the research project. From the beginning, middle school teachers were more open-minded towards the professional development course and were immediately interested in what it will be about in more detail. Even though the interviews show that also among middle school teachers, some do not offer much potential for change, these teachers still get involved in in-service training on new topics voluntarily. The fact that there are such noticeable differences in this respect between these types of teachers might be attributed to a wide variety of reasons: Teacher education has been structured differently and anchored at different institutions until two years ago in Austria. Regulations concerning professional duties differed as high school teachers had no obligation to undergo further training after graduation. This might have led to an image that this is not part of their job but more something like a hobby for the over-idealistic. In contrast, middle school teachers are accustomed to investing at least 15 hours per year for this purpose (which is still no guarantee for developmental work as you only need to be physically present to get your certificate). Moreover, the student clientele differs greatly in terms of social background, which makes collegial cooperation in middle schools all the more necessary to cope with possible challenges. The list can certainly be continued. Still, it does already show that socio-political guidelines and school conventions greatly influence the success of professional development initiatives and how much innovative, science-based knowledge actually ends up in the classroom. However, as these described differences between high school and middle school teachers derived from the data and experiences with a rather small group of teachers of only two different schools, generalization of findings can only be done cautiously, and there might be different results in other areas and contexts.

To narrow the gap between theory and practice in the future, it seems particularly important to focus on the struggling teachers and strengthen those who have ideas but do not put them into practice for various reasons. Much potential for innovation will remain unused if these teachers are not supported in ways that allow them to realize what they learned is best for their students. Since the reasons for the theory-practice gap are manifold, there will not be one single way to solve the issue. Rather, interlocking initiatives at different levels could help move in the right direction and, above all, support those open to development and innovation. After all, it became clear that the extent to which innovations find their way into the classroom thus depends on a wide variety of interlinking governmental, political, cultural and social structures. The individual teachers' vision alone will (most of the time) not be enough for getting new research-based insights into practice. Decisions on how teacher education programs are structured, how cooperation between university and school institutions is promoted, how traditional the school structures are, and the legal framework conditions for teachers can strongly influence how much of the vision is carried out in reality.

The construction of low attainment in mathematics – why are primary school children selected for intervention programs? Results from a meta-analysis of case studies

Andrea Tiedke[1], Timo Dexel[1] and Ralf Benölken[1]

[1]University of Wuppertal, Germany; tiedke@uni-wuppertal.de,

benoelken@uni-wuppertal.de

This paper presents a study based on a meta-analysis of 43 case studies on primary school children participating in an extracurricular support program for low attaining children named MaKosi ('Mathematische Kompetenzen sichern'). Whereas this program particularly aims at identifying low attaining children and supporting their arithmetic skills, this paper investigates social factors that can be identified as shared and comprehensive to this group of children attending the support program. As part of the case studies, interviews were conducted with the children, their parents, and (mathematics) teachers in order to examine factors that may lead to or influence the assumed low attainment in mathematics. The results indicate an interplay between individual, social, and school-related factors, such as gender, self-concept, and the quality of classroom management.

Keywords: Low attaining children, case studies, social factors.

Introduction

Teachers, parents, and students typically assume that there are children who easily learn mathematics – and that there are those who do not. In psychological approaches learning difficulties are described as a consequence of dyscalculia or individual learning disorders that need to be 'cured' or, at least, need intervention (Kuhn, 2015). Some mathematics educational researchers conceptualise dyscalculia or learning disorders as the result of inappropriate teaching and individual difficulties and, therefore, call for improvement of assessment and the quality of teaching. In addition, training or intervention programs, e.g., in universities have been implemented (in Germany at the universities of Münster, Wuppertal, Bielefeld, and others) linking the identification and support of children, the training of student teachers, and research on learning difficulties. However, in this paper we follow Uwe Gellert's assumption that the characterisation of a group says more about the characteriser than about the characterised (Gellert, 2013). The phenomenon of low-attaining children in this understanding is not a natural or biological description of reality, but constructions that emerge in social and political contexts (ibid.). Low attainment can be problematised as a consequence of inequality. Consequently, socio-political perspectives on mathematics education focus on the contexts of the construction problems, e.g., in classroom interactions (Gellert, 2008; Heyd-Metzuyanim, 2013), as a matter of identity (Andersson et al., 2015) or (auto-)exclusion (Kollosche, 2019). A research desideratum addresses the question of how other agents involved such as teachers and parents come to the conclusion that there are learning difficulties that cannot be solved in the standard lessons. Complementing these studies, we ask, *which social factors can be identified regarding primary school children's attendance at an* *intervention program for low-attaining children.* We would like to change the perspective by not examining what these learners need or what their (lacking) competences are, but why they are perceived as children who have difficulties and, therefore, are selected for intervention and in what way social factors affect this selection. To answer these questions, we draw on data of 43 case studies constructed by student teachers about children who are characterised as low attaining learners especially in arithmetic and attend an intervention program. First, we give a brief overview of the theoretical frameworks with respect to explanations for low attainment in mathematics and its construction in classroom interactions. After that, the study's methodology is outlined and justified against the theoretical frameworks. Finally, the results are presented and discussed.

Theoretical frameworks

As there are many definitions, classifications, and understandings of having problems in mathematics such as a (mathematical) learning disability, special needs in mathematics, mathematical learning difficulties, or dyscalculia (Scherer et al., 2016), in this paper we use the term low attainment with focus on arithmetic contexts. The term low attainment means that children do not show the teacher's expectations of mathematical performance. It involves individual aspects of learning as well as social and cultural factors and, thus, can be seen as a complementing perspective on other (psychological) classifications (for an overview see Fritz et al., 2019; for a social-political perspective see Straehler-Pohl et al., 2017).

Low attainment in mathematics (LAM) between school, family, and the child

From a mathematics education viewpoint (unlike a psychological one) low attainment is conceptualised as a psycho-social interplay. Gaidoschik (2017) states that there are no actual evidence-based *causes* of LAM but numerous factors that make LAM more likely. These factors can be seen in the realms of school (lack of assessment, teaching mistakes, discontinuity, etc.), family (lack of support, anxiety, drill, etc.), or the child itself (self-concept, motivation, etc.). Benölken (2016) developed a model of LAM that connects inter- and intrapersonal 'risk factors'. Whereas family, peers, and the context of school are *inter*personal factors, there are further possible *intra*personal risk factors such as difficulties in concentrating, unfavourable mathematics-related self-concepts, or self-efficacy expectations, often as a result of multiple experiences of failure. Psychosocial approaches emphasise that such risk factors can exist not only within the individual, i.e., due to intrapersonal determinants or processes but also outside the individual, i.e., in their social environment: Family conditions are unfavourable, for example, due to an environment that is poor in stimulation and experience with regard to points of contact with mathematical content. Until now, there is a lack of empirical research on these risk factors and how they are connected to learner's development of LAM, but one can find hints in studies that research learner's identities or give reasons for (auto-)exclusion from mathematics education. Among others, Andersson et al. (2015) find out, that the identity of being a 'math hater' and corresponding disengagement in class can change over time. They state, that the contexts of task, situation, school organisation, and the socio-political context matter and that identity narratives change in relation to available contexts. Kollosche (2019) asks why learners reject mathematics and describes that auto-exclusion is motivated by the organisation of mathematics education and closely linked to the subject of mathematics itself and, therefore, also represents a didactical problem.

In all these considerations of what may cause LAM, in these approaches it is clear that there is an unsatisfactory performance in mathematics and that this must lead to support (Scherer et al., 2016). Other approaches, instead, question whether this shown performance corresponds to ‘reality’ at all or if it is a result of interactional (co-)constructions.

Construction of LAM in classroom interactions

Uwe Gellert and colleagues use Basil Bernstein’s theoretical frameworks of pedagogic codes and their modalities of practice:

> When the mathematics teacher poses a problem, students need to respond in a manner that is seen as appropriate. They must be able to recognise that particular responses are expected, and they must be able to produce a desired response. (Gellert, 2008, p. 218)

These abilities are distributed unevenly with respect to the different socio-economic backgrounds of the children. Gellert shows, that achievement is not primarily based on childrens’ mathematical abilities, but on their differential rule recognition responses (Gellert & Straehler-Pohl, 2011). In a case study, Heyd-Metzuyanim (2013) shows that ‘learning disability’ is not an individual characteristic, but an interactional co-construction between teacher and learner, relying on the interplay of following rules and routines in the classroom. In this case, the learner responded to the rules of participation, but the mathematical content was mostly inappropriate so that she could not negotiate mathematical meaning. She had no choice but following routines without understanding. “The implications of these findings lie in highlighting the necessity of taking into account the social and affective, as well as the cognitive, aspects of learning difficulties in mathematics.” (Heyd-Metzuyanim, 2013, p. 362).

These studies reconstruct the emergence of disparity while participating in classroom interactions. In contrast, Straehler-Pohl and Pais (2013) reconstruct mathematics educational failure as a consequence of very low academic expectations and, therefore, provoke learner’s resistance. As non-participation is no legitimate option for children in everyday lessons, it leads to exclusion. Within these perspectives, LAM appear to be an interactional construction caused by practices and routines in school. In addition, however, this is criticised as the reasons for inequality can also lie outside the school context.

Researching the connection between social factors and the construction of LAM

Gutiérrez (2012) reminds us that “[…] learning is intricately connected to the contexts in which it occurs” (p. 18). She argues that there is a need to reclaim space for studies that focus on learning in context. Researchers must consider the complexity of the phenomenon. Pais criticises that “[a]ll the complexity of the social and political life of the student is wiped out of the research focus. The student is reduced to a biological entity, likely to be investigated in a clinical way.” (Pais, 2012, p. 53). Though we do not agree with his overall assumptions, we emphasise taking social factors and contexts of learning into account. Our theoretical assumption is that performance in class is not the only reason for being assigned as low attaining but it is also a result of social constructions. Yet, the process of these constructions is not alone in the hands of teachers. We assume that there is an interplay between the teacher's and the learner's views, between the quality of teaching, and the learner's situation. We seek to explore these complex interplays.

Methodology: Data collection and analysis

This exploratory study is based on a meta-analysis of 43 case studies on primary school children who participated in a support program for low attaining children named *MaKosi* ('Mathematische Kompetenzen sichern' – 'ensure mathematical competences', translated from German). The long-term project *MaKosi* was conducted from 2014 to 2018 under the supervision of Ralf Benölken at the University of Münster (Germany) in cooperation with a primary school (Benölken, 2016, 2017). It was organised as a 'learning-teaching-laboratory', i.e., a project seminar that links student teachers' theoretical and practical education by working with children. It mainly aims at developing student teacher's professional competences and supporting children characterised as low attaining in mathematics. In each semester the program took place in the afternoon at the primary school once a week over a period of four months. Each 90-minute-session was divided into three parts: at the beginning and at the end playful problem tasks respectively games were offered to support children's self-perception and joy of engaging in mathematics. The main part of the sessions was the 60-minute diagnostic and support unit in which one student teacher and one child worked together in one-to-one-interactions in established teams. During these sessions, the children worked on various tasks and the student teachers noted down the children's ways of thinking as well as aspects, that stood out to them and that they considered particularly important and relevant, in an observation log. Teachers and parents decided on the children's participation in the program: First, teachers were given information about the program and the theoretical framework. They elected children providing a written rationale. Then, parents were asked to fill in a consent form. The data we refer to in this study is drawn from the individual case studies that student teachers produced following the project *MaKosi* as part of bachelor's (in total 18) and master's (in total 25) theses on the children they worked with in the project over the full period. The case study approach provides a profound, multi-faceted appreciation of an issue, which is intended to paint a holistic and realistic picture of the social world (Lamnek, 2010). In case studies, triangulation of different methods, e.g., participant observation or (guided) interviews, is often used in order to capture all significant dimensions and facets of an issue and to be able to gain a more precise insight into how the diverse factors interact (ibid.). The case studies were primarily aimed at reconstructing the child's difficulties as well as risk factors that could promote these difficulties. In addition to the above-mentioned observation log on the children's way of thinking and their task completion, the students also used guided interviews with the children, their parents, and the mathematics teachers as data collection instruments. From these data, the students worked out how the child's development (including physical and academic development) progressed, how his LAM manifested itself, and what aspects they perceived as risk factors for LAM.

As stated in the introduction, we would like to change the perspective by not examining what these learners need or what their (lacking) competences are, but why they are perceived as learners who are low attaining. In other words, our aim is to reconstruct factors, especially social ones, that lead to these children being characterised as low attaining. Therefore, we conducted a meta-analysis that includes 43 case studies written as part of the project *MaKosi*. Using qualitative content analysis (Mayring, 2015), the risk factors described in the case studies were first coded using three categories deductively derived from theory: *child*, *school*, *social environment* (Benölken, 2016; Gaidoschik, 2017). Subsequently, five subcategories were formed from the data in conjunction with the theoretical models of Benölken (2016) and Gaidoschik (2017) for each of the three superordinate categories: (1) The factors relating to the category *child* included the subcategories *work habits* (e.g., lack of independence, low perseverance or difficulties in concentrating), *developmental factors* (e.g., difficulties in motor skills, perception or language), *affective-motivational characteristics* (e.g., unfavourable mathematics-related self-concept or negative attitude towards the subject of mathematics), *general school-related insecurity* (e.g., discomfort, feelings of inferiority, or emotional reactions), and *relevance* (especially not recognising the importance of the subject for life). (2) For the category *social environment* the five subcategories *lack of stimulation* (e.g., an environment that is poor in stimulation and experiences for dealing with mathematical topics), *learning environment at home* (e.g., lack of support, difficult and unsettled family circumstances), *negative role models* (family members who have also been characterised as mathematically low-attaining or have unfavourable mathematics-related self-concepts), *lack of participation* (and of interest of parents in school-related matters), and *emotional stress* (e.g., due to divorce of parents or pressure) were formed. (3) The subcategories *discontinuity* (e.g., class repetition or frequent change of teachers), *relationship* (especially a negative relationship between child and mathematics teacher), *situation of the class* (e.g., restless classes with many learners or a negative atmosphere in the class), *classroom management* (quality of teaching, individual promotion) and *cooperation* (e.g., between teachers and parents or of different professions) are subsumed under the category *school*.

For each child, it could now be noted whether each factor was perceived as a relevant factor in the context of the case study. It was only asked whether the respective factor played a role and not how strongly it was perceived, i.e., no weightings were applied.

Results

Across the 43 case studies, the comparison of the categories showed that the subcategories belonging to the category *child* were most often perceived as risk factors for the children's LAM. The factors *work habits* (in total 36 times), *developmental factors* (32 times), and *affective-motivational characteristics* (28 times) were each described in a majority of the case studies. *Emotional stress* (20 times) and *lack of stimulation* (17 times) were the most frequently perceived factors in the category *social environment*, and in the category *school*, these were the two subcategories *classroom management* (26 times) and *discontinuity* (21 times). *Relevance* (7 times) and *cooperation* (4 times), on the other hand, were rarely assessed as relevant factors. When comparing the case studies with each other, the wide range of combinations of the fifteen subcategories perceived as risk factors is striking. For example, while only three relevant factors were identified for one child (all can be assigned to the category *child*), there are children for whom up to ten different factors were observed. Furthermore, the distribution of the perceived factors in the three areas of *child*, *school*, and *social environment* varies depending on the case study. In this respect, Figure 1 shows a possible typification of the individual cases in which, depending on the focus of the factors described, they were either primarily assigned to one of the three categories or located at the interface of two or all three categories.

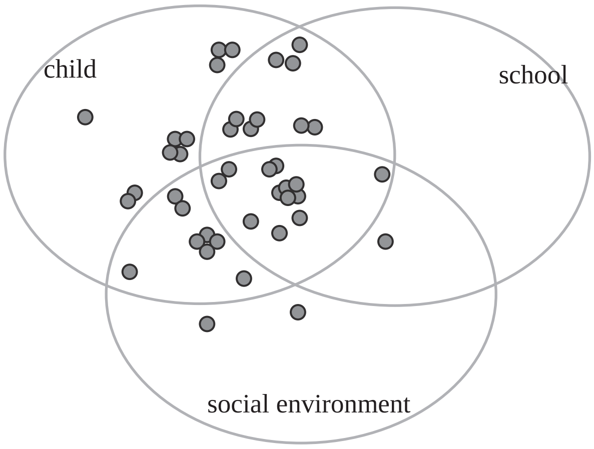

Figure 1: All cases

As can be seen in Figure 1, most of the individual cases are located in the centre or the upper-left area of the mapping. The focus of reconstructed factors for most of the children was, thus, on intrapersonal factors, i.e., category *child*, or at the interface of this category with one or both of the other categories. Furthermore, it can be seen that for none of the children in our case studies a clear focus on *school* factors was described. Nevertheless, as shown above, *classroom management* was one of the most frequently mentioned factors. The meta-analysis also showed that a large proportion of the individual cases considered (a total of 30 out of 43, i.e., almost ¾) were female. If we now look at the focal points of the factors described in the case studies for girls and boys separately, as shown in Figure 2, we can see that the individual case studies of boys are quite scattered.

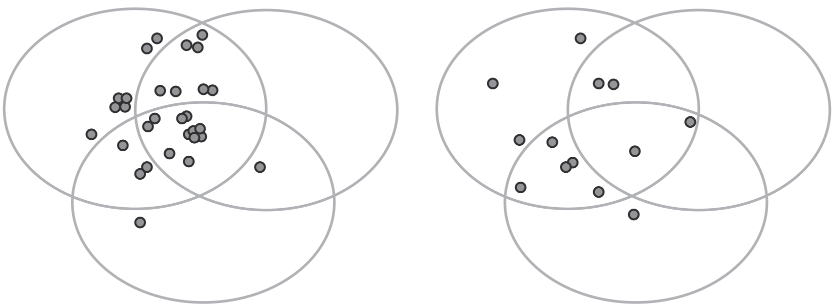

Figure 2: Cases split by gender (on the left: girls; on the right: boys)

Rather often, however, they include types that combine factors that can be assigned to the area of the *social environment*, but have fewer *school*-related factors. Many girls, on the other hand, show a combination of factors belonging to the categories *child* and *school*, whereby an accumulation of affective-motivational characteristics is particularly noticeable. Thus, 23 girls were perceived to have an unfavourable mathematics-related self-concept. In summary, it can be stated that a combination of different factors from the three categories seems to be prevalent in many children, whereby in the case studies the students mainly reconstructed factors regarding the category *child*. In the other two categories, individual factors were dominant, for example classroom management or emotional stress.

Discussion

The results confirm that there is a complex interplay between perceptions of LAM. Especially girls with a negative self-concept and unfavourable motivational factors were selected. Two points seem important to us: first, inequality with respect to gender is a well-known and unsolved problem in Germany. Cultural factors seem to play a role as there are other countries where these differences do not exist to the same extend. Second, the question of individual factors corresponds to the assumption of Heyd-Metzuyanim (2013, p. 363): "The problem lies in the permanence of the disability title and the apparent disregard for the social and affective processes that may be (at least partially) responsible for its development in the first place." The girls are labelled as having problems and see themselves similarly, which, again, has consequences for their performance. In addition, the children's education is characterised by discontinuities. Many of them repeated or were repeating a school year. However, Gellert's (2008, 2013) results show precisely that being perceived as high- or low-performing is related to following rules of discourse. If children do not have access to these rules, repeating a school year does not change that. Benölken (2016) and Gaidoschik (2017) focus on risk factors that lead to LAM. We also found a striking relation between classroom management, emotional stress, and school-related insecurity in general. In addition to Gaidoschik's and Benölken's views we argue that these social factors may indeed have an impact, but especially they make a categorisation of children more likely. In our case studies we found a low attaining girl who scored high achievements in other mathematical assessments conducted by student teachers. All in all, we identify several aspects that seem to influence teachers' and parents' decisions for selecting children – at least gender and self-concept play a role – that appear in mathematics lessons as performance or attainment. These social factors seem to be 'hidden' under the construct of low attainment. At the same time, we recognise a low quality of mathematics lessons and teaching, discontinuities in didactics, and an unfavourable learning atmosphere. None of this will change by learners attaining intervention programs because the lessons and school contexts themselves are problematic. When it comes to supporting learners, it seems adequate to focus not only on mathematical, but broader facets like motivation and self-concept (which is indeed intended in *MaKosi*). Surprisingly, we could not find any relation to socio-economic factors. This leads to the limitations of our study. As the program was conducted at *one* school in a relatively privileged region, there were few economically disadvantaged children. We see our study as work in progress; more children with various backgrounds and at different schools need to be included.

How the structural crisis in the labour market impacts the quality and identity of mathematics teacher students

Jasmijn Vosbergen

Amsterdam University of Applied Science, the Netherlands; j.vosbergen@hva.nl

This paper analyses the impact of two structural context factors on mathematics teacher students. First, the Netherlands is coping with a massive mathematics teacher shortage. Second, the Dutch knowledge-economy feeds the private tutoring sector. The impact on young teacher-students is tremendous; they start working as a teacher too early. Besides successful studying, broader professionalization and quality of mathematics education are in jeopardy. A quick-fix for mathematics education might do more damage than foreseen.

Keywords: Teacher students, teacher shortage, shadow education, identity, quality of education.

Introduction

This paper contains an overview of the current situation in the Netherlands when it comes to mathematics education and mathematics teacher training. Many teacher training students start working as an unqualified teacher before they finish their teacher training. The shortage of mathematics teachers and private forms of education lure teacher students into the work field earlier than preferred. Research on this situation seems to be primarily focused on pupils and teachers and not on teacher training students.

Quality of mathematics (teacher) education

There is no single definition of quality in higher education. Harvey and Green (1993, as cited in Onderwijsraad, 2015) distinguish five different definitions of quality. One of them is quality as transformation. It stands for a mutual process between provider (teacher training) and participant (teacher student). This process adds value to the participants and empowers the participant to influence their own transformation into a professional. The educational work field can be seen as a connection between teacher student and teacher training through traineeship, in alignment with the intentions of both teacher training and teacher student. All from the perspective of safe and solid development of professional mathematics teachers.

Biesta (2020a) states quality is not the right word to use in relation to teacher training, because who is against quality? Quality stands for measuring and scoring, which fits the tenor of the knowledge economy in which scoring as high as possible is the most important goal. Commissie Beleidsevaluatie Lerarenopleidingen (2013) emphasizes it is crucial to keep a broad perspective on the development of teacher students. Thinking in competences in teacher education may keep the focus on the technical aspects of professionalization and may lead to a 'training' model instead of a broader 'forming' model. Competencies are important, but should be seen in a broader normative professionality. This 'forming' model and the model of quality of transformation come near to

Biesta's (2020b) vision about education. Education should not be only about knowledge and competencies employed from the perspective of the current social order. The pedagogical mission of education contains socialization; developing identity and subjectification; being invited to be a subject in and with the world, being a 'self', all in interaction with and interruption by 'the other'.

If mathematics education should involve more than a focus on competencies and qualification, it is important to give mathematics teacher students the opportunity to experience mathematics, mathematics education and the role of mathematics (education) in society in as much depth as possible. The Dutch Knowledge Base is used by universities of applied science to guarantee quality in mathematics teacher training and can be found on the website 10voordeleraar.nl. It is composed by mathematics teachers and teacher trainers and describes the minimal knowledge an incipient teacher should have about mathematics. It states that besides mathematical knowledge (being able to do the math), a teacher should develop general mathematical skills. This means for example being able to use ICT, specify how mathematics is used in other school subjects and 'indicate the impact of society on the development of mathematics'. A broader perspective would be the addition 'how can mathematics be used in other subjects and how does or can mathematics have impact on developments in society'.

In 1980s and 1990s a reform of the Dutch secondary mathematics education curriculum was initiated and implemented. The new Realistic Mathematics Education curriculum (RME) had the aim of making mathematics meaningful for everyone, being connected to reality and being relevant to society (Hoogland, 2020). Students should be supported by constructing their own knowledge and developing mathematical insights (Gravemeijer et al., 2016). In the 1980s the market was led by mathematics textbooks inspired by RME. The tendency of teachers and textbooks to think of instruction in terms of individual tasks and their focus on procedures that generate answers quickly are reasons RME-goals weren't reached (Gravemeijer et al., 2016). Besides that, Dutch mathematics teachers have the tendency to depend on their textbooks (Daemen et. al, 2020). A new curriculum for secondary education is in development. It seems mathematics education might be stuck in a focus on qualification for now, despite the original intentions of RME.

Mathematics teacher education

The Amsterdam University of Applied Science (AUAS) houses the bachelor-study for becoming a mathematics teacher for junior secondary school (age 12-16). The teacher student population is diverse. There are students from urban and rural areas, students with a bi-cultural background, students with a refugee-background, first-generation-students and students who enter from a vocational school or enter from another university. If a teacher-student is successful, the student manages to finish within 4 or 5 years. Unfortunately, not all teacher students are successful. To illustrate this: from the 63 teacher students starting in 2018, only 43% passed the first year course after 2 years of studying. Only half of the 30 full-time teacher-students who started in 2015 with the main phase of their study, a 3 year program, graduated 4 years later. Student teachers who take more than 5 years to study are called 'slow students' (langstudeerders).

Different obstacles cause students in general to need more time to finish their study. Elffers a.o. (2018) distinguish formal obstacles and informal obstacles. A formal obstacle could be not passing exams and informal obstacles are for example being a first generation student or studying with a disability. Student-engagement and thorough guidance of students are important factors for study-success, especially in the first year of studying (Diepen & Elffers, 2019). Although improvement is always possible, pre-teacher-education at AUAS is investing in student engagement. The question arises if there might be other reasons why a substantial number of students are dealing with a substantial study delay. At this point it is time to include factors relating to shortage in the teacher labor market and private tutoring.

Teacher shortage: unqualified teachers, freelancers and growing inequality

The Netherlands has a shortage of qualified mathematics-teachers. A quick search at ‘www.meesterbaan.nl’, a national vacancy-website for education, shows 85 vacancies for mathematics teachers for secondary education (learners age 12-18) at the beginning of the school year 2021/2022. Assuming these are vacancies at different secondary schools this means 4,7% of all secondary schools in the Netherlands are searching for a mathematics-teacher. Schools are allowed by government to hire unqualified teachers, like guest teachers, teacher students or teachers in another subject to fill the gaps. It is one of the reasons why it is hard to define the exact shortage of qualified teachers (Adriaens et al., 2017). Still the education inspectorate states that in 2016 mathematics was the school subject with the highest number of unqualified teachers, namely 7,4%.

The question of supply and demand on the teacher labour market causes a growing number of teachers to start freelancing for financial reasons and to avoid workload. The Chamber of Commerce claims that the number of freelance teachers in general almost tripled in the past seven years. Freelance teachers are more expensive for schools to hire and freelancers have the opportunity to make demands. For example one can come to an agreement not to attend meetings or seminars at school, do surveillances during examinations or start extra educational projects. This undermines schools being a community or a system in which teachers are caring for the development of their students and each other not only during class, but also outside classrooms. Or put another way, it will reduce schools to institutions for qualification, with less opportunities for socialisation and subjectification.

The number of vacancies is concentrated in the western part of the Netherland. This is the densely populated area of the Netherlands and has more urban regions. Figure 1 shows the expected teacher-shortage in the Netherlands in 2025 compared to 2019. Mathematics (wiskunde) has by far the worst prognoses. De western areas (NH and ZH) will have a shortage of respectively 57 and 73 FTEs. A tight teacher labour market increases turnover in highly urban areas and schools with disadvantaged children. In urban areas there are less young teachers, which could indicate it is difficult to find replacements for leaving teachers (Dijkslag, 2019). When it comes to shortages in urban areas: teaching in a superdiverse context requires extra skills. Teaching in general has the characteristic of being a lonely job and requires full responsibility from day one (Snoek, 2016). The complexity of teaching in a superdiverse environment causes starting teachers to choose 'less complicated' schools (Dijkslag, 2019; Gaikhorst et al., 2019).

The shortage of qualified teachers in these areas has a negative effect on equality of opportunities for students (Elffers, 2019a). The education inspectorate states on their website that students in areas coping with a shortage of teachers receive their lessons more often from non-graduated teachers. Besides that, they have more teachers in one school year than schools in other areas. A teacher shortage enhances inequality of opportunity, stimulates a group of teachers to start freelancing and the number of vacancies for mathematics teachers rises.

Figure 1: Extra vacancies teacher per subject and province in 2025 vs. 2019 (Adriaens et al., 2017)

Shadow education: inequality of opportunity

The Netherlands has a knowledge economy, which brings focus on qualification. Parents put their effort into ensuring their children are as highly educated as possible. This has contributed to the rise of shadow education in the Netherlands. The term shadow education stands for privately funded extra educational activities for learners after school with the intention to improve performance at school (Elffers & Jansen, 2019). Examples are homework guidance, extra private lessons in school subjects, training for exams and summer schools. Mathematics, being an obliged subject in most routes in Dutch secondary schools preparing for university and university of applied science, has been doubtless a profitable school-subject for shadow-education in the Netherlands. Figure 2 shows the spending on shadow education increased eightfold in almost two decades (Elffers, 2019a). Shadow education can cause inequality of opportunity. Not all parents are financially able to pay for private education after school. Teachers might spend less time to give extra guidance to their students and refer to extra lessons (Elffers & Jansen, 2019).

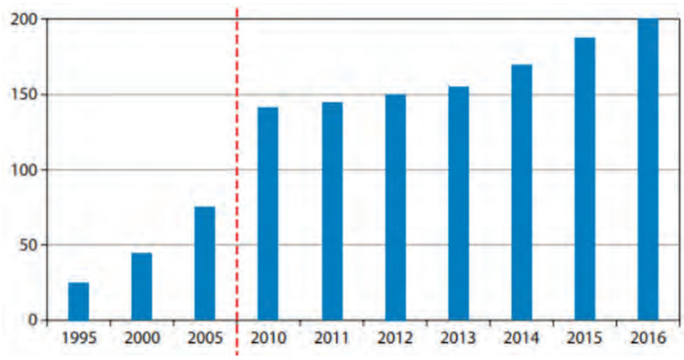

Figure 2: Spending on shadow education in the Netherlands (Elffers, 2019a)

After corona: public and private forms of education can start dating again

Because of the corona-pandemic and its negative influence on education, the Dutch government released 8 billion euros to support national education. This ‘Nationaal Programma Onderwijs’ gives secondary schools two years of funding to help learners get rid of disadvantages due to the corona-crisis. Money can be spent on interventions that are proven to be effective. This can be for example: extra lessons, extra teachers, teacher support, summer programs and weekend schooling. This support plan is the government’s open invitation for public and private forms of education to start to cooperate even more. Shadow education entering public schools is not a totally new phenomenon (Bisschop & de Geus, 2017). The market for shadow-education has been growing due to the Dutch knowledge-economy. (Elffers, 2019a). It seems, when it comes to private education in public schools, in most cases even before the corona pandemic, schools bore the costs or parents were asked for compensation. (De Geus, W. & Bisschop, P. 2017) Both Elffers (2019) and De Geus and Bisschop (2017) conclude more research has to be done on the effects of shadow education on teachers and pupils. An important group of participants is missing in this conclusion, because who are filling the gaps?

Mathematics teachers education students fill the gaps

Since government allows non-qualified teachers to teach at schools in combination with the current teacher shortage, teacher training is coping with schools offering teacher students a job or asking them to do extra educational activities, even before they have finished their teacher-training. This phenomenon is called green picking (groenpluk) (Diepen & Reumerman, 2018).

The AOb, a Dutch teachers union, conducted research with 606 teachers younger than 35 years old by bureau Investico with the topic ‘starting teachers’. The article indicates that almost 60% of the respondents had a job as a teacher before graduation.

Reasons for students to accept a teaching job include: financial incentives, being ‘honored’ and having a ‘good connection with the school’. Not all schools provide proper guidance for starting teachers. About 30 % of the teachers quit after 5 years, because of workload and burn-outs. (Pol & Tunali, 2021).

A short inventory by the author about shadow education and green picking among 24 teacher-students in their first year of study (2020-2021) is shown in Table 1. 12 out of 24 students state they have been active in some form of shadow education. 20 students have been active in some form of private education, which could be, for example, helping a neighbor’s pupil for a fee.

Table 1: Results inventory on activities in education by first year students

Question	Number of students	Percentage
Have you been working as a mathematics teacher besides your traineeship?	7	29 %
Have you been offered a job as a mathematics teacher?	6	25%

Did you receive more tasks besides your internship?	6	25%
Did you give exam training through a tutoring company?	8	33%

So while public education and private forms of education compete and cooperate for employees in the teacher labor market, mathematics teacher education students are filling gaps and put effort in to getting students to access the highest levels in the knowledge economy.

Possible consequences

More research on this topic needs to be done, but still possible consequences can be mentioned. Of course a positive effect might be that teacher education students gain more experience and have context to connect information and activities from their teacher training with their daily practice. However, the way in which the Dutch mathematics curriculum for secondary education has been handled over the past 30 years does not show an inspiring example for a rich mathematics education. Early adoption by the educational field and early development of identity as a mathematics teacher might make it more difficult to stay open to other ideas and concepts. Because teacher students are busy working they will have less time to be creative and innovative and they will have little time to reflect on their experiences being a teacher. The importance of reflection and personal professional development might shift to the background, already being 'on board'. Even more, hiring teacher students as an unqualified teacher might make them think they are ready to be a teacher. Like a student stated in van Diepen en Reumerman's research (2018, pp. 19): *'Thirty hours a week for four years: what is that about? My trainee school says I can be a teacher by the end of this year.'* Just like their employer they will be focused on fast qualification. This might endorse the mindset of 'finally finishing the training' instead of the concept of a lifelong personal and professional development. A generation of teachers may stay underdeveloped while being absorbed by the field.

Conclusion: narrow teacher training, narrow mathematics education

Mathematics teacher shortage and shadow education impact the broader development and professionalization of mathematics teacher students. It doesn't matter if students are 'slow' or 'fast'. Either way they might have the tendency to be focused on their own quick qualification. Meanwhile, they already serve the knowledge economy without room for creative input or any healthy criticism. Since the professional development of teacher students seems to narrow because of this structural crisis on the mathematics teacher labor market, mathematics education itself will stay narrow. This is an alarming situation. Mathematics teachers should not be able to just 'indicate the impact of society on the development of mathematics'. In current times mathematics education should take part in addressing challenges like climate change, data-abuse or inequality of opportunity and contribute actively to personification and subjectification, a quick-fix for mathematics education is creating the opposite.

Conceptualising and operationalising socio-mathematical agency

Pete Wright

University College London, Institute of Education, London, UK; pete.wright@ucl.ac.uk

In this paper, I introduce a new theoretical construct of 'socio-mathematical agency' (SMA), which I define as the ability to use mathematics effectively to argue collectively for social change. I present a conceptualisation of SMA which embraces the need to generate powerful mathematical knowledge, and which draws on critical mathematics education in foregrounding the need to attend to learners' individual and collective agency. I propose that developing SMA in learning mathematics can make a significant contribution towards cultivating the collective knowledge and critical understanding needed to address environmental, economic and social challenges facing global society. I present some suggestions for how SMA might be operationalized in the classroom, which I hope will generate further debate about the efficacy and possible future development of SMA.

Keywords: Socio-mathematical agency, powerful knowledge, student agency, social justice.

Introduction: What is 'socio-mathematical agency' and why is it needed?

In this paper, I introduce a new theoretical construct of 'socio-mathematical agency' (SMA), which I define as the ability to use mathematics effectively to argue collectively for social change. The need to develop SMA amongst students is highlighted by recent calls from intergovernmental educational policy-making organisations for a more humanistic school curriculum that cultivates the collective knowledge and critical understanding needed to address the environmental, economic and social challenges facing global society (Organisation for Economic Co-operation and Development [OECD], 2018; United Nations Educational, Scientific and Cultural Organization [UNESCO], 2015). I propose that focusing on the development of SMA in learning mathematics can make a significant contribution towards these aims. The benefits of SMA are exemplified by the impact of a report by the Imperial College COVID-19 Response Team (2020), released soon after the initial outbreak of the pandemic, which used mathematical modelling of coronavirus infections to predict over half a million deaths in the UK if existing precautions were not strengthened. The report led to a significant change in public attitudes towards the virus, prompting the UK Government to introduce additional measures, including social distancing, which prevented an even greater death toll (Skovsmose, 2021).

Mathematical skills are widely recognised as essential for solving real life problems. There is growing consensus among mathematics education researchers that, to develop powerful mathematical knowledge (needed to solve real life problems), students need to be given opportunities to experience processes mathematicians go through in generating new knowledge (Mason et al., 1985; Schoenfeld, 2012). These include working collaboratively (most new knowledge is generated by mathematicians working in teams), posing questions, conjecturing, reasoning, explaining, justifying. Gutstein (2006) argues that engaging in complex mathematical tasks, through a curriculum that emphasises reasoning, communication and problem-solving, is essential for the empowerment of mathematics learners.

The recent Covid-19 pandemic has highlighted how understanding mathematical concepts, such as exponential growth and moving averages, is necessary for individuals to make sense of data presented in the media and hence arrive at rational decisions about behaviours that take account of the risks to health. Mathematical knowledge is important in helping generate a wider understanding of the many crises currently facing humanity. Coles et al. (2013) highlight how gaining an appreciation of the shape of a normal distribution curve, and how this relates to the mean and standard deviation, can help to explain why global warming is also associated with more extreme cold spells. However, mathematics does not always serve the public good. Skovsmose (2021) highlights how mathematics sometimes (as in the examples presented above) helps to 'picture' a crisis, but at other times can actually 'constitute' a crisis, e.g. in situations where complex mathematical algorithms have led to a collapse in the stock market or to automated reactions of an aeroplane that prevent the pilot from averting a disaster. Mathematics can also 'format' a crisis, e.g. the choice of mathematical models we use to predict climate change can influence how we interact with the climate in future. Careful thought therefore needs to be given to the type of mathematical knowledge, skills, behaviours and dispositions that learners need to develop if they are to make effective use of mathematics to advocate and bring about future social change for the public good.

Theoretical framework: Conceptualising socio-mathematical agency

The content of school curricula has invariably proved contentious, which is hardly surprising given the competing ideological perspectives of those different interest groups involved in their development (Wright, 2012). Even amongst those who champion the empowerment of learners, there is disagreement over how this should be achieved. Social realists, such as Muller and Young (2019), claim that some types of knowledge, particularly those which are formal and specialised, are inherently powerful. They draw on Bernstein's (2000) contention that abstract knowledge is powerful in that it can extend learners' horizons by allowing them to think 'the unthinkable' and the 'not-yet-thought'. It should be noted that Muller and Young's view of 'powerful knowledge' includes an appreciation of 'disciplinary meaning' (how new knowledge is generated within the discipline) as well as understanding abstract concepts, thus endorsing the generally accepted notion of powerful mathematical knowledge described in the Introduction. Muller and Young (2019) blame the involvement of politicians in curriculum-making for an increasing tendency to prioritise the nurturing of skills and competences that are seen as contributing towards economic growth at the expense of powerful knowledge. They claim that knowledge is consequently viewed primarily as an individual asset, rather than for the public good.

In contrast, critical realists argue that abstract knowledge alone should not be considered powerful, since its power largely depends on the agency of the learner (Manyukhina & Wyse, 2019). Given the possibility that mathematics can constitute or format a crisis (Skovsmose, 2021), particular attention must be given to developing learners' agency, to ensure that mathematical knowledge is used for the public good. Before going further, it is important to clarify what is meant by 'public good' and 'social justice' in this paper. I draw here on Tawney's (1964, cited in Reay, 2012) notion of 'the good society' which strives to eliminate all forms of special privilege within education and within society more widely. A socially-just society is one based around cohesion and solidarity in which individuals share a common interest and treat others in the same way they would like to be treated themselves. Similarly, a socially-just education system is one which aims to secure for all children what a wise parent would seek for their own child.

Recent events, such as 2020 US Presidential election and the Covid-19 pandemic, have raised awareness of how misleading statistics and media reports can influence the voting habits and behaviour of millions of people (Alderson, 2020). This, in turn, has refocused attention on the school curriculum as a means of fostering the type of critical understanding and collective knowledge needed to promote human rights, equality and social justice (UNESCO, 2015), and to address the social, economic and environmental challenges facing global society (OECD, 2018). Those who misrepresent powerful mathematical knowledge as purely abstract and apolitical and ignore the role that agency plays in empowering learners may be diverting attention away from tackling these challenges. Locating the power required to advance social justice primarily within abstract knowledge is an 'epistemic fallacy', which ignores the reality that such power is dependent on the agency of the 'knower' and rests on the false assumption that school is a level playing field (Alderson, 2020).

Manyukhina and Wyse (2019) describe learners' agency as having two dimensions: 'sense of agency' (a feeling of control over their own learning) and 'agentic behaviour' (exercising control through making decisions and taking actions). Both dimensions need to be present if students are to be empowered as autonomous learners. Instilling learners with a sense of agency is of little use if they are not provided with real opportunities within the curriculum to exercise that agency. Manyukhina and Wyse argue that the structure in which learning takes place and the agency of the learner have mutual causality. Providing a context-sensitive learning environment in which students have space to explore and to be creative helps develop their sense of agency. Conversely, allowing students to exercise their agency and become actively involved in their learning promotes academic achievement and impacts positively on learners' views of themselves and their place in the world. There is a danger that knowledge-based curricula, such as the current National Curriculum in England, which place too much emphasis on acquiring disciplinary knowledge at the expense of shaping learners' identities, neglect the development of the values and attributes students need to contribute towards the public good:

> … it is critical to support young generations in developing the capacity to think critically and independently, engage in autonomous decision-making based on informed choice, and act effectively in a manner that ensures the essential balance between individual and societal interests and priorities. (Manyukhina & Wyse, 2019, p.239)

Skovsmose (2011) highlights how mathematics teaching around the world tends to be dominated by an 'exercise paradigm', in which the teacher presents the solution to a closed mathematical problem on the board before inviting students to complete a series of almost identical problems. Given the status of school mathematics as a gatekeeper qualification, such an approach may be empowering in a pragmatic sense, as it is assumed to help learners acquire the qualifications that they need to access higher-paid employment. However, it is disempowering in a socio-political sense as it stifles opportunities for learners to develop their mathematical agency, i.e. the ability to apply powerful mathematical knowledge in solving real-life problems. Skovsmose proposes an alternative ‘critical mathematics education’ in which students reflect ‘through’, ‘with’ and ‘on’ mathematics by: participating in meaningful investigations in which they make their own decisions, pose their own questions, interact and communicate with other learners; carrying out mathematical inquiries which deepen their understanding of their social, cultural, political and economic situations; questioning the nature of mathematics and how it can be used to make decisions affecting them and others.

For mathematical knowledge to be used to advance the public good, consideration needs to be given to collective, as well as individual, mathematical agency. Freire (1974) contends, in his theory of ‘education for critical consciousness’, that genuine understanding can only be achieved through learners developing a critical awareness of their own situations and how these relate to their studies. From Freire’s perspective, the purpose of education should be to meet the collective needs of the community (or society), rather than for individuals to achieve success within the system, through raising awareness of, and challenging, structural inequalities. Emphasis should be placed on mobilising solidarity with those who are marginalised or oppressed and engaging in collective action to challenge exploitation. Freire’s (1972) notion of ‘praxis’, i.e. “reflection and action directed at the structures to be transformed” (p. 96), is used by Gutstein (2006) in proposing a framework for ‘reading and writing the world with mathematics’, in which students use mathematics to “investigate and critique injustice, and to challenge, in words and actions, oppressive structures and acts” (p. 4). Through generating an understanding of power relations, and how these relate to their own lives and experiences as mathematics learners (both in terms of how they may be exploited themselves as well as being complicit in the exploitation of others), students develop their sense of social agency and self-efficacy, i.e. a belief that they can influence or change society. However, such an approach requires a fundamental shift in students’ orientations towards mathematics and in the relationships between mathematics teachers and learners.

In conceptualising SMA, i.e. the ability to use mathematics effectively to argue collectively for social change, I have argued in this section that it is necessary to consider students’ development of powerful mathematical knowledge, including an appreciation of disciplinary meaning, as well as their ability to apply this knowledge in solving real-life problems (see elements 1 and 2 below). However, SMA must also involve a readiness of students to use mathematical inquiries to deepen their understanding of exploitative power relationships within society and a disposition towards using mathematical arguments to expose and challenge injustices they encounter (see elements 3 and 4 below). Finally, SMA needs to enable learners to foster a sense of collective agency (see elements 5 and 6 below). Therefore, I propose the following conceptualization of ‘socio-mathematical agency’ (SMA) which incorporates six elements drawn from the theoretical frameworks presented above (Gutstein, 2006; Manyukhina & Wyse, 2019; Muller and Young, 2019; Skovsmose, 2011):

1) An appreciation of disciplinary meaning (how new knowledge is generated) in mathematics.

2) An ability to apply abstract mathematical concepts in solving meaningful real-life problems.

3) A readiness to use mathematics to explore and develop understanding of social justice issues.

4)A disposition towards using mathematics to expose/challenge exploitation and social injustice.

5) A willingness to work with others in using mathematics to construct an argument for change.

6) Confidence that it is possible to influence society through mathematical argument and action.

Classroom practice: Operationalising socio-mathematical agency

In this section I consider what SMA might look like in the classroom and some strategies/conditions that are likely to promote its development. Firstly, it is worth stressing that I believe that there will always be a place in the mathematics classroom for explaining abstract mathematical concepts and practising routine mathematical procedures. However, there are far more engaging ways of doing this than resorting to the 'exercise paradigm' (described earlier), such as making use of richer tasks that provide opportunities for extensive practice through 'mathematical etudes', which have proved just as effective for attaining procedural fluency (Foster, 2018). Having said that, developing SMA necessitates students engaging regularly with open-ended tasks in which they are given greater control over their own learning through making their own decisions about the direction this will take. They should be encouraged to review their own learning, e.g. by reflecting on any errors they make and non-productive paths they explore along the way. Students should also be provided with regular opportunities to work collaboratively, explain and justify their mathematical reasoning to others, listen to and respect each other's points of view, and appreciate the fallible nature of mathematics in which new knowledge is generated through conjecturing, argumentation and arriving at consensus (Hudson, 2018). Frequent opportunities should also be created for students to generate mathematical models to solve meaningful real-life problems, which involve making simplifying assumptions, choosing which mathematical procedures to apply, and considering the limitations of the solution in relation to the initial assumptions (Schoenfeld, 2012). SMA might then be demonstrated through students discussing these solutions and presenting their findings to others.

Findings from the Teaching Maths for Social Justice (TMSJ) research project (Wright, 2017; 2021) demonstrate students' enthusiasm for exploring social justice issues (such as voting systems, Fairtrade and measures of inequality) in the mathematics classroom. Identifying and building on the strong links that exist between mathematical concepts and social justice issues helps students to develop their understanding of both areas simultaneously and to appreciate the legitimacy of such explorations in the mathematics classroom. These links also provide starting points for teachers to bring social justice issues into the mathematics classroom, whilst navigating the pressures they face in getting through an often-demanding scheme of work. An example of an activity that provides such a starting point is investigating how various methods for counting votes (including Borda Points) can be applied in determining the outcome of an election and then considering which method is 'fairest' (Wright, 2016). Note that Borda Points are based on assigning terms from arithmetic or geometric sequences to different preferences for candidates in an election, which means this activity could easily be attempted as part of a unit of work on sequences (students might go on to explore other types of sequence and consider whether applying these might be 'fairer'). Findings from the TMSJ research project suggest that, as well as developing understanding of social justice issues and related mathematical concepts, such activities also have a positive impact on students' overall engagement with mathematics, as they become more aware of the relevance of the subject to their own lives and society in general (Wright, 2017; 2021).

Developing SMA necessitates going beyond merely exploring social justice issues and requires students to use the increased awareness they gain by doing so to expose and challenge exploitative power relationships. Another activity generated during the TMSJ research project highlighted the challenges teachers might face in doing this and how it might require a re-evaluation of the relationships between teachers and students. The activity involved investigating the proportion of the price paid for a chocolate bar that goes to the cocoa producers and other parties (retailers, importers, etc.) and comparing differences in these proportions between Fairtrade and non-Fairtrade chocolate. One teacher researcher was initially frustrated following a heated class discussion in which students began to question the validity of Fairtrade, as they considered the 4% of the price for Fairtrade chocolate that went to the producers to be grossly unfair (despite this being eight times as much as for non-Fairtrade chocolate). On reflection, however, the research team saw this as a positive development, with students beginning to challenge and question commonly held assumptions about Fairtrade (which might perhaps be more accurately described as 'less unfair trade'), and subsequently decided to change the title of the activity to 'How fair is Fairtrade?'

In Freire's (1974) terms, the events described above might be interpreted as students moving away from a position of 'naïve' awareness towards one of 'critical' awareness, as they begin to question unequal power relationships within Fairtrade production, which might be indicative of the development of SMA. The role of the teacher is crucial in such situations. Freire would argue that the teacher should adopt a 'radical' perspective by promoting debate and reflection, working with learners to develop critical awareness, and helping them to arrive at their own solutions (rather than imposing her/his own views). This approach complements the adoption of open-ended and collaborative tasks referred to above that aim to develop mathematical agency. Such a 'radical' stance also requires teachers to reflect critically on their own positions of power, their own views of social justice issues and the extent to which they, themselves, may be privileged. Sticking with the same scenario, a 'radical' teacher might further cultivate students' SMA by prompting debate around whether Fairtrade (despite being only slightly less unfair than conventional trade) might still have strategic benefits, e.g. in putting pressure on chocolate companies to make modest improvements to the conditions of producers, and the potential for the collective power of students (as consumers purchasing Fairtrade products) to impact on the lives of producers in less wealthy countries.

Collective agency, which involves students developing confidence that collaborative action can bring about change and working with others in using mathematics to generate powerful arguments, is an essential element of SMA. This was apparent in the 'Making a Change' activity developed during the TMSJ research project (Wright, 2016; 2017; 2021). In this activity, students worked in small groups, to choose an issue of interest to them, research it and develop a mathematical argument to support a change they would like to see made. Finally, they were asked to present their argument to the rest of the class, which prompted further debate amongst students around the full range of social justice issues explored. The activity prompted exceptionally high levels of engagement amongst students, including those who had previously appeared disinterested in the subject. Students were excited by the opportunity to use mathematics to explore an issue that was of particular interest to them, which was something of a novelty for most students.

The role of the teacher is again of crucial importance in such situations, with the need to maintain a balance between allowing students space to follow their own lines of inquiry and providing them with the support needed to develop a powerful mathematical argument. During the ‘Making a Change’ activity, the support provided by teachers included discussing issues to be considered in collecting and analysing statistical data on other students’ opinions on the chosen issue, and discussing the difference between mathematical and non-mathematical statements, such as “School absence rates have fallen recently” and “The percentage of students with persistent absence (defined as missing at least 15% of school days) fell from 12.5% in 2006/07 to 8.4% in 2011/12” (Wright, 2016, p.45). Encouraging students to plan in advance, and to evaluate their approach after completing such activities, is important for developing SMA. For the ‘Making a Change’ activity, students might be asked to reflect on questions such as: ‘Is your suggestion for change achievable? How effectively did you use mathematics to strengthen your argument? How well did you work together as a group?’ Establishing genuine collaboration within groups of students, based on solidarity, trust and assigning value to communal effort (Radford, 2012), is an essential aspect of SMA. Boaler (2008) offers various strategies for encouraging students to respect each other’s views and to take responsibility for everyone’s learning (related to the notion of ‘relational equity’), including allocating group roles and recognising the achievements of all students.

Concluding remarks

In this paper, I have outlined a new theoretical construct of ‘socio-mathematical agency’ (SMA) and reflected on some classroom practice that provides a useful starting point for its operationalization. I hope this will stimulate debate amongst researchers and curriculum makers around how mathematics teaching can contribute towards the development of the collective knowledge and critical understanding needed for today’s learners to address the environmental, economic and social challenges facing global society. I plan to work collaboratively with teachers in conducting research in schools to further develop and refine the conceptualisation and operationalisation of SMA presented in this paper, and to explore the potential of SMA for cultivating the collective knowledge and critical understanding needed to address the environmental, economic and social challenges facing global society. I aim to report on the findings of this research in the near future.

Scottish teachers' perceptions of marginalisation in school mathematics

Constantinos Xenofontos[1] and Sinem Hizli Alkan[2]

[1]Oslo Metropolitan University, Norway; constantinos.xenofontos@oslomet.no

[2]University of Stirling, UK; sinem.hizliaalkan1@stir.ac.uk

Several studies highlight significant differences between the mathematical performances of white middle-class boys and several other groups of children with other demographic characteristics. Across different countries, discussions about who is marginalised vary. In Scotland, marginalisation is typically associated with social class and children's socioeconomic backgrounds. In this paper we explore Scottish teachers' perceptions of the causes of marginalisation in school mathematics. 29 teachers from different school levels participated in individual semi-structured interviews. All teachers' responses reflected the social-class discourse of policymakers. Few teachers recognised other marginialising variables (i.e. gender, English language competence) as well. We conclude that the intersectional character of marginalisation needs to be promoted more explicitly in both initial teacher education and continuous professional development programmes.

Keywords: Teachers' perceptions, marginalisation, school mathematics, Scotland.

Introduction

In recent years, mathematics education has taken a more explicit socio-political turn (Gutiérrez, 2013), by raising and examining questions regarding, inter alia, who decides what is included in school curricula (Appelbaum & Davila, 2007), who gets excluded from school mathematics (Xenofontos, 2015), and how concepts like equity and social justice have their place in the field's discourse (Xenofontos et al., 2021). This paper draws on data from a wider project in Scotland examining teachers' perceptions of marginalisation and equitable teaching practices, as well as teachers' understandings of concepts like equity, diversity, inclusion and social justice in relation to school mathematics. Here, we explore the following research question: *What are teachers' perceptions of marginalisation in relation to school mathematics?* Before we present findings from our work, we turn our attention to the international literature on marginalisation in mathematics education and the importance of transitioning from one school level to another.

Who is marginalised in mathematics education?

In an initial conceptualisation of equity, Gutiérrez (2002, p. 153) envisioned a stage at which mathematics education stakeholders would be

> unable to predict student patterns (e.g., achievement, participation, the ability to critically analyze data or society) based solely on characteristics such as race, class, ethnicity, sex, beliefs and creeds, and proficiency in the dominant language. Being unable to predict mathematics patterns based solely on certain student characteristics addresses issues of power. Rather than expecting that mathematics reform will lead to middle-class White men falling out of power only

to be replaced by another group (e.g., students in poverty, Black women), an equitable situation is when no group oppresses another.

Sadly, the current reality is still far from such a stage. Several studies, typically from North America and many European countries, indicate large discrepancies between the mathematical performances of white male middle-class pupils (the so-called dominant group) and pupils from marginalised groups. These groups include, but are not limited to, girls (Stoet & Geary, 2018), LGBTQI+ children (Leyva, 2017), those whose home language is other than that of school and instruction (Chronaki & Planas, 2018), children with intellectual, emotional, and kinaesthetic disabilities (Watson & Gable, 2012), and those from low socioeconomic backgrounds (Gates, 2019). In fact, things become more complicated when marginalising variables are considered in intersectional manners, like, for instance, the intersection of gender and race (for example, Joseph et al., 2019, write about black girls and their struggles in the white, patriarchal structures of mathematics education).

It appears that different countries and educational systems, not least at the level of policy-making and research, adopt specific lenses through which marginalisation in school mathematics is examined (Graven, 2014; Xenofontos, 2019). In the US, the focus is almost exclusively on race and ethnicity, specifically in relation to the Black and Latinx communities; in several European countries (i.e. Spain, Cyprus) these issues are typically approached in relation to immigration and other-language learners, while in China and many Latin American countries discussions mainly revolve around rurality. In the UK, marginalisation is typically seen through a social-class lens (Gates, 2019), with Scottish policies being no exemption. Specifically, the Scottish educational system explicitly uses the term *poverty-related attainment gap* (Scottish Government, 2018), to describe discrepancies regarding performances and participation rates between pupils who live in economic deprivation and those from affluent backgrounds. To identify the extent to which an area is deprived, the Scottish Government uses measures across seven domains (income, employment, education, health, access to services, crime, housing), and calculates a relative measure of deprivation, called the Scottish Index of Multiple Deprivation (SIMD). All areas in Scotland are given an integer SIMD value, from 1 (most deprived) to 10 (least deprived). Schools receive direct additional financial support, based on how many children from low SIMD's attend each school.

Transitioning from one school level to another

Studies around the world indicate that, as children transition from one school level to another, there is a general decline in their engagement with mathematics (Martin et al., 2015), a decline of their self-efficacy beliefs, motivation, and performance (Deieso & Fraser, 2019), and a reinforcement of stereotypes regarding gender-based mathematics performance (Denner et al., 2018). These observed differences are typically attributed to factors such as teachers' self-efficacy beliefs (Midgley et al., 1989), teachers' and parents' emphases on goal (Friedel et al., 2010), as well as teachers' different approaches in using instructional materials (Fan et al., 2013).

The Scottish Government (2016) makes clear that central to its political agenda is to "improve educational outcomes in communities with a high concentration of children living in poverty" (p. 25); therefore, "[e]nsuring effective transitions between primary and secondary education is particularly important” (p. 14), especially for children from less affluent backgrounds. A deeper understanding of the extent to which teachers’ perceptions converge or diverge will help us pinpoint continuities and discontinuities in children’s lived school experiences, and consider how to better celebrate or address them.

Methodology

Participants

The General Teaching Council of Scotland (GTCS), the body responsible for teacher registration, registers teachers either as primary or secondary (www.gtcs.org.uk). Primary teachers are generalists and work with students of ages 3-12, in nurseries and primary schools. Anecdotally, some primary teachers self-identify as early-years teachers, due to their preference of working with children of ages 3-7. Those using the primary teacher label prefer working with children of ages 7-12. Secondary teachers teach their specialist subject area and work with students of ages 12-18.

Participants in this study were teachers working in the Central Belt of Scotland, a large region with areas of different affluence levels, but also with those areas with the lowest SIMDs in the whole country. Volunteer teachers were sought via the networks of local authorities, our own professional networks, and on social media. Teachers who expressed interest passed the details onto other potential participants, in the form of snowball sampling. In total, 29 teachers were recruited, 8 of whom identified as early-year teachers (EY), 11 identified as primary teachers (PT), while 10 were secondary mathematics teachers (ST). Other than one teacher in early-years, two primary and one secondary, all other participants had more than five years of professional experience.

Data collection and analysis

All participants were invited to an individual semi-structured interview. Each interview was audio-recorded, lasted approximately 45-55 minutes, and was held at each participant’s school. As part of a wider project, the interview protocol included questions about teachers’ perceptions of and experiences related to (a) marginalisation and the attainment gap in mathematics, (b) equitable mathematics teaching practices, and (c) concepts like equity, inclusion, diversity, and social justice. Below, we present some sample questions, to give a sense of the interviews’ content:

1. As you may be aware, here in Scotland there is extensive discussion on the *attainment gap*, especially in mathematics/numeracy. How do you understand this attainment gap?
2. Could you give any examples from your own professional experiences where you observed gap(s)? How does it impact your day-to-day life as a mathematics teacher?
3. Why do you think some children do not perform as well as others in school mathematics? Why are some children sent to the margins?

A thematic data analysis was employed. Following Braun’s and Clarke’s (2021) suggestion, we moved away from a need to achieve data saturation; we rather aimed at dwelling “with uncertainty and recognise that meaning is *generated* through interpretation of, not excavated from, data” (p. 201). Due to the exploratory nature of this study, no predetermined coding scheme was utilised. The two authors worked separately and together, to generate codes and later collate them to generate themes, in similar ways, grounded theorists discuss moving from open to axial coding (Scott & Medaugh, 2017). As a result of focusing on the richness of our data, and not data saturation, we were not particularly interested in quantitative measures (i.e. frequencies, percentages, number of respondents) in presenting our themes. Instead, we followed a phenomenographic approach. Phenomenography explores variation in the ways a phenomenon is perceived by a group of people (Cope, 2004), by taking a second-order perspective, mapping people's experiences and attempting to see the world through the eyes of those experiencing it (Marton, 1981).

Findings

Data analysis brought to surface two themes related to teachers' perception about the causes of marginalisation. Specifically, all participants talked about social class as the main marginalising variable in school mathematics, while very few made scatter references to other variables. Below, these themes are presented in more detail.

Social class as the main marginalising variable

A great homogeneity was observed regarding what teachers distinguished as the main marginalising variable for children's participation and attainment in mathematics. In ST9's words, "students from more affluent households are more willing to give things a go, perhaps get it wrong, mess it up a bit" compared to their classmates from deprived areas. Using vocabulary that reflected national policies, *all* 29 teachers across the three school levels referred to poverty, low socioeconomic status, and SIMDs. Some representative examples are presented below:

> "I suppose the attainment gap reflects the, I don't know what you would call it, the affluence gap. I don't know. Monetary gap. Economic gap. In my experience, they have reflected each other almost identically." (ST7)

> "The school that I teach in has a lot of pupils from low SIMDs. Most of the children are level 3 in the indication mark-up. There's a high level of students who get free school meals and as a result, our school gets quite a lot of funding from the National Improvement Framework. […] And a lot of parents are proud, they don't want to tell you that they're struggling or whatever. But you're aware that these children are not getting proper meals." (PT2)

Nevertheless, some participants emphasised the important role of teachers and schools in addressing all children's learning needs as they navigate through the challenges caused by poverty. The quotes below are representative of an early-years teacher and a secondary mathematics teacher:

> "What's really nice about the nursery here is that I've seen children really flourish, who come from a really poor background, a really poor housing area and yet they are doing absolutely fabulous work in the nursery just because the educators have got the right way of doing things with them and give the right direction, if you like." (EY1)

> "We're certainly not a school that feels sorry for itself and where we're situated. […] We know where the school is situated, we know the catchment area, the SIMD values, but that's it. Nothing is mentioned beyond that. […] We're a school that strives to be the best, it doesn't matter where we are. […] A lot of it comes from leadership, from the staff but often the

> pupils, too. If there are discrepancies in behaviour or homework, then they are minorities. They understand that that's not how you're expected to behave here. That's not the standard that we expect from you." (ST10)

In summary, teachers' responses put poverty and socioeconomic status at the center of their perceptions of the causes of marginalisation. This is, in a way, unsurprising, as it reflects the adoption of a social-class perspective on marginalisation in education expressed by UK policies in general (Gates, 2019) and Scottish policies in particular (Scottish Government, 2018).

Scatter references to other variables

Few references were made by teachers across school levels about other marginalising variables. These can be grouped in two broad areas. The first concerns *family-related issues/dynamics*, like parents' lifestyles, family structures, and family-school relationships. According to PT6, typically "we consider poverty as an indicator, but for some children why they are not attaining has nothing to do with poverty", therefore, "what's most important is the school's knowledge of children's families". From this perspective, teachers pointed out that low attainment can be a result of "the chaotic lifestyles that some families have" (EY1). As EY3 commented, "I've seen parents' anxiety and mental health be so prevalent that they won't allow their child to go to school because they can't be without them".

The second area is related to students' *individual differences*, such as gender, disability, English language competence, and other developmental issues. PT8, for instance, pointed out mathematical difficulties faced by children with English as Additional Language (EAL). In her own words, "I've got children who are in that gap because they're EAL. They can literally do their simple 1 + 1, but they can't do word problems". Likewise, ST3, a female secondary teacher, discussed many girls' low confidence as opposed to that of their male classmates:

> "I feel like girls have a very low confidence of maths and they don't want to put an answer down because they don't want it to be wrong. […] Boys are overly confident and therefore don't study and do worse than they should do, and girls have very low self-esteem, get very anxious and don't want to attempt." (ST3)

Interestingly, most references to family-related issues were made mainly by early-years and primary teachers, while discussions of students' individual differences were made by primary and secondary teachers. This move from socio-cultural to cognitive/affective concerns appears to be in accordance with general trends of mathematics education research on transitioning from one school level to another. For example, many recent studies examining transitioning from pre-school or kindergarten to elementary school focus on the impact of family-related factors (i.e. Niehues et al., 2021). Conversely, recent studies focusing on the elementary-secondary transition are typically more interested in cognitive/affective issues and students' individual differences (i.e. Cantley et al., 2021).

Conclusions

In a sense, it was not surprising that *all* 29 teachers in our study pointed out that social class, poverty, and pupils' socioeconomic status constitute variables associated with pupils' mathematical performance and participation. One the one hand, we consider the fact that few teachers talked about other marginalising variables (e.g. gender, English language competence, disability) encouraging, as those teachers demonstrate some awareness that reality is more complicated than focusing exclusively on social class. Nevertheless, we are aware that simple references to other variables do not necessarily mean that teachers approach marginalisation from intersectional perspectives. As several studies inform us, many teachers have social and political intuition; they sense the interplay between school mathematics and political issues, but do not always know how to put intuition into practice in ways that help their students (de Freitas & Zolkower, 2009; Xenofontos, 2016). Our findings stress an urgency for more intersectional approaches in examining marginalisation in mathematics education, something that could originate from research in teacher education (both initial teacher education and continuous professional development), aiming at having an impact on policy-making, teachers' practices, and students' lived school experiences. Besides, as Freire's (1970) writings have taught us over 50 years now, instead of wait for systemic changes to happen "miraculously", those of us involved in education and share values of equity and social justice could start by initiating small projects in their immediate professional environments.

To conclude, our findings concur with ongoing calls for employing more intersectional approaches, and critical and nuanced discussions on how inequities and marginalisation are constructed and/or even normalised in mathematics education. Intersectionality, as an analytic framework, allows scholars in different fields to explore, inter alia, the structural interplay of variables such as race, class, gender, sexuality, and disability. Yet, we need to acknowledge that we cannot always capture social experience with a finite number of marginalising variables, to describe the intersectional identity of a person (Appelbaum, 2002). At best, we can have an approximation based on important characteristics of how identity is read by others in a social situation. Teacher education initiatives should be designed to address more sophisticated understandings of concepts like marginalisation, equity, and social justice. Hence, mathematics teacher education, we believe, must challenge the current simplistic understanding of marginalisation and provide targeted support to teachers so to rethink their narratives around practices that aim at helping children regardless of background.

Keywords: Algorithms, algorithmic thinking, teaching and learning of algorithms.

In CERME12, our working group "Algorithmics" started its work as a newly established TWG. Since algorithms have always been at the heart of mathematics and their importance has been steadily increasing since the beginnings of theoretical computer science, the design and analysis of algorithms – called *algorithmics* (Traub 1964, Knuth 1985) – lies at the intersection of mathematics and computer science. For this reason, on the one hand, various algorithms and algorithmic activities have their traditional place in mathematics curricula at all levels. At the school level, mathematics and computer science have interacted since the 1980s, when many schools set up labs with computers equipped with programming software. On the other hand, many questions arise in the context of teaching and learning algorithms: a first, more applied group of questions aims at algorithms in mathematics education and curricula, a second, more theoretical group of questions seeks to clarify the concepts of algorithm and algorithmic thinking.

Conference presentations

Due to the Corona pandemic, the conference was held as a virtual event. Nevertheless, a total of 11 papers and 7 posters were presented remotely by their authors at the conference, with a total of 24 group participants from 11 countries. The contributions were considered in four themes, as follows.

Theme 1: Beliefs and domains in which algorithmic thinking occurs

A first group of papers focuses on the place and importance of algorithms in mathematics in general and arithmetic in particular. They assess the beliefs of experts about the role of algorithms in mathematics and mathematics education or their role in mathematics courses.

- Lockwood, DeJarnette, Thomas and Mørken offer three perspectives on algorithms, particularly in computational settings: an algorithmic approach in a mathematical example, the view of a mathematician, and the view of an undergraduate students taking a course in mathematics.
- Geraniou and Hodgen interviewed two mathematics educators who had experience using technology to solve mathematical problems, and they, too, shared very different views on algorithms in mathematics education, one even not seeing the use of algorithms as a mathematical activity.
- Kortenkamp analyzes an arithmetic course for pre-service primary teachers. He identifies several algorithmic activities in the topics covered in the course, such as designing algorithms, specifying algorithms, performing algorithms, proving their correctness, and comparing algorithms.

- Leifeld and Rezat's poster provides a thorough analysis of the possibilities of certain arithmetic algorithms for addition and subtraction to deepen students' understanding of inverse operations.

Theme 2: Teaching and learning of algorithmic thinking at primary level

Another group of papers focuses on teaching and learning algorithmic thinking in primary school. They use different tasks with different goals: Some use algorithmic thinking as a means to an end (in the sense of learning a new mathematical concept), some use algorithmic thinking as a goal (in the sense of understanding a given algorithm, or developing an algorithm to solve a problem):

- Crisci, dello Iacono and Ferrara Dentice explore how primary school children can be stimulated to learn new mathematical concepts by Scratch. In their report, they present a specially designed task that required visual programming to complete a given figure so that it becomes axially symmetric. The children developed two different strategies to solve this task. For example, they found out that points that are axially symmetrical to each other must be equidistant from the axis.
- Funghi and Ramploud are interested in how to teach the standard long-division algorithm so that children understand why it "works." To this end, they had fourth graders compare the optimized, digit-by-digit long-division procedure with the procedure in which the divisor is repeatedly subtracted from the dividend. Their analysis of class discussions suggests that this approach could actually result in less rote learning, but in more conceptual learning.
- Zindel's study wants children to acquire algorithmic thinking without using computers. In her papers, children are instructed to decrypt and encrypt certain words. They had to articulate the necessary steps themselves and record them in writing. Although these texts show great differences, the author succeeds in reconstructing some constituents of algorithmic thinking.
- In Gaio's study, too, children are asked to develop algorithms in the sense of systematic procedures, without the help of computers. Here, the tasks given to children of different school levels (3rd to 8th grade) are in the context of sorting problems. As the author reports, he can see traces of classical algorithms in the procedures that the children have worked out cooperatively.

Theme 3: Teaching and learning of algorithmic thinking at university level

Concerning the development of algorithmic thinking at university, the discussions showed two big issues: the development of algorithmic thinking and algorithmics in mathematics, for students, independently of their projects, and more specifically, the development of algorithmic thinking in mathematics for future teachers, and in particular future primary teachers.

Four papers dealt with algorithmic thinking in advanced mathematics, three at university, and one concerning an education program for gifted students. Above them, three were interested in links with discrete mathematics, combinatorics, graph theory, which illustrates the specificity of those mathematical fields, at the interface with computer science:

- De Chenne and Lockwood explore the use of programming and computer science in solving basic counting/combinatorics tasks in college, and how the knowledge of student in computer science can influence their solving strategies and support their learning.
- Medová, Milicic and Ludwig study the competencies involved in algorithmic thinking for university, and in particular abstraction, modelling, and visualization skills which are difficult to master for students, and questions the development of computational thinking in mathematics.

- Bóra and Gosztonyi analyze the place given to algorithms and what could be seen as algorithmic problem solving, in Hungary's advanced mathematics programs, questioning what can be considered traditionally as algorithmic in mathematics and its place according to mathematical culture of the country.
- The paper of Calor, Palha and Kubbe concerns at the same time advanced mathematics and pre-service secondary teachers' education. It deals with analysis, and in particular developing instructional material concerning differential equations for algorithmic thinking and programming. First results show that students did indeed develop algorithmic thinking in their work.

The two other contributions dealt with algorithmic thinking in and for primary teacher training:

- Weber's paper examines primary teachers' use of loops to solve a geometrical problem and their conceptions of the loop construct. It elaborates some challenges in their conceptions and some misconceptions that require deepening their understanding from a teacher training perspective.
- Dobgenski and da Fontoura's poster presents and reflects on an experience of making pre-service primary teachers deal with computational thinking using Scratch.

Theme 4: Concepts related to algorithmic thinking: computational thinking, algebraic thinking, problem solving, and mathematical literacy

The last group of contributions deals with different, no less relevant aspects of algorithmic thinking:

- Rafalska's paper illustrates how tasks could be constructed in order to lead children in mathematics lessons (without the use of computers) to algorithmic thinking in the sense of developing a solution strategy and which individual learning processes can be triggered by these tasks.
- Pohlkamp and Lengnink's paper takes a different look at algorithms: It discusses algorithms that make decisions and are thus socially relevant. Addressing and studying them in the classroom would mean taking more seriously the educational mandate to teach social skills as well.

Finally, two poster proposals deal with two concepts related to algorithmic thinking:

- Rekstad and Rasmussen investigate the question to what extent aspects of computational thinking mentioned in the literature are also reflected in teachers' beliefs when asked about the role of computational thinking in mathematics education.
- The relationship between algorithmic and algebraic thinking is the subject of Müller-Späth, who plans to investigate how algorithmic thinking (realized by an app) affects the development of the ability to generalize and thus of algebraic thinking.

Conference discussions

As mentioned earlier, our working group has just begun its work, and a common understanding of the concepts has yet to be developed: What does algorithmics mean in the context of teaching and learning mathematics? What is algorithmic thinking? To this end, after the presentations in which quite different views were expressed, we worked on the following three questions:

Question 1: Which mathematical algorithms could stimulate algorithmic thinking?

The discussion of this question revealed relatively unanimously five mathematical types of algorithms: i. Algorithms based on the place value system (standard algorithms for addition etc., algorithm for calculating logarithms), ii. graph-theoretic algorithms (shortest path problem, Königsberg problem), iii. approximation algorithms (Heron's algorithm, Newton's method, etc.), iv. sorting algorithms (heap sort, bubble sort, etc.), and v. miscellaneous (Gauss's Easter algorithm, etc.). We were not in agreement of whether each procedure is also an algorithm. For example, everyday procedures (tying shoes, making jam sandwiches, etc.) were not considered by all participants to be suitable for addressing and promote algorithmic thinking in its "proper sense" because they show only one characteristic feature of algorithms: the order of steps.

Question 2: Which mathematical topics could promote algorithmic thinking?

The discussion of this somewhat broader question also yielded five topics from which tasks could come to stimulate algorithmic thinking: i. number theory (arithmetic, prime number tests, factorization), ii. discrete mathematics (graph theory, combinatorics, counting problems, etc.), iii. geometry (transformations, algebraic geometry), iv. computer science (cryptography, etc.), and v. games and puzzles (Rubik's cube, tower of Hanoi, etc.). One participant's question about what properties these fields would have in common was discussed intensively and controversially.

Question 3: What (human) activities with algorithms can we think of?

The activities discussed suggest a wide range of possible activities to deal with algorithms: i. creating (developing algorithms, improving algorithms, debugging algorithms, optimizing algorithms, transferring algorithms to an analogous situation, etc.), ii. analyzing (effectiveness and proof, efficiency, complexity, stability, similarity etc.), and iii. comparing (comparing different algorithms for the same problem, comparing analogous algorithms for different problems, classifying algorithms, etc.). Although executing an algorithm without any reflection would be a possible activity with algorithms, most participants do not want this to be understood as algorithmic thinking.

Surely the reader can think of further examples or answers to these questions. In other words, the three questions need to be discussed further and their answers are still quite open.

Outlook

As the overview of the contributions as well as the first answers to central questions show, there is a great variety of approaches (theories, methods) and views (topics, perspectives) in our working group. Given that we are entering a young (or at least long-neglected) area of research in mathematics education and that we have just begun work in our TWG, it was to be expected that the results would be disparate and sometimes controversial. However, in terms of a first step towards a robust and sustainable understanding of concepts, this diversity makes us confident that there are many more questions around the challenging topic of algorithms and algorithmic thinking that are worth working on. With this in mind, we look forward to CERME13 and hope for a fruitful continuation of the work we have begun – and that it can then be carried out again as a physical conference.

Keywords: Hungarian mathematics education; gifted students; series of problems; algorithmics; discrete mathematics.

Introduction

Algorithmics is not an autonomous domain required by Hungarian mathematics curricula. The introductions of the latest curricula consider the development of algorithmic thinking as an aim of mathematics education (together with logical thinking and problem solving), but don't develop this intention further. The teaching of algorithms and algorithmic thinking is included in another discipline, informatics, an autonomous discipline since the 1990s (Kőrösné 2009), where algorithmics is associated with programming.

However, algorithms and algorithmic thinking seems to appear frequently in Hungarian mathematics education, even if these appearances are not explicit and not associated with programming or computers. The identification of (implicit) appearances of algorithmics in Hungarian curricula and teaching practices needs further systematic research. Here, we show a more obvious example, issued from a (well-known and highly influential) mathematical program for gifted students, developed by the mathematician Lajos Pósa. In this program, different problems related to discrete mathematics play an important role and several of them can be clearly associated with algorithmics.

Pósa math-camps

Lajos Pósa has been developing his talent-nurturing method since 1988. He created an environment where talented and motivated students can develop their problem-solving skills. The main goal of his mathematical "camps" is that students could experience the joy of problem solving. His method can be described as a mix of discovery and guided learning approach (Győri & Juhász, 2018). Students enter the program typically at grade 7 and leave around grade 12.

In the Pósa math-camps problems are not stand-alone problems. They are carefully designed and organized into complex series of problems (Gosztonyi, 2019) constructed by various problem-threads. Problem-threads are sequences of problems organized into an intertwining structure of problems. Each problem can be a part of multiple sequences. The nature of connection can be various such as: topical connection (the topics of problems are related) or the core-ideas of a solution are similar.

Problems analyzed

The following 2 problems from the “scale” problem-thread (targeting gifted 12-14-year-old students) will be analyzed in the poster. Ideas related to algorithmics appear quite clearly in this thread. It starts with a quite well-known problem. In the poster more examples will be represented exploring the connection between problems within this specific thread and within the program as well.

1.a We have some weights; one is slightly heavier than the rest. Can you find which one is heavier with the help of a balance? Use the least possible number of steps.

3. We have 8 weights, six of them are 1000g, one is 1010g and another one is 1020g. Can you find, with the help of a scale, which weight is 1010g and which is 1020g? (Scales are different from a balance. They have only one plate and they indicate the weight of the items on it.) Use the least number of steps possible.

Conclusion

As our examples will illustrate questions related to algorithms appear repeatedly and to a certain degree explicitly in Pósa’s program. Algorithms must be constructed in order to solve certain problems. Questions related to the efficiency of algorithms are raised. Related proofs appear, often in form of impossibility proof. Coding of information is necessary in certain cases. However, computers are used in no case in Pósa’s program. We have good reason to think that ideas related to algorithmics appear recurrently in ordinary mathematics education in Hungary as well.

Aim and rationale of the study

In the past decade, computational thinking (CT) has been a hot topic in educational research and practice (Grover & Pea, 2013; Selby & Woollard, 2013). CT might have a positive influence on learning mathematics (Barcelos et al., 2018). The aspects of CT include algorithms and algorithmic thinking (AT) (Shelby & Woollard, 2013).

AT is a skill that is not easy to develop for students in secondary and higher education. In-service teachers should be better prepared to teach in ways that involve AT. There is a lack of instructional materials to implement AT in in-service teaching trainer programs. The aim of our research is to develop and investigate tasks that enhance in-service teachers' knowledge about AT.

The rationale of our study relies on a system of assessments originally used in Computer Science Education by Grover et al. (2015, pp 209). It describes eight ideas for a high school curriculum involving algorithmic problem solving, two of which involve AT. These are 1) algorithms and pseudocode and 2) algorithmic flow of control, particularly sequence, serial execution, and loops. We understand AT as 1) understanding how an algorithm works, 2) being able to describe an algorithm as pseudocode, 3) knowing how simple loops work, and 4) understanding how commands are executed in sequence.

Method

Tasks for AT in Dynamical Systems course

In the Dynamical Systems course of our in-service teacher training program, students learn to find exact solutions for differential equations. However, sometimes exact solutions do not exist, and solutions need to be approximated with numerical algorithms. To introduce AT into higher teacher education, we replaced an optional part of the Dynamical Systems course (fractals) with the subject of numerical methods. It is important that students understand numerical algorithms. Students should also be able to implement the numerical algorithms in a computer program and test and debug the program. In other words, students must learn CT skills, in particular learn to think algorithmically, to move from a mathematical model (the differential equation) to a reliable approximate solution. The assignment involves Euler's method to solve a first-order initial value problem. The goal is to make students understand that the steps made with Euler's method form an algorithm, which can be described with pseudocode that includes loops.

We developed a number of tasks that aim to elicit AT. The first design principle regards the context in which the AT takes place. Because we wanted to investigate AT in its natural context (in-service teacher training programs), we chose a content topic that was part of the higher education program and a subject that involved the use of algorithms in a meaningful way. Therefore, we chose a course in differential equations (Dynamical Systems). The second design principle concerns the nature of the tasks. We developed tasks existing of activities that require AT, such as creating a pseudocode involving serial execution and/or loops (Grover et al., 2015). In this study, we investigated how one in-service teacher solved these tasks and engaged in AT in the first design cycle.

Analysis

We investigated how the task (the finishing of the pseudocode in Euler's method) can elicit AT through task-based interviews and the thinking out loud method (Schellings et al., 2006). In the thinking out loud method, the student is asked to constantly articulate his or her thoughts. The students were selected by the teacher of the course on the basis of their mathematical knowledge level (two with an average mathematical knowledge level and two with a higher-than-average mathematical knowledge level, and in each pair of students, one student was chosen at random). Each student was interviewed individually by one of the authors of this paper, and the interviews were video recorded and then transcribed. Analysis of the transcripts was based on the categories of Grover et al. (2015) Here, we report on the results of one student.

Preliminary results and further research

Analysis of this student's think-aloud protocol while solving the task revealed aspects of AT. The results showed that the student was able to explain the Euler algorithm and create the pseudocode (including loops), which are forms of AT according to our analytical framework. The assignments therefore seem to have potential for the development of AT. However, there are aspects that need to be improved. The next steps are to further develop our coding scheme for AT and to investigate how our research can contribute to teachers' work on algorithms in their practice.

A digital artefact based on visual programming for the learning of axial symmetry in primary school

Rosamaria Crisci[1], Umberto Dello Iacono[1] and Eva Ferrara Dentice[1]

[1]University of Campania "L. Vanvitelli", Department of Mathematics and Physics, Italy; {rosamaria.crisci; umberto.delloiacono; eva.ferraradentice}@unicampania.it

In this work we used visual programming in order to mediate the learning of axial symmetry in primary school. More in detail, we designed and implemented an a-didactical activity in the Scratch programming environment in which students have to symmetrize figures with respect to oblique axes. We tested the learning activity with fifth-grade students with the aim of understanding to what extent algorithmics and visual programming influenced the rise of new solving strategies by students. Preliminary results from a qualitative analysis seem to show that students were able to improve their strategies in the programming dimension and to evoke some aspects of axial symmetry.

Keywords: Elementary school mathematics, programming, symmetry.

Introduction and theoretical background

In recent years, several national and international institutions promoted the introduction of algorithmics and computer programming in the school. For example, the Italian Ministry of Education (MIUR, 2018) and the European Commission (https://ec.europa.eu/education/education-in-the-eu/digital-education-action-plan_en) encouraged the introduction of computational thinking, coding and the creative and critical use of digital technologies since primary school. Already in the 1980s the research in education was oriented towards the development of new programming languages and techniques, increasingly accessible to primary school students. In those years, Papert (1980) created the LOGO programming language, used, for instance, by Bideault (1985), Salem (1988) and Clements et al. (2001) for learning geometry in primary school. More recently, Bartolini Bussi and Baccaglini-Frank (2015) used the programmable robot Bee-Bot in order to deal with geometric aspects. Tchounikine (2016) underlines how visual programming and algorithmics are suitable tools for conveying content from different disciplines. In this view, many authors (for example, Benton et al., 2018; Forster et al., 2018; Zhang & Nouri, 2019) used the Scratch visual programming language (https://scratch.mit.edu/) for learning mathematical concepts. Scratch was also used in the French project EXPIRE (https://expire.univ-grenoble-alpes.fr/) to deal with mathematical contents in primary school (Chaachoua et al., 2018).

This work arises from the context described above. It is a part of a broader research project whose aim is to investigate students' difficulties related to symmetries (Dello Iacono & Ferrara Dentice, 2020), and to design suitable learning activities to try to overcome them. In particular, in this work, we decided to use Scratch programming language to mediate the learning of axial symmetry in primary school. Indeed, axial symmetry, like any non-identical geometric transformation, is associated with the idea of movement, as underlined by Ng & Sinclair (2015). Also Jagoda & Swoboda (2011) emphasize the importance of associating symmetries with movement, and they invite to provide students with tasks and tools that allow them to manipulate objects and to experience the action of geometric transformations and their results. In this regard, Scratch programming language could be a suitable tool as it allows students to interact dynamically with the environment. So, we designed an a-didactic situation (Brousseau, 1986) in the Scratch programming environment that involves the use of algorithmics in the students' task. Students have to work on a digital artefact, with figures to be symmetrized with respect to oblique axes. The choice of the oblique axis of symmetry wants to create a cognitive conflict in students (Fischbein, 1989), who are often accustomed to working with horizontal or vertical axes of symmetry. In this way, the intuitive model of an object symmetrical with respect to a horizontal or vertical axis can be replaced by the rigorous mathematical model of an object symmetrical with respect to an axis, regardless of the position of the latter with respect to a reference system such as a sheet of paper or a squared grid.

We experimented our a-didactic activity in a fifth-grade class. In this work, we show the preliminary findings of a qualitative analysis whose aim is to understand to what extent the algorithmic and the visual programming underlying the activity we designed influenced the emergence of new solving strategies by students, linked to the construction of symmetrical images with respect to an axis.

Design of the digital artefact

We designed an a-didactic activity requiring students to work on a digital artefact in the Scratch programming environment. The scene involves three students from a dance school, Piero, Isabella and Giada, moving across a stage to create choreographies for a show. Piero and Giada's movements are already pre-established, while students have to guide Isabella's movements through the creation of a program by dragging and encapsulating some available instruction blocks (see Figure 1).

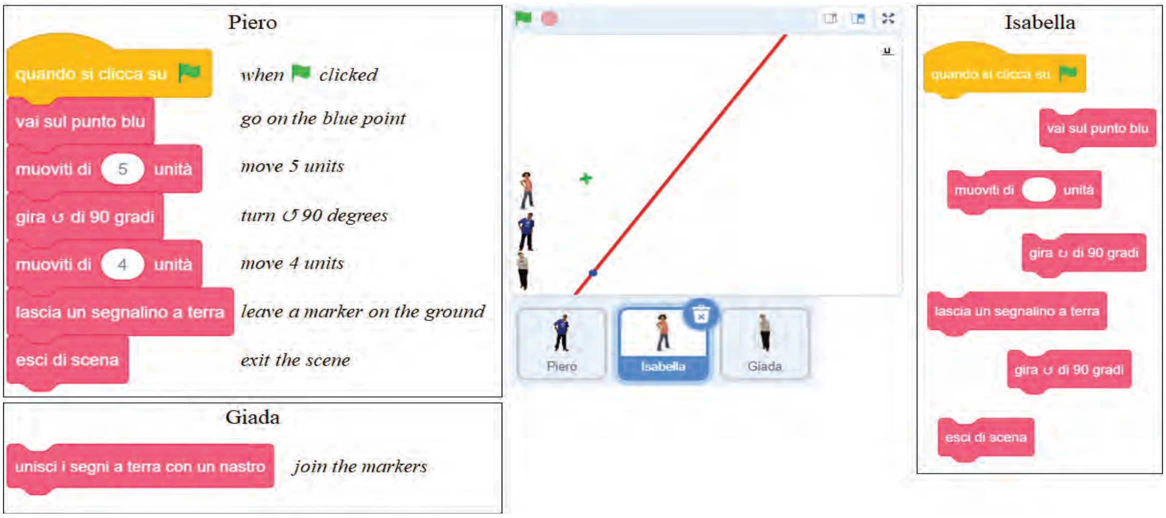

Figure 1: The Scratch visual programming artefact

The activity begins by clicking on the flag and executing Piero's program. Piero moves and performs a sequence of steps, leaving some markers on the stage (the markers represent the points to be symmetrized). Through the digital artefact, students have to provide instructions to Isabella, so that she can perform a choreography symmetrical of Piero's one with respect to a line crossing the stage transversely. By clicking on the flag again, students simultaneously display Piero and

Isabella’s movements on the stage. In this phase, they can carry out a first visual check on the correctness of the program she created for Isabella, by observing if the simultaneous Piero and Isabella’s movements create symmetrical choreographies. Finally, students execute Giada’s instruction “join the markers”. So, the artefact returns in feedback an image obtained by joining the markers left on the stage by Piero and Isabella with a broken line. In this way, students can verify if the geometric figure is symmetrical or not with respect to the line (see Figure 2). Therefore, they can check (in two different moments and in two different ways, that is by looking at the characters’ movements or by visualizing the figure obtained by joining the markers) if the instructions given to Isabella’s character are correct or not. If students are not satisfied with the program created for Isabella, they can make changes at any time.

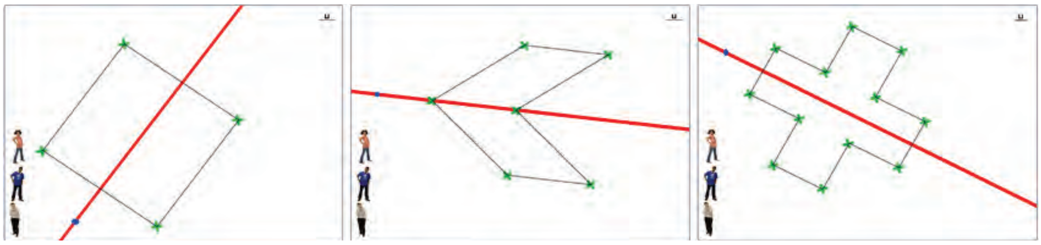

Figure 2: Examples of figures to be obtained on the stage at the end of the activity

The instruction blocks were created in the Scratch environment specifically for this activity by collecting different standard instruction blocks, in order to relieve students of the aspects related to programming and to not significantly affect their cognitive load. The text in the instruction blocks was designed to bring out mathematical meanings related to the concept of axial symmetry.

Methodology

The a-didactic activity, involving the use of the digital artefact described above, was experimented with 21 students of a fifth-grade class of the primary school of the “Istituto Comprensivo San Giovanni Bosco”, near Benevento (Italy). They had already carried out classroom activities with their teacher on axial symmetry, but only with vertical/horizontal lines, and they had never handled activities related to computer programming.

The experiment took place in the classroom, during 3 curricular lessons of 90 minutes each, in the presence of a researcher and the mathematics teacher of the class. It was conducted during the Covid-19 pandemic and the students respected the rules of distancing and the use of masks. In the first lesson, the students became familiar with the digital artefact. The researcher presented the characteristics of the Scratch environment by means of a video projection and she invited the students, divided in groups, to manipulate Scratch on the class computer. In the next two lessons, the students were divided into pairs based on their closeness in the classroom (only one group consisted of 3 members) and each student worked on her laptop.

Each lesson consisted of two main moments: an a-didactic moment and a moment of collective discussion, at the end of which the researcher carried out the institutionalization. During the a-didactic moments the students acted on the digital artefact and, for each choreography, they carried out the following task: “Create a Scratch program for Isabella to replicate Piero’s movements on the other side of the red line. Then ask Giada to join the markers”. Students communicated with each other to verbally validate their strategies.

Afterwards, the researcher delivered to each group a paper sheet with the screenshot of the stage on the PC as it appeared immediately after the execution of Piero’s program, that is, with the markers left on the ground by Piero. The students, communicating with each other to agree on shared answers, first carried out the following task: “Draw the marker(s) left by Isabella on the other side of the line. Then join the markers”. Then, they answered the following open questions: “What do you observe looking at the figure?”, “What do you observe looking at the programs of Piero and Isabella?”. In answering the questions, they could visualize the work done with the digital artefact.

We collected the following data: the video recordings of the screens of the PC used by the students; the paper sheets relating to each choreography filled in by students after the activity with the digital artefact; for each group, audio recordings of the whole activity with the digital artefact, as well as of the collaborative work moments related to the filling in of paper sheets; the audio recordings of the collective discussions guided by the researcher; the notes collected in class by the researcher and the teacher. To analyze video/audio data, we identified critical events, and transcribed and coded them to construct the storyline (Powell et al., 2003).

Preliminary findings

In this section, we show the preliminary findings of a qualitative analysis aimed to point out the students’ programming strategies during the learning activity. In the analysis, we took into account explicit references to the digital artefact - or its characteristics - appeared when the students worked with it, or in students’ oral and written productions. Out of respect for ethical requirements, in the following analysis students’ names are fictional.

The first programming strategy we observed is as follows: the students first visualized the execution of Piero’s program, then they created a program for Isabella and, finally, they simultaneously performed both Isabella’s and Piero’s programs. Only once the students thought they had obtained the right programs, they clicked on the flag in order to visualize their execution. This strategy was employed by most students in the initial phase of the activity with the artefact. Table 2 shows an example of application of this strategy realized by Sabrina.

Table 1: The first programming strategy used by Sabrina

			min. 2.02: Sabrina clicks on the flag and she	*min. 6.06*: She clicks on Isabella's icon.	*min. 10.33*: She creates Isabella’s program.	*min. 11.11:* She launches both Piero and Isabella’s

visualizes the execution of Piero’s program.			programs.

Sabrina visualized the execution of Piero’s program only once (see Table 1, min. 2.02) before constructing Isabella’s program (from min. 6.06 on). Later, after completing Isabella’s program, she ran both programs simultaneously (see minute 11.11). Nevertheless, after checking the execution of Isabella’s program, she understood that the program she created did not satisfy the required task (Isabella’s movements on the stage did not correspond to Piero’s ones on the other side of the line). At time 11.43, her groupmate Arianna, who had already completed the task, intervened in order to help Sabrina in programming, and, while observing Sabrina’s screen, she suggested a new strategy:

1	Arianna:	Let’s compare it with Piero, I copied from Piero, but… just I changed turn in that way, because she has to turn here, do you see? So, go on Piero and look that these do not have to be here *(she refers to some instruction blocks of Isabella’s program)*... So, go on Piero… [...]
2	Sabrina:	*(Sabrina clicks on Piero’s icon)*
3	Arianna:	Well, do not touch Piero’s program… *(Arianna clicks on the flag and she performs Piero’s program)* This is Piero’s program… Now you have to do the same thing with Isabella… Here it is *(Arianna scrolls the code area until she finds Piero’s program)* Here it is… I copied everything from here, just I changed...
4	Sabrina:	But so did I...
5	Arianna:	Here it is, now go on Isabella…

The strategy suggested and clearly explained by Arianna was the following: to “copy” the instructions included in Piero’s program, by dragging them, in the same order, in the code area of Isabella, reversing the direction of rotations (‘I changed turn in that way, because she has to turn here’, see line 1). After Arianna’s explanation, Sabrina seemed to focus on the aspect related to the reversing of the direction of rotations (line 4), by saying that she considered this aspect during the construction of the program, too. Afterwards, still interacting with Arianna, Sabrina edited Isabella’s program, by using the strategy suggested by her groupmate.
Table 2 shows an excerpt of application of this second strategy.

Table 2: The programming strategy used by Sabrina discussing with Arianna

		
min. 13.03: Sabrina clicks on Piero’s icon and she visualizes Piero’s program.	*min. 13.24*: Sabrina, interacting with Arianna, modifies the number of steps in Isabella’s program.	*min. 14.09*: Still interacting with Arianna and visualizing Piero’s program, Sabrina correctly builds Isabella’s program.

In this excerpt we see that Sabrina switches from viewing Piero’s program to correcting/constructing Isabella’s program. This passage from one character to another is repeated several times until Piero and Isabella’s programs appear “symmetrical”. Later in the activity, all the students in the class adopted this programming strategy, considered more effective.

In applying the first programming strategy (see Table 1) students focused on the visualization of Piero’s movements on the stage during the execution of the program. The absence of a grid made this strategy expensive, as the students had to establish the number of characters’ steps without a visual reference. On the other hand, the second strategy (see Table 2) was based on the direct visualization of Piero’s program, regardless of its execution.

As a result of using this second strategy, explicit references to the Scratch programs created by the students appeared in several students’ answers in the paper sheets delivered to them after working with the digital artefact. In particular, some students explicitly referred to some sentences displayed on the instruction blocks, such as “turn ... 90 degrees”, also reporting in written form the symbols of the arrows (see Figure 3). Furthermore, from some written productions relating to the question “Look at the program you created for Isabella and compare it with Piero’s program. What do you observe?”, it emerged that the students recognized that there was a sort of symmetry between the two programs.

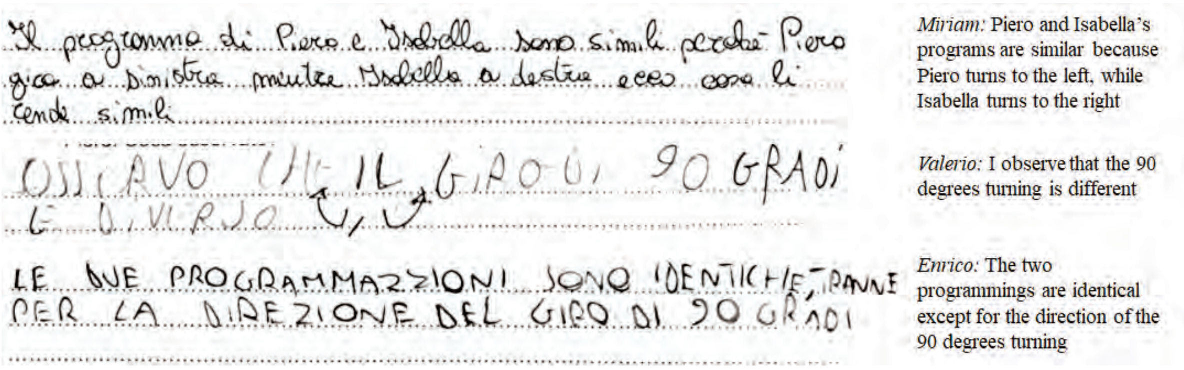

Figure 3: Some students’ written productions

As Figure 3 shows, the students spoke of “similarity” (e.g. Miriam) or even of “identicalness” (e.g. Enrico) between the programs of the two characters, except for the direction of rotations. Such observations became more and more frequent in the written and oral productions of students.

The use of the second strategy could indicate a purely reproductive (and not productive) students’ attitude. However, the reflection on aspects related to computer programming has allowed them to identify new strategies, better than the previous ones and more effective. In fact, the students, in using the first strategy, were not able to produce “symmetrical images”. It was precisely the failure of the strategy that led them to look for a new one, which allowed them not only to produce “symmetrical images” but also to identify aspects related to the definition of axial symmetry, such as the equidistance of corresponding points from the axis. This emerged, for example, during a moment of collective discussion, when a student, Francesco, referred to the movements of Piero and Isabella using the expression “the same distance run on one side and on the other side”.

Discussion and conclusions

This research aims to contribute to study how algorithmics and visual programming can be integrated into teaching practices as tools for learning mathematical concepts. Specifically, we designed an a-didactic activity based on the use of a digital artefact, realized in Scratch visual programming environment, for the learning of axial symmetry in the primary school. The task requires that three characters, Piero, Isabella and Giada, perform some choreographies in a show. The students visualize the predetermined Piero's movements, and they have to create a program for Isabella, by manipulating some suitable instruction blocks, so that Isabella realizes a choreography "symmetrical" to Piero's one with respect to an oblique line. The visualization of the execution of the predetermined Giada's program returns figures that students can verify as being symmetrical or not w.r.t. the line.

We experimented this activity with students of the fifth grade of primary school, who never handled classroom activities related to computer programming. The aim was to understand how the a-didactic activity, involving algorithmics and visual programming, influenced the rise of new solving strategies by students, linked to the construction of symmetrical images with respect to an axis. The qualitative analysis took into account the programming strategies adopted by students and the references to the algorithmic dimension in their oral and written productions. The preliminary findings showed the emergence of two main programming strategies. Firstly, most students created Isabella's program only by visualizing Piero's movements, and not the computer program which generated those movements. Such a strategy soon proved to be expensive and ineffective, in the sense that only few students were able to perform programs responding to the task. This encouraged the rise of a new strategy, also due to the collaboration among the students. The new strategy consisted of replying Piero's program for Isabella, by paying attention to reversing the directions of the rotations. Indeed, Piero and Isabella's programs had to allow their respective characters to move symmetrically w.r.t. the line. So, the directions of rotations had to be the one the reverse of the other. The emergence of this second strategy was linked to the identification of a sort of "symmetry" between the two programs. The new strategy was more effective than the previous one, both from an informatic point of view (i.e. students were able to realize "correct" programs) and, most importantly, from a didactic point of view (it allowed students to figure out some aspects linked to the axial symmetry, as, for instance, the equidistance of corresponding points from the axis). Therefore, visual programming could be a valuable learning tool, able to mediate mathematical meanings. Moreover, it could enable students to devise (new and more effective) solving strategies. In the future, we plan to test the a-didactic activity also with lower and higher secondary school students.

Acknowledgments

We would like to thank Mrs. M. E. Riccitelli, head teacher of the "Istituto Comprensivo S. Giovanni Bosco", San Salvatore Telesino (South Italy), and the teachers of the class involved in the experiment. This work is supported by a grant of the University of Campania "Luigi Vanvitelli" in the framework of V:ALERE 2019 (GoAL project).

Listing algorithms for combinatorics problems with variable parameter values: a case study

Adaline De Chenne[1] and Elise Lockwood[2]

[1]Oregon State University, United States; dechenna@oregonstate.edu

[2]Oregon State University, United States; elise.lockwood@oregonstate.edu

In this paper, we explore how a student used computer programming to solve counting problems with variable parameter values. We present a case study where a student, Allen, used computer programming as an aid in finding a closed-form solution for C(n,k)*, the number of ways to select* k *objects from a set of* n *distinct objects. We document some of his difficulties, as well as aspects of his solution that were key to his success. We discuss implications for future research that examines listing algorithms to find closed-form solutions for general problem types in combinatorics.*

Keywords: Combinatorics, student thinking, algorithmic thinking.

Introduction

Combinatorics is an increasingly relevant area of mathematics due to its applications in fields such as computer science and information science. Yet, research in combinatorics education indicates that students at all levels struggle to learn combinatorics (e.g., Batanero et al., 1997; Eizenberg & Zaslavsky, 2004). A repeated conclusion is that attending to the objects being counted in a problem (i.e., the set of outcomes) is productive for students (Lockwood, 2014), and there has been attention to how listing the outcomes can impact student understanding of underlying counting principles (Lockwood & Gibson, 2016; Wasserman & Galarza, 2019). Some of this work specifically focuses on students writing computer programs to list the outcomes (Lockwood & De Chenne, 2020; Medova & Ceretkova, 2021), where the students solve a counting problem by exhaustively listing and counting the outcomes using fundamental tools of Python, such as nested for loops and conditional statements. Because this line of research allows for students to construct and reason about algorithms for the purpose of better understanding an important area of mathematics, there is motivation to examine how similar methods can be applied to other topics in combinatorics.

In our previous work we have explored students writing computer programs in Python (e.g., Lockwood & De Chenne, 2020), and in these studies we have only examined students' solutions to counting problems with fixed parameter values. In these solutions, some of the parameter values are encoded as an intrinsic part of the structure of the code, such as the number of loops. However, many combinatorial problems, such as binomial identities, have variable parameter values and are almost never stated with fixed values. A next step is to examine how students can write computer programs to solve counting problems with variable parameter values. This next step has many anticipated difficulties, and in particular computational solutions to variable parameter problems often require recursion while their fixed-parameter-value counterparts do not. This can be a barrier for researchers and students, and researchers might look for alternative ways of addressing problems with variable parameter values that do not include the use of additional tools or techniques.

In this report, we analyze case-study data of a student who wrote a sequence of computer programs to aid in finding a closed-form solution for $C(n,k)$, the number of ways to select k objects from a set of n distinct objects. In doing so, we distinguish between combinations, which are unordered collections of objects, and permutations, which are ordered collections. By presenting these data, we seek to better understand (1) how the utility and development of algorithms for problems without fixed parameter values differ from those in existing literature, and (2) some of the difficulties and successes of the student that are unique to problems without fixed parameter values.

Literature Review and Theoretical Perspective

Student difficulties in combinatorics are well documented, and they include difficulty with distinguishing between problem types (Batanero et al., 1997) and with verifying that solutions are correct (Eizenberg & Zaslavsky, 2004). Lockwood (2014) has proposed a set-oriented perspective to counting, which is “a way of thinking about counting that involves attending to sets of outcomes as an intrinsic component of solving counting problems” (p. 31). Sets of outcomes refer to the collections of elements being counted in a counting problem. This perspective includes examining and using properties of individual outcomes, as well as structure in the entire set of outcomes, and is reinforced by Wasserman and Galarza (2019) describing how the encoding and conceptualization of sets of outcomes can influence solutions for category I and category II combination problems.

Additional research has investigated combinatorics in a computational setting, such as Medova and Ceretkova (2021) quantitatively assessing the relation between computing ability and combinatorial reasoning. In line with such work, we have examined ways to use computer programming as a means for students to interact with individual outcomes, and to write algorithms that would list the set of outcomes (e.g., Lockwood & De Chenne, 2020). We adopt the term ‘listing algorithm’ to refer to an algorithm that exhaustively lists and counts the set of outcomes, with the intention of being used to design a computer program. We are cognizant that algorithms are far broader in general and enumeration algorithms in combinatorics need not be used in a computer program. Hence, our use of listing algorithm is not intended to encompass all types of enumerative algorithms in combinatorics. When creating a listing algorithm, students must first decide on an appropriate way to encode the outcomes so that every outcome is represented, and no outcome is represented more than once. Then, the students must decide on an algorithm to list the set of outcomes. Hence, students have the opportunity to reason about outcomes individually, as well as the set of outcomes collectively, which reflects important aspects of a set-oriented perspective. Although there are numerous ways to write listing algorithms, the primary tools in this report are for loops and conditional statements in Python.

Medova and Ceretkova (2021) have reported on computational solutions to problems with variable parameter values done by students in a Programming 2 course, but it is unclear how students with less programming experience may approach similar problems. We have previously only had students write computer programs to solve problems with fixed parameter values, while many common combinatorial problems have variable parameter values. For example, a fixed-parameter-value problem might be “How many ways can you flip a coin 5 times if exactly 3 of the coins landed on heads,” while a problem with variable parameter values is “How many ways can you flip a coin n times if exactly k of the coins landed on heads." Designing listing algorithms for problems with variable parameter values presents additional difficulties, which may include learning new computational skills such as recursion. We are motivated to examine ways that students can engage in generalizing solutions from problems with fixed parameter values.

Methods

We present a case study of one student, Allen (pseudonym), who wrote computer programs to aid in finding a closed-form solution for $C(n,k)$ during a set of task-based interviews. These data come from a study conducted in the United States that examines the role of computing in combinatorics education. Allen was recruited from an introductory computer science class; he was selected based on a survey, which indicated that Allen had not taken a discrete class, and although he had been exposed to some counting problems in high school, he did not appear to recall formulas from that period. He also indicated that he had taught himself how to write programs in Python in high school and was interested in pursuing a degree in computer science. We chose Allen as a participant because he exhibited a strong computer science background. We interviewed Allen in person over three 90-minute sessions, and we focus on the last session in this paper. We chose these data because they provide an example of a student using computational techniques to solve a problem with variable parameter values. We do not claim that other students would produce similar results. Indeed, Allen's mastery of fundamental computer science ideas indicates that most students would not produce similar results, but we nevertheless feel our findings have useful theoretical implications about using programming to solve problems.

Task

These data occurred after Allen compared an incorrect solution to a correct solution of the Book Problem, which states "Suppose you have eight books and you want to take three of them with you on vacation. How many ways are there to do this?" The solution to this problem is $C(8,3) = 56$. This was the first time the authors presented a problem involving combinations (rather than permutations) to Allen, and his original solution was $P(8,3) = 336$. After the authors asked Allen to list the first ten outcomes that a listing algorithm would produce, Allen noticed that his solution (which he had developed for permutation problems in previous interviews) was incorrect because it produced the same outcome more than once. While Allen was able to create a listing algorithm that gave him the correct answer, he was unable at first to justify an appropriate mathematical expression by hand. The data we present in this report is of Allen finding a closed-form solution for $C(n,k)$ by writing a sequence of computer programs to find specific values of $C(n,k)$ and comparing those values to $P(n,k)$, which he could produce by hand. These data were unanticipated by the authors, who did not ask Allen to find a closed-form solution for $C(n,k)$, but in the course of the interview decided to allow Allen to pursue a solution. Allen's work occurs in three stages: writing a listing algorithm for $C(8,3)$, writing a listing algorithm for $C(n, 3)$ for various values of n, and writing a listing algorithm for $C(n,k)$ for various values of n as k increased.

Allen had previously worked on problems involving Cartesian products, arrangement with repetition, and arrangement without repetition. We provided Allen access to a Jupyter notebook on a desktop computer while he was being interviewed, which allows users to write computer programs in Python as well as write prose in Markdown. Jupyter notebooks are arranged into cells, where computer programs can be written into individual cells in the same notebook. This allows for a single notebook to include multiple questions and listing algorithms simultaneously, so that the user can easily reference prior work. During the first session, we included a brief Python primer that described how to use fundamental tools in Python, such as lists, loops, and variables. Allen had already written listing algorithms for problems involving Cartesian products, arrangement with repetition, and arrangement without repetition. We provided printed problem statements and paper to write on.

Data Analysis

We chose this episode because it demonstrates how a student used computational techniques to aid in the development of a closed-form solution for a problem with variable parameter values. The first author identified key moments where Allen used his computer programs to reason about the relationship between *C(n,k)* and *P(n,k).* She then created an enhanced transcript of the episode by including pictures of Allen's work and screenshots of the computer programs he wrote. This analytic process allowed us to make a narrative of Allen's reasoning about *C(n,k)* as it relates to *P(n,k)*, facilitating our articulation of Allen's case and the role of listing algorithms in his work .

Results

We categorize the results into three sections: listing algorithm for *C(8,3)*, listing algorithm for *C(n,3)*, and listing algorithms for *C(n,k)*; this reflects the chronological order of Allen's progress, and informs us of the difficulties Allen encountered, and how he resolved them. Further, this progression demonstrates distinct steps Allen took as he generalized his listing algorithm.

Listing Algorithm for *C(8,3)*

Allen's first solution to the Books Problem was $8 \times 7 \times 6$, which is the number of ways to arrange three of the books. However, this expression accounts for different arrangements of the books as distinct outcomes, whereas the question does not. A correct solution is $8 \times 7 \times 6/3 \times 2 \times 1$. We asked Allen to verify if his solution was correct by describing a listing algorithm, and then writing down the first ten outcomes the algorithm would produce. Allen described an algorithm that would list all arrangements of three books (which he had implemented in Python for previous problems), which is incorrect but consistent with his solution. Allen then wrote the outcomes in Figure 1.

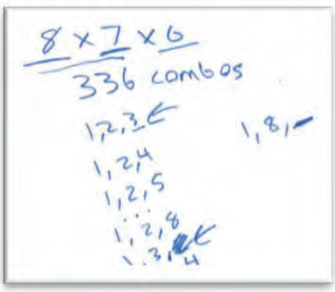

Figure 1: Allen's Partial List of Outcomes for the Books Problem
