The second step is to analyse in terms of task type T_i and corresponding techniques τ_i used to solve T_i. Let us first take an example from arithmetic where students are asked to calculate the following tasks (Lindhardt et al., 2021, p.104).

a. $6+(-7)$
b. $5-(-7)$
c. $-3-(-6)+(-4)-2$

Tasks a. and b. are simple (they can be solved by one technique). Task a. is what we have named type T_4: addition of negative integer to a positive integer, with corresponding technique τ_4: $a+(-b)=a-b$; where b. is a task of type T_6: subtraction of negative integer from negative integer, with corresponding technique τ_6: $a-(-b)=a+b$. Task c. requires both techniques τ_4 and τ_6 and is thus a combination of more elementary tasks.

An example of a type of task from algebra is T_{15}: solve a first-degree equation. Tasks of this type appear for instance in the written national 2019 exam (Prøvebanken, 2021)

Solve the equations

d. $5x+9=34$ $\qquad x=$ _______
e. $3x+4=6x-5$ $\qquad x=$ _______

They can be solved by the technique τ_{15}: involving addition, subtraction, multiplication, and division on both sides of the equal sign.

In general, exercises can contain several questions, where not all questions can be answered by a single technique. This means, that once a model of types of tasks and corresponding techniques has been established, more complex questions must be decomposed in tasks of the types established (Winsløw et al., 2013). It is relatively straightforward to identify types of tasks and techniques in arithmetic and algebra as shown above (cf. Wijayanti & Winsløw, 2017). The next step is to identify *themes* (groups of practice blocks unified by a technology) and *sectors* (groups of themes unified by a theory).

Example of PRM theme and sector

The problem of ordering two given fractions can, according to special cases, necessitate different techniques. It thus leads to group of practices which are taught together and are unified by a shared discourse about techniques, involving characteristics of the special cases, and descriptions of the techniques. Table 1 is type of task T_i and corresponding techniques τ_i from the analysed textbook material and written exam and gives an overview of the theme of PRM according to fractions.

Table 1. Theme of PRM based on textbooks (Kontext) and written exam (FSA) according to fractions

Type of task	Techniques	Kon-text+ 5	Kon-text+ 6	Kon-text+ 7	Kon-text+ 8	Kon-text+ 9	FSA 2020 Dec	FSA 2021 May
T_{19}: Given two unit fractions $\frac{1}{a}$ and $\frac{1}{b}$, which is largest	τ_{19}: The fraction with the lowest denominator is largest i.e., $a < b \Rightarrow \frac{1}{a} > \frac{1}{b}$							
T_{20}: Examine which fraction with like denominator and different numerators, $\frac{a}{c}$ and $\frac{b}{c}$ is largest.	τ_{20}: The fraction with the highest numerator is largest i.e., $if\ a < b \implies \frac{a}{c} < \frac{b}{c}$							
T_{21}: Examine which fraction with like numeration and different denominators fraction $\frac{a}{b}$ and $\frac{a}{c}$ is largest.	τ_{21}: The fraction with lowest denominator is largest i.e., $if\ a < b \implies \frac{a}{b} > \frac{a}{c}$							

It is characteristic of Danish textbooks that the same types of tasks reappear year after year, while the theme as a whole may still be relatively disconnected. This theme is a part of a larger "fraction sector", unified by a theory which involves both informal and more formal representations and properties of fractions, from addition of simple fractions with pizza diagrams to calculation rules given with algebraic symbolism.

Methods to construct the diagnostic test tool

The aim of the diagnostic test tool is to detect what arithmetic and algebraic techniques are particularly problematic for Danish students at early lower secondary school, and to get insight in the students' theoretical knowledge especially in relation to basic algebra. The development of the diagnostic test tool is based on the PRM and was inspired by an earlier project by Cosan (2021) on middle school arithmetic.

Items designed to test techniques are straightforward to construct. And several items can be included to investigate how variations influence on success rates. For example, the item "Compute $6 + (-5)$" represents the type of task T_4: addition of negative integer to a positive integer, as defined above.

It is more difficult to design items that detect students' theoretical knowledge which includes technology to describe and explain techniques. The item "Explain why $a - (-a) = 2a$" requests from students a piece of discourse justifying the algebraic rule, which may appeal to more or less formal theoretical principles. For instance, some students may refer to "two minuses can be replaced by a plus" as an overarching principle in such contexts; this could, in fact, be part of a theory that some students hold. In the ATD sense such theory elements are empirical objects, to be discovered and traced.

Items can also simply request a description of a technique (i.e., a technology), e. g. "Explain how you would determine which of the fractions $\frac{2}{5}$ *and* $\frac{3}{5}$ is largest"

Results from the pilot test of the diagnostic test tool

The diagnostic test has been pilot tested by 25 grade 7 students (12–13-year-old) in lower secondary school in the capital of Denmark. The students got 45 min. to do the 67-item paper and pencil test.

Table 2. Sum of type of answers in the test

Correct answer	Incorrect answer	No answer	Sum
455	306	914	1675

Table 2 shows that more than half of the items has not been answered by the students. Despite this, it is possible to give some preliminary results. The following are examples of analyses of test answers in relation to the previously selected examples from the PRM.

Table 3. Item and associated sum of answers in the test

Item	Item number	Correct answer	Incorrect	No answer
$6 + (-5) =$	1.4	20	2	3
$7 - (-9) =$	1.5	8	16	1

Table 3 shows that almost all the students can solve the item of task type T_4: addition of negative integer to a positive integer. But only a third of the students could solve the item of task type T_6: subtraction of negative integer from negative integer. This result indicates that students know that adding opposite is the same as subtraction, but they cannot apply the rule $-(-a) = a$.

By varying the items given for a specific type of task, we can also discover specific features of type of task. For example, the test contains variations of the task type T_{15}: solve a first-degree equation (discussed above). These variations result in hugely different success rates.

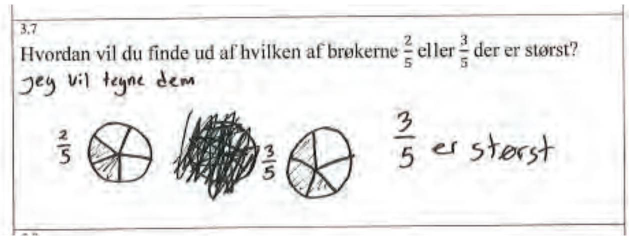
Table 4. Test results of variations of the task type T_{15}

Item	Item number	Correct answer	In-correct	No answer
$36 - \_\_\_\_ = 29$	1.1	21	2	2
$8 + 4 = \_\_\_\_ + 5$	1.6	4	18	3
$\_\_\_\_ - 32 = 45$	2.1	23	1	1
$2x = 10$	2.5	10	1	14
$7x - 7 = 13 - 3x$	4.7	8	9	13

When comparing the results from item number 1.1, 1.6 and 2.1, item number 1.6 has significantly fewer correct answers. One possibly crucial difference between 1.6 and the other questions is the location of the unknown. In 1.6 the unknown is located on the right side of the equal sign. That this could make a big difference is confirmed by a longitudinal examination of how middle school students understand the equal sign and equivalence of equations (Alibali et al, 2007).

The purpose of item number 3.7 is to get insights in students' argumentation for which fraction is largest. And we get answers like: "If the denominators are the same, I just look at the numerators which are the highest" and "I look at the denominators and if the fractions have the same denominator, then I will look at the numerator which one is the largest". With such items, we can detect not only a (correct) technique but also what it is, and a level of technology.

In the following two examples, the student's argumentation is based on pizza representations of fractions, which are also extensively used in Danish textbooks. Figure 2. "I want to draw". Figure 3. "By seeing it as a circle and look where there are most fields that are filled".



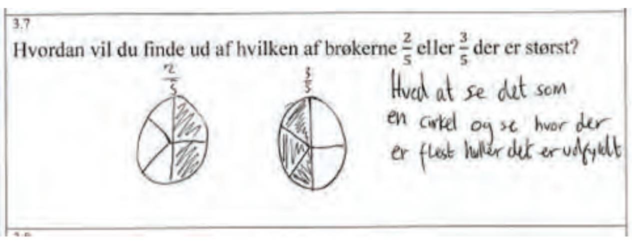


Figure 2. Student answer to question 3.7 **Figure 3. Student answer to question 3.7**

In Figure 2, we can see the representation serves as an argument but in Figure 3, this wordless technology fails because of missing the usual convention, that the circle must be divided into equal parts. The diagrammatic representation has evident forces in giving meaning to fractions (between 0 and 1) for young children; but the division of a circle into five equal parts is also a task which contain other meanings (including angles etc.) that are in some sense irrelevant to the task. Varying this task to include fractions with large denominators or nominators would evidently also make this technology fail.

Conclusion

In this paper, we have shown by a few examples, how ATD and the construction of a PRM, can be used as a foundation for developing a diagnostic test tool, to examine students technical and theoretical knowledge. By first constructing the PRM based on textbook material, written examination, and common core. Then grouping the task and corresponding techniques in themes and sectors according to shared technology and theory. The PRM is then used to design the diagnostic test items in line with the tasks, techniques, and level of theory in the PRM. In that way the diagnostic test is aligned with the knowledge to be taught and provide explicit control on what is being tested.

Among the examples from the pilot test, we discussed the students' difficulties with relating subtraction and additive inverse, and especially with repeated additive inversion. These examples indicate that the diagnostic test, based on the PRM, can be used to identify significant obstacles. This is crucial for the next steps in our doctoral project.

The next step in the project is to apply the results from the pilot-test to inform and strengthen the PRM. Then to revise the diagnostic test tool and complete the final test in four classes, before and after the teaching intervention. The overall aim is to investigate the transition from arithmetic to algebra and to explore if and how interventions with research-based material can support teachers' efforts to teach basic algebra.

Primary school children's justifications of equalities

Susannah Unteregge

TU Dortmund University, Germany; susannah.unteregge@tu-dortmund.de

A focus on mathematical structures and relationships in mathematical activity is important for the development of algebraic thinking. A comprehensive and flexible understanding of equality, which in particular includes a relational perspective on equality, is an important prerequisite for this. In the project, that forms the basis of this paper, substantive learning environments were further developed by use of Term fields and tested in teaching-learning experiments. In the video-based qualitative analyses, the focus is on the justification processes of fourth graders in the context of equalities. This paper presents and discusses the main results of the study, four different ways of justifying equalities and their characteristics.

Keywords: Early algebra, understanding of equalities, equal sign, mathematical reasoning.

Introduction: understanding of equalities in primary school

A call for greater support of algebraic thinking in the early grades is made in current research (e.g., Steinweg, 2017). Particular emphasis is placed on mathematical structures, found to be central to the development of early algebraic thinking (Hewitt, 2019; Steinweg, 2017). According to Steinweg (2017), *equivalence structures* are an algebraic key idea that focuses on the relation of given numbers, sums, products, etc. in equations. However, in primary school the equal sign is often introduced as an operational sign, prompting calculation.

Studies have found that students interpret the equal sign predominantly operationally and have difficulty taking a relational and structural view when needed (e.g., Eichhorn et al., 2018; Stephens et al., 2013). Some authors further differentiate between views of the equal sign. For example, regarding the relational understanding of the equal sign, Stephens et al. (2013) distinguish between a *relational-computational* view and a *relational-structural* view. A relational view is crucial for flexibility in mental calculation (Rechtsteiner & Rathgeb-Schnierer, 2017; Steinweg, 2017). This is an important skill in elementary school arithmetic and also essential as preparation for algebra (Jones et al., 2012).

In addition to the numerous studies concerning the use of the equal sign and the solving of formal equations, approaches have also investigated the content-related understanding of equalities in primary school (Mayer, 2019; Nührenbörger & Schwarzkopf, 2015). In these studies, substantial learning environments were developed, incorporating task formats that children are familiar with from textbooks, such as *Number walls* and *Computing chains*. These task formats share a specific external structure, combining numbers and operations in a way that allows numerous basic mathematical activities to explore structures and relationships. Thus, the learning environments focus on equality but without the use of the equal sign. The results of these studies show that primary school children can indeed take a relational view of equalities and interpret them structurally.

Comparing the results of the studies described above using quite different learning environments, it is evident that children interpret equalities differently depending on the context and form in which they are presented. Seo and Ginsburg (2003) use the term *pseudo-flexibility* to describe children's context-dependent interpretation. Children can take an operational view or different relational views of equalities, but these views appear to be entirely determined by the context and are mostly not linked to each other.

The project, from which data is excerpted and analyzed in this paper, has two objectives. On the one hand, a teaching-learning arrangement was developed that can stimulate a comprehensive and flexible understanding of equality in children by using *Term fields* (see Figure 2). On the other hand, the children's justifications of equalities are analyzed qualitatively. The concepts from the literature described above serve as a starting point for analyzing the justifications provided by the children in this project. This paper focuses on the research question: How do children justify discovered equalities in the context of the developed learning environments?

Methodology and design

In line with the aim of the project, qualitative interview studies about German primary school children's conceptions of mathematical equality were conducted. The studies focus on two learning environments that were planned on the basis of already existing well known substantial task formats such as *Arithmetic triangles* and *Number sequences* (see Figure 1). The latter were enriched by using design principles developed from theory and study results.

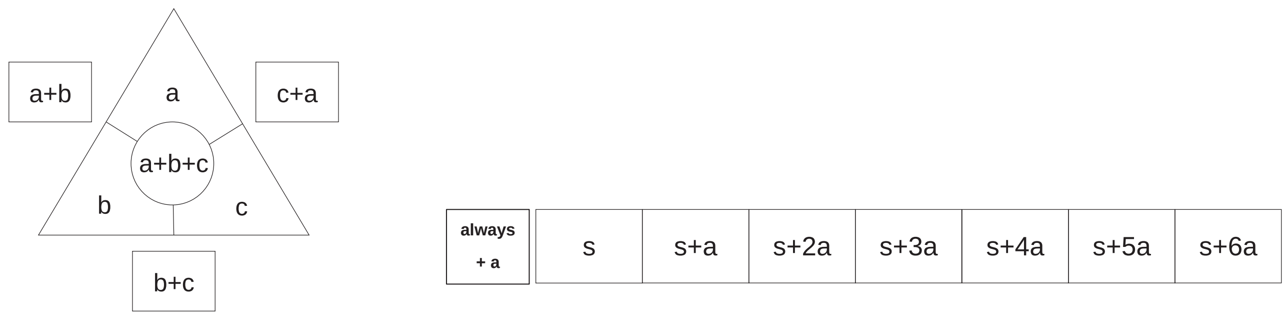

Figure 1: General structure of the task formats *Arithmetic triangles* and *Number sequences*

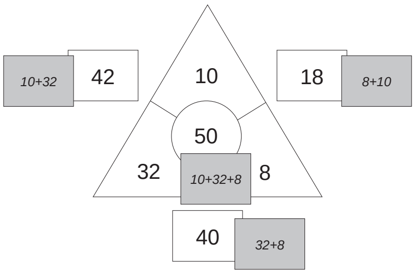
The central feature of both learning environments lays in the combination of a substantial task format and formal representation of appropriate equations. The children first work on tasks that encourage them to explore equalities in the context of the task formats and ask them to describe and justify these equalities (e.g., "Calculate the sum of the inner numbers and the sum of the outer numbers of the arithmetic triangle."). The goal is to develop a content-related relational concept of equality. Content-related does not refer to a factual context, but to the task formats, e.g. the arithmetic triangles. The relationship between the numbers of an arithmetic triangle is supported by the visual structure of the task format. Similar to the way Nührenbörger and Schwarzkopf (2015) used "Term walls" with notated calculations instead of results in the context of "Number walls" in their study, the learning environments in the present study were enriched by using Term fields, i.e. small sticky notes with terms (e. g. 10+32) related to number fields (e. g., 42) of the task format (see Figure 2).



always + 4	10	14	18	22	26	30	34
	10	10 +4	10 +4+4	10 +4+4+4	10 +4+4+4 +4	10 +4+4+4 +4+4	10 +4+4+4 +4+4+4

always + 8	10	18	26	34	42	50	58
	10	10 +8	10 +8+8	10 +8+8+8	10 +8+8+8 +8	10 +8+8+8 +8+8	10 +8+8+8 +8+8+8

Figure 2: Term fields that explicate calculations behind the numbers

Term fields are meant to serve as a kind of exploration tool to make explicit the essential structure of the task formats. They should be used as a basis for explaining relationships between number fields of the task format. In this way, children have an opportunity to focus on structures between terms in addition to compute them. Based on students' work with the Term fields, the students are given appropriate tasks for assigning equations to arithmetic triangles and number sequences, as well as tasks for evaluating, completing, and correcting equations. The equations always consist of terms that arise or potentially arise from the task format (Figure 3, see associated arithmetic triangle and number sequence in Figure 2). The children's attention is to be focused on the structure of the terms by means of certain guiding questions that are repeatedly asked during the interview (e. g., "From which triangle/number sequence was the equation formed?", "Why is the equation (not) correct?").

$$\boxed{2 \cdot 10+32+8 = 10+32 + 32+8 + 8+10}$$

$$\boxed{10 + 8+8+8 = 10 + 4+4+4+4+4+4}$$

Figure 3: Equations consisting of terms that arise from an arithmetic triangle and a number sequence

A total of 42 collaborative peer interviews, each with two fourth grade children, were conducted on the described learning environments. A pre-test was administered to each student at the beginning of the first interview. Students were given a set of equations to sort into two boxes ("true" and "not true"). Some equations were incomplete and had to be completed first. The pre-test was used to determine the children's interpretation of the equal sign before working in the learning environments. The children were randomly selected by the teacher and had neither previously encountered the Term field learning environments nor Arithmetic triangles or Number sequences in class. At the beginning of the interview series, the task formats were worked out together. The interviews were videotaped and largely transcribed. The analysis of the data follows the interpretative paradigm (Krummheuer & Naujok, 1999; Voigt, 1991). In particular, Steinbring's theory of the construction of new mathematical knowledge in classroom interaction is used to reconstruct the respective reference contexts of the children while they were justifying equalities (Steinbring, 2005). Thus, different ways of justifying were inductively reconstructed. These are presented and discussed below.

Empirical results and discussion: ways of justifying equalities in a range between result orientation and structure orientation

Equalities can be interpreted in different ways and, accordingly, justified differently, depending on which aspects of equality are focused on. The data analysis showed that children develop and use different justifications for equalities in the context of the learning environments, which can be located in a range between result orientation and structure orientation (see Figure 4). Previous findings from the literature described above were incorporated and extended in the development of the four categories. For example, the analyses confirmed the two relational views of equality, relational-computational and relational-structural, suggested by Stephens et al. (2013). In the study presented here, it was found that these views of equalities could be further differentiated by distinguishing between determination of overall and intermediate results (category 1 and 2), and using structure with or without generalized approaches (category 3 and 4). Category 1 and 2 correspond to a relational-computational view as defined by Stephens et al. (2013), while category 3 and 4 correspond to a relational-structural one (see Figure 4). The children in the study didn't show a purely operational view of equalities in the interviews. However, students' operational view was evident in the separate pre-test. The learning environments were intentionally designed to stimulate a relational interpretation of equalities by including the task formats Arithmetic triangles and Number sequences.

Justifications by
1. determining **overall results**

2. determining **intermediate results**

3. using a **structure** of the arithmetic terms

4. using a **structure** of the arithmetic terms
with generalized approaches

Figure 4: Justifications for equalities in the range between result orientation and structure orientation

In contrast to the study by Stephens et al. (2013), the study presented here reconstructed the particular situational view behind a justification, rather than investigate a child's fundamental concept of equality. In the following, the four categories of justifications are explained using selected episodes from the interviews.

Justifications by determining overall results

One way of justifying equality, evident in the present study, is based on determining the overall results of the terms. Each term in an arithmetic triangle or a number sequence is perceived as a separate task and their respective values are determined independently, and then finally compared. Charlie and Fabian evaluated equations formed from arithmetical triangles and corrected them if necessary. The following equation was placed on the table: 42 + 8 = 10 + 32 + 8

Interviewer: Why is that true (points to the equation)?
Charlie: (Pulls the equation towards him.) Forty-two (points to 42 on the left side of the equation) plus eight (points to 8 on the left) is fifty. Ten (points to 10 on the right) plus thirty-two (points to 32 on the right) is forty-two plus eight (points to 8 on the right) is fifty.

Charlie determined the overall results of both sides of the equation separately (50) by adding the summands linearly from left to right.

$$\underbrace{42 + 8}_{50} = \underbrace{\underbrace{10 + 32}_{42} + 8}_{50}$$

Figure 5: Reconstruction of Charlie's justification by determining overall results on each side

Justifications in this category suggest that the children make a strongly result-oriented interpretation of the terms. They do not direct their attention to the mathematical regularities underlying the terms but focus on the results. In the range between result and structure orientation, such a way of reasoning is to be located correspondingly far to the left (see Figure 4).

Justifications by determining intermediate results

Another way of justifying relies on the determination of intermediate results. This involves determining selected term components of arithmetic triangles and number sequences and comparing the resulting partial results. Characteristic for such justifications is the omission of obviously equal term components occurring on both sides of the equation (e.g., equal starting numbers in number sequences or equal inner numbers in arithmetic triangles). Sometimes longer components of the terms are left out of the evaluation of equality, sometimes only single numbers, as in the following example. Lara and Grace evaluated equations which could have been formed from number sequences: 10 + 3 + 3 + 3 + 3 = 10 + 6 + 6

Interviewer:	Why does it fit?
…	…
Lara	That's both twelve (points to the equation), always.
…	…
Lara	So that together are twelve (taps the sixes on the right side) and three plus three plus three plus three (taps the threes on the left side) are also twelve again.

The summand *10*, which occurred on both sides of the equation (starting number in the task format Number sequences), was omitted by Lara when evaluating the equality. She calculated only the non-identical term components (12 each), compared the intermediate results and concluded based on their agreement that the equation is correct.

$$10 + \underbrace{3 + 3 + 3 + 3}_{12} = 10 + \underbrace{6 + 6}_{12}$$

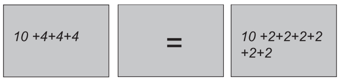
Figure 6: Reconstruction of Lara's justification by determining intermediate results on each side

Justifications in this category, point to a predominantly result-oriented understanding of equality. Compared to the previous category, however, such justifications are still somewhat more relational, since equal values are compared and deliberately disregarded. The location of these justifications in the range between result orientation and structure orientation is therefore on the result-oriented side, although not quite as strongly to the left as that of the first category (see Figure 4).

Justifications by using a structure of the arithmetic terms

Another way of reasoning is based on focusing and comparing the two terms of an equation with respect to their structure and their relation to each other. The justifications refer to the concrete numerical values. There are many differences in how the children relate the structures of the terms. This depends on which mathematical laws they (implicitly) refer to. Rachel and Kate each wrote down different plus numbers and the corresponding term fields for a number sequence with starting number 10 and target number 22. As part of the task, the interviewer combined one of Rachel's term fields (10+4+4+4) and one of Kate's (10+2+2+2+2+2) into an equation. The children agreed with it and justified their decision:

Kate: Here are (points to term field 10+2+2+2+2+2) uh, wait a minute (.) one two three four five six times (taps on the twos one after the other) and here are three times (points to term field 10+4+4+4) and that (points to the left term field) is the double of it (points to the right term field) so that- and here (points to the right term field) are six times and there are three times (points to the left term field) and three is half of six



… …

Rachel: And two and four is also the - so two $\#_1$ is half of four.

Kate: $\#_1$ Exactly. I just said that.

… …

Rachel: Yes, because here are six t- oh (points to term field 10+2+2+2+2 and moves it by mistake) six times (points to the term field again) and there are three times (points to term field 10+4+4+4) and then it must work.

The terms were interpreted multiplicatively. The size and the number of the summands of one side (size: 2; number: 6) were related to the size and number of the summands of the other side (size: 4; number: 3). The reasoning implicitly referred to the law of constancy of the product.

$$\begin{aligned} 10 + 4 + 4 + 4 &= 10 + 2 + 2 + 2 + 2 + 2 + 2 \\ \boldsymbol{10 + 3 \bullet 4} &= \boldsymbol{10 + 6 \bullet 2} \\ &= \boldsymbol{10 + (6:2) \bullet (2 \bullet 2)} \end{aligned}$$

Figure 7: Reconstruction of Rachel's and Kate's justification by using a structure of the arithmetic terms (based on the law of the constancy of the product)

Justifications in this category point to a predominantly structure-oriented interpretation. The interpretation implies mathematical regularities that underlie the structure of the terms. Such justifications are accordingly on the structure-oriented side.

Justifications by using a structure of the arithmetic terms with generalizing approaches

The fourth way of justification, like the third one, refers to the comparison of the structure of terms and their relation to each other. The justifications are also based on mathematical laws. However, such a reasoning is not only based on the concrete numerical values, but is detached from them by making generalizable statements. The degree of generalization can vary. Lara and Grace used term fields to justify why 34 occurred in both the +8-sequence and the +4-sequences. Lara's reasoning was similar to Rachel's and Kate's, but showed clearly generalizing approaches:

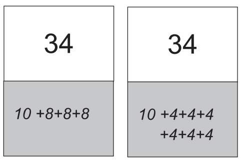


Figure 8: Term fields for the 34 from the +8 sequence and the +4 sequence to which the children refer

Lara: Then you have to take those two times, that's six and then six times (writes down her idea on a piece of paper)

$3 \cdot 8 = 24$
$2 \cdot 3 = 6$
$6 \cdot 4 = 24$

… …

Lara: So, I first have three times eight are twenty-four, uh but because I have half of the eight, uh you have to take the double of the front, so what you, with which number

	you multiplied that. So we have to- theoretically you have to halve here (points to "8" in "3•8=24" on her note) and double here (points to "3" in "3•8=24" on her note).
…	…
Lara	So, you you you double the three (points from "3" in "3•8=24" to "6" in "6•4=24") and halve the eight (points from "8" in "3•8=24" to "4" in "6•4=24"). Then a four will be written there and, you know what I mean? (Looks at Grace.)
…	…
Lara	You halve, you dou- halve the front number (points briefly to her note) or you halve the back number, you halve one number and you double the other one and then the same result comes out.

Lara justified the equality of the terms based on her written representation of her idea. She shortened the terms of the relevant term fields by multiplicative representation of the same summands and by omitting the identical starting numbers. Her justification contained generalized approaches. She replaced the number of summands, now represented by the first factor in each case in her representation, with a general description ("with which number you multiplied that"). When Grace didn't understand, she first concretized her idea using the exemplary numbers of the task ("you double the three and half the eight"). In terms of content, Lara's idea referred to the constancy of the product. Later she expressed her idea again in a highly generalized way. She replaced both the first and the second factor with a general description ("You (...) halve the front number or you halve the back number, you halve one number and you double the other one and then the same result comes out."). In addition, Lara clarified that it doesn't matter which of the numbers is halved and which is doubled. She moved away from concrete numerical values and instead used descriptive word variables.

$$
\begin{aligned}
10 + 8 + 8 + 8 &= 10 + 4 + 4 + 4 + 4 + 4 + 4 \\
\mathbf{10 + 3 \bullet 8} &= \mathbf{10 + 6 \bullet 4} \\
&= \mathbf{10 + (2 \bullet 3) \bullet (8:2)}
\end{aligned}
$$

(one number : 2) • (2 • other number) = one number • other number

Figure 9: Reconstruction of Lara's justification by using a structure of the arithmetic terms with generalized approaches (based on the law of the constancy of the product)

Justifications of this category suggest that the children have a strong structure-oriented understanding of equality. The relationship between the terms is interpreted and explained on a more general level with regard to the mathematical regularities on which it is based. The classification of such generalizing justifications takes place far on the structure-oriented side.

Closing remarks

The analyses showed that children use different justifications in the range between result orientation and structure orientation, (implicitly) refer to appropriate mathematical laws and generalize these to different degrees. The way of justification depends on different factors, e.g. on the numerical values, the suggestions of the other child or the impulses of the interviewer. This connection will be examined in more detail in further data analysis.

The presented learning environments, which combine content understanding and formal representation of equations with the help of term fields and focus on sharing discovered equalities and possible justifications of these, can contribute to stimulate a flexible understanding of equalities.

Students' intuitive conceptions regarding the concept of set

Ioannis Vlachos

National and Kapodistrian University of Athens, Greece; jvlah@math.uoa.gr

Abstract: *In this study, a questionnaire was administered to different-aged students in order to explore the intuitive conceptions they hold regarding the concept of set. A number of different conceptions emerged. Students' scores per grade were compared in order to investigate the effect Mathematics education has on their conceptions.*

Keywords: Set, intuitive conceptions, infinity.

Introduction

The concept of set is fundamental in modern mathematics. In school mathematics, the concept of set is used in various contexts, generally in an inconsistent manner (Fischbein & Baltsan, 1998). In the curriculum of most countries, sets are included in Algebra as a means of defining the concept of function, express the solution of an inequality etc.

The set concept is accepted in mathematics as a primitive, undefined concept. Instead of a formal definition one starts with an intuitive model, the idea of a collection of objects (Fischbein & Baltsan, 1998). In order to grasp the essence of a set, students need to be taught the formal properties and aspects of sets in school mathematics. If that doesn't happen, students can only rely to their intuitive conceptions regarding the set concept. Spontaneous conceptions are the result of generalization of everyday experience in the absence of systematic instruction and can lead to the creation of "spontaneous concepts" (Karpov, 2003). Such concepts are not conscious and often differ from scientific ones. Scientific concepts, once acquired by students, begin to mediate their thinking and problem solving. Thus, the instruction of such concepts plays a decisive role in their mental development facilitating their ability to operate at the level of formal-logical thought (Karpov, 2003).

Theoretical framework

Spontaneous conceptions that are contradictory to scientific conceptions (conceptions that experts have consensus on) are named misconceptions. Fischbein and Baltsan (1998) identified a number of students' misconceptions. The most profound being the following: (a) there must be at least one common property or a relationship between elements of a set; (b) a set must contain at least one element; (c) a set can contain repeated (not discrete) elements; (d) two sets are equal if they contain the same number of objects; and (e) a set cannot contain an infinite amount of elements. Bagni (2006) showed that students might be unable to distinguish between the concepts of "inclusion" and "belonging" especially when they are dealing with various semiotic systems (verbal, diagrammatic and symbolic). Lastly, Tsamir (2001) found that students hold contradictory ideas when they are asked to compare the number of elements of infinite sets. The most prominent categories of ideas were: (a) all infinite sets are equivalent; (b) infinite sets are incomparable; (c) if set A is a subset of set B then A has fewer elements than B; and (d) 2 sets are equivalent if there is a one-to-one correspondence between their elements.

Fischbein and Baltsan found that the formal mathematical properties of sets, which usually contradict the corresponding intuitive ones, are "forgotten as an effect of age" (1998, pp. 20). In Greece, students are using the concept of set in various contexts, even before it is formally introduced to them. They learn about number sets and they define a circle as a set of points on a plane that are equidistant from a given point. The concept of set is first taught in grade 9 in the course of Probabilities and then in grade 10 in the course of Algebra. In both grades the curriculum suggests that the teacher will spend two lessons teaching the concept of set and the operations between sets. In most cases, even those two lessons are neglected and the set is just being seen as a supplementary concept in different contexts like geometry, algebra, analysis, or probabilities. The research questions of this study are: (1) What conceptions do different-aged students have regarding the mathematical concept of set?; and (2) What effect does age have in the understanding of the set concept and its properties?

Methodology

The research tool was a questionnaire, consisting of 11 questions, which were constructed based on the aforementioned findings of previous research regarding the concept of set. Questions regarding the concept of set and equality between sets (1 to 7) were included in the questionnaire given to all groups, while questions regarding union, interception, inclusion, belonging and comparison of infinite sets (8 to 11) were only included in the questionnaire of groups 2 and 3. The questionnaire was administered to 116 grade 6 students (group 1, primary school), 127 grade 9 students (group 2, junior high school) and 154 grade 12 students (group 3, high school), from various schools around Greece. Students from the first two groups had never been explicitly taught anything regarding sets. Some of the students of the third group had been provided with a definition for the concept of set in grade 10 (two years prior to this study), but all of them use sets regularly, in the form of "the domain" or "the range" of a function. Data were analyzed with IBM SPSS Statistics 26. To answer the first research question we calculated the percentages of students that held each conception (questions 1 – 7, 11). We will present and discuss the results from some of the questions that we find particularly interesting. As far as the second research question is concerned, we conducted an ANOVA test to check the hypothesis that, no differences were found between the scores of the three groups.

Results

First research question

We begin by addressing our first research question, namely, what conceptions students have regarding the mathematical concept of set. For that purpose, we are going to present some of the questions from our questionnaire and we will discuss the results.

Question 1.

What do you think a set is in mathematics?

In the first question of our questionnaire we found a number of different conceptions students have regarding the set concept. We will provide some examples of answers and elaborate on how we coded them. A student answered that "a set is the collection of similar objects and their classification into a group”. In our understanding, this student saw sets as both a *collection* and as a *group* (the Greek word for group can also be translated as team). As expected, there were answers like “a set is any collection of objects” or “a set is a group of objects”, for which the coding is obvious. Another student described a set as “a collection of numbers”. This student thought of sets as a collection of *numbers*, not accepting non numerical elements. A student wrote that “a set is a group or a category of similar objects, rational numbers for example”. That student thought of sets as both *groups* and *categories* and gave the example of rational numbers. In our estimation, this is not enough evidence to assume that he only accepts numbers as the elements of a set. There was a student that gave us the simple answer “the whole”. Others wrote that a set is “the whole or a group with some common element” or “something complete”. These students were considered to hold the conception that a set is *the whole*. Some students used the Greek word “plethos” saying for example that a set is “a plethos of elements that meet certain conditions”. The word plethos can be translated as “a number of”, “a multitude”, or in some cases “a crowd”. We chose the code *multitude* for those answers. Lastly, a lot of students provided answers like “for me, a set is the outcome”, or “I perceive this in two ways, as the outcome of an addition or as a group”. Those students seemed to conceptualize a set as *the outcome* or the sum of certain numbers. One would expect that every student that holds that conception accepts only numbers as the elements of a set. However, this was definitely not the case in our survey, as there were different conceptions for sets, sometimes contrasting ones, coexisting in students’ minds.

There were also students whose answers were out of context or formulated in a way that didn’t allow for a proper coding or they were simply unintelligible, for example “I think that the elements of a set must have a common property” or “something that is concentrated”.

Table 1: Words used by students in order to define the set concept

What do students think a set is in Mathematics	Percentages of students holding this conception
A collection	2.3%
A group	28.7%
A category	2.3%
The whole	5.5%
A multitude	6.9%
The outcome	24.2%
A cluster of numbers	5.6%
Out of context/ unintelligible	21.2%
Missing values	19.1%

Since a student can use more than one of the aforementioned words, the percentages do not add up to 100%. One thing that stands out is the fact that 24.2% of the students think of a set as the outcome of an operation (or the sum of certain numbers). If we include the number of students that chose (a) or (b) on question 4 (see below) and those that answered question 7c (see below) incorrectly (both implying that those students are adding up the elements) then we find that 49.4% of students think of sets as the outcome of an operation or a sum. That is probably due to the fact that, in Greek the word for "set" is commonly used as "total". It is also interesting that 28.7% of students view a set as a "group" or a "team" of elements, probably implying a uniformity between the elements of a set, while only 2.3% of them think of a set as a collection of objects (which is the term used to "formally" describe a set).

Question 3.

Do you think that the elements of a set must have a certain common property?

The students' answers to the third question (Table 2) show that most students thought that the elements of a set must have a certain common property or conform to a certain criterion that allows them to be included in the set. This finding is consistent for all three groups. Fischbein and Baltsan (1998) found that the proportion of wrong answers increases generally with age. This doesn't seem to be the case in our study since the percentage of wrong answer is almost the same for all groups. This misconception is common among prospective teachers as well (Fischbein & Baltsan, 1998). It is worth noting that the description of a set in the Greek textbook used in grade 9 highlights that we use to collect or choose certain objects and sort them into groups or categories, for example, numbers, letters of the alphabet, books in a library depending on their content, and that, groups or categories like those, are called sets. Albeit not wrong per se, such a description can easily foster the misconception that the elements of a set must be of the same kind.

Table 2: Group * Question 3 Crosstabulation

Group	Yes	No
1	77.7%	22.3%
2	76.8%	23.2%
3	80.7%	21.4%
Total	78.6%	21.4%

Question 4.

Mark each of the following answers that seem correct to you. The set of the letters of the word "TENNIS" is:

(a) {5}
(b) {6}
(c) {T,E,N,I,S}
(d) {T,E,N,N,I,S}

On the 4th question (table 3) we examine whether students think that a set can contain repeated elements (those that answered {6} or {T,E,N,N,I,S}) or not. We found that most students think that it is acceptable for a set to contain repeated elements. That is especially true for groups 1 and 2 (younger students). It is also important to note that only 27.7% of the students marked only the correct answer (students were allowed to mark more than one answers in this question), which is {T,E,N,I,S}.

Table 3: Question 4 – Percentages of students accepting repeated elements in a set

Group	Repeated elements are allowed.	Elements of a set must be discrete.
1	78.3%	21.7%
2	76.0%	24.0%
3	56.5%	43.5%
Total	69.0%	31.0%

Question 5.

Do the following collections define a set? Choose the correct answer.

(a) Natural numbers greater than 8 and smaller than 10.
  i. Yes, {9}
  ii. No, a set must have more than 1 element.

(b) Natural numbers greater than 8 and smaller than 9.
  i. Yes, {}
  ii. No, a set must contain at least 1 element.

On the table below, we examine whether students accept the notion of a "unit set" (question 5a) and the notion of an "empty set" (question 5b). We found that almost half the students think that a set must have two or more elements, while 63.9% of the students think that a set must contain at least one element.

Table 4: Group * Question 5 Crosstabulation

	Question 5a		Question 5b	
Group	Correct	Wrong	Correct	Wrong
1	53.6%	46.4%	36.0%	64.0%
2	37.8%	62.2%	32.3%	67.7%
3	58.4%	41.6%	39.2%	60.8%
Total	50.4%	49.6%	36.1%	63.9%

Question 7.

Describe the following statements as true (T) or false (F).

(a) {1,2,3,4}={4,3,2,1}
(b) {1,2,3,4}={a,b,c,d}
(c) {1,2,3,4}={1,2,7}

This question is an extension of Fischbein's and Baltsan's (1998) observation that, two sets are equal if they contain the same number of objects. We presumed that some students were going to think of a set as "an ordered n-tuple", thus answering that {1,2,3,4}≠{4,3,2,1}, or as "the sum of all elements", thus answering that {1,2,3,4}={1,2,7}. From the following table we infer that: (a) 22.8% of the students think that {1,2,3,4}≠{4,3,2,1} which implies that the order of the elements play a role when describing a set; (b) 57.7% of the students believe that {1,2,3,4}={a,b,c,d}, which means that two sets are equal when they have the same number of elements; and (c) 21.9% of the students answered that {1,2,3,4}={1,2,7}, which could imply that two sets are equal if their elements add up to the same number.

Table 5: Group * Question 7 Crosstabulation

	Question 7(a)		Question 7(b)		Question 7(c)	
Group	Correct	Wrong	Correct	Wrong	Correct	Wrong
1	77.9%	22.1%	37.1%	62.9%	73.7%	26.3%
2	77.4%	22.6%	41.1%	58.9%	74.6%	25.4%
3	76.5%	23.5%	47.4%	52.6%	84.3%	15.7%
Total	77.2%	22,8%	42.3%	57.7%	78.1%	21.9%

Question 11.

Describe the following statements as true (T) or false (F).

(a) The number of elements in an infinite set is larger than the number of elements in any of its proper subsets.
(b) All infinite sets have the same number of elements.
(c) Infinite sets are incomparable.

In question 10 (not listed here), which was included only in the questionnaire for groups 2 and 3, we asked the students to compare some infinite sets. We used different representations, known to elicit specific answers (Maria et al., 2009, Tirosh & Tsamir, 1996, Tsamir, 2001). For example, we gave them the sets A={1,2,3,4,5,…} and B={1,4,9,16,25,…} and asked them whether the number of elements in set A is larger, smaller, or equal to the number of elements in set B, or if it the two sets are incomparable. Then we gave the students the sets A={1,2,3,4,5,…} and B={1^2,2^2,3^2,4^2,5^2,…}, and asked them the same question. The first representation is known to lead students to answer in terms of "inclusion", while the second is supposed to lead them to consider "one-to-one correspondence" as the appropriate way to answer the question (Maria et al., 2009, Tirosh & Tsamir, 1996, Tsamir, 2001). The main reason for using this question was to engage students with a task regarding the cardinality of infinite sets and then, explicitly ask them about their ideas, in question 11.

In question 11 (table 6), which was also included only in the questionnaire for groups 2 and 3, we verified Tsamir's (2001) findings that some students come up with contradictory ideas when they are asked to compare the number of elements of infinite sets. Specifically, 32 junior high and high school students marked both Q11a and Q11b as true (“true” being the wrong answer), 38 of them marked both Q11c and Q11a as true (also wrong) and 29 marked both Q11b and Q11c as true (also wrong). It is important to note that 15 students didn’t answer Q11a, 17 didn’t answer Q11b and 15 didn’t answer Q11c, and so they are excluded from the following table. We should also point out that, Tsamir (2001) used the phrase “number of elements” in her study. In our questionnaire, written in Greek, we actually used the word “plethos” instead of “number”. The Greek word for “cardinality” is derived from the word “plethos”.

Table 6: Question 11a, 11b, 11c – Crosstabs

		Q11b				Q11a				Q11c	
		Cor.	Wr.			Cor.	Wr.			Cor.	Wr.
Q11a	Cor.	64	113	Q11c	Cor.	114	46	Q11b	Cor.	44	74
	Wr.	52	32		Wr.	64	38		Wr.	116	29
	Total	116	116			178	84			160	103

Second research question

Fischbein and Baltsan (1998) found that the formal mathematical properties of set are “forgotten as an effect of age”. To check that hypothesis, we decided to use our questionnaire as a test, thus, calculating the total score of each student for questions 1-7 (those that were included in the questionnaires of all three groups) and then, to compare the mean scores of the three groups (Table 7 and Table 8, SUM1_7). What we found was that group 3 (high school students) scored significantly higher than the other two groups. That finding could be explained due to the fact that, in Greek schools the concept of set is almost never taught explicitly even though students are using it in various contexts. It is impossible to forget something that you have never been taught, so the effect of age cannot be explained in terms of forgetfulness.

Table 7: Oneway ANOVA for Sum1_7

	Sum of Squares	df	Mean Square	F	Sig
Between Groups	95.246	2	47.623	11.335	0.000
Within Groups	1655.384	394	4.201		
Total	1750.630	396			

Table 8: ANOVA – Post Hoc Tests – Homogeneous Subsets – Tukey Ba,b – Sum1_7

Tukey B[a,b]		Subset for alpha = 0.05	
Group	N	1	2
1	116	6.9397	
2	127	6.9843	

3	154		7.9675

Means for groups in homogeneous subsets are displayed

a. Uses Harmonic Mean Sample Size = 130.502

b. The group sizes are unequal. The harmonic mean of the group sizes is used.

Discussion

All misconceptions found by previous research (Fischbein & Baltsan, 1998, Tsamir, 2001) were verified by our study and some new ones were added in the mix. The most prevalent conceptions that differ from the formal use of the set concept were: (1) a set is an outcome, (2) a set is a group of objects, (3) elements of a set must conform to a certain criterion, (4) a set must have at least one element, (5) a set can contain repeated elements, (6) a set is an “ordered n-tuple”, (7) two sets are equal if they contain the same number of elements, (8) two sets are equal if their elements add up to the same number (only apply to number sets), (9) the number of elements in an infinite set is larger than the number of elements in any of its proper subsets, (10) all infinite sets have the same number of elements and (11) infinite sets are incomparable.

When we compared the mean score of each group, we found no significant difference between groups 1 (primary school) and 2 (junior high school). High school students (group 3) scored significantly higher than their younger counterparts. This discrepancy may be due to the fact that 12th graders have gained more experience in sets as a result of using them in Algebra and Analysis courses in High School. Fischbein and Baltsan (1998) found that the percentage of wrong answers increases as age increases. This wasn’t the case in any question of our survey. On the other hand, Tsamir’s (2001) findings that some students hold contradictory ideas when they are asked to compare the number of elements of infinite sets were in accordance with our findings.

Basic Mental Models of Equations - Theoretical Conception and Practical Meaning

Hans-Georg Weigand[1], Guido Pinkernell[2] and Alexander Schüler-Meyer[3]

[1]University of Würzburg, Institute of Mathematics, Germany; weigand@mathematik.uni-wuerzburg.de

[2]Pädagogische Hochschule, Heidelberg, Germany; pinkernell@ph-heidelberg.de

[3]Eindhoven University of Technology, The Netherlands; a.k.schuelermeyer@tue.nl

A Basic Mental Model (BMM) of a mathematical concept is a content-related interpretation that gives meaning to this concept. There exist many suggestions for BMMs in mathematics education, e.g., for natural numbers, functions, derivatives or integrals. In this article we present four BMMs of an equation and discuss the relation between these BMMs and the solving of equations. Particularly, we are interested in the interrelationship between these BMMs and the use of digital technologies in this solving process. These theoretical considerations bring up research questions which should be answered to achieve a better understanding of the concept of equation and the solving processes.

Keywords: Equation, solving of equations, Basic Mental Models, digital technologies.

Basic Mental Models (BMM)

The concept of Basic Mental Model (in German: Grundvorstellungen) has been well established in German-speaking didactics of mathematics for many years (Hofe v. & Blum, 2016). *A BMM of a mathematical concept is a content-related interpretation that gives meaning to this concept, providing relations to meaningful contexts* (see Greefrath et al., 2016). The *meaning* of a concept is constituted by its interpretation in scientific mathematics, in school mathematics and in the (historical) development of the concept (Kilpatrick et al., 2005). BMMs can be conceived as prerequisites for students to deal with mathematical concepts in an insightful way.

The concept of BMM can be used both in a *normative* (prescriptive) and an *individual* (descriptive) sense (see Hofe et al., 2005).

- *Normative* BMMs are the answer to the question: How should students generally and *ideally* think of a given mathematical concept? They are identified by didactical analyses of the mathematical concept. They can be used as educational guidelines and to specify learning objectives for mathematics lessons. The determination of BMMs is a didactical challenge for researchers and requires a subject-oriented classification of mathematical and real-life situations of the concept.
- *Individual* BMMs are individual mental models or concepts students *actually* develop in learning processes and problem-solving situations. They can vary from or represent only part of normative BMMs, they even can be based on misconceptions. Individual BMMs are the result of the personal development of meaning and the integration of the concept into an individual's personal worldview.

BMMs of mathematical concepts can be considered within the theoretical framework of “Concept Image – Concept Definition” (Tall & Vinner, 1981). They are parts or subsets of the “Concept Image” of a mathematical concept. While “Concept Image” refers to all individual mental images identified with the concept, BMMs are the *core* or *central components* of these images.

The development of BMMs is a creative task for mathematics educator. Based on the concept definition, a critical investigation of the use of this concept and the involved perceptions in problem solving situations in scientific mathematics, in university mathematics lessons and in the school curriculum give hypotheses of the existence of different BMMs. These have to be empirically verified, like Greefrath et al. (2021) have done this for the concepts of derivative and integral.

A mathematical spotlight: equations and equivalence of equations

Equations with only numbers or quantities are statements which can be true or false. E.g., the equation $3 + 5 = 8$ is a true, $3 + 5 = 7$ is a false statement. Equations with unquantified variables, e.g., $T_1(x) = T_2(x)$, T_1, T_2 algebraic terms, are predicates, which will turn into statement if the variables are quantified, e.g., for $x = 4$, $3 \cdot x + 1 = 7$ is a false statement, for $x = 2$ it is a true statement. Two equations are *equivalent*, if

- their sets of solutions are the same or
- there is an equivalence transformation which transforms one equation into the other.

Each injective function applied to both expressions of an equation is an equivalence transformation. This applies especially for the elementary transformations like addition and multiplication with real numbers (for more details see Arcavi et al., 2017).

BMMs of an equation

BMMs of an equation form a content basis for what students normatively need to work with equations. They are central and important in developing perceptions and (mental) representation about basic activities while solving equations. BMMs are based on mathematical aspects of equations: the definition of an equation, the use of the equals sign and the relationship between the equation concept to the concepts of algebraic expressions and functions.

- **Operational BMM**: An equation is understood as a calculation or transformation. The equal sign is seen as an operational sign, which indicates a reading direction of the equation in the sense of a "resulting-in” sign.
  - Arithmetic calculations: The equation $3 + 4 = 7$ can be expressed as "$3 + 4 \rightarrow 7$" or verbally by "3 plus 4 results in 7". It is the predominant BMM of an equation in primary school.
  - Transformations of algebraic expressions: Equations like $(a+b)^2 = a^2 + 2ab + b^2$ can be expressed by $(a+b)^2 \rightarrow a^2 + 2ab + b^2$ or verbally by “expanding $(a+b)^2$ results in $a^2 + 2ab + b^2$”. "Results in" can also be read—with “factorizing” instead of “expanding”—in the other direction.

- **Relational BMM**: An equation is understood as a task to determine numbers or quantities for the expressions on both sides of the equation to get the same value or quantity on both sides. The equal sign is seen as a relation sign. The variable here is understood as an unknown which has to be determined.[1]

The visualization for or a representation of this BMM is the model of an equal arm balance. In this model, each expression is represented as a combination of weights. Numerical values are represented by unit weights and each variable value is assigned by a fixed—initially unknown to the spectator—weight. The equality of values of both terms is expressed in the balance of the scales. Like in Figure 1, the balance model is suitable especially for linear equations. These are carried out as actions of removing the same weights from or adding the same weights on both scales.

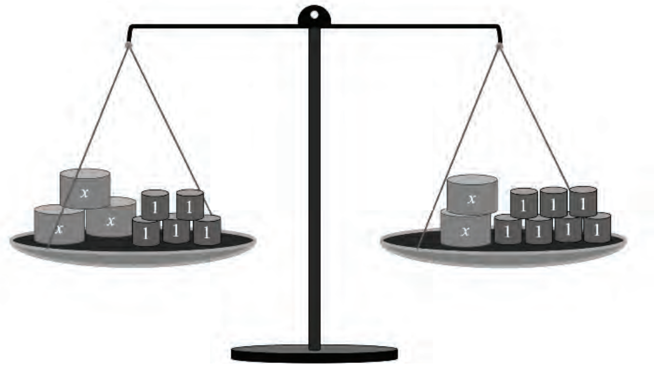

Figure 1. An equal arm balance

- **Functional BMM**: An equation $T_1(x) = T_2(x)$ is a comparison of two expressions which are understood as functions with $y = T_1(x)$ and $y = T_2(x)$. Here, too, the equals sign is understood relationally, but the BMM of the variable is that of a changing number or quantity.

In this functional interpretation, the variable x "passes through" the values of the definition range of the two terms $T_1(x)$ and $T_2(x)$. This results in the equation becoming a false or true statement, depending on the values of $T_1(x)$ and $T_2(x)$. However, we want to determine the value(s) x_o with the same function values $T_1(x_o) = T_2(x_o)$. In a graphical representation of the two functions with $y = T_1(x)$ and $y = T_2(x)$, solving an equation means determine the intersection points of the two function graphs. This is possible for nearly all types of functions. Figure 2 shows an example of a quadratic equation.

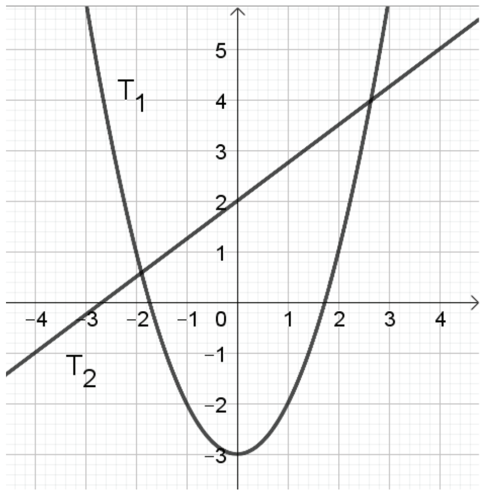

Figure 2. The equation $x^2 - 3 = 0.75x + 2$ leads to the two functions with $T_1(x) = x^2 - 3$ and $T_2(x) = 0.75x + 2$

This BMM can be transferred to a system of equations with 2 variables if a function is defined by each of the two given equations whose common function values are to be determined.

- **Object-BMM**: An equation is regarded as a mathematical object that has characteristic

[1] We refer to the three central BMMs for variables without explaining their background (see e.g. MacGregor and Stacey (1997) or Oldenburg (2019) for details): The variable as a general number, the variable as an unknown number and the variable as changing number or quantity.

properties, such as the number of possible solutions, the definition range or special solution algorithms. E. g.

- The quadratic equation $x^2 + x - 3 = 0$ has exactly two solutions. There exist several methods to calculate these solutions.
- The equation $x^2 + y^2 = z^2$, $x, y, z \in \mathbb{N}$ is a Diophantine equation whose solutions are called Pythagorean number triples.
- The equation $x^2 + y^2 = r^2$ with $x, y \in \mathbb{R}$, $r \in \mathbb{R}^+$ is an equation of a circle with the coordinate origin as the center and the radius r.

The first two BMMs are based on the operational and relational meaning of the equal sign and thus mark the transition from the arithmetic-dominated mathematics of the primary level to the algebra of the secondary level. The third and fourth BMM represent an understanding of equations on (lower and upper) secondary level. They will be especially important while working with digital technologies. There is a hierarchy in the appearance of these BMMs from primary to upper secondary school: Operational BMM → Relational BMM → Functional BMM → Object-BMM .

Central activities and working with equations

The meaningful working with and the flexible use of concepts require a wider view of the concept, especially seeing the concept in relation to different applications and to different representations (see e.g., Freudenthal (1983)). At least since the works of Piaget and Aebli, and further those of Vygotsky and Leont'ev, real hands-on activities are seen as central and fundamental for the development of mental structures or (thinking) operations. The development of BMMs must therefore be seen in close relation to activities and related tasks with this concept.

Referring to the quite elementary "Input-Operation-Output"-model concerning the working with tasks (see e.g., Günster and Weigand (2020)), this model can be transferred to three *central activities* while working with equations (in mathematics lessons). These *central activities* are:

- **Input or setting up an equation**: Setting up an equation in such a way that the central relations presented in a problem are expressed appropriately in the equation. It is therefore a matter of translating a problem situation into the language of mathematics.
- **Operate on or anticipating and applying transformations**: Developing strategies which can be flexibly used to solve equations in a problem-adequate way.
- **Output or interpreting**: Gaining insights into an issue by means of an equation, appropriately transformed equations or the solution(s) of an equation.

These central activities require *syntactic* knowledge concerning the structure of expressions that determine the equation and knowledge of solution strategies concerning different equation types. Furthermore, flexibility and symbol sense are required, and the ability to transfer equation to other (equivalent) equations (see Kieran (1992), Oleksik (2019)).

Semantic knowledge is required with regard to the meaning of equations in relation to environmental situations, inner-mathematical models and representations, and the interpretation of the solution(s) in relation to these situations.

Digital technologies—nowadays and in the future

For solving equations, there is already a wider range of digital technologies that can be roughly divided—not non-overlapping—into two categories: on the one hand, *tools* for solving equations and, on the other hand, *learning environments*. *Tools* such as spreadsheets or computer algebra systems allow the user alternative ways of using them. *Learning environments* are structured learning arrangements designed with a teaching objective, using tools and visual aids. Figure 3 shows an interactive digital simulation of a beam balance and the solving of a linear equation. Moreover, there are digital assessment systems such as STACK (Sangwin, 2013) or learning apps like *Photomath*[2], *Chegg Math Solver*[3], *Cymath*[4] or *Mathway*[5]. A didactic discussion of such programs can be found in Arcavi et al. (2017, p. 106). These systems will certainly be further developed in the coming years.

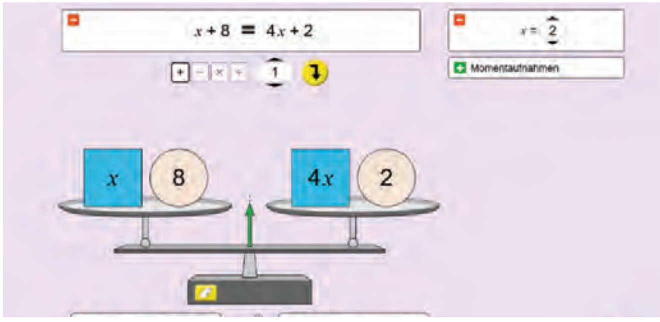

Figure 3. Simulation of a balance (University of Colorado Boulder)

BMMs and the solving of equations with digital technologies (DT)

The four BMMs allow meaningful explanations for different algebraic methods of solving equations. Since the main focus here is on the significance of the BMMs and the use of DT, the operational BMM, which essentially plays the significant role in primary school and lower secondary school, will not be discussed (cf. Arcavi et al. (2017)).

The Object-BMM

A CAS solves equations on the numeric and symbolic levels, and it is a formulary that offers formulas for linear, quadratic, like in Figure 4, and special types of polynomial functions of higher order than 2.

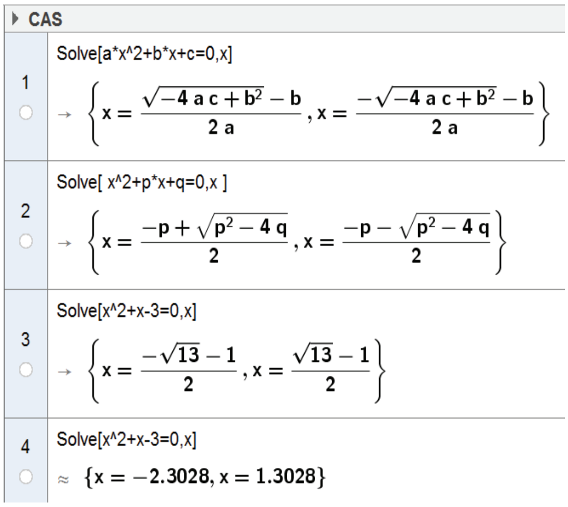

Figure 4. Solving quadratic equations with a CAS

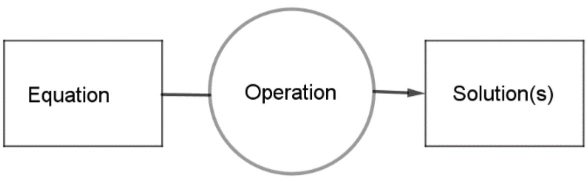

2 https://photomath.app/
3 https://www.chegg.com/math-solver
4 www.cymath.com/
5 www.mathway.com

The Object-BMM can be integrated into an Input-Operation-Output model:

“Operation” may be seen as a “black box”, if the learner does not know the algorithm used in this “box”. But it might also be a “white box”, if the CAS is “only” used as a tool to get the result quicker than with paper and pencil. Furthermore, to turn the “black box” into a “white box” it might be helpful to explain “Operation” and the Object-BMM—in dependence of the type of the equation—by referring to the relational and the functional BMM.

The functional BMM

A CAS allows the solving of equations on different representation levels. It calculates the zeros of (special types of) functions on the symbolic and numeric level by only pressing one button and it visualizes the solutions on the graphic level. The solutions are the zeros of the function. Figure 5 shows an equation with a parameter, the solutions are given dynamically by varying the parameter b with a slider.

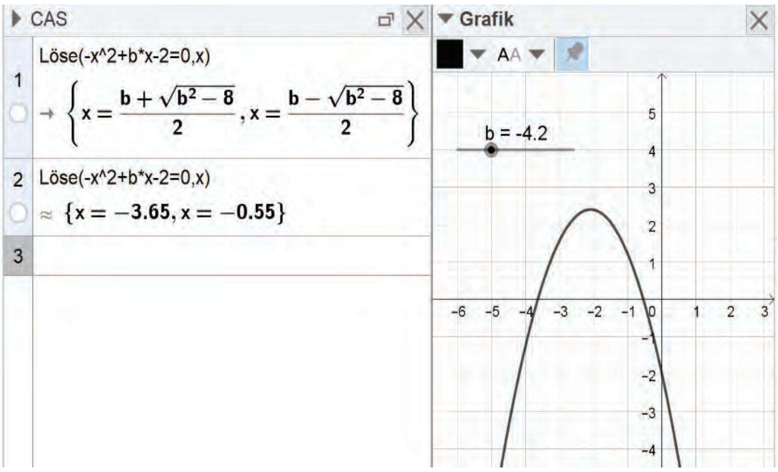

Figure 5. Solving quadratic equations (with a parameter b) and the functional BMM

Special equations of higher degree, particularly equations of degree 3 and e.g., trigonometric and exponential equations can be solved—quite often—numerically, sometimes symbolically, and nearly always graphically.

Solving (more complex) equations with a CAS is not only a “pressing a button”-activity. Basic knowledge of solving different types of equations and different strategies for solving of equations are necessary, especially if an approach that had been used did not lead to a successful solution. Figure 6 shows an example of the solving of the equation $1 + sin(x) = 2^x$. In this case, trying to get a symbolic or numeric solution with a CAS is not possible.

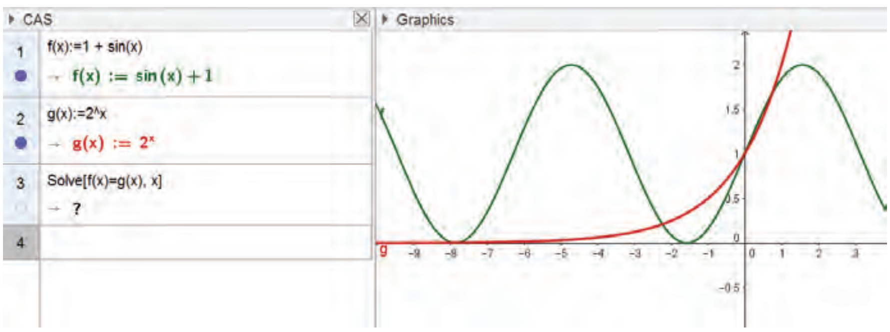

Figure 6. Graphical solution of the equation $1 + sin(x) = 2^x$

The relational BMM

Concerning the functional BMM, a CAS is a *tool* for solving equations. However, a CAS can also be used as a *teaching-learning system* and integrated into a *learning environment*. An example is the step-by-step execution of (equivalence) transformations for an equation. For this, arithmetic operations are applied to an equation as a whole while the algebraic transformations can be visualized graphically. The rather confusing static Figure 7 has to be seen in a dynamic step-by-step presentation to show more clearly the invariance of the x-coordinate of the intersection point of the graphs and hence the consistency of the solution of each transformed equation.

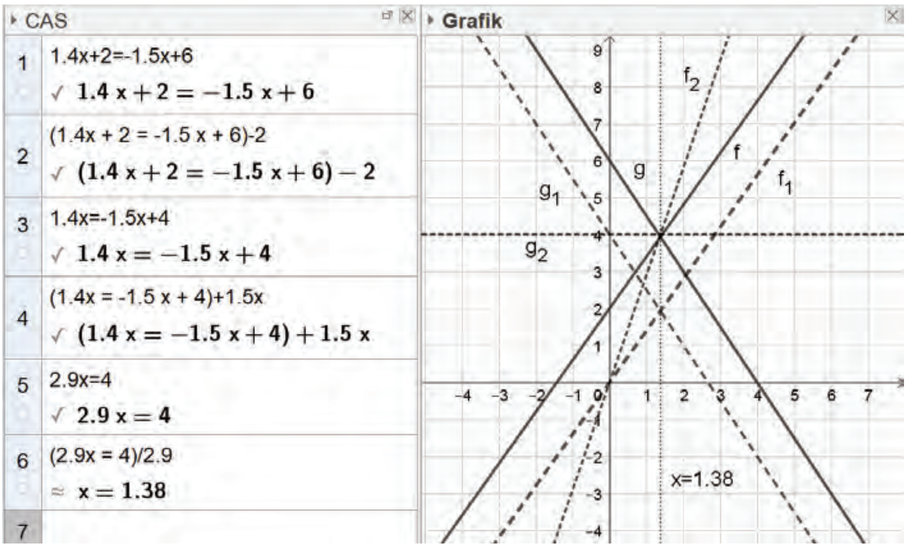

Figure 7. Step-by-step transformations of an equation

Conclusion and research questions

Solving of equations—in this article—is seen in relation to the BMMs of equations (operational, relational, functional BMM and Object BMM) and the use of DT, mainly CAS, but with different kinds of representations. The first research question is the substantial question about the existence and the kind of individual BMMs:

1. *Are the four BMMs represented in students' thinking if they solve equations and how is the relationship between BMM and the way of solving an equation?*

We suspect that the BMMs have to be distinguished concerning different types of equation, especially linear, quadratic and "other" equations, and different methods of solving equations (especially symbolic, graphic, numeric).

The second research question is about the three *central activities* while working with equations and their relation to the BMMs?

2. *How do the BMMs of equation interact with the central activities while solving equations?*

Concerning the solving of equations with DT, the interrelationship between three dimensions—BMMs, DT and central activities—seems to be a crucial point. The third research question aims to get criteria for the development of tasks for constructively generating BMMs of equations.

3. *Which tasks and activities—especially with the use of DT—support the development of BMMs for equations (depending on the different types of equations)?*

The analyses in this article are the theoretical basis for answering these research questions empirically. This will be the next step in this research project.

Student definitions of equivalence: structural vs. operational conceptions, and extracted vs. stipulated definition construction

Claire Wladis[1,2]; Ben Sencindiver[2]; Kathleen Offenholley[1]; Elisabeth Jaffe[1] and Joshua Taton[2]

[1]Borough of Manhattan Community College, City University of New York, USA; cwladis@bmcc.cuny.edu, koffenholley@bmcc.cuny.edu, ejaffe@bmcc.cuny.edu

[2]The Graduate Center at the City University of New York, USA; bsencindiver@gc.cuny.edu, jtaton@gc.cuny.edu

In this study, we describe a model of student thinking around equivalence (conceptualized as any type of equivalence relation), presenting vignettes from student conceptions from various college courses ranging from developmental to linear algebra. In this model, we conceptualize student definitions along a continuous plane with two-dimensions: the extent to which definitions are extracted vs. stipulated; and the extent to which conceptions of equivalence are operational or structural. We present examples to illustrate how this model may help us to recognize ill-defined or operational thinking on the part of students even when they appear to be able to provide "standard" definitions of equivalence, as well as to highlight cases in which students are providing mathematically valid, if non-standard, definitions of equivalence. We hope that this framework will serve as a useful tool for analyzing student work and exploring instructional and curricular handling of equivalence.

Keywords: Equivalence, solution set, operational-views, structural-views, definitions.

Equivalence is central to mathematics at all levels, and across all domains. In mathematics education, much research has focused on studying how students think about the equals sign in primary (Knuth et al., 2006) through post-secondary (Fyfe et al., 2020) school, because student conceptions of the equals sign are related to their arithmetic and algebraic calculations. However, equality is just one example of the larger concept of equivalence—other types of equivalence occur extensively throughout the K-16 curriculum, but are rarely, if ever, taught under one unifying idea called equivalence (Wladis et al., 2020). On the other hand, multiple types of equivalence (e.g., similar/congruent figures, function types, equations with the "same form") are contained in the *U.S. Common Core Mathematics Standards* but are never explicitly labeled as a type of equivalence. When equivalence is not explicitly defined, students may extract their own non-standard, ill-defined, or unstable definitions, or they may inappropriately use the definition of equivalence from one area (e.g., expressions) in another area where it cannot be directly applied to obtain the "standard" definition expected of them (e.g., equations). In this paper we will illustrate this problem by presenting examples of student definitions around equivalence and a model for analyzing student definitions, focusing on college students' definitions of equivalent equations. Examples of student work will be used as vignettes to illustrate the model. Our aim in presenting this model is to start a conversation about student definitions of equivalence and to present an initial framework that can then be further tested, refined, and revised by future empirical work.

Theoretical framework

We frame the analysis of student definitions of concepts in terms of Tall and Vinner's (1981) concept image and concept definition constructs. A person’s *concept image* describes the “total cognitive structure that is associated with the concept, which includes all the mental pictures and associated properties and processes” (p.152). Their *concept definition* describes a “form of words that a learner uses for his own explanation of his (evoked) concept image” (p.152). Hence an individual’s *personal* concept definition is idiosyncratic to the individual, may vary based on the context it is evoked, and may deviate from the larger mathematical community (the *formal* concept definition). When we refer to a student’s ‘definition’, we are referring to their personal concept definition.

In this paper, we define the *formal* concept definition of equivalence as an equivalence relation. The formal definition of an equivalence relation most often given in advanced mathematics classes is that of a binary relation that follows the identity, symmetry and transitive properties. However, another equivalent but more accessible definition of an *equivalence relation* is that of a partition on a set, or more informally: If we have a set of objects and a mathematically well-defined rule for sorting objects into sets so that each goes into one and only one set, then this “sorting” is an equivalence relation, and two objects are equivalent if they belong to the same set. Using this definition as an analysis tool allows us to account for many types of equivalence, with many different mathematical objects (e.g., numbers, algebraic expressions, algebraic equations) and equivalence relations (e.g., equality of expressions; insertion equivalence of equations; Wladis et al., 2020; Zwetzschler & Prediger, 2013). (We note that this definition is an analysis tool that is not necessarily intended to be given to students.)

From this perspective, a student’s personal definition of equivalence in a given context is valid in so far as it is an equivalence relation and can be expressed in a mathematically well-defined way by the individual. When students have no explicit definitions of equivalence, this presents several potential problems: (1) students may incorrectly apply one definition to another context where it fails to produce the “standard” definition (e.g., definition of equivalent expressions to equations); (2) they may have only ill-defined or operational definitions of equivalence which inhibit their ability to reason through problems; or (3) they may use valid but non-standard definitions of equivalence, in which case they are being penalized for not knowing certain socio-mathematical norms (Yackel & Cobb, 1996) even when they are reasoning correctly. We argue that the model presented here allows us to better recognize when these three situations (as well as others) might be occurring with students.

Model of equivalence

Our model of student thinking about equivalence conceptualizes student definitions as existing on a two-dimensional plane with two axes: operational vs. structural conceptions of equivalence (Sfard, 1992), and extracted vs. stipulated definitions of equivalence (Edwards & Ward, 2004). A student with an *operational* conception thinks of mathematical entities as a process of computation, while a student with a *structural* conception thinks of them as abstract objects which can then be acted on by even higher-order processes. A student with a structural conception sees objects as reified processes (e.g., $6x$ is seen as an object itself, and not just as the process of multiplying x by 6), however when students view something as an object which is not the reification of any process, this is called a *pseudostructural* conception (p.75, Sfard, 1992). We see Sfard’s constructs as related to the computational/relational distinction made in research on the equals sign, where the computational view is a cue to calculate, and the relational view focuses on equality as a relationship (e.g., Knuth et al., 2006). Our model can be seen as a generalization of the computational/relational distinction made in research on the equals sign, where equivalence structures (the equivalence relationships) are core objects that justify computation. This is in contrast to Sfard's description of structures (e.g., algebraic expressions) being viewed as a normative process which is reified into an object.

Extracted definitions are created to describe actual observed usage of a term (e.g., a student may extract a meaning for equivalence from their instructional experiences, whether or not they have encountered an explicit definition). In contrast, *stipulated* definitions are those definitions that are stated explicitly—to determine if something fits the definition one must consult the definition directly (Edwards & Ward, 2004). We note that in our model, a stipulated definition may be stipulated by the student or an authority—the key features we use to determine if a definition is stipulated in our framework is whether it appears to be explicit, well-defined, and stable across contexts. We note that while we have displayed our model in Table 1 as a two-by-two grid for the sake of simplicity, but we conceptualize these categories as a spectrum (thus, Table 1 is actually a continuous 2D plane).

Table 1: Model of student thinking about equivalence

	Extracted Definition	**Stipulated Definition**
Operational Conception of Equivalence	**Pseudo-process view:** Students see equivalence as a computational process, and their approaches to those processes are dictated by prior experience in ways that are extracted rather than stipulated. Definitions of equivalence are typically non-standard, ill-defined, and/or unstable.	**Process view:** Students see equivalence as a process, but do process computations by referring to stipulated rules or properties. Students with this view may be able to perform calculations correctly but this does not necessarily translate to being able to use stipulated definitions to recognize equivalent objects.
Structural Conception of Equivalence	**Pseudo-object view:** The student is able to consider whether two objects are equivalent without reverting to an explicit computation, perhaps by considering the structure of the objects; but definitions of equivalence are typically extracted in some way from experience rather than based on stipulated definitions of equivalence, and as a result are typically non-standard, ill-defined, and/or unstable	**Object view:** The student is able to consider whether two objects are equivalent without reverting to an explicit computation, perhaps by considering the structure of the objects; definitions of equivalence used to determine equivalence are stipulated. The student conceptualizes equivalence classes (or solution sets) as objects, although they need not do this formally.

Methods

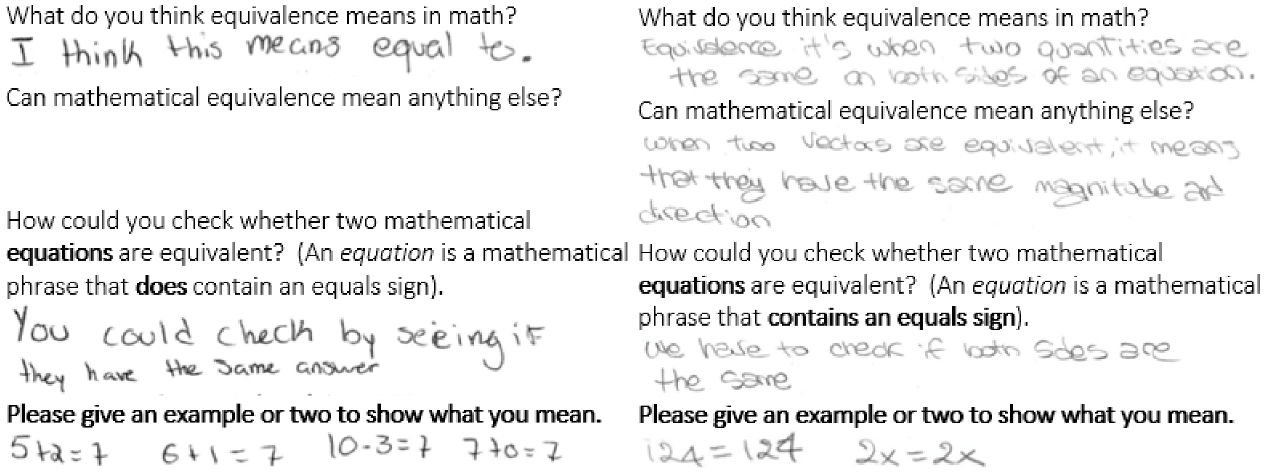
Data for this study were collected from 124 students at an urban community college in the US through open-ended questions in 18 different courses, from developmental elementary algebra (similar to Algebra I in secondary school) to linear algebra. Student responses were analyzed using thematic analysis (Braun & Clarke, 2006), combining codes from the model above with an emergent coding scheme. Multiple coders participated in several rounds of coding until consensus was reached. Responses coded as indicative of an operational view of equivalence provided evidence of thinking of equivalence as an algorithm; those coded as indicative of a structural view of equivalence provided evidence of thinking of equivalence as a fixed trait of an object, or reasoning about equivalence via its general properties. Further coding details are described below.

Results

Students often struggled to provide definitions of equivalent equations for several different reasons.

One issue appears to be that students attempted to apply the definition of equivalent expressions to that of equivalent equations.

Pseudo-process view (extracted and operational): For example, in Figure 1, we see the work of two students, one in elementary algebra, and one in linear algebra, both of whom give somewhat similar definitions of equivalent equations. The elementary algebra student gives a more ill-defined definition ("same answer") but we see from the examples that they provide that they appear to be thinking about equivalent arithmetic expressions. We would classify this response as a pseudo-process view, as the definition is not well-defined and appears to center around arithmetic calculation.



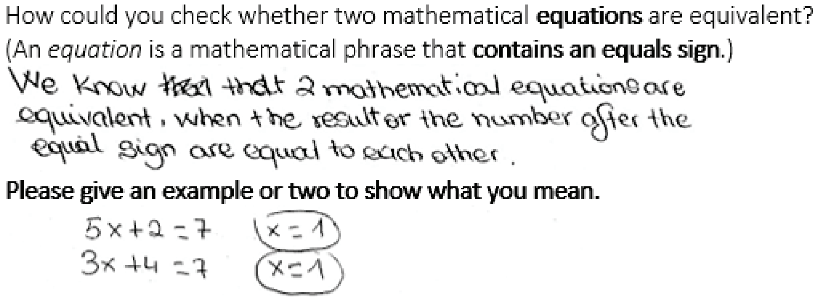
What do you think equivalence means in math?
I think this means equal to.
Can mathematical equivalence mean anything else?
How could you check whether two mathematical **equations** are equivalent? (An *equation* is a mathematical phrase that **does** contain an equals sign).
You could check by seeing if they have the same answer
Please give an example or two to show what you mean.
5+2=7 6+1=7 10-3=7 7+0=7

What do you think equivalence means in math?
Equivalence it's when two quantities are the same on both sides of an equation.
Can mathematical equivalence mean anything else?
when two vectors are equivalent, it means that they have the same magnitude and direction
How could you check whether two mathematical **equations** are equivalent? (An *equation* is a mathematical phrase that **contains an equals sign**).
We have to check if both sides are the same
Please give an example or two to show what you mean.
124=124 2x=2x

Figure 1: Definitions from an elementary algebra student, pseudo-process view (on left) and a linear algebra student, extracted view (on right)

Operational view: We see similar work by the linear algebra student in Figure 1, with some differences; they give broader examples of equivalence (describing also vectors) and their definition is more detailed ("when two quantities are the same on both sides of an equation"). But like the elementary algebra student in Figure 1, they conflate the definition of equivalent expressions with equations (they include an algebra example, but only show identical expressions as equal). Their definition of equivalent equations is also not fully well-defined ("check if both sides are the same"), because the word "same" is not well-defined. While their answer shows signs of having seen more examples of mathematical equivalence, this does not appear to have positively impacted their definition of equivalent equations; we classify their definition as extracted, because it is ill-defined.

Structural view: Students who apply the definition of equivalent expressions to equations may even do this in a way that is mathematically valid (i.e., fits the definition of an equivalence relation), even though it is not a "standard" definitions of equivalent equations (e.g., same solution set). Consider Figure 2, where a precalculus student has defined equivalent equations as two equations where "the result or the number after the equal sign are equivalent". Based on their examples, they seem to be suggesting that any equations of the form $expression = n$ for fixed n would be equivalent. This is similar to definitions given by other students in other research (Wladis et al., 2020). This example is particularly interesting, because the two equations given here also happen to have the same solution set, so it is unclear if this is also an implied part of the student's definition. Whether the definition includes this feature or not, we would classify it as structural even though it is a "non-standard" definition, because the student has given what could be a well-defined but alternate definition of equivalence (whether or not their definition is fully well-defined is unclear)[1].



How could you check whether two mathematical **equations** are equivalent?
(An *equation* is a mathematical phrase that **contains an equals sign**.)
We Know that 2 mathematical equations are equivalent, when the result or the number after the equal sign are equal to each other.
Please give an example or two to show what you mean.
$5x+2=7$ $x=1$
$3x+4=7$ $x=1$

Figure 2. Precalculus student's non-standard structural definition of equivalent equations

In contrast to the previous examples, some students did draw in some way on the notion of "solving" equations or the solution sets of equations when defining equivalence. However, the ways in which students drew on notions of "solving" also fell into different areas of our framework. Simply talking about the "solution" of an equation was not sufficient to classify work as either stipulated or structural even though it sounds like it is related to the standard insertional equivalence definition of equations (i.e., same solution set).

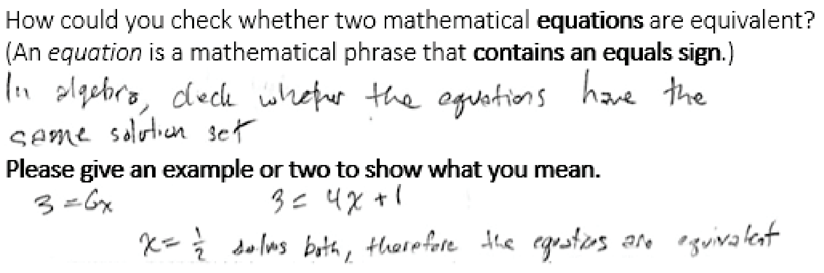
Structural view: In Figure 3(a), we see the work of a Calculus III student, who appears to have a well-defined and structural view of equivalent equations: they define equivalent equations as having the same solution set (seeming to conceptualize the solution set as a fixed object); and their definition appears to be well-defined, not just because of their stated definition, but also because the example they give which shows that their interpretation of "same solution" appears to be the "standard" one. We note that this is critical, as many students used the language of "same solution" but actually meant it to describe equivalent sides of an equation (equivalent expressions) rather than solution set.

Pseudo-process views (operational and extracted): See, for example, the work of an introductory statistics student in Figure 3(b). This student wrote that two equations are equivalent if you "substitute the value in for x and the solution is the same for both equations": this sounds like the standard definition of equivalent equations (if an incomplete one that does not account for the possibility that x may have more than one value), however, looking at the example they provided, we see that to them "solution" denotes the quantity resulting from simplifying one side of an equation (not the solution set of an equation). In this sense, the student's definition is ill-defined, because the vocabulary that they are using appears to be ill-defined and has multiple, perhaps vague, meanings. For these reasons, we would classify this work in (b) as a pseudo-process view, even though on the surface the definition initially looked similar to the one in (a). The student work in Figure 3(c) shows another common approach that students used, in which they drew on notions of solving when asked about equivalent equations, but struggled to relate these notions to any well-defined definition of equivalence. This

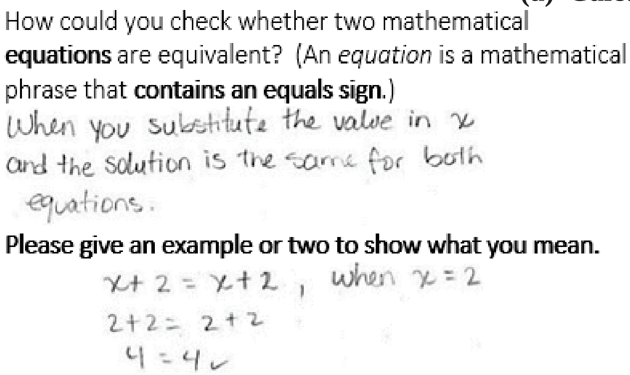
---

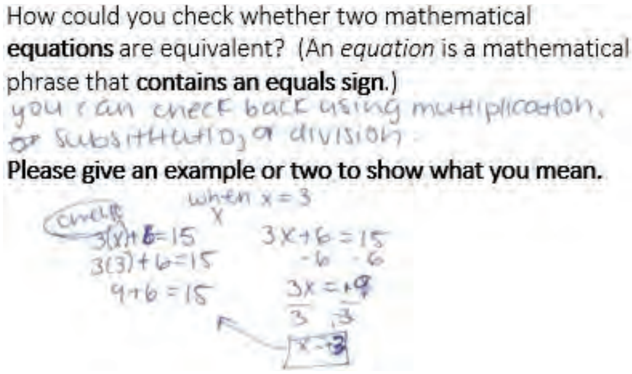
[1] This student may be drawing on notions of equations with the "same form" (e.g., $y = mx + b$, $ax^2 + bx + c = 0$) which is another type of equivalence that is commonly used in the algebra curriculum, even if it is not called equivalence in the curriculum (however, "same form" could in fact be codified as a formal equivalence relation, and students may be noticing this when they draw on it in their equivalence definitions (Wladis et al., 2020)).

student has solved an equation and checked the solution by substituting it back into the original equation; however, it is unclear what the definition of equivalent equations is, or even which two objects the student is claiming are equivalent (perhaps equivalence for them is not about the relationship between two objects, but instead names a process of checking the solution of an equation). Thus, we classify this as a pseudo-process view—there is no well-defined stated definition, and the student's focus is on computation.



(a) Calculus III student





(b) introductory stats student **(c) intermediate algebra/precalculus student**

Figure 3: Examples of different ways that students used "solving" in defining equivalent equations

Students also gave other non-standard definitions of equivalence that might have been well-defined equivalence relations (e.g., equivalent arithmetic equations as ones that express the same additive relationship; equivalent algebraic equations as ones that express the same relationship between the variables). However, we note that by de-coupling our categorization of student definitions of equivalence from what is "standard" and thinking more carefully about the extent to which student definitions of equivalence are stipulated (and an equivalence relation); and the extent to which student conceptions of equivalence are structural or operational, we may be able to achieve two critical goals more effectively: (1) we may be able to better identify student thinking which "sounds right", but is actually ill-defined; and (2) we may be able to identify valid student thinking that simply does not adhere to "standard" definitions. Both of these goals may better help us to tailor instruction to students.

We now briefly describe some overall trends we found in coding responses to open-ended questions on definitions of equivalence (Table 2). Students primarily associated equivalence with equality, and rarely cited other forms (e.g., equivalent equations), although the incidence of non-equality examples rose somewhat with course level. Similarly, students at all levels were extremely likely to give ill-defined or vague definitions of equivalence when asked. When asked about their definitions of equivalent equations, most students conflated this with the definition of equivalent expressions; this did not appear to improve with course level, suggesting that the lack of explicit definitions of equivalent equations in textbooks and curricula (Wladis et al., 2020) may well be contributing to student difficulties in understanding how definitions of equivalence vary in different contexts. Some of these definitions, while non-standard, may have been equivalence relations, and therefore reflect mathematically valid reasoning—the prevalence of this was not correlated with course level, suggesting that students at all levels may sometimes be generating valid but non-standard definitions. Many students associated equivalent equations with solving, but this was rarely done in a well-defined way: roughly one quarter of all students at all course levels solved an equation but did not relate this in any well-defined way to the definition of equivalent equations (most commonly they solved a single equation and then checked the answer, with no mention of which two things were equivalent); a smaller percentage of students did this at levels of precalculus and above, but the differences by course level were small. Some students interpreted equivalent equations as equations with the same solution set, and did so in a well-defined way; this was slightly more common as course levels went up; however, the vast majority of these students did so in an operational way (i.e., solved two equations and said they were equivalent, without discussing the solution set in a more general or structural way). This is perhaps to be expected, given the operational way in which the question itself was phrased, however, this does follow patterns observed in questions without this more operational wording, such as the more general question about the definition of equivalence given on this set of questions (although the tendency to use structural rather than operational definitions did increase with course level). However, we note that overall, structural and well-defined definitions were rare among all students, suggesting that instruction which specifically includes explicit stipulated definitions, and which encourages structural reasoning, is needed at all levels.

Table 2. Summary of student definitions of equivalence

	elementary alg. or below	intermediate alg. or 100-level	200-level or above
General definition of equivalence			
ill-defined or vague	67%	71%	60%
cited equality	94%	87%	80%
other valid definition	0%	3%	16%
operational definition	41%	18%	17%
structural definition	0%	2%	17%
How to tell if two equations are equivalent			
conflated w/ equiv. expressions	44%	48%	44%
of these, possible well-defined defn.	19%	6%	16%
finding solution set, operational	0%	3%	8%
related to "solving" but ill-defined	22%	29%	16%
solution set, structural	0%	2%	4%
total *n*	36	62	25

Discussion and conclusion

Our model of student definitions of equivalence aims to refocus our attention from whether definitions look “standard” to whether student definitions are well-defined equivalence relations, and whether their definitions are structural vs. operational. Using this lens allows us to pinpoint when students appear to understand a standard definition, but upon deeper analysis we find that their definition is ill-defined or wholly operational, limiting their ability to use it. On the other hand, this model also allows us to recognize students’ mathematically valid definitions even when they are nonstandard or students are not able to explain them fully formally. Evidence from examples of student work suggests that students do notice many kinds of “sameness”, yet struggle to articulate this in mathematically well-defined ways, just as they struggle to articulate “standard” definitions of equivalence in well-defined ways. This suggests that students are capable of noticing and using more generalized notions of equivalence, but need more explicit definitions and language in order to be able to do this rigorously. Future research is necessary to better understand what kinds of explicit definitions of equivalence work best for students in different contexts, and the extent to which discussions of the more general notion of an equivalence relation might be helpful in instruction. This framework may also be able to serve as a framework for instruction and curricula, to assess how the concept of equivalence is presented to students as they are learning at various levels in the curriculum.

[2]The Graduate Center at the City University of New York, USA; bsencindiver@gc.cuny.edu, jtaton@gc.cuny.edu

This empirical paper explores students' conceptions of transformation as substitution equivalence by linking it to their definitions of substitution and equivalence. This work draws on Sfard's (1995) framework to conceptualize conceptions of substitution equivalence and its components, equivalence and substitution, each on a spectrum from computational to structural. We provide examples of student work to illustrate how students' understandings of substitution, equivalence, and substitution equivalence as an approach to justifying transformation may relate to one another.

Keywords: Equivalence, substitution, substitution equivalence, transformation, definitions.

Transformation has been framed as a core mathematical activity (Kieran, 2004), and all mathematical calculation can be viewed as a process of transformation. Researchers such as Kirschner & Awtry (2004) have found that students' thinking about transforming symbols tends to be rooted in visual patterns of symbols rather than a deeper understanding of mathematical structures. Since algebraic transformation is often taught procedurally, there is a need to frame these manipulations in a structural way. By exploring the core mathematical ideas that justify why particular transformations are mathematically valid, we conceptualize transformation as a process of replacing one symbolic object with an equivalent one, and name this process substitution equivalence (Wladis et al., 2020). This includes the process of identifying sub-objects and replacing them with equivalent ones in order to generate a new equivalent object. This identification process is non-trivial for many students, and we hypothesize that thinking around substitution equivalence may be intimately connected to many of the struggles that students have with transforming symbolic mathematics in various contexts, yet this idea has rarely been explored in research. Here we present a model of students' thinking around substitution equivalence and illustrate potential affordances it might have in analyzing student work.

Conceptual framework and Prior Research

Substitution equivalence as a lens for mathematical transformation

In this paper, we focus on students' thinking around *substitution equivalence*, or the notion that two expressions, equations, or other mathematical objects are equivalent if one can be generated from the other through a sequence of substitutions carried out using standard interpretations of syntactic structure and mathematically valid uses of mathematical properties (Wladis et al., 2020).

Definition of substitution

In order to see how all mathematical activity could be viewed through the lens of substitution equivalence, we define *substitution* more broadly than has been done explicitly in much existing research and curricula. Jones and colleagues (2012) describe substitution as "the replacement of one representation with another" (p.167). Our definition builds on this idea by requiring the equivalence of mathematical objects being replaced and extending to other mathematical objects as well, such as equations. For us, substitution is the process of replacing *any* mathematical object (or any unified subpart of an object) with any *equivalent* object, regardless of complexity. This includes not only the replacement of x in $2x^2 - 2x + 1$ with -3, but also the replacement of $x^2 - 6x = 1$ with the equivalent equation $x^2 - 6x - 1 = 0$ during solving.

Definition of equivalence

Substitution equivalence is dependent upon an underlying equivalence relation. This may be a context-specific definition of equivalence (e.g., insertion equivalence in Zwetzschler and Prediger, 2013), or a more generalized concept of equivalence (e.g., an equivalence relation). Indeed, any definition of equivalence that satisfies equivalence relation criteria could be used.

Definition of substitution equivalence

Despite the importance of substitution equivalence to algebraic justification, little research has focused explicitly on substitution equivalence (see e.g., Pinkernell et al., 2017). A search in ERIC (the education research database maintained by the US Institute of Education Sciences, https://eric.ed.gov/) yields no results for *substitution equivalence*, *substitutional equivalence* or *substitution property of equality*. Other researchers have explored the "substitution principle", which refers to the structural sameness preserved when replacing a variable with a compound term, or vice versa (Musgrave et al., 2015). While this is related to our definition, as both rely on the substitution property of equality, this is not how we use this term. We define the domain of substitution equivalence as composed of two main ideas:

1. The general notion of substitution equivalence: A student understands that we can replace an object with any other equivalent object when problem-solving.
2. The notion that substitution of unified sub-objects preserves equivalence: A student understands that objects can be broken into unified sub-objects, and that replacing any unified sub-object with an equivalent unified sub-object produces an object that is equivalent to the original one (as long as substitution leaves the rest of the structure of that object unchanged).

The second notion leads us to another core definition: We use the term *subexpression* (or sub-object, more generally) to denote a substring of an expression (or other object) that can be treated as a unified object without changing the syntactic meaning of the original expression (or object). For example, $a - b$ is a subexpression of $a - b - c$, but $b - c$ is not (because putting brackets around $b - c$ would change the syntactic meaning of the whole expression). This different from, but related to, what Kieran (1989) refers to as surface structure (identifying the syntactic meaning of a symbolic algebraic representation) and what Malle (1993) refers to as *Termstrukturen* ("expression structuring") (identifying all algebraic expressions with the same syntactic meaning).

In this paper, we use Sfard's (1995) work to frame our thinking about student conceptions, where student thinking about a concept may be operational (as a process, often of computation) or structural (as an abstract object in and of itself). We conceptualize students' definitions on a continuum that can be primarily structural, primarily operational, or somewhere in between. A student may vary along the spectrum flexibly, but the ability to think structurally, at least some of the time, is necessary in order to progress to some higher order processes (Sfard, 1995).

Aside from Wladis et al. (2020), we have found little (if any) work on student conceptions of substitution equivalence, although there has been substantial work around equality. One common strand focuses on conceptions of the equal sign, where students see the symbol either operationally (as a ‘do something symbol), or relationally (as a relationship between two entities) (Knuth et al., 2006). In terms of substitution, relatively little work has been done, although some research has explored student notions of substitution equivalence in the context of arithmetic (Jones et al., 2012).

Model of operational and structural view of substitution equivalence

Wladis et al (2020) described key features of students’ thinking around substitution equivalence on a spectrum from structural to operational approaches. This paper aims to take this further by drawing on empirical data to explicitly describe how students’ conceptions of substitution equivalence may be dependent upon their definitions of substitution and equivalence (see Figure 1).

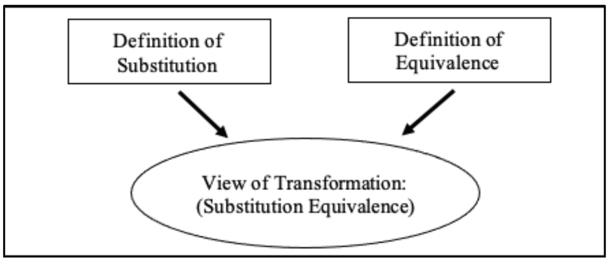

Figure 1: Model of student thinking about substitution equivalence

Method

This work draws on data collected from multiple classes across six years at an urban community college in the US, including cognitive interviews and open-ended questionnaires. Open-ended questionnaires and cognitive interviews were distributed to participants in courses from elementary algebra through linear algebra within a larger data collection process in efforts to develop an algebra concept inventory. These data were analyzed using grounded theory (Strauss & Corbin, 1990) to generate and refine models of students’ conveyed meanings to explain their written and spoken work. Categories developed during analysis were heavily influenced by the work of Sfard (1995), and existing literature about students’ understanding of the equals sign (e.g., Knuth et al., 2006). An initial coding scheme was developed by a single coder, and then in subsequent rounds, multiple coders revised the scheme until consensus was reached; coders included mathematicians, mathematics education researchers, and elementary algebra instructors.

The Model

Table 1: Components of substitution equivalence model

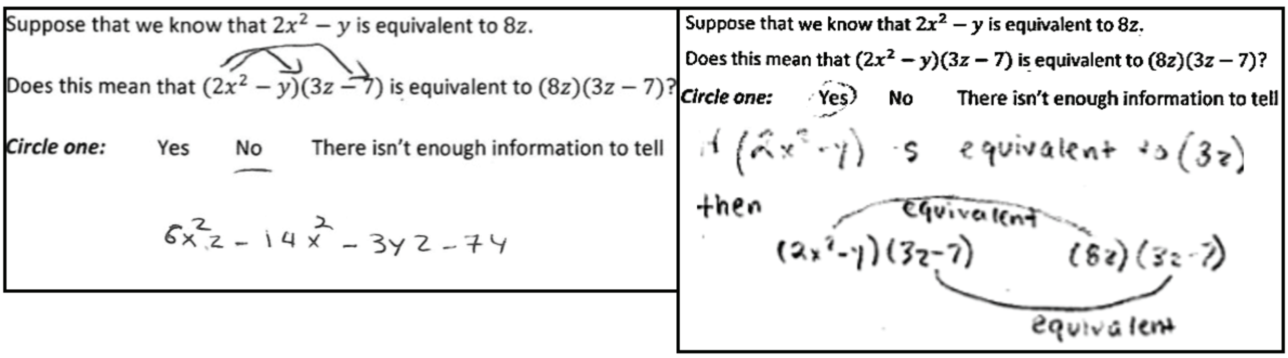
	Operational Thinking	**Structural Thinking**
View of Transformation	Students see transformations of expressions and equations (or other objects) as a process of “operating on” the original object itself. They may or may not see this as linked to any notion of equivalence.	Students see each step in a transformation as the process of replacing one object with an equivalent one through substitution, using properties and existing syntactic structure. They appear to have some notion of an equivalence class as an object (which need not be formally defined).

Definition of Equivalence	Students either ignore the notion of equivalence entirely, or appear to have only vague, ill-defined, or unstable notions of equivalence, or try to apply one definition of equivalence that works only in one context to another context.	Students have a well-defined and relatively stable definition of equivalence, and recognize that it is context-dependent. They recognize that equivalence is a fixed trait (two objects are either equivalent under a particular definition or not—they do not "become" equivalent).
Definition of Substitution	Students see substitution only as plugging a number in for a variable (and then computing the result). They see variables as representing only numbers.	Students see replacement of any object (or sub-object) with an equivalent one as substitution. They see variables as representing any valid mathematical object, including numbers or (potentially complex) expressions.

In the model in Figure 1, holding well-defined and standard definitions of both substitution and equivalence are necessary but not sufficient conditions for students to develop a view of transformation justified by substitution equivalence. A student may have trouble thinking of transformation as substitution equivalence because (a) their definitions of substitution are too narrow; (b) their definitions of equivalence are ill-defined, unstable, or mathematically invalid; (c) they do not draw on their knowledge of substitution and/or equivalence when performing transformation; or a combination of all of these. We conceptualize students' views of substitution, equivalence, and transformation as being on a continuum from operational to structural (Table 1). This model is based on the notion that the *ability* to conceptualize transformation as a process of substitution equivalence may be useful for students in developing deeper understanding of the justification behind their transformation work (and a way of checking the validity of that work).

Vignettes: A model in action

We now provide examples of students' written work from our dataset to illustrate how one might use the model we present here. These are intended to highlight the continuum of operational and structural views. To see how students' views of transformation as substitution equivalence can vary along this spectrum, we present two developmental algebra (a non-credit course with similar content to Algebra I from secondary school) students' responses about assessing whether two expressions are equivalent (Figure 2), where the first response (Figure 2a) exemplifies an operational view and the second response (Figure 2b) exemplifies a structural view.



(a) **(b)**

Figure 2: Examples of responses rooted in an operational (a) and structural view (b) of equivalence

The first student's response (Figure 2a) foregrounds computation and symbolic manipulation, so we classify it as an operational view of transformation. In cognitive interviews, students on similar problems have provided similar work and explained that they can only tell if two expressions are equivalent if they both simplify to the same final "answer". Hence we see the approach taken in

Figure 2a as indicative of having an internal computational definition of equivalence of “expressions that simplify to the same thing”. In contrast, the response in Figure 2b illustrates exactly how the two equivalent subexpressions are substituted into the larger expressions using arrows to indicate the relationship between each piece and to highlight the structure of the two expressions. This student mapped each unified subexpression in the first expression to an equivalent unified subexpression in the same place in the second, in order to illustrate why the two expressions are equivalent. Though the student didn’t use the word “substitution”, we see evidence that they were depicting a replacement or exchange of one equivalent sub-part with another.

Student definitions of equivalence

To see how students’ definitions of equivalence can vary, we refer to the previous examples and consider the definitions of equivalence the students seem to be evoking. These responses exemplify operational and structural definitions of equivalence, respectively. In Figure 2a, the student attempted to simplify the expressions to determine whether they are equivalent, and then appeared to decide that the expressions were not equivalent after they could not simplify them further. This definition (“two expressions are equivalent only if they simplify to the same thing”) of equivalence appears to be computational, and their work doesn’t seem to explicitly acknowledge equivalence relationships which justify their work. Because the student abandoned the attempt after simplifying did not work, this suggests that they did not see a way to use the structure of the given expressions to determine equivalence beyond simplifying both sides to see if the results are the same. In contrast, the response in Figure 2b suggests that the student may have a structural definition of equivalence. They drew on the structure of two complex expressions to show how they map to one another in such a way that each subexpression is either the same or equivalent, and they leveraged that structure to show that the final result is equivalent. This definition of equivalence appears to be well-defined and to be identifying fixed traits of the expressions.

Student definitions of substitution

To demonstrate differences along this spectrum, we look at two students’ definitions of substitution evoked from the prompt “In math, what is substitution? (Or what does it mean to substitute?)”. One student wrote “To substitute is to replace a number with a variable”, and further provided an example “$2x + 3 = 9$; $2(3) + 3 = 9$; $x = 3$”. This response (“putting a number in for a letter”) was one of the most common given by students at all levels, from elementary algebra through linear algebra. We classify this narrow definition of substitution as operational, whereas the response “To replace one number, variable, or expression for another” (a response from another student) was classified as structural definition of substitution. This is because their definition affords a greater variety of terms to be replaced for one another, which involves conceptualizing complex subexpressions as objects.

In order to see how students’ views of substitution may impact their view of transformation of expressions, we further examined their responses to a task to identify instances of substitution, and found that their responses were typically consistent with their definitions (e.g., only recognizing transformation as substitution when it involved a number being substituted in for a letter if that was their stated definition); we include one such example of this in the next section.

Using the framework to analyze student work longitudinally

In order to illustrate the potential of this model for deeper analysis, we consider examples from a single Algebra I student (whom we call Epsilon, like ε) across multiple tasks and points in time.

Substitution

We first consider Epsilon's definition of substitution, who gave the response that classified as an operational definition of substitution in the prior section. This correlates with the extent to which they identify different computations as substitution in the following work (Figure 3).

	Is it substitution? Circle one.	Explain how you know. If you don't know, please explain what you are thinking that makes you unsure of the answer.
$2x-9 = 2(3)-9$	Yes (circled) No I don't know	x is being replaced with 3
$(9+2)+8 = 9+(2+8)$	Yes No (circled) I don't know	No variables are being replaced
$10+(3+6) = 10+9$	Yes No (circled) I don't know	No variables are being replaced
$ab+ac = 2x+2y$	Yes No (circled) I don't know	Nothing is being replaced
$ab+c = 2(x-1)+3y$	Yes No (circled) I don't know	Nothing is being replaced
$8(x^2-9) = 8((x+3)(x-3))$	Yes No (circled) I don't know	Nothing is being replaced Just a different equivalent equation

Figure 3: Epsilon's interpretations of substitution in specific contexts

We can see in Figure 3 that Epsilon rarely identified computation as substitution when it was more complex or generalized. They noticed, for example, that the expressions in the last question in Figure 3 are equivalent, but they did not see replacement of the subexpression $x^2 - 9$ with $(x+3)(x-3)$ as an instance of substitution ("nothing is being replaced"), which is consistent with the more limited operational definition of substitution that they provided in the previous section.

Equivalence

Now we consider Epsilon's definition of equivalent expressions. When given the prompt "How could you check whether two mathematical expressions are equivalent? (An expression is a mathematical phrase that does not contain an equals or inequality sign)", Epsilon wrote "If they both have the same correct answer". Epsilon provided a seemingly correct (if perhaps incomplete or ill-defined) definition of equivalent expressions. We cannot be sure whether they understand that expressions must have the same value for every possible combination of variable values or that this applies to algebraic and not just arithmetic expressions, and the word "answer" is ill-defined; however, their definition is in line with the standard definition used in algebra, and they correctly identified that the algebraic expressions in the last question in Figure 3 were equivalent (as well as in other questions not shown here). Their definition also appears to be operational, as it is rooted in computations with expressions.

Substitution equivalence

Now we consider the extent to which Epsilon recognized instances of substitution equivalence in certain algebra examples. Epsilon was given the following two questions: 1.) "Suppose we know that $2x^2 - y$ is equivalent to $8z$. Does that mean that $(2x^2 - y)(3z - 7)$ is equivalent to $(8z)(3x - 7)$?" and "Suppose we know that $3a + b$ is equivalent to $42a$. Does that mean that $7a - 5 + (3a + b) + b^2 - 3a^2$ is equivalent to $7a - 5 + 42a + b^2 - 3a^2$?". Epsilon did not recognize either example as substitution equivalence, given that his response was "I don't know". To the first prompt, they wrote

"$24z^2 - 64z$" seemingly to simplify the expression "$(8z)(3x - 7)$" (in line with their definition of equivalence in the prior section), but this did not help them to identify whether the two expressions are equivalent. They did not appear to draw on the given fact that $2x^2 - y$ is equivalent to $8z$ when attempting to determine if the two larger expressions are equivalent. They provided no additional inscriptions in response to the second question.

This suggests that they may not have a notion of substitution equivalence or may be unable to draw on it in this problem context. Epsilon's operational approach when attempting to determine if the two expressions are equivalent suggests that their operational conception of equivalence may be limiting their ability to recognize and use substitution equivalence when performing mathematical transformations. Another potential barrier to Epsilon developing a robust notion of substitution equivalence and linking this to their transformation work may be their narrow notion of substitution itself. They likely did not recognize the transformations in the questions presented here as substitution just like they did not recognize most of the transformations in Figure 3 as substitution.

Potential impacts of instruction

Epsilon was part of a cohort that took part in a semester-long classroom intervention in which students were taught broader structural definitions of substitution, equivalence, and how to view transformation as substitution equivalence explicitly (as well as other concepts). After the intervention, Epsilon was not able to identify substitution equivalence in all cases, but they were able to recognize it in cases similar to those in the prior section. When given the prompt "Suppose that $3x = 2y + 1$. Does that mean that $5x^2 - (3x) + 7 = 5x^2 - (2y + 1) + 7$?", Epsilon wrote "Yes because $3x = 2y + 1$; its plugged in correctly". From this response, we see how they were able to recognize a complex equation as an equivalence relationship between two structurally identical expressions where one equivalent subexpression could be conceptualized as having been substituted for another. Epsilon's use of the words "plugged in" is a common phrase often used by students to indicate substitution. We do note, however, that this language still suggests a computational approach. However, Epsilon is drawing on structural features of equivalent algebraic expressions through the lens of substitution equivalence, even if their approach is still partially operational. We have insufficient space to discuss the intervention at length here—we simply include this short example to demonstrate that more structural and well-defined definitions of substitution, equivalence, and substitution equivalence approaches to transformation can all be learned by students, even those in developmental mathematics courses, when students are given the right supports.

Conclusion

We have presented a model that describes how students' definitions of substitution and equivalence may related to their ability to justify transformation through the lens of substitution equivalence. Using students' work, we have illustrated some of the affordances of this lens. We have demonstrated that students may struggle with substitution equivalence for different reasons, which may then require different instructional approaches. For example, if a student's definition of equivalence is ill-defined, it may be important to find ways for them to improve their personal definition; whereas if a student has broad and well-defined definitions of substitution and equivalence, a more effective approach may be to help them to see connections between this existing knowledge and their computational work when performing transformations. These are very different approaches to solving what might on the surface look like similar errors, but which stem from very different underlying patterns of how students think about mathematics. Thus, we hope that this model may aid us to better tailor instruction to respond to how to students think, and to better think about how definitions of substitution and equivalence are presented in instruction. We have also shown through one student's work that, with the right kind of instructional approaches, students can learn to think about transformation through a substitution equivalence lens. Further research is needed to investigate which ways of thinking may be most productive for students in different contexts.

A dynamic early algebra approach for transitions from describing figures to transforming expressions

Alexandra Tondorf[1] and Susanne Prediger[1,2]

[1]TU Dortmund University, Germany; alexandra.tondorf@tu-dortmund.de

Early algebra approaches have prepared the transition from arithmetic to algebra for concepts such as variables and the equal sign. In this paper, we focus on necessary transitions for the concept of equivalence of expressions. The design research project shows how fifth graders can develop an understanding of the transformations of expressions by dynamically restructuring figures.

Keywords: Early algebra, equivalence of expressions, connecting multiple representations.

Introduction: Early algebra for preparing transitions from arithmetic to algebraic concepts – the case of the concept equivalence of expressions

Students' challenges in the transition from arithmetic to algebra are widely documented empirically (Kieran, 2004). In different theoretical frameworks, two main instructional strategies have been applied to prepare these transitions: (a) *Making differences explicit,* e.g. between the operational and the relational meaning of the equal sign (Knuth et al., 2006), (b) *Preparing algebraic concepts* already in arithmetic in early algebra approaches, e.g. generalization activities for the later formal introduction of variables (Mason et al., 1985), but also the early confrontation with relational meanings of the equal sign (McNeill et al., 2019). These approaches can be effective in enhancing students' understanding that is fundamental for the later symbolic formalism for variable and equal sign. But as transitions are also necessary for a third algebraic concept, equivalence of expressions (equalities), we pursue the research question: *How to enhance the connection between different characterizations of equivalence to prepare the transition to algebra?*

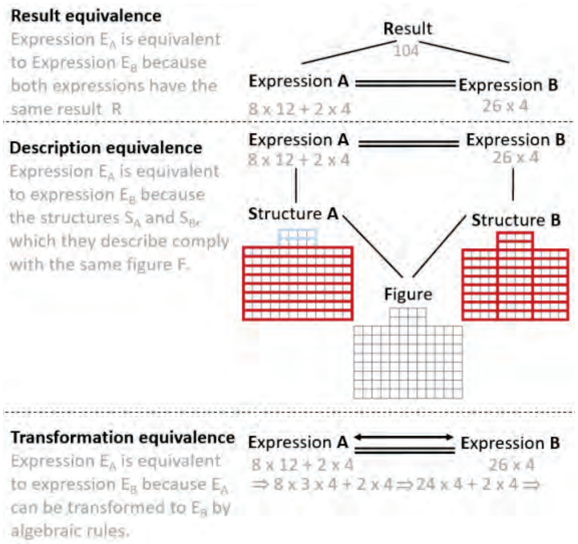

Figure 1: Three characterizations of equivalence of expressions (adapted from Tondorf & Prediger, submitted)

Background: Existing approaches and our design approach

Existing approaches for enhancing students' understanding of algebraic equivalence

For refining the research question, we adopt an epistemological perspective and first specify different characterizations of equivalence (Kieran, 2004; Zwetzschler & Prediger, 2013). Students usually start with an operational characterization of equivalence, *result equivalence* (defined as two numeric expressions are equivalent if they have the same result, see example in Figure 1). However, students also need to become aware of a relational characterization as *description equivalence*. Description equivalence is defined as two expressions are equivalent if they describe the same situation or figure, however, our learning environment, focuses on geometric figures, see example in Figure 1. In a later phase, the transition (or flexible move forward and backward) to a transformational characterization of *transformation equivalence* is needed (defined as two expressions are equivalent if they can be transformed into each other according to transformation rules) (Kieran & Sfard, 1999). Strategy (b) was already realized to facilitate a transition from result to description equivalence (Mason et al., 1985; Kieran & Sfard, 1999). However, the connection between description and transformation equivalence has hardly explicitly enhanced, so far. Based on the existing approaches, we conduct a design research project for developing and investigating an early algebra approach for bridging this gap for expressions without variables. On this background, we refine our research question as follows: *How can early algebra students' connection between description and transformation equivalence for expressions be enhanced?*

Based on a literature review, we briefly sketch two existing approaches for establishing these two characterizations: (1) Early algebra approaches can provide first opportunities for students to experience how different expressions can describe the same situation or geometric figure through connecting different representations (e.g. Mason et al., 1995). Some algebra approaches also make explicit that these pairs of expressions are then called equivalent, thus fostering the characterization of description equivalence (Zwetzschler & Prediger, 2013; Sfard & Kieran, 1999). However, the transition to transformation equivalence is hardly supported. (2) If the learning of the characterization of transformation equivalence is supported, then starting from result equivalence, not from description equivalence (e.g. Schwarzkopf et al., 2018). Usually without reference to a described situation or figure, these approaches engage students in discussing why two expressions have the same result by investigating involved expressions and the structure of their sub-expressions, e.g. by using the distributive law intuitively to summarise sub-expressions. As they do not yet sufficiently involve the connection of multiple representations, the representations will be a focus of our qualitative analysis.

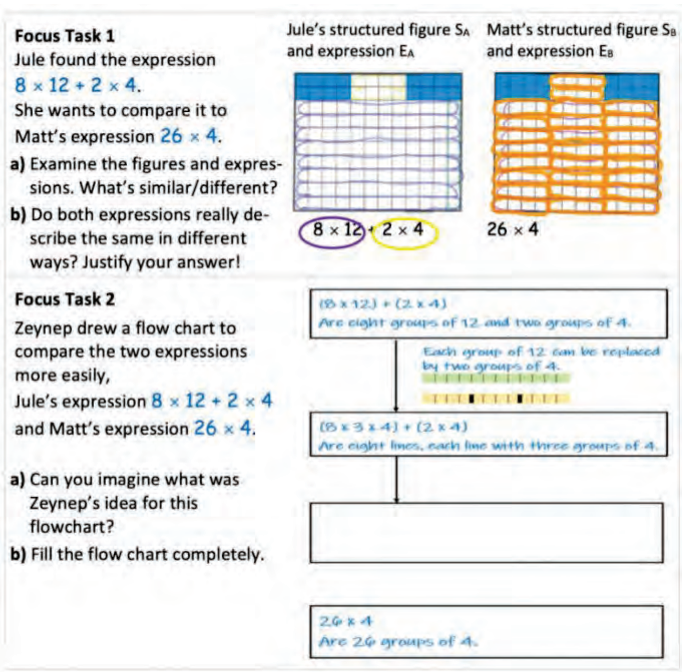

Figure 2: Task 1 for description equivalence, Task 2 for transcription to transformation equivalence

Our first design approach for connecting description and transformation equivalence

As the state of research shows, establishing a strong fundamental understanding of equivalence of expressions by the relational characterization as description equivalence is crucial, e.g. by connecting multiple representations

(Mason et al., 1995). However, existing approaches do not sufficiently support the connection of description and transformation equivalence. We designed a learning environment to engage students in activities that could lead to a recognition of this aspect of equivalence. Figure 2 shows two tasks focussed on in this paper: Students worked out the connection of structures of expressions and subexpressions to geometric structure in the figures and the characterization of description equivalence in previous tasks. Focus Task 1 then asks in a first approach to compare two different geometric structures and also their respective expressions.

Focus Task 2 then was the preliminary version designed to engage students in the connection to transformation equivalence by asking to connect each step of transformation to the geometric figures in a way that each expression can be replaced by a description-equivalent-one.

Methodology of the design research study

Within the chosen Design Research methodology (Gravemeijer & Cobb, 2006), we developed the initial design (from Figure 2) and investigated the research question mentioned above.

Methods of data gathering. Up to now, design experiments have been conducted in laboratory settings with seven pairs of fifth graders. In total, 27.5 hours of video were recorded and partially transcribed. In this paper, we analyze a case of two girls, Lea and Linda (10-11 years old), described as high-achieving by their teacher. This case was chosen due to its significance in illustrating two complementary phenomena concerning the task potential with respect to the research question.

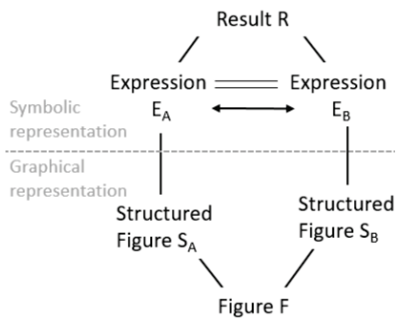

Figure 3: Analytic framework for capturing representations and connections addressed in students' utterances

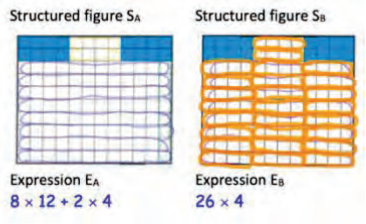
Methods of data analysis. According to the analytic procedure developed in Tondorf & Prediger (submitted) for other cases (Figure 3), the transcript was qualitatively analyzed in two steps: In step 1, the students' utterances are coded according to the addressed components: result R and the expressions E_A and E_B, in symbolic representation, or in the graphical representation the structured figures S_A or S_B, and the figure F. In step 2, students' utterances were coded regarding the implicitly or explicitly drawn links between the components and marked in the analytic framework (═ marks the conclusion that E_A and E_B are equivalent, ↔ marks a transformation between E_A and E_B , — marks the connection of two concerned / marked objects. The coding was conducted by the first author, checked by the second author, missing intercoder agreement was solved by consensual discussion.

Empirical insights into students' transition pathways

Episode 1: Students' invention of restructuring from one structured figure to the next

Episode 1 illustrates students' emerging idea of a *dynamic comparison* of the given structures that we identified empirically: By dynamic we mean a comparison which results from a stepwise modification of one object into the other (e.g. E_A to E_B in transformation equivalence). We distinguish it from *static comparison*, which is bound to a third stable object of comparison (like result equivalence comes from connecting both expressions E_A and E_B independently of one another to result R). In Task 1 of Figure 2, Linda and Lea are asked to compare the two structured figures (named S_A and S_B for easier analysis) and the expressions E_A and E_B with respect to similarities and differences. The girls had already allocated the structure of the expressions to the structure of the figures by explained marking of S_A coming from E_A or rather by finding E_B coming from S_B, described how both expressions are description equivalent, and named same-structured and different-structured areas of S_A and S_B. When asked to transfer their discovery onto the symbolic representations, Linda focused on S_A and S_B and starts to describe the relation between 8×12 in E_A and groups of fours in E_B.



49	Linda:	Here [gestures along the rows of structured figure S_B with 3 groups of 4], when you take that together
50	Teacher:	Um, that is a great idea, can you also.
51	Linda:	four, eight, twelve

Linda described the relation between three groups of four in one row of structured figure S_B and one complete row of 12 (like in S_A). Even though she used merely the vague "here" to refer to the units (Turn 49) and a language of symbolic representation for the process ("take together" in Turn 49), she hinted at the structured figure S_B (Turn 49) and explained how the 3 groups of 4 in a row are related by counting up in units of fours (Turn 51). We interpret her dynamic notion ("take together") and the counting in units as her explanation of how a row with 3 groups of 4 can be dynamically modified into 1 group of 12. Within our analytic framework in Figure 4, we thereby inserted an additional edge between S_A and S_B that we had not found in the literature prior to our analysis.

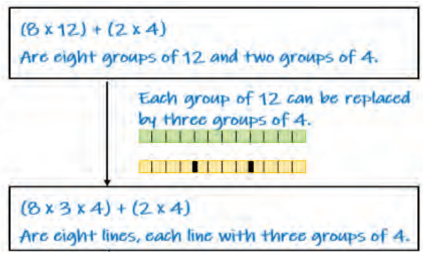
Figure 4: Additional edge for students' restructuring process from S_B to

The case of Lea and Linda resonates with other cases analysed in Tondorf & Prediger (submitted), in which we identified similar dynamic descriptions of the structured figures. With different technical or everyday phrases ("break apart", "draw a line"), students express emerging ideas of restructuring the figures. So, the extension of the analytic framework by a new edge (not anticipated from the literature) is not only a technical analytic detail, but an important finding of a forth characterization of equivalence that the first group of students invented. It can be seen as the graphical counterpart of the symbolic transformation equivalence. We call this dynamic relation between structured figures *restructuring equivalence* (represented by the double arrow between S_A and S_B).

Episode 2: The connection of transforming and restructuring expressions

Linda and Lea continued to build upon the dynamic connection between the structured figures S_A and S_B (that they invented in Episode 1): Episode 2, documented in the next transcript, took place in the beginning of their discussion of Task 2 (from Figure 2), when they tried to retrace the ideas of the fictitious student Zeynep and connected her idea to their previous idea from Turn 49/51:

154	Linda:	She [the fictitious student Zeynep in Task 2] always means, um, she writes always what is here [points at “Each group of 12 can be replaced by 3 groups of 4.”], above.
155	Lea:	Uh-huh, she describes the expressions, always.
156	Linda:	[After 10 sec break] Ok. [reads out loud] “Each group of 12 can be replaced by two groups of 4.” That works, because four, eight, twelve [gestures along the yellow line in the picture]. Just like it was done by Matt [hints at S_B]. And then, he has done also always, uhm uh-huh, groups of 12 always into groups of 4. Just like here, also here [hints at the green and yellow line]. She [referring to Zeynep] says, what you could do.
157	Lea:	Yes, every [group of] 12 can be, by three fours
158	Linda:	be replaced
159	Lea:	Can be replaced.
160	Linda:	Yes, and that works, actually
	…	
162	Linda:	And here [unclear where exactly she points at]. Three times – um – eight times three plus – no: eight times three times four. Two fours
163	Lea:	#plus two times four. This is here, that, though [shows the upper lines in S_A/S_B which only two groups of four squares are marked] two times four.
164	Linda:	Yes, she has only splitted them, here [hints at $8 \times 3 \times 4$], hasn’t she?



When Linda read the given explanation of a replacement process in Turn 156, she immediately connected it to the dynamic modification she conducted in Turn 51 in Episode 1 (when taking together the 3 groups of 4 into 12) and interpreted this modification backwards, as splitting the 12 into 3 groups of 4. Whereas the phrase “can be replaced” in the task is more static (i.e. not involving dynamic restructuring processes), her interpretation was expressed dynamically as “done […] groups of 12” (Turn 156). This approach of dynamic modification of the figures is then transferred to making sense of the symbolic transformations in the following lines: Examining the expression $8 \times 3 \times 4 + 2 \times 4$, Linda mixes language of symbolic representation (Turn 162 “eight times three time four”) and referring to the graphical representation of multiplication (Turn 162 “two fours”). We interpret this as an indication that she mentally connects the graphical and symbolical representations to one object. Lea strengthened this connection by articulating how both representations match each other (Turn 163). Apparently, Linda and (maybe also) Lea succeed to connect the known characterization of description equivalence with their emerging characterization of restructuring.

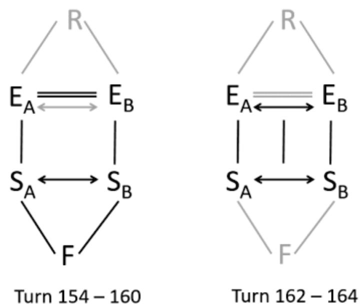


Figure 5: Students’ process of argumentation and connecting of restructuring and transformation

Based on this connection, Linda started a first attempt to explain the change within the symbolic expression (Turn 164). She addresseed the transformation of 8×12 into $8 \times 3 \times 4$ (Turn 164), again expressed with reference to the graphical representation (“splitted”), which refers to her underlying characterization of restructuring. Although her description of the process is not completely explicit, her emergent meaning-making of the transformation process is recognizable. Both girls constructed the meaning of transformations starting from the geometric characterization of description equivalence given in the task. However, they used a further bridging characterization for this transition, their dynamic characterization of restructuring equivalence.

Other students in our design experiments also used this newly emerging idea of restructuring as a bridge from description equivalence to transformation, so again, the identified phenomenon was not only specific to Linda and Lea. Like for Task 1, students used various ways of articulating their ideas to bridge the gap and explain the connection. Also in Task 2, they varied in the degree of explicitness when describing and explaining the transformation of expressions. However, they had in common to connect both processes, restructuring and transforming, in their meaning-making processes (for further cases see Tondorf & Prediger, submitted). The empirically identified phenomenon lead to another extension of our analytical and epistemological framework in Figure 5: the additional vertical edge between the double arrows links the restructuring from S_A to S_B and the transforming between E_A and E_B. This extension signifies the mentally constructed connection between both characterizations.

Discussion and conclusion

Summary and embedding of findings

Our research question, *how students' mental connections of description equivalence to transformation equivalence for expressions can be enhanced*, was addressed in a design research methodology (Gravemeijer & Cobb, 2006). Our preliminary design answer developed in the first design experiments was to present expressions $8 \times 12 + 2 \times 4$ and 26×4 that describe the same geometric figure structured in two different ways, and to engage the students not only in discussing similarities and differences of the structured figures (Task 1 in Figure 2) but also to stepwisely compare bridging expressions from $8 \times 12 + 2 \times 4$ via $8 \times 3 \times 4 + 2 \times 4$ and $24 \times 4 + 2 \times 4$ to 26×4.

The empirical analysis of the presented case (and further cases in Tondorf & Prediger, submitted) reveals that students can even go beyond the stepwise static comparisons initiated in the task (e.g. between the subexpressions 8×12 and $8 \times 3 \times 4$): several (but not all) students were found to adopt a dynamic approach to find the modifications made in the structured subfigures and explain how to restructure one subfigure into the other. They articulate these restructuring activities in dynamic wording ("take together", "break apart", "split"). Whereas a dynamic approach is usually only used for the transformation of symbolic expressions, we learned from these students that a dynamic approach can be used already earlier, when working with the graphical representations. Thereby, they constructed a fourth bridging characterization that we named *restructuring equivalence*, for which we see a huge potential to prepare the meaningful ground for transitions to later algebraic transformations.

The activity of restructuring figures is used by mathematicians in so-called proofs without words for proving the equivalence of symbolic expressions by restructuring figures, of course while acknowledging that an explicit articulation of connection is also required (Nelsen, 1993). Our study reveals a possibility for students to discover the underlying restructuring equivalence when working with geometric figures and we argue that this has important theoretical implications. We further develop this empirically grounded theorisation in Tondorf & Prediger (submitted).

In our data, we found a second important phenomenon that contributes to the theorisation: Students use the restructuring equivalence to make sense of transformation equivalence. When trying to make sense of the transformation of the expression, many students connected the symbolic and graphical representations intensely, e.g. by combining references to symbolic representation and graphical representation to describe the expression or figure (like Lea in Turn 162 of Episode 2). In these contexts, students built upon their dynamic approach (constructed for comparing structured figures) to explain the transformation steps between the bridging expressions. Thus, they made sense of transformation equivalence by explicitly connecting it to restructuring equivalence. The restructuring equivalence thereby takes the role of an important new bridging characterization in a dynamic approach (Figure 6) that prepares not only the shift from graphical to symbolic representations, but also the transition from the static approach of description equivalence to the dynamic approach of transformation equivalence. With the new bridging characterization, we can engage students in connecting multiple representations which has often been shown to be effective for learning (e.g. Mason et al., 1995). Moreover, we can engage them in connecting concepts and procedures, which is of major importance for the successful transition from arithmetic to algebra (Kieran, 2004).

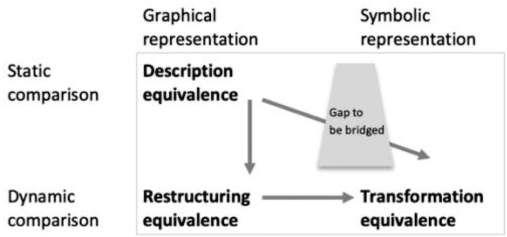

Figure 6: Restructuring equivalence as bridging characterization in early algebra

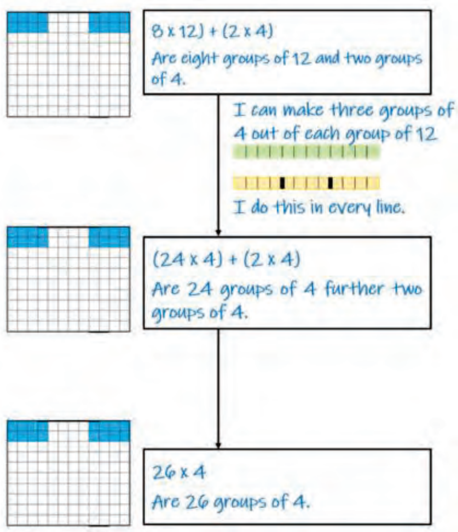

Figure 7: Revised Task with a more dynamic approach

Introducing bridging characterizations might be another instructional strategy (c) that can enrich strategy (a), making differences explicit, and (b), treating core ideas of algebraic concepts before the formal symbolism of variables is introduced, (see introduction).

Consequences for our instructional design

We used the empirical findings for revising the task in our second design experiment cycle: In order to enhance *all* students' mental connections of graphical and symbolic representations as identified for Lea and Linda, figures were added in each step of transformation and restructuring. Additionally, the explanation in the first step was phrased in a more dynamic way to support students' dynamic thinking (Figure 7). As the analysis of processes initiated by the refined Task 2 reveals (Tondorf & Prediger, submitted), these revisions allowed also students who could not adopt a dynamic approach in Task 1 to take over the offered dynamic language to describe and partially explain the transformation by restructuring. With these additional supports, the bridging characterization seems to be in reach for many students.

Methodological limitations and concluding remarks

The presented design experiments provide promising insights into how one may enhance students' understanding of transformation equivalence. However, there are still many gaps to fill. Firstly, we have not yet transferred the idea to other expressions and other transformation processes. Secondly, the presented task and the learning environment do not include the transition to generality which is crucial in early algebra as well. Thus, students' learning is not yet enhanced beyond the concrete case given in the task. There is need for further research to develop learning opportunities in which the contextual ideas can evolve into general concepts.

Keywords: Geometry education, tools, teacher training, geometry task.

Introduction

The TWG04 is concerned with research on geometry teaching and learning from kindergarten to university, including teacher education. In particular, it aims to contribute to the congress and research by discussing new and upcoming matters regarding the teaching and learning of geometry and, at the same time, continuing the discussions on the issues raised in the last CERME.

At virtual pre-CERME12 in 2021, two topics were discussed (*The specific aspects of mathematical activity in geometry* and *Teaching and learning geometry*), around questions such as "Which competencies (visual, reasoning, operational, and figural) should students/pupils have acquired/developed at the end of a specific school level?", "Which is the impact of online teaching and learning geometry?", and "What geometry our students should know when they move from primary to secondary to tertiary education?". Crucial points highlighted by several contributions are the relevance of language from a very early age, the use of material and digital tools, and the focus on visualization. At CERME12, in TWG04, we intended to continue discussing the two issues proposed for pre-CERME12 and relaunch a third issue, *Teacher education in geometry*.

Around 25 researchers from South Africa, the Middle East, East/Central/West Europe, the USA, and South America participated in TWG04 during the online sessions. The TWG04 work was stimulated by and organized around nine research papers and three posters. This group's exciting and relevant feature was its polyphony: a blend of experienced and young researchers discussing geometry teaching and learning. In the concluding survey, the participants indicated that participation in the TWG04 was an enriching experience.

Organization of the TWG04 at the congress

The papers and posters were divided into three topics, concerning their primary focus on *Teacher education in geometry*, *Use of tools in geometry teaching and learning*, and *Students*.

The fundamental elements of all the papers and posters were presented by the authors and discussed in groups. In particular, in each session, two papers/posters were introduced by a participant, and then a collective discussion followed. In turn, one participant was in charge of writing down the questions and comments arising during the discussion on an open document, as well as each participant could contribute by writing questions/comments on the same open document. At the end of the work on the set of papers/posters concerning a topic, the participants were divided into three subgroups to discuss related questions, which were formulated by the team of group co-leaders to guide them towards a synthesis of the previous collective discussion. Finally, the last session was dedicated to sharing the synthesis of all the discussions and small group works to prepare the final report of this working group.

Focus on teacher education in geometry

This topic includes contributions that have teacher training and reflections on teachers' beliefs on geometry as crucial elements.

In her paper, Kuzle investigates the value of geometry in mathematics instructions through a questionnaire proposed to a sample of 120 German in-service teachers. She analyses two items of that questionnaire: the first item aims to collect teachers' opinions on the role of geometry instruction in elementary school, and the second item asks to mark the most significant reasons for neglecting geometry education. A result of this research is that geometry is still insufficiently taught compared to other areas of mathematics, in particular arithmetic, even if positive changes are observable. In general, the predominance of arithmetic seems related to time-practical reasons rather than a disregard for geometry. Nevertheless, there seems to be a difference between prospective and in-service teachers, related to the insecurity that prospective teachers have with respect to geometry content knowledge. Two reasons could explain this difference: a lack of mathematics knowledge from school as learners and insufficient preparation at the university level as teachers. From this research emerges the question of knowing if there are some geometry topics teachers feel more insecure about teaching them. Further research could provide elements to plan teacher education from different perspectives.

Finally, the discussion on the paper confirmed the relevance of the investigated question "What role does geometry instruction have nowadays in school mathematics?" for all the teachers, and the relevance of taking into account how textbooks convey an image of geometry with respect to the other parts of mathematics curriculum (i.e., starting from the organization of chapters in the textbook).

Hausler and Kuzle's poster contributes to the discussion on teachers' images of geometry. By "Imagine you are an artist. A good friend asks you what geometry is. Draw a picture in which you explain to him or her what geometry is for you. Be creative in your ideas", prospective primary teachers attending a geometry course at the university were invited to perform two drawings, one at the beginning of the course and the other at the end. The two authors analyse the drawings to detect changes due to the attendance of the course taught by one of the authors.

Although research is carried out on teachers' beliefs (e.g., see other CERMEs groups), these two contributions emphasize that in teacher education, it is vital to consider not only primary teachers' beliefs about mathematics but also about particular fields of mathematics and its teaching, as in this case geometry. From this point of view, it might become fundamental to investigate which activities/tasks affect prospective teachers' attitudes towards geometry and its teaching and define criteria for identifying their impact on teachers.

The questions concerning the relation between teachers' content knowledge, their difficulty in teaching geometry, and didactical tasks are also investigated in other papers from different perspectives.

Ratnayake et al.'s paper focuses on secondary school prospective teachers and their difficulty in enacting geometry in the classroom. In the trend of research focusing on teachers' mathematical knowledge, their research project aims to offer a set of criteria for developing aspects of examples in tasks to analyse teachers' knowledge in geometry. In particular, with this work, the analysis of figures and their attributes in solving tasks is discussed.

Several questions emerged, such as which tasks can be considered emblematic for prospective teacher education in geometry. The papers presented by Bernabeu et al., Giménez et al., and Brunheira et al. contributed to the discussion on primary school teacher education. In particular, Bernabeu et al. and Giménez et al. propose classification tasks, the former on quadrilaterals and the latter on 3D figures. Brunheira et al. focus on the reasoning process in the context of a task on 3D figures. In all these papers, the features of the tasks allow highlighting the knowledge that students possess and the knowledge that teachers need to develop for geometric thinking.

Bernabeu et al. analyse quadrilateral classifications to bring out the definitions possessed by prospective primary teachers and to identify prospective teacher profiles. Although their research focuses on the mathematical knowledge of prospective teachers, the task analysed here can be interpreted between specialized content knowledge and pedagogical knowledge (Ball, Thames & Phelps, 2008). The researchers do not collect quadrilateral definitions and classifications with direct questions but as responses to a professional task given to prospective teachers. Specifically, they analyse teachers' knowledge through their answer to the request to anticipate children's answers for a classification task. The analysis shows that only around 30% of the teachers use hierarchical definitions involving the transitivity of inclusion relations (although with some non-economic definitions). The discussion of this paper also led to a comparison of quadrilateral classifications and definitions in the primary school of participants' countries, showing how classifications can be relevant – referring to Usinkin and Griffin's work (2008) – for comparing and examining curricula and textbooks (for instance, see the definition of rhomboid/parallelogram or trapezoid/trapezium).

Giménez et al. analyse the answers to the task of constructing polyhedra using material half-cubes and classifying them; they aim to identify which types of knowledge prospective teachers possess. As in Bernabeu et al.'s paper, they are interested in mathematical content knowledge; nevertheless, the authors also consider the meta-didactical knowledge on the value of the classification process in learning geometry. Indeed, the questions they ask students include important mathematical knowledge and invite discussion of the relevance of the processes activated in these tasks (for instance, "Why do you consider that when we study various types of figures, a fundamental process to work with is classification?"). The analysis highlights that even at the undergraduate level, the perceptual appearance dominates over certain conceptual aspects: most of the classification criteria are based on a description of the object with a low level of structuring. Despite having manipulative elements which could support them, prospective teachers are not capable of expressing mathematically well-formulated explanations. For instance, they use terms from plane geometry in their discourse on spatial geometry, and their arguments are very similar to those that pupils use. Thus, the question of what role the construction of tangible models plays in developing prospective teachers' geometrical thinking and knowledge for teaching geometry remains relevant.

In Brunheira et al.'s paper, 3D geometry is the context in which the researchers study prospective (primary and secondary) teachers' knowledge of reasoning process within the framework of specialized mathematics knowledge for teaching. The task for prospective teachers proposed in the paper consists of two parts: in the first part, the prospective teachers have to identify the reasoning processes involved in the task which will be proposed to students; in the second part, prospective teachers are asked to discuss on students' reasoning that emerging in an excerpt of a dialogue between students and teacher. The analysis shows that this kind of task and context promotes the knowledge of reasoning processes.

The discussion which developed in the working group proposed additional issues, such as:

- It is significant to bring together the mathematical properties and visualization processes involved in solving a geometric problem.
- There is a need for more collaboration between researchers and teachers in the research field of geometry education.
- The role embodied context plays in geometry teaching and learning, particularly the use of tools, types of tasks, and activities.
- Research could focus on the learning trajectory between primary and secondary education and its relation to the education of prospective teachers.

Finally, two suggestions emerged for further research contributions. The first suggestion is the following research questions: "Do teacher training programs in different countries have geometry/ teaching geometry courses (and to what extent)?" and "How can this choice influence prospective teachers' efficiency/preparation for geometry instruction?". The second suggestion concerns the development of research on secondary teacher education in geometry in connection with primary teacher education.

As pointed out in the discussion of some of the papers in this section, tasks on 3D geometry seem to be a good context for exploring geometrical thinking. The papers in the next section also focus on this content using DGS and material (tangible) models.

Focus on the use of tools in geometry teaching and learning

The group discussed this topic based on three contributions: one paper concerns using the 3D environment of GeoGebra DGS, and the other papers report two experiments with material (tangible) models of 3D figures made with different tools (3D pens and construction kits). All these papers refer to secondary school. They are based on different theoretical frameworks (i.e., the theory of semiotic mediation and embodied learning).

In Sua et al.'s paper, 3D DGE mediates the relationships between 2D space and 3D space. The task described in the paper involves geometrical constructions and their meaning in plane geometry and pays attention to the meaning of correct constructions (corresponding to several solutions) for constructions in 3D space. The dimension of space is the only variable of the task: the request for constructing triangles (isosceles and equilateral ones) is the same in the two spaces, 2D and 3D, starting from the same kind of initial object (the side of the triangles). While adapting the 2D procedure, the students consider the new dimension of the space passing from circles to spheres in their constructions, but they do not control the intersections between the drawn spheres as they do with the circles. On the other hand, the syntax of some commands in 3D DGE does not match 2D procedures; the transition between environments also requires a different and new conceptualization of 2D objects by students. This paper opens several research questions on: 3D visualization mediated by the DGE, cognitive and epistemological control in the transition from 2D to 3D spaces, awareness of this transition for students (it seems to observe a misattributing of 2D properties to 3D objects). Finally, in general, which is the challenge of this kind of task for secondary students?

The two other papers investigate 3D geometry using 3D pens and construction kits.

Palatnik and Abrahamson develop an enactivist argument for learning 3D geometry by constructing tangible models in their paper. They describe the gap between the geometry taught at school, mainly 2D geometry with 2D tools, and the 3D space where students live and experience 3D objects. From an embodied perspective in mathematics education, the authors investigate students' cognitive processes in 3D tasks with tools for constructing 3D models of solids (i.e., cube and tetrahedron) in small and medium sizes (hand-held and human-scale models) (Herbst, Fujita, Halverscheid & Weiss, 2017). These tasks foster the transition between 2D and 3D figures and models and, in general, between 2D and 3D space differently from that analysed in Sua et al.'s paper. Students' physical actions led to shifts in perceptual-motor attention, which involve a refinement of geometric reasoning.

Rosenski et al.'s research focuses on emotional aspects and the influence of affect in 3D problem solving using 3D pens. Their results show the relevance of those aspects in learning geometry with tools and the potential of the 3D pen for engaging students in spatial geometry tasks. Compared to the construction kits, the 3D pen is an emerging technology for mathematics education. Subsequent group work discussed the role of the novelty of material and digital tools in student engagement, particularly when the novelty of a tool is neutralized by regular use in the classroom.

The discussion in the group raised several questions, such as: "What is the added value of tangible and/or digital/virtual manipulatives in geometry instruction?", "Is it important to start a teaching experiment from material manipulatives with students?", "What are the affordances and constraints of using material manipulatives?". For students in different age groups, we asked: "What constitutes learning of geometry when they use physical models?", "When is it useful to propose material tools, and when is it necessary to let students work only with their mental images?", "What are principles of task design with manipulatives?", "What makes work with manipulatives (material and virtual) exciting for students (except the novelty of medium)?". Furthermore, "Why is 3D DSE especially important as a tool of semiotic mediation?". These questions remain open for research.

Our group agreed on the importance of using material tools to teach geometry in elementary school, high school, and even at university level. Nevertheless, the idea that manipulatives and digital tools are age-sensitive emerged: some tools (or some ways of using them) are adequate for younger or older students; so, while moving between different manipulatives or a manipulative and symbolic forms, the meanings that need to be constructed have to be in focus. Material and digital tools offer a combination of representations, which is very important in geometry teaching and learning (Herbst, Fujita, Halverscheid & Weiss, 2017). In some cases, as with 3D pens, boundaries between material and digital tools, novel and traditional mediums, 2D and 3D, are constantly crossed; thus, it becomes interesting to study them. Although the novelty of a tool is a factor of motivation and reinforcement in the learning process, it seems that students' motivation in activities with tools cannot be ascribed to their novelty alone; the creative and collaborative nature of activities could maintain student's interest because they made something together, they have to communicate, and so on.

The discussion proposed additional issues, such as:

- Taking into account instrumental genesis for students and teachers and the importance of students' experience with tools.
- Identifying the tool's novelty effect on students' engagement and motivation.
- Considering the change of didactical contract when a new tool is introduced in the class for planning activities and identifying students' engagement.
- Emphasizing connections between geometry education and its applications in the real world (e.g., architecture, mechanical engineering, and art).

Focus on students

The discussion on the third topic was based on three papers concerning students in grades 5, 6, and 9. These papers are developed within different theoretical frameworks (e.g., embodied cognition, realistic geometry, van Hiele Levels, PISA framework for competences) and focus respectively on abstraction in geometry (Boonstra), problem solving requested by online DGS tasks in the time of COVID (Edamus et al.), and assessment of geometrical competencies (Bočková et al.).

The contributions of Boonstra and Edamus et al. discuss the same mathematical content, the geometric reflection, and pay attention to static and dynamic aspects concerning the reflection in two different environments. Grounded in the realistic mathematics education approach, Boonstra focuses on the processes activated by 5-6-grade pupils facing two problems on reflection through the use of a mirror ("Move the chess towers in front and behind the see-through mirror and let them meet in the mirror"; "Place a see-through mirror in the correct position on the line") to investigate how embodied activities support abstraction. This paper suggests discussing which characteristics and properties the tasks should have to support abstraction and which is the role of the tool (e.g., tasks with a mirror and tasks without a mirror) within the embodied research design.

Edamus et al. analyse the resolution of a task on the composition of two reflections with parallel axes to study students' understanding of reflection from a functional point of view. In particular, after constructing the symmetrical figures, two students have to collaborate online to solve the task of moving axes and describing/explaining what happens to the symmetrical figures. In the discussion on students' processes, the questions on why students must move between static and dynamic aspects for understanding reflection and how this helps them in their learning process are asked. The setting of the experiment is interesting for fostering communication between the students, the emergence and development of mathematical language: in pair work, one student gets access to the online DGS file and shares his screen; only this student can manipulate the DGS figure while the other one is forced to verbalize his ideas and give instructions.

The third contribution brought in the discussion on the assessment of geometrical competencies. The heart of the matter is which strategies and methods researchers and teachers have at their disposal to assess students’ competencies in geometry. The assessment involves choosing what is to be evaluated, a framework for geometry learning and competencies, and a format in which questions are asked. The crucial question arises as to a suitable framework for constructing a good test to measure geometric thinking.

In the discussion, additional issues emerged, such as:

- Different types of tasks and content (i.e., the inclusion of non-Euclidean geometry; topology; task with manipulatives) can surface different aspects of students’ geometric thinking, reasoning, behaviour, argumentation, …
- Engaging students in collective visualization is challenging in the absence of physical manipulatives.

Finally, other questions emerged for further research contributions, for instance, concerning social aspects of students learning of geometry (i.e., gender differences in participation)

Future Directions for TWG04

The discussions in this TWG were vibrant and, as a good discussion, posed more questions than answers. In this paper, we leave some other suggestions for the next TWG on geometry teaching and learning.

In the frame of the geometry education research community considering the possible international study on the geometry content knowledge necessary for (primary/secondary) teachers:

- What research questions should be considered?
- Which differences and similarities of national curricula should be taken into account?
- Which theoretical perspectives on geometry teaching and learning should be taken into account?
- What tools does the current research provide for teacher education in geometry?

In the paper and poster presentations, we observed three essential processes involved in students’ work when they engage with a geometric problem/task: visualization, argumentation, and the transitions between different representations (e.g., 3D geometrical objects and their 2D representation). As researchers and/or teachers, how can we become aware of/observe when our students engage in those different processes? Finally, how can we foster/promote the activation of those processes?

We hope that this TWG on geometry teaching and learning continues to advance the research on geometry education, paying attention to the changes in scholarly contexts and the new educational needs that arise.

This study aims to characterize the preservice primary teachers’ curriculum reasoning when anticipating primary students’ answers to figure classification tasks. Anticipating answers to figure classification tasks involves considering the relationship between the definition and classification and the characteristics of geometrical thinking progression. We analyzed the definitions of geometric figures posed by twenty-eight preservice primary teachers to quadrilateral classification tasks. The results show three preservice primary teachers' profiles taking into account the specialization/generalization of the quadrilateral definitions provided and the transitivity of inclusion relations. These results indicate features of curricular reasoning in anticipating tasks as part of preservice primary teachers’ curricular noticing.

Keywords: curricular noticing, anticipating students’ answers, geometric reasoning, hierarchical classification, definition of geometric figures.

Introduction

Previous researches (Jones & Tzekaki, 2016; Sinclair et al., 2016) argue that it is important for teachers to understand the elements that condition understanding of inclusive relationships to plan geometry instruction. This generates the need to know how preservice primary teachers (PPT) reason when anticipating student answers as an aspect of *curricular noticing* (Dietiker et al., 2018). This construct describes a set of professional practices that allow teachers or preservice teachers to recognize, interpret, and generate learning opportunities from teaching-learning situations when they interact with curricular materials. In these situations, they had to carry out the *curricular reasoning* (Breyfogle et al., 2010), which has been defined as the thought processes in which teachers or preservice teachers engage when working with curricular documents or materials to plan, implement and reflect on instruction.

Theoretical Background and Framework

A key aspect in the progression of geometric thinking, whatever the educational level, is understanding a geometric figure as an example of a class of figures (hierarchical classification). The understanding of hierarchical classifications is linked to the definition of the figure. These hierarchical classifications imply that, for example, a figure (square) in a class A (rectangle) has all the properties of the class B (parallelograms) that includes it. There are two processes for defining these figures. On the one hand, the *specialization* process, in which to get an example of A, attributes have been added to the definition of B (more general class); and, on the other hand, the *generalization* process, by suppressing attributes from the definition of an example of A to create a more general class, like B. The process of including an example within a more general class, and so on (A is an example of B, B is an example of C, so A is an example of C) is known as *transitivity* (de Villiers, 1994) (Figure 1).

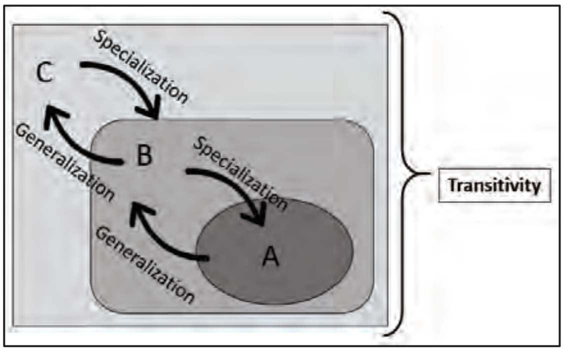

Figure 1: The specialization and generalization of the definitions and the transitivity of the inclusion relations

However, understanding the *specialization* and the *transitivity* in the hierarchical relationships between figures is difficult (Fujita, 2012; Fujita & Jones, 2007). Previous research (Brunheira & da Ponte, 2019) showed that prospective teachers, after a teacher education experiment that includes this kind of classifications, had a limited figural concept, and therefore, difficulties in the hierarchical classifications using the transitivity. These difficulties may be a problem for prospective teacher when they will have to plan the teaching/instruction.

For planning the teaching of hierarchical relationships of geometric figures in primary education, PPT should anticipate the thinking processes that the tasks may promote in students considering the cognitive abilities of the students (both mathematical and didactic contents). For example, PPT should consider, as key aspects in learning, the process of *specialization* of the definition (adding properties to a general class) as well as the *transitivity* of the inclusion relations (A→B and B→C, then A→C) (de Villiers, 1994). The way in which PPT use these two features of inclusion relations between geometric figures could provide information on how they reason about the hierarchical classification tasks. In this sense, anticipating students' answers to hierarchical classification tasks in a lesson is a skill linked to *curricular reasoning* (Breyfogle et al., 2010) as an aspect of *curricular noticing* (Dietiker et al., 2018). Thus, this study aims to find out:

- How do PPT reason when anticipating correct answers in hierarchical classification tasks as an aspect of curricular noticing?

Method

This study involved 28 PPT who participated in a learning environment (4 sessions of 2 hours) aimed at developing *curricular noticing*. The content of the learning environment includes the characteristics of geometric thinking development in primary education and the types of tasks for enhancing the students' geometric thinking along the lesson plan. The PPT, during the learning environment, analysed primary school students' answers, anticipated answers from primary school students to the tasks of classifying geometric figures and shapes, and analysed teaching activities to support understanding of inclusion relationships (Lehrer et al., 2014). These actions related with the *curricular noticing* are what the PPT would put into practice during their teaching practices at school and in their future as teachers. At the end of the learning environment, PPT solved a task on anticipating primary school students' answers to an activity in inclusive relations between geometric figures (Usiskin & Griffin, 2008). In this study, we analysed the PPT's answers given to this last task through a qualitative analysis (Figure 1).

The task

The task is contextualised in the planning of a lesson with the learning objective: *inclusive relations between geometric objects*, for pupils aged 10-12 years. The focus was the relation between definitions of geometric objects and classification. Three versions of the same task were proposed in the domain of quadrilaterals (Figure 2). The task highlights the *curricular reasoning* processes (Breyfogle et al., 2010) of PPT by anticipating possible student answers considering mathematical knowledge and the development of geometric thinking in primary education (Sánchez-Matamoros et al., 2019). PPT should take into account the process of specialization (add conditions to generate subclasses) and the transitivity of the inclusion relationships of quadrilaterals. For example, in version 1b task, the rhombus must have *four equal sides* to be a particular example of the rhomboid class (*quadrilateral with two pairs of opposite sides parallel*) (Table 1).

Some of these quadrilaterals often appear in the primary school curriculum with partitive (non-inclusive) definitions, such as defining trapezium as a quadrilateral with only two parallel sides. Thus, this task has a high cognitive demand for PPT, as it requires modifying and overcoming the definitions associated with prototypical images and partitive definitions.

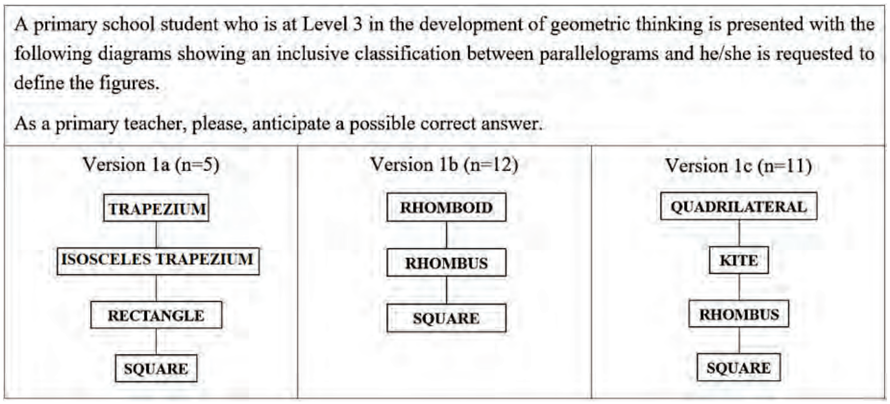

Figure 2: Task of anticipating student answer as part of teaching planning

Version 1a	Version 1b	Version 1c
Trapezium: quadrilateral with two parallel sides.	Rhomboid: quadrilateral with two pairs of opposite sides parallel	Quadrilateral: polygon with four sides

Isosceles trapezium: trapezium with congruent diagonals.	Rhombus: rhomboid with congruent sides.	Kite: quadrilateral with perpendicular diagonals and two pairs of adjacent congruent sides.
Rectangle: isosceles trapezium with congruent angles.	Square: rhombus with congruent angles.	Rhombus: kite with congruent sides.
Square: rectangle with congruent sides.		Square: rhombus with equal angles.

Table 1: Possible definitions and inclusive relationships between quadrilaterals

Analysis

For the analysis of the task answers, we considered three criteria:

- The economy of the definition, i.e., if the definition included the minimum and sufficient conditions or redundant conditions. In addition, we considered if the definitions derived from the perceptual references of prototypical examples (*prototypical judgement, type 1*), from the attributes of prototypical examples (*prototypical judgement, type 2*) or using attributes relevant to the concept (*analytical features, type 3 judgement*) (Hershkowitz, 1990).
- The *specialization* of the definitions, i.e., to what extent it was considered that adding attributes to the general class generate a subclass. For example, in task 1c, to define a rhombus, it is sufficient to add having equal sides to the definition of a kite (see Table 1).
- The *transitivity* of the definitions (A→B and B→C then A→C). For example, that the definitions given allow us to see that, if a square is a rhombus, and a rhombus is a rhomboid, then the square is a rhomboid, but not inversely (there are rhomboids that are not squares) (asymmetric relations between the inclusion relations between geometric figures).

Regarding of procedure followed, we analysed the answers following the above criteria (Figure 3) and then compared the answers with each other, identifying similarities and differences, generating patterns of answers. These patterns of answers were considered as profiles PPT's anticipatory competence of anticipating primary school students' answers to a task on figure classification as a part of the acquisition of the curricular noticing. One student out of 28 provided an answer that was inconsistent with the required task, so it was not considered in characterising the profiles.

Preservice teacher 17 (PPT17)'s answer	**Pre-analytical comments**
Rhomboid: Parallelogram with interior angles less than 180°, and with 4 sides parallel two by two. *Rhombus: Rhomboid with 4 equal sides and perpendicular diagonals* *Square: Rhombus with four right angles*	- *Uneconomical* definitions (non-minimal) (e.g., if you say the rhomboid is a parallelogram, you do not need to say 4 parallel sides two by two) - There is *transitivity* (the square is a rhombus; the rhombus is a rhomboid). - Use *specialization* by adding attributes to the more general class it belongs to.

Figure 3: Example of analysis of the PPT17's answer

Results

The analysis has generated three PPT's profiles.

Profile 1. No use of hierarchical definitions nor of the transitivity process (n=7)

Preservice primary teachers in this profile do not recognise the process of generating subclasses as they do not take into account any case the specialization of definitions, and they fail to consider the transitivity between inclusion relations. In this profile, PPT seem to base their definitions on prototypical images, generating *prototypical judgements of type 1*. For example, the preservice teacher PPT10 in task 1b, Rhomboid→Rhombus→Square, indicated,

- *Rhomboid: A geometric figure with four sides that do not form right angles, of which the opposite sides are equal, and the adjacent sides are unequal.*
- *Rhombus: Geometric figure with four equal sides that do not form right angles.*
- *Square: Figure having four equal sides that form four right angles.*

This PPT use partitive definitions and removes the possibility of generating subclasses from the more general classes by indicating that: the rhomboid has the *adjacent sides unequal*, excluding the rhombus as a subclass of the rhomboid; the rhombus *has no right angles*, eliminating the possibility of squares as a subclass of the rhombus; and the rhomboid *has no right angles*, excluding squares as a subclass and thus preventing *transitivity* between inclusion relations.

Profile 2. Partial use of hierarchical definitions, but not transitivity process (n=12)

PPT in this profile show a partial understanding of the specialization process. They define the figures considering only some of the inclusion conditions indicated in the task. Furthermore, they show a lack of understanding of the transitivity of inclusion relations by defining some figures using attributes of the prototypical figures, but not all the necessary attributes or using some definitions incorrectly. In this profile, PPT seem to use attributes of the prototypical examples as reference, generating *prototypical judgements of type 2*, as they use attributes of the identified figures. For example, the preservice teacher PPT2 in task 1a, Trapezium→Isosceles Trapezium→Rectangle→Square, indicated

> *As the student is at level 3, he can analyse the properties of geometric figures giving the sufficient and necessary indications, relating the properties to each other:*
>
> - *The trapezium is a quadrilateral with only two parallel sides.*
> - *The Isosceles trapezium is a quadrilateral with two equal angles two by two.*
> - *The rectangle is a quadrilateral with all right angles.*
> - *The square is a quadrilateral with all sides equal and all right angles.*

By defining trapezium as a quadrilateral with *only two parallel sides*, it excludes the possibility of considering the rest of the parallelograms (rectangle and square) as subclasses, and therefore does not take transitivity into account. By defining isosceles trapezium as a *quadrilateral with [two] equal angles two by two* it seems to be using some properties of the prototypical figure, but not all of them.

Finally, the definitions and the relation of inclusion between squares and rectangles are adequately indicated, reflecting judgements supported by the attributes of the prototypical figures and evidencing the characteristic of *specialization* between the rectangle and the square.

Profile 3. Use of hierarchical definitions involving the transitivity of inclusion relations (although with some non-economical definitions) (n=8)

In this profile, PPT use the specialization of definitions and the transitivity of inclusion relations. They define geometric figures considering, in all cases, the process of adding attributes to a class to generate a subclass (*specialization*), which entails the *transitivity* of inclusion relations. Furthermore, in most cases, they define geometric figures using the relevant attributes of the concepts (*analytical features*, *type 3 judgement*), although in some cases they provide redundant data. For example, the participant PPT17 in task 1b, Rhomboid→Rhombus→Square, explains,

- *Rhomboid: Parallelogram with interior angles less than 180º, and* <u>*with 4 sides parallel two by two*</u>.
- *Rhombus: rhomboid with four equal sides and* <u>*perpendicular diagonals*</u>.
- *Square: rhombus with four right angles.*

This PPT adds redundant information in the definition of rhomboid: *parallelogram with angles less than 180º and parallel sides two by two*. However, he explicitly uses the process of *specialization* of definitions (*a rhombus is a rhomboid that ...; a square is a rhombus that* ...), showing the *transitivity* of inclusion relations.

Discussion

The aim of this study was to characterise the PPT's curricular reasoning when anticipating correct answers in tasks involving inclusive relations between geometric figures as an aspect of *curricular noticing*. The results show three profiles of the PPT's curricular reasoning in the classification tasks, considering how they considered the *specialization* of definitions and the *transitivity* of inclusion relations. The three profiles described in the result section show two ideas. Firstly, about the preservice primary teachers' understanding of the relationship between defining and classifying, and secondly, about the characteristics of the PPT's curricular reasoning regarding the student's geometrical thinking in anticipating tasks.

Preservice primary teachers' understanding of the relationship between defining and classifying

The *specialization* of definitions and *transitivity* of inclusion relations are key to understanding the relationship between the processes of defining and classifying. On the one hand, the process of *specialization* allows us to understand how adding properties to figures generates a subclass of a class. Furthermore, considering the definitions of geometric figures to reflect two (or more) inclusion relations is a key aspect that must be understood by PPT when they think about the cognitive demand of tasks for the primary students. On the other hand, the *transitivity* of inclusion relations is linked to the process of *generalization* of definitions, which allows to include a figure (A) within a class (B) and, to include this second class, within another more general class (C) (Figure 1). Understanding these relationships between figures, dismissing misconceptions generated by prototypical examples (profile 3) and using *Analytical Features* (type 3) (Hershkowitz, 1990) seems to be a necessary condition in PPT's understanding of the potential of teaching activities in primary education. Thus, PPT using in their definitions some references to prototypical examples or attributes of figures to express the inclusive relationship between geometric figures (*prototypical judgement 1 and 2)* (Hershkowitz, 1990), seem have limited ability to anticipate primary school students' answers to the classification tasks of geometric figures.

Characteristics of preservice primary teachers' curricular reasoning in anticipating tasks

The PPT's curricular reasoning in anticipatory tasks indicates ways of thinking about teaching activities considering the students' geometrical thinking. In this study, the ideas of *specialization/generalization* of definitions and *transitivity* of inclusion relations have been considered as key aspects when PPT anticipate student answers in the teaching activities focused on the relationships between defining and classifying. In this way, anticipating student answers has shown features (profiles) of the PPT's curricular reasoning as part of *curricular noticing* (Amador et al., 2017). Furthermore, these results show that if a PPT uses correctly all the process to anticipate a hierarchical definition from a classification (specialization and transitivity), he/she has acquired one of the aspects of the curricular noticing.

For example, the inclusion relationship between the Rhomboid→Rhombus→Square has been the one in which the least students have applied the process of *specialization*, generating non-inclusive definitions and using the attributes of the prototypical figures, which tend to be exclusive. Possibly, using prototypical examples of the concept of quadrilateral makes it difficult for PPT to use the relevant attributes of different quadrilaterals to establish inclusive relationships between them. Moreover, in the definitions in which excluding attributes have been used the most, so that neither *specialization* of the definition nor *transitivity* of the inclusive relations can occur, it has been in the quadrilaterals in the first inclusion relation of the three graphs (e.g., in task 1b Rhomboid→Rhombus). We think that this may be due to the difficulty involved in the process of *generalization* (eliminating certain properties or substituting some for more general ones) when the concepts have already been acquired (*a posteriori classification*) (de Villiers, 1994) (Figure 3), to include the rest of the quadrilaterals that make up the inclusive relation within this more general class.

Keywords: van Hiele theory, geometric thinking, nine–grade pupils

Geometry is one of the most important topics of mathematics education. Even though most pupils just see geometry as the study of objects, points, shapes, geometry, is also applied in other subjects such as engineering, architecture or music. For these reasons, a very important teachers´ role is to arouse pupils´ interest in geometry and create a positive relationship with it. Sometimes it is a challenging mission because as we can observe in recent years, students in Slovakia achieve a relatively low level of geometric knowledge (Bočková, Pavlovičová, Čeretková, 2020). The pupils´ problems with geometry can be caused by the fact that pupils are at a very low level of geometric thinking or mathematics competencies in geometry. For this reason, it is very important to use van Hiele theory at all levels of education.

Dutch mathematicians Pierre van Hiele and Dina van Hiele – Geldof tried to understand and eliminate pupils' problems in geometry. Based on their observations, they described the model of geometric thinking in 1957. Van Hiele theory consists of five hierarchical and sequence levels (visualization, analysis, informal deduction, formal deduction, rigor) (Usinkin, 1982; Van Hiele, 1986). Today, van Hiele model of geometric thinking forms the basis of the content of education in various countries, such as the United States, Russia, Netherlands and Taiwan.

The main aim of this poster is to present the research about geometric thinking and mathematics competencies in the geometry of nine-grade pupils in Slovakia, who finished the lower middle school level of education. The research is focused on determining the level of geometric thinking of pupils The aim of the research is a quantitative evaluation of the solution of geometric problems, too. We also would like to find out the connection between the correct solutions of the geometric problem at different levels of mathematics competencies in geometry and the level of geometric thinking according to Van Hiele theory.

The levels of pupils´ geometric thinking were determined by using the van Hiele geometric test. The test was applied with the consent of Professor Zelman Usiskin. We suggested the valid and reliable Test of mathematical competencies in geometry, too. In the test, we used PISA division of mathematical competencies into three competency clusters: reproduction, connection and reflection. The test contains three tasks for each of the three levels of mathematical competencies. The research was realized in May – June 2021. The research sample consisted of 760 nine–grade pupils, who solved the van Hiele geometric test and Test of mathematical competencies in geometry.

According to Mc Anelly (2011), who has stated the separated levels of geometric thinking in the age category, pupils in the second stage of elementary schools should be at the level of analysis or informal deduction. Our research shows that 50.5 % of pupils achieved the required level of analysis or a higher level of geometric thinking (21.3 % - analysis level, 24.2 % - informal deduction level, 5 % - formal deduction level). The surprising finding is that 7.4 % of pupils did not even reach the level of visualization and 27.5 % of pupils achieved the visualization level. 14.6 % of pupils did not assign any level of geometric thinking. We compared same-age pupils from other countries with similar research, which was carried out by Usiskin (1982), Haviger, Vojkůvková (2013), Adelabu, Makgato, Ramaligela (2019) and Idris (2009). Slovak students have a similar or higher level of geometric thinking.

From the solution of geometric problems at different levels of mathematical competencies, it follows that pupils have a lot of misconceptions of basic knowledge in geometry. They cannot identify or use the formula for geometric shapes. They do not determine the length of the sides and the length of the altitude of geometric shapes from the picture, they have problems read from the image. Pupils also use the Pythagorean theorem in the general triangle and they have an incorrect conception of a straight angle.

We used statistical implicative analysis methods, specifically C.H.I.C. statistical software (Classification Hiérarchique Implicative et Cohésitive) to compare and reveal the connections between the level of mathematics competencies with the attained level of geometric thinking according to Van Hiele theory. An important finding is that we confirmed the interconnection between the solutions of individual tasks of both tests, with the achieved level of geometric thinking as well as with the correct solutions of tasks at a certain level of competence.

Embodied abstraction in geometry learning in grades 5 to 6

Karel Boonstra

University of Applied Sciences Utrecht & Utrecht University, The Netherlands;
karel.boonstra@hu.nl

Keywords: *Embodied design, design research, geometry, abstraction*

To explain, interpret and distinguish the large diversity of visual information and spatial phenomena in today's world, children need to be able to grasp and understand the underlying mathematical and geometrical structures. Relating these real-life spatial phenomena with their underlying geometrical characteristics can be regarded as abstraction, one of the core aspects of mathematical thinking according to Drijvers (2015). How to foster the process of abstraction in geometry in primary school is the central question of my research. Practical and theoretical perspectives on geometry and abstraction, together with the theoretical lens of embodied cognition, led to design criteria for activities fostering abstraction in geometry. Accordingly, activities on mirroring for students from grade 5 to 6 have been designed, based on an embodied abstraction approach.

Theoretical background and research question

Geometry education in the Netherlands is characterized by a realistic approach, described by Freudenthal (1973) as grasping space, "the space that the child must learn to know, explore, conquer, in order to live, breathe and move better in it" (p. 403). It encompasses problems, tasks and activities experienced in our direct surrounding, with the aim of learning about mathematical objects and concepts.

Based on the definition of abstraction by Dreyfus (2014), as the attempt to reach an understanding of the structure of a mathematical concept, and the notion of reflective abstraction by Piaget (1985) the process of abstraction in geometry can be regarded as the discovery and formalizing of new (to the learner) mathematic structures in spatial orientation through a process of reflection on experiences and explorations.

The theoretical lens of embodied cognition is used in this study for an embodied approach of abstraction in geometry. Embodied cognition theory emphasizes that all cognition is rooted in bodily experience; in the interaction of the body with the physical environment (Abrahamson & Lindgren, 2014). The definition of abstraction in geometry through the lens of embodied cognition that is used for the design reads: the process of describing, explaining, reflecting on, and structuring of action in the experienced world using mathematical artifacts. The design principles for the learning environment have their origin in action-based embodied design, one of the design genres introduced by Abrahamson et al. (2020). In action-based design: "participants … tackle motor-control problems: they are assigned the task of performing a technologically mediated manipulation of material or virtual objects, in an attempt to achieve a specified goal state." (p. 5). The research question we try to answer with this design is: how can embodied activities in geometry contribute to the process of abstraction by children in grades 5-6.

Methods

The study can be characterized as a design study (Bakker, 2018). During a series of design cycles, a learning environment on embodied tasks on mirroring is developed and tested. Criteria for the environment are outlined in a design table and based on the definition of the process of abstraction (see above) and elements of embodied design: enactment, expected verbalizing, degrees of freedom, and attentional anchors. The tasks focus on the geometrical properties of mirroring: perpendicularity, equidistance and angle of incidence begin equal to the angle of reflection. This is done using a see-through mirror, chess pieces and a laser pointer. The designs are tested during task-based interviews with 8 individual children from grade 5 and 6. The interviews, which took 30 minutes on average, are video-taped. Data are in the process of analysis in a bottom-up theory-guided coding process.

Results

During acting, all students discovered the correct position (equal distance to the mirror and on a straight line perpendicular to the mirror) of the chess pieces on either side of the see-through mirror. When explaining their solutions, they showed an understanding of equal distances of object and reflection image. Several students were able to write a clear instruction, including a drawing, of how to position the chess pieces, thus showing promising steps in the process of abstraction. Although they showed an understanding of the need of perpendicularity, they still struggled with the abstraction hereof.

Conclusion

This embodied design shows mixed, but also promising, results in fostering abstraction in the designed tasks on mirroring. More work is needed to further investigate embodied design in this and other areas of geometry.

Developing prospective primary teachers' knowledge of mathematical reasoning processes in the context of a geometry task

Lina Brunheira[1], Lurdes Serrazina[1] and Margarida Rodrigues[1]

[1]Escola Superior de Educação, Instituto Politécnico de Lisboa, UIDEF, Instituto de Educação, Universidade de Lisboa, Portugal; lbrunheira@eselx.ipl.pt; lurdess@eselx.ipl.pt; margaridar@eselx.ipl.pt

This paper aims to discuss the prospective primary teachers' knowledge of reasoning processes, namely the way they relate several reasoning processes, when solving a didactical task involving geometry. Data were collected by audio and video records of lessons, participant observation and the collection of written records of the prospective teachers. The results show how a group of prospective primary teachers may reach a high level of knowledge when involved in didactical tasks that are supported by relevant mathematical tasks and real classroom episodes, while working collaboratively. In particular, geometry tasks that involve spatial structuring favor the emergence of different reasoning processes and its relationships.

Keywords: Mathematical reasoning processes, Prospective primary teachers, Geometry, Spatial structuring

Introduction.

Teacher education should give special attention to mathematical reasoning, considering both the ability to reason, and knowledge about the reasoning processes (Stylianides & Stylianides, 2006). In particular, developing mathematical reasoning processes in the domain of geometry, in early years classrooms, implies specifically developing visualisation and spatial reasoning (Moss et al., 2015) since the central processes of generalising and justifying (Rodrigues et al., 2021), in this case, are founded on the geometric properties and on the objects´ structure.

This paper is part of the *Mathematical Reasoning and Teacher Education* (REASON) project, which aims to study the mathematical and didactical knowledge teachers need to carry out a practice that promotes pupils' mathematical reasoning and to study the ways to foster its development in prospective and practicing teachers of primary, middle and secondary school. In our communication we intend to discuss the knowledge of reasoning processes of a group of prospective primary teachers, when solving a task involving geometry, namely the way they relate several reasoning processes. This task was the fifth one implemented in a teacher education experiment carried out in 2019/20.

Conceptual framework

Reasoning in geometry

Reasoning geometrically about a spatial entity (object, diagram or concept) implies constituting an adequate mental model, that is, one that captures its relevant spatial structure and its geometric properties. Battista et al. (2018) state that "spatial and geometric structuring are types of spatial and geometric reasoning, respectively, that play vital roles in the construction of appropriate mental models for geometric reasoning" (p. 202). For spatial reasoning to adequately support geometric reasoning, these mental models must incorporate operational knowledge of relevant geometric properties and concepts, using mental models that integrate geometric properties into their structure and operation (Battista, 2007).

Lannin et al. (2011) distinguish two aspects in the generalisation: (i) identify common elements in different cases; (ii) extend reasoning beyond the domain for which common elements were initially identified, that is, thinking about a relationship, idea, representation, rule, pattern or other mathematical property considering it in a broader domain. For example, when, at the beginning of school, a student identifies squares as the figures that have four equal sides, he is making a generalisation that is false, but it is a generalisation. For these authors, the process of justifying consists of building a logical sequence of statements, each one relying on established knowledge in order to reach a conclusion. Thus, constructing a valid justification for a generalisation is not easy as it has to be verified that the generalisation is true for all cases in the domain, resorting to valid implicit relations. A valid justification must explain why by offering a view of the underlying relationships that exist in all cases.

Thus, we consider that the process of generalising is fundamental in Mathematics when we intend to "make general statements about properties, concepts or procedures" and that "justification is central to making it possible to mathematically validate" those statements (Mata-Pereira & Ponte, 2018, p. 783). These two processes interact with each other, as in many situations the language used in justification has to be general so that its applicability to the entire domain is clear; on the other hand, when some generalisations are established, it is because, at least implicitly, there are already justifications for them. For Jeannotte and Kieran (2017), exemplifying is an auxiliary process of generalising and justifying, which allows inferring data about a problem by generating elements that support those processes. In the process of generalising, it is essential to look for similarities and differences through the production of examples, in which case it is necessary to mobilize the process of comparing. In turn, in justifying the examples can be critical, for example when using counterexamples. For these authors, classifying consists, through the search for similarities and differences, identifying common and distinct points in different objects, joining them or separating them into a class of objects based on mathematical properties or definitions. This process involves comparing and, by stating that all elements of the class obey certain characteristics, it establishes a generalisation (Brunheira, 2019). For Mason (2001), “classification is not just about making distinctions and describing properties, but about justifying conjectures that all possible objects with those properties have been described or otherwise captured” (p.7). Mariotti and Fischbein (1997) state in the following way what means to classify in geometry:

> A classification task consists of stating an equivalence among similar but figurally different objects, towards a generalisation. That means overcoming the particular case and consider this particular case as an instance of a general class. In other terms, the process of classification consists of identifying pertinent common properties, which determine a category. (p. 244)

Thus, in addition to identifying the different reasoning processes, it is essential to have a deep understanding of the meaning of each one in order to establish relationships between them, thus reaching a high level of knowledge (Rodrigues et al., 2021).

Reasoning in preservice teacher education

Several studies (Lannin et al., 2011; Stylianides & Ball, 2008; Stylianides & Stylianides, 2009) indicate that prospective elementary school teachers must have opportunities to develop their mathematical reasoning if they are to work on it with their students, particularly in geometry.
In the field of geometry, Battista (2007) states that reasoning is strongly based on the spatial structuring of objects or situations, that is, on mental models that are activated to interpret and reason about these objects or situations. In the context of preservice teacher education in geometry, Brunheira (2019) suggests that processes such as classifying and justifying generalisations about geometric figures are influenced by the quality of spatial reasoning, but they are also promoters of its development. For Lehrer et al. (2013), geometric concepts such as shapes and relationships between them, for example congruence, constitute opportunities to build those relationships.
In addition to developing their own reasoning, Francisco and Maher (2011) refer to the need to create opportunities for teachers to learn about how to develop mathematical reasoning in students. In the same sense, Stylianides and Ball (2008) defend the need to develop in teachers the ability to plan and implement tasks that promote the development of reasoning in their students.

Methodology

The study reported here followed a qualitative-interpretative approach (Erickson, 1986) since it aims to understand the way prospective teachers relate several reasoning processes. Its context is a teacher education experiment developed in 2019/20 with 31 prospective primary teachers, attending a Master Degree certifying for teaching in primary schools (grade 1 to 4) and teaching Mathematics and Natural Sciences in grades 5 and 6. It took place during six lessons, one per week, each lasting two hours and 30 min and focused on mathematical reasoning, addressing specialised mathematics knowledge for teaching. All the tasks were initially explored autonomously by the prospective teachers, organised into eight groups, and were subsequently discussed by the class as a whole.

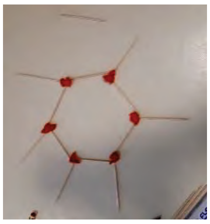
The data were collected through participant observation of the lessons, by the team Project, using audio and video recordings of the autonomous work carried out by two groups of prospective teachers (Groups 1 and 2) and the whole class discussions, and documents collection (all tasks resolutions). The data reported here are from Group 2. According to the ethical criterion of confidentiality, all the prospective teachers signed a free and informed consent form, in relation to the data collection methods, and are given fictitious names.

This paper refers to a didatical task about reasoning in geometry. Figure 1 presents an excerpt of the task.

Consider the task *Let's learn about pyramids*, proposed to 3rd grade students. In the previous year, the class had already come into contact with pyramids and prisms, in a first approach to their characteristics. So the teacher introduced the task by projecting the image below and asking *What is the intruder?*

After the initial discussion, the students started solving the task in pairs, using some models of pyramids in cardboard and wood, match sticks, toothpicks and plasticine balls.
3. Identify the reasoning processes involved.

4. Read the following dialog. The students had already analysed the possibility of building a pyramid with 13 edges using the material, as shown in the image. They were currently analysing the same issue for 15 edges.



Teacher — So, with 15 toothpicks, 15 edges, what happened?
Student — It would be missing 1.
Teacher — So and how many toothpicks did you put in the base?
Student — Eight.
Teacher — Eight. And now how many do you have to put on the side edges?
Student — Oh my God...
Teacher — OK, you can look at what you've done!
Student — Seven.
Teacher — So, can we build with 15?
Student — No… there was a toothpick missing… with odd numbers I couldn't do it.
Teacher — Ah! So tell me why it's not possible with odd numbers.
Student — Because one is missing or one is left.
Teacher — And why does this happen? What happens to the edges in the pyramids?
Student — Hmm... Here (points to the base) and here (points to the place where the side edges would be) must have the same number.

4.1. Discuss how the student's reasoning evolved, relating it to the interaction she established with the teacher.
4.2. Explain the role of the manipulative material in this situation and throughout the task.

Figure 1: An excerpt of the task

We used content analysis (Bardin, 2010) of the data using the framework we elaborated before (Rodrigues et al., 2021) concerned with knowledge of reasoning processes. The categories correspond to the reasoning processes worked in the teacher education experiment: generalising, justifying, exemplifying, comparing and classifying. Each of these categories were divided into subcategories corresponding to six levels of specialised mathematical knowledge of the content, presented in hierarchical form (Table 1).

Table 1: Framework for knowledge of mathematical reasoning processes

Category	Subcategories
Knowledge of the reasoning process	5. Knowledge of the process fits the definition presented, and includes its relationship with the other reasoning processes
	4. Knowledge of the process fits the definition presented, and is explicitly outlined by enunciating the properties of the process
	3. Knowledge of the process fits the definition presented, and is explicitly outlined through illustrative example(s)
	2. Recognising a reasoning process though considering only 'correct' processes
	1. Knowledge of the process takes on the meaning of the term in everyday language
	0. The process is confused with other processes

Results

Episode 1

In this episode, we analyse the reasoning processes that the group of prospective teachers identified to be used by the 3rd grade students during the solution of the intruder task (Figure 1). This lesson intended to support the introduction of the classification process which is, in our perspective, the main process in question. In fact, to find the intruder, students must identify pertinent common properties that determines the pyramids as a class (for example, they all have triangular faces that converge at a vertex) where the prism does not belong. For this, they should also ignore their particularities (for example, distinct bases) and consider them as representatives of a more general class (Mariotti & Fischbein, 1997).

Nuno:	OK. "Identify the reasoning processes involved". Here, I think that . . . the most obvious common is generalisation. They identify a property that fits all the pyramids.
Lara:	Yes.
Daniela:	Yes, Yes.
Nuno:	So one of them is to generalise. To compare...
Daniela:	Also to compare. You don't think so?
Nuno:	Between several...
Daniela:	Between figures, yes.
Lara:	To generalise they compare, don't they?
Nuno:	Yes, yes. They exemplify, here it does not...
Lara:	No.
Daniela:	No.
Daniela:	Compare between what?
Lara:	Among the different figures so that you can generalise.
Helena:	For example, here they made a comparison. When they had to select what it was [the intruder].
Nuno:	Yes, that's a fact. Between the ones that are and the ones that are not [pyramids].
Helena:	Exactly.

As expected, the prospective teachers did not report the classification process, but their analysis clearly identifies the generalising process that is strongly related to that process (Jeannotte & Kieran, 2017; Mariotti & Fischbein, 1997). Furthermore, Nuno explains the substantiation of this generalisation by saying that it corresponds to the property that “fits all pyramids”, an idea that gathers consensus. Associated with the process of generalising, the group also refers to the process of comparing as a support process because, as Lara says, it is necessary to compare the different figures “so that you can generalise”, which is also consistent with the literature.

The group agrees and is sure about the two identified processes, when one of the elements raises the hypothesis that the process of justifying may be also involved:

Lara:	To justify I don't know if it makes sense. Okay, you find properties that you can justify, but properties are generalisations.
Nuno:	Yes, yes. So, to generalise.
Helena:	I think it's enough to generalise and to compare.
Nuno:	Although, in order to generalise, they will also have to justify first, generalising is the most comprehensive of all. They will say first that the pyramid is a pyramid...
Helena:	Because so, so and so. Exactly.

Nuno:	It is a quadrangular pyramid, because the base is a square and because the faces are triangles, it has x vertices...
Daniela:	I think that, in order to reach the generalisation, they start with justification.

What started out as a tentative hypothesis from one of the prospective teachers turned out to be a meaningful possibility for everyone. The idea that the process of justifying may be involved derives from the perspective that, in this case, when we generalise we already have justification in mind or, to put it another way, we generalise because we know why. This idea is consistent with the suggestion by Mason (2001) when he states that the process of classifying also involves justifying conjectures that all possible objects with those properties have been described. Furthermore, in the particular case of geometry, as Brunheira (2019) states, the justification of generalisations concerning a class of geometric figures is based on a mental model of the class of objects, that is, its spatial structure that often presides over the formulation of generalisations.

In this way, we consider that the group's dialogues are quite relevant as they identify interactions between the processes of generalising and justifying, also showing understanding about all processes already dealt with, which corresponds to level 5.

Episode 2

Lara:	She started, she realized first that with 13 [toothpick] it would be left with one, right? That was the first thing she noticed. With 13 there would be one left, then with 15…
Daniela:	Yes, but here…
Lara:	One would be missing.
Lara:	She only realized the 15… she only gave the answer to 15 so quickly, because she had already done the one for 13.
Helena:	Because she had already done for 13.
Lara:	Because she even said there was one missing. Do you understand?
Daniela:	Yes…
Nuno:	Then we have to make a comparison with what the teacher was saying. Right here at the beginning, the teacher refers to another example, so she can...
Lara:	So, she can make a generalisation.
Nuno:	A generalisation, exactly.
Daniela:	So, the student began by understanding that with 13 toothpicks, one would be missing to complete the pyramid.
Nuno:	Then the teacher … encourages the student to go further…
Lara:	By giving another example.
Nuno:	…and it presents a new example, in this case with 15 toothpicks. Then the teacher encourages the student to go further by presenting a new example. She presents a new example, enabling the student to use the reasoning process, to generalise. She gave this example so that she could later conclude that it couldn't be an odd number.

In the written record with the answers to the task, the group summarizes the previous ideas and adds:

> In order to lead the student to a generalisation, the teacher guided her, leading her to understand that the number of toothpicks could not be odd. Also, the teacher asks why this happens, prompting justification. In a first moment, the student does not justify it, she only describes what happened. After the teacher's insistence, the student points to the material and justifies why her generalisation is valid. (Group’s record on question 4)

In this episode, the prospective teachers elect three processes that are mobilized: to generalise (that there are no pyramids with an odd number of edges), to exemplify (for 13 and 15 edges) and to justify (why an odd number of edges is impossible). Regarding the first process, the group correctly identifies that it is a generalisation when the student extends her conclusion (about 13 and 15) to the domain of odd numbers, corresponding to the definition of the generalisation process that was established. With regard to the process of justifying, it is noteworthy that the group is able to distinguish a simple description of an event (when the student says "Because one is missing or one is left") from a justification, relating this process with the investigation of the underlying reasons why it is true (Lannin et al., 2011). Finally, about the process of exemplifying, actually the examples used (with 13 and 15 edges) are suggested in the task. However, the group recognizes the support these examples provide for both the processes of generalising and justifying (Jeannotte & Kieran, 2017). In the first case, they consider that it is based on the attempt to build a pyramid with 13 edges that the student quickly concludes that it is impossible to construct a pyramid with 15 edges. In addition, they also realize that these two examples are fundamental to generalise and to justify, as they recognise the understanding of the situation they generate, allowing the student to understand why the number of edges cannot be odd.

Conclusion

The didactical task led the group of future teachers in a discussion about the reasoning processes involved in task on the properties of pyramids. In this discussion, the group was able to easily recognize, in context, the characteristics of the process of generalising, as well as its relationship with the process of comparing and exemplifying. However, the richness of the context involved–the establishment of the class of pyramids–enhances the emergence of various reasoning processes that occur in a non-linear way, generating a discussion about the distinction between generalising and justifying. Despite some hesitation, participants used the association between the process of justifying and the understanding of why a relationship works (Lannin et al., 2011) as a selection criterion for that process, which is found to be appropriate. Furthermore, they are also able to understand the supporting role that the process of exemplifying assumes in establishing a justification without confusing the role of empirical examples in establishing a statement, which is very common (Stylianides & Stylianides, 2009). On the contrary, the group seems to recognize that, in geometry, a justification must be associated with the spatial structure of objects (Brunheira, 2019).

This paper focused on a group of prospective teachers who shows a maximum level of knowledge about reasoning processes and its relationships, highlighting the importance and potential of didactical tasks that promote this knowledge, including the idea that different kinds of tasks can offer different kinds of opportunities for reasoning (Stylianides & Stylianides, 2006), which may be promoted using real classroom episodes. This research should be developed further highlighting the difficulties felt by other future teachers and ways to address them.

Concept Formation of Geometrical Reflection in a Digital Learning Setting

Anna Edamus[1] and Ralph Schwarzkopf[2]

[1] Carl von Ossietzky University of Oldenburg, Germany; anna.edamus1@uol.de

[2] Carl von Ossietzky University of Oldenburg, Germany; ralph.schwarzkopf@uol.de

This paper gives insights into an ongoing study that investigates pairs of students working on geometrical tasks in a cooperative way. The goal of the study is to learn more about students' understanding of geometrical reflection. First results of the study show that «symmetry» and «congruence» are useful categories to describe the students' learning processes on reflections. This paper briefly summarises the theoretical background of the study. Subsequently, it discusses two examples of observed phenomena about these categories of the conceptual understanding.

Keywords: Geometrical reflection, conceptual learning, basic ideas.

Introduction

The formation of conceptual structures is a central aim in the teaching of mathematics, in particular in geometry. The students have to form mental images of objects and their mathematical properties mediating between their real-world experiences on the one hand and the abstract mathematical structures on the other hand. Developing these representations and concepts to capture the meaning of concepts requires a social process (Dörfler, 1995). This includes explanations, drawings, negotiations and discussions in interactive settings (Krummheuer, 1995; Voigt, 1995). During the pandemic these learning-processes had to take place in online learning environments. Schwob and Gudladt (2021) show that online learning environments can support successful interactions and enable the exchange of individual knowledge. Based on this research, the present project uses the dynamic geometry software «GeoGebra» within such online learning environments to gain insights into the students´ understanding of the congruence mapping reflection. This contribution discusses very first results of the ongoing project, focusing on the following question: Which conceptual aspects of reflection can be observed?

Theoretical Background

This paper focuses on the teaching and learning of mathematical concepts. More precisely speaking, the aim is on the students´ understanding of reflection. From our theoretical point of view, the matter of understanding a concept goes beyond the knowledge about the mathematical definition of concepts (Tall & Vinner, 1981). Roughly speaking, the students have to develop *basic ideas*[1] about what reflections mean within different demands. For example, in figure 1 below we can understand reflection in a statical way: If you see one quadrangle *ABCD* you can use the characteristics of reflection to check out whether *g* is a symmetry-axis of the figure. Hence, symmetry is understood as

[1] "basic ideas" is our translation of the term "*Grundvorstellungen*", which is used by vom Hofe and Blum (2016).

a static basic idea of reflection. If the students ask themselves whether both halves are equal or not while solving the tasks, the category «symmetry» may be prominent. On the other hand, you can also see the triangles ABC and ACD and ask yourself, whether these two triangles are congruent to each other. In this case, you have to activate a more dynamic view on reflections: Can we move one triangle on the other one by reflection at the axis *g*? In order to build a comprehensive concept it is necessary for the students to work empirically by operating with the objects and thus gaining insights in their properties (Dörfler, 1995). In terms of a comprehensive concept students would benefit from getting to know static and dynamic aspects of reflection.

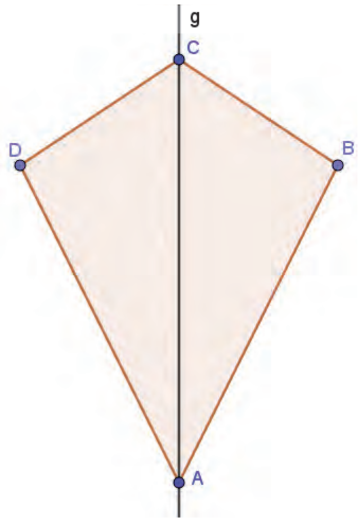

Figure 1: Basic ideas of reflection at quadrangle ABCD

Of course, for the mathematical experts, both meanings of reflection result from the same mathematical definition. But, from our point of view, they are different *basic ideas* that serve as a bridge between individual images and officially and formal definitions.

> So, *Grundvorstellungen* can be construed as mediating elements or as objects of transition between the world of mathematics and the individual conceptual world of the learner. GVs thus describe relationships between mathematical structures, individual-psychological processes, and subject-related contexts, or, in short: the relationships between mathematics, the individual, and reality. (vom Hofe & Blum, 2016, p. 231)

These basic ideas can be differentiated into two aspects: The *normative aspect* describes what concepts the students should have (vom Hofe & Blum, 2016). The *descriptive aspect* shows the occurring activated concepts of individual students (vom Hofe & Blum, 2016). The focus of the present project is on the descriptive aspects of basic ideas.

The Benefit of Using Dynamic Geometry Software[2]

Researchers like Ng and Sinclair (2015) combined analogue (paper-and-pencil work) and digital settings (dynamic computer-based environment) for reasoning about symmetry. The students worked

[2] Hereafter often abbreviated as DGS.

on the topic of symmetry for three lessons and increasingly used functional relationships to discuss the symmetry of objects e.g. by dragging them to explore the connection of pre-image and image. Starting from a static understanding of reflection, students seem to have extended their knowledge by operating with the respective figures in this manner. In addition, students developed new terms while communicating about symmetry (Ng & Sinclair, 2015). In other studies, the influence of the dynamic geometry software GeoGebra was investigated. Here it was shown that students who had to reflect drawn objects by using GeoGebra performed better in geometric transformations, especially in reflection (Pavethira & Kwan Eu, 2016).

Methodology and Methods

With the aim of gaining insights into descriptive aspects of the explored basic ideas we planned online interviews via the meeting tool «BigBlueButton» (https://bigbluebutton.org/) with pairs of students in secondary education (communication *through* technology) (Drijvers et al., 2016). While the interviews feature pairs of same-aged students, every student works on his or her own computer at home without enabling their webcams. One of them gets access to the tasks in «GeoGebra Classroom» (https://www.geogebra.org/) and has the authority to manipulate applets and share his screen. Based on the shared screen the students and the interviewer discuss the effects of manipulating reflections in the dynamic geometry software «GeoGebra» (communication *of* technology) (Drijvers et al., 2016). The interviews feature students from sixth to tenth grade. This age range was deliberately chosen because curricular standards on the topics symmetry and congruence are often not properly implemented in German schools. The students in the following episodes are in grade 9 (episode 1) and grade 6 (episode 2). The examples show that an adequate conceptual understanding of reflection doesn’t necessarily depend on the grade level. Both student groups have basic knowledge of the DGS «GeoGebra» and its functionality.

Working on the student´s understandings, we decided to organise our research as a *qualitative* study. The interviews are being transcripted[3] and analysed applying ethnomethodological methods (Krummheuer, 1995; Voigt, 1995) to work out different conceptual understandings of reflection. Furthermore, the transcripted episodes will be analysed by using comparative analysis to connect the theoretical background and empirical results via reconstructive categories (Krummheuer, 2018).

The Learning Environment

Altogether the learning environment includes eight tasks. Based on the work of Senftleben (1996) the tasks contain four phases: First, the researcher asks about the effects of a geometric operation and supports the students with a visualisation of the initial geometric construction of the object (Figure 2) below. Secondly, the students work on the question in a cooperative way. It is important that they do not use any representation within this phase – all operations are performed in their mind only. At the end of this phase, the students make a hypothesis about the effects of the discussed operation. Within the next phase, this hypothesis is validated by performing the operation within «GeoGebra». If the original hypothesis proves to be wrong, the students are then asked to find an explanation for

[3] All transcripts in the present paper have been translated to English by the authors.

their observation. While one of the students may manipulate objects on the screen at his free will, the other student is forced to verbalise his ideas and give instructions. Through this interaction both students must *discuss-the-screen* (Drijvers et al., 2010).

Example: Two Episodes

The students in the following episodes worked on six tasks before. The first three tasks encompass the reflection at one axis: The *Pentagon1* was reflected at the straight line g, so that the image *Pentagon2* originates. The students worked on the manipulation of *Pentagon1* (one vertex and position of *Pentagon1*) and the single axis of reflection g and their effects on *Pentagon2*. Afterwards the tasks focus on a double reflection at two parallel axes (figure 2): First the *Pentagon1* was reflected at the straight line *g*, so that the image *Pentagon2* originates. In addition, *Pentagon2* was reflected at the straight line *h*, the image is named *Pentagon3*. First, the interviewer explains this double reflection. In the following we provide an analysis of two episodes that focus on the following question:

"*Imagine you move the axis of reflection g towards pentagon1. What happens to the pentagon 2 and 3? Describe and explain.*"

In the following episodes the pairs of students work on this question. The students have already discussed their ideas within the first phase of the task, i.e. they built a hypothesis about the expected movements of the pentagons. The episodes start with the (very short) discussion of the accompanying hypothesis.

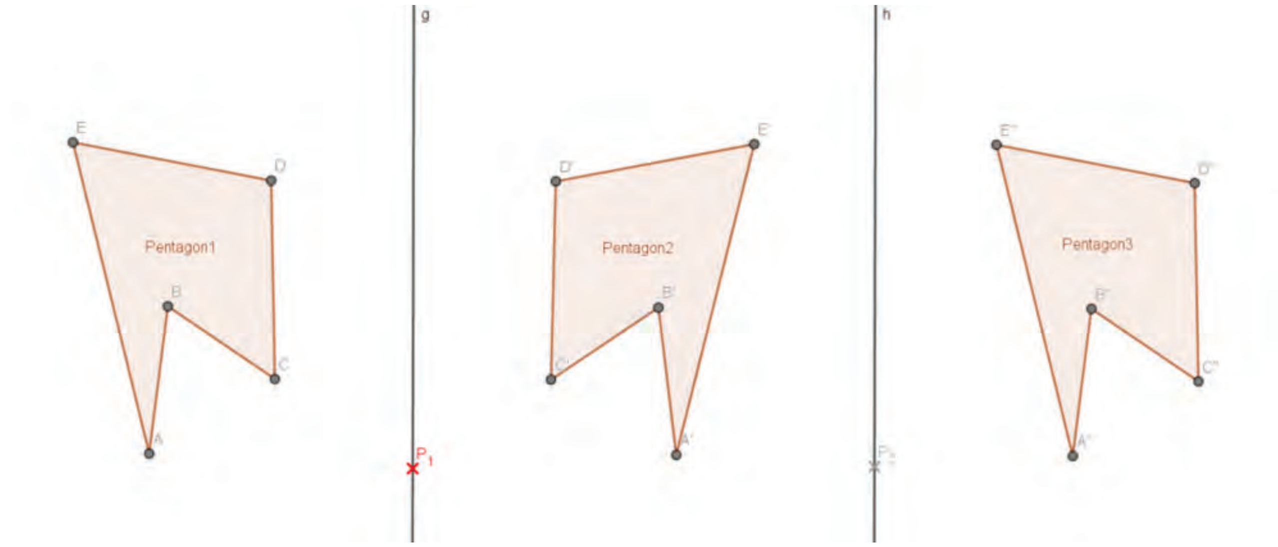

Figure 2: Construction of the task

Episode 1: Symmetry

Both students assumed what happens to the pentagons while moving the axis of reflection *g* . This episode begins with the verbalisation of the hypothesis and continues with the interviewer's question on what happens to the pentagons:

203	Michael:	this is exactly the same as the task before, that 2 stops and that the 1, err pentagon 1 moves to the left
204	Nicolas:	yes and 3 stops also, doesn't it?

During line 205 and 208 the students verify their hypothesis.

209	Interviewer:	what happened now?
210	Michael:	err pentagon 2 moves towards pentagon 1 and 3 moves to the side
211	Interviewer:	and why?
212	Michael:	so to the right (…) do you have an idea why?
213	Nicolas:	um move the axis a little bit to the left (8 sec.) yes because, yes because the first reflects err the second which is symmetrical again and then the second is mirrored again err to the third and the third must also have the same distance again as the second so they are symmetrical again. you know?
214	Michael:	oh yes.

Michael and Nicolas relate their hypothesis to the previous task, dealing with the same pentagons and reflections. But, within that task, the reflection axis *h* was moved. Hence, only pentagon 3 moved. Both assume that pentagons 2 and 3 wouldn't move (turn 204) because the axis of reflection *h* isn't shifted. They hypothesise, that only pentagon 1 would show an effect by "[moving] to the left" (turn 203). At first sight, this hypothesis sounds strange. But, having in mind a statical conceptional understanding of reflection, it seems quite plausible: Assume that the students understand pentagons 1 and 2 as a single figure and the line *g* as its symmetry-axis. Within this interpretation of the figure, it is very rational (besides alternative hypotheses) to expect that a movement of *g* would cause a movement of pentagon 1 in order to maintain the symmetry-axis of the figure.

When the students check their hypothesis by manipulating the objects in the «GeoGebra» applet (turn 210 and 212), they are confronted with the correct movements of the pentagons. The interviewer then asks them to find a reasoning for their observation (turn 211). Nicolas comes up with the explanation that pairs of subsequent pentagons are symmetrical (turn 213). One possible interpretation could be that he combines pentagons 1 and 2, which are described as symmetrical to each other, as well as pentagons 2 and 3. In this interpretation, pentagon 2 belongs to both combined symmetrical figures and represents one half of each figure. As Nicolas focuses on pentagons 2 and 3 and their respective distances to h, a static understanding of reflection can be assumed. The role that pentagon 2 has within this interpretation won't be further explained here. Within this episode, the research question can be answered as follows: The students Michael and Nicolas seem to have a statical basic idea of reflection, as they apparently combine two pentagons to one symmetrical figure. So, it seems that the category of «symmetry» has been activated in the students in this context.

Episode 2: Congruence

Both students assumed what happens to the figures while moving the axis of reflection *g*. At the beginning of this episode Niklas and Jonas present their hypothesis:

395	Niklas:	pentagon 2 pulled itself <u>towards</u> pentagon 1 and pentagon3 moves itself <u>away</u> from pentagon 2

During line 396 and 400 the students verify their hypothesis.

401	Interviewer:	very good. okay. now here’s the same question again. why is nothing happening with pentagon 1?
402	Niklas:	um (*moves the line g in the applet back and forth*)
403	Jonas:	maybe because pentagon 1 is the main figure (*hesitant*) (..)* that was drawn created?
404	Niklas:	* (*laughs*)
405	Interviewer:	what do you mean by main figure?
406	Jonas:	the one that has been drawn first and the others are just the reflections of it
407	Interviewer:	mhm (*affirmative*)
408	Niklas:	oh so this is the starting figure of the reflected pentagon 2 and 3 both of which are reflections. so they must be reflected err, towards pentagon 1 don’t they? so pentagon 3 to pentagon 2 of course.
409	Jonas:	yes.
410	Interviewer:	what is the difference between the main figure or the, the original figure and the pentagons 2 and 3?
411	Niklas:	um pentagon 2 and 3 (*mumbling*) (6 sec.) so they sort of need this exact reflection to continue being reflections, don’t they?
412	Jonas:	they even need pentagon 1 to exist because the other two are only reflections

Niklas presents a correct hypothesis about the movement of pentagon 2 and 3 when the axis of reflection *g* is shifted in the direction of pentagon 1. He assumes that they would move according to the respective changes in distance to the axes of reflection *g* and *h* (turn 395). As the students verify their hypothesis, they are asked to find a reason why pentagon 1 doesn’t move (turn 401). They describe pentagon 1 as the main figure (turn 403) that was drawn first (turn 406). In contrast to this main pentagon, the others are identified as only reflections (turn 408). Since they describe the three pentagons with different terms, one can assume that the students interpret them as distinct geometrical objects, which are congruent to each other. The interviewer then asks them to explain the difference between the main figure and the reflected figures (turn 410). At this point, Jonas stresses the necessity of the main figure (pentagon 1) for the existence of the reflected figures (pentagons 2 and 3; turn 412). Within this episode, the research question can be answered as follows: The students Niklas and Jonas seem to have a dynamic view of reflection, as they apparently compare the pentagon 1 as the main figure with the pentagons 2 and 3 as reflected figures. So, it seems that the category of «congruence» has been activated in the students in this context.

Discussion

A comparison of the two episodes shows very different views on the geometrical objects and thematised operations. These different views depend on the question, whether the students understand the pentagons as different objects or not. An interpretation of the pentagons as halves of a summarised figure, as in the first episode, leads to an understanding of the lines *g* and *h* as axes of symmetry. If, on the other hand, the students’ concept of reflection is different, as within the second episode, the lines are interpreted as axes of a congruence mapping that leads to a movement, i.e. the basic idea of congruence is activated. Both interpretations of reflection are important for students’ understanding of the concept of geometrical reflection. In some situations, the static basic idea «symmetry» may enable students to construct symmetrical figures or identify properties of figures etc. In contrast the dynamic basic idea «congruence» may be important in situations where more figures and the functional relationship between them are relevant. To be clear the tasks in the learning environment focus from a normative point of view on the dynamic basic idea «congruence». However, both basic ideas can be used to solve the tasks successfully.

The flexibility of switching through previous tasks in «GeoGebra Classroom» may support students in answering questions like "Did figure one move in previous tasks?" or “Which operations have been executed in these tasks?”. By dragging objects in the respective applets, students may realise, that figure one only ever moves if it is dragged directly. Based on this observation, technology could potentially support the understanding of the functional relationship between the pre-image and its images. Thus, conducting research on how a connection between image and pre-image is established, could lead to further insights. In this context it might be interesting to consider whether the categories «symmetry» and «congruence» affect the students’ understanding of this functional relationship.

Classifying 3d figures by prospective primary teachers

Joaquín Giménez[1], Yuly Vanegas and [2] Juan-Pablo Vargas[3]

[1]Barcelona University, Spain; Faculty of Education, quimgimenez@ub.edu

[2]University of Lleida, Spain; Faculty of Education, yuly.vanegas@udl.cat

[3]Barcelona University, Spain; Faculty of Education, jvargahe9@alumnes.ub.edu

This research aims to characterize how prospective primary school teachers describe and classify solids. A professional task is designed and implemented with 148 future primary teachers. The task is structured in four sections in which construction, composition and decomposition, visualization, identification of attributes of 3D figures and their classification are promoted. The development of the task involves the use of manipulative material (half cubes). For the analysis, some tools of the model of Didactic-mathematical Knowledge and Competences of the mathematics teacher are used. It is observed that most of the future teachers recognize mainly perceptual elements of the figures, which makes them construct dichotomous classifications, and only a few interpret the classification utilizing global characteristics.

Keywords: Didactic-mathematical knowledge, future teachers, solids, classification, primary education

Introduction

It is widely accepted that the geometry of solids has been neglected in many curricula, and 3D geometry teaching receives limited or insufficient attention in primary school classrooms. Prospective teachers are suddenly engaged in plane representations of solids, but when doing classifications, they are proposed to analyse just general polyhedra observations and constructions. Many teachers who deal with geometric concepts have an approach in which they memorize the names of the figures and some of their characteristics are privileged (Copley, 2000). Furthermore, the representations used to show these figures are centred on a prototypical view of them. Authors such as Sinclair and Bruce (2015) point out that little research has focused on the geometric thinking of children (and prospective teachers) concerning these types of figures and the process of classification.

Therefore, our study aims to show an approximation to the mathematical knowledge evidenced by future primary school teachers when they tackle a task of construction, analysis and classification of 3D figures, based on the tools of the CCDM perspective (Godino, 2009; Pino-Fan & Godino, 2015; Godino et al., 2016).

Theoretical framework

In previous research, figures that students or future teachers must recognize are presented by the teacher, noting how they identify the properties that underlie these forms and if this helps the teacher classify them (Guillen & Figueras, 2005; Patkin, 2015). According to the approaches of Vinner (1991) and Fujita (2012) when students decide whether an object belongs to a certain category, they can give biased answers because in their decision prototypical or common forms are privileged. This suggests that figures presented in the same position and with little variety of examples allow deeper consideration and analysis of them. We assume that we should have greater knowledge regarding how future teachers face such classification problems of solids. Identifying this knowledge is a key aspect to adapt and improve training proposals to promote geometric reasoning in future teachers.

In this model CCDM, it is considered that two key competencies that the mathematics teacher should develop are mathematical competence and the competence of analysis and didactic intervention. It is suggested that the knowledge necessary for teaching mathematics implies a deep knowledge of mathematics and its teaching that is, a didactic-mathematical knowledge. However, mathematical knowledge alone is not sufficient for the adequate practice of the mathematics teacher (Pino-Fan et al., 2015). From the CCDM model, it is proposed that to achieve suitable teaching, a mathematics teacher must possess different types of knowledge. On the one hand, you have to know the school mathematics of the educational level at which you teach. Additionally, it is necessary to understand elements of later levels, what is referred to as the 'knowledge of the mathematical content per-se'. This knowledge is divided into two types: common mathematical knowledge and extended mathematical knowledge.

The first refers to the knowledge regarding the mathematical object that is necessary to put into play to solve problems and activities related to a specific mathematical topic at a particular educational level. It is generally associated with the level at which it is taught. The second refers to the fact that the teacher, in addition to knowing how to face problems and activities on a certain topic, must have advanced knowledge, which is part of higher levels.

Methodology

A professional task was designed and implemented with 148 students studying Primary Education at a university in Spain. The task introduces the process of constructing solids using one, two, three and four half cubes. The future teachers construct the figures by using plane development. They talk about the observed properties of the shapes and provide one or more classification ideas for the shapes. The key questions analysed in this paper are described in table 1. The task was solved collaboratively, which resulted in the configuration of 33 groups. Our data is the protocols written by each of the groups. From the analysis of the productions of future teachers, the types of constructions are identified; the criteria used to classify 3D figures, and the value given to the classification process from the didactic perspective.

As it is in our interest to analyze the types of knowledge that emerged in the development of the proposed professional task, we will base ourselves on the analysis of three fundamental questions that reveal fundamental elements for the discussion that we want to raise. Table 1 presents the selected questions, the type of knowledge that is valued and its intentionality.

Nº	Question	Type of knowledge	Intention
2.b-c	Build all the polyhedra that could be constructed with the four pieces (half cubes). Make a table where you present the graphic	Common	Obtain figures through composition. Identify a variety of shapes

	representation, the name and the characteristics of the obtained figures.		Know specific language to describe geometric figures
2.d	Define criteria and classify the figures that you have obtained in section b. Explain what you have considered to define the criteria	Extended	Generate categories from the characteristics of different figures.
2.e	Why do you consider that when we study various types of figures, a fundamental process to work with is Classification?	Extended and Meta-didactic	Promote an attitude of inquiry. Recognize the intentions and motivations of a classification task.

Table1. Questions in the professional task

We grouped similar responses belonging to the same category. From this categorization, information was obtained that allowed for describing difficulties, errors and justifications presented in the common knowledge of the content that future teachers have concerning 3D figures and their classification. To systematize the answers given to a question about classification, we show the process of recognizing emerging categories associated with the texts of future teachers.

Examples of texts found	Emergent category
They establish a table where it is grouped according to the number of vertices. [Identify most constructed figures that have 8 vertices. Most have between 6 and 12 vertices. None have 11 ...]	Perceptive appearance according to Battista (2012).
Figures 1,2 and 3 (cube, octahedron and triangular prism) can be classified within the same group since they are regular polyhedra, while figures 4,5, 6 are totally irregular, and therefore do not have all the equal faces. Therefore, we have two groups, regular and irregular.	Attempt to classify by grouping known features in 2D (regular, irregular) but with errors.
We have taken into account the type of polyhedron according to its bases, the regularity, the number of faces (bases and sides), the shape of its bases,	Correct recognition of 2D characteristics applied to 3D.
We have considered if it is concave or convex, the number of vertices and edges, and the symmetry.	Recognition of characteristics associated with the global observation of 3D figures.

Table 2. Emerging categories in ideas and classification criteria

To systematize the look at mathematical objects, we looked for the type of characteristics used from the classification. For this, the idea of the configuration of objects and processes of the Onto-semiotic perspective is used, looking at the definitions, arguments and propositions used.

Example of given argumentation	Emergent category
"… Since it allows children to group objects according to their similarities and differences, based on different criteria: shape, colour, size ... These relationships serve as the basis for the construction of logical-mathematical thinking. Piaget considers that these logical relations are the base of the classification, seriation, notion of the number and graphical representation".	It allows to establish logical relationships and discover new concepts
"The fact of classifying allows us to compare and see the differences of the other groups. Thus, it also allows us to look for regularities between shapes and their properties, to compare similarities and differences using the appropriate vocabulary, to understand the relationships between different three-dimensional figures, using the properties that define them, and to look carefully at the regularities and changes that occur they produce in a collection or a sequence".	It allows to compare, recognize common characteristics, through similarities and differences
"Classification is important because it allows ordering or organizing the figures into groups following common criteria, which facilitates the development of logic".	Allows an organization

Table 3. Argumentation categories given to the rank value

Results

We then recognized characteristics of the mathematical knowledge of the students in three sections: common knowledge about 3D figures; extended knowledge about the meaning given to the classification and the value of the solid classification itself.

Common knowledge of 3D figures. Each group built and recognized different polyhedra, the triangular prism being the one that the majority built (27.7%), followed by the trapezoidal prism (in some cases incorrectly named hexahedron) and the rectangular prism, both with a 23.1 %. Only four groups (6.2%) speak of a parallelepiped. Two groups (3.1%) mention an octahedron. When some groups were unable to assign a "known" mathematical name to the constructed figure, they proposed real names such as "chair", "bridge", "podium", among others (28.6%). In the descriptions they make of each figure, some teams state characteristics related to parallels, incidents, or perpendicularity, and express them correctly.

Students consider length as a differentiating element of solids, thus, for example, a triangular prism built with two half-cubes assumes it differently from a triangular prism built with three half-cubes. On the other hand, they identify regular and irregular bodies (which is used as an initial classification criterion in some cases). The use of informal language is evidenced to describe elements that are named in the geometry of solids; they name vertices, corners etc. Most students use the term equality to refer to situations of congruence, which in addition to being an error, triggers elements of greater concern, such as the mixture of terms from plane geometry with the geometry of space. It seems to us that it is due to the difference between equality and congruence, which is not sufficiently emphasized in school geometry.

Among the errors, we find eight groups that form a solid with the four half cubes that they identify with a cube, but which is not. Indeed, with four half cubes, we can never obtain a cube. This shows a difficulty associated with visualization because when joining the four half-cubes, a rectangular prism with two square faces and four rectangular faces is obtained as shown in Figure 2. Only in some cases do they show that this is not the case, saying that it is a prism with a square base, but with a height less than the side of the square. The other wrong example is to name one of the constructed figures an octahedron since by combining the four half cubes we can never get a face that is an equilateral triangle. In this case, there is only one group making this mistake.

Regarding the extended knowledge about classification. Most of the groups point to elements of a visual and descriptive nature to classify the solids. They mention, for example, the number of faces, vertices, sides and bases that the polyhedra they managed to build have. In these cases, they classify considering these attributes.

Although other groups allude to global characteristics proposing a classification of the figures as regular and irregular polyhedra, they do so in the incorrect way, since none of the constructed figures is a regular polyhedron. Other groups, when doing the classification, speak of figures that it is not possible to get with half cubes such as pyramids. Few groups speak of prisms as convex polyhedra, which is correct. Table 3 shows the percentages according to the elements that the future teachers considered for the classifications.

Reference to a classification	**Perceptive appearance**	**Characteristics Symmetry**	**Other classification**	**Global view**	**None**
Number of teams	18	1	10	3	1
Average	54,54 %	3,03 %	30,3%	9,09 %	3,03%

Table 4. Elements used by prospective teachers for classifying

Most of the classification criteria depend on a mere description of the object, that is, they do not address some more advanced theoretical element. Rather remain in a process of visual verification; only one group manages to rescue elements from the origin of the half cube as a section of the cube and the configuration of the 2D figures when locating to build a body in 3D. The classification process depends on the ability to identify similarities and differences between figures and explain why a certain figure is an example of such a class (Walcott et al., 2009). When describing elements of the classification, the examples and characteristics are usually shown but not so much the common and distinguishing criteria, although they are being valued as important. In the same way, we found that future teachers find it difficult to recognize how certain visualization elements are associated with representations that allow recognizing properties. For example, we expected that there would be classification proposals where the number of concavities or symmetries were considered.

Extended and meta-didactic knowledge about the value of the classification process. The importance given to the classification process by future teachers focuses on aspects such as establishing relationships; the identification of properties; the recognition of common and uncommon characteristics of the idea of classification as a grouping. As can be seen in Table 5, all groups focus on the importance of classification as it allows distinguishing attributes based on the comparison. Others simply refer to the classification as separation, posing simple dichotomous groupings, but without an adequate appropriation of the characteristics of the figures.

Explanation Categories	Nº of groups
It allows to establish logical relationships and discover new concepts	17
It allows to compare, recognize common characteristics, through similarities and differences	33
Allows an organization	4

Table 5. Elements valued as important in the classification process

After what has been observed, we can say that most of the groups identify the recognition of common characteristics as a great value of the classification, but at the time of classifying, they do not explicitly state the criteria, but rather emphasize the name given to a group of figures as evidence of the classification.

Final considerations

In relation to the common knowledge of mathematical content, this study found that the perceptual appearance dominates over certain conceptual aspects (Bernabeu et al., 2017; Gonzato et al., 2013). Future teachers identify visual arguments, similar to those used by children themselves in the early ages. An application of the assumed mathematical knowledge of the known classifications of figures in the plane is not observed in the case of prisms.

The language that is established in the group of students for teachers is mostly descriptive and suggests that its members are at the second level of van Hiele (Gutiérrez & Jaime, 1998). We can say that we interpret our results in the sense of showing the difficulty in relating the understanding of geometric figures to the coordination of two semiotic systems of representation. The discursive (oral or written) and the non-discursive (drawings, photos of the figures) (Duval, 2017). Indeed, despite having manipulative elements, students are not capable of formulating mathematically well-formulated explanations.

The analysis carried out has made it possible to identify a perceptual domain in the characterization of 3D figures and a low level of structuring from properties. Although the arguments given by future teachers about the value of the classification are at an initial level, it shows how they could deal with this process in the mathematics class in primary education in the future. Solving the question itself led future teachers to question the classification models that they had learned in their school years, but as they did not have a broad appropriation of the attributes of solids, they could not recognize generalizable properties that would allow them to make rankings richer.

The results of this study show that some future teachers like to define a mathematical object by describing its characteristics or properties. Future teachers manage to be surprised by the great variety of figures that can be built with the manipulative material worked on in the professional task. Moreover, it does not seem enough to recognize, for example, that different types of prisms can be obtained, and that this variety. It makes it possible to propose various types of classifications, starting with those in which one type of attribute is privileged (dichotomy), to then give way to more complex ones where there is a combination of attributes. No inclusive classifications are noticed.

The use of manipulative material as a mediator of the observations and responses allowed opportunities for reflection on the congruence of figures that can be observed in different positions. Moreover, common mathematical knowledge is not sufficient, because many groups are not able to systematize the process of the construction of figures, and they are satisfied with having found a few. Photography has made it possible to overcome the problems of drawing, which in turn has helped the classification process. Despite this, some groups were not able to identify the global pieces built, and they continue to look at the individual elements of shapes.

Impact of a geometry course on pre-service teachers' images of geometry through the lens of fundamental ideas

Theresa Häusler[1] and Ana Kuzle[2]

Keywords: Geometry, teacher education, fundamental ideas, mental image.

Introduction and theoretical framework

Geometry is an important part of mathematics instruction. It is the basis of other sub-areas of mathematics, different fields in science, technology, and arts (Wittmann, 1999). Furthermore, it is a tool for the acquisition of intellectual, cognitive, and practical life competencies (Wittmann, 1999). Despite the recognition of the role that geometry plays in school mathematics, it is often neglected compared to other areas of mathematics, such as arithmetic (Backe-Neuwald, 2000). These findings raise certain questions regarding current geometry education: What meanings do learners (i.e., students, pre-service teachers) assign to geometry? What geometrical concepts do they learn?

Geometry curriculum is nowadays structured around so-called fundamental ideas, which can be seen as "tools to organize the phenomena of the physical, social and mental world" (Freudenthal, 1973, p. 41). In the literature (e.g., Backe-Neuwald, 2000), different conceptualizations of fundamental ideas for structuring the geometry curricula are reported. Based on Wittmann's model (1999) of fundamental ideas of geometry, Kuzle and Glasnović Gracin (2020) proposed the following empirical model: geometric forms and their construction, operations with forms, coordinates, special relationships and reasoning, measurement, geometric patterns, geometric forms in the environment, and geometrization. They showed that primary grade students (Grades 3–6) had a rather narrow image of geometry regarding fundamental ideas, which primarily reflected the first fundamental idea. This was partially due to the mathematics curriculum itself (Kuzle & Glasnović Gracin, 2020), but may have also been due to the role that geometry plays in school mathematics as well as in-service teachers' insecurity both regarding the selection of central geometry contents and the criteria that determine their significance (Backe-Neuwald, 2000).

Research questions and method

Based on the theoretical considerations and empirical results, we sought to study pre-service teachers' images of geometry through the lens of fundamental ideas of geometry as they progressed through a two-semester geometry course. The term image "refers to mental representations of a cognitive structure associated with a particular concept (i.e., geometry), built up over the years through various experiences" (Kuzle & Glasnović Gracin, 2020, p. 13). Two research questions guided the study:

- What fundamental ideas of geometry can be seen in pre-service teachers' drawings?
- How do pre-service teachers' images of geometry change during the geometry course?

Within the exploratory qualitative study presented in this poster, a cohort of pre-service teachers in primary mathematics (Grades 1–6) that were enrolled in the course "Geometry and its didactics I and II" participated in the study. The course itself was structured around the fundamental ideas of geometry, which were continuously made explicit. The main source of data were two drawings, which the pre-service teachers were to submit at the beginning and the end of the course. Drawings as a data tool were chosen because they are understood as expressions of mental images and provide unique insights into individuals' minds (Kuzle & Glasnović Gracin; 2020, Luquet, 1927/2001). The data included only 43 sets of drawings due to the second semester being administered in a digital format. The first author analyzed the data using an inventory developed by Kuzle and Glasnović Gracin (2020). Here, every drawn object was categorized into one or more fundamental ideas according to its interpreted meaning. Afterward, the descriptive statistics were calculated.

Results and discussion

The results revealed that the first fundamental idea was illustrated by all pre-service teachers at both measuring times. All other fundamental ideas were drawn by more pre-service teachers at the end of the two-semester course. The largest increase showed the idea of geometric patterns (37% more second drawings included a pattern compared to the first drawings), followed by geometrization with 32%. The number of drawings including the idea of operation with forms increased by 26%, followed by the idea of coordinates, special relationships and reasoning (18%), and geometric forms in the environment (14%). The lowest increase had the idea of measurement (9%), which was already drawn by a relatively high number of pre-service teachers at the beginning of the course. Thus, the fundamental ideas that were already highly presented at the beginning of the course showed a slight increase, whereas the fundamental ideas that were not that strongly represented showed a stronger increase. The results showed that the pre-service teachers' image of geometry broadened and became more multifaceted during the two-semester geometry course. Most of the pre-service teachers thought of more different fundamental ideas than before. Concretely, the drawings revealed, which course topics, thoughts, and new insights shaped the pre-service teachers' images. Based on these findings, the geometry course can be further developed to enrich the pre-service teachers' ideas of geometry even more, and consequently counteract their insecurities regarding teaching geometry.

The teaching of geometry in primary education: Is geometry still neglected in school mathematics?

Ana Kuzle

University of Potsdam, Germany; kuzle@uni-potsdam.de

Primary school mathematics has undergone many changes in the last twenty years. Geometry in particular was re-evaluated due to a paradigm change and was attributed greater importance in curricula worldwide. Despite a clear consensus that geometry instruction is an indispensable component of mathematics even in primary education, the status of elementary school geometry is still considered unsatisfactory in many cases. This report aimed to find out if earlier findings that geometry is neglected in school mathematics instruction can be confirmed based on new empirical data using a questionnaire. In total, 120 primary grade teachers participated in the study. The study confirmed the results from previous research, but also shed light on new emerging factors contributing to the unsatisfactory state of current geometry teaching in primary education.

Keywords: Geometry, teaching geometry, primary education, in-service teachers.

Introduction

For several decades, researchers have emphasized the importance of teaching geometry (Franke & Reinhold, 2016; Sinclair & Bruce, 2015; Vigilante, 1967). Engagement with geometric content promotes basic cognitive skills, allows the development of specific mathematical ways of thinking, and contributes greatly to understanding the world in which we live (Bauersfeld, 1992; Franke & Reinhold, 2016). Furthermore, all mathematics is permeated by geometric ways of thinking, because whenever a piece of visual information is perceived, analyzed, and stored, geometric thinking is fundamental to this process. Despite the acknowledged importance of geometry, it seems to have lost its position in school mathematics developing the reputation of being the "problem child" of mathematics teaching as was reported by Backe-Neuwald (2000) more than two decades ago.

Mathematics teaching in elementary schools has been influenced by many changes that have taken place in the last 20 years. Firstly, to counteract the worldwide trend of the reduction of geometry in the school curriculum (Clements, 2003; Van de Walle & Lovin, 2006), the role of geometry concerning perspectives on the teaching of geometry for the 21st century has been reassessed (Mammana & Villani, 1998). Secondly, the teaching of geometry has been re-evaluated due to a paradigm shift in school education to a focus on process-oriented mathematical competencies, such as problem solving and argumentation. The fundamental question of whether geometry is being neglected remains open, arguably with good reason, as the status of elementary school geometry instruction is still considered unsatisfactory, especially compared to arithmetic (Clements, 2003; Franke & Reinhold, 2016). Similar results were reported in the study by Backe-Neuwald (2000) in which nearly 80% of primary grade teachers agreed with the statement that the teaching of geometry is neglected and mostly serves as entertainment rather than important mathematical content. Since these findings, however, the mathematics curriculum in Germany has been revised, making a reassessment of the empirical findings of Backe-Neuwald (2000) necessary. Furthermore, only a few studies (e.g., Sitter, 2019; Wiese, 2016) are based on recent data subsequent to the paradigm shift.

This paper takes into consideration a number of the recent discussions in the literature by focusing on the role of geometry instruction in elementary school mathematics. Specifically, utilizing two questionnaire items adapted from Backe-Neuwald (2000), I investigate whether there are any changes in the previously reported situation regarding the neglect of geometry in school mathematics.

Related literature

The study by Backe-Neuwald (2000) involving 108 in-service teachers represents a milestone in the contemporary empirical examination of geometry in primary schools and its role in the school structure, its results have been followed up in the form of a replication (Sitter, 2019) and an extension study (Wiese, 2016). The teachers' perceptions of school geometry were very ambivalent: when asked about associations with geometry instruction in elementary school, some teachers described it as "a welcome change" or "an exciting thing," whereas others considered it "secondary," "beside the point", or "not important" (Backe-Neuwald, 2000, p. 16–18.). As noted earlier, almost 80% of the in-service teachers surveyed believed that geometry was neglected in elementary school, not because of the curricular requirements of the syllabi, but due to issues concerning its actual implementation in the classroom (Backe-Neuwald, 2000). Only 15% of the teachers surveyed disagreed with the statement. In 89 cases (82.4%), the teachers stated that they have to utilize the available instructional time for more important mathematical content, namely arithmetic, which was identified as the main reason for the neglect of geometry in school mathematics. Moreover, many teachers (n = 65; 60.2%) shied away from the preparation intensity of geometry instruction (Backe-Neuwald, 2000) which was identified as the second reason for geometry being neglected in school mathematics. This was confirmed in the work of Sitter (2019). Along these lines, the third reason reported was that too little support in the form of additional materials is available for the preparation of geometry lessons.

Teachers themselves play a crucial role when it comes to explaining the deficit in the teaching of geometry. Teacher training has been strongly criticized in the past. Bauersfeld (1992) noted that elementary school teacher education is divided among different faculties into subject and pedagogical content knowledge which does not reflect school reality and, above all, limits development in the field of didactics. Such shortfalls are specifically attributed to geometry courses, which lead to subject-didactic uncertainties that either partially or completely prevent teachers from teaching geometry (Sitter, 2019). Further, Clements (2003) reported that a large proportion of prospective mathematics teachers only reached Level 2 of the van Hiele model of geometric reasoning (i.e., descriptive reasoning). Similar phenomena were reported in the study by Backe-Neuwald (2000). The teachers viewed their own previous education with regard to geometry topics and content as insufficient (n = 28; 25.9%) and they felt insecure teaching geometry (n = 21; 19.4%). The latter was most prominent in teachers with little teaching experience as well as out-of-field teachers (i.e., non-specialists). According to Backe-Neuwald (2000), this leads to a high degree of professional uncertainty in the conveyance of geometric content and, ultimately, to the deprioritization of geometry lessons. Textbooks were identified as the sixth main factor (n = 18; 16.7%) contributing to the neglect of geometry because textbook suggestions were perceived as being too trivial, easy and not challenging enough. Other reasons, such as time intensive methodological preparation, intensity of subject preparation, and difficulty of student assessment, were mentioned by less than 10% of teachers. Difficulty of student assessment was also reported by Sitter (2019).

Research process

For this study, a mixed-methods **research design** was chosen. Elementary schools were selected through existing contact with the resercher's university and random inquiries. The **sample** of 120 in-service primary teachers (Grades 1–6) consisted of 22 male teachers (18.3%) and 97 female teachers (80.8%). One participant did not provide gender information. A total of 90 teachers taught mathematics as subject specialists (75%) and 29 of them were non-subject specialists (24.2%). The data of one participant was not provided. In terms of professional experience, 16 teachers (13.3%) have been teaching mathematics for less than or up to two years, 18 (15%) for up to 5 years, 19 (15.8%) for up to 10 years, 16 (13.3%) for up to 20 years, and 51 (42.5%) for more than 20 years.

The **main source of data** was a questionnaire on the state of the teaching of geometry in primary grades that was based on an adaptation of the instrument of Backe-Neuwald (2000). Additionally, new items were developed based on literature published in the last 20 years (e.g., Clements, 2003; Franke & Reinhold, 2016). To cover a broad field of research, six sections were included. Each section consisted of several items with both open and closed questions. In addition to personal information, there were questions about the characteristics of geometry lessons, the use of materials, the goals and aspects of teaching geometry, possible reasons for the neglect of geometry, and the participants' personal attitude toward teaching geometry. The questionnaires were either distributed on site or were sent by e-mail. All questionnaires were returned to the author by mail.

In this report, I focus on the section of the questionnaire dealing with the possible neglect of geometry, which was measured with two items. Both items were **analyzed** in order to answer the research question. The first item was as follows: *"It is frequently claimed that geometry instruction is neglected in elementary education and only leads a 'Cinderella existence' there. What is your opinion?"* (Backe-Neuwald, 2000). Three options were given for the item where one response was to be marked and then justified in a free-form text response. In addition to *"I agree because..."* and *"I do not agree because…"*, *"Other"* was provided as a third option. It was assumed that there may be teachers who are not in a position to or are unwilling to take a position. The analysis of the item was based on qualitative content analysis according to Mayring (2010). For this report, the analysis-guiding categories emerged inductively from the hypothesis, in particular, the analysis variables of teaching experience, professional background, and teacher gender. In contrast to the first item, the second item was a standardized item which was slightly adapted from Backe-Neuwald (2000). It included statements on reasons leading to the neglect of geometry instruction. Here, 12 statements taken from Backe-Neuwald (2000) were supplemented with three additional statements (i.e., 5.2.1, 5.2.6, 5.2.7) which were identified in the recent literature (Clements, 2003; Franke & Reinhold, 2016), with an option of writing an additional statement (i.e., 5.2.16). The in-service teachers were asked to mark the aspects that were most significant to them, and to rank five responses accordingly (e.g., 1-most significant). The item was evaluated according to the frequencies of all response options as well as according to assigned rankings. The items complemented each other; by evaluating the open-ended item, teachers could express themselves freely without having been steered in one direction by predetermined response options. Through the additional evaluation of the standardized item, the spectrum of answers was expanded.

Results

Here, I present the results concerning the two items. The first item explicitly addressed the question of whether geometry instruction is neglected in the teachers' opinion and asked them to give reasons for their answer. In total, 45.8% of the participants agreed with the statement (n = 55), 35.8% of them disagreed (n = 43), and 14.2% did not take a clear position (n = 17). Five surveys were disregarded because either no information was provided or more than one answer was given. The affirmative responses were relatively evenly distributed across gender, professional background, and teaching experience in the groups with up to 5, 20, and more than 20 years of experience. However, affirmative responses were represented above average (60%–66%) in teachers with up to 2 years and 10 years of teaching experience. Conversely, 40% to 44% of those teachers with up to 5, 20, and more than 20 years of experience did not agree with the statement.

For the qualitative analysis of the item, the responses were categorized along the chosen focal variables of teaching experience, professional background, and teacher gender and presented as a selection, since there was often considerable overlap between the answers. Looking at the teachers' justifications for their respective statements, several commonalities stand out. Geometry instruction is <u>neglected</u> in elementary school [...] because

> "for almost all teachers arithmetic is in the foreground." (female, up to 20 years, specialist)
> "when there is time pressure, practicing 'arithmetic' is preferred." (female, over 20 years, specialist)
> "the weighting of work in the textbooks is also evident. Few textbooks deal adequately with geometry topics, especially in Grades 1–4. This means that the teacher has to provide a lot of additional material and it also gives the impression that it is of less importance." (female, up to 10 years, specialist)
> "the RLP [curriculum] is crammed with other elementary basic knowledge and a lot of time is lost to the sustainable learning of the basic arithmetic operations." (female, up to 10 years, specialist)
> "many consider the topic of 'Numbers and operations' to be the absolute No. 1 and since it is so packed, geometry goes under." (female, up to 10 years, specialist)

The predominant reasons given for the neglect of geometry were time pressure (n = 15), and the importance of arithmetic (n = 22). The latter was often mentioned in connection to the mathematics standards for primary education. Furthermore, the often very time-consuming and material-intensive preparation was also frequently mentioned as a factor contributing to the neglect of geometry (n = 7), which was also brought up in connection with textbooks. The reasons given mainly focused on practical requirements and perceived constraints (i.e., time pressure, the importance of arithmetic) or convenience (i.e., intensity of preparation). A disregard for the content of geometry was rarely communicated in the statements, but did occur occasionally:

> "it does not have the same value as imparting basic knowledge." (female, over 20 years, specialist)

Finally, in five cases the opinion was expressed, especially by those with more teaching experience, that non-specialist teachers in particular simply do not have the necessary qualifications to teach geometry confidently and appropriately:

> "many (colleagues) feel insecure or perceive it as a 'gimmick'." (male, up to 20 years, specialist)
> "there is a lack of trained professionals." (female, over 20 years, specialist)
> "lateral entry employees often lack the ability of methodical approach in teaching geometry." (female, over 20 years, specialist)

There are some comments stating that geometry is not neglected, but on closer inspection these display a misunderstanding of the question: they do not offer a general assessment of elementary school geometry as a whole (except in three cases), but rather refer primarily to the teacher's own practice based on school or state curricula (n = 33). Geometry instruction is <u>not neglected</u> in elementary school [...] because

> "I always meet the curriculum requirements." (female, over 20 years, specialist)
> "one lesson per week is a fixed geometry lesson." (female, up to 5 years, non-specialist)

The results from the standardized item of the questionnaire concerning the reasons for the neglect of geometry instruction in primary school is shown in Table 1. In addition to marking the factors influencing the implementation of geometry in school mathematics, the teachers were asked to rank the five most significant factors (i.e., statements). From this, a simple score was generated, which awarded the most important reason five points, the second most important four points, and so on. The score, as opposed to just looking at the absolute frequencies, allows a better assessment of the importance of the reasons for neglecting the teaching of geometry – even though both metrics show an almost equal ordering of the reasons. Out of 120 surveys, 117 teachers filled out this item. Additionally, not all participants ranked their answers (n = 24), so that this data was not taken into consideration for the Top 5 Score. The teachers' answers on this item predominantly confirmed the findings of the aforementioned open responses item. Accordingly, the importance of arithmetic was again the primary reason given for neglecting geometry (items 5.2.6 and 5.2.8). Item 5.2.8 was evenly distributed across the professional background with two-thirds of participants from both groups agreeing with this statement. The intensity of preparation for geometry continued to be significant, especially as evidenced by the comparatively high score (item 5.2.3). Similarly, the role of the teacher was addressed in the sense of uncertainty in the conveyance of geometry content (items 5.2.11 and 5.2.2). Item 5.2.11 was also relatively evenly distributed across professional background; 38.9% of subject specialists and 48.3% of non-specialists agreed with this statement.

Table 1: Reasons for neglect of the teaching of geometry

Item	Statement	Absolute frequency (max. 93)	Score Top 5
5.2.8	The arithmetic topics have to be worked through, leaving little time for geometry topics.	80	251
5.2.3	Geometry lessons require a lot of preparation in terms of the creation and provision of materials.	76	193
5.2.6	The arithmetic topics are more relevant for the school track than geometry topics.	54	137
5.2.11	Teachers feel insecure when teaching geometry.	49	113
5.2.5	Student performance is difficult to assess and time-consuming.	47	85
5.2.2	Geometry instruction requires a lot of subject preparation.	41	105

5.2.9	There are too few aids for the preparation of geometry lessons.	40	92
5.2.4	Geometry lessons require a lot of methodical preparation effort.	36	89
5.2.1	The learning objectives for teaching geometry do not seem as clear as for teaching arithmetic.	29	88
5.2.15	Many of the suggestions in textbooks for teaching geometry are trivial, too easy, and not challenging enough.	25	46
5.2.10	Teachers perceive their own previous education with regard to geometry topics and content as insufficient.	21	50
5.2.7	Geometry topics seem arbitrary compared to arithmetic instruction.	14	40
5.2.16	Other: __________________	14	23
5.2.13	The development of geometric skills is subject to an inner maturation process in children, which can neither be accelerated nor halted.	13	25
5.2.12	The goals of geometry instruction are not as important because ________.	5	6
5.2.14	Geometry instruction does not begin until secondary school.	2	0

Thus, the issue of neglect seems to originate predominantly from temporal-practical reasons, and not from a disregard for the importance of geometry. One of the most frequent reasons that the teachers gave on item 5.2.16 (i.e., "Other: ________") was the limited material availability in schools, including both analog and digital tools. This opens up a certain area of tension, since apparently teaching material in the sense of geometry as a visual instruction is quite appreciated, but it is more likely to be made available by the school rather than to be developed as a part of the teachers' own lesson preparation. Moreover, the teachers also reported that mathematics textbooks contributed to the negative trend for the following reasons: poor coverage of geometry topics, lack of usable tasks, and lack of integration of geometry topics into the "overall mathematics".

Discussion and conclusions

In the literature, it has been postulated – often on an insufficient empirical basis – that geometry is neglected in mathematics. This paper focuses on the question of whether there are any changes regarding the neglect of geometry teaching in the last two decades in relation to two items adapted from Backe-Neuwald (2000). The study results confirmed the hypothesis that despite the paradigm shift that occurred two decades ago, geometry is still insufficiently taught compared to other areas of mathematics, but positive changes were observable compared to findings reported two decades ago.

While about 80% of the participants in the study by Backe-Neuwald (2000) agreed with the thesis that geometry instruction is neglected in elementary school, only 45.8% of participants in this study agreed with that statement. In other words, 15% of participants from the Backe-Neuwald (2000) study and 35.8% of participants in this study disagreed with the thesis. Despite the positive trend over the last two decades, the perception that geometry is neglected still exists to a high degree that cannot be disregarded. The main reason for this seems to lie predominantly in the perceived importance of arithmetic (n = 80; 86%, item 5.2.8), especially in the early school years as has been reported previously in the work of Backe-Neuwald (2000) (n = 89; 82.4%). The fact that geometry can and must be the basis of arithmetic, both in terms of content and in the formation of mathematical teaching-learning processes (Bauersfeld, 1992), is not taken into consideration by the teachers at all. Similarly, the teachers from both studies identified the preparation intensity of geometry instruction in terms of material creation and provision (item 5.2.3) as the second reason for the neglect of geometry. Both groups also emphasized that standardized materials were only available to a limited extent. Geometry lessons are guided by the visualization of different concepts and the provision and use of materials in this respect is paramount, but the reality in schools still seems to be deplorable. If improvements in this situation would make it possible to upgrade elementary school geometry, such measures should certainly be taken, because the value of continuous material use for the learning success, especially in the area of spatial imagination, is undisputed (Franke & Reinhold, 2016). It is worth noting, however, that an improved availability of materials, as an essential requirement of making changes to the teaching of geometry, would not alleviate the perceived time pressure under the impression of the excessive weight of arithmetic; yet this is a particularly pressing problem of geometry instruction for teachers. Two reasons for neglecting geometry that played a minimal role in Backe-Neuwald (2000) with less than 10% of teachers identifying them, seem to play a greater role two decades on. Difficulties regarding performance assessment in geometry (item 5.2.5) was ranked fifth (n = 47; 50.5%), and intensity of subject preparation (item 5.2.2) was ranked sixth (n = 41; 44.1%). This may be due to curricular changes which placed extensive focus on process-oriented mathematical competencies such as problem solving and argumentation.

The present work has highlighted various aspects of geometry teaching that have direct implications for professional practice. As in the study by Backe-Neuwald (2000), teachers felt insecure when teaching geometry (item 5.2.11). Even though this was ranked as the fourth reason in this study and the fifth reason in the study by Backe-Neuwald (2000), the new results call for attention. The feeling of insecurity more than doubled in the last two decades, from 19.4% to 52.7%. Whereas in the study by Backe-Neuwald (2000) the perception of inadequate previous education (item 5.2.10) was the fourth reason given (25.9%), this was reported by 22.6% of teachers, and hence was ranked 11th. The open-response items in particular bring these issues even more to light. The finding that the qualifications of many teachers, especially those who are not fully trained, not only are insufficient to teach geometry competently but also raise insecurities in teaching geometry should give cause for concern, especially since this aspect has not yet appeared as a prominent reason in the literature. Comprehensive teacher training focusing on both content and pedagogical content knowledge is essential as well as supplementary training in order to dispel uncertainties when teaching geometry (Jones & Mooney, 2003). Also, the collaboration between researchers and practitioners (e.g., design research, action research) may provide teachers with the needed support. We need to understand how teachers may be better prepared to play the roles that have been emphasized in the literature as well as ongoing developments (Sinclair & Bruce, 2015). The importance of this aspect can hardly be overemphasized, especially given the increasing proportion of not fully trained teachers. It should not be forgotten that the participating teachers only represent in-service primary teachers to a limited extent. Despite this drawback, the study results not only provide an up-to-date insight into elementary school geometry teaching but also provide new evidence for questions that have not yet been examined in the literature which call for immediate attention that should be examined by educators.

Escape From Plato's Cave: An Enactivist Argument for Learning 3D Geometry by Constructing Tangible Models

Alik Palatnik[1] and Dor Abrahamson[2]

[1]The Hebrew University of Jerusalem, Israel; alik.palatnik@mail.huji.ac.il

[2]UC Berkeley, USA; dor@berkeley.com

Like Plato's allegorical cave-dwellers, students of three-dimensional geometry seldom get to handle the real thing, working instead with two-dimensional silhouettes. Such historical sensory deprivation may partially explain students' generally poor conceptual understanding of this core content and alienation from the field. Operating from a perspective of embodied learning, our design-based research study invited middle-school students to collaboratively construct and investigate voluminous objects. We present qualitative analyses of empirical results from implementing two experimental geometry activities. For both cases, we characterize students' critical insights as shifts in perceptuomotor attention leading to refinement of geometric argumentation. We implicate students' realization of an available 3D medium affordances catalyzing these shifts. The findings contribute to a socio-material elaboration of embodied learning for school geometry.

Keywords: Spatial geometry, Embodiment, Manipulatives, Visualization

Introduction

Historically, the mathematical discipline of geometry originated from mundane practice—situated, embodied know-how serving personal, social, and professional contexts, such as carpentry, agriculture, and navigation. However, while humans live and act in 3D space and engage voluminous objects as part of this naturalistic spatial comportment, geometry scholarship—the reification and scrutiny of these objects' structural properties—has historically depended on 2D material media and their consequent "flat" perspectives (Alsina, 2010). This dependence has a price. For example, a recent study by Fujita et al. (2020) documents elementary- and middle-school students' poor performance on spatial geometry problems, especially those requiring multiple reasoning steps.

Scholars from different disciplines have claimed that if students began studying geometry with their embodied sensibilities, we could preempt their poor engagement and low performance in the discipline (Freudenthal 1971; Thompson, 2013). Pedagogical advocacy to work with "the thing itself" harks back to Enlightenment (Rousseau, 1755/1979; Froebel, 1885/2005) and modernity (Montessori, 1949/1967), bolstered by Gaspard Monge and Felix Klein's approach to the development of intuition about complex structures through the construction of concrete models (Mueller, 2001). Still, after over 60 years of empirical research on the use of manipulatives in mathematical classrooms, their cognitive effects and optimal utilization have yet to be established (Bartolini Bussi et al., 2010).

We argue that realizing a material transformation in (spatial) geometry instruction, from 2D to 3D, demands a paradigmatic epistemological shift from idealistic to realistic views on geometry; from a representationalism model that separates perception, cognition, and action to an embodied model.

Cognitive argument: from a perception-cognition-action model to embodied cognition

Per Plato, she who seeks mathematical knowledge should strive to obtain mental representations as close as possible to the ideal (non-physical) forms. Millennia later, Platonic metaphysics persevere through cognitive-science theoretical models that box the mind inside the skull as an amodal ethereal switchboard between its earthly perception input and action output (Hurley, 2010). Over the recent decades, however, cumulative data from various fields (neurobiology, robotics, kinesiology) is casting doubt on this classical model (e.g., Willems & Francken, 2012).

The embodied turn in cognitive science rejects the hierarchical mind–body separation and stresses that perception and action are formatively constitutive of our thinking—cognition is modal and situated activity (e.g., Chemero, 2013). The mind's function is not to *represent* the environment precisely but to *engage* with it dynamically vis-à-vis socio–biological task demands and emergent contextual contingencies. The environment offers opportunities for potential action—*affordances* (Gibson, 1986)—that the agent interactively discerns and incorporates. When we engage the world with fellow humans, we coordinate with them perceptual orientations in relation to shared situations, from early development (Tomasello, 2019) and through to professional practice (Goodwin, 2018).

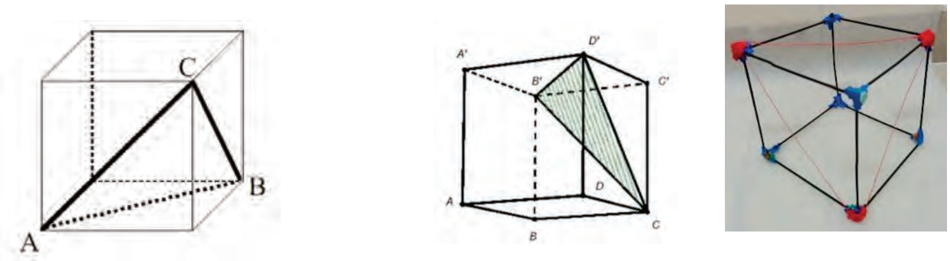
Imported to mathematics instruction, tenets from the embodied paradigm of the cognitive sciences suggest that learning new concepts begins with discovering new ways to act in the environment, using new instruments to perform tasks on discovered affordances (Abrahamson & Bakker, 2016). Working with the things themselves, students develop a capacity to act efficiently, describe the world mathematically to coordinate collaborative actions, iteratively encounter more complex problems, and ultimately modify the environments to solve emergent problems (Abrahamson et al., 2020).

Spatial geometry challenges and possible theoretical and practical solutions

Roth and collaborators demonstrated that geometry knowledge may emerge as enacted exploration of concrete instructional resources. Their examination of primary-school students' classification of geometric objects fuses material phenomenology and phenomenological sociology to view geometry as cultural–historical motivated sensuous labor (e.g. Bautista & Roth, 2012). Yet, whereas overtly embodied routines, such as gesturing, manipulating objects, and applying mechanical construction tools, are considered essential for young students' geometric reasoning and problem solving (Kaur & Sinclair, 2014), these resources almost disappear from older schoolchildren's instructional activities. Perhaps most acutely, mainstream spatial geometry education skips "the real thing," immediately requiring of students to visualize 3D objects given their 2D representations (Widder et al., 2019). Consequently, students struggle "to overcome the perceptual appearance (or 'look') of the given diagram" (Fujita et al., 2020, p. 235). For instance, for one of their survey items (see Figure 1, on the left), just 17 % of the 5th-grade students, 34% of 7th-grade students, and 52% of 9th-grade students marked the correct answer (percentages rounded). In light of their results, Fujita et al. (2020) call to revise primary and secondary school curriculum to provide students with more opportunities to develop both spatial skills and geometric knowledge for productive argumentation. However, the researchers do not indicate what types of tasks could possibly serve as context for realizing this call.

Investigating a 3D DGE (dynamic graphic environment), Mithalal and Balacheff (2019) explored conditions in which construction tasks stimulate students' transition from working with drawings and iconic visualizations to perceiving geometric properties of figures and non-iconic visual displays.

They claim that this transition depends on students' ability to perform certain figural operations (dimensional and instrumental deconstruction) in tasks designed to hone this ability.



In a cube, can you identify the shape ABC? Choose your answer from (a) – (e).

(a) Right-angled triangle
(b) Isosceles triangle.
(c) Right-angled isosceles triangle
(d) Equilateral triangle
(e) Scalene triangle

ABCDA'B'C'D' is a cube. Answer the true/ false questions and explain your reasoning.

1. CB'D' is a right-angled triangle. The right angle is ___?
2. B'D' is the shortest side of the triangle CB'D'.
3. Triangle CB'D' has an obtuse angle.
4. In triangle CB'D', all angles are equal.

Figure 1: Tasks involving 2D representations of 3D geometrical shapes

With Fujita et al. (2020) and Mithalal and Balacheff (2019), we acknowledge the key cognitive role of sensory perception in understanding spatial geometrical forms. Yet, *we conceptualize sensory perception as necessarily serving and emerging from goal-oriented action*. We thus seek to investigate how students ground geometry concepts in action-oriented perception. Our study accordingly evaluates a set of enactive tasks designed for high-school students to develop geometrical perceptions through multimodal action-based interactions with concrete material.

Constructing tangible models as embodied design for spatial geometry learning

Supported by the embodied perspective, we are looking to capture and theorize conceptually significant shifts in students' perceptuomotor attention towards voluminous geometrical solids. The two vignettes, both from video-recorded data gathered in Jerusalem, Israel[1], illustrate how each activity's unique sensorimotor affordances enabled students to engage in conceptually generative collaborative enactment and argumentation. The first vignette (V1) presents a task (Figure 1, right) designed to stimulate perceptual coordination of 2D diagrams and their 3D counterparts: students use a "3D pen" to construct a voluminous cube from its "flat" image, then they manipulate the model to investigate its properties per the problem instructions. The vignette exemplifies a "first step out of Plato's cave," where students tentatively realize what they can, may, and should do with a 3D model. In the second vignette (V2), students assemble a very large multi-unit geometrical form and then identify the "hidden" form that emerged in between the units. This vignette exemplifies students' zealous unshackling of any remaining "geometry-is-flat" predilections.

[1] Qualitative analysis of additional cases is currently underway to evaluate for generalizability of these case studies

V1. Stepping out of the cave: Learning a 3D model's affordances for spatial problem solving

The teaching experiment presented in this vignette is a part of a wider educational research project evaluating students' experiences with 3D pen sketching while solving spatial geometry problems (for details, see Rosenski & Palatnik, 2021). Three 10th grade students (T, G, & M) faced the task shown in Figure 1 (right) for approximately 20 minutes. Male student G drew the triangle inside the cube with a 3D pen. Next, over approximately 8 minutes, the students discussed the problem but made no significant progress. They were inclined to believe that CB'D' is a right-angled triangle.

T:	No, but you know that this is a cube, and this (cube face) is a square, and then, this is 90 degrees, then this is 90 degrees, and then it (diagonal) bisects the angle, so it is 45(degrees).
G:	The question is, if we rotate (two faces, where the edge is an axis) [gestures "rotation" with two palms as faces], would it be the same angle? Could it be?
M:	To them, it (the angle) in the picture also looks like that (90 degrees).
T:	In the picture, it is just from a different angle, if you turn it like this [adjusts the model], you can see that this [points] is the right angle if this is stretched [pulls up the slightly sagging plastic diagonal of the top face of the cube.]

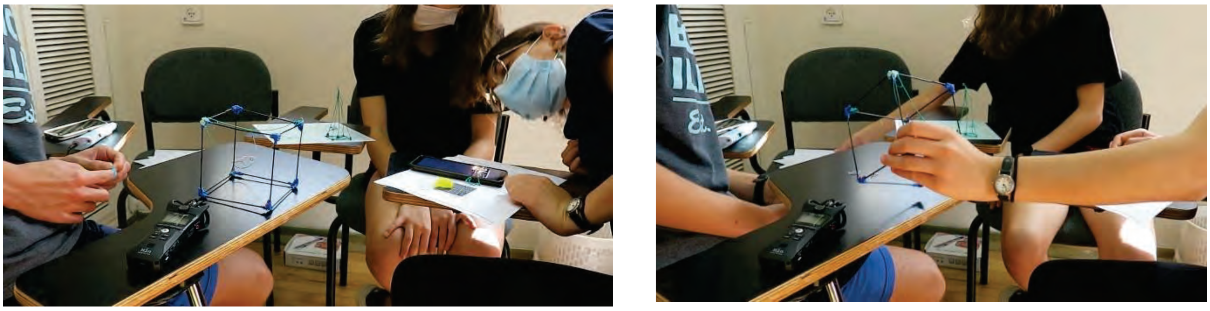


Figure 2: Investigating 2D representations of 3D geometrical shapes

During these eight minutes, students left the model standing between them on G's writing surface (see Figure 2). Remarkably, the students made inferences and conjectures about the task without taking the model in hand, only lightly touching it and making minor adjustments. Most of these adjustments reoriented the 3D model vis-à-vis the given 2D diagram.

In this phase of problem solving, the students were reluctant to make inferences based on the appearance of the 3D model. They approached the 3D model to correlate it with a cultural form that they are used to—a 2D diagram. In particular, the students sought to "flatten" the 3D model such that it would be seen as identical to the 2D diagram, where CB'D' presents an apparent right angle (see Figure 2-left, where T twists her body). However, a retinal image of a 3D object is not similar to a 2D projection. As Gibson (1986) has argued, we notice optical invariances of the object under the movement of the source of light, movement of the observer, movement of an observer's head, and manipulations and local transformations of the object itself. Naturalistic interaction could possibly untether the students from "paper math." Soon after, indeed, the students utilized these affordances of their 3D model, discerned it invariant features by handling it, and made correct inferences.

Several factors prepared the A-ha moment. For instance, G was unsatisfied with the claim that CB'D' is a right-angled triangle. He argued: "If these two angles look like the same shape, if they are both right angles and a triangle has a total of 180 degrees, then the triangle cannot exist”; “This is impossible. If you rotate it each way to make it (one of the angles) look like a right angle, then you can rotate it in a different way (to make other angle look like a right angle)”. Yet his teammates, still “deep in the cave,” had still to be convinced.

At the 14th minute of tackling the task, we witness a shift in students’ interaction with a model. T took the model in hand (Figure 2-right) for the first time, rotated it for five seconds, and 20 seconds later said, “Now I get it.” In the next minute, T tried to formulate her vision, accompanying her explanation with more than 5 complex model rotations (i.e., more than 2 axes involved). The core of her argument was in line with what G had previously argued: from different angles, the triangle appears isosceles, and yet its angle “can’t be 90 for all of them.” During this minute, G’s attention was on the rotating model, enabling him to see it under these transformations. In contrast, M focused only on the 2D diagram and tried several times to draw her peers’ attention to it: “Look at the picture!” It took another minute for G to formulate an answer and a valid argument.

T:	So you think all the angles are 60 degrees? Is it an equilateral triangle?
G:	Yeah, look, all the sides are of the same length [traces with finger three sides in succession] if you look at it. Is that true?
T:	Mmmm…I don’t know.
G:	Look [adjusts the model], all the sides (of the triangle) are exactly a diagonal [traces a diagonal of the upper face], the diagonal of a square. All the squares are the same. And that means, if all of the sides are equal [points on a different face], all of the angles are equal, and they’re all 60 degrees.
T:	Ok... [types into the response form] We think that all sides are equal; therefore, the angles are also equal... equal to 60. It’s an equilateral triangle.

To summarize, the task was difficult for the students, even with a 3D pen and a model. In line with Fujita et al. (2020), the task demanded that students harmonize their spatial reasoning skills with domain-specific knowledge of planar geometry (properties of squares and triangles). It took students time to utilize an available 3D medium and realize its affordances (a spectrum of perspectives on the equilateral triangle for the team members). M’s decision to stick to a 2D drawing may explain her low contribution to the final effort. In contrast, when T physically rotated the model, her actions apparently spurred and supported her spatial reasoning and were visible to G. He, in turn, observed these *physical* rotations, which allowed him to refine his previous arguments based on *mental* rotations and apply the corresponding geometric knowledge to the new 3D situation.

V2. Further steps: Constructing enactive argumentation—gesture, action, medium

In the second teaching experiment, part of “Geometry In… and Out” (Benally et al., 2021), four 7th grade students constructed voluminous solids (Figure 3) then worked on the following questions: “Comparing the volumes of the large and small tetrahedra that you built, how many times the volume of the large tetrahedron is greater? Explain your answer. Several small tetrahedra compose the large tetrahedron. Can you describe a three-dimensional shape between them? Can you construct it?”

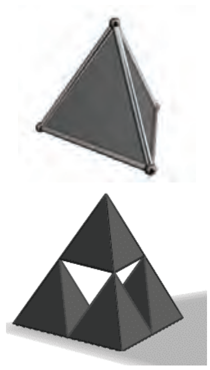
Once the group had constructed the first small pyramid, Yali placed it on his head (Figure 4a). Nami, using Yali as a stand, gestured on him that this polyhedron is called “arba-on” (“arba” is four in Hebrew). The palms of her hands present the polyhedron’s faces. Then, removing the model off Yali’s head, Nami gestured similarly, though with her forearms, to present the same four faces (Figure 4b).

It took the students approximately 11 minutes of collaborative work to construct a large model and begin answering the items. Their plan for estimating the large tetrahedron's volume was to decompose it into its component parts. They easily recognized four small tetrahedra: "three at the base, and one at the top." However, the students were not sure about the shape of a three-dimensional hollow between the tetrahedra (the octahedron outlined in red, for your convenience, in Figure 4c).

1) Your team has to construct a three-dimensional model of the following geometrical solid using a construction kit. The solid has the following properties:

- All the faces are congruent equilateral triangles.
- The same number of edges converge at each vertex.

2) The polyhedron you've constructed is called a tetrahedron. Construct a similar polyhedron whose edges are 2 times larger than the original one. You can use the image below for construction.



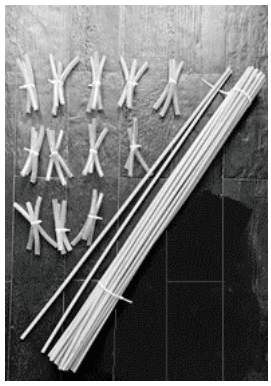


Figure 3: The tetrahedron construction task and materials.

a b c d

Figure 4: Different affordances of the available media as manifested in students' actions

Tami, Nami, and Gali suggested that the hollow is also shaped as a tetrahedron. Yali disagreed and offered to count the faces of the "empty space." He rotated the large model, hoping to render it more familiar, yet that action proved unhelpful. Tami remonstrated, "You just can't *see* this (tetrahedron)." To support her claim, she grabbed two sheets of paper lying on the desk and applied them successively as the polyhedron's faces, expecting these to total at four. Immediately, Yali appropriated Tami's strategy, just to disprove her. Summoning more paper sheets and distributing them over more group members, he marshaled an "octopus of hands" to simultaneously cover all the polyhedron's faces. The introduction of these auxiliary objects helped students to solidify the shape (Figure 4d), count the faces, and eventually write the following definition: "The polyhedron between four triangular (pyramids) has eight identical faces. Each face is an equilateral triangle."

This vignette illustrated the emergence of students' enactive argumentation through collaborative semiotic evolution of gestures into concrete media. Students' hands, semi-constructed models, and even repurposed found objects became instrumental in shaping a void—rendering a contested obscure object into an articulated, unequivocal, and publicly inspectable form. The hidden octahedron was born as a "prospective indexical" (Goodwin, 2018) then came forth through pointing, formative gestures, and construction media. Thus, the hollow solid inhabiting the larger structure was substantiated, reified. Eventually, once the form was delegated from imagination to media, the students could allocate cognitive resources to enumerate its facets and name the new geometric object.

Discussion and Conclusion

This article aimed to present theoretical foundations and empirical arguments for a set of embodied spatial-geometry curricular resources for middle school. We submitted that historical dependence of geometry education on 2D media is implicitly rooted in an idealistic Platonic tradition and the representational cognitivist model. We conjectured that tasks in which students construct 3D objects are more than “working with manipulatives”—they let students use their natural capacities of multimodal perception and collaborative action. We supported our argument through qualitative analysis of two vignettes exemplifying embodied design for spatial geometry learning.

We demonstrated how a group of middle-school students grounded geometric concepts of solids, their cross-sections, faces, and edges in goal-oriented, situated activity of constructing concrete 3D models. Our first vignette demonstrated that coordination of traditional and novel medium is not easy for students. They tentatively experiment with their new degrees of modal freedom—looking at objects, pointing at them, touching them, lifting and rotating them. New affordances catalyze shifts of students’ attention to relevant features supporting their geometric reasoning.

Mithalal and Balacheff (2019) considered the possibility of a continuous evolution from iconic to non-iconic visualization, where the figural operation of instrumental deconstruction would play a cohesive role. Our second vignette provides an empirical basis for this assumption. The transition from iconic visualization to non-iconic visualization was carried out by introducing tangible auxiliary elements (paper sheets in the form of polyhedron faces) into the 3D model. Thus, the students performed a naive instrumental deconstruction of shape, a mereological deconstruction of a 3-dimensional shape into four tetrahedrons and an unfamiliar shape, and finally a dimensional deconstruction of a 3-dimensional shape, which focused their attention on the 2-dimensional faces of the octahedron (see Palatnik & Sigler, 2021, for a theoretical discussion on the introduction of an auxiliary element as a shift in attention). This argumentation by action was later transformed into a normative formulation of properties—the formal definition of a geometric solid.

Constructing and manipulating tangible models creates opportunities for students to harmonize spatial skills and rigorous geometric argumentation as well as bridge iconic and non-iconic visualization. Yet, it is challenging to step out of Plato’s cave after a lifetime of unwitting incarceration. Middle school geometry should organize students’ engagement with 3D objects as one would any artifact—with untampered senses; with gross and fine motor actions; with all the tacit, evolutionarily endowed naturalistic sensibilities for orienting in the environment. Once students realize how to work with three-dimensional objects in mathematical activities, they can tap their know-how to build valid arguments grounded in enactive experience.

Developing tools to analyse secondary teachers' mathematical knowledge for teaching basic geometry

Iresha Ratnayake, Shikha Takker, Jill Adler and Craig Pournara

University of Witwatersrand, South Africa;

There has been extensive research on investigating teachers' mathematical knowledge in different topics and more recently at different school levels, with some work towards this in geometry (e.g., Ko & Herbst, 2020). In this paper we provide examples of research tasks used to describe and investigate teachers' knowledge of basic geometry. By basic geometry we mean concepts, theorems and properties of lines, angles and triangles in the junior secondary curriculum of South Africa. Since the choice of examples is a key element of any task, we offer a set of criteria for developing aspects of the example (i.e., figure in case of geometry) in tasks. The tasks, in turn, provoke teacher responses that enable us to describe aspects of teachers' mathematical knowledge for teaching geometry. We do this using a framework for producing tasks of varying difficulty level for teachers that could be used to illuminate their geometry knowledge for teaching.

Keywords: geometry, mathematics teacher knowledge, tasks.

Background of the study

Geometry is an important topic in school mathematics. Euclidean geometry is part of the school curriculum in many countries and the foundation for Euclidean geometry starts from primary grades by introducing shapes and their properties. However, geometry continues to be a topic that students struggle with (e.g., Luneta, 2014; Steele, 2013). One of the many reasons for students' low achievements, especially in geometry, is teachers' difficulty in teaching geometry (e.g., Bowie, 2013; Steele, 2013). Based on recent experience of working closely with different groups of secondary teachers in Gauteng, South Africa, the team of the Wits Maths Connect Secondary (WMCS) project recognized the need to support teachers to improve their knowledge of basic geometry.

The aim of our project is to understand the knowledge that teachers need to teach basic geometry in schools and then to support them through a professional development (PD) programme. Our definition of teachers' knowledge is based on Ma's (2010) conception of profound understanding of the content with breadth and depth of knowledge. We can also consider this knowledge as common content knowledge (CCK) (Ball et al., 2008) but it is specialised and needed for teaching. In order to understand this knowledge, we are in the process of developing a framework which focuses on developing teachers' mathematical knowledge *for* teaching, which is defined as including both *knowledge of mathematics* and *knowledge of mathematics teaching* (for details, see Adler, 2021).

We did not find any literature dealing with teacher knowledge when their mathematical knowledge is weak and little dealing with teaching basic geometry or teacher knowledge of basic geometry. By basic geometry we mean concepts, theorems and properties of lines, angles and triangles in junior secondary curriculum of South Africa. We are working with a relatively unique group of teachers who acknowledged the weaknesses in their geometry knowledge base. They openly discussed these and requested a course to help them to improve their geometry knowledge.

The PD provided us with a unique opportunity to understand what knowledge they bring, what is lacking and how we might help them to build their knowledge to the point where they can teach geometry with confidence and competence. So, from a research perspective, we asked ourselves how do we "measure" teachers' starting base and then "measure" gains over time? We do not focus in this paper on teachers' knowledge *per se*, nor the PD, nor do we look at change. None of these is possible without a framework that is geometry-specific for classifying tasks that would appropriately elicit teachers' knowledge. A key element of any task is the example/s used and in this paper we offer a set of criteria for developing examples within the tasks. In turn, these tasks provoke teacher responses and thus enable us to describe aspects of their mathematical knowledge for teaching geometry.

Literature Review

Several scholars since Shulman (1986) have tried to define specialised aspects of teachers' knowledge. Ball, Thames and Phelps (2008) categorised teachers' knowledge to specify different aspects which need to be focused upon. Following from Ball and colleagues' delineations of subject-matter knowledge (SMK) for teaching, Herbst and colleagues (e.g. Ko & Herbst, 2020) designed an instrument SMK-G to measure teachers' knowledge of geometry. They focused on tasks for teaching to capture differences in teachers' mathematical knowledge for teaching high school geometry. Through this work they offer distinctions between different SMK-specific tasks of teaching. For example, in one item teachers are provided with four algebraic expressions and asked to choose a set of measures for angles in a parallelogram that can be given to students as an exercise after they have learnt about interior angles of a parallelogram.

There are several other studies on designing assessment instruments to measure teachers' mathematical knowledge for teaching geometry. For example, in contrast to the assessment tools developed for assessing teachers' mathematical knowledge in a broader range of mathematical topics, Martinovic and Manizade (2018) proposed "that the measures should be designed as 'probes' around specific topics commonly taught by a targeted group of teachers" (p. 613). They developed a probe for a task on *Area of a Trapezoid* and developed a pedagogical content knowledge (PCK) instrument with rubrics used to "measure teachers' responses and … create PCK profiles" (p. 615). They propose that secondary mathematics teachers' PCK is a complex and multidimensional phenomenon with five dimensions: geometric knowledge; ability to provide geometric extensions; knowledge of applicable instructional strategies and tools; ability to ask diagnostic questions and knowledge of student challenges and conceptions. In another approach, Steele (2013) designed open-ended tasks and rubrics to understand teachers' thought processes in solving problems on geometry and measurement.

In the South African context, Bowie (2013) argued that both the research and curriculum documents acknowledge the difficulty that teachers face in enacting geometry in the classroom. In a study with 128 first year pre-service teachers, Luneta (2014) found that the majority of the participants had limited knowledge in basic geometry, falling within Level 1 of Van Hiele's theory. He argued that the participants "required not remedial but re-learning of basic these concepts" (p. 71). An earlier investigation in South Africa echoed this and showed that both pre-service and in-service teachers failed to reach the competence level expected of Grade 7 students (van der Sandt, 2007). It is therefore clear that the teachers we are working with in this study constitute a small sample of a much larger group of teachers in South Africa who have limited knowledge of basic geometry.

We draw on the existing literature to design tasks to investigate teachers' knowledge in geometry. However, to engage with pedagogical aspects successfully, teachers need strong content knowledge. In the context of our work, teachers needed support in understanding *basic* knowledge of geometry. In the existing literature, examples that are used in tasks are not problematised. The examples are a critical aspect of designing tasks for teachers, particularly those with a low knowledge base because it is essential that teachers are able to make a start on the tasks, even if they cannot complete all aspects of the task. In this paper, we focus on exemplification including tasks and examples for the purpose of describing teachers' knowledge. We now turn our attention to the theoretical framework which foregrounds examples in understanding teachers' knowledge.

Theoretical framework

We turned to Adler and Ronda (2015) for a theoretical framework on Mathematical Discourse in Instruction (MDI) where they focused on *object of learning*, *exemplification*, and *explanatory talk* (see Figure 1). Using a socio-cultural framework (Vygotsky, 1978), the authors (ibid) consider mathematics teaching as goal directed. In MDI, how an object of learning is exemplified is important. Another aspect, which is important in exemplification is the principle of variation. In their work, Adler and Pournara (2020) developed the use of exemplification for mathematics teacher education. They focused on algebra and functions. In MDI for algebra, examples and figures are different. By contrast, in geometry the example and the figure are the same (or at least inextricably linked). We therefore asked ourselves what does it mean to use exemplification in the topic of geometry? In the MDI framework (see Figure 1), exemplification is classified into examples, representations and tasks. This requires adaptation for geometry.

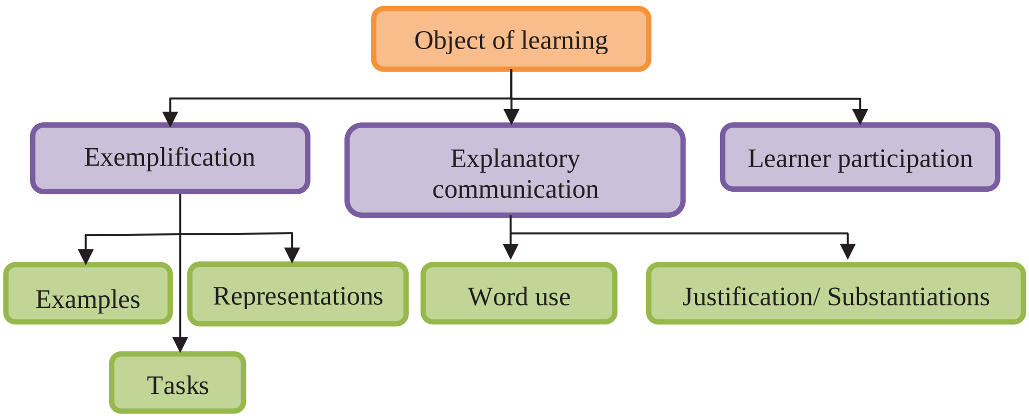

Figure 1: The MDI conceptual framework (Adler & Mosvold, forthcoming adapted from Adler & Ronda, 2015).

Developing the framework for geometry: Exemplification

The framework MDI focuses on the object of learning, exemplification, explanatory communication and learner participation. In developing the current framework for geometry, we borrowed these elements from MDI framework and modified them according to the needs of using it to examine the tasks used in the data collection tools pre-assessment, worksheets, and questions for the focused interview (see Takker et al., 2021). In this paper, we will focus on exemplification in geometry using examples as a means to access and ultimately to describe teachers' knowledge.

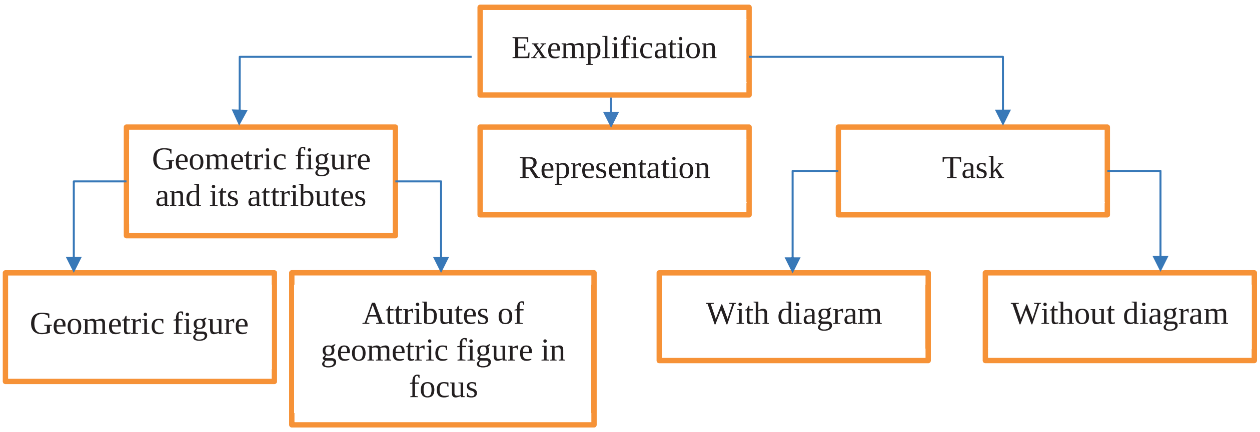

Figure 2: Exemplification aspect of the framework

The exemplification element is divided into three categories: (a) Geometric Figure (GF) and its attributes, (b) Representations, and (c) Tasks. These three categories are further divided into subcategories (see Figure 2). For instance, GF and its attributes is sub-divided into GF and attributes of GF in focus, whereas the task category is sub-divided into tasks with a diagram and tasks without a diagram. These subcategories are then examined under different levels. We needed a relatively fine-grained measure to describe and categorise teachers' knowledge, particularly as we worked in the largely unchartered waters of teachers' low knowledge base in geometry where we ultimately seek to investigate changes in their knowledge.

For us, categorising the tasks and examples is a start. And this is what is being offered in this paper. For example, GF is categorised into three levels with two sub levels based on the number of GFs in the given diagram, namely: one GF; two GFs (with same type of figures or different) and three or more GFs (with same type of figures or different). The *attributes of GF in focus* are categorised into three levels depending on axioms, definitions or theorems needed to solve the problem. In geometry it is important to identify the properties when the diagram is in a familiar orientation as well as in an unfamiliar orientation. Therefore, we categorised representation in standard orientation, in non-standard orientation or in multiple orientations. By *standard orientation* we mean the most familiar and common orientation. For example, having the "unequal side" of an isosceles triangle in horizontal position. And *non-standard orientation* refers to any other orientation than the familiar or most common orientation. In a complex figure, if one or more GF is in standard orientation and others in non-standard orientations then we consider the diagram is in multiple orientations. The subcategories for the third main category, i.e., task, are distinguished by whether the task comes with a diagram, or whether it is expected that a diagram (or a part of it is) be drawn as part of the solution. Six levels were set for a task which comes with a diagram whereas five levels were set for a question which does not come with a diagram. The levels for the task category were also based on the difficulty level of the task. For example, is it a numerical measure problem, or does it include algebra or a simple proof, or a complex proof without numerical measures, or perhaps algebra is also required? In rating the tasks of each data collection tool, the first two authors examined them individually and then discussed to ensure the validity. There were not many differences in each examination and agreement was quickly reached. We present three different tasks and their classifications using the framework.

EXEMPLIFICATION	
Geometric figure (GF) and its attributes	
GF (and diagram complexity)	*Attributes of GF in focus*
L1: One GF L2(a): Two GFs – same type of GFs L2(b): Two GFs – different types of GFs L3(a): Three or more GFs – same type of GFs L3(b): Three or more GFs – different types of GFs	L1: Use of axioms, definitions to identify instances of GF L2: Use of axioms, definitions, or properties in solving problems. L3: Use of axioms, definitions, properties or theorems in solving problems
Representation (diagram and symbols)	
L1: Standard orientation L2: Non-standard orientation	L3: Multiple orientations
Task	
With diagram	*Without diagram*
L1: Numerical measure problem L2: Algebraic measure problem L3: Numerical proof problem L4: Algebraic proof problem L5: Simple proof L6: Complex proofs and converse	L1: Draw a diagram based on given information for one GF L2: Extend a given figure L3: Draw a diagram based on given information for two or more GFs L4: Construct a simple figure with one GF L5: Construct a complex figure with two or more GFs

Figure 3: Levels in exemplification aspect of the framework

Examples of Tasks

We provide examples of three tasks and their analysis using the levels of the framework. The exemplification aspect of the framework guided us to design geometric problems with different combinations of levels. For instance, Example 1 (see Figure 4) has one GF in standard orientation and a numerical measure. The properties that can be used include sum of the interior angles of a triangle and angles opposite equal sides of an isosceles triangle. Therefore, this was categorised as L1, 2, 1, 1 which is explained in Figure 4.

In ΔXYZ, $YX = YZ$ and $\hat{Y} = 102°$. Is the information given in the question sufficient to find the size of $\hat{Z}$. Give reasons. 	**GF -** L1: one GF **Attributes of GF -** L2: two geometric properties to solve: sum of the interior angles add up to 180^o and opposite angles to opposite equal sides are equal **Representation -** L1: Standard orientation **Task: with a diagram -** L1: a numerical measure problem

Figure 4: Analysis of Example 1

In the second example, (see Figure 5) there are two GFs in a non-standard orientation (because the parallel lines are not horizontal) and algebraic measure. The properties that can be used include angles formed on a pair of parallel lines cut by a transversal; vertically opposite angles and angles on a straight line. Therefore, this was categorised as L2(a), 2, 2, 2.

You will use algebra to answer this question. (a) Determine the value of x. Give reasons. (b) Determine the value of y. Give reasons. (c) Fill in the sizes of all 8 angles on the diagram. 	**GF** – L2(a): two GF **-** a pair of parallel lines with a transversal **Attributes of GF -** L2: geometric properties such as: angles formed on a pair of lines cut by a transversal; vertically opposite angles; and angles on a straight line **Representation -** L2: non-standard orientation **Task (with diagram)** – L2: Algebraic measure problem

Figure 5: Analysis of Example 2

The third example involves geometric proof. Example 3 (Figure 6) was categorised under L3(a), 2, 2, 6. The diagram given in the question includes three GFs - an isosceles triangle, a line parallel to one side and an angle bisector, and therefore coded as L3(a). The task was coded with L2 for *Attributes of GF in focus* since axioms, definitions and properties such as the properties of an isosceles triangle, definition of a bisector of an angle, properties of parallel lines, angles on a straight line, angles at a point need to be used to solve this problem. The diagram of Example 3 is not in standard orientation and that is the reason why it was classified as L2 for *Representation*.

While this is not a very complicated geometry task, it proved to be quite a challenging problem for the target group of teachers, as we saw in their difficulties with this and similar tasks. Therefore, we categorised Example 3 under L6 for the *task* aspect - a complex proof involving *if-then-because* reasoning.

In the given diagram, lines GC, HB and FE intersect at point A, BC = AC, and AH bisects GF. Prove that EF is parallel to BC. 	**GF -** L3(b): three GFs **-** isosceles triangle, a pair of parallel lines and an angle bisector **Attributes of GF -** L2: geometric properties such as: opposite angles to opposite equal sides are equal; sum of the interior angles add up to 180^o; bisection of an angle; angles formed on a pair of line cut by a transversal; vertically opposite angles need to be used to solve the task

	Representation - L2: non-standard orientation **Task (with diagram)** – L6: a proof of a non-numerical rider involving *if-then-because* reasoning

Figure 6: Analysis of Example 3

Discussion and Conclusion

The existing literature (e.g., Ko & Herbst, 2020), contains research on the use of measures to assess teacher knowledge in geometry. But there is no instrument to investigate teacher knowledge of *basic geometry* and hence a focus on content knowledge needed by teachers with a low knowledge base. We have presented part of the framework on exemplification used to develop tasks for investigating mathematical knowledge for teaching *basic geometry*. We showed how the framework is used to categorise the difficulty levels of the tasks. While using the exemplification aspect of the framework to design tasks for different levels of difficulty, we use the explanatory communication aspect to analyse the teacher responses to course tasks, including the pre-assessment, worksheets, and a focused interview. By analysing data, we hope to identify the mathematical knowledge that is needed to teach basic geometry. Although we are working with a small and special group of teachers, they represent a much larger group of teachers in South Africa, and possibly in other parts of the world, with low levels of geometry knowledge. This unique opportunity holds the potential to identify the structure of profound knowledge needed for teaching basic geometric ideas, relevant for teachers and teacher educators in planning tasks to support teacher learning.

Acknowledgement

This research and development work is supported financially by the First Rand Foundation, the Department of Science and Innovation and the National Research Foundation (South Africa). We thank the WMCS project team for fruitful discussions about the ideas on which this paper is based.

Construction of an equilateral triangle in the plane and space: an analysis from the theory of semiotic mediation

Camilo Sua, Angel Gutiérrez and Adela Jaime

Departamento de Didáctica de la Matemática, Universidad de Valencia, Spain; jeison.sua@uv.es, angel.gutierrez@uv.es, adela.jaime@uv.es

Dynamic geometry environments provide users with several tools to construct geometric objects. In the use of these tools, convergence of personal to mathematical meanings has been recognized, because the tools provided by the environment embody theoretical relationships of Euclidean geometry. In this document we analyze the productions of two mathematically gifted students when solving a construction problem in a dual 2-dimensional and 3-dimensional setting. Supported by the theory of semiotic mediation, we show the nature of the signs exhibited by the students and some difficulties that can occur when they move from a 2-D representation to a 3-D one.

Keywords: Theory of semiotic mediation, 3-Dimensional geometry, Geometrical construction, Dynamic geometry environments.

Introduction

There is wide recognition of dynamic geometry environments (DGE), their characteristics and the challenges to incorporate this resource in ordinary teaching and learning of mathematics (Sinclair et al., 2016). These authors inform on efforts by mathematics education researchers made in this regard. Despite this, many research has been carried out focusing on DGE for 2D geometry, but it is much scarcer the research on the use of DGE for 3D geometry (Gutiérrez & Jaime, 2015).

The relationships established among mathematics and DGE is of an epistemological nature, since it happens through a process of mediation (Bartolini-Bussi & Mariotti, 2008). In this process, mathematical objects are shared and thought through their representations. Technology offers possibilities for such representations, as well as a space for communication between student and teacher in which a shared language circulates (Noss & Hoyles, 1996).

The construction on DGE of geometric objects and the justification of its validity can be conceived as a route towards the identification of geometric properties in the representations offered by the software, since the available construction tools allow establish a semiotic relationship between (i) personal meanings caused by the activities of construction and verification by dragging, and (ii) theoretical aspects of geometry that underlie these constructions through the tools used, which support the validity of the construction (Mariotti, 2012). To analyze this relationship, a semiotic perspective about the students' mathematical activity while solving geometric construction problems is pertinent. We have adopted the *theory of semiotic mediation* (TSM) (Mariotti, 2019) to study the production, nature, and evolution of signs present in students' activity in a DGE. In this paper we present solutions to a problem asking to make a construction in 2-D and next to make the same construction in 3-D and justify that the constructions are correct. The research objective is to analyze the students' solutions to that construction problem to identify the signs and signs' meanings exhibited by the students while solving the problem, and the influence of the 2-D construction on the 3-D construction.

The Theory of Semiotic Mediation

The TSM is supported by the Vygotskian notion of *semiotic mediation*, as well as the role of technology (Mariotti, 2019). This theory explains the process of learning mathematical contents when an artifact is used to solve a task (Drijvers et al., 2010). When experts (teachers) use an artifact to solve a problem, they recognize mathematical notions through its use. However, when novices (students) use the artifact, they do not recognize immediately the mathematical meanings that emerge, but students see them linked to the artifactual context in which the mathematical contents are used (Mariotti, 2019).

A *sign*, from Pierce's perspective, is "anything" that represents "something" to "someone" in some aspect or degree (Bartolini-Bussi et al., 2012). The TSM interprets students' production of signs and the evolution of such signs, whose meanings move from personal to mathematical, close to the teaching objective (Mariotti, 2019). In this process, the use of specific tools by the teacher, together with her actions, to promote students' learning is recognized and has relevance (Mariotti, 2012).

The signs can be characterized according to the nature of students' productions (verbalizations, writings, gestures…) and the ways the artifact is used. Some signs are close to the activity done with the artifact and others are close to the aimed mathematical meanings. When student's explanations move from references to the use of the artifact towards references to the mathematical context, different signs are used, which mirror the state of students' learning process. We consider three types of signs (Bartolini-Bussi & Mariotti, 2008): *Artifacts signs* point the use of the artifact or to actions linked to it. *Mathematics signs* refer to mathematical elements of the context; they are related to mathematical meanings and are expressed by propositions that satisfy standards of the mathematical community. They constitute the achievement of the semiotic mediation process orchestrated by the teacher. *Pivot signs* are present in actions, carried out with the artifact, where specific instrumented actions and natural language referring to mathematical contents are involved; their polysemic nature implies that these signs are used to advance from artifactual to mathematical context.

Construction problems and learning to prove within a DGE

DGE support the learning of proof (Mariotti, 2012). In our study, special emphasis is placed on learning of proof in the context of construction problems; we consider a proof as a mathematical argument, both empirical and deductive, aiming to convince of the validity of a mathematical statement, in our case, the validity of a construction in the DGE. Construction problems consists of (i) creating in the DGE a figure having some properties that remain constant under dragging and (ii) explaining the procedure used to construct the figure and validating it (Mariotti, 2019). DGE tools allow the construction of geometric objects on the screen, which provoke personal meanings by suggesting dependency relationships, that may be confirmed by dragging some objects. Furthermore, the tools are related to theoretical elements of Euclidean geometry that could help students to create a proof of the validity of constructions (Mariotti, 2012). Since DGE embody systems of theoretical relationships, solving construction problems leads students to accept the possibilities that the software offers them and the underlying logical system. Therefore, geometric constructions also have a purely theoretical nature, so the solutions may involve proving a theorem to validate them (Mariotti, 2019).

According to Mariotti (2019), in some DGE tools we can recognize presence of (i) graphical representations of geometric objects having some known properties, which are useful for the construction of the objects thanks to the verification by dragging; and (ii) geometric properties that can be evoked, useful to support constructions and that are framed in a mathematical theoretical domain. Therefore, solving geometrical construction problems in a DGE can make students evoke the theoretical meaning of the constructions embodied in the artifact (Mariotti, 2019).

Methodology

The content of this paper is part of a doctoral research, based on case study methodology. We analyze mathematically gifted students' learning of mathematical proof in 3-D geometry with GeoGebra mediating their activity. We designed and implemented a sequence of 18 construction problems in 60-minute sessions, conducted by the first author. Students initially solved the problem and then discussed their results with him, who conducted the dialogue to justify of the results. The problems involved objects and properties of equidistance in the plane and the space, in a way that each problem provided instrumental and conceptual elements useful to solve subsequent problems. The students had to construct the geometric objects with GeoGebra and justify that the constructions were correct.

Four Spanish mathematically gifted students (11 to 14 years old) in grades 1 to 4 of secondary school participated in the experiments. Besides the ordinary schooling, the students had participated in programs of attention to general giftedness (AVAST) and mathematical giftedness (ESTALMAT). As students were in different school grades and had different previous knowledge, the teaching sessions were organized as individual clinical interviews.

We present a fragment of the solutions to the 7th problem by two students, Juan (14 years old in grade 4) and Jorge (11 years old in grade 1); the names are pseudonymous. This problem asked to create an isosceles and an equilateral triangle in GeoGebra 2D and next in GeoGebra 3D. We analyze the two students' solutions to show the similarities and differences. In their approaches to the solution of the problem, we identified whether their expressions alluded exclusively to actions carried out with GeoGebra (artifact sign), if they also included mathematical properties close to those expected (pivot sign) or if they were completely in the domain of mathematics (mathematic sign).

An example: creating an equilateral triangle in the plane and the space

Students had to create an isosceles triangle and then an equilateral triangle, both having a given segment as a side. The triangles had to be created first in GeoGebra 2D and then in GeoGebra 3D, where the given segment was not contained in the XY plane. In previous problems the students had learned to create and use in GeoGebra spheres, circles, perpendicular bisectors, and bisector planes. Here we analyze the construction of the equilateral triangles.

Juan's solution

Juan had constructed 2D isosceles triangles by using the given segment, AB, its perpendicular bisector, and the circle with center in B and AB as radius (Figure 1a). The teacher asked Juan to delete the constructed triangles and find the position of the third vertex of the requested triangle. Juan pointed at point E, one of the intersection points of the circle and the perpendicular bisector, as a solution (Figure 1b). He explained that *the distances BE and BA will be the same… Then, AB and AE* *will be the same… Then, the three* [segments] *will be equal and it will be equilateral*. In this answer, Juan did not evoke actions with GeoGebra, but only geometrical properties used in the construction and other properties logically derived from them, which shows the emergence of a mathematical sign.

Figure 1: Juan's construction of an equilateral triangle in 2-D

As it was not clear how Juan had deduced the congruence of the three segments, the teacher asked him for a more detailed justification. Juan justified it in a different way: *By symmetry, if I draw the circle with center A and radius AB, the intersection would be… E… Then, AE would be equal to AB. AB would be equal to BE, all sides would be equal*. In this new explanation, Juan evoked an auxiliary construction and properties of it allowing him to prove that the triangle is equilateral. This answer reveals the (mental) use of GeoGebra and mathematical properties, so now Juan showed a pivot sign.

The last answer led the teacher to make Juan note that he had not used the perpendicular bisector of AB, previously used by Juan to create an isosceles triangle (Figure 1a). Juan changed again his justification: *If I draw the perpendicular bisector of AE, it passes through B. As BA is a radius, it is equal to BE. And since E is in the perpendicular bisector of AB, then all 3 sides are equal, and the triangle is equilateral*. This new answer had the potential to support the validity of the construction and, like the previous justification, has the characteristics of a pivot sign.

In GeoGebra 3D, Juan first constructed the bisector plane of AB and a point C on this plane, to create an isosceles triangle ABC (Figure 2a). Then, he built the sphere with center B and point A (Figure 2b). Initially, Juan wanted point C to be at the intersection of the sphere and the plane, although later he expressed that he wanted point C to be *on the perpendicular bisector of AB and on the bisector plane*, a property that he re-stated as C *being at the intersection ... between the plane and the sphere, but at the midpoint*. These last ideas were not clear, so Juan continued exploring the construction, and he created the circle intersection between the sphere and the bisector plane (Figure 2c).

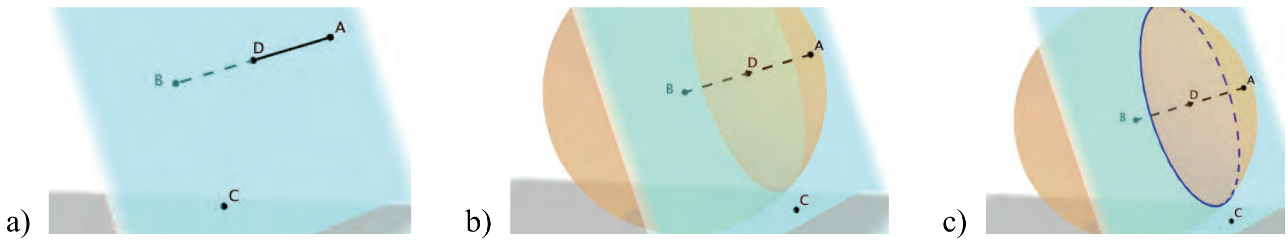

Figure 2: Juan's construction of an equilateral triangle in 3-D (first part)

Juan needed point C to belong to this circle, so he dragged C to the circle. Juan explained that point C *would have to be like here ... Or here* [while dragging C to two specific positions in the circle (Figure 3). Juan's specificity in his answer led the teacher to question these positions for point C. Juan considered it necessary because *there, C would be in the perpendicular bisector of A and B*. The teacher asked him about the possibility of placing C in another position, and Juan replied that *any point of the intersection serves*. To finish, Juan explained that C must be in the circle because *the distance from A to C will be the same as from C to B, because it* [C] *is in the bisector plane*. He completed this justification by saying that *since the sphere has the center in B, and radius BA and also BC, because C is at the intersection of the sphere and the bisector plane, then the three segments* [AB, AC, BC] *are equal*.

Figure 3: Juan's construction of an equilateral triangle in 3-D (second part)

By using the bisector plane of segment AB as reference and placing point C in the positions presented in Figure 3 indicate that, although using GeoGebra 3D, Juan used 3-D geometric objects as if they were in GeoGebra 2D. Juan's idea of using the intersection between the sphere and the plane suggests the recognition, albeit implicit, that the characteristic properties of the points of the 2-D circle used in the first part of the problem are also properties related to equidistance between the constructed points in the 3-D circle; hence this discourse shows a pivot sign, since it combines mathematical and artifactual elements. Additionally, the actions declared by Juan at the beginning of the second construction show that he knew the way to obtain the third vertex of the equilateral triangle given the 3-D configuration that he had on the screen. This leads to his actions serving a declared objective, which is clear from a mathematical point of view, as well as permeated by a deductive language. Therefore, this part of the solution evidences a mathematical sign.

Jorge's solution

Given segment GH as side, Jorge's construction of the 2-D equilateral triangle began with the construction of the circle with center in G and point H (Figure 4a). Jorge then created point I on the circle, segment GI and the circle with center at H and point G (Figure 4b). Jorge dragged point I to an intersection of the circles (Figure 4c), but he changed his mind: eliminated point I, constructed a new point I as one of the intersection points of the circles, and created the triangle GHI (Figure 4c).

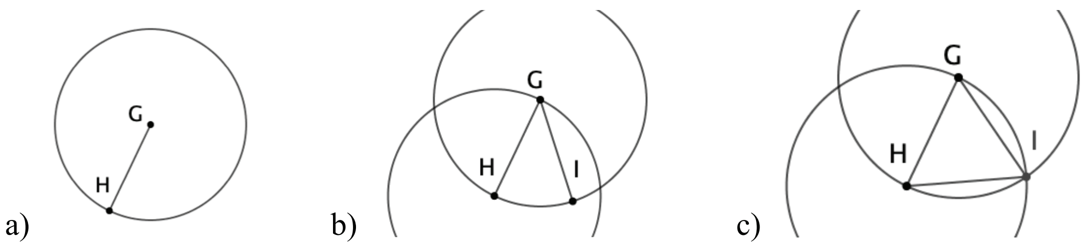

Figure 4: Jorge's construction of an equilateral triangle in 2-D

When the teacher asked Jorge about the validity of his construction, he replied: *the circles… were to copy segments, so I have used them so that all sides are the same length*. Jorge was asked about the choice of point I as the intersection of the circles, and he mentioned that any other point would be closer to one point (G or H) than the other.

To create the 2-D triangle, from the very beginning Jorge tried to use two circles having segment GH as their radii. So, the third vertex would then be one of the intersection points of these circles. Jorge first wanted to guarantee the congruence of segments GH and GI and then, with the help of the second circle, determine the place to which point I should be dragged so the triangle GHI would be equilateral. This strategy was modified, and the justification offered by Jorge was supported by the representation on the screen. His actions had been mobilized as reaction to what he observed on the GeoGebra 2D screen, for example the location of point I. Jorge did not use mathematical elements to justify the congruence of the segments, so these actions determinate a pivot sign.

In GeoGebra 3D, given the segment AB, Jorge created the sphere with center A and point B, and the sphere with center B and point A (Figure 5a). He constructed point C very close to the intersection of the two spheres and the triangle ABC (Figure 5b). Jorge believed that this triangle was equilateral because *each point is at the same distance from the two others... A from B and C, B from C and A, and C from A and B*. He continued explaining *we already have an intersection point. Well, we have two that are the same distance from A and B... we already have an equilateral triangle*. The teacher asked Jorge about the number of solutions, and he replied that he believed that there were more.

The construction that Jorge proposed, although correct, did not have any theoretical support. It is interesting to note that the solution presented by Jorge only considers two points at the intersection between the spheres as potential vertices of the equilateral triangle. This is evidence that Jorge had in mind the 2-D construction of the equilateral triangle he had just made, where the intersection of two congruent circles with the same radii leaded to this solution. We then see a potentially useful idea worked in GeoGebra but not fully developed, so presenting a pivot sign.

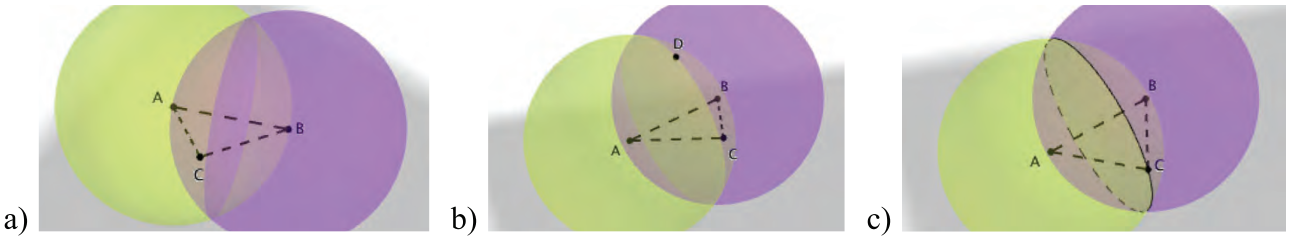

Figure 5: Jorge's construction of an equilateral triangle in 3-D

With some teacher's help, Jorge stated that the intersection of the spheres contained the solutions to the problem, so he created it on the screen (Figure 5c). Jorge tried to validate his answer by constructing some points in the intersection circle and calculating the distances from them to the centers of the spheres, A and B, but the teacher did not allow him to develop this idea and, instead, he asked Jorge to justify why the equidistance that he had stated was true. Jorge replied that *it is a circle, and all the points in a circle are at the same distance from the center*. Although the teacher showed Jorge that the centers of the spheres were not the center of the intersection circle, Jorge explained that *they are like a kind of center that has moved ... it is not in the center, but it is like a line that crosses the center*. Jorge tried to validate his construction based on some cases with the help of the artifact (an artifactual sign). He then made a progress by incorporating theoretical elements, such as the definition of circle, albeit in a wrong way, and equidistance to support the equidistance of each point of the intersection circle to the centers of the spheres. It seems that Jorge considered the centers of the spheres as points belonging to a line perpendicular to the circle and passing through its center; this constitutes a pivot sign that could have been used by the teacher to delve in his ideas. Even so, the language used is not precise and does not confirm this hypothesis.

The teacher did not develop Jorge's last idea but, instead, he asked him about the nature and properties of the circle in which the solutions to the problem were contained. Jorge mentioned that the circle was the intersection of the spheres, *which measure the same*, referring to the congruence of their radii. Additionally, the conversation with the teacher about a new point E on the circle led Jorge to mention that *they are at the same distance… Because E is at the intersection of A and B. So, like point C… it could be made equilateral triangles at all positions of the intersection*. This explanation was not entirely convincing, so the teacher insisted on asking why the points on the circle were equidistant from the centers of the spheres. Initially Jorge assured that this was true because *it is where… the spheres A and B intersect. So, it is like when the perpendicular bisector intersects the segment, they will always be at the same distance, any point on the circle*. The teacher modified his question and asked Jorge to explain why the distances AB and AE were the same. Jorge quickly replied: *Because they are in the… the spheres, any point is the same distance, right? from the center ... So, if there is a point where two spheres intersect, that point will be the same distance from the two centers*. We see that, in this conversation, Jorge managed, with the help of the 2-D construction, to connect the necessary elements of the 3-D construction to deductively justify the validity of his conjecture. This reveals at the end of Jorge's explanations a mathematical sign.

Discussion and conclusions

We have illustrated the mediating role of DGE and some semiotic signs produced by two mathematically gifted students while solving a construction problem, as well as differences and similarities between them. An interesting aspect which arises is the dynamic nature of the semiotic signs: in the excerpts presented, we can see that, at different moments in the solution of a problem, the students have exhibited signs of different types, not hierarchically sequenced; it happened that, even when mathematical signs were identified, setbacks with the presence of other types of signs were observed later. This could be because the problem selected was in the middle of the experimental sequence and students felt the need to produce deductive justifications, although they also showed traces of empirical, artifactual reasoning or parts of informal reasoning and language.

A second interesting aspect has to do with the content of students' outcomes when solving the problems in GeoGebra 3D. When constructing the 2-D equilateral triangle, differences could be observed in the students' performances, both in the geometric objects used and the degree of abstraction with which they justified their constructions. However, when working on the 3-D construction, both students agreed on the number of points that could serve as the vertices of the equilateral triangle. The solutions to this problem illustrate the ease with which the students modified the objects involved in the 2-D construction to adapt them to the 3-D construction. However, the reasoning that accompanied the constructions carried out was not adapted to the 3-D space; for instance, both students, guided by their 2-D experience, only identified two 3-D points as solutions.

Although this error was easily fixed, it is interesting to note the sustained influence of the representations and results got in GeoGebra 2D when moving to GeoGebra 3D.

We have presented only one short episode. More far-reaching studies are necessary to be able to advance in the characterization of the semiotic signs present in the justifications of solutions to geometric construction problems, the evolution in the meanings of the signs used, the relationship between the signs' meanings and the types of proofs produced, and the influence of the DGE.

Secondary students’ experience using 3D pen in spatial geometry: affective states while problem solving

Dina Rosenski[1] and Alik Palatnik[2]

[1]Hebrew University of Jerusalem, Faculty of Education, Jerusalem, Israel; dina.rosenski@mail.huji.ac.il

[2]Hebrew University of Jerusalem, Faculty of Education, Jerusalem, Israel; alik.palatnik@mail.huji.ac.il

One’s affective state can change our actions and thought process while learning. The interplay of student’s emotion and problem solving in spatial geometry has not been thoroughly studied. We present qualitative analysis of individual and collaborative problem solving of spatial geometry tasks by middle school students (8 students in a lab setting, and 21 students in group interviews in a classroom setting). We use the concept of embodied learning design, with the 3D printing pen as a medium, to make the process of converting 2D sketches to 3D models more explicit. Findings revealed that the students’ affective state significantly influenced the way they solve the problems in spatial geometry. 3D sketching environment allows students to build a bond (intimacy) with the material and use their emotions as signals for heuristic changes (integrity). The discrepancy between 2D and 3D visualization in spatial geometry tasks may lead to students’ emotional tension.

Keywords: Spatial geometry, secondary school mathematics, embodied learning, 3D sketching affective states, problem solving

Introduction and Theoretical Background

Spatial geometry

Grasping spatial geometry calls for command of five different types of mathematical thinking: spatial structuring, measurement, representing 3D objects, spatial ability, and conceptualizing mathematical properties (Pittalis & Christou, 2010). Students and teachers have historically relied on traditional 2D media and materials and their resulting “flat” perspectives (Alsina, 2010). Students struggle with spatial geometry tasks, especially those requiring several reasoning steps (Fujita et al., 2020). Applying a dynamic geometry environment (DGE) to spatial geometry fosters innovation in didactic and research methods and may stimulate geometrical reasoning (Mithalal & Balacheff, 2019). However, even 3D DGE are limited to the two-dimensional medium (screen) and thus may create perceptual problems (Dimmel & Bock, 2017). Therefore, we are seeking a teaching method that can provide students with a three dimensional and multimodal experience and facilitate the development of the five types of thinking mentioned above.

3D pen—a novel technology for freehand drawing of 3D models

The 3D pen is a relatively novel technology which application to spatial geometry instruction has not been significantly studied. The pen excretes hot plastic which allows one to draw in three dimensions free hand. The use of the 3D pen in mathematics education was presented by Ng, et al., (2020) in which elementary students were studied using the pen in comparison to dynamic geometry programs. It was found that long term retention of the group using the 3D pen was significantly better.

Our study focuses on cognitive and affective states of middle school students to find the potential of this novel medium in learning environment that promotes interaction between the object and the person (via gestures, movements and embodiment of the physical world) which is not possible when using a 2D medium (paper or screen). Assuming that using a 3D pen will make the 2D to 3D conversion visible and therefore easier and more natural for learners, we aim to characterize learners' emotions when solving non-standard spatial geometry problems.

Embodied learning of geometry

Embodied learning, an educational approach based on the role of the body — through movement, action, and gesture as a powerful tool for understanding and learning school subjects — is gaining ground in educational research (Abrahamson et al., 2020; Kim et al., 2011). Embodied learning is based on embodied cognition which suggests there is some level of interaction between the body's physical actions and movements in its environment and our cognition (Wilson, 2002).

The activities in which students solve spatial geometry questions by constructing tangible models may potentially bridge the gap between intuitive and disciplinary ways of mathematical reasoning (Palatnik & Abrahamson, 2021). Tasks in which students sketch with the 3D pen to visualize a problem can be considered as a sub-genre of embodied design activity—compelling students to use movements and gestures (c.f. Abrahamson & Lindgren, 2014).Research that combines the theory of embodied design with the effect on students' affective state is relatively rare (Sinclair & Heyd-Metzuyanim, 2014). This study focuses on students' emotions and meta-affective abilities while solving nonroutine for them problems (spatial geometry) using non-routine medium (3D sketching pen).

Theoretical framework for influence of affect on problem solving

While solving non-routine problems, many students are overcome by their emotions and unable to continue to solve the problem, however other students can maneuver their emotions, think of an alternative solution, and therefore solve the problem (McLeod, 1988). When students are aware of the feeling of frustration, for example, they can use it as a sign to give up and move on to the next problem, or as a sign to reevaluate their solution and find an alternative solution (Debellis & Goldin, 2006; McLeod 1988; Hannula, 2015).

Debellis and Goldin (2006) define mathematical intimacy as the students' emotional engagement with mathematics and mathematic integrity as their sense of "fundamental commitment to mathematical truth" and pursuit of understanding (Debellis & Goldin, 2006, p.132). The individual's ability to solve problems is influenced by their control of their emotions, their awareness, context and situation, mathematical education, attitudes, values, beliefs held by themselves and the environment and normative emotional expectation (Debellis & Goldin, 2006). Educators, curriculum developers, instructional coordinators, and textbook writers who are aware of students' emotions and the effects on their learning patterns, can use this to their advantage when searching for methods to create optimal learning environments.

McLeod (1988) characterizes these affective states based on magnitude (intensity), direction (positive or negative), level of awareness (of their meta-affective processing), duration, and level of control.

According to Debellis and Goldin (2006) mathematical intimacy refers to a specific, emotional engagement with mathematics. Mathematical integrity relates to one’s affective state when determining if a solution is satisfactory or should be praised. This leads to the pursuit of understanding and the students’ commitment (or lack thereof) to the mathematical truth. Students with high mathematical integrity recognize their insufficient knowledge or understanding and decide to change their solution or direction when problem solving.

Our research is situated on a nexus of spatial geometry content, embodied pedagogy, and the emotional component of students’ learning. This research report focuses on the following RQ:

How does the experience of 3D sketching influence the students’ affective state and their awareness of these states while solving spatial geometry problems?

Methods

The cases reported in this paper are part of a larger research project which explores the effect of the use of embodied learning design on spatial geometry problems (Palatnik & Abrahamson, 2021; Rosenski, 2021). We tested 9 students in individual interviews in a lab setting, and 25 students in group interviews in a classroom setting. Of the 9 students interviewed in the lab setting, 8 were included in the data analysis. The students were chosen based grade level (9^{th}-11^{th} grade), as they have all studied concepts in planar geometry necessary to solve the problems given. Of the 25 students interviewed in group settings, 21 students were included in the data analysis. The others were omitted for not completing the entire question set.

	Given	Section	Question	True / False	
	ABCDA’B’C’D’ represents a cube. E is the middle points of A’C. F is the middle point of B’C’.	1	B’ is a point on AE.	True	False
		2	ABFE is an isosceles trapezoid. The equal edges are _____.	True	False
		3	ABFE is a right-angled trapezoid. The right angles are_____.	True	False
		4	AE is the longest edge of quadrilateral ABFE.	True	False

Figure 1: Example of question #3

Before beginning the main activity, the students were asked to answer a computerized test of 30 questions that test spatial ability. The test is based on mental rotation and ability to rotate 3D objects projected on the screen. Subsequently, the students were given a 3D pen and were asked to sketch a pyramid with the 3D pen to practice drawing lines in the air. Most students were able to sketch freely with the pen within 10 minutes. The main activity of the study includes 3 questions in spatial geometry. Figure 1 shows the last question in the series of items. The students answered the questions by sketching a 3D object (shown to them on a 2D sketch) inside a plastic wire model of the cube and then using mathematical reasoning. Our decision to have the students sketch the drawings, is not only for the use of the 3D pen technology, but also to make the process of converting 2D sketches to 3D models more explicit and potentially overcome the difficulties associated with this process as described by Fujita, et al. (2020). We hypothesize that students struggle to use spatial visualization and property based spatial analytic reasoning, but the physical act of sketching in 3D allows the student to develop new ways to interact with the 3D model using embodied cognition to overcome this issue. After the students have sketched their 3D models and move on to the phase of problem solving. After solving each question, the students were asked to express how confident they were in their answers. This allowed us to see if students who answered incorrectly were sure or unsure of their solutions. The three questions increase in terms of difficulty and familiarize students with the 3D model affordances.

After completing the questions, the students participated in a task-based interview (Goldin, 2000) about the questions themselves along with a semi-structured interview about their overall experience and feelings. Some of the question in the interview were open ended while some questions asked students to 'rate their feelings' on a scale from 1-10. In open ended questions, many students do not elaborate, but in the direct 'rating' questions students felt comfortable answering. The one-on-one interviews allows participants to expand on their experience of answering questions. The entire session was audio and video recorded (the students' face off frame) in order to properly record and analysis the students' actions and arguments and answers.

Our analysis used triangulation of data from the videos, responses, and field notes of the researcher. The data was transferred to detailed transcripts which were coded freely. The student's internal affects are inferred from external factors such as observable behavior in individual children's mathematical problem-solving during task-based interviews (Debellis & Goldin, 2006). The affective states and emotions of the students were characterized as suggested by McLeod (1988) magnitude (intensity), direction (positive or negative), level of awareness (of their meta-affective processing), duration, and level of control. Throughout the coding process, the main themes surfaced, and we were able to categorize the various aspects of the students' experience.

Findings

Mathematical intimacy

Mathematical intimacy is the deep engagement of participants while solving the problems (Debellis, & Goldin, 2006). These feelings can be positive or negative and have varying magnitudes. Most of the participants of our study experienced mathematical intimacy while facing the tasks. Namely, the students were emotionally connected to the activity and showed (verbally and via behaviors) their deep care as the activity advanced from question to question. For instance, when answering the questions, a participant C was supposed to have a break for lunch. However, he did not agree to leave the room for the break until he finished the question he was working on. Note that C initially answered most of the questions incorrectly, but then saying aloud, "I'm not sure I sketched it correctly," felt he had made a mistake and corrected all his answers to the correct answer.

Each participant had a different range of emotions at all stages of the study, but there are several "common scenarios." Some participants were excited when they drew a 3D model but sad when they could not immediately answer the question, were satisfied when answering the question, and described strong positive emotions about the activity during the interview. The other participants were frustrated at their inability to find the correct explanation for their answer, making them give up and move on to another question. These students still got the correct answers and were able to solve the problem. Some participants were restrained when drawing with a 3D pen but expressed extreme excitement when asked about their experience during interviews.

The emotions in the students after finishing the activity were generally positive in fairly high magnitude. Most participants felt the activity was generally good, while others felt deep feelings of excitement and amusement, directly connecting a 3D pen experience with this feeling. For instance, participant O5 claimed it was “a thousand times more fun” than a “traditional math class.” When asked directly to rate their experience of 3D sketching while solving a problem on a scale of 1-10 in one of the emotionally charged characteristics, participants answered in the following way:

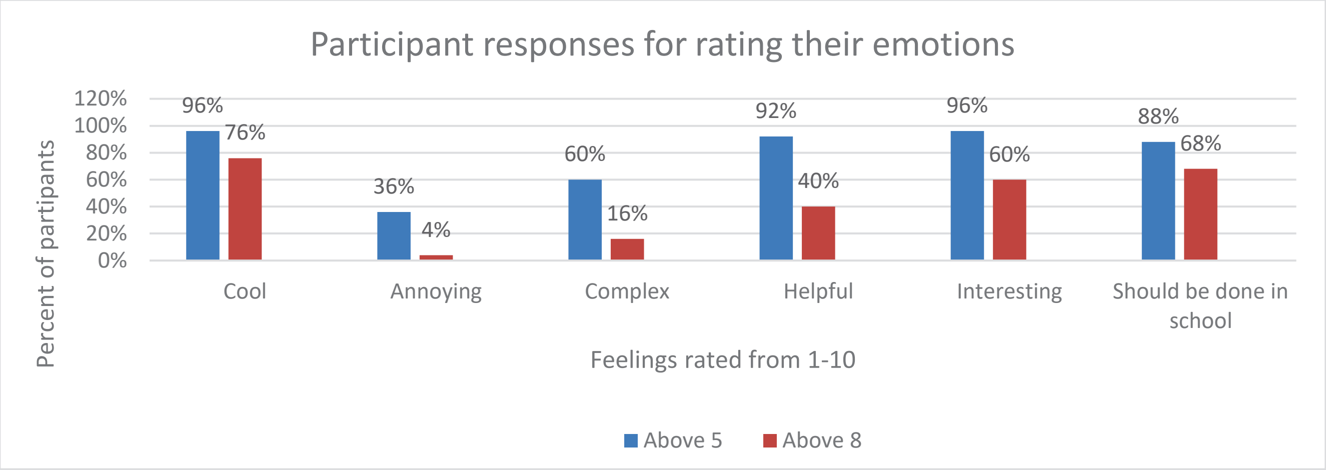

Figure 2: Participant responses for rating their emotions, post activity

As can be seen in Figure 2, the students felt that the activity and use of the 3D pen was cool, not very annoying, not very complex, quite helpful, interesting, and should be done later in the school year. While asking students to describe the magnitude of their emotions is not necessarily the most accurate measurement, these numbers relate to a general feeling among the students and is corroborated with the findings throughout the interview. When solving the problem, the participant A, after 3 minutes of searching for the solution, suddenly found the answer and screamed “Oh! I know! The diagonal and the side are never equal in a square.” His task-based interview confirmed his deep satisfaction in solving the problem: “It was really fun, there was a lot of hands-on work which is nice. It makes you think in a way you usually don’t”

Mathematical integrity.

Some of the participants of our study demonstrated mathematical integrity related to problem solving in general and spatial reasoning in particular. For instance, M, struggled to understand the characteristics of the 3D figure and when asked if the trapezoid she had drawn was isosceles (shown in Figure 1, question #3, section 2) she said “Based on how it looks I think no [not an isosceles trapezoid] I’m trying to think how I can prove why….um, wait I need to understand this” and later said “wow this is hard.” Her acknowledgement of lack of understanding, eventually led her to the correct answer. She used this seemingly negative emotion to alter her problem-solving plans and change her thinking. In this case, M's negative feelings were at a low magnitude, and they allowed her to change direction without being overcome by anxiety or despair.

We also observed interesting manifestations of mathematical integrity pertinent to the material and visual aspects of 3D sketching activities. One participant explained that the 3D pen's biggest disadvantage is not being "exact" enough, the lines drawn are "not straight" and it's too bad that they did not use a ruler. This may relate to the participants' values or previous beliefs about mathematics in general, but also shows his search for 'exact' and 'true' mathematical representations, rather than ones that are not exact. Another student, A, consistently looked to the given 2D sketch when solving the problem instead of using the 3D model (c.f. Palatnik & Abrahamson, 2021 for the similar phenomenon). He explained in the interview that "I used the sketch because it's more exact.". It seems that A feels that in order to align with his own 'mathematical truth' all the sketches must be exact. Throughout the problem-solving process, he decided to use calculations with Pythagorean theorem, despite not needing them to prove his answer. However, for him, it may have been the best way to solve the problem. When solving the trapezoid question (shown in Figure 1) section 4, he used complex calculations and an auxiliary line drawn with the 3D pen to explain his answer. When trying to thoroughly explain the calculations to the researcher he laughed and seemed to realize the excess calculations. He took this struggle with explanation 'lightly' and was able to solve the problem.

The participants of the study used their mathematical integrity to solve non-routine problems successfully without allowing their affective states of frustration or anxiety overcome their ability to make heuristic decisions and changes. This allowed them to describe their experience of using 3D pen and a tangible model to solve spatial geometry problems as positive. Students who can feel comfortable in a state of 'unknown' while searching for the right solution, will be able to solve non-routine problems (Debellis, & Goldin, 2006).

Discussion.

We conducted a study of middle-school students facing the spatial geometry tasks while sketching with a 3D pen. We sought to find out how does the experience of 3D sketching influence the students' affective state and their awareness of these states while geometry problem solving. The participants demonstrated a high level of mathematic intimacy—connection and strong emotions and mathematic integrity, the ability to use the intimacy to their favor. The students showed strong positive emotions such as excitement, satisfaction, and awe. The nature of the activity in the study gives students the ability to sketch 3D figures by themselves, rotate the figures, and change or add auxiliary lines. The two-dimensional diagrams on which the school's spatial geometry curriculum is based represent three-dimensional bodies in a distorted form (Widder, et al., 2019). This quality can create a sense of alienation in students. However, the affordances given by the 3D sketching develops the students' bond with a problem. This bond gave them general positive feelings about the activity, despite being a nonroutine and challenging problem to solve.

Students in the study showed a high level of mathematic integrity as they were able to recognize their own lack of spatial understanding or geometric knowledge which led them to reassess their problem-solving strategy. Most of the students navigated their emotions of dissatisfaction, lack of confidence, or frustration and were able to successfully solve the problems. In certain cases, we observed a type of mathematical integrity specific to 3D representation and sketching. Students are accustomed to using 2D sketches of 3D figures, and therefore some of them felt that the 2D sketch was more exact or closer to their own ‘mathematic truth.’ Educators and educational designers should be aware that the discrepancy between 2D and 3D visualization in spatial geometry tasks can lead to emotional tension for students. Some secondary students may have feelings of antagonism towards the novel medium of 3D sketches and require mediation before beginning the activity.

The participants' level of intimacy and integrity shows a high level of comfort and openness throughout the activity. Our study used a learning environment based on the principles of embodied learning. Abramson and Lindgren (2014) suggest that one may create a deep understanding by physical interaction with the environment. The 3D model of the cube allows students to “off load” at least some of the cognitive processes (mental rotations, imaginary auxiliary elements) needed to complete the task (Wilson, 2012). The use of the 3D pen affords students a physical visualization of the conversion process from a 2D sketch to a 3D model. In its "purely mental" form, this process proves to be very challenging for students of all ages (Fujita, et al., 2020). Throughout the intervention phases, the participants’ affective states can be seen as ‘pathways’ that may guide them to various directions and changes in the heuristic decisions (Debellis, & Goldin, 2006). The students in our study used their recognition of inadequate justifications as a signal to make a heuristic change (McLeod, 1988). In many cases this recognition was directly connected to the manipulation of 3D model and in particular 3D sketching.

In this study we found that the students’ affective state significantly influenced the way they solve problems. The awareness of the students’ emotions and its effect on how they solve problems can allow both students and teachers to mitigate the negative emotions and reroute them to an alternate solution. This topic demands further examination with research using a variety of geometry tasks and populations. The high school curriculum in Israel is focused on having students successfully pass matriculation exams and spatial geometry tasks are part of the exams on all the levels. Thus, drawing on our findings on secondary students’ experience while using 3D pen in spatial geometry, we suggest that teacher professional development programs consider recent advancements of embodied learning, novel medium (as 3D pen) ,and student’s affective states as well as the connection between these fields.

Introduction

The working group gathered 39 participants from 14 countries, from Asia to South America, with 26 papers and six posters. The participants were introduced to the three subthemes identified as emerging across all submissions. In particular, submissions focused on "Teacher education", "Reasoning about data" and "Statistical and Probabilistic Thinking and Reasoning". We prepared three guiding questions to support in the discussions on the three subthemes. The questions were: "*Considering these presentations, what contribution do they make to what we now know about teacher education/reading the data/statistical and probabilistic reasoning?*", "*Considering these presentations, what issues (regarding (mis-)conceptions, teaching approaches, resources, assessment etc.) do they highlight/raise about teacher education/reading the data/statistical and probabilistic reasoning*?" and "*What comments or thoughts do you have now with regard to teacher education/reading the data/statistical and probabilistic reasoning, from a research and practice point of view, to advance future research?*".

Teacher education

There were ten papers focusing on the subtheme of *Teacher Education.* They represented a broad gamut of research examining the disciplinary foci of statistics, probability and STEM. These research studies considered the experiences of students, preservice and practicing teachers across various educational settings, including early childhood, primary, secondary and college-level learning environments. They also explored a variety of learning opportunities to support the development of understanding including the use of innovative technologies, lesson study and a range of professional development opportunities. One of the themes that emerged from the research presentations was the need for researchers to engage in more effective communication with statistics and probability educators. The field is a fast-evolving landscape and new knowledge and understandings about pedagogies are constantly being developed. Our responsibility is to assist teachers in identifying these critical and desirable facets of statistics and probability education. This communication should focus on:

(1) The purpose and rationale for teaching statistics education. We need to remind teachers that our goal as educators is to engage students in statistical thinking and reasoning, develop statistical literacy and learn how to critically read the world and how we represent it statistically.

(2) Identifying the desirable feature of good statistics teaching. This includes teaching statistics through projects and investigations, open questions, and the need to address meaningful problems. We need to better communicate and provide a justification for how these desirable practices relate to the previously expressed purpose and rationale of statistics education

(3) Explaining the limitations of some common approaches to teaching statistics and probability. Examples are a focus on technical procedures, calculations of descriptive statistics in isolation from developing conceptual understanding and the use of closed questions that don't promote inquiry and a questioning stance.

(4) Providing insights into what it feels like to engage in these desirable pedagogical practices. It is important that teachers are provided with rich experiences of engaging in statistical investigations so that inert theoretical knowledge becomes meaningful. It is very valuable for teachers to have the opportunity to experience the practices of statisticians and experience the benefits for the learner of engaging in these practices.

A second theme that arose was recognition that statistics and probability education continue to evolve rapidly. Consequently, we need to continually remain open to and expand our conceptualization of the field. Moving forward the statistics and probability educational research community need to better leverage the use of contexts in our practices. This involves moving beyond meaningless and trite textbooks problems to a focus on addressing meaningful problem that may have personal relevance to learners or engage them in considering real life global problems and challenges. Many of these types of problems occur in rich interdisciplinary contexts such as STEM and embracing these new contexts provides numerous opportunities for the development and use of innovative pedagogies. Some of these opportunities include a move to new technologies and tools that allow us to explore large and open-source data sets that represent real problems and provide new lenses and ways of visualising data. Considering these responsibilities as researchers to embrace and manage change, we identified the emerging challenge for us as statistics and probability educators to balance context and at the same time ensure a focus on desirable learning outcomes. We communicated this concern and culminated our discussions in the form of a driving question for future consideration: How can we foreground statistics and probability when engaged in interdisciplinary collaborations and at the same time not lose sight of the important contexts that drive and underpin investigations and inquiry?

Statistical and Probabilistic Thinking and Reasoning

Eleven papers were presented under the subtheme of Statistical and Probabilistic Thinking and Reasoning. Five of those focused on probabilistic reasoning in relation to risk perception, decision making under uncertainty, random variation and sample space, covariation tasks in a Bayesian situation, and combinatorics. In these studies, the participants were primary, secondary, and university students. The other six papers investigated students' statistical conceptions with regard to frequency tables, statistical content in terms of statistical literacy and reading levels of statistical graphs in the mathematics textbook, the exploration of real and rich data with the use of technology tools and communication of results. Most of these studies involved secondary school students, but one study focused on primary school students. Textbook analysis research included primary and secondary grades.

From the discussions of these presented papers, three main themes emerged: 1) The emphasis on statistical reasoning in all phases of statistical investigation cycle and consideration of individual's dispositions like attitude towards statistics led to a broader view of statistical reasoning; 2) The research suggested the importance of rich learning experiences in support of critical thinking through the use of meaningful context and real data sets, the implementation of project-based learning in statistics education, and promoting probabilistic reasoning in data-based decision-making processes. 3) Fostering informal ideas with regard to statistical and probabilistic reasoning with younger learners is still relevant. In addition, some concerns have been expressed about the readiness of teachers and students for open-ended tasks suggested by research as well as the limited sources and time for implementing statistical projects. Critical discussions on the future of statistics and probability education have raised the questions of (1) relying on "better" textbooks versus "more" digital tools in school education, (2) communicating appropriate use of probability language, especially related to the everyday language (e.g., chance, luck, randomness), in the classroom, and (3) increasing the role of researchers in task design, textbook and curriculum development related to probability and statistics.

Reasoning about data

Within the five papers in the section "reasoning about data" four papers have had a specific focus on Data Science Education and to related fields like big data and machine learning. We discussed several core ideas and fundamental aspects to develop a competent reasoning about data in a sustainable way and across all age levels.

(1) At first we identified that it is important that there is a continuous development of data competence (from primary school to adult education) in the sense of a spiral curriculum.

(2) Second, the appropriate use of digital tools (like Gapminder, CODAP and TinkerPlots) can reduce the extraneous load in working processes and make learners able to explore large and multivariate data and to explore their data with regard to their specific inquiry questions. One crucial point in this respect is the choice of the digital tool. Educational software like TinkerPlots do not need a specific programming language (but are limited in some sense with regard to the data exploration capabilities). In contrast professional software like R or Python offer a broad range and landscape of statistical activities, but are more difficult to learn and learners may concentrate on programming and technical issues rather than on the content and the statistical exploration. So there is the danger that technical issues distract from the content issues.

(3) A third core idea to develop a competent reasoning about data, which was raised in the discussion, was the cooperation with other disciplines, e.g., the STEM disciplines.

(4) A fourth point is that the kind of data which is used for teaching and learning issues plays an important role: learners should be given real, meaningful data, which is authentic and offers

multivariate explorations. In addition to that the role of task design is central. In the discussion it was mentioned that teachers are often not comfortable with complex open problems which do not show clear steps to solve the task. To prepare teacher to consider using open tasks and problems and to make them familiar with these kinds of tasks was identified as a huge task for teacher education.

(5) A last, but fundamental issue with regard to reasoning about data which was mentioned was Data Science. Data Science was figured out to be an emerging field in statistics education and includes aspects like Big data, Open data, other data collection methods (e.g., Sensors, Webscraping). These new concepts, issues and ideas of Data Science led to the re-interpretation of fundamental ideas and concepts in statistics education (e.g., PPDAC cycle).

Looking ahead in the context of Data Science new approaches like Machine Learning in education are very new topics and one should use the opportunity to share all the different approaches arising and to include all the things we "know" by now (open projects, problem oriented learning, using new technology…). Given that four of five paper in the rubric "Reasoning about data" have tackled issues with regard to Data Science, we see that that this topic becomes more and more important in the statistics education landscape. Looking forward three big issues were identified which seem to be very relevant for a future perspective on reasoning about the data. Specifically more qualitative, design-based and quantitative research is needed in the following three fields: integration of Data Science into the classroom, connection of informal and formal concepts for reasoning about data and the connection of data, chance and context.

Organization of the TWG sessions

In the first session, we explained the organization of the Sessions. We were divided into two groups for some sessions: TWG5a with Caterina Primi, Sibel Kazak and Orlando Rafael Gonzalez and TWG5b with Aisling Leavy and Daniel Frischemeier. Each group used breakout rooms to create smaller groups. In this way, also with virtual modality, we tried to promote the famous three Cs of CERME Communication, Cooperation and Collaboration. To create a collaborative atmosphere that would support the discussions and feedback over the following days, we started with an ice-breaker activity "Speed dating" involving all the participants. Participants got to know their TG5 colleagues in a friendly context through this activity. We created groups of three randomly and for 3 minutes each participant introduced themself shortly before swapping to a new random group. At the end of each session for each group, a Padlet has been created to document and to write down the results of the discussion. There was a corresponding card in the Padlet for each of the guiding questions. In addition to that, there were two further cards for raising other issues, thoughts, etc. regarding the papers. All the contributions we collected were significant for a successful and substantial concluding discussion on the last day of CERME-12 when we summed up all our insights during the CERME-12 week. The last day we had a culminating session with all participants with the aim being to engage in an in-depth discussion on subthemes and to share the contributions discussed during each session.

Supporting teachers' confidence to teach statistics through a blended professional development approach

Kemal Akoğlu[1] and Hollylynne Lee[2]

[1]Boğaziçi University, Faculty of Education, İstanbul, Turkey; kemal.akoglu@boun.edu.tr

[2]North Carolina State University, USA; hstohl@ncsu.edu

The Teaching Statistics Through Data Investigations (TSDI) professional development course is a Massive Open Online Course (MOOC) designed to strengthen participants' ability to use a statistical investigation cycle to teach statistics and help students explore data using technology tools and make evidence-based claims. The case of interest for this research were 63 MOOC participants who also participated in one of nine professional learning teams (PLT) during 2016-2017. Quantitative data was analyzed using statistical tests to measure significance in growth of confidence to teach statistics, and qualitative data used to confirm or refute quantitative data-based claims. Results from the study indicate that a blended approach to professional development is an effective way to increase statistics educators' confidence to teach statistics.

Keywords: Statistics education, teacher confidence, MOOC, professional growth.

Background

In their seminal paper from a study of how statisticians think and work, Wild and Pfannkuch (1999) claimed that doing statistics involves a process of data investigations and specific ways of thinking about data. Teachers need to be knowledgeable about this method to enhance students' learning (Franklin et al., 2007). The GAISE K-12 report represented the work of Wild, Pfannkuch, and others to organize teaching statistics as phases in a statistical investigative cycle: posing a question, collecting data, analyzing data, and interpreting results.

In 2015, Hollylynne Lee and colleagues launched the Teaching Statistics through Data Investigations (TSDI) massive open online course (MOOC) to prepare middle school, high school, and postsecondary teachers in pedagogy for teaching statistics (see http://go.ncsu.edu/tsdi). The TSDI MOOC was part of a larger effort at the Friday Institute for Educational Innovation at North Carolina State University to create and implement MOOCs designed specifically for educators, to use design principles based on effective professional development and are specifically targeted at better preparing educators for the current challenges in K-12 education (Kleiman et al., 2013).

Lee and Tran (2015) proposed the Students' Approaches to Statistical Investigations (SASI) framework to help statistics teachers support students. The SASI framework builds on the GAISE K-12 framework (Franklin et al., 2007) and is grounded within four phases of statistical investigation (pose a question, collect data, analyze data, interpret results). The TSDI course introduced participants to this framework and built opportunities for participants to learn how to apply these ideas in task design, engage in data investigations themselves, and analyze students' work. It was designed to strengthen participants' skills and prepare them to use a statistical investigation cycle to teach statistics and help students explore data to make evidence based claims (see http://go.ncsu.edu/tsdi). There was a two-step registration process; first registration was for the platform that offers the course along with other MOOCs, and the second registration was specifically for the course. There were five units in the TSDI MOOC course. Unit 1 was titled *Considering the Possibilities of Teaching Statistics with Data* and focused on what statistics is and why it is taught in schools. Unit 2 was titled *Engaging in Statistics*, and it offered a careful look at what it means to engage in statistics. Unit 3 focused on *Introducing Levels of Statistical Sophistication* and presented a framework for supporting growth in students' statistical sophistication and digged deeper into statistical habits of mind. Unit 4 was titled *Delving Deeper into the Investigation Cycle*, and it provided teaching and learning materials to assist participants in understanding the different components of a statistical investigation, including several resources that can be used directly with students. Finally, Unit 5 engaged participants in *Putting It All Together* to consider how to change teaching practices that can really engage students in doing statistics with real data. Each unit was similarly structured by containing the following sections: *Hear from your instructor*; *Engage with essentials*; *Learn from our expert panel*; *Dive into data*; *Investigate: assessment items*; *Discuss with your colleagues*; *Extend your learning*; *Demonstrate your learning*; and *Unit feedback survey*. The course included instructor videos explaining the units, expert panel videos, videos of real students and teachers engaging in statistics work, animations depicting student work in statistics, brief readings, excerpted readings from articles or books, various data analysis tools (open source), and lesson plans, tasks, online apps, and videos that can be used in the classroom.

With a small grant funded by the American Statistical Association, Hollylynne Lee aimed to support local changes in statistics teaching and collaborative learning among teachers by supporting professional learning teams (PLT) among TSDI MOOC-Ed participants during fall 2016 and spring 2017. In those small teams, groups of participants were supposed to meet several times (online and if possible, face-to-face) and share their learning and experiences in the course, as well as their statistics teaching practices. The plan was to pursue a blended approach to professional development among teachers of statistics.

There is a common and strong issue with teachers' confidence to teach statistics (Estrada et al., 2011; Lovett, 2016; Stohl, 2005). Teachers mostly escape from teaching statistics for various reasons. One of those reasons was the lack of their knowledge about different strategies in teaching statistics (Hill et al., 2005). Thus, given the description of MOOC and PLT above, the research question guided this study is: In what ways does participation in a MOOC and in a PLT focused on teaching statistics impact teachers' confidence to teach statistics?

Theoretical framework

Clarke and Hollingsworth (2002) explains teachers' professional development and recommends key considerations for in-service and pre-service teacher training programs. The authors describe six perspectives about teacher change: (1) changes as training; (2) change as adaptation; (3) change as personal development; (4) change as local reform; (5) change as systemic restructuring; and (6) change as growth or learning. The authors state that those perspectives are not mutually exclusive, and they are interrelated. However, most professional developments align with the change as growth or learning perspective. In this perspective, change is identified with learning, and it is regarded as a natural and expected component of the professional activity of teachers and schools (Avineri, 2016) and, historically, "teacher change has been directly linked with planned professional development activities" (Clarke & Hollingsworth, 2002, p. 948). A model to explain the process of teacher change was developed by an international group of researchers (Teacher Professional Growth Consortium, 1994), as the Interconnected Model of Teacher Professional Growth. The Interconnected Model of Teacher Professional Growth suggests that professional growth (change) occurs through the mediating processes of reflection and enactment in four domains that encompass the teacher. These domains are (1) the personal domain (teachers' knowledge, beliefs, and attitudes); (2) the domain of process (teachers' professional experimentation); (3) the domain of consequence (salient outcomes of professional development); and, (4) the external domain (sources of information, stimulus, and support). The Interconnected Model of Professional Growth is updated to frame this study and used as the model for explaining teachers' change or professional growth in this study (Figure 1).

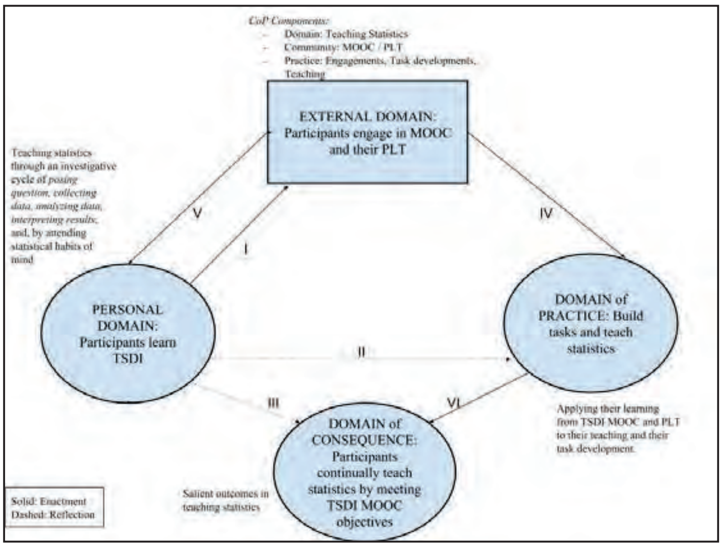

Figure 1: The interconnected growth model for blended PDs of MOOC and PLT

According to Clarke and Hollingsworth (2002), there are two different mechanisms (or two mediating processes) to account for change or professional growth effects: enactment and reflection. Enactment is the mechanism by which a teacher puts a new idea, belief, or a practice into action. Reflection, on the other hand, is defined as "active, persistent, and careful consideration" (directly quoted in [Clarke and Hollingsworth, 2002, p. 954], from [Dewey, 1910, p. 6]). In order to answer the research question of this study *(In what ways does participation in a MOOC and in a PLT focused on teaching statistics impact teachers' confidence to teach statistics?)* the following construct is provided as guiding hypotheses.

> <u>External domain >> Personal domain:</u> We hypothesize that participants' engagements in MOOC and PLT influences their knowledge of and confidence in teaching statistics. For example, a teacher explores a conceptual misconception discussed in a MOOC forum and realizes that he/she also has that misconception and tries to overcome it. (*Reflection)*

Methods

The largest group in this study is all TSDI MOOC participants (804 enrolled participants in total) for fall 2016 and spring 2017. The case of interest for this research are the 63 TSDI MOOC participants that also joined one of nine PLTs. There were four PLTs formed during fall 2016, and five PLTs formed during spring 2017. The study focuses on understanding the experiences of members of the nine PLTs situated within the larger MOOC community to find out about the change in their confidence about teaching statistics.

The Self-Efficacy for Teaching Statistics Survey (SETS; Harrell-Williams et al., 2014; Harrell-Williams et al., 2017) is designed to evaluate participants' confidence about teaching various aspects of statistics (e.g., estimate a population mean or proportion using data from survey; calculate the correlation coefficient between two variables, using technology; interpret measures of association). According to Lovett (2016), the SETS survey aligns with Bandura's (2006) construct of self-efficacy measuring expectations, and it measures teachers' efficacy for tasks and task levels that align with the GAISE framework. Those levels (Levels A, B, and C) are considered to have increasing statistical sophistication. The levels are aligned to some specific statistical content. Level A represents topics for novice statistics learners; Level B represents more complex content; and Level C represents more advanced content (Franklin et al., 2007). The SETS instrument consists of 44 items which are categorized as Level A, Level B, and Level C items. 11 items in the SETS instrument correspond to GAISE Level A (confidence to teach basic statistical content); 15 items correspond to GAISE Level B (confidence to teach more complex content); and 18 items correspond to GAISE Level C (confidence to teach more advanced statistical content). The SETS instrument has been validated as an appropriate instrument to measure confidence, on a scale from 1-6, for each of the 44 items. For each item in the SETS survey, participants rate their confidence in teaching the skills necessary to successfully complete the task on the following scale: 1-not at all confident; 2-only a little confident; 3-somewhat confident; 4-confident; 5-very confident; 6-completely confident. Content validity is established using experts' (college-level statistics educators, including teacher educators) judgement, focus groups (preservice and in-service teachers), and several pilot studies. Structural, substantive, and content validity evidence for the scores from the SETS instrument were outlined, and confirmatory factor analysis results provided evidence for treating the SETS as a two-dimensional (for SETS-Middle School, Harrell-Williams et al., 2014), and three-dimensional (for SETS-High School, Harrell-Williams et al., 2017) instrument aligned with GAISE Pre-K-12 framework. Within the TSDI MOOC, the SETS surveys were given to the participants twice. Participants could take the survey while they were in Unit 1 of the course (pre-SETS), and the survey was again available in Unit 5 (post-SETS). There was one open-ended question on the survey for participants to elaborate on factors that affect their confidence. In Unit 5, they were specifically asked to discuss any changes in their confidence in discussion forums. Thus, the SETS survey results can help describe the growth in participants' confidence about teaching statistics. The quantitative data for this research included SETS survey results. The statistical method for analyzing the SETS survey results is to examine scores for their total confidence pre and post, as well as gain scores for each level (A, B, C) of statistical sophistication of topics. The PLT participants who took the post-test were identified and pre-test takers were filtered to be in the same group. The SETS questionnaire has 44 Likert-scale prompts; these prompts are separated into three blocks, and each block represents different levels of sophistication (A, B, or C). The analysis is conducted for every sub-scaled score of these different levels and for the total. After matching pre- and post-surveys, 28 PLT participants took both the pre- and post-SETS. A dependent samples t-test was used to determine whether there was an increase in participants' gain scores in confidence to teach statistics after their participation in the course and PLT. The increase in participants' confidence to teach statistics is examined by analyzing SETS results and other qualitative data.

Results

Since a paired t-test is a parametric test with an assumption of normality, the distribution of gain scores for the total confidence score (postTotalSETS-preTotalSETS) should be checked for normality. Using Wessa's (2017) online tool, a Normal QQ Plot was created with the total SETS gain scores, which indicated the distribution was somewhat normal (See Figure 2). The assumption of normality was then assessed via Kolmogorov-Smirnov (*K-S*) test, and the results suggested that normality was a reasonable assumption for our data set. For example, the *K-S* test for total SETS gain scores had a test statistic value of .1546. Larger values of the *K-S* test statistic indicate the distribution does not follow a normal distribution. Since .1546 < .2499 (*K-S* test critical value for α=.05), the data is a reasonably good fit with the normal distribution, and a paired t-test can be used.

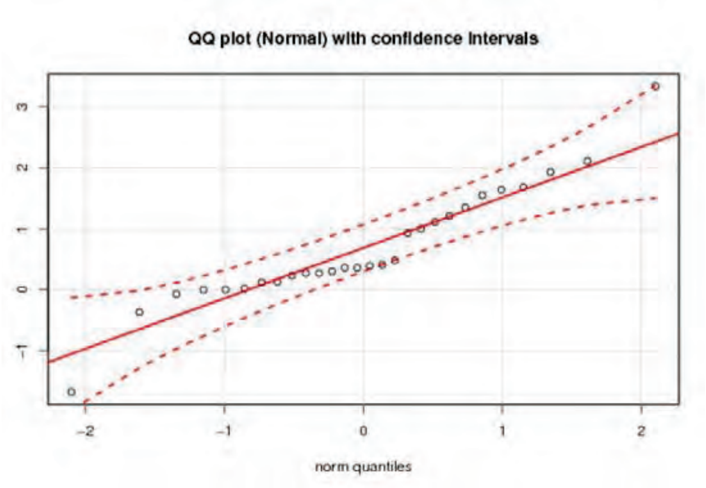

Figure 2: Title of the figure, no dot at the end

The question being asked for this analysis is: Is there sufficient evidence to suggest that PLT and MOOC participants' confidence in teaching statistics was increased after they took the TSDI MOOC and they participated in PLT? In other words, is there sufficient evidence to suggest that the mean score is greater for the post-SETS than the pre-SETS?

Ho: There is no difference between post and pre-SETS test scores. $Md = M2 - M1 = 0$

Ha: $M2 > M1$

Table 1 represents the SETS survey data for 28 PLT participants that completed both the pre- and post-SETS instrument. As seen in the table, in all three levels (A, B and C), it is observed that by participating in the MOOC and the PLT, participants SETS scores increased. Thus, we reject the null hypothesis and conclude that there is sufficient evidence to say that participants' confidence to teach statistics was increased by this phenomenon (participating in both MOOC and PLT). As a conclusion of looking to quantitative data of SETS results, we could claim that after participating in both MOOC and PLT PD projects, the PLT participants' confidence to teach statistics increased.

	Pre-SETS Mean	Post-SETS Mean	Difference Mean	Standard Deviation	*t*-test
LevelA Scaled[a]	4.19	4.82	.63	.90	3.71***
Level B Scaled[a]	3.87	4.63	.75	1.06	3.76***
Level C Scaled[a]	3.83	4.48	.65	1.05	3.30***
Total Scaled[a]	3.93	4.62	.68	.96	3.77*

$N = 28$.
[a] Scaled to 1 - 6.
* $p < .05$, ** $p < .01$, *** $p < .001$.

Table 1: PLT participants' SETS results

At the end of the pre-SETS survey, participants answered a similar question with minor differences. The open-ended question in pre-SETS was as follows: *“Consider some of the topics that you were most or least confident teaching. What may be some reasons that teachers might be more or less confident in teaching those topics?”*

In the end post-SETS survey, participants were expected to answer the following open-ended question: “*Consider some of the topics that you were most or least confident teaching. Did anything we did in this MOOC help you gain confidence in those areas? For the areas you are still less confident with, what may help build your confidence?”*

In the pre-SETS question, the goal was to make participants reflect on their own explanations of reasons for their least and most confident topics in teaching statistics; in the post-SETS question, we aimed to have them re-visit those topics and reflect on their own perspectives about how their participation affected their confidences to teach them.

Our desire was to figure out whether there was a change in their reflection about their confidence to teach statistics after participating in the MOOC and the PLT. Table 2 provides a sample of four PLT members’ responses to the open-ended questions.

Term/Years of Experience	**Pre-SETS**	**Post-SETS**
Fall / 9	I've only rarely taught about fitting data to models.	The concept of sample vs. population and the ideas around variability are two areas that I find are greatly improved using some of the real-time examples and simulations from this MOOC.
Fall / 1	I feel like I do not have enough practice or knowledge about these topics to be able to teach them to my students.	I am more confident in creating experiments and gathering data. I feel like I could have used more help in analyzing the data.
Spring / 5	Teachers might be more or less confident in teaching certain topics due to experience and education background.	Being able to talk with others and play with data helped me to gain confidence in those areas. The whole idea of exploration really helped me to gain confidence. I think having resources and activities with the activities I am less confident in would help me to gain confidence.
Spring / 27	As math teachers, we probably feel more confident with topics that involve calculations and less confident about topics that involve things that can limit the conclusions of those calculations, such as lurking variables and weaknesses in the data collection techniques.	I gained confidence in the technology end of things by reviewing some of the resources (that are bookmarked, but I do not recall their names off of the top of my head) presented in this course.

Table 2: SETS open-ended response examples

As seen in the table above, these four participants reflected on the change in their confidence in their own words. For example, a fall participant with one year of experience answered the question saying that he or she did not have enough experience or knowledge; on the other hand, the post-survey response of this participant included a detailed description of the impact stating that he or she had gained confidence in creating experiments and collecting data. The teacher directly reflects on the change in his or her confidence in conducting a statistics lesson using SASI framework.

The participant on the fourth row stated that math teachers used to feel more confident in more 'mathematical' subjects, and statistics is not one of those. In the post-survey, the participant said that she or he gained confidence in using technological tools. As a teacher with 27 years of experience, that participant gives a good sense about the strong connection between confidence to teach statistics and being able to use technology for teaching.

There were 15 participants (out of 28 who took both pre- and post-SETS survey) who gave us evidence of self-reflection on the positive change in their confidence to teach statistics. Looking at both participants' SETS quantitative results and open-ended responses, results showed that the phenomenon (participating in MOOC and PLT) helped them to gain confidence in teaching statistics.

A response given to a question in the end-of-course survey ("What was the most valuable aspect of this MOOC-Ed in supporting your personal or professional learning goals?") also showed evidence supporting increased confidence after participating in MOOC and PLT.

"This course gave me some great lesson plan ideas. It also made me more confident in teaching statistics where before I felt like I knew nothing about teaching statistics. After this course, I feel like I would teach it to my students." (PLT member, 8 years of experience)

Conclusion

Participating in the MOOC and PLT increased participants' confidence to teach statistics. Most of the teachers went from a "I know nothing about teaching statistics," or "I am clueless about statistics myself, how could I teach it?" level, to an "I can do it!" level. Attending the TSDI MOOC and PLT, the participants reflected that their self-confidence to teach statistics increased. This claim is supported by both SETS quantitative results and open-ended responses in SETS. The results of the study are valuable, because as stated before, there is a common and strong issue with teachers' confidence to teach statistics (Estrada et al., 2011; Lovett, 2016; Stohl, 2005).

The findings can be used to help statistics education researchers, as well as others in any educational discipline, to design more MOOC and PLT professional development projects to contribute to teachers' professional growth. The findings also can be used to create a common drive to change problematic aspects of statistics in curriculum.

Covariational reasoning in primary school: A qualitative approach.

Martin Andre[1], Daniel Frischemeier[2] and Christoph Schneider[3]

[1]University College of Teacher Education Tyrol, Austria; martin.andre@ph-tirol.ac.at

[2]University of Münster, Germany; dfrische@uni-muenster.de

[3]University College of Teacher Education Tyrol, Austria; christoph.schneider@ph-tirol.ac.at

Keywords: Covariational reasoning, gapminder's dollarstreet, education for sustainable development.

Introduction

Covariational reasoning includes recognizing patterns and interpreting the relationship in bivariate data (Garfield & Ben-Zvi, 2008). Although it is important to focus on enhancing young learners statistical thinking in various facets (Ben-Zvi, 2018), most curricula address this topic only in later years of statistics education. With this poster, we want to present the idea of using qualitative data such as photos from the Dollarstreet to address young learners covariational reasoning.

Theoretical framework

Many researchers recognize the value of a real context meaningful for students (e.g., Garfield & Ben-Zvi, 2008) and emphasize the importance of teaching and learning of statistics for democracy and citizen education (Nicholson et al., 2018). Recommendations to regard students as active learners when constructing their statistical knowledge often imply the use of technology and tools to explore real datasets (Garfield & Ben-Zvi, 2008). The databases and visualization tools provided by Gapminder (Rosling et al., 2005) including the photo database Dollarstreet (Rosling, 2015) give many opportunities to explore real datasets in statistics education at school level. In that direction, Andre et al. (2020) investigated how the context of sustainable development can enrich pupils' statistics education. Anyway, many authors also found difficulties in addressing young learners covariational reasoning, and recommend using alternatives to scatterplots (Konold, 2002).

Methods and Implementation

Following design-based research approaches (Bakker, 2018), in the summer term of 2021, we designed a seminar for six primary school teacher students focusing on important issues for Education for Sustainable Development and statistics education (Andre et al., 2021). The major task for the students in this seminar was to design and implement a learning trajectory for pupils of grade 1. Besides addressing other statistical ideas, it was mandatory for students to include two tasks as shown in figure 1 where pupils should relate the quality of sanitation facilities to various income levels and interpret a scatterplot in the same context. The implementation took place in a primary school class with 18 children. The students had to write a report and transcribed the interviews with the children when solving the mandatory tasks. We analyzed these interviews and the students' reports in several dimensions. This poster focusses on pupils covariational reasoning with qualitative data.

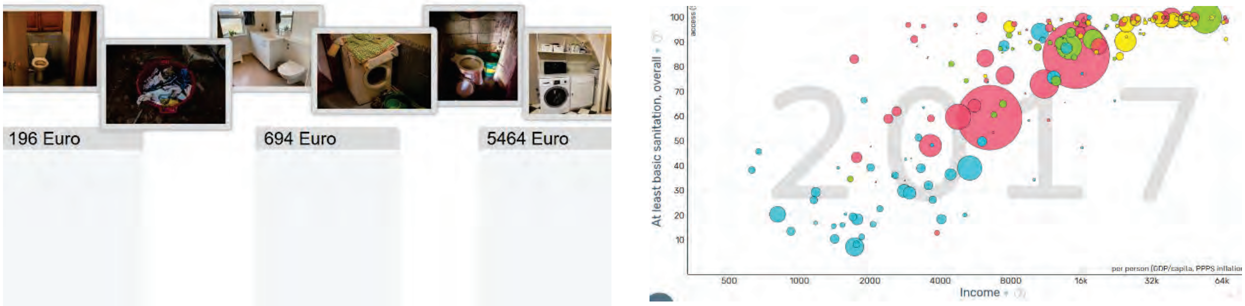

Figure 1: Left: Drag-and-drop task for qualitative covariational reasoning; Right: Gapminder's scatterplot showing income data and data of sanitation standards (Andre et al., 2021)

Results

While struggling to interpret the scatterplot, all children managed to relate qualitative data from photos to quantitative data, i.e., the income level. In our analysis we found several opportunities to further address supplementary aspects such as causality and variance (Andre et al., 2021).

Reading levels in the activities related to statistical graphs in Costa Rica textbooks

Pedro Arteaga[1], Maynor Jiménez-Castro[2] and José A. Garzón-Guerrero[1]

[1]University of Granada, Spain; parteaga@ugr.es, jgarzon@ugr.es

[2]University of Costa Rica, Costa Rica; mynor.jimenez@ucr.ac.cr

In this paper we present results of analysing the reading levels, according to the model proposed by Curcio and collaborators of statistical graphs in Costa Rica compulsory education textbooks. The activities linked to statistical graphs included in three complete textbooks series in each of the primary (grades1 to 6) and secondary education (grades 7 to 9) were analysed.

Keywords: Statistical graphs, reading levels, textbook analysis, compulsory education.

Introduction

Statistical graphs are essential for communicating information in many different areas, and appear frequently in the media, and for this reason a minimal statistical literacy is needed for the citizen to be able to interpret these graphs critically (Weiland, 2017). This need is still more urgent in the current pandemic situation, where citizens need to understand statistical information mainly distributed in graphs to collaborate with political and health authorities (Batanero et al., 2021). Moreover, graphical competence is part of statistical literacy defined by Gal (2002) as the ability to interpret and critically evaluate statistical information, data-related arguments, or stochastic phenomena, which they may encounter in diverse contexts, joined to the ability to discuss or communicate reactions to such statistical information, when required (pp. 2-3).

Consequently, graphical competence is a main goal in school curricula in many countries. This is the case of the compulsory education curricula in Costa Rica (MEP, 2012) that, for primary education recommend that children are requested to collect and record data to answer statistical questions about themselves and their environment, using bar and line graphs, tables and pictograms, as well as to read and interpret these representations since the 1st grade. Further study of graphs is accomplished in secondary education, where histograms, frequency polygons and pie charts are also introduced with the aim of improving students' graphical abilities. These goals can only be achieved with a correct teaching of the topic and the use of adequate textbooks.

Research analysing different content in textbooks is increasing today, since these books are a main didactical tool for teachers and students and constitute an intermediate stage between the official curricular guidelines and the teaching implemented in the classroom (Fan et al., 2013). Consequently, the aim of this research was to analyse the activities where statistical graphs are used in the Costa Rica textbooks and, more specifically the reading levels required from the students to complete these activities.

Below we describe the foundations, method and results of the research and we finish with some considerations to improve the teaching of statistical graphs in compulsory education.

Foundations

The work is supported, in the first place, by theoretical models on difficulty levels in reading graphs, and secondly on some research that have previously studied statistical graphs in primary school textbooks which is used to compare with our results.

Reading Levels of Graphs

A graph is a complex semiotic object, due to the different components that need to be comprehended in order to fully understand the information displayed (title, scales, types and amount of data and graphical elements used to represent the data). The graphic builder encodes the information represented by means of these elements and the reader of the graphic should carry out a series of interpretative processes for each of these components and for the graph as a whole as well as of the relationship of the graph with the information context (Arteaga & Batanero, 2011; Sharma, 2006; Spence, 1991).

Consequently, the interpretation of a graph is more or less complex, depending on the information that needs to be extracted from the graph and for this reason, several authors have defined levels in the reading of graphs. These levels reflect the fact that on the same statistical graph, we can raise questions of different levels of difficulty, which can refer to the title and scales, the variables and values being represented, the interpolation or extrapolation of values, and even to the detection of biases in the graph or in statements based on the graph. In this research, we relied on those defined by Curcio and his collaborators (Friel et al., 2001; Shaughnessy, et al. 1996; Curcio, 1989):

L1. Reading the data, where only the literal reading of a graph element is requested, for example, reading the graph title, the scale labels or the frequency for a given value.

L2. Reading between the data. Besides the literal reading of the graph, in this level the child has to compare various data represented in the graph or complete some arithmetical calculations with the data.

L3. Reading beyond the data. This level involves a generalization of the values in the graph, for example, interpolating or extrapolating the information displayed.

L4. Reading behind the data. A person attains this level when he or she is able to make a critical valuation of the graph, of the way it has been constructed or can discuss a statement related to the graph content.

Previous research

We also draw on other research that analyses statistical graphics in primary school textbooks, most of which only dealt with primary education textbooks. Díaz-Levicoy in various works analyses statistical graphs in primary school textbooks (primary education Chilean and Spanish textbooks in Díaz-Levicoy et al. (2016), grades 4 to 6, Argentinean textbooks in Díaz-Levicoy et al. (2017), Peruvian textbooks in Díaz-Levicoy et al. (2018)), with very similar conclusions. The authors study the type of graph proposed, the activity requested of the child, and the reading levels required in the activity. They conclude that bar graphs are most frequently used, with little weight given to other types of graphs in the curriculum. The most frequent activity in Spanish textbooks is reading graphs, while calculating was predominant in the Chilean books.

The most frequent reading levels in Curcio's (1989) classification were L1 followed by L2 in Chile and Spain; L2 being the most common level in Argentina. Level L3 appears from 4th grade in Spain and 3rd grade in Chile, and is not proposed in Argentina textbooks. As regards L4 only grades 5 and 6 in Spain and grades 4 and 6 in Argentina consider this level. The tendency was different in the Peruvian textbooks, were half activities in grade 1 correspond to level L1 and the remaining to L2, which predominates in all the other grades with very scarce activities in levels L3 or L4,

A direct precursor to this work is that by Jiménez-Castro et al. (2020), who analysed statistical graphs and reading levels in the activities related to them in two series of primary school textbooks (grades 1 to 6 in Costa Rica). Bar and line diagrams (single and multiple), pie charts, dot plots and pictograms were observed, with a large predominance of bar charts. Generally, the reading level required in the activities was L2 level.

All the above research deals with primary education textbooks and only that by Jiménez-Castro et al. (2020) was carried out in Costa Rica. This paper expands research by Jiménez Castro et al. (2020) with the analysis of a new editorial (6 new books) and expand the study with an investigation of three complete editorials for secondary education (grades 7 to 9, additional 18 textbooks) with particular focus on the reading levels requires in the activities proposed for statistical graphs in these textbooks. Below we describe the method, present the analysis categories and discuss the results. We conclude with some implications for the teaching of statistical graphs.

Method

This is a qualitative research, based on content analysis, which was carried out through the following phases (Porta & Silva, 2003):

- Fixing the object of analysis: In each textbook, the activities that incorporate statistical graphs were studied.
- Determining the categories or coding rules: The categories were the reading levels identified a priori based on previous research (Friel et al., 2001; Shaughnessy, et al., 1996; Curcio, 1989)
- Checking the reliability of the coding-categorisation system: the coding was reviewed several times by one author and discussed with other colleagues until an agreement on the coding was reached. These categories are presented in section called “Analysis categories”.

The information of the variable “Reading level” was coded, following an inductive and cyclical process; a detailed reading of each activity was carried out, the data obtained were interpreted and reviewed to make sense of the analysis, the data were related to the defined categories. This process was carried out of one of the authors of the paper as part as his doctoral thesis, consulted with the director of the doctoral thesis and with other colleagues, to give greater validity to the study.

Sample of textbooks and activities

The sample includes all the activities related to statistical graphs (activities where statistical graphs appear or activities that propose to build a statistical graph) in three books series of primary education (grades 1 to 6, 18 textbooks) and in another three series of textbooks directed to secondary education (grades 7 to 9, 18 additional textbooks). All the editorials were selected because they are most widely used in Costa Rica and are listed in the Appendix. In total. the number of activities analysed were 579 activities in primary education and 363 in secondary education.

Analysis categories

We used the reading level required, using the classification by Curcio (1987), and Friel et al. (2001). Below we include examples of activities classified in each of these levels:

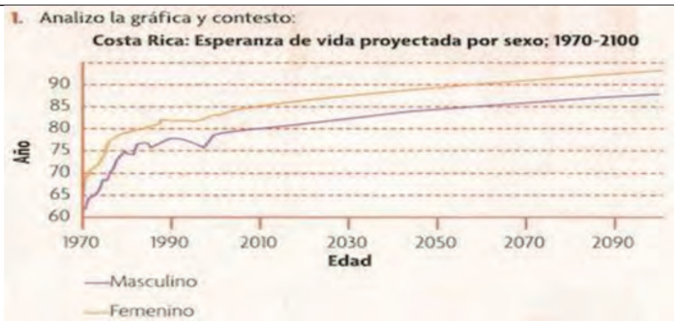
L1. Reading the data: At this level the activity concentrates on answering questions about the frequency of a value for a variable (or the value to which a frequency corresponds), without going so far as to make other connections or perform other calculations with the data. An example is shown in Figure 1, where children should complete a bar graph to represent the frequency of a series of objects (previously classified) shown in an image.

Figure 1. Example of reading level L1 "reading the data" (Source S1, p. 298)

L2. Reading between the data: this level applies when comparisons or operations must be made with the data obtained from a graph in order to solve the activity. It involves identifying relationships between the data, as in questions b of the activity presented in Figure 2, where, after reading the data, operations have to be performed on the data. Question f also corresponds to this reading level, because depending on the year of birth, the student must locate such data on the graph, and if the year is not a multiple of 10, he/she needs to locate it on the X-axis in order to identify the life expectancy corresponding to that year.

L3. Reading beyond the data: This reading level is achieved in activities where we ask to obtain data not explicitly represented within the graph, which includes interpolating or extrapolating a piece of data on the graph. We classify questions a and c in Figure 2 at this level as well, as the trend is not explicitly represented but must be inferred from reading the values on the graph and comparing along the time axis.

L4. Reading behind the data. The solution of activities qualified at this level require from the solver a critical appraisal of the method of data collection, validity, or reliability or to justify the conclusions made. Although this level of reading is not common in textbooks, we have encountered some examples in activities such as the one presented in question d in Figure 2, where the student is asked to think about the reasons explaining the increase in life expectancy along time.



a. Which tendency shows the life expectancy? Does it increase or decrease? Justify
b. How many years of difference there is between 1970 and currently?
c. Is the tendency similar for both genres? Explain
d. Suggest two reasons why the life expectancy follows this tendency
e. Comment two consequences of this tendency for our society
f. Taking into account the year you were born. Which is your life expectancy?

Figure 2: Task reproduced from AL5 p. 166

Results and discussion

In Table 1 we present the percentage of activities that were classified in each of the reading levels defined by Curcio and his collaborators (Friel et al., 2001; Shaughnessy, et al., 1996; Curcio, 1989) by school grade. We can observe the predominance of level L1 (reading the data), where only a literal reading of the data displayed in the graph is required from the students in the first three grades, in particular in the first grade, where the children are only starting to be introduced to some statistical ideas. This level diminishes in relevance since grade 4 in favour of upper reading levels.

Table 1: Percentage of tasks by reading level and school grade

	Primary education						Secondary education		
Reading levels	1st (n=50)	2nd (n=108)	3rd (n=97)	4th (n=109)	5th (n=93)	6th (n=122)	7th (n=176)	8th (n=82)	9th (n=105)
L1	68.0	42.6	44.3	24.8	22.6	32.8	21.0	30.5	29.5
L2	30.0	43.5	40.2	52.3	52.7	50.8	59.1	52.4	46.7
L3	2.0	7.4	6.2	16.5	16.1	7.4	13.6	15.9	10.5
L4		6.5	9.3	6.4	8.6	9.0	6.3	1.2	13.3

The reading level L2 (reading between the data, where students are also requested to perform some computations or comparisons with the data in the graph) was very frequent along all the school grades, including secondary education. It was the most frequent level in grades 4 to 9 because in these levels' graphs are also used to facilitate the computation of central tendency and spread measures and for this reason, the students are requested not only to read the graph but to compute mean, mode, range or other statistics with the data represented in the graph. Interpolation and extrapolation activities (reading level L3), as well as critical reading activities (Level L4) appear with low frequency in all the grades, although they are a bit more frequent in secondary education.

These results contrasts with what is reflected in the study described by Díaz-Levicoy et al. (2016), where Spanish and Chilean books remain only at reading level L1 in the first two grades and is still the most frequent level along all the primary education. In Costa Rica, reading levels 3 and 4 appear significantly from the second year onwards and increase in frequency until the sixth year. In the Spanish context, the maximum reading level only appeared in the fifth grade, whereas in the Chilean context, it is incorporated in a sustained manner from the fourth grade onwards, coinciding with the recommendations given in NCTM (2000) to promote the making of inferences and the obtaining of predictions from the data analysed. In Argentina, L3 is not taken into account and L4 only in grades 4 and 6. So, the distribution of reading levels in primary education in our research is more similar to that in the Peruvian textbooks, were half activities in grade 1 correspond to level L1 and the remaining to L2, which predominates in all the other grades with very scarce activities in levels L3 or L4.

In Table 2 we analyse the reading levels of the activities analysed by editorial, and we can observe some differences. As regards primary education, AL present more than half the activities in the L2 reading between data level, which suggest a stronger emphasis in computation in this publisher. EV is the editorial with less activities in this level, while it put more weight in L1 reading the data, in order to reinforce in the children, the learning of the different graphs before going further in more complicate activities. All the three editors include a small percentage of L3 and L4 activities which are those promoting statistical reasoning in dealing with predicting variables not in the graph and reinforcing the critical reading of the information.

Table 2: Activities with different reading levels in the various editorials

	Primary education			Secondary education		
Reading levels	AL (n=147)	EV (n=181)	SA (n=251)	PI (n=126)	PO (n=92)	SA (n=145)
L1	27.2	47.0	34.3	31.7	33.7	15.2
L2	54.4	40.3	46.2	58.7	41.3	57.9
L3	8.8	5.5	13.5	7.1	13.0	18.6
L4	9.5	7.2	6.0	2.4	12.0	8.3

As regards secondary education, SA is the editor with less L1 reading the data activities, which are less important at these teaching levels, given the age of students. PO is the publisher with less L2 activities, implying a smaller emphasis in computation. This is the editorial with a more balanced distribution of reading levels in the activities, since it includes more than a 10% of activities in each of the levels L3 and L4.

Conclusions

In this paper we present the analysis of the reading levels collaborators (according to the model by (Friel et al., 2001; Shaughnessy, et al., 1996; Curcio, 1989) required to complete the activities linked to statistical graphs contained in the most widely used textbooks in Costa Rica, at primary and secondary school levels.

The study reveals a predominance of the first two levels “reading the data” where only a direct reading of the information in the graph is required and “reading between the data”, where only comparisons or computation with that information is needed. Specifically, this second level is predominant in most grades even at secondary education level, which suggest an excessive emphasis in developing the computational abilities, instead of focusing in fostering their statistical literacy or reasoning.

We particularly point to the scarceness of level L4 “reading behind the data” activities, which will be particularly relevant in the education of secondary school students. These activities serve to develop in the student their ability to reason with statistical information, to discuss arguments based in statistics information and to assess the reliability of such information and in this way, help improving the students’ statistical literacy.

Also note that the L3 level in secondary school textbooks is not much considered, this type of level requires the student to be able to perform interpolations and extrapolations of the data presented in a graph, which is considered an important part of graph comprehension (Friel et al., 2001)

We suggest that especially in secondary education, it would be important to incorporate a greater number of L3 and L4 activities, which are closely related to the skills necessary to develop good statistical literacy levels (Gal, 2002)

As we pointed out in the previous sections, there are scarce research examining statistical graphs in secondary school education textbooks, and therefore this research should be continued with the analysis of other variables and textbooks in other countries. However, we hope our research make teachers conscious of the importance of taking into account all the possible reading levels when working with statistical graphs at school and help them organise teaching to take into account this didactical variable.

Insights into the design of an introductory course for data science and machine learning for engineering students

Katharina Bata[1], Angela Schmitz[1] and Andreas Eichler[2]

[1]TH Köln – University of Applied Sciences, Germany; katharina.bata@th-koeln.de; angela.schmitz@th-koeln.de

[2]Universität Kassel, Germany; eichler@mathematik.uni-kassel.de

Due to their interdisciplinary nature, data science methods, such as machine learning, can be taught in many different ways. This paper presents an approach that takes advantage of the close content connection to statistics and of the mathematical structure of data science methods to develop an introductory course for engineering students. Following the research methodology of design research, we discuss the theoretical motivation and methodological implementation of the design principles for the course and show first insights into empirical results from the design cycles.

Keywords: Data Science, Machine Learning, Design Research, SRLE.

Introduction

A large proportion of the methods attributed to data science are (computer-aided) applications of statistics, making data science an essential topic in the statistics education research community (Engel, 2017; Gould, 2017). The possibility of applying data science methods in almost all areas of industry and research has created a need for subject-specific concepts for teaching the methods over the past years (Engel, 2017; Grillenberg & Romeike, 2018).

Due to the interdisciplinarity of data science between mathematics, statistics, computer science, ethics, and the respective reference science, there are many ways to approach the topic. We want to show insights into the design of an introductory course for data science (DS), particularly machine learning (ML), for early mechanical engineering bachelor students in a few lectures focusing on statistics, particularly mathematics. The development of the course follows the methodology of design research (Gravemeijer & Cobb, 2006).

In this paper, we motivate the design principles of the course and present their respective elaboration. For this reason, the central part of this paper is theoretical, followed by examples from the introductory course that illustrate the explicit implementation of the design principles. In the end, we switch to a first empirical evaluation and give a brief insight into the students' views on the developed introductory course.

Theoretical considerations for designing the introductory course

This section gives insights into the current state of research regarding teaching DS and in the methodology of design research, followed by the theoretically motivated design principles.

The current state of research in teaching data science with a focus on machine learning

In a DS study program, the versatility of what can be taught and in which ways it can be taught is wide (Grillenberg & Romeike, 2018). There are different approaches to the concretization of a DS curriculum for schools (Heinemann et al., 2018), undergraduate programs (De Veaux et al., 2017), and competence models for sub-aspects such as data literacy (Ridsdale et al., 2017) or data management (Grillenberg, 2019). One subfield of DS and part of many DS curricula is data analysis, especially ML (Grillenberg & Romeike, 2018). There are many open questions and few empirical studies about how learning ML occurs under different teaching methods (Steinbach et al., 2020).

Especially for students without a mathematical or computer science background, there are different approaches to how to deal with the more complex mathematical and programming details that seem to be a hurdle for students (Lavesson, 2010). Suppose one additionally considers the easy accessibility of methods nowadays, there is a danger: Using ML without theoretical expertise, for example, on fundamental mathematics and statistics, creates the risk of harmful socio-technical systems (Heuer et al., 2010). To date, there is little consideration of the role of ML in the context of statistical literacy and data literacy (Grant, 2017; Kadijevich & Stephens, 2020; Schüller, 2017). In this context, the distinction between the terms statistical and data literacy is still fluid, with broad similarities, and somewhat arbitrary (Gould, 2017; Schüller, 2017).

Theoretical considerations on design research

The research methodology of design research focuses on the close connection between the systematic design of teaching-learning material and the investigation of learning processes working with this material (Gravemeijer & Cobb, 2006). Especially in the case of little empirically tested teaching-learning material, design research can be used sensibly with the two following goals: To get empirically tested and cyclically improved teaching-learning material and to get research results on the learning processes of the target group when working with the material.

For this purpose, first, a prototype of the teaching-learning material is developed, considering the so-called design principles (see section *The design principles for the introductory course*). The development of the prototype also includes theoretical considerations about the students' learning processes, so-called intended learning trajectories. Subsequently, the prototype is tested with the target group in the so-called design experiments, for example to compare the students' individual learning paths with the intended learning trajectories. By analyzing the design experiments, a local (concerning the target group and the material) teaching-learning theory emerges, which contributes to the further development of the material. A cyclical continuation then provides improved teaching-learning material and a sharpened local teaching-learning theory (Gravemeijer & Cobb, 2006).

The design principles for the introductory course

In this section we motivate the design principles (DP) of the course and explain their methodical implementation. In the following section *Insights into the course,* two examples, *The unit square* and *Reflection tasks*, illustrate how the design principles are incorporated into the design of the course.

The first design principle is *Strong inclusion of statistics and mathematics to approach the DS/ML methods* (DP1). There are two main reasons for this design principle: One is the proximity between DS and statistics, respectively mathematics, in terms of content and the personal interest in this connection. The other is the fact that engineering students are, due to their curriculum, a target group with a comparatively strong mathematical background.

To implement the first design principle, we use the “four-level approach for specifying and structuring mathematical learning content” (Hußmann & Prediger, 2016). The four-level approach illustrates how to proceed methodically when the focus within a design research project is on analyzing the learning content. Using the approach, the prototype of the material emerges by answering a series of systematic questions on three theoretical levels in the sense of a “classic didactical analysis of subject matters” (Hußmann & Prediger, 2016). The first level, the formal level, addresses the logical structure and the formal representation of the (mathematical) learning content (objects and procedures). The second, the semantic level, addresses the sense and meaning of the objects and procedures under study; helpful representations and mental models are identified and linked to each other (see a concrete example in section *The unit square*). On the subsequent concrete level, the last theoretical level, learning situations, and examples for experiencing the concepts and procedures are developed (see a concrete example in section *Reflection tasks*). The fourth level then equals the implementation and evaluation of the design experiments.

The second design principle is *Embedding all methods in the overall context of data analysis* (DP2). It is an idea, which is used in several different contexts while learning methods to handle with data (Heinemann et al., 2018; Wild & Pfannkuch, 1999).

This design principle is implemented by using the “CRoss-Industry Standard Process for Data Mining” (CRISP-DM, Chapman et al., 2000) model to structure the course and some teaching activities. The CRISP-DM model is a process model that describes all essential steps of a DS process in an industrial context, starting with a question and ending with the implementation of the results. It has already been fruitfully used in other projects to structure teaching activities in the context of DS (Heinemann et al., 2018). The CRISP-DM also gives an overview of some core ideas of DS, according to DP3 (*core ideas of DS and ML,* see next paragraph), and we additionally use it in the sense of DP4 (*classroom activities,* see next paragraph) to design tasks that encourage students to discuss core ideas and own proceedings (see a concrete example in section *Reflection tasks*).

The further four design principles (DP3 to DP6) refer to the basic ideas of the “Statistical Reasoning Learning Environment” (SRLE, Garfield & Ben-Zvi, 2008). The SRLE is a well-structured and proven approach to create teaching-learning environments in the context of data. The origins of the SRLE go back to Cobb (1992) and were developed further by different statistics educators within the following decades. Because of the close proximity of DS and statistics in terms of content, it offers to use some ideas of the SRLE as design principles for the introductory course.

The following ideas from the SRLE (Garfield & Ben-Zvi, 2008) are adopted as design principles: *Focusing on the developing core ideas of DS and ML* (DP3, original: “Focus on developing central statistical ideas”), *Using classroom activities to support the development of students’ reasoning* (DP4), *Using realistic and motivating data sets* (DP5) and *Integration of appropriate technological tools* (DP6). DP4, DP5 and DP6 are adopted literally from the SRLE.

Insights into the course

To give an overview, we first present the content components of the course. Then we illustrate how the design principles shape the course by giving two examples.

The course components

The selection of the learning content is mainly based on the subjectively set goal of the course to convey the usefulness, practical relevance, and methodology of DS, especially ML, in the engineering sciences. Students shall be enabled to delve deeper into the topic of DS and ML. This goal results in three sessions of approximately 3 hours each:

Session 1 - fundamentals: A first overview of the possibilities to use DS methods in engineering is shown, and the CRISP-DM model is introduced. The handling of data within this setting is discussed and the basic concepts of ML up to classification are introduced.

Session 2 - k-nearest-neighbor classification (kNN): The basic concepts of ML are explored in depth by discussing the kNN as a possible method for classification.

Session 3 - model quality of classification models: Model properties (variance and bias), as well as different performance measures (accuracy, precision, recall), are discussed to be able to evaluate and compare classification models and to select the model parameters for a specific question.

The following example *The unit square* shows the use of the "four-level approach" on the first two levels, and thus gives insights into the implementation of DP1. The next example *Reflection task* shows the use of CRISP-DM as the elaboration of DP2 and some synergies with the design principles adopted from the SRLE (DP4 to DP6).

The unit square – An example for the analysis of the learning content on the first two levels

In Session 3, *model quality of classification models*, different model characteristics and performance measures are discussed with the students. When creating a classification model, the available data set consists of examples with the characteristics of the independent variables (called features) and a dependent variable (called a label). The total data set is first divided into training data and test data. The training data is used to build the model, and the test data is then used to check how well the model can predict the correct label. Concerning a binary classification model, the testing phase is usually represented using a confusion matrix as in Figure 1. Here, the number of correctly classified examples (true positive and true negative) separated by class is on the main diagonal, and the number of incorrectly classified examples (false positive and false negative) is on the opposite diagonal.

		Actual Class	
		Class 1	Class 2
Predicted Class	Class 1	true positive	false positive
	Class 2	false negative	true negative

Figure 1: Example of a confusion-matrix

All performance measures and performance criteria are derived from the values in the confusion matrix. A content analysis of the learning object, as it has been done on the formal level of the four-level approach, reveals that all performance measures can be represented by a probability space, which explains the relations of the values among each other:

Each example classified by the model[1] can be represented as $\omega^i = \left(\omega_1^i, \omega_2^i\right), i = 1, \dots n,$ where $\omega_1^i, \omega_2^i \in \{1,2\}$ with ω_1^i representing the actual class of the example and ω_2^i representing the new

[1] We continue to consider a binary classification problem here, a transfer to higher dimensionality does not pose a problem.

classified class. n is the number of examples. This gives $(\Omega, \mathcal{P}(\Omega), \mathbb{P})$ with $\Omega = \{\omega^i : i = 1, \dots, n\}$ and $\mathbb{P}$ as the normalized count measure, a probability space that represents the testing phase.

Going on in the formal level, all addressed performance measures and their interrelationships among each other can be represented based on this probability space (for example, certain performance measures are equivalent to conditional probabilities). On the subsequent semantic level, the following questions arise concerning the prerequisites of the target group: How can the performance measures and their interrelationships be communicated without addressing this probability space and, for example, conditional probabilities?

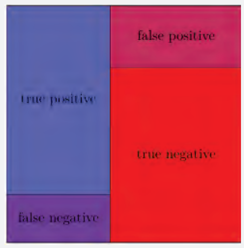

Figure 2: Example of a unit square

The unit square (see Figure 2) is considered to be a proven means to visualize proportions and probabilities up to conditional probability (Böcherer-Linder et al., 2017). The analysis in the two levels reveals that the unit square provides a way of representing the testing phase. The unit square in addition can visualize the performance measures to show them as formulas based on the values of the confusion matrix. Thus, by linking the content to mathematics, the unit square is included as a visual representation in the course.

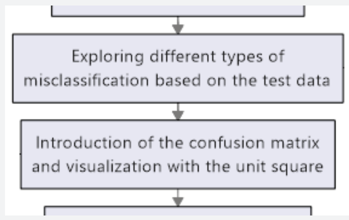

Figure 3: Excerpt of an intended learning trajectory

Besides the elaboration of different representatives of the performance measures (in this example, the unit square, the formula, and the values calculated by hand or with Python), the core ideas of Session 3 (such as the distinction between types of misclassification, which can also be visualized in the unit square) emerge from analyzing the learning content up to the semantic level. The analysis of core ideas, connections, and representatives results in a theoretical sequence in which they can be worked out: the intended learning trajectory (see Figure 3).

Reflection task – An example for considerations on the third level

The work areas of the CRISP-DM are learning objectives (see Session 1). The CRISP-DM is also used to structure the course (see section *The design principles for the introductory course*). The structure is implemented, among others, by giving students a task at the end of each session to reflect on the learnings in the framing of the CRISP-DM. For example, at the end of the third session, when students have to design a model and use the model for a decision afterwards (Bata et al., in press), this task reads:

Reflect on your decision in the Jupyter Notebook together in groups in the context of your notes from the last lecture[2] *and the CRISP-DM. If you find it useful, complete your answers again.*

This task demonstrates the incorporation and the interrelation of some design principles while formulating explicit learning opportunities on the third level of the “four-level approach”: Students work with a data set regarding the quality of steel (*realistic data sets*, see DP5), the Jupyter Notebooks are used as technical support throughout the task (*appropriate technological tools*, see DP6). The

[2] This refers to the notes of the reflection task of the past lecture (Session 2).

open assignment encourages students, who are working together in groups at this point, to discuss their results and to defend them argumentatively using the CRISP-DM (*overall context*, see DP2, *classroom activities,* see DP4).

First empirical insights

The design cycles and data collection

The introductory course has been conducted in two design cycles in different settings so far. In the first cycle, seven students participated in a laboratory setting (in groups of two and three, accompanied by the lecturer during the processing of the tasks). In the second cycle, 39 students participated in a course setting. The third session was additionally conducted with 4x2 students in a laboratory setting. All sessions took place via an online conference tool. Each session was video-recorded and transcribed. The group work was additionally documented using written products.

In addition, data were collected using a one-minute paper in each session. Students were asked five questions per session, each to be answered at one point after the session within a given time (usually one minute) and without looking into the learning material. The five questions were intended, among others, to help gather information about the learning environment. The evaluation gives a first insight into the students' views, from which we present first results.

Results

The question of the one-minute paper "How relevant do you think the content of the past lecture is to your studies and future career, and why?" was evaluated using points to characterize the students' answers: 0 points means no relevance, 1 point means medium relevance and 2 points means high relevance. In addition, the reasons were collected and grouped into content-related groups. Mean values between 1.81 and 1.92 across the cycles indicate that most students perceive the learning content as very relevant. However, the reasons for their ratings varied: Only about 10 percent of the students justify the relevance with concrete content like "validation of ML models"; instead, general facts are used as reasons. For example, students mention the presence and relevance of DS and ML in engineering or everyday life or Python as an essential competence for jobs and studies.

Two questions of each one-minute paper focused on the content goals of the particular session, for example: "For which data sets is the performance measure accuracy not recommended?" To evaluate the questions, 1 point (answered completely correctly), 3 points (answered partially correctly), or 5 points (answered incorrectly or not answered at all) were assigned to each response. The scores give an overview regarding the students' learning results concerning the questions. The questions were largely answered in a meaningful way in terms of content, the mean values of the answer points per question ranged from 1.95 to 2.63 across both cycles.

Discussion

This paper gives insights into the design principles and development of a short introductory course for DS and ML for engineering students. Especially the first design principle, implemented by the approach of specifying and structuring the learning content focusing on its statistical and mathematical aspects, opens a way to analyze ML methods, which have so far rarely been investigated from the perspective of the classic didactical analysis of subject matters. For example, the connection to the unit square has two potentials: On the one hand, learning methods with threshold parameters, which are discussed in every advanced ML course, can be transferred to the representation of the performance measures with an animated unit square. This visualization can show the direct influence of the threshold parameter on the performance measures. On the other hand, the very visual representation of the unit square can be used when students' backgrounds are not as mathematical as in the case of mechanical engineers.

The first analysis of the one-minute-paper questions shows a pleasing result, as the planned contents seem to reach the students and seem relevant to them. Nevertheless, the question arises about how the design principles, and the resulting developed or chosen representations, visualizations, and instructional activities contribute to the students' learning processes. The overall design study aims to explore students' individual learning paths through a qualitative analysis of the resulting video material to address this question. From this analysis, results are expected on whether and how the statistical and mathematical details are learned by students (which is unanswered by now) and used when applying the methods (first results see Bata et al., in press). Based on these findings, the role of statistics and mathematics in ML, specifically in the context of data and statistical literacy, can be addressed in greater depth.

University students reflecting on a problem involving uncertainty: what if the coin is not fair?

Francesco Beccuti[1] and Ornella Robutti[2]

[1,2] University of Turin, Italy; francesco.beccuti@unito.it, ornella.robutti@unito.it

How do university master's students in mathematics reason about a simple problem involving coin tosses? We answer to this question by analyzing the participants' written reflections in terms of recency and equiprobability effects understood non-normatively. Overall, the participants display a strong tendency to deem the problem's coin to be fair despite indication that this should be the case and contrary to explicit evidence presented in the problem. In view of this, we further elaborate on the connection between the participants' answers and their education in mathematical probability.

Keywords: Probabilistic reasoning, university students, recency effects, equiprobability effect.

Introduction

The recency and equiprobability effects are well-known phenomena related to people's interpretations of problems involving uncertainty. The *positive recency effect* is the tendency to interpret the manifestation of some event as evidence that the same event is likely to happen again in the future. Conversely, the *negative recency effect* is the tendency to interpret the manifestation of some event as evidence that the same event is less likely to happen again in the future. Moreover, the *equiprobability effect* is the tendency to judge a set of events as all equally likely to happen.

These definitions differ from the ones usually employed in the literature (e.g., Gauvrit & Morsanyi, 2014; Morsanyi & Szucs, 2014; Chiesi & Primi, 2009) essentially in the fact that they are explicitly non-normative: i.e., they do not account for whether the aforementioned effects are against the assumed normatively-correct interpretation of the problem under consideration. Indeed, these effects have been often termed "biases" or "fallacies" or "misconceptions" as they have been mostly problematized with reference to cases in which the respondents' answers to word-problems were considered wrong (cf. Chernoff & Sriraman, 2020; Batanero, 2020).

For instance, an influential article by Fischbein and Schnarch (1997) contained the following question posed to, among others, 18 prospective teachers specializing in mathematics:

> When tossing a coin, there are two possible outcomes: either heads or tails. Ronni flipped a coin three times and in all cases heads came up. Ronni intends to flip the coin again. What is the chance of getting heads the fourth time? (p. 98)

The answer "equal to the chance of getting tails" was taken to be the correct answer (given by 17 students). The answer "smaller than the chance of getting tails" was taken to be evidence of a negative recency effect (given by no student), while the answer "greater than the chance of getting tails" was taken to be evidence of a positive recency effect (given by one student).

As to this student, was he or she simply incorrect or perhaps just interpreting the described fictional situation differently? After all, nothing in the statement of Fischbein and Schnarch's word problem as reported suggests that the hypothetical coin tossed by Ronni has to be considered a *fair* coin or that the way in which Ronni tosses the coin is not biased towards heads. As Gigerenzer (1991, 1996) has argued, probabilistic word-problems usually do not have only one correct answer over which there exists unquestioned consensus. It is true that often people's answers deviate problematically from the generally accepted norm. However, this discrepancy could be caused by the respondents' divergent interpretation of the situation presented to them (Chiesi & Primi, 2009, p. 152). How come that, we may in turn ask, the great majority of the students tested by Fischbein and Schnarch were keen to interpret the problem as involving a fair coin and a fair toss despite the information provided? According to the non-normative definition given above, we may also read these responses as manifestations of an equiprobability effect which we may also problematize. And what about the other responses? Unfortunately, Fischbein and Schnarch did not report on the participants' reflections and hence it is not possible to reconstruct their reasoning.

In this paper we address the following research question by means of a problem involving coin tosses analogous to the one employed Fischbein and Schnarch: *how do university students in mathematics reason about uncertainty?* We answer by means of an analysis of the students' written responses based on the definitions of recency and equiprobability effects given above. Furthermore, nuancing the students' reflections will give us the opportunity of discussing them in relation to their usage of acquired probabilistic concepts and ideas. Notice that our intention in this study is mainly descriptive: while we will discuss the problematic nature of many of the participants' responses, we will not attempt here to suggest any related pedagogical or curricular ameliorations.

Summary of relevant research

The study of Fischbein and Schnarch tested primary and secondary school students together with, as said, prospective teachers specializing in mathematics. Concerning the problem quoted above, the authors found that the negative recency effect decreases with age, while the positive recency effect is almost negligible. Normative equiprobability answers to this problem also increase with age. The authors hypothesized that their findings could be linked to the participants' education in probability. Rubel (2007) in turn tested various problems involving coin tosses on secondary students and analysed the justifications the participants gave for their responses (classified according to a belief framework). Overall, she showed that older children are not more subject to errors connected equiprobability and recency than younger children. However, she hypothesized that this could be due to the fact that the students she tested had only limited exposure to instruction in probability.

Chiesi and Primi (2009) tested primary school children and university students with problems involving drawing marbles with replacement from two bags. As to problems involving bags containing an equal number of marbles, they showed that the positive recency effect decreases with age while the negative recency effect increases and is found at remarkable rates in university students. The equiprobability effect linked to such questions also increases with age but is stable at a significant rate after Grade 5. When considering bags with different numbers of marbles, non-normative equiprobability answers were also remarkably chosen by university students. Furthermore, Morsanyi et al. (2009) enacted a cross-educational and cross-national study testing mainly university students in psychology with various problems involving uncertainty. They found that non-normative equiprobability answers are correlated to the participants' formal education in statistics. Overall, researchers have established an interesting link between the equiprobability effect (understood normatively as a bias) and education: the effect increases with age and is correlated to education in probability and statistics (Chiesi & Primi, 2009; Morsanyi et al., 2009; Saenen et al., 2015). In particular, Chiesi and Primi (2009) and Morsanyi et al. (2009) explicitly argued that the equiprobability effect could be a consequence or a "side-effect" of formal education.

These findings seem to echo insights from qualitative socio-cultural research focusing on word problems. These have suggested that many people approach word problems as activities reduced to the execution of some predetermined operations or algorithms without consideration of possible reality-constraints that might be implied by the problem itself and often neglecting their own everyday knowledge (cf. Verschaffel et al., 2020). Verschaffel and colleagues – surveying a large set of empirical studies mostly involving lower grades pupils – conclude that such conducts develop as a consequence of education in schools, which tacitly but systematically determines how students have to behave. Comparable conducts were reported by research on theorem proving testing both compulsory school pupils (e.g., Harel & Sowder, 1998; Paola & Robutti, 2001) as well as undergraduate students in mathematics (Stylianou et al., 2006): students seem to privilege justifications of mathematical theorems via ritualistic and/or authoritarian proof schemes, possibly as an effect of their years-long exposure to traditional teaching practices.

The present study

Participants

The participants are 84 students (34 males and 50 females of median age 24) of the course "Didactics of Mathematics 1" within the master's degree in mathematics at the University of Turin, Italy. This is a program focusing on advanced mathematics. Access to the program is conditional on holding a bachelor's degree in mathematics obtained with good proficiency from a recognized university. All the participants have passed at least one compulsory university course in probability and statistics (typically presented within an axiomatic framework). The following experiment was performed by testing two cohorts of students in two subsequent years with the same procedure involving a short computer-based questionnaire.

Procedure

The questionnaire was divided into two tasks requiring the students to work individually. The questionnaire was part of a larger written assignment which included a variety of mathematical questions and problems proposed to the students during the class as a test aiming to evaluate their general competence in solving mathematical problems. As to the questionnaire relevant for this study, each participant was presented with the following multiple-choice question:

Task 1

Sara tosses for ten times a coin and for ten times she obtains heads. Sara then asks to Piero to bet on the outcome of the next toss. Piero then bets five euros on the next toss resulting in heads again.
Do you agree with Piero's choice?

Yes No In part I am not sure

After the student submitted the answer, the computer immediately presented a related second task:

Task 2

Explain your reasoning.

The student could answer by submitting a text possibly containing mathematical symbols. The answers were automatically recorded by the computer.

Explanation of the choices

The possibilities provided in the multiple-choice question of Task 1 were selected as to allow the participants to nuance broadly their judgement concerning the fictional situation presented. We chose to proceed in this way in order to not necessarily force on the participant a yes/no answer, but rather to stimulate reflection over the problem in view of Task 2, the main focus of this paper. We leave a detailed analysis of the interrelations of the participants' answers to Task 1 and Task 2 to a subsequent paper. Task 2 in turn was formulated as an open question in order to offer to the participants opportunity for ample reflection in consideration of our research question. Overall, the problem was formulated as asking for a judgement towards a fictional decision-problem rather than as a problem of direct estimation of probability, likehood, or chance. This choice was made in order to induce in the participants a detached viewpoint towards the situation described and in order to avoid the difficulties of interpretation connected with most-likely/least-likely questions (cf. Rubel, 2007, pp. 533–534). Nonetheless, we hypothesized that the students would themselves refer to the possibility of estimating the outcome of a hypothetical 11th coin toss. Thus, we anticipated to be able to nuance the participants' reflections on the problem in relation to recency and equiprobability and in connection to acquired probabilistic concepts.

Method of analysis

For the present article we concentrate primarily on the analysis of the written responses to Task 2. Concerning the latter, we classified each answer according to a deductive coding procedure (cf. Braun & Clarke, 2006, pp. 83-84) based on the definitions of equiprobability and recency effects given in the introduction. Having found that the great majority of the participants articulated an equiprobability answer, we decided to further divide this category of answers into two groups (equiprobability with or without reservation). This choice was made in order to nuance whether the participant questioned equiprobability or else simply assumed it without problematizing it. More explicitly, we classified an answer as *Equiprobable tout court (Group A)* if the text argued without reservation that the outcomes of an 11th coin toss are equiprobable. On the other hand, we classified an answer as *Equiprobable with reservation (Group B)* if the text argued that the outcomes are equiprobable but explicitly expressed some reservation about it. We further classified an answer as *Heads is more likely (Group C)* or *Tails is more likely (Group D)* if the text argued that outcome of an 11th coin toss is more likely to be heads or tails respectively. Finally, we classified an answer as *Mixed (Group E)*, if the text did not conclusively favor any of the above options.

Results

Table 1 summarizes the participants' answers.

Table 1: the participants' answers to Task 1 and Task 2

	Group A Equiprobable tout court	Group B Equiprobable with reservation	Group C Heads more likely	Group D Tails more likely	Group E Mixed	Empty	Total
Yes	3	1	6	0	0	1	11
No	14	13	0	3	0	0	30
In part	15	15	5	0	5	0	40
Not sure	2	1	0	0	0	0	3
Total	34	30	11	3	5	1	84

As to Task 2, we present each group of answers individually together with exemplifying excerpts from the submitted texts which were translated from Italian into English as literally as possible. In presenting the results we pay particular attention to the structure of the arguments expressed and to how these connect to probabilistic concepts and ideas.

Group A

The majority of the participants state that heads and tails are equiprobable without explicit reservation (34 participants). Indeed, most students state that it does not matter what Piero chooses, nor what happened in the first 10 tosses.

> The events of heads and tails are equiprobable. The fact that heads was the outcome […] does not determine a greater probability in the following event.

All the texts categorized in this group are structurally very similar. These students typically state the fact that the events are equiprobable as an unquestioned starting point of their reasoning. This is usually formulated as a statement of the logical-geometric properties of sample-spaces linked to idealized fair coins as described in typical textbooks in probability theory. Other information concerning the previous tosses is then simply dismissed in view of the assumed hypothesis of equiprobability or sometimes not even discussed.

Group B

A consistent group of participants similarly argue that the events of heads and tails are equiprobable. However, these students are careful to explicitly indicate that this depends on the assumption that the coin or the toss is not biased (30 participants). The equiprobability assumption is then given as an explicit (but questionable) hypothesis from which their argument develops. The option of the coin or the game being biased is usually briefly considered as a possibility at the start of the text but dismissed as a result of a deliberate argumentative choice in line with the usual assumptions underlying the practice of problem-solving in probability courses.

I started from the assumption that the coin was not rigged. The probability […] is the same […] independently from the previous results.

Interestingly, 5 participants explicitly characterize assuming the equiprobability hypothesis as the more "mathematical" way of reasoning.

Mathematically, the next toss is independent from the previous tosses.

Group C

A smaller group of students argues that an 11th toss is more likely to result in heads (11 participants). This is argued by deeming implausible that a fair toss involving a fair coin could land ten times in a row on heads. Remarkably, 4 participants express this as a contradiction between mathematical thinking and everyday thinking.

Mathematically the probability for each side is one half. However, since the outcome was 10 times heads, I think that the coin is loaded.

Thus, according to these students, "mathematically" the probability of obtaining head or tails is the same. Nevertheless, if we disregard this, then we can conclude that the coin is loaded.

Group D

Very few students state that an 11th coin toss is more likely to result in tails (3 participants). Interestingly, all these students justify this by giving a mathematical (unsound) argument. For instance, one student argues that if he bets on heads then

[…] Piero has only $1/2^{11}$ probabilities to win.

Group E

Some texts contain considerations on different conflicting aspects of the fictional situation, which they leave unresolved (5 participants). Among these, 3 texts contain reference to unsound mathematical arguments similar to those given by students in Group D.

Discussion

In summary, only a small number of participants shows the positive recency effect (Group C), while a negligible amount manifests negative recency (Group D). A large majority instead inclines towards the equiprobability solution (Group A and B). These results contrast with the findings on university students of Chiesi and Primi (2009) and align better with the results of Fischbein and Schnarch (1997). This happens possibly because the curriculum of studies of our participants is more similar to the curriculum of the students involved in Fischbein and Schnarch's experiment.

As to the participants who manifest the equiprobability effect, their answers show to be connected either directly or indirectly to their education in mathematical probability. The answers of those who do not problematize the equiprobability hypothesis (Group A) may be seen as resulting from applying it as an unquestioned assumption associated with the usual presentation of fictional situations involving idealized games of chance within mathematical textbooks or courses in probability and statistics. As to the students who are keen to problematize the equiprobability hypothesis (Group B and C), they nonetheless state equiprobability as (even explicitly) the more mathematically-proper assumption, i.e., as the assumption which is more appropriate to adopt in a mathematical context. Some of the students even describe an openly-perceived conflict between mathematical and everyday reasoning (a phenomenon also discussed by Rubel, 2007). In particular, positive recency answers and mathematical-probabilistic assumptions were rather presented by the students as conflicting (Group C). On the contrary, the participants who manifested negative recency (Group D) did so when trying to frame the problem in terms of mathematical probability. Given that these were a negligible amount against the total of the participants, we do not attempt to infer more general implications from this particular finding. However, it could be the case that a similar phenomenon is also at work in groups of advanced students in other disciplines who manifest negative recency more consistently (e.g., Chiesi & Primi, 2009).

Thus, we observed an overwhelming tendency by these university students in mathematics to deem the problem's coin to be fair despite indication that this should be the case and contrary to explicit evidence presented in the problem. The equiprobability effect (understood non-normatively) appears to be related to the participants' education in probability, in a way which resembles analogous phenomena reported by socio-cultural qualitative research on word-problems (Verschaffel et al., 2020) and on mathematical proving (Stylianou et al., 2006). Further research testing participants with different mathematical backgrounds using the same procedure would be needed to substantiate this conclusion. Additional research would also be needed to understand if the same students would give substantially different responses when asked the same or an analogous question in a different setting (e.g., in a non-educational setting) or presented by means of a more realistic procedure (e.g., by observing an experiment featuring actual coin tosses). More theoretical elaboration as well as further empirical data would serve in turn to illuminate the relationship between the equiprobability effect and the equiprobability bias.

In conclusion, we have shown how university students in mathematics reason about a problem involving uncertainty. The discussed connection between the equiprobability effect and instruction in probability may be in itself not surprising. Indeed, the equiprobability effect is in general the result of a sound mathematical axiomatization of uncertainty (cf. Gauvrit & Morsanyi, 2014). Some could even argue that the outcome of a formal education in probability should prompt equiprobability answers in all relevant cases. However, the way in which our participants answered show that many of them applied equiprobability as an unquestioned assumption, possibly as a result to concepts and definitions narrowly presented by textbooks and courses in probability and statistics (cf. Batanero, 2020, p. 685). This fact in turn may be problematized as contrary to a full critical understanding of situations involving uncertainty. What if the coin is not fair?

Communicating data exploration insights through posters – A preliminary analysis of primary students´ learning outcomes

Lisa Birk[1] and Daniel Frischemeier[2]

[1]Westfälische Wilhelms-Universität Münster, Germany; lisa.birk@uni-muenster.de

[2]Westfälische Wilhelms-Universität Münster, Germany; dfrische@uni-muenster.de

Since data and its representations have gained a significant role in our society, mathematics education has to adapt by finding ways of teaching students statistical literacy from primary school onwards. In a teaching unit that was designed as part of a bachelor´s thesis, students of a fourth grade (10 to 11 years old) were introduced to group comparisons with the help of TinkerPlots and asked to create posters on statistical mini-projects. This paper aims at providing first ideas for a framework for the analysis of such means of communication to understand what results the young students communicate and how they do so. The posters show that the primary school pupils already employ not only local perspectives but utilize more global views to interpret the data.

Keywords: Data exploration, group comparisons, poster presentations.

Introduction: The relevance of teaching statistics

Understanding statistics has become a highly relevant skill set in our times as data and its representations confront us daily. It is for that reason that we need to become literate with regards to what the data tells us and how to interpret it (English, 2014). This has led to the acceptance of statistics into school curricula, even as early as the primary level. In Germany, for instance, creating graphical representations of data and their interpretation are part of the curriculum (Hasemann & Mirwald, 2012). The United States, as well as Australia and New Zealand, have also introduced standards at the beginning of the century to ensure that these topics are covered obligatory at school (Ben-Zvi & Garfield, 2004). Hence, the need for teaching concepts and new insights into the understanding of statistics as part of a successful didactic approach to the field has become apparent. There is more and more research on statistical inquiries in the fields of mathematics education. Some fundamental ideas of statistics have been identified for instance by Burrill & Biehler (2011). Concerning reading and interpreting statistical displays, Friel et al. (2001) have developed a framework consisting of three different levels of understanding statistical representations of data and there is a variety of sets of recommendations to follow when designing a statistical teaching-learning environment (Garfield & Ben-Zvi, 2008). These conceptions are further supplemented with subject-unrelated approaches, for instance using design-based research as a method to develop theory and simultaneously successful teaching-learning sequences (Bakker & van Eerde, 2015). Another relevant aspect is the increasing interest in using digital tools when exploring data (Biehler et al., 2013) - they facilitate the creation of graphical representations in large and multivariate data, leaving more cognitive capacities to work on higher-level tasks such as interpreting the presented data (Garfield & Ben-Zvi, 2008). TinkerPlots is an adequate tool that also finds application in primary contexts and enables learners to realize also sophisticated statistical activities like group comparisons on a basic level (Konold, 2007). Therefore, a teaching unit has been developed that is grounded on the specific characteristics and requirements mentioned above (Schäfers, 2017). The goal of the teaching unit was that the young learners realize and conduct their own statistical (mini-)projects answering a statistical question that is derived from the students´ interests. This means that the young students experience all phases of the PPDAC cycle (Wild & Pfannkuch, 1999). Posters were created as a means of communicating results of the statistical project. In this paper, we take a closer look at the learning outcomes of primary school students and how they communicate their findings of data exploration in form of posters. The aim of this paper is twofold: it will (1) suggest first ideas for a framework to evaluate the learning outcomes which are communicated through the posters and (2) it will present first empirical insights on how primary school students´ communicate findings of their data explorations through posters. By working on these issues, we wish to contribute to the advancement of data exploration at a primary level and the communication of results and lay a possible groundwork for a deeper understanding of students´ learning processes in this particular field.

A teaching unit to develop reasoning about data in a primary school setting

The designed teaching unit aimed at promoting reasoning about data (in particular group comparisons) among fourth graders (10 to 11 years old) in a public German primary school and concluded in individually conducted statistical projects towards the end of the unit.

Methodology of the development of the teaching unit & design principles

The teaching unit was part of a design-based research project (Bakker & van Eerde, 2015) which creates theory on primary school students´ abilities to compare groups using TinkerPlots as a digital data analysis tool. In multiple cycles, the (re-)design of teaching elements, their theoretical foundation as well as their evaluation based on classroom experiments are combined to foster the interrelations between teaching practice and theory. The FUNKEN-model (Prediger & Zwetzschler, 2013) poses a similar approach focusing on the specifics of particular teaching contents. This teaching unit was conducted as the second cycle within a design experiment to develop local learning theories on group comparisons in primary schools and on supporting learning arrangements for this content. Building on the first cycle and its results, adaptations had been made on teaching materials concerning the group comparisons.

Research suggests certain design elements for developing statistical reasoning. Garfield and Ben-Zvi (2008) refer to them as *Statistical Reasoning Learning Environments* and argue in favor of, for instance, the use of real data, a focus on core competencies of statistics, utilizing digital tools, and an adapted form of assessment to develop and deepen students´ statistical reasoning. The teaching unit implemented these aspects - having students collecting their data on statistically relevant questions of interest to them, using TinkerPlots to explore real and multivariate data, and realizing statistical (mini-)projects with posters as learning outcomes that were used for assessment.

Data explorations and group comparisons as central topics in the teaching unit

Developing statistical reasoning is a central concern of teaching statistics. It is considered to be “the study of arguments that use statistics as evidence” (Burrill & Biehler, 2011, pp. 59f). This comprises understanding data and its possible representations, amongst other competencies (Ben-Zvi & Garfield, 2004). Graphs are graphical representations of data and therefore central to statistics. Friel et al. (2001) have differentiated between three levels of graph comprehension: *reading the data* as the ability to read the individual data (representations), *reading between the data* as the ability to understand and interpret relationships within or between different data sets and *reading beyond the data* as the ability to infer consequences and possible predictions from the represented data. It implies a shift from a rather local point of view towards a more global perspective which is based on interrelations and possible dependencies (Bakker & Gravemeijer, 2004). Group comparisons focus on more than one variable and investigate differences between groups defined by one of the variables (Konold, 2007). They are considered engaging, yet complex from an educational point of view. Group comparisons are closely connected to the idea of variation (Garfield & Ben-Zvi, 2008), which Burrill and Biehler (2011) defined as one fundamental statistical concept among others like representation. TinkerPlots can be used to support young learners to create graphical representations of data to facilitate the group comparison process. Even though it facilitates the drawing of the graph, it also stimulates the fundamental skills needed to create and understand the visual representations (Konold, 2007). Stacked dot plots and hat plots form the graph types that are employed by the tool and modal clumps are used as a possible means of comparison (Konold et al., 2002). Hat plots can be considered a more flexible form of a box plot as the crown can be regulated as to what percentage of the dataset it should enclose (Garfield & Ben-Zvi, 2008; Watson et al., 2008).

Poster as a means of communication in the teaching unit

Communicating (results) plays a central role in the mathematics classroom and is therefore regarded as a procedural competence within the German educational standards, also applying to the teaching of statistics (Sill & Kurtzmann, 2019). According to Wild and Pfannkuch (1999), communication is central to statistical tasks, and therefore included in their adapted PPDAC cycle within the phase of conclusions. For statistical classrooms, the aim is to foster communicational skills so that results can be summarized, more global coherences can be harnessed to interpret the data, and the context of data is considered (Peck, 2005). Posters are a possible way to communicate mathematical results and were used within the teaching unit as an assessment and a means to document the students´ learning outcomes. As posters are frequently used as means of communication, there are criteria to evaluate them by. For a contest, the ISLP has proposed a set of possible standards that focuses on the statistical contents of the posters (International Statistical Literacy Project, 2020). Selected important criteria include the interpretation of the collected data with regards to the statistical question, the integration of adequate graphical representations, as well as the portrayal of the collection of data. These standards will be included when evaluating the posters and proposing a possible framework for the analysis. Statistical representations such as graphs bear the opportunity to function as a means of communication themselves when being properly interpreted and understood (Friel et al., 2001). One challenge for young students is to verbalize their findings from data exploration, for instance in the context of group comparisons.

The contents of the teaching unit

The teaching unit on which this paper is based comprised ten lessons, each lasting 45 minutes. Students were introduced to the basics of statistics, the sub-processes involved in a statistical project, the use of the Software TinkerPlots as well as group comparisons (Schäfers, 2017). In the first part of the teaching unit (Lessons 1-3) the students are introduced to the first ideas of empirical and statistical work (getting to know about variables, learning about the PPDAC cycle as a means for structuring own statistical projects, collecting data, etc.). In the second part (Lessons 4-5) the students analyzed data about their class and learned, for instance, how to draw and read bar graphs. In Lessons 6-8, the students were introduced to the software TinkerPlots. Finally, in Lessons 9 and 10, the students worked on a statistical (mini-)project on their own, applying and testing said acquired competencies when working on individually developed statistical questions regarding group comparisons and presented their findings to their classmates via posters. More details on the teaching unit can be found in Frischemeier (2020). The posters were used as an opportunity to document the results of the data exploration and were to include a title, their statistical question as well as the results of their project answering their question.

An accompanying empirical study: Communicating results of a data exploration through posters

Research questions

Since the original research has suggested the validity of teaching group comparisons to primary school children (Frischemeier, 2020; Schäfers, 2017), the focus of this sub-project is to concentrate on how the learning outcomes of a data exploration are communicated through posters. It has led to the following research questions: What results of their own statistical (mini-)projects do fourth graders of a German primary school communicate through posters after 10 lessons on the foundations of group comparisons? In which way do they communicate their results of a data exploration through posters?

Data collection & participants

As the purpose of this article is to analyze the students´ learning outcomes and to present first ideas on a framework for further use within teaching arrangements like the one presented, we concentrate on the stage of conclusions within the PPDAC cycle (Wild & Pfannkuch, 1999). The students were asked to create posters in small groups to present their outcomes so that these posters were collected and will be used as the data to be analyzed. The posters consisted of a headline, a representation, and a box in which the representation was described and the statistical question answered. Twelve fourth graders of a German primary school (Ages 10 to 11) attended the lessons of the teaching unit. All of them had been introduced to data collection and presentation in grade three but there was no standardized test to pinpoint their prior knowledge on the acquired competencies or other skills that might help the statistical group comparison (Frischemeier, 2020).

Data analysis

To fulfill the purpose of this paper, a qualitative research approach was chosen for the sub-project. With the help of qualitative content analysis (Mayring, 2014), three dimensions were formed that serve as the basis for the proposed framework. They were derived from the current state of research on characteristics of group comparisons, graphical representations of data as well as pre-existing criteria on posters as a means of communication and the contents of the teaching unit. Therefore, the dimensions of special interest are (i) the statistical features included in the group comparisons (Frischemeier, 2019) and their level of abstraction, (ii) the levels of graph comprehension (Friel et al., 2001), as well as (iii) the components of a statistical project as recommended in the ISLP poster requirements (International Statistical Literacy Project, 2020). They function as the main points of interest to which segments of the texts and of the data material are sorted and then evaluated (Mayring, 2014). The coding manual as well as specific categories and sub-categories need to be further developed in a next step. Following the aim of this paper and the chosen qualitative approach, one poster will be analyzed exemplarily along the above-mentioned dimensions to give first insights into how results of a group comparison are communicated by fourth graders. The poster was chosen as a representative example of young students´ data exploration processes.

Results

A group of four students worked on the yellow poster which presents data on the shoe sizes of all fourth graders of their school. The goal was to find out whether the boys on average have larger feet than the girls. 77 pupils were questioned, 37 of them female and 40 males.

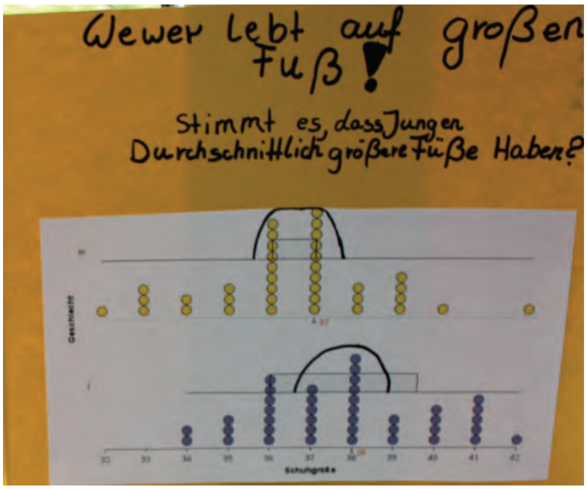

Figure 1: Headline and statistical display of the Data poster "Wewer lives on a large foot" [in German] from the group *Yellow*

Group Yellow: Wewer lives on a large foot! Is it true that boys on average have larger feet than girls? The fourth graders of the Almeschule in Wewer (Germany) were asked which shoe size they had. Among the girls, the smallest shoe size was 32 and the largest 42. Among the boys, the shoe sizes are closer together. Here, the smallest shoe size was 34 and not 32 like among the girls. The largest shoe size is 42, just like among the girls. Many shoe sizes of the boys accumulate at shoe sizes 37, 38. Among the girls, there is an accumulation at shoe sizes 36,37. Among the boys, the brim is slightly shorter than among the girls. But the crown is longer. Among the girls, it is the other way around. Here the brim is long and the crown is short. The median provides a center value of the distribution. The median of the girls is 37 and the median of the boys is 38. The center value of the girls is, therefore, smaller than the one of the boys. This means that the boys on average have larger feet. These results of the survey show that boys on average have larger feet.

To answer their statistical question, the students compared the maximum and the minimum of the distributions, argued with the help of the median as well as the components and positions of the hat plots. Furthermore, they considered modal clumps as accumulations of data with a certain value. Even though local characteristics such as the maximum as well as the minimum are considered, the most reliable source of information to the group is the median. It is misinterpreted as the arithmetic means of the distribution and articulated with the word "average" ("The median provides a centre value of the distribution […]. The centre value of the girls is, therefore, smaller than the one of the boys. This means that the boys on average have larger feet."). As crown and brim of hat plots are based on ideas of the spread of the middle half of the distribution, they are understood to be rather global. Since they are taken into account, it can be deduced that the group of students has succeeded in working towards a more global view on data even though some characteristics of the groups such as differing group sizes were ignored. Regarding the levels of graph comprehension, the students prove that their understanding exceeds *reading the data* as more global features such as the median are employed to answer the statistical question ("The median provides a centre value of the distribution. The median of the girls is 37 and the median of the boys is 38. The centre value of the girls is, therefore, smaller than the one of the boys. This means that the boys on average have larger feet."). In addition, as two datasets are compared based on relationships within each distribution, we can assume that our young students show the ability to *read between the data* ("Among the girls, there is an accumulation at shoe sizes 36, 37. Among the boys, the brim is slightly shorter than among the girls. But the crown is longer. Among the girls it is the other way around. Here the brim is long and the crown is short."). As no consequences or further deductions are proposed, the third level of *reading beyond the data* may not be attested at this time. The poster as a means of communication presents a title, the statistical question in form of a hypothesis, a graph that visualizes the distributions, the corresponding hat plots, and manually added modal clumps with labels for the axes (Figure 1). The text box gives information about the participants, which insights the group gained, and how they concluded that it is true that the boys have larger feet than the participating girls on average. Regarding the components of the poster (as suggested by the ISLP poster competition criteria), it only lacks in the sense that the method of data collection is not explicitly mentioned as well as a clear connection between the chosen title of the poster and the statistical question fails to appear. Although some minor mistakes were made mathematically, the group used appropriate means to compare the groups and to answer their question. In conclusion coherence between the interpretation of the data and the research interest can be attested.

Conclusion

Teaching statistical group comparisons in primary school settings with the help of digital tools such as TinkerPlots can be successful. Of special interest for this paper are the communicative means that the students employed. This paper has therefore shown first empirical insights into how primary students´ learning outcomes in form of posters can be analyzed based on fundamental concepts of statistics education as well as standards on statistical posters that might function as the grounds for a framework. One main concern is the shift from a rather local view to a more global perspective on the represented data (Bakker & Gravemeijer, 2004) which can already be seen on the posters. To communicate their findings, students use statistical properties of the data by expressing them verbally and also visually within the graph. Further research must be conducted on how students come to said learning outcomes, complementing the analysis of products with interviews to create an understanding of learning processes as well. In the next steps, the implied framework will be developed further and is supposed to be supported by a coding manual including exact definitions of categories with their sub-categories and examples to strengthen the comparability of the results. It should then also be applied to the other posters derived from the teaching unit as well as a generally bigger sample size to be able to advance the framework. Furthermore, the use of gestures and facial expressions as means of communication should be taken into consideration for a more in-depth analysis of the students´ presentations. As the teaching unit was part of the second cycle of a design experiment, further adaptations have to be made based on classroom experiences and student interviews to promote the development of local learning theories on group comparisons and reasoning about data as well as the advancement of supporting teaching-learning arrangements.

Learning opportunities for pre-service teachers to develop pedagogical content knowledge for statistical inference

Per Blomberg[1,2], Per Högström[1] and Yvonne Liljekvist[2]

Recently, researchers have encouraged the teaching of statistical inference to students at all levels. However, what constitutes pre-service teachers' pedagogical content knowledge for statistical inference has not yet been given specific attention in research. This paper presents a qualitative study of pre-service teachers participating in a collaborative learning setup in a mathematics course to be prepared for teaching statistics in primary school aged 6–10 years. The study reported here is the first cycle of a design research project. The findings show that pre-service teachers' learning opportunities regarding pedagogical content knowledge for statistical inference are insufficient. Based on the initial results, an initial conjecture map was constructed that guides the forthcoming design cycle.

Keywords: Content representation, design research, pedagogical content knowledge, pre-service teachers, statistical inference.

Introduction

Informal statistical inference (ISI) (Makar & Rubin, 2009) is often considered an essential ability of statistically literate citizens and the root of understanding formal inference (Biehler & Pratt, 2012). Much research focusing on ISI has been carried out with recommendations for powerful statistical ideas to introduce in primary school (Makar & Rubin, 2018). Despite prevalent international research findings, ISI has only made breakthroughs in the primary school curricula of a few countries. Therefore, researchers have called for ISI to be explicitly included in school curricula and teacher education (e.g., Langrall et al., 2017). However, in teacher education, limited time is spent on statistics. Thus, we need to learn to endorse ISI pedagogical knowledge for pre-service teachers through well-designed and effective arrangements (de Vetten et al., 2018). In line with Makar and Rubin (2018), we shift the focus from questions about what constitutes ISI to more knowledge of teaching statistical inference (SI) and design educational settings that provide prerequisites for pedagogical content knowledge (PCK) regarding SI.

Lehrer and English (2018) emphasised that children's informal reasoning about insecurity is formed both in and outside formal schooling. The same can be expected to apply to pre-service teachers, which makes it interesting to investigate the extent to which they pay attention to inference as a learning object in an existing learning environment. This paper presents the first cycle of a design research project (cf. Bakker, 2018), conducted in a mathematics course for pre-service teachers in Sweden. The design aims to provide knowledge to improve teacher education, from an educational setting focusing on statistical literacy to a setting supporting pre-service teachers' development of PCK for SI. We ask: How can a collaborative teaching strategy that mainly promotes statistical literacy skills support pre-service teachers' PCK for SI? Based on the findings, we propose an improved teaching strategy that is beneficial for developing pre-service teachers' PCK for SI.

Theoretical background

Statistical inference in statistics education

SI is usually associated with methods and concepts at the tertiary level, such as point interval estimates and hypothesis testing. By proposing a broader use of the term inference and making inferential reasoning available to all ages, Makar and Rubin (2009, p. 85) identified three key principles of ISI: "(1) *generalization*, including predictions, parameter estimates, and conclusions, that extend *beyond describing the given data*; (2) the use of data *as evidence* for those generalizations; and (3) employment of probabilistic language in describing the generalization, including informal reference to levels of certainty about the conclusions drawn". Acting on these principles can direct teachers' attention to children's abilities to communicate probabilistic predictions and generalisations from data. For example, Shaughnessy (2019) proposes a learning trajectory for the early years where children are initially encouraged to explore the use of statements such as 'likely' or 'unlikely', and thereafter propose and justify conclusions and predictions based on data, followed by designing studies for further investigation. Furthermore, Makar and Rubin (2018) acknowledge the *integration of contextual knowledge* and *consideration of the aggregate* as having key roles in making inferences. The proposed broad approach aligns with frameworks such as *data modelling* and the *statistical investigation cycle*, all of which incorporate the importance of teaching the overall picture of a statistical investigation rather than divided parts (Lehrer & English, 2018).

Several frameworks have been developed to describe a statistical investigative process. Findings from prior research (e.g., Blomberg, 2015) suggest that *data*, *distribution*, and *inference*, each associated with the earlier phases, constitute the core of statistics in education at all stages, including younger students. At the school level, the GAISE Pre-K–12 Report (Bargagliotti, 2020) proposes a model of four components: 1) Formulate Statistical Investigative Questions; 2. Collect/Consider the Data; 3) Analyse the Data; and 4) Interpret the Results. In line with Shaughnessy (2019), we consider distribution and inference to be the heart and soul of statistics. When composed into a somewhat simplified format that we believe can serve pre-service teachers who are to teach younger children, a statistical process follows three phases: data generation (e.g., problem context, statistical question, collect and organise data), analysis (e.g., use appropriate displays to represent data, distribution, variability, expected value), and communication (e.g., inference, generalisation, based on data, with uncertainty). To summarise, for students of all ages to have access to the aforementioned desirable inferential ideas, pre-service teachers not only need content knowledge of statistics, but they also need PCK for SI. What constitutes PCK and how to measure PCK for SI in teacher education are presented in the following section.

The quality of pre-service teachers' pedagogical content knowledge

Since the introduction of PCK (Shulman, 1986), the concept has been interpreted and operated in various ways in different research domains. The resulting theoretical diversity of PCK models motivated Carlson and Daehler (2019) to develop a refined consensus model (RCM). In addition to *content knowledge, pedagogical knowledge, knowledge of students, curricular knowledge,* and *assessment knowledge*, this model also considers *collective* (*cPCK*), *personal* (*pPCK*) and *enacted* (*ePCK*) as aspects of teachers' professional knowledge. To shed light on how to support pre-service teachers' development, the RCM of PCK is expected to contribute to situating the research and identifying elements to study. Based on the RCM of PCK, Chan et al. (2019) suggested a framework for measuring the quality of teachers' PCK. The framework consists of the following five key components: 1) selection and connection of big ideas, 2) selection of instructional strategies and representations, 3) recognition of variations in student understanding, 4) integration between PCK components and 5) pedagogical reasoning. These PCK components are not intended to constitute a fixed framework but are rather open to adaptation within different contexts. Thus, they are flexible enough to measure the quality of different variants of pre-service teachers' PCK, such as what a group of pre-service teachers knows, what a single pre-service teacher knows and does, and expressed pedagogical reasons for judgement and action.

Methods

Context and participants

The RCM model of PCK centres around the teacher's ePCK, which can be characterised by planning, carrying out that plan and reflecting on instructions and student outcomes. However, in this study, the pre-service teachers' reports did not include an enacted teaching context with students in schools. The empirical data occurred when groups of pre-service teachers planned and reflected upon a hypothetical teaching situation. Thus, this study falls within the realm of cPCK, which is considered a result of transformations of pre-service teachers' pPCK in a learning context in which pre-service teachers initially individually reflect and thereafter collectively reflect and plan. As the study was conducted during the COVID-19 pandemic, a remote teaching setup was used. Lectures and group work were conducted online in digital meetings.

The participants in the study came from one class in teacher education that focused on becoming a teacher for students aged 6–10 years. The participants studied a course in mathematics, including statistics, during the second of four years of study. The class consisted of 62 pre-service teachers, 33 of whom signed an informed consent form to participate in the study. The mean age of the participants was 29 years, with a standard deviation of 7.7 years. The research project has been ethically reviewed and approved by the Faculty of Health, Science and Technology at Karlstad University.

Design, data, and analysis

The teacher educators have been involved in planning and evaluating the study's design and have provided significant knowledge of the inherent possibilities in hypothetical learning trajectories and design conjectures (Bakker, 2018). Hence, a research model was developed that matched the purpose of the study and the teacher educators' planning. The teaching of statistics was carried out in six steps over two weeks. The learning objectives with these six occasions can be summarised as emphasising statistical literacy, developing statistical thinking and conceptual understanding rather than knowledge of the modelling process and procedural skills. Teaching statistical literacy emphasises statistical knowledge and skills in contextual settings and the need to critically evaluate studies and reports based on statistics and to communicate critical ideas (Sharma, 2017). Such an approach calls for developing pre-service teachers' ability to plan, enact and evaluate teaching-learning settings that focus on developing skills to evaluate statistical studies' quality and findings rather than practical skills that come with performing studies.

The six occasions are briefly depicted next: 1) A homework assignment that consists of reading and performing tasks in teaching material on probability and statistics for teachers. The learning content consists of basic concepts from the descriptive statistics such as mean, median, mode, range, boxplot, and how to compile and represent data with different types of diagrams. In addition to a short section that addresses the challenge teachers face in choosing an appropriate activity for teaching statistics, the teaching material includes no more than a short repetition of what the pre-service teachers have encountered in primary and secondary school. 2) A lecture, which highlights the purpose of statistics in teaching and in everyday life; descriptions of the subject and central concepts (as mentioned above, reliability and validity), drawing on practical examples. 3) A homework assignment involving individual work of self-selected statistical material and reflections based on support questions from the teacher educator. One question concerns inference: "In what way can conclusions be drawn (generalise, predict, etc.) and with what certainty do you think it can be done?" 4) Group work: The participants in the study were randomly divided into 11 groups, with 3–4 members in each group. Each group chooses one of the group members' self-selected statistical materials from the third occasion. Each group completed a description of the content in a hypothetical teaching situation covering three big ideas for teaching statistics for students aged 6–10 years, supported by a so-called *Content Representation* (CoRe) (e.g., Hume & Berry, 2011). A CoRe is a template for teachers to portray big ideas of concepts and skills related to a particular topic with answers to critical pedagogical challenges. 5) Each group presents their planned teaching situation by recording a video. Finally, 6) Group work: Each group compiles written feedback for three films.

This study focuses on data materials from occasion four, the pre-service teachers' CoRes, compiled in groups. Using CoRe as a reflective tool can transform teachers' tacit pPCK into explicit cPCK (Alonzo et al., 2019). Therefore, the knowledge expressed in a CoRe that was put together by a group of pre-service teachers represents their cPCK (Carlson & Daehler, 2019). A *content analysis* approach was used in this study (Robson & McCartan, 2016). The analysis used the five key PCK components (Chan et al., 2019) as operationalised categories. Within each of these components, the pre-service teachers' written outcomes related to statistical conceptual ideas were identified. Our focus was on identifying content related to inference. The first author of this paper is responsible for the analysis. To ensure validity, the findings have been discussed with both teacher educators and co-authors.

Results

The first key PCK component concerns the selection, connection and coherence of big ideas. In total, the 11 groups proposed 29 big ideas. To get an idea of the pre-service teachers' knowledge of big ideas in statistics, their stated outcomes of big ideas were interpreted and placed in one of the following five categories and their accompanying distribution and examples of the stated big idea followed by the expected learning outcome: 1. Data (10): "How to measure and compare data – To be able to formulate a question to be able to find out a specific matter", "With the help of statistics, you can find out various questions", "Statistics is a collection ... – Collection is an important process; it is important for students to get an understanding of who to ask or what to look for", 2. Analysis (9):

“Interpret – reading the diagram”, “The bars represent data – To be able to create bar charts after collected data”, “Analyse – comparison of the data presented in the diagrams”, 3. Communication (0), 4. Critical (1): “Statistics can be misused and misunderstood - All available statistics should not be trusted. It is important to be critical of sources”, and 5. Other topic (9): “Stress – We think that students should learn that stress can be both positive and negative depending on how you deal with it”, “Risks with an increased use of the Internet”, “Values – We want our students to gain knowledge about the Convention on the Rights of the Child”. Summing up, the analysis of the pre-service teachers’ CoRes showed that most of their stated big ideas connected to data generation, followed by analytical skills and other topic. One group stated a critical approach to statistics and no big idea was qualified in the category of communication.

The second key PCK component, teaching strategies, highlights the selection of instructional strategies and representations regarding the stated big ideas. Several groups suggest a modelling approach, meaning that students conduct their surveys and create diagrams. Furthermore, we can see traces of outcomes of PCK for teaching statistics, such as starting from everyday questions and showing examples of statistics that can be interesting, showing films about statistical investigation and practicing interpretations and comparisons of existing diagrams. We also note some outcomes of general pedagogical ideas, such as individual work, classroom discussions and a combination of these (individual-pairs-all), without relating to statistics.

The third key PCK component, students’ understanding, draws attention to a student-focused classroom climate based on the individuals’ knowledge and recognises the variation in students’ learning. In addition to activities that engage students’ interests, it is also desirable to uncover their thinking. Overall, pre-service teachers identify a wide range of student-focused factors that affect their teaching ideas at a general level. Raised challenges are, for example, different levels of students’ preconceptions, language difficulties, lack of interest and unproductive attitude. Pedagogical ideas to address these issues were, for example, conducting investigation, diagram creation, presenting these to each other, making comparisons and discussing each other’s presentations. When it comes to outcomes regarding inference, there are no traces of possible difficulties that students may have.

In the fourth key PCK component, integration between PCK components, attention is drawn to the teachers’ ability to plan the next teaching step and adapt this to how the students have received teaching. Since the study does not include a context in which pre-service teachers practice teaching, it is impossible to infer anything about their adjustment skills within this component. However, based on existing data, it is possible to identify pre-service teachers’ presumptive ideas about obtaining students’ learning big ideas and adjusting teaching practices. For example, some groups expressed ideas about controlling how students design, interpret, and analyse diagrams.

The fifth key PCK component, pedagogical reasoning, focuses on pedagogical issues as a teacher’s ability to justify decisions and actions within a teaching situation. Supporting questions in the CoRe evoked pedagogical reasoning and thus became applicable as an empirical basis for this fifth component. The arguments for the selected ideas are anchored in the importance of being a competent consumer of statistics. It was seen as important that the students understand the purpose of using diagrams and being critical of the statistics presented to them. Some stated the importance of students engaging with an investigation, compiling diagrams and interpreting and drawing conclusions based on the results. Both teaching methods and the arguments behind these choices vary. Some groups highlighted the importance of motivating students to learn and suggested using up-to-date social issues and topics that were close to the students' interests. Others mentioned teaching methods such as classroom discussion to introduce students to making interpretations and conclusions and equal collective understanding to reduce the variation in students' knowledge in the classroom. In addition to these outcomes of reasoning, most of the pedagogical reasonings was inadequate or missing.

Conclusion and discussion

Regarding the implications and limitations of the study, we would like to draw the reader's attention to the fact that the study should not be regarded as an isolated case study but as a first sub-study of design research consisting of several iterative studies (Bakker, 2018). The study was conducted in a specific context that limits the generalizability of the results to similar conditions. The study was also limited to one group of students who carried out all work during remote teaching due to the pandemic. The dropout rate was 47 %, most likely due to the pandemic.

Regarding the question of how the collaborative teaching strategy promotes pre-service teachers' PCK, we see, with the support of Carlson and Daehler (2019), that when students in groups plan to teach and then assess each other's work, they are offered the opportunity to exchange knowledge from pPCK to cPCK and back to pPCK on several occasions. In addition, students acquired professional knowledge bases such as content knowledge about statistics and curriculum knowledge via the internet. The results from the study depict a somewhat fragmented picture of the pre-service teachers' knowledge about big ideas in statistics education as emphasised by Shaughnessy (2019). The pre-service teachers' outcomes regarding inference in accordance with Makar and Rubin's (2018) ideas are almost non-existent. However, there is a clear emphasis on compiling and organising data, interpreting data, and being statistically literate. It is noteworthy that the setting triggered nearly half of the participating groups to choose topics from statistical contexts, separate from statistics, as big ideas. Indeed, *knowledge of the problem context* is a central conception in statistics education, and the stated big ideas, which were identified as statements about societal issues, are relevant to students. However, in this learning context, statistics was the subject of focus. Therefore, the results indicate that learning objectives for statistics are partly outperformed by learning objectives for other topics. Based on these results, we infer that a statistical literacy approach to teaching does not provide satisfactory outcomes in pre-service teachers' PCK for SI. Therefore, we suggest a draft of a conjecture map (Table 1) to guide the next cycle.

In accordance with Lehrer and English (2018), our suggestion for an improved strategy for high-level teacher educators with high-level conjecture is to emphasise a more explicit focus on practicing data modelling and highlight what characterises SI in education. We choose to complement the design conjectures of existing tools (e.g., CoRe) and participant structures (collaborative learning) within the embodiment of putting the conceptual framework of ISI modelling into practice. The design includes a lesson plan in which the development of content knowledge encompasses PCK. Our ideas of theoretical conjectures, meaning the produced desired outcomes from the mediating processes, include appropriately emphasising inference as a big idea, describing its key principles in accordance with Makar and Rubin (2009), and connecting inference to other core statistical conceptions such as data generating and distribution. Furthermore, according to Table 1, we suggest a designed mediating process that produces outcomes for how SI can be made teachable for the age group in focus, as well as pedagogical reasoning for selected teaching methods at both class and individual levels. The initial conjecture map presented in Table 1 will guide the forthcoming design cycle of our design research project. The plan is to carry out a second-phase study at the end of 2021. We intend to present preliminary results from the forthcoming study at CERME 12.

Table 1: Conjecture Map - Statistical Inference Modelling Teaching

High-level conjecture	Embodiment/design	Mediating processes	Pre-service teachers' outcomes
Conceptual framework of ISI modelling in education, and cPCK can contribute to pre-service teachers' ability to plan and reflect on teaching SI appropriate for a particular age.	• Putting ISI modelling into practice. • Completing a CoRe. • Planning for a hypothetical lesson or lesson sequence in statistics. • Using peer review. • The development of content knowledge encompasses PCK. • Collaborative learning as a participant structure.	• Experiencing ISI modelling cycle. • Identifying inference as a core concept and its connections to other big ideas in statistics education. • Expressing in speech and writing about planning for SI modelling teaching. • Reflecting in writing on other students' video presentations.	• Describing inference as a big idea together with other big ideas and concepts in statistics education. • Specifying how SI can be made teachable for the age group in focus. • Arguing for selected teaching methods at class and individual levels.

Evaluating the risk of a hypothesis given some indicators for the hypothesis is a crucial example for conditional probability reasoning. Calculating the probability of a risk when a set of parameters (e. g. the so-called base rate, true- and false-positive rate) is given, is a task which is referred to as a Bayesian task, as it can be solved with the Bayes' formula. The conceptual understanding of a mathematical formula (and of Bayesian tasks more specifically) implies being able to reason about effects of changes in the given quantities. Based on the dimensions of the concept of functional thinking we propose to refer to this aspect as "Covariation" of Bayesian reasoning. However, hardly any studies have so far investigated Covariation in a Bayesian situation. In this paper we present a study in which participants are asked to reason about changes of the base rate and introduce a coding system with which their answers can be analyzed.

Keywords: Bayesian reasoning, covariation in Bayesian situations, statistics education.

Introduction

Evaluating Bayesian situations, i. e. the risk of a hypothesis (*H*) given some indicators (*I*) for the hypothesis, is important for experts from different fields (e. g. medicine and law) in everyday practice and a crucial part of conditional probability reasoning. The comprehension of Bayesian situations has so far almost exclusively been tested with the capability to calculate a probability for the positive predictive value (PPV), that is $P(H|I)$. This is a conditional probability indicating that a hypothesis H (e. g. a medical condition) is true, if an indicator I for the hypothesis (e. g. a positive test result in a medical test) is given. This probability can be calculated with the Bayes' formula when the base rate of the hypothesis $P(H)$, the true-positive rate $P(I|H)$ and the false-positive rate $P(I|\overline{H})$ of the indicator are given: $P(H|I) = \frac{P(H)\cdot P(I|H)}{P(H)\cdot P(I|H)+P(\overline{H})\cdot P(I|\overline{H})}$.

Summarizing the results of previous works (Binder et al., 2021; Böcherer-Linder et al., 2017; Böcherer-Linder & Eichler, 2017) of our ongoing research program, we argue that three aspects are necessary for a comprehensive understanding of a Bayesian situation: Being able to calculate one specific probability such as $P(H|I)$ in a Bayesian situation using Bayes' formula (we refer to this aspect as "Performance"), to assess the influence of changes of the given parameters of the situation (we refer to this aspect as "Covariation") and to discuss the result's impact (we refer to this aspect as "Communication"). While the aspect of Performance has been studied repeatedly, we are aware of hardly any studies for the remaining two aspects.

As part of a larger project we test and train all aspects of understanding a Bayesian situation (http://bayesianreasoning.de/en/bayes_en.html). In the training, participants learn to systematically combine two beneficial strategies, first representing the statistical information of the Bayesian situation in natural frequencies (McDowell & Jacobs, 2017) and second depicting the structure of the problem in a suitable visualization (e. g. Binder et al., 2020; Böcherer-Linder & Eichler, 2019; Khan et al., 2015). In this paper we present insights from a study which was conducted in preparation for designing these trainings. Thereby, we focus on the aspect of Covariation which we regard referring to the medical situation similar to the one shown in figure 1.

<table>
<tr><td colspan="2">Example for a medical diagnostic test: $P(H) = 0.1, P(I|H) = 0.8, P(I|\overline{H}) = 0.1$</td></tr>
<tr><td>Representation of the statistical information in form of natural frequencies:
100 out of 1000 people are infected.
80 out of these 100 infected people receive a positive test result.
90 out of the 900 uninfected people mistakenly receive a positive test result.
Calculation of the positive predictive value (PPV):
$$P(H|I) = \frac{80}{80+90} \approx 47\%$$</td><td></td></tr>
</table>

Figure 1: Example for the two beneficial strategies representing the statistical information with natural frequencies and depicting the situation in a visualization, here the unit square

To the best of our knowledge, Covariation as an aspect of Bayesian problems has only been tested once before (Böcherer-Linder et al., 2017). There, it was demonstrated that the effect of base rate change – that is, an increase or a decrease of $P(H)$ - is easier to understand with a unit square than with a frequency tree as a supporting visualization. Yet, this study does not shed light on the question why participants made mistakes and how they approached these questions.

Therefore, we want to provide an insight into first results of our study in which participants' reasonings for evaluating the change of the base rate in a Bayesian situation are analyzed. Our main question in this paper is: How can students' reasonings about Covariation (with a focus on a base rate change) in a Bayesian situation be categorized? In order to answer the question, we introduce a category system in this paper with which it is possible to analyze and cluster the level of different reasonings for evaluating the change of the base rate.

Theoretical Background

"It is believed that teaching students how to perceive formulas as covariational entities based on the provided context is essential. This skill can enable them to consider formulas as dynamic functions" (Sokolowski, 2021, p. 184). Even though this quote by Sokolowski has been formulated in the context of teaching physics, we argue that the covariational understanding of a function is equally important in conditional probability reasoning. We thereby refer to Borovcnik (2012, p. 21) who proposes "to investigate the influence of variations of input parameters on the result [i.e. $P(H|I)$]" aiming to strengthen a conceptual understanding instead of a more superficial numerical understanding of the concept of conditional probability and thereby of Bayesian situations.

Hence, we understand the Bayes' theorem not only as a formula but as a function that expresses the dependence of the posterior probability on three parameters. By appreciating Bayesian situations in the context of functions we combine two fields of mathematics education, i.e. statistical education with functional thinking. Consequently, we comprehend the central aspect of functional thinking, i.e. *Covariation* (Lichti & Roth, 2019), also as a part of Bayesian thinking. Covariation stresses the dependence of the independent variable on the dependent variable and the association between changes of both. A typical question for Covariation in the field of Bayesian reasoning is the following: "How does the positive predictive value $P(H|I)$ change when the base rate $P(H)$ increases/decreases?" In the following figure 2, it is illustrated in the unit square how the PPV is affected by an increase/decrease of the base rate.

Base rate	100 out of 1.000 (10%)	500 out of 1.000 (50%)
Unit square		PPV	$\frac{80}{80+90} \approx 47\%$	$\frac{400}{400+50} \approx 89\%$

Figure 2: Dependence of the PPV on the base rate illustrated in the unit square

Considering the effects of changes of the base rate is specifically important, as its influence often causes errors and misunderstandings when calculating the PPV (Kahneman & Tversky, 1982). For instance, in the situation of medical diagnostic tests (Fig. 1), very low base rates can cause a counterintuitive statistical phenomenon since in that case false-positive test results are more likely than true-positive test results and therefore the PPV is considerably low despite good test parameters (i.e. high true- and low false-positive rate). In such situations people tend to ignore the influence of the base rate which is called the "base rate neglect" (Kahneman & Tversky, 1982).

Analysing students reasonings about changes of the base rate can be significant in order to identify their conceptual understanding of the Bayesian situation. The SOLO-taxonomy of Biggs and Collies (1982) proposes a model with which it is possible to cluster the Structure of Observed Learning Outcomes (SOLO) into distinct levels. These levels differ with regard to the amount of (relevant) information which is used and linked to the cue in the students' arguments. Thereby, they distinguish five different levels of observed learning outcomes which can be applied to the teaching of various topics. We propose to apply the SOLO taxonomy by Biggs and Collis (1982) to the categorization of reasonings which are given about changes of the base rate in a Bayesian situation. In order to apply this model to tasks on Covariation, we identify what information is relevant for this task and thereby adapt the levels by Biggs and Collies to Covariation tasks in a Bayesian situation.

The PPV $P(H|I)$ in a Bayesian situation is calculated by $P(H|I) = \frac{P(I|H) \cdot P(H)}{P(I|H) \cdot P(H) + P(I|\bar{H}) \cdot P(\bar{H})}$ (Fig. 1). Thus, when reasoning about changes of the PPV it is necessary to consider alterations in both quantities representing the multiplied probabilities $P(I|H) \cdot P(H) = P(H \cap I)$ and $P(I|\overline{H}) \cdot P(\overline{H}) = P(\overline{H} \cap I)$ and then analyze their effect on the fraction (i.e. the PPV). Both quantities are dependent on the base rate. Illustrated in the unit squares in Fig. 2, one can see that the amount of infected people with a positive test result represented by $P(H \cap I)$ in the Bayesian formula increases with a higher base rate, whereas the amount of uninfected people with a positive test result represented by $P(\overline{H} \cap I)$ decreases when true- and false-positive rates stay the same. The relative increment of infected people with a positive test result (nominator) is higher than the relative increment of all people with a positive test result (denominator). Therefore, the PPV increases with an increase of the base rate. The different levels in the SOLO-model adapted to a Covariation task are described in figure 3.

Level	Description by Biggs & Collis	Covariation task in a Bayesian problem
Pre-structural	An irrelevant feature might be linked to the cue.	No explanation is given for the described relation between base rate and PPV or irrelevant consequences of the base rate change are described (e. g. on $P(\overline{H} \cap \overline{I})$).
Uni-structural	One relevant feature is linked to the cue.	The effect on only one of the relevant quantities ($P(H \cap I)$ or $P(\overline{H} \cap I)$) is considered or the effect of several quantities in the Bayesian situation is considered, but only one of them is relevant.
Multi-structural	Several relevant features are linked to the cue.	Both relevant quantities ($P(H \cap I)$ and $P(\overline{H} \cap I)$) are considered, but their relation to the PPV is not clearly spelled out.
Relational	All relevant data are considered and put into a conceptual scheme.	Both relevant quantities ($P(H \cap I)$ and $P(\overline{H} \cap I)$) are considered and their relation to the PPV is clearly spelled out.
Extended abstract	All relevant data are considered and subsumed in an abstract model.	A general model for the dependence of the PPV on changes of the base rate is generated.

Figure 3: SOLO model (Biggs & Collis, 1982) applied to Covariation tasks in Bayesian situations

In this study, we want to describe how we developed a coding system for the reasonings about Covariational tasks in Bayesian situations in order to classify them within these categories. Moreover, we will describe which further categories we inductively derived in order to code differences. Consequently, we will outline in the results section how the different levels of reasoning are distributed among preservice teachers, who were the subjects of our study.

Material and methods

Study design

Every participant answered five questions about a Bayesian situation such as the medical situation shown in Fig. 1. Thereby, we used two different Bayesian situations: one context about breathalyzers and another one about a mammography screening. The first task was always to a) calculate the PPV. The consecutive tasks were to determine how b) an increase of the true-positive rate, c) an increase of the false-positive rate, d) a decrease of the base rate and e) an equally large increase of the true- and the false-positive rate simultaneously affected the PPV. Answers were given in form of single choice questions with three options: the PPV i) decreases, ii) stays the same, iii) increases. Task a) was always the first one and task e) was always the last one. Tasks b) to d) were presented in a random order. Each participant was asked to give a reasoning for their choice of answer in one of the single-choice questions of b) to e). The answer to which a participant was asked to formulate a reasoning was chosen randomly. In the results section we only refer to the reasonings which participants have given for their decision of the effect of the base rate change.

Materials

Since visualizations and natural frequencies help to understand the influence of the base rate (Böcherer-Linder et al. 2017, also compare Fig. 2), we investigate how people reason about Covariation with the help of these two beneficial strategies (Fig. 1). As visualizations, we used a double-tree and a unit square which were more supportive in tasks of Performance than the simple tree diagram (Böcherer-Linder & Eichler, 2019) as we suppose that Performance is a prerequisite for Covariational tasks. Thus, the Bayesian situation was described with probabilities and also displayed in a visualization (unit square or double-tree) with frequencies.

Participants

230 pre-service teachers (181 females, 47 males, 2 unknown) participated in this study. They all study to become teachers in mathematics and another subject but for different age groups (e. g. some for primary school others for secondary school). They did not receive any prior training in stochastics. 60 out of the 230 participants were asked to give a reasoning for their answer to the single choice question about changes of the base rate.

Results

Developing categories for the data analysis

In this section we illustrate, how we coded the different reasonings and their belonging to the different levels of the SOLO taxonomy. Thereby, we refer to four exemplarily reasonings below. The initial question was: “Imagine: The probability that a driver is under the influence of alcohol is actually smaller than 10%. How does that affect the probability that a driver is actually under the influence of alcohol, if (s)he receives a positive test result in the breathalyzer?” After selecting if $P(H|I)$ increases, decreases or remains constant, the participants were asked to explain their choice:

Example 1: “The precision of the test is not changed by the description in the text.”

Example 2: “$0.1 \cdot 0.9 = 9\%$, *something smaller than* $0.1 \cdot 0.9 =$ *something smaller than* 9%”

Example 3: “As the number of people who are under the influence of alcohol decreases, the probability also decreases, that a positively tested person is also under the influence of alcohol. The nominator of the fraction decreases and the denominator stays the same. Thus, the result is smaller.“

Example 4: “Number of people under the influence of alcohol decreases, analogously 90% positive → less under the influence of alcohol and positive and number of false positively tested bigger. Denominator bigger and nominator smaller therefore result is smaller.”

First, we coded to which probabilities/quantities of the Bayesian situation the reasonings made a reference to. Example 1 refers to the true- and false-positive rate of the test (“precision of the test”), whereas examples 2 and 3 both refer to the quantity of true-positives (the numbers of the Bayesian context were chosen in a distinct way so we made this inference in example 2). In example 4 references to the quantity of true-positives and false-positives are drawn. However, in example 4 we can also observe that the conclusion for the denominator of the fraction for the PPV is wrong (i.e. it actually decreases as well). In total we observed six types of quantity-references (QR), some including further subtypes: no reference to any probability or quantity (e. g. "somehow seems logic", QR0), references to one or more probabilities of the test (e. g. true- or false-positive rate, QR11-QR14), references to one of the joint probabilities (e. g. true- or false-positives, QR21-QR22), references to two joint probabilities or joint events with only one of them being relevant (QR31-QR32) or both of them being relevant (QR33-QR34), description of a direct link between a decreased base rate and a decrease PPV without further explanation (QR40) and between a decreased base rate and an increased PPV (QR50). The types QR33 and QR34 differ only in their implications on the PPV: while both correctly describe the changes in the two joint probabilities, only QR34 draws the correct conclusions from it while QR33 doesn't. In figure 4 we display how we have assigned the different observed probability/quantity references to the levels in the SOLO taxonomy.

Level	Observed probability/quantity reference
No level	QR0 and QR50
Pre-structural	QR11-QR14 + QR40
Uni-structural	QR21-QR22 + QR31-QR32
Multi-structural	QR33
Relational	QR34
Extended abstract	No observations.

Figure 4: Observations of quantity/probability references in the different levels of the SOLO model

Apart from differences in quantity references we noted further differences and inductively generated additional categories to quantify these differences. First, we noticed a difference in the reference to the context of the Bayesian situation. While in example 2 there is no reference to the context at all, examples 3 and 4 refer to the specific context of the Bayesian situation. Example 1 refers to a more general context, as the "precision of the test" is just as suitable for the breathalyzer context as for the mammography context. Therefore, we differentiated between the connection of a rationale with a specific context with three codes: no context (C0), specific context (C1) and general context (C2). Second, we observed a difference in the representation of the described (changed or unchanged) quantities/probabilities. In example 2 only percentages are used, in example 4 percentages, references to a fraction and absolute frequencies are used. In example 3 probabilities, references to a fraction and absolute frequencies are used. For each reasoning we coded if each of the following types of representations was used (code 1) or not (code 0): probability (R1), percentage (R2), frequencies (R3), fraction (R4), proportion (R5), quota (R6) and size of an area in the unit square (R7).

Reporting the data within the categories

Two raters independently coded all 60 reasonings for effects of the base rate change with the coding system described above. We report inter-rater-reliability that was assessed for all categories described in a first attempt without further training. For the reference to the context Cohen's Kappa was 0.75 (95% CI: [0.59;0.9]) and therefore substantial. For each representation an interclass correlation coefficient (ICC) was calculated. The ICC for a quota as a representation was poor with an ICC of 0.381 (95% CI: [0.144;0.577]. Yet, the other representation types were coded with a good to excellent inter-rater-reliability with a range from 0.687 (95% CI: [0.528;0.8]) for frequency, to 0.92 (95% CI: [0.841;0.94] for proportions. For the quantity-representation the Cohen’s Kappa was 0.76 (95% CI: [0.63-0.88]). Overall, apart from the coding of the quotas as representation the inter-rater reliability seems satisfying. The results of the ratings of both raters are represented in figure 5.

	Context			**Representation**						
	no (C0)	specific (C1)	general (C2)	prob. (R1)	perc. (R2)	frequ. (R3)	frac. (R4)	prop. (R5)	quota (R6)	area (R7)
No level (25/20)	(12/11)	(11/9)	(2/0)	(13/8)	(6/5)	(6/1)	(4/2)	(2/0)	(3/1)	(2/0)
Prestructural (15/23)	(2/9)	(10/11)	(3/3)	(11/13)	(8/8)	(3/2)	(0/2)	(1/4)	(1/0)	(1/0)
Unistructural (18/15)	(1/1)	(15/14)	(2/0)	(10/9)	(10/4)	(9/11)	(3/1)	(2/0)	(0/0)	(1/1)
Multistructural (1/1)	(0/0)	(1/1)	(0/0)	(0/0)	(1/1)	(1/1)	(1/1)	(0/0)	(0/0)	(0/0)
Relational (1/1)	(0/0)	(1/1)	(0/0)	(1/1)	(0/0)	(1/1)	(0/0)	(1/1)	(0/0)	(0/0)

Figure 5: Number of Answers in each of the categories (rater 1/rater 2)

Discussion

Bayesian tasks have so far almost exclusively been studied as tasks of Performance. These tasks are known to be difficult and one of the assumed reasons for that is the base rate neglect, thus the cognitive error by which the influence of the base rate on the PPV is overlooked. We have introduced the concept of Covariation (which is an established dimension of functional thinking) to Bayesian tasks. With Covariation tasks in a Bayesian situation one can directly assess the participants’ ability to judge the influence of the base rate on the PPV. Asking for a reasoning of the given answer (as we did in this study) allows to qualitatively study the participants understanding of the Bayesian situation. The coding system which we have introduced in this paper can be of special help when teaching about Bayesian tasks, since arguments which belong to the different levels of the SOLO-model reveal different issues about the understanding of the Bayesian situation. For instance, students who reason according to the prestructural level clearly lack an understanding of the Bayesian situation itself as they are unaware of the relevant quantities which have to be considered in the particular Bayesian task. Therefore, they should revise the basics again (e. g. what sets and subsets are described in the situation and how can they be quantified and used to calculate the PPV). On the other hand, students whose reasoning belongs to the multistructural level are very well aware of the structure of a Bayesian situation. They might only need some support in how to argue about changes in a fraction. Thus, the coding system can help to tailor the support to the students’ needs. Moreover, it is evident, that the reasoning level in Bayesian situations is generally rather poor with 40 out of 60 students whose reasoning remains on the pre-structural level or cannot be assigned to either level. This observation confirms prior research about Bayesian reasoning in so far as Bayesian tasks have generally been shown to be considerably challenging and counter intuitive without any training.

A consecutive cluster analysis with the data derived from the coding system together with additional information from the study will reveal if and how the levels in the reasoning about Covariation coincide with other aspects (e. g. the capability to correctly calculate the PPV or the type of visualization which was used as a supportive tool). This will shed more light on how to successfully teach a conceptual understanding of conditional probabilities.

In order to foster the learning of mathematics, the teacher must be able to interpret and analyse the students' mathematical activity. This cognitive analysis competence allows the teacher to understand the processes of mathematical learning, to foresee conflicts of meanings and to establish different possibilities for institutionalising the mathematical knowledge involved. In this paper, we are concerned with assessing the initial knowledge and competence of prospective primary school teachers in order to analyse responses of primary school pupils when solving urn probability comparison tasks. Specifically, we are interested in analysing what degrees of proportional reasoning the prospective teachers identify in the pupils' answers. The results reveal the prospective teachers' limitations for correctly identify proportional reasoning, specially to discriminate additive and multiplicative comparison.

Keywords: Probability, proportional reasoning, specialized probabilistic knowledge, teacher's education, urn tasks.

Introduction

A critical issue in mathematics education research is to clarify the type of didactic-mathematical knowledge that mathematics teachers should have in order to develop their teaching work in an appropriate manner (Chapman, 2014; Mason, 2016). The mathematics education research community accepts that teachers should have a certain level of mathematical competence, that is, they should be able to perform the mathematical practices necessary to solve the problems that the curriculum proposes and to articulate them with the subsequent mathematical contents. Teachers should also have a specialized knowledge of the content itself, of the transformations that have to be applied to it in teaching and learning processes, and of the psychological, sociological and pedagogical factors, among others, that condition these processes. Although the analysis of pupils' thinking is considered one of the main tasks of mathematics teaching, identifying the mathematical ideas inherent to the strategies that a pupil uses during mathematical problem solving could be difficult for the teacher (Fernández et al., 2013). In this sense, several researches indicate that both pre-service and in-service teachers have difficulties to interpret the responses of primary education students when solving mathematical tasks involving proportional reasoning, as well as making action decisions based on how pupils seems to understand proportionality (Buforn et al., 2020; Fernández et al., 2013). These investigations concluded that further research is needed on pre-service teachers' didactic and mathematical knowledge related to proportional reasoning.

The aim of this work is to assess the knowledge and skills of prospective primary school teachers to interpret pupils' responses to probability comparison tasks, identify incorrect strategies and recognise proportional reasoning in their mathematical activity. We address the following research questions:

What do prospective teachers understand by proportional reasoning in the context of probability comparison tasks? How do they identify and use it to justify their assessment of pupils' solutions?

Proportional and probabilistic reasoning are strongly linked; both involve quantitative and qualitative analysis, establishing relationships, making inferences and predicting outcomes. The results will allow us to design, implement and evaluate training actions to develop these didactic-mathematical knowledge and skills in prospective mathematics teachers.

Previous research

Proportional reasoning, understood as the ability to establish multiplicative relationships between two quantities and to extend this relationship to another pair of quantities (Lamon, 2007), is an objective present in the Primary Education curriculum, which integrates both the various interpretations of the rational number (ratio, operator, part-whole, measure and quotient) and the ways of reasoning with these meanings (up and down reasoning, relational thinking, covariance, etc.). Proportional reasoning is "a form of mathematical reasoning that involves a sense of co-variation and of multiple comparisons, and the ability to mentally store and process several pieces of information. Proportional reasoning is very much concerned with inference and prediction and involves both qualitative and quantitative methods of thought" (Lesh et al., 1988, p. 93).

Extensive research has focused on investigating pupils' strategies and levels of proportional reasoning in the context of probability, mainly in the urns probabilities comparison setting (Bryant & Nunes, 2012; Cañizares & Batanero, 1998; Langrall & Mooney, 2005; Van Dooren, 2014; Watson, 2005). According to Falk et al. (1980), probability can be thought of as being composed of two sub-constructs: chance and proportion. Various researches in mathematics education reveal that both students and teachers have difficulties in applying proportional reasoning in statistical and probabilistic contexts (Gal, 2002). Specifically, the lack of proportional reasoning to solve elementary probability comparison problems is found not only in students, but also in prospective primary school teachers (Contreras et al., 2011; Gómez et al., 2016; Vásquez & Alsina, 2015). Begolli et al. (2021) suggest that "prior knowledge of proportional reasoning reveals deeper insights into students' potential for learning about probabilistic reasoning, than prior knowledge of the concept of probability itself" (p. 462). For this reason, it is essential that prospective teachers be aware of the different components of proportional reasoning and how they appear in probability.

Didactic-mathematical knowledge and competence model

The study of the type of didactic and mathematical knowledge and competences that teachers should have in order to manage the pupils' learning process has generated several models that intend to characterize such teachers' knowledge and competences (Chapman, 2014; Hill et al., 2008). In this research we adopt the teacher's Didactic-Mathematical Knowledge and Competence (DMKC) model (Godino et al., 2017) developed within the Onto-Semiotic Approach (OSA). The DMKC model considers that the teacher should have a *common mathematical knowledge* regarding a certain educational level where he/she teaches, as well as an *expanded mathematical content knowledge* that allows him/her to articulate the content with higher educational levels. In addition, as some mathematical content is put at stake, the teacher should have a didactic-mathematical or *specialized knowledge* of the different facets involved in the educational process: *epistemic* (institutional content meanings), *ecological* (aligning tasks according to institutional mandatory curriculum), *cognitive* (understanding student's thinking), *affective* (reacting to anguish, indifference, anger, etc., manifested by students), *interactional* (identifying and answering to students' conflicts and interactions), and *mediational* (choosing the best suitable resources for teaching). In the epistemic facet, the specialized knowledge allows the teacher to recognize the diversity of meanings involved, be able to solve the task using different strategies and justify the accuracy of the procedures. In the cognitive facet, the specialized knowledge guarantees the teacher being able to understand the ways of reasoning, difficulties and personal meanings that students may present when working with the specific mathematical situation. It makes the teacher competent to identifying possible different solution strategies in a probability problem, assessing students' responses and recognizing the mathematical objects involved. In particular, analyzing the proportional reasoning put at stake in the mathematical practices involved in their resolutions. This will provide teachers appropriate responses to real classroom situations.

Method

We performed a content and descriptive analysis of the written solutions to the problem in order to classify the responses into different categories building on previous research and refining these categories through a cyclical and inductive process; this is typical of qualitative research. This research was conducted with 116 prospective primary school teachers (PPT in the following) at a Spanish university. During their undergraduate studies, these prospective teachers received specific preparation on the epistemic, cognitive, instructional and curricular aspects of teaching statistics and probability. Specifically, the intervention was carried out once the training process of the PPTs on the main contents of Data Processing, Chance and Probability had been completed. This deals with the fundamentals of the Didactics of Mathematics in terms of the main concepts, properties and procedures that form the primary school mathematics curriculum, mathematical learning, errors and difficulties and instructional aspects (tasks, materials and resources) related to this content. The task (see Figure 1) was proposed to the PPTs to be solved individually and voluntarily. The written answers of the PPTs to this task were analysed using content and descriptive analysis methods.

Below you find a problem and some solutions to it developed by primary school pupils.

> In box A two white balls and two black balls have been placed. In box B there are 4 white balls and 4 black balls. In which box is there a greater chance of getting a black ball?
>
> Alba: "In box B because it has 2 more black balls than box A".
> Daniel: "The same, because in box B there are 2 more white balls, but there are also two more black balls".
> Lucía: "The same, because in both the white balls are half as many as the black balls".
> Salva: "The same because in box B the number of white and black balls has been multiplied by 2 compared to A".

Justify whether each pupil's answer seems correct or incorrect and identify proportional reasoning in the pupils' answers.

Figure 1: Task proposed to PPTs to assess the analysis of pupils' solutions to a probability comparison problem

To assess the cognitive facet of the PPTs' didactical-mathematical knowledge and competence, we proposed to the participants to analyse the correctness degree of different pupils' solutions to a probability comparison problem in urns, identifying the proportional reasoning involved or not, as a relevant mathematical element of pupils' mathematical thinking when solving this type of task.

Notice that Alba's answer is incorrect, as she only compares the favourable cases, which leads her to decide that in box B the probability of drawing the black ball is higher. To Daniel, the probability is the same, "because in box B there are two more white balls, but there are also two more black balls". Daniel compares in an additive way the unfavourable cases (white balls) and the favourable cases (black balls) of both boxes: as the difference between the unfavourable cases of both boxes and the favourable cases of both boxes is the same, two, he concludes that the probability of drawing a black ball in both boxes is the same. This argument is not correct, since it only leads to a right answer in the case where the number of favourable cases matches the number of unfavourable cases. In Lucía's solution, it is true that "if the number of unfavourable cases is the number of favourable cases multiplied by a scalar (in our case 2) the probability remains constant". However, it is not true that "in both cases the white balls are half of the black balls". It seems that Lucía confuses "unfavourable cases" with "possible cases". We note that Lucía uses a correspondence strategy (proportional reasoning) but the multiplicative relationship that she establishes in one urn to be extended to the other is not correct. Finally, to justify that the probability of drawing a black ball in both boxes is the same, Salva uses proportional reasoning: the probability, as the ratio between the number of favourable and possible cases (favourable plus unfavourable) remains constant if both the number of favourable and unfavourable cases is multiplied by a scalar.

Results

Of the 116 participants, 100 (i.e., 86.21%) considered Daniel's answer to be correct, but only 73 (62.93%) provided some conclusive justification. Table 1 shows that more than half of PPTs (50.86%) considered Lucía's solution to be right, however, just 24 (20.69%) of them gave a clear description of why the argument used by this student is appropriate. Of the 84 (i.e. 72.41%) PPTs who explained why they considered the solution given by Salva to be correct or not, 78 (67.24%) considered it to be correct and only 6 (5.17%) considered his argument to be inadequate (they believe that it is only valid in this particular case or that he should have relied on the use of Laplace's rule). In addition, two PPTs considered all pupils' answers to be correct, without justifying their assessment. These two PPTs were the only ones who implicitly considered Alba's solution being right, for which 106 (91.38%) PPTs justified her error.

Table 1: Frequencies (percentages) in the assessment of the correctness degree of pupils' responses

	Alba	Lucía	Daniel	Salva
No answer/Not conclusive evaluation	10 (8.62)	35 (30.17)	34 (29.31)	32 (27.59)
Pupil's solution correct	0 (0)	24 (20.69)	73 (62.93)	78 (67.24)
Pupil's solution incorrect	106 (91.38)	57 (49.14)	19 (16.38)	6 (5.17)
Total	116 (100)	116 (100)	116 (100)	116 (100)

In view of the interest of this paper, of the arguments used by PPTs to justify their assessment of primary school pupils' answers as correct or incorrect, we focus our attention on those evaluations that refer to the presence or absence of proportional reasoning (see Table 1). This will give us useful information about what prospective teachers understand by proportional reasoning in the context of probability comparison problems and when and how they identify it in the pupils' responses.

As we see in Table 2, eleven PPTs consider that comparing only favourable cases in an additive way shows an absence of proportional reasoning in Alba's strategy, which they interpret in the context of probability as the ability to establish a proportion, or to establish a multiplicative relation/comparison. For example, PPT41's answer:

PPT41: I have been able to identify proportional reasoning in pupils who think that there is the same probability due to the fact that the number of balls in one box is proportional to the number of balls in the other box. Error that Alba may have made is assuming that because there are more black balls in one box than in the other, there is a much higher probability of getting a black ball, regardless of the number of white balls.

Table 2: Reference to proportional reasoning in the PPTs' assessment of pupils' solutions

Student	Reference to proportional reasoning	Frequency
Alba	Lack of proportional reasoning (multiplicative comparison, covariation) as a cause of error	11
	Evidence of proportional reasoning understood as a "more, more" type comparison	7
	Evidence of proportional reasoning understood as an additive comparison	3
Lucía	Evidence of proportional reasoning (multiplicative relationship) leading to the conclusion that there is the same probability	31
	Inadequate or incomplete proportional reasoning (multiplicative relationship) as a cause for her error	10
Daniel	Proportional reasoning (proportion, equivalence of fractions) as a guarantee of successful response	19
Salva	Proportional reasoning (proportion, equivalence of fractions) as a guarantee of successful response	13
	Proportional reasoning (multiplicative relation, variation) guarantee of successful answer	26

Furthermore, we note that seven PPTs of the 106 that identify and justify Alba's answer as incorrect, identify proportional reasoning like a "more, more" type comparison. See for example, PPT52's answer:

PPT52: […] In Alba's solution, a proportional reasoning can be identified, since the student observes more balls in box B and therefore thinks that there is a higher probability of drawing one in this box.

Three other PPTs also identify proportional reasoning in Alba's incorrect answer, which they interpret as an additive relationship. For example:

PPT110: In Alba's answer we can notice some proportional reasoning, she has taken into account the increase of two balls in the black colour [...] That would explain her mistake, to have thought proportionally in only one colour.

Likewise, other participants contemplate that Lucía has an error due to the use of proportional reasoning when it was not appropriate ("the main error refers to using proportional reasoning when it was not appropriate to do so", PPT24). They consider that the most suitable strategy is to stablish an additive comparison. In this sense, the analysis of the PPTs' reports shows that several participants show inadequate knowledge of proportional reasoning because they consider it in terms of additive comparisons. That is the case of PPT18:

PPT18: We can say that proportional reasoning is found in the following three answers [referred to Daniel, Lucía and Salva], in all three the same amount is added or taken equally in the two boxes. There is the same probability in box A as in box B.

Furthermore, 22 PPTs points out that pupils correctly apply proportional reasoning when they understand and use relevantly the equivalence of fractions and employ it to calculate and compare probabilities. They consider this leads to success for Daniel and Salva in their response. For instance, PPT38:

PPT38: Regarding proportional reasoning, I identify it in two cases, Daniel and Salva, since both have taken into account the equivalence of fractions. Thus, they have observed that in box A there are 2/4 white and 2/4 black, while in box B there are 4/8 white and 4/8 black, which means that the probability in both cases is the same.

To 50 (i.e., 43.10%) of the PPTs, proportional reasoning is involved in those pupils' answers in which a multiplicative comparison is established (see Table 2). This is observed in the evaluations of Lucía or Salva:

PPT11: Lucía has reasoned that in box A, there are half as many black balls and half as many white balls as in box B. She aimed to say, in some way, that the quantity in one box and the other changes proportionally.

PPT45: Salva uses proportional reasoning because he says that in box B both black and white balls have been multiplied by two with respect to box A.

As we can see, PPT11 and PPT45 consider the multiplicative relation between the favorable cases (and unfavorable cases) of both boxes. Other participants look at the correspondence within each of the boxes to ensure the same probability. For instance, PPT38 considers "there is the same number of both white (2) and black (2) balls in box A and, also the same number of white (4) and black (4) balls in box B, so the ratio is maintained and the probability is the same".

In summary, we have noticed that, a high-rise percentage of prospective teachers consider proportional reasoning to be based on "more …, more …" relationships (these descriptions appear in 23.91% of the occasions in which PPTs identify proportional reasoning). Besides, even when some prospective teachers discriminate between additive comparisons and multiplicative comparisons, they do not always properly describe the multiplicative relationship, or the magnitudes involved in the proportionality correspondence. That is, they do not always correctly establish a multiplicative comparison between the ratios of favorable and unfavorable cases (or of favorable and possible cases) within both boxes, or between the ratios of favorable cases between the boxes and of unfavorable or possible cases between the boxes. Furthermore, some participants, consider that the establishment of a multiplicative relationship only between favorable cases or (also solely) between possible cases is sufficient to identify proportional reasoning and respond successfully to the task.

Implications for teaching and research

"The identification of the relevant mathematical elements in a problem and the interpretation of how they are present in the students' answers allow prospective teachers to be in better conditions to make relevant instructional decisions and help students develop their proportional reasoning" (Llinares, 2013, p. 81). Hence to interpret different pupils' solution to a probability comparison task by recognising how proportional reasoning is involved in their answers, can help to enhance prospective teachers' didactic-mathematical knowledge and competences (especially in the cognitive facet) regarding this topic.

Our results show the need to strengthen teachers' education in relation to the connection between proportional and probabilistic reasoning. Prospective teachers find limitations in identifying and justify possible erroneous strategies behind pupils' incorrect answers. A biased or insufficient knowledge of proportional reasoning could explain why PPTs do not identify it in the incorrect answers and when they do, they show errors when interpreting the proportionality relationship and the properties that characterise it (Burgos & Godino, 2021).

We think that our results provide additional valuable information for the design of materials in teacher education programs that consider the characteristics of prospective teachers' understanding of proportional reasoning in probability tasks. First, to guarantee that prospective teachers are able to recognize and respond to students' errors, teacher education programs should develop a deep understanding of the conceptual, propositional and argumentative components of proportional reasoning involved in probability setting. On the one hand, proportional reasoning is an integral part of probabilistic reasoning. But on the other hand, probability is an enabling environment for future teachers to overcome a limited view of proportional reasoning linked to solving missing-value problems. "Balancing the amount of probability instruction with proportional reasoning instruction may be more successful than teaching only about probabilities" (Begolli et al., 2021, p 463). Therefore, specific actions should be designed in teacher training to reinforce the structural components of proportional reasoning by integrating it with probabilistic reasoning.

Learning opportunities for statistical literacy in German middle school mathematics textbooks

Christian Büscher

University of Duisburg-Essen, Germany; christian.buescher@uni-due.de

The development of statistical literacy is an important goal for middle schools, where statistics education mostly takes place within mathematics classrooms. Here, textbooks provide the most important tool for many teachers, guiding the content of their lessons. However, little is known about the statistical content of middle school mathematics textbooks. This study reports on a qualitative document analysis of three German Grade 6 textbooks. The results show that a large majority of tasks in textbooks revolve around technical constructions of diagrams and calculations of measures. Less space is allocated towards more conceptually demanding tasks like interpreting models or analysing and reflecting statistical arguments. This implies that teachers need to actively adapt their textbooks in order to unlock the potential for developing statistical literacy of these textbooks.

Keywords: Statistics education research, statistical literacy, textbooks, document analysis, middle school.

Introduction

In recent years, researchers in statistics education research have elaborated the importance of statistical literacy for aspects of digitalization such as big data and machine learning (François et al., 2020). It is becoming increasingly clear that statistical literacy cannot be reduced to a skill of specialists, but rather will be important for every citizen in the 21st century (Wild, 2017). Therefore, the development of statistical literacy becomes an important task for middle schools.This is a challenging task, as in many countries, statistics is considered only a small part of middle school mathematics instruction, and only very limited time can be allocated to statistics (Zieffler et al., 2018). Although researchers in statistics education research have begun to address this issue, insights into how statistical literacy can be developed in middle schools are limited yet (Büscher, in press). Thus, teachers have to contend themselves with the learning opportunities for developing statistical literacy that are provided by their mathematics textbooks.

This makes mathematics textbooks an important object of study. The content of textbooks largely defines the content of mathematics classrooms, as content that is not included in textbooks generally is not taught in class (Stein et al., 2007). Textbooks need to provide teachers with the suitable didactical instruments for developing statistical literacy. This study aims to provide insights into the learning opportunities for statistical literacy afforded by middle school mathematics textbooks.

Theoretical background

Statistical literacy as selective and imaginative readings of statistical information

Statistical literacy generally refers to the ability to understand and to critically evaluate statistical information presented in everyday media like newspapers, articles, or infographics (Gal, 2002). Whereas earlier conceptualizations of statistical literacy mostly related citizens to the role of “data consumers” (Gal, 2002), researchers recently have emphasized that statistical literacy also requires the development of skills more in line with data producers (Weiland, 2017). In order to integrate the two perspectives of data producer and data consumer, this study conceptualizes statistical literacy as the two processes of *selective and imaginative reading of statistical information* (Figure 1, Büscher, in press). *Selective reading* refers to the process producing concise statistical arguments. During this process, selective activities reduce the available information (illustrated by the progressively smaller boxes in Figure 1): A phenomenon is *encoded* into data by selecting only certain aspects that are then quantified. The data are then *abstracted* into a model by mathematizing certain relationships within the data. Finally, the model is *interpreted* by combining some of these relationships with a claim about the phenomenon under investigation, resulting in a statistical argument.

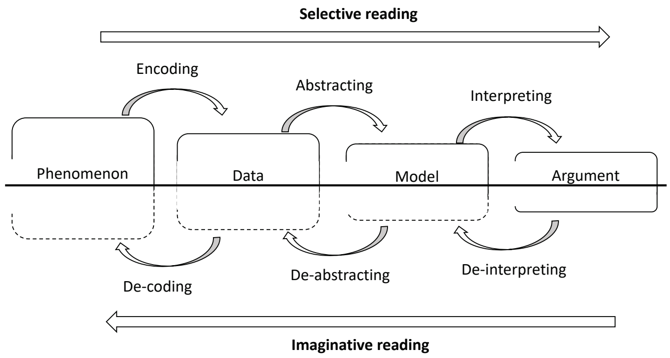

Figure 1: Statistical literacy encompasses activities of selective and imaginative reading

Crucially, a reader that is presented with a statistical argument in, for example, a social media post, likely does not have access to the underlying model or data. In order to critically evaluate the statistical argument, one has to revert the acts of selective reading through *imaginative reading* of what could have resulted in the argument (the dashed boxes in Figure 1). A statistical argument has to be *de-interpreted* to intuit the underlying model behind the argument, for example by guessing the type of measure of centre that an argument simply refers to as "average". Such a model only represents relationships in data, not the data themselves. The reader has to *de-abstract* from the model to imagine possible data behind the model, and what features of these data a median might or might not represent well. And finally, one has to recognize that the data only provide a quantified description of some aspects of the phenomenon that were obtained through certain methods of data collection. A *decoding* of the data might reveal important aspects that cannot be captured by the data. In this way, imaginative reading aims to discover possible causes and possible limitations of a statistical argument even if crucial information is missing.

This specification of the learning content of statistical literacy allows to decompose the larger construct into smaller activities that each can be the object of focused instruction. Instead of a holistic approach, teachers can create focused learning opportunities for each of the activities of selective and imaginative reading. This should not be taken as the claim that these activities should always be treated separately. Still, by identifying smaller activities, this conceptualization allows to identify the potential contributions to statistical literacy in many statistical tasks which are presented in textbooks.

Textbooks in statistics education research

Textbooks have a large impact on the enacted curriculum of schools, and Weiland (2019) proposes that this is especially true for statistics, where teachers have little prior experience. Thus, they might tend to adhere to the textbook more closely with statistics than with other subjects. In his study on United States high school textbooks, Weiland (2019) investigates what kinds of contexts are supplied in textbooks and how they are used. He finds that the contexts used "generally go no further than those typical of 'small talk', such as the weather, sports, personal preferences, or related to work or business" (Weiland, 2019, p. 32). He instead calls for textbooks to feature controversial socio-political issues to prepare students to be critical citizens. Tran and Tarr (2018) also investigate US high school textbooks, focusing on the complexity of the investigation of bivariate data in textbook tasks. They find that students are not required to formulate their own statistical questions, but are always given a fixed question in the tasks. Most of the time, students are provided with the data, which generally consists of fewer than 20 values and show no "messy" features like missing values. Thus, the textbooks provide little learning opportunities for organizing real, unstructured data.

Apart from these studies, not much research could be found that investigate the statistics content of textbooks. Under the statistical literacy perspective employed in this study, the existing studies suggest that the statistical arguments about contexts in the textbooks are uncontroversial, and thus might not motivate a deeper investigation of the sources of possible controversies through imaginative reading. Where selective readings are elicited, they are performed in a very fixed way, possibly emphasizing activities of abstracting over the more open activities of encoding and interpreting.

Research questions

A statistically literate citizen needs to be able to engage in activities of selective and imaginative reading. Textbooks need to provide teachers with suitable instruments to create learning opportunities for these activities. The little empirical knowledge available about textbooks suggests that textbooks might not be well equipped for this task, but further insights are needed. This study aims to provide a contribution by investigating the following research question:

(RQ 1) Which learning opportunities for activities of selective and imaginative reading are provided by German middle school textbooks?

(RQ 2) Which differences in learning opportunities exist between German middle school textbooks?

Method

Selection of textbooks

This study took the form of qualitative document analysis (Bowen, 2009). As a first step, relevant textbook series to be used in the analysis had to be selected. This proved a difficult task: In Germany, educational policy is a matter of the 16 federal states, which leads to variations in the mathematics curriculum and to state-specific textbooks. Additionally, textbook publishers generally do not disclose the market shares of their textbooks, so that little objective criteria exist for selecting textbook series for study. In the end, a theoretical sampling resulted in the selection of three textbook series. Two of these series, *Lambacher Schweizer* ("LS", Jörgens, 2009) and *Elemente der Mathematik* ("EdM", Griesel et al., 2014), are textbook series used in German middle schools tracked for academic education. According to the publishers' description of their teaching conception, both textbook series provide a clearly structured learning progression with possibilities for differentiation and an emphasis on exercises. These series were selected to allow the identification of possible differences in learning opportunities for similar teaching conceptions. In contrast, *mathe live* ("ml", Glöckel et al., 2014) is a textbook series for integrated middle schools that introduce academic tracking only in later school years. According to the publisher, the teaching conception focuses on exploring mathematics in real-life situations and on individual approaches to mathematics.

From each textbook series, only the textbook for Grade 6 was included in the analysis. This decision was made because the mathematics curriculum for Grade 6 includes a relatively large part of statistics in relation to other grades. Content includes the construction and critical evaluation of various diagrams as well as measures of centre, which are important models for a statistically literate citizen. Only the chapters focusing on statistics were included in the analysis, and chapters focusing on probability were not included. This resulted in a data corpus of 371 tasks.

Data analysis

For data analysis, codes were assigned to each task according to the activities of selective and imaginative reading elicited by the tasks. For this, a coding scheme had to be developed in a multi-step approach consisting of deductive and inductive analytic phases. The assigned codes were compared and contrasted to identify possible incongruences in assigning the codes and to find the central categorial cuts between the codes. In the end, a coding scheme emerged that identified codes based on the *source* and the *goal* types of statistical information (phenomenon, data, model, argument). The source refers to the type of statistical information given in the task; the goal refers to the type of statistical information required as a solution to the task. The identification of the type of statistical information considered the language employed for giving the information: (a) statistical information on a *phenomenon* is characterized by rich descriptions of contextual knowledge without exact quantification. (b) Statistical information on *data* is characterized by atomic quantifications of certain aspects of the phenomenon. This includes categorical data as well as frequency data. (c) Statistical information on *models* refer to relationships within the data that are not reported by the data itself, but by additional models. Such models can be measures of centre as well as diagrams like pie charts, which can illustrate the proportional relationships between frequency data. Finally, (d) statistical information on *arguments* comprises justifiable claims about the phenomenon that are based on a model. Mere verbal descriptions of models are not considered statistical arguments; instead, an interpretative step has to be performed that situates the model in the larger phenomenon by incorporating additional context knowledge or by generalizing from the model.

Table 1 gives illustrates the final coding scheme. This scheme was applied in a final deductive step of analysis by identifying source and goal of the statistical information and assigning codes according to the coding manual in Table 1. Throughout the whole process, the assigned codes were discussed in the research team of the author and two colleagues. Not every task fit neatly into the coding scheme. These cases were discussed with the research team to provide a consensual validation of the coding.

In some cases, the team concluded that it was not possible to assign a code to a task. Such tasks often consisted of purely mathematical questions or were too unspecific to be clearly assigned to any activity. Although a skilled teacher might still use these tasks to develop statistical literacy, they could not be included in the analysis. Due to the complexity of the coding and the need for inductive development of the coding scheme with a research team, a test of inter-rater reliability was not applicable. Thus, the results of the analysis should be interpreted as exploratory findings on statistical literacy content in textbooks.

Table 1: The coding scheme for identifying activities of selective and imaginative reading

Activity	**Source**	**Goal**	**Example task**
Encoding	Phenomenon	Data	- *Conduct a survey about leisure activities in your class*
Abstracting	Data	Model	- *Given is a table with frequency data on leisure activities in class, Draw a pie chart.* - *Given is a table with daily sleep time in the class. Find the average.*
Interpreting	Model	Argument	- *Given is a chart on students' long jumps. Who should win the competition?*
De-Interpreting	Argument	Model	- *Given is a newspaper article. What does the author mean by "average"?* - *Tobias claims that boys are keener on sports than girls, Aylin disagrees. Find a justification for the claims in the data.*
De-Abstracting	Model	Data	- *The median daily sleep time is 8h. Which data could have produced the median?*
De-Coding	Data	Phenomenon	- *Given is data on youths' internet activities. Does this fit your own experiences?* - *Given is data on students' commutes to school by bus. Find a possible reason why some values are very high.*

Results

Table 2 provides an overview about the codes given in the analysis. The data is also visualized in Figure 2. Percentages do not add up to 100%, as some tasks were assigned multiple codes, and few tasks did not fit the coding scheme and were not assigned any codes.

Table 2: Codes assigned to the tasks in three textbooks

Textbook	**Tasks**	**Encoding**	**Abstracting**	**Interpreting**	**De-Interpreting**	**De-Abstracting**	**De-Coding**	**n/A**
EdM	130	14 *(11%)*	77 (59%)	9 (7%)	14 (11%)	13 (10%)	5 (4%)	19 (14%)
LS	146	8 (5%)	88 (60%)	3 (2%)	6 (4%)	35 (24%)	2 (1%)	15 (10%)
ml	95	3 (3%)	57 (60%)	11 (12%)	7 (7%)	11 (12%)	4 (4%)	6 (6%)

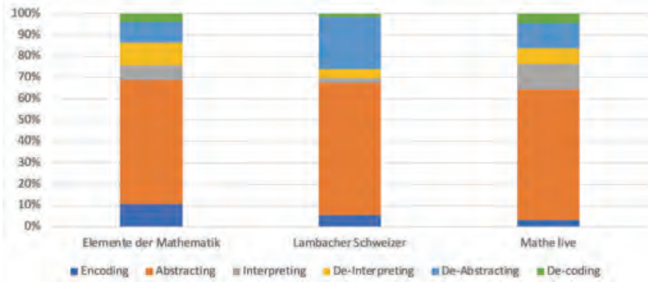

Figure 2: Textbooks heavily emphasize abstracting, but other activities vary

The data show that across all textbooks, the large majority of tasks (about 60%) elicit the selective activity of abstracting. The imaginative activity of de-coding shows the least occurrence in all of the textbooks, with only 1% to 4% of tasks eliciting this activity. Apart from these similarities, the other activities are featured very differently in the textbooks. *EdM* has the largest occurrence of encoding (11%) and de-interpreting (11%), *LS* by far has the largest amount de-abstracting (24%), and *ml* places a stronger emphasis on interpreting (12%) compared to the other textbooks.

Dimensions of differences between the textbooks

A comparison between the textbooks shows the very different learning opportunities for statistical literacy provided by the textbooks. A first dimension of the differences concerns the *technical nature of the tasks*. The activities of abstracting and de-abstracting in the textbooks are often elicited in tasks where a diagram has to be drawn based on given data (abstracting), or where possible data values have to be reconstructed given a measure of centre (de-abstracting). Both activities require no contextual knowledge, and can be solved in a very technical way. In *LS,* these two activities combined make up for 83% of the tasks. This technical nature could be the result of the exercise-driven approach of the textbook – although *EdM* also emphasizes exercises, and seems to provide more learning opportunities for more conceptually demanding tasks. Another dimension of the differences could be provided by the different treatment of the activities of interpreting and de-interpreting. *EdM* and *ml* show a very different emphasis on these activities, with *EdM* favoring de-interpreting (11%) over interpreting (7%), and *ml* favouring interpreting (12%) over de-interpreting (7%). This could be explained by the different approaches of the textbooks. *ml* claims to follow an exploratory approach. This resonates with the activity of interpreting, in which conclusions about a phenomenon have to be drawn actively based on a model. In contrast, the activity of de-interpreting consists of searching for a fitting model for a given conclusion. As such, the differences between these two textbooks could be considered on a dimension of *exploratory vs. confirmatory data analysis*.

Summary

For all textbooks, the activity of abstracting is by far the activity with the most learning opportunities, as more than half of all tasks elicit this activity. Generally, all textbooks provide more learning opportunities for selective reading than for imaginative reading. This does not mean that the textbooks adequately support the development of selective reading, and do not support the development of imaginative reading. The overemphasis on abstracting also leads to only few learning opportunities for the other activities of selective reading. The results suggest that the textbooks themselves are less suited for developing the whole processes of selective or imaginative reading. The activity of decoding is almost absent from textbooks. However, learning opportunities for other selective or imaginative activities do exist in the textbooks. Where the textbooks do not mostly consist of technical tasks, they provide different learning opportunities for (de-)interpreting depending on an exploratory of confirmatory approach to data analysis.

Conclusion

Statistical literacy is an important skill for all students (Wild, 2017). As statistics is commonly taught within mathematics, statistical literacy needs to be developed in middle school mathematics classrooms. Here, textbooks play an important factor for the enacted curriculum. However, not much is known about the statistical content of mathematics textbooks in middle schools (Weiland, 2019). To uncover the statistical literacy potential in mathematics textbooks, this study provided a specification of the learning content of statistical literacy through different activities concerning the selective and imaginative reading of statistical information (Büscher, in press). Selective reading refers to the process during which a phenomenon gets encoded into data, from which a model is abstracted, which is then interpreted in a statistical argument. During each of these steps, information gets lost. Imaginative reading refers to the process of intuiting this lost information in activities here denominated as de-interpreting, de-abstracting, and de-coding. Three German Grade 6 textbooks were then investigated in a qualitative document analysis study (Bowen, 2009). The results show that all textbooks overemphasize the selective reading activity of abstracting. Learning opportunities for other more conceptually demanding activities of statistical literacy do exist, but risk to be overshadowed by the possibly very technical activities of abstracting and de-abstracting.

These results can highlight the importance of the teacher for developing statistical literacy. Teachers need to use textbooks as didactical instruments to provide and adapt them for their own goals. One the one hand, a skilled teacher could add a small question that elicits interpreting or de-interpreting to a task which itself only requires abstracting. The specification of the activities of statistical literacy might provide such a teacher with a conceptual framework for analysing and adapting their teaching. On the other hand, inexperienced teachers might very well overlook the potentials for developing statistical literacy, and studies have shown that teachers tend to adapt tasks mostly to make them "manageable", instead as to adapt the content of the tasks (van Steenbrugge & Ryve, 2018).

Limitations

The textbooks analysed here provide only a limited window into the development of statistical literacy in middle schools. Even in Germany, there are many regional differences in textbooks, and the selection of textbooks cannot be considered representative even for German schools. It also might well be the case that the potential for statistical literacy is different in the textbooks for grades other than Grade 6. Finally, as outlined above, there exist a difference between the textbook content and the curriculum enacted by teachers. Instead of providing empirical insights into the actual state of teaching, this study shows that learning opportunities for statistical literacy can vary wildly between different textbooks, and that textbooks run the danger of overemphasizing parts of statistical literacy. This study's specification of activities of selective and imaginative reading can provide a framework for researchers and teachers to evaluate learning opportunities for statistical literacy as well as an orientation for adapting their own teaching or didactic materials for fostering statistical literacy.

This paper presenting one aspect of a design-based research project examines the development of a teacher's noticing skills in the context of data analysis and interpretation during her involvement in an online professional development program (OPD). For this purpose, the noticing skills of the teacher for the strategies used in the given students' responses were identified according to the modified version of the Jacobs et al.'s (2010) framework. By examining the teachers' discussions in the OPD, how the teacher's noticing expertise evolved throughout this process was investigated. Findings show that the teacher had difficulties in each interrelated skill of noticing at first. However, enhancement in her noticing of students' thinking in the context of data analysis was observed throughout her participation in the OPD.

Keywords: Collaboration, data analysis and interpretation, online professional development, teacher noticing

Teacher noticing, which is a key part of teaching expertise (van Es, & Sherin, 2021) and has been a prominent construct in the mathematics education literature for the last 20 years, is generally defined as all the processes that teachers engage to deal with the ongoing information in the classroom (Sherin, Jacobs, & Philipp, 2011). Teacher noticing is essential for efficient instructional practice (Blömeke et al., 2015) and has a direct influence on students' learning (van Es & Sherin, 2021). Although different conceptualizations exist about teacher noticing, researchers generally regard it as including two main processes: paying attention to and making sense of the notable situations in the classroom (Sherin et al., 2011). Jacobs and her colleagues (2010) add one more process to the above description, which is decision-making. Furthermore, they focus particularly on noticing students' mathematical thinking, which is an essential practice to promote students' learning (National Council of Teachers of Mathematics [NCTM], 2014).

Despite the value of teacher noticing, the relevant studies suggest that noticing is not an innate ability and the teaching experience alone does not provide sufficient improvement (Jacobs et al., 2010). Therefore, researchers attempted to develop teachers' noticing skills through variety of ways. For instance, Fernandez, Llinares, and Rojas (2020) showed evidence of enhancement in prospective teachers' noticing skills through sharing narratives about their own practices in an online forum and collaborating with their partners and tutor. Moreover, Fernandez et al. (2020) and several other researchers (e.g. Klein, Fukawa-Connelly, & Silverman, 2017) agree that online systems "slow down the process of learning" (Clay, Silverman, & Fischer, 2012, p. 762) by giving teachers extra time to reflect on the situations, which allows them from different contexts to collaborate around instructional situations. The necessity for such environments has been felt even more during the COVID-19 pandemic. Taking into account the advantages of online environments for teachers' professional development and its particular need during the pandemic, in this paper, we report one aspect of a larger research project which aims to support middle school mathematics teachers' noticing skills of students' mathematical thinking through their involvement in an Online Professional Development (OPD) program.

Although we focus on various mathematical contents in the project, the specific domain of students' mathematical thinking considered in this paper is about analyzing and interpreting data which is the core process of the statistical reasoning (Jones et al., 2004). More specifically, this process includes "recognizing patterns and trends in the data and making inferences and predictions from data." (Jones et al. 2004, p.103). In this research paper, our aim is to examine to what extent a middle school mathematics teacher attends to and interpret students' inferences from a given data and how the teacher base their decisions on students' understandings. Moreover, we are interested in how the teacher's participation in the OPD could support the development of her noticing skills. In other words, the following research question guided the research study: How do a middle school mathematics teacher's noticing of students' thinking in the context of analyzing and interpreting data develop throughout her involvement in an online professional development program?

Alternative to the studies that use online systems for developing teachers' noticing skills (Fernandez, Lilinares, & Valls, 2012; Fernandez et al., 2020), synchronous modes of communication were also used in the present study. Furthermore, in this research, we work with in-service teachers who have less than 15 years of experience. By this way, we have a chance to investigate novice teachers' development of noticing skills regarding students' understanding through collaboration with other colleagues from different schools across Turkey. Lastly, we particularly focus on the content of data analysis and interpretation, which gets relatively less attention in the available literature. Hence, this study may provide valuable information to the teacher noticing literature about the nature and development of middle school mathematics teachers' noticing skills in the context of data analysis.

METHOD

This study is part of a large research project, which adopt design-based research as its methodology (Bakker, 2018). However, in the current study, we limited ourselves to a teacher, Aslı, as our case and examined how her noticing skills developed during her participation in the OPD.

Participants

The teacher Aslı was selected among the project participants who are 35 middle school mathematics teachers whose professional experience did not exceed 15 years and working in public schools in different cities of Turkey. We selected Aslı, who has 8 years of teaching experience, for this study because she was one of the very active teachers in the OPD. She tried to enhance collaborative discussion environment by challenging the other teachers through her questions and making comments to their opinions.

Data collection

The data of the study was collected through the basketball problem, shown in Figure 1 below. This item was adapted by Gökce (2019) from the work of McGatha, Cobb and McClain (2002). In the problem, the scores of two basketball players were given during the last 10 games and the students were asked to decide which player the coach should choose. To decide, students should analyze the given data by using appropriate measures of central tendency and variability, and interpret the results in the given context. Research suggests two strategies that students generally use while answering such comparison questions. Therefore, student responses including those strategies are provided under the problem to examine how teachers notice them. As shown in Figure 1, Student 1 (S1) chose Barış by focusing on the mean score of each player. Her reasoning was partially correct since she ignored the variability of the given data. On the other hand, Student 2 (S2) also chose Barış by only focusing on the scores above a certain value, 15. Since he ignored the data less than 15, reasoning of S2 was not correct.

The coach will select one player from the school's basketball team to play in the all-star tournament. Below is a listing of points scored by the two candidates, which the coach thinks choosing, for the last ten games of the season.

Players	**Points Scored in Games**									
Arda	8	14	11	13	15	12	10	10	9	13
Barış	4	15	8	17	18	9	19	6	18	5

Which player would you recommend the coach to choose? Explain why.

Your students, Student 1 and Student 2, responded as follows:

Student 1 (S1)'s response:

He should choose Barış because while Arda's average is 11.5, Barış's average is 11.9.

Student 2 (S2)'s response:

He should choose Barış because he scored 15 or more in half of the games that he played.

Figure 1. The basketball problem

To determine the teachers' noticing skills before the discussions held in the OPD, teachers were asked to answer three questions suggested by Jacobs et al. (2010) based on the given cases. Subsequently, the basketball problem was discussed in the OPD with all teachers and research team during 3 weeks period. To summarize the discussion in the OPD, a synchronous session was conducted by the facilitator, a member of the design team and researcher who has many research studies on statistical thinking. In that session, teachers were expected to ask any questions they have in their mind regarding the problem and state their opinions regarding the online asynchronous discussion held among the teachers. Moreover, the facilitator mentioned some big ideas, such as the importance of the context in interpreting the given data, that did not get enough attention in the discussion. Lastly, semi-structured interviews were conducted to get in-depth information regarding the change in teacher's noticing skills after asynchronous and synchronous discussions. Teacher Aslı's written answers about two students' strategies, participating teachers' comments in the asynchronous discussion held in the OPD and summary session, and Aslı's interview transcripts were constituted the data for this study.

Data Analysis

For the analysis of the data, the theoretical framework by Jacobs et al. (2010) was modified by taking into consideration the data collected and the Teacher Recognition Skills framework developed by Kilic and Dogan (2021). Accordingly, while teachers' attending skills was examined at four levels, the skills of interpreting students' understanding and deciding how to respond were examined at five levels. In particular, teachers' attending skills, the ability of teachers to identify the mathematical details in students' strategies, were categorized as No Attempt, Lack, Limited and Robust Evidence as different from Jacobs et al.'s (2010) framework. For interpreting skill, identification of students' understanding based on their strategies, one more category, Substantial Evidence was added to the categories of attention. In relation to the last skill, the teachers' ability to base their decisions on students' understandings, were not evaluated as lack, limited and robust. Instead, categories named as No Attempt, Ignorance, Questioning, Challenging and lastly Responding to child and Incorporating were used based on the data. Based on this framework, we firstly determined the noticing skills of teacher Aslı. Then, by examining the teachers' discussions in the OPD and the interview of Aslı, we tried to find evidence in the development of her noticing skills and how those developments occurred.

Findings

In this paper we aimed to examine the development of a teacher's noticing skills during her involvement in the OPD program. Below, teacher's responses and the changes in her ideas during and after the discussions in the OPD will be provided for each noticing skill, respectively.

The teacher's evolving expertise in attending and interpreting skill

The below response presents teacher's attention to the given students' strategies before the discussion in the OPD:

Aslı: For S1, mean is the best way while comparing two groups. For S2, if the range is too much among the given data, it is correct to use median and the data which are above the median. We can say that statistical reasoning of S2 was correct if we just evaluated the player Barış. However, if the range is not too much while comparing two groups, as in the two groups in this question, comparison using mean will be a better approach just like S1 did. (Pre-test)

In this response, teacher attended that S1 used mean while comparing two groups, but she could not notice that S1 did not consider the variability while interpreting the given data. In other words, since she could not attend all the details in S1's strategy, she evaluated her reasoning inaccurately. The teacher managed to attend S2's reasoning as not correct; however, she focused on a concept, median, which was not used by the student. For these reasons, the level of teacher attention to the given student strategies was coded as lack.

Aslı began the discussion in the OPD with the same arguments in the pre-test . Following her comments in system, the below discussion held among some teachers.

T1: …I believe that S2 chose Barış by considering the mode of the given data. Even though the answer of S2 is correct, I do not think that his reasoning is true.

Aslı: If S2 used the mode of the given data, should not he consider 18 [the mode of the data for Barış]? If S2 were to use mode, did not he say that 18 repeated much in the given situation; thus, I choose Barış? I thought that since the sixth data is 15 when all of them are ordered, S2 focused on the median of the given data.

T1: I stated that S2 used the mode by grouping all the data, which are above 15. I do not think that we can take 15 as median since there are 10 games in total.

T3: Differently from above discussion, I think that neither S1 nor S2 reasoned correctly about this question. S1's reasoning is missing since she does not know that it is not enough to just look at one central tendency when the averages are so close to each other. In here, she should look at the ranges of the given data additionally. I could not understand which statistical concept S2 used with his statement of '15 and more points'. I do not think that he used the mode or median as mentioned in above comments.

Since teachers could not agree on evaluating S2's strategy, facilitator posed some questions to let teachers think and interpret the meaning of mode and median for the given data sets. After a long discussion in the system, teachers agreed that S2 did not use the concepts of mode or median, but simpler reasoning. In other words, they agreed that he only concentrated on the highest points in the given data. The following comment of Aslı in the discussion indicated that teacher's expertise in attending S2's strategy improved after this fruitful discussion.

Aslı: I believe that to organize data by grouping (She means to group the data with respect to highest and lowest scores) is correct to understand the nature/tendency of the data. However, it is missing. This is also valid for S2. While thinking the scores which are above 15, the data which are below 15 were lost. (Discussion)

When the data was analyzed in terms of interpreting skills, again her response indicated the lack of evidence in interpreting the students' mathematical understanding. The following response was received before the discussion in the OPD when Aslı was asked to interpret the students' mathematical understanding by considering the given students' strategies:

Aslı: For S1, the mean; that is, all values in the data group, is important because it is affected by the change of each data. For S2, on the other hand, if the difference among the data is high, to look at the median and the data above the median is a more accurate way to interpret the data. Because of the skewed distribution of the data , looking at the median is the most useful method for S2. (Pre-test)

Although teacher thought that S1considered the importance of all data, S1's solution is not enough to make this claim. For S2's strategy, the teacher again focused on the concept of median as she attended in the first question. She argued that S2 knew to use the median when the data set is skewed; which indeed cannot be concluded from the student's strategy. Furthermore, the teacher did not mention variability or representativeness while interpreting the students' mathematical understanding.

When teachers were asked to interpret students' mathematical understanding in the given student responses in the OPD, Aslı's comment was as follows:

Aslı: S1 used only the mean when comparing the data groups, but did not include the concept of range, she should interpret these two concepts together. In S2's interpretation, grouping (She means to group the data with respect to highest and lowest scores) can be used to organize the data, but it is insufficient on its own for data analysis. It is seen that S2 has no knowledge of the concepts of mean, median, and range when looking at the solution. I think that the starting points of both students' reasoning are correct, but they are insufficient. To interpret the data with a single concept will not be sufficient in data analysis. (Discussion)

Most of the other teachers agreed with Aslı's comment in the following parts of the discussion. It was observed that Aslı mentioned the concepts of mean and range, which are necessary to interpret the mathematical understanding of the S1's strategy. For S2, teacher gave up her idea of median. Since teachers did not focus on the meaning that S1 attributed to the mean, facilitator let teachers discuss this through her questions. After this discussion, she interpreted S1's strategy by referring to the concept of representativeness during the interview while she did not mention it in her first comment in the OPD. Lastly, Aslı's following expression regarding her own development gave us one more evidence that discussions nurtured her interpreting skills of students' understanding. "The discussions in the OPD enabled us to brainstorm. It made me realize some new ideas. In particular, I became aware of the concept of range for this question".

The teacher's expertise in deciding skill

Before the discussion in the OPD, Aslı responded her next instructional moves as in the following:

Aslı: To show that both students' reasoning can differ with respect to the different situations, I give two data sets whose ranges are high and low and I ask which student is more successful. For example,

Case 1: Ayşe's savings during five months: 10, 50, 90, 90, 100 (Mean=68)
Case 2: Ali's savings during five months: 70, 80, 85, 85, 100 (Mean=84)

If we look at the mean, we interpret correctly and say that Ali is more successful. I can relate this question with the given problem situation by stating that it is not correct to say that Ayşe is more successful since she has 3 data which are above 90. (Pre-test)

During the interview, Aslı stated that she would use the above example for S2. Since Aslı believed that the use of mean is better for this problem, she asked such a question to S2 so that student can realize that he should use mean while answering this question. In other words, her aim of asking this question is to lead S2 to the teacher's correct answer. In addition, Aslı added some questions to understand both students' strategies better such as "Why did you use 15 in your answer?" or "Why did you use the mean?". For these reasons, the level of her expertise in deciding how to respond based on the given students' strategies were determined as questioning.

On the other hand, Aslı began the asynchronous discussion held in the OPD with the argument below:

Aslı: S1 should feel the need to look at the range while interpreting the data. So, for this purpose, I would ask which players she would choose if the mean of them were equal. Similarly, I would ask S2 which players he would choose if the number of data, which are above 15, were equal. My aim in this part is S1 and S2 should notice that their reasoning is missing and only one method is not enough while analyzing data. (Discussion)

Different from her first comment in the pre-test, Aslı asked some probing questions for S1 to let her notice that she should consider the variability of the given data. In the same way, the questions for S2 were to guide him to consider the data which are below 15. In other words, the teacher started challenging students, a higher level in the framework, to make them realize that their reasoning is underdeveloped. Although Aslı did not provide any explanation regarding how to guide S2 to the use of average in her first comment in the OPD, she offered some ways for this aim after the facilitator's question. During the discussion in the OPD, most of the teachers agreed with the Aslı's first comment. On the other hand, during the interview, when she was asked about her next problems to the students after the basketball problem, she stated that "I again present a problem that students can provide different comments…Indeed, I would change the context. However, the characteristics of the data would be the same so that to calculate just the mean would not be sufficient." With this description, we can say that the teacher thought providing new contexts for students. However, her aim seems to make students practice the ideas discussed in the given problem, not to emphasize the importance of the context, which was discussed by the teachers and facilitator during the synchronous session.

Discussion

The case of Aslı was presented to illustrate that the OPD can help teachers in their development of noticing skills. At the beginning, the teacher had difficulties in each interrelated skill of noticing. However, the findings showed enhancement in her noticing of students' thinking in the context of data analysis throughout her participation in the OPD. During the discussion, teachers had a chance of observing different ideas, posing questions, and making suggestions to each other. Also, the facilitator let teachers focus on the important concepts through her prompts. All these interactions might direct the teacher's focus on students' mathematical thinking deeply as consistent with the study of Fernandez et al. (2020). In other words, it can be inferred that the collaboration among the teachers and the facilitator throughout the discussion might allow the teacher to attend the details of the given strategies and interpret students' understanding by covering all the essential concepts such as variability and representativeness. Moreover, the teachers were provided with two students' strategies and the solution of S2 was particularly challenging and unfamiliar for the teachers. This could have led the discussion environment to be more productive, which in turn might have increased the collaboration among teachers.

Another factor contributing to the development in the teacher's noticing skills could be the asynchronous nature of the OPD. Clay et al. (2012) argues this mode of communication slows down the process of learning, which could enable teachers spent more time to consider and revise their ideas (Fernandez et al., 2012; Klein et al., 2017). Indeed, this was shown by Aslı's one of the statements during the interview: "Discussions in the OPD provided us to think more on the students' answers." Thus, asynchronous modes of communication provided via the OPD might play an effective role in developing the teacher's attention to the given task; leading fruitful communication among teachers which in turn enhance her noticing skills.

Although there was clear improvement in attending and interpreting skills of the teacher, deciding how to respond based on students' understandings was more difficult for her. Preceding the discussion, the teacher's questions were like directing students to the correct answer which was also observed by Klein et al. (2017). Even though the teacher suggested asking probing questions to challenge students throughout the discussion, she had difficulty in extending students' understanding to a further point after the discussions. Although some new ideas were presented by the facilitator during the synchronous session such as the use of graphical representations of the data presented in the basketball problem and the importance of context for interpreting data, these ideas were not reflected in the teacher's responses during the interview. Therefore, in future research, we suggest carrying such specific ideas into the OPD to enable teachers create more productive discussion environment for the deciding skill. Lastly, it would be good to examine how the teachers' evolving expertise is reflected into her instructional practices in further research studies.

In Hungary, teaching of statistics has been part of the curriculum for only 20 years. The introduction has been gradual: while the earlier curricula aimed at a low level of statistical literacy, the recent curricular changes have moved to a higher level. Despite initial difficulties, the subject is now popular with students and teachers alike. To maintain this, it is important that teachers are given adequate support to teach statistics at a higher level. In this article, we describe the development and current situation of teaching statistics in Hungary, and the research and development activities that have been taking place in this field. We examine whether teachers' attitudes, skills and interest in statistics (education) are congruent with the development of the statistics curriculum in Hungarian schools.

Keywords: Statistic education, curriculum development, teacher attitudes.

Introduction, theoretical framework

There is a wide range of international literature on the development and teaching statistical literacy. Developing statistical literacy is an important task for schools in our data-driven everyday lives (Watson, 2003a). Secondary schools play an important role and offer many opportunities in this process (Watson, 2003b). Over the last 20 years, there has been a growing demand for education to focus more on statistical literacy, reasoning and thinking (Ben-Zvi & Garfield, 2004). However, it is not unique that statistics education is nevertheless often simply a matter of learning and practising definitions and new procedures, without the need for a deeper understanding of the underlying concept (Batanero & Borovcnik, 2016). The term statistical literacy increasingly carries the connotation that an individual can be goal-oriented in a specific field, rather than simply acquiring basic knowledge (Gal, 2002). In recent years, the critical handling and interpretation of data has also become emphasised in terms of growing up and taking responsibility (Schiller & Engel, 2018). Another important task related to this topic is designing curricula around statistics and the targeted organisation of classroom procedures (Ridgeway, 2015). Examining teachers' skills and attitudes towards teaching statistics in primary level (Chick & Pierce, 2008) and secondary level is a crucial phenomenon for development.

In Hungary, statistics was introduced as a separate subject in secondary education in the 1950s, but only in vocational schools (Tóth, 2006). In secondary grammar schools, the subject of statistics did not appear in the final exam requirements before 2000. However, in the last 20 years, there have been many changes in this field in Hungary. In this essay we present a brief history of the topic, the current situation and possible directions for further development. First, we would like to demonstrate the changes in the curriculum, then we analyse the requirements of school-leaving examination, and finally introduce the results of a teacher survey. In this way, we aim to provide a complex picture of the circumstances of statistics education in Hungary today.

As for the possible way forward, several doctoral research projects have currently been dealing with the teaching of statistics in Hungary, and this is one of the main elements of a four-year research project launched by the Hungarian Academy of Sciences in September 2021. As an essential element of the thorough investigation of sources conducted by the authors of this article, a system for defining levels of statistical literacy has also been developed. The system defines 3 levels, grouped according to statistical content (measures of central tendency and variability, charts). The first level is characterised by the application of basic conceptual knowledge and the ability to perform simple calculations. The second level is characterised by the skill to solve more complex, multi-step tasks, and to compare and contrast them. The third level is characterised by reasoning, argumentation, generalisation and abstraction. Considering that the incorporation of elements of statistical literacy is still at an early stage, 3 levels are sufficient to describe the characteristics currently want to be observed.

Development of teaching statistics in Hungary since 2000

In order to understand the changes in teaching statistics, we will examine different segments of education: the official curricula, the requirements and tasks of the final examination (which have a greater impact on the content of education than the curriculum itself).

Curricula

In Hungarian public education, teaching statistics was not included in the requirements at all in the 20th century. The first time when statistical knowledge appeared within mathematics was in the framework curricula of the National Curriculum, which were prepared in 1995 and came into force in 2000[1]. Since then, the National Curriculum and the framework curricula have undergone several major and minor changes (one major change in 2012, the other in 2020). The 2000 (Sajtóiroda, 2004) and 2012 framework curricula (Oktatási Hivatal, n.d.) had very similar requirements within the subject of statistics. In grades 1–4, the requirements included collecting data, making tables and graphs, reading and interpreting them; interpreting the arithmetic mean of some numbers, introducing the concept of "average", using it to characterise sets of data. In grades 5–8, the pie chart, the mode, the median and the analysis of data sets were also introduced. In addition, in grades 9–12, the ability to measure the standard deviation of data, to know the sampling with or without replacement and to solve problems related to them.

The 2020 framework (Oktatási Hivatal, n.d.) has introduced significant changes in several aspects, mainly in the requirements for secondary schools. In grades 9–10, the interpretation and evaluation

[1] In Hungary, since 2000, the content of teaching and learning in schools has been determined by a three-tier curriculum regulation, as prescribed by law. The top level of regulation is the National Core Curriculum. The second level of content regulation is the framework curricula, which provide both curricular and methodological support. The third, local, level of regulation is the pedagogical programme of the schools and the local curriculum drawn up by the teachers in the schools.

of data, the drawing of simple statistical conclusions, the choice of the appropriate type of graph to represent a specific set of data and to answer a statistical question, the creation and reversal of a pie chart into a bar chart, the recognition and correction of graphical manipulations in graphs are new items. Also new materials in grades 11–12: visualisation of the concept of a representative sample; classification and characterisation of statistical data using quartiles, means and scatter; construction and use of box-plot diagrams; interpretation and evaluation of data, statistical inference; recognition of statistical manipulations in graphics and text.

In addition to the changes in content, another important difference is that the 2020 framework proposes significantly more time (more than 50% more than in the 2012 curriculum) for teaching probability and statistics.

Requirements and tasks of the final exam

One of the characteristics of Hungarian mathematics education is that classroom practice is influenced more by the requirements and tasks of the final exams than by the curriculum itself. In Hungary, a new final exam[2] system was introduced in 2005 (Csapodi, 2016). The requirements for the intermediate level exam were determined by the content of the National Core Curriculum and the basic curriculum, while the requirements for the advanced level exam were more in line with the needs of higher education. Changes in the curriculum are of course always followed by changes in the requirements for the final examination. Knowing that the secondary school curriculum devotes 9% of the available time to probability and statistics, it is interesting to see that the examination requirements of these topics in the examination papers for the baccalaureate are 15%, which is much closer to the 12% timeframe in the new curriculum.

The current requirements for the exam are generally quite simple, falling into level 1 mentioned in the introduction: the ability to draw pie charts and bar graphs and to read data from them; to calculate mean, mode, median and standard deviation. The only requirement that goes perhaps a little beyond these is to be able to compare data sets using the statistical indicators learned.

Due to the changes in the curriculum in 2020 and the increase in the time available for teaching statistics, the requirements for the baccalaureate will also change from 2024. In addition to the previous requirements, the concept of quartiles and box-plot diagrams will be introduced, but more importantly, the requirements include the ability to choose the appropriate diagram for the situation and to argue for the choice, and at advanced level the ability to choose a mean value that well characterises the data set, to argue for the choice, and to evaluate and analyse the statistical indicators obtained and to draw statistical conclusions. These are a very big changes from the more traditional closed-ended tasks in Hungary.

Looking at the sets of tasks over the last 15 years, we see that the tasks on statistics do not go beyond level 1 of statistical literacy (the level system mentioned in point 1), as required: making simple diagrams, reading data from diagrams, calculating means and dispersion coefficients. The evaluation

---

[2] By *final exam* we mean an exam that is to be performed by those who leave secondary school at the age of 16 or 18, before entering higher education. This type of exam is also called *matura*, *baccalauréat* or *graduation exam*.

of the results obtained, and the analysis of the data have not been included in the questions so far. In the 50 or so sets of intermediate level questions that have been used since the introduction of the new examination system, there are few that require more complex thinking.

Research on the detailed analysis of final exams (Csapodi, 2016; Csapodi & Koncz, 2016) show that students at both levels are successful in solving statistics problems and, where there is an opportunity, they are willing to choose the corresponding problems[3]. Knowing that statistics is a relatively new subject in schools, there are two possible explanations for this. It is possible that the statistical literacy of teachers (see the results of the teacher survey later) and the available teaching materials have improved as well. On the other hand, we have also seen that, out of understandable caution, the requirements for these subjects only ask candidates to demonstrate basic knowledge. One of the consequences of this is that the examination requirements for these subjects from 2024 onwards will require a greater amount of knowledge and more complex competences from candidates than in the past, albeit to a lesser extent.

RQ 1. Whether or not teachers' attitudes, skills, and interest in statistics (education) are congruent with the development in the curriculum of statistics at Hungarian schools?

RQ 2. What is the attitude of Hungarian math teachers to further expansion of the statistical curriculum?

Methodology

Designing the teacher questionnaire survey

In connection with the current changes, we have conducted a survey for research purposes, involving secondary school teachers. As a research method, a questionnaire survey was chosen due to the uncertainties of the epidemic situation. This quantitative research method is easy to conduct online, and the results can also be evaluated in this form. The aim of the survey was to obtain information on the studies, attitudes, and classroom habits of teachers in the field of teaching descriptive statistics. Taking these details into consideration, further education and development opportunities should become more targeted, both in terms of teacher education and teacher training.

The questionnaire consisted of four main parts: background data on the respondents; rating of statements on a 5-point Likert scale in 2 groups of questions: (1) How much do they agree with the given statements about the teaching of statistics? (2) To what extent do they feel that the given statements about the teaching of statistics are true for them? The fourth part of the questionnaire measured the popularity of teaching particular mathematics areas. A total of 28 statements were assessed in parts 2 and 3. The main statements: 7 + 6 + 7 statements were included for basic attitudes, assessment of students' knowledge, and framework knowledge. The sub-statements: 3 + 3 + 2 statements are listed in order of opinion on the working methods used, about the assessment and the current requirements. The questionnaire was tested on a small sample, using convenience sampling.

[3] It is not necessary to solve all the problems in the exam to get the maximum score, both at intermediate and at advanced level students can skip one of the exercises.

Results of a teacher survey

The questionnaire for an online survey was completed by 181 teachers. Although the survey is not representative, we can say in terms of background data, that the composition of the respondents is similar in terms of both settlement type and school type to the proportions measurable in the society of Hungarian teachers. As far as professional background is concerned, more than 80% of respondents have been teaching at secondary grammar schools for more than 15 years. Nearly 30% indicated their own secondary school studies as the source of their knowledge needed to teach statistics, 56% chose their own university studies, 76% chose 'their own teaching experience', and almost 60% mentioned their 'own research'. The following table summarizes the proportion of groups with different professional experience in details (measured in years) that indicated their own secondary education as a source, their university studies and their teaching experience gained during their work. (Several sources could be marked, not just their main one.)

Table 1: Distribution of teachers by teaching experience and source of statistical knowledge

Years in public education	Number of teachers	Secondary school studies	University studies	Teaching experience
More than 25 years	65	8 (12%)	38 (59%)	58 (89%)
15–24 years	78	12 (15%)	38 (49%)	61 (78%)
5–14 years	24	13 (54%)	15 (63%)	18 (75%)
Less than 5 years	14	14 (100%)	11 (79%)	8 (57%)

Given the detailed data, just a small proportion of teachers who have been teaching for more than 15 years have high school statistical studies and also in these age groups there is the lowest indication of university statistical qualification. In the case of those, who have been teaching less than 15 years, the presence of high school statistics education can be well traced. The teaching experience is also expected to decrease as the number of teaching years decreases.

During the examination of the sources used to teach statistics, we found that, that 78% of respondents use the available textbooks and 91% use available exercise books and 92% work with statistical tasks in the graduation task series of previous years. Thus, we can say that the need for purposeful preparation for output requirements is very strong, and that it is substantial to examine the available textbooks and exercise books when inspecting the teaching of statistics thoroughly.

Based on the evaluation of the 12 statements of the second part, we can say that the majority of teachers (60%) fully or largely agree that the students' knowledge meets the current requirements, their fulfilment does not mean any difficulties. The statistical questions of the final leaving exam are not considered difficult, however, they do not support raising the level of questions, as well as raising the number of lessons devoted to the topic and expanding the curriculum in this field. On the other hand, there is a great deal of interest and willingness to participate in in-service teacher training on statistics (74.6%).

The 16 statements in the third part included, for example, statements about the framework curriculum. It was found that only 50% of the respondents stated that they were aware of the changes in the framework curriculum, on the other hand, as a result of all this, there is a very high degree of indifference – more than 57% – to the changes in the framework curriculum. The feedback on classroom habits is more varied. The new elements – reasoning, data evaluation (S2, S3), analysis (S13, S14), statistical conclusions (S4) – were not welcomed, although, according to the answers, the graph shows that the new methodological expectations have become part of the teachers' daily work.

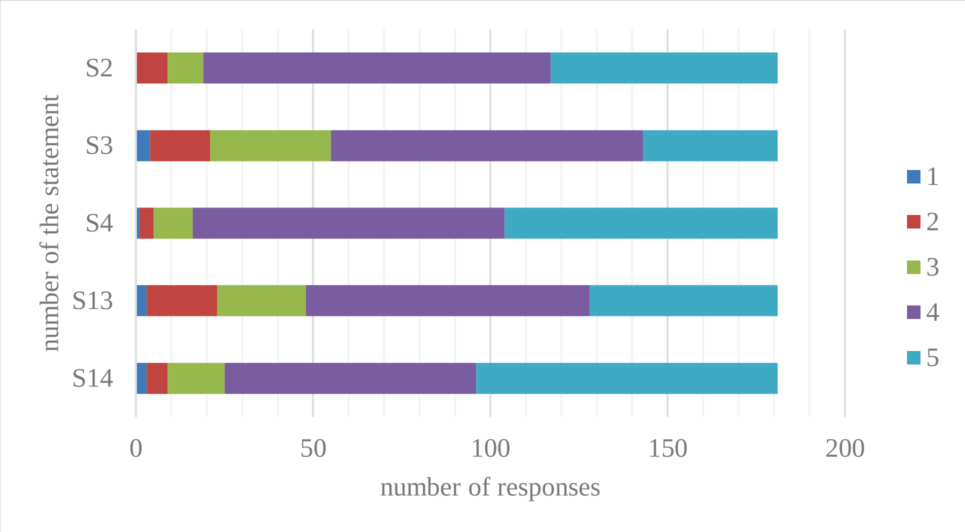

Figure 1: Grading statements about the appearance of interpretation and evaluation in teachers' own classroom work

In written school exercises and tests, open items that require justification or reasoning are not used and are not welcomed.

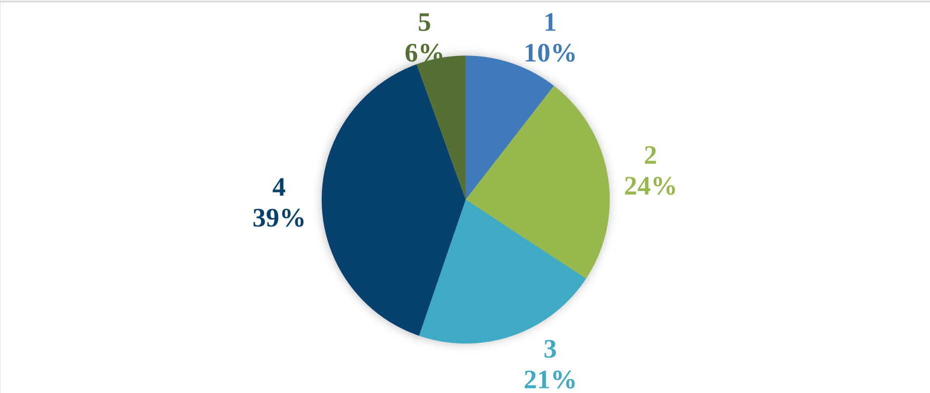

Figure 2: Integrating analysis and evaluation into tests with statistical content

In the fourth, concluding part of the questionnaire, the respondents rated how willing they were to teach certain areas of mathematics. (1 = very much dislikes, 2 = dislikes, 3 = indifferent, 4 = likes, 5 = very much likes). According to this ranking, it seems that the classical topics with a long tradition (equations, algebra, sets, functions, etc.) are the most popular whereas, for example, logic and probability only achieved lower scores, statistics and graphs were in the lower midfield.

Conclusion

Based on the responses to the 28 statements in the questionnaire, we can therefore say that teachers are generally satisfied with the current statistical requirements, the number of the proposed lessons and the achievement of their students (RQ1). However, the direction of stepping forward is less popular, both in terms of increasing the number of lessons in the field, expanding the content, and changes in final exam requirements (RQ2). Preparation for the exam requirements is still highly emphasised. To change the basic approach, it is necessary to incorporate new expectations and methodological issues in both teacher education and teacher training in statistics education; and to support colleagues' work by creating a novel, free-to-use task collection.

Summary and outlook

Regarding to the situation of descriptive statistics education in Hungary, based on the above, we can state that many positive changes have taken place in this field since 2000: basic knowledge of statistics has been included in the curriculum and among the final exam requirements; based on the research, statistics have become a popular topic for students, they successfully solve these types of tasks, for example on the final exam; the proportion of this topic has increased during the latest curriculum developments; there has been a shift in the curriculum and in the graduation requirements from the simple return of conceptual knowledge towards application, interpretation and analysis; basically teachers like teaching descriptive statistics. At the same time, it is evident in addition to positive changes, that there are areas where further development may be substantial: it is worthwhile (in line with international practice) to add additional elements to the statistical part of the mathematics curriculum, for example, the possibility of regression and correlation calculation, as well as the possibility of hypothesis testing in the curriculum should be examined; the statistical part of textbooks and exercise books should be expanded and enriched, the authors of this article play an active role in this work; to deepen the knowledge of teachers, to help their methodological preparation, to consider important to expand statistical knowledge, to prefer to deal with the teaching of statistics.

How does noise affect our health? Analysing a project-based activity in Statistics at secondary level

Maria Josep Freixanet[1], Montserrat Alsina[1] and Marianna Bosch[2]

[1]Universitat Politècnica de Catalunya, Barcelona, Spain; maria.josep.freixanet@upc.edu; montserrat.alsina@upc.edu;

[2]Universitat de Barcelona, Spain; marianna.bosch@ub.edu

Teaching statistics through projects brings to life in the classroom aspects of working with data that are not usually part of traditional paper-and-pencil activities. There exists a generalized agreement about the positive effects of this kind of teaching proposals and number of international and local initiatives to foster them at secondary and tertiary level. Despite all this, their sustainability as normalized classroom activities is very fragile, given in particular the extra amount of work required to teachers willing to implement them. Research in didactics can help better understand the conditions that enable the introduction and management of statistics projects in the classroom, as well as the – sometimes invisible – constraints that hinder their development. We illustrate it with a case study based on the implementation of a statistics project in a classroom of Grade 9 students, using recent developments of the anthropological theory of the didactic.

Keywords: Statistics education, project-based teaching, noise pollution, study and research paths, anthropological theory of the didactic.

Introduction: Statistics project competitions in Catalonia and Spain

Despite the influence of recent didactics research in the Spanish intended curricula at secondary level, one can still find in textbooks “some inertias, inherited from previous curricula and from traditional uses of statistics, with many algorithmic procedures, leaving few spaces for critical thinking, decision making, and analysing solutions within a context. Additionally, the official intended curriculum still has some outdated standards regarding the use of tables, and an excessive emphasis on mathematization of statistical procedures” (Rodríguez-Muñiz et al., 2018, p. 419). Furthermore, the topics of statistics tend to remain the last to be taught at the end of the academic year, and thus the first to suffer reduction due to rescheduling necessities (Angulo et al., 2013).

Since 2006 in Spain and 2009 in Catalonia, university departments of statistics supported by scientific societies launch annual competitions for projects based on surveys and experiments carried out by secondary school students. In the case of Catalonia, about 70 projects are presented every year, with 200 students, 30 teachers and 15 schools (1.5% of the total). The contest includes three categories. These competitions appear as good opportunities to involve teachers and schools in the implementation of inquiry- or project-based teaching proposals, creating an external motivation for students and increasing the visibility of their work. What teachers and students do and how they organise their inquiries is certainly very diverse. According to Markulin et al. (2021), project-based learning in statistics is a broad term that refer to different teaching proposals, ranging from open individual inquiries to strongly guided collective activities.

The teaching proposal we are analysing emerged in this context of statistics competitions. It was implemented by the first author, a mathematics teacher with 16 years of experience. It has evolved during the past five years as the teacher, together with the students and schools, have gained more experience. We focus on the last project implemented in the academic year 2020/2021 with Grade 9 students, which won both the Catalan and the Spanish awards in their category. After describing the experience, we will introduce some analytical models from the anthropological theory of the didactic, especially the notion of "study and research paths" (Chevallard, 2015) to present a critical analysis of the didactic process. The results obtained will help us draw some hypotheses about the difficulties found for the implementation of such proposals and possible ways to overcome them.

A Statistics project in Grade 9 about noise pollution

Five years developing projects to teach statistics

The project we are considering was implemented in a secondary school in Rubí, an industrial town in the outskirts of Barcelona with around 90.000 inhabitants. The idea of teaching statistics through projects in secondary education first appeared six years ago when the teacher had to deal with a group of unmotivated students with low skills in mathematics. To raise interest in the class she designed a survey with a topic of interest for the students, they gathered the information and then perform a simple descriptive statistical study: tables of frequency, graphics and centralization and deviation measures. The following years, the implementation of the projects went on, and the way of teaching statistics was improved through them. One fact that fostered this improvement was the contest "Incubator/Seedbed of surveys and experiments". In addition, the attendance to the awards ceremony, where winner projects are presented, also helped widen the teacher's perspectives. This led to last year's project "The noise and how it affects our health", which was run during 24 weekly sessions of 50 minutes with two groups of 30 students and consisted of two phases or parts.

First part: How noisy is our town?

The first phase of the project took place in the first 12 sessions. It consisted of an investigation to know how noisy Rubí is. We can distinguish different steps in the project development. For the first two sessions, the teacher searched previous studies and information about the topic and prepared a presentation about what the noise is, an official noise map of the city published in the Town Hall website, a Google Maps for each student to locate a pin in their home address. Once the class saw that students' neighbourhoods could "cover" a vast enough space, the teacher proposed a survey with questions about the characteristics of the streets that can affect the noise level. She also presented DecibelX, a sound level meter app. Students answered the survey and carried out a descriptive statistical analysis. With all the information, students made their own hypotheses.

The data gathering was done in two steps. With the help of the mobile application DecibelX, students measured the amount of noise outside their houses. Measurements were carried out for two weeks, starting on the 5th of October 2020 and finishing on the 18th of October 2020, and on certain times: from 7am to 8am (morning), from 5pm to 9pm (afternoon), from 9pm to 11pm (evening) and from 11pm to 7 am (night). With every measurement, students filled out a Google Forms with the email address, the number of decibels, the time and a picture of the measurement from the app.

For the statistical analysis, all the information in the Google Form was downloaded to an Excel file. The students, in groups of 4, calculated the mean, standard deviation and coefficient of variation of the measures per each time slot and made graphics (Figure 1).

	Mean	Std Dev	CV
Morning	39,04	3,67	9,41%
Afternoon	35,56	2,41	6,78%
Evening	35,63	2,95	8,29%
Night	34,27	2,97	8,67%

Figure 1: Results of the statistical analysis of one of Rubí's areas

With the analysis, students could contrast the hypotheses previously raised. They discovered, among others, that:

1. Two main parts of the city could be distinguished: the city centre (called "the red zone") and the outskirts (called "the green zone"), where the difference of decibels was notorious.
2. Some items not considered in the hypotheses could be identified; for instance, the proximity to children parks, which affected the amount of noise in the afternoon.
3. The Noise Map provided by the Town Hall had higher levels of noise in some parts of the city centre than those measured by students. As a possible reason it was pointed up that some streets had become pedestrian since the map was published in 2012.

Finally, to show the results of the study, the teacher selected the places where students had gathered enough noise measures (at least 70% of the number agreed in advance) and uploaded the results in a digital map provided by the Cartographic Institute of Catalonia, called Instamaps (Figure 2).

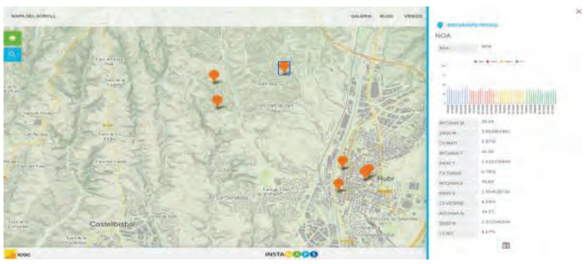

Figure 2: Instamaps of Rubí (www.instamaps.cat)[1]

Second part: How does noise affect our health?

The second part of the project followed the same structure as the first one and took place during the next 12 sessions. However, in this case, the previous study was carried out entirely by the students. In groups, they looked for information about how the noise affects our health and summarised it in an infographic made with Canva, which they shared with the rest of the students making an oral exposition in class. They then made their own hypotheses considering the previous research and gathered data in two steps. First, students, always in groups, proposed the type of questions they

[1] https://www.instamaps.cat/visor.html?businessid=b099e4b7093f76d5bf574d1e26dc4893&3D=false#14/41.5007/2.0225

should ask to the inhabitants of the city to study if the noise affected their health. Questions were shared in a padlet, commented in class to select the most suitable ones. Students administrated the survey in the two different parts of the city identified in the previous phase of the project: the city centre or red zone and the outskirts or the green zone. A total of 435 answers were collected.

Again, for the statistical analysis, all the information in the Google Form was downloaded to an Excel file and the students, in groups of 4, made a descriptive statistical analysis (Figure 3).

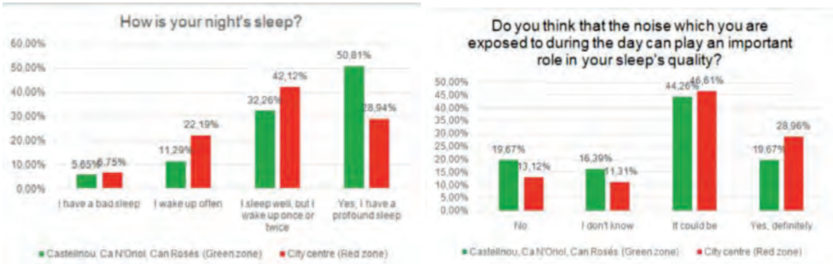

Figure 3. Examples of figures summarising two answers from the survey

As final results, students found that: most of the people were aware that the exposition to high amounts of noise for a long period of time could cause health problems; there was a difference between the people in the two zones in terms of their sleeping quality; and people suffered more from anxiety and stress than from physical health problems. At the end of the project, students made some general proposals to improve the noise pollution in the town, like installing porous paving which absorbs a high quantity of the acoustic wave, increasing the amount of pedestrian zones, organising workshops at schools, and using the local media (radio, magazines, newspapers) to make people aware of noise pollution and give advice on how to reduce the noise.

Analysing a teaching experience from a research perspective

Study and research paths as descriptive and analytical models

Researchers working in the Anthropological Theory of the Didactic (ATD, Chevallard, 2015) have been developing a methodology of analysis for teaching experiences that can be ranged into the category of inquiry-, problem- or project-based learning and are conceptualised as *study and research paths* (SRPs). These instructional practices correspond to the pedagogical *paradigm of questioning the world*, where one studies open questions and develops knowledge – with other kind of tools – to provide answers to them. Some difficulties found in implementing projects can be explained by the prevalence, at school, of the *paradigm of visiting works*, in which curricula are first proposed in terms of organisations of knowledge to study (or "visit") and problems, projects or investigations tend to be subordinate to them: one approaches a question – or carries out a project – to encounter some specific knowledge organisation.

As shown by Bosch (2018), SRPs are not only instructional proposals designed and implemented within the ATD, but they can also be used as *models* in the scientific meaning of the term: not examples to follow, but conceptual constructions to better analyse empirical experiences. The main research question motivating these analyses is to better know the conditions that can foster the implementation of project-based teaching and the barriers or constraints that hinder it. The set of conditions and constraints of all kinds (curricula and pedagogical resources, classroom management, school organisation, society determinants, etc.) correspond to what we call the *ecology* of teaching and learning processes.

The study we present here is an example of the use of SRPs as a descriptive and analytical tool applied to an empirical teaching process organised in terms of project-based learning that was implemented by a teacher without any connection to didactics research, let alone the ATD. In fact, the teacher decided to teach statistics through projects without relying on any specific PBL perspective. Our purpose is to show some key elements of the teaching process – now interpreted as an SRP – that help to better understand its ecology. In the next sections, we introduce at the same time the notion of SRP and the analysis of the teaching process only for the first part of the project.

The Herbartian schema

In an SRP, the generating question is the main purpose of the inquiry. Students, guided by the teacher, address them by proposing new derived questions, searching data and pieces of information potentially useful, and studying them. The results of the study are then contrasted and validated with the data and old information available, which usually produces new interrogations calling for new data and information, etc. At the end, what matters is to be able to provide an acceptable answer to the initial question and disseminate it. The Herbartian schema proposed by Chevallard (2011) identifies some key elements of an SRP. The reduced form of the schema $S(X; Y; Q) \hookrightarrow R^{\heartsuit}$ indicates a didactic system S where a group of students X with the help of a group of teachers Y address a question Q to provide their own answer $R^{\heartsuit}$. The developed form of the schema $[S(X; Y; Q) \rightarrowtail M] \hookrightarrow R^{\heartsuit}$ includes a *milieu* M with all the resources used by $S(X, Y, Q)$ during the inquiry: questions Q_i derived from Q, external answers or works $A_j^{\lozenge}$ elaborated by others that seem useful to address Q, empirical data D_k and other pieces of knowledge, virtual and material objects O_m :

$$[S(X; Y; Q) \rightarrowtail \{Q_i, A_j^{\lozenge}, D_k, O_m\}] \hookrightarrow R^{\heartsuit}.$$

Some commonalities have been identified in the teaching experience:

- The starting point is an initial question, called the "generating question", the teacher raises in a global way, to the whole group of students.
- The project is a collective work, that is, the answer to the question is a joint report from the whole class, which will be submitted to the contest. Despite some of the work was organized in small teams, students share their results and the new questions or directions to follow.
- The work is guided through partial questions, with some given or requested answers.
- Several supports and tools were used: interactive maps, mobile applications, digital campus, etc.

Using the Herbartian schema, we have a single teacher $Y=\{y\}$, a whole class X consisting of students x_i sometimes organised in teams X_j. The generating question Q was divided by the teacher into two sub-questions: how noisy the city is ($Q1$) and how noise affects our health ($Q2$). Along the experience other questions, proposed by X or y, appeared and they were related to institutional answers $A_j^{\lozenge}$, (like the definition and measure of noise, or the statistical notions to determine a sample, organise data, summarise and visualise it, etc.). Material and digital tools were mobilised: Excel, DecibelX, Instamaps, Canva, GoogleForms, etc., together with the students' familiarity and knowledge about the town and what produces noise. Finally, an important element of the project is the data collected D_k, linked to new knowledge work as its quality, reliability, representativity, etc.

However, an SRP is a dynamic entity where questions generate the need for answers with, in turn, raise new questions in a kind of selfsustained process (Bosch & Winslow, 2015). Next some examples are given, to show the dialectic between questions and answers and its crucial role in the dynamics of the process.

The questions-answers dialectic of the first part of the project

In an SRP many questions are raised, some more explicitly than others. Pieces of answers are provided to these questions, by the teacher or the students, using available resources or producing them by themselves. Space limitation only permits us to present a short account of the questions and answers that appeared during the first part of the project, those more implicit are indicated into brackets. We will next use this summary to analyse the teacher's and students' role in the inquiry.

Q1 Is Rubí very noisy?

Q1.1 What is noise and how to measure it?

→ A1.1 Teacher's presentation about noise A1.1.2 Introduction of the app DecibelX

Q1.2 [What do we know about Rubí's noise?]

→ A1.2 Official noise map of Rubí in 2012

Q1.3 Is the map still valid today? Can we reproduce it partially?

  Q1.3.1 Where do we live in Rubí?

  → A1.3.1. We are distributed in different zones of the town

  Q1.3.2 What are the characteristics of the surroundings of where we live?

  →A1.3.2 Google Forms answering some questions

  Q1.3.3 [How to collect data?]

  → A1.3.3 Using DecibelX in each student's zone in different hours, with a survey

  Q1.3.4 How many data are necessary?

  → A1.3.4 Formula and determination of the sample size

  Q1.3.5 How are we going to analyse the data?

  →A1.3.5 With the mean, standard deviation, coefficient of variation and graphics

  Q1.3.6 How many data do we have? How are they? Are there errors?

  →A1.3.6 Data collection check

  Q1.3.7 What do the collected data say?

  → A1.3.7 Data cleansing, numerical and graphical summaries, interpretation

→ A1.3 In some zones, Rubí is less noisy than in 2012 […]

Figure 4 shows the map of questions and answers only for the first phase, using the above notation.

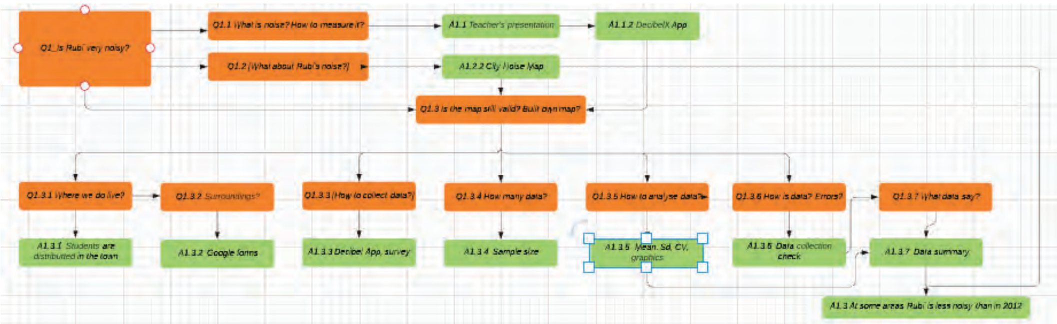

Figure 4: Map of questions and answers of the first part of the project

Some of the questions were proposed directly by the teacher, such as $Q1.1$ and $Q1.2$; few of them by the students. Some questions were answered using established works introduced by the teacher (the study dimension of SRP), while others need ad-hoc elaborations based on students' hypotheses, data compilation and exploitation (research dimension). The sharing of responsibilities between teacher and students was analysed. Table 1 summarises the involved elements (what), the class organisation (how) and the persons assuming the main active role (who) for the first 12 sessions. Remember that y represents the teacher, x_i individual students and X_j a students' team.

Table 1: Elements, methodology and main agent for the first 12 sessions of the project

#	What (elements)	How	Who	#	What	How	Who
1	Q1, Q1.1, A1.1, Q1.2, A1.2	Class	y	7	A1.3.5	Class	y, x_i
2	Q1.3, Q1.3.1, A1.3.1, Q1.3.2	Class + Indiv	y, x_i	8	Q1.3.6, A1.3.6	Class	y, x_i
3	Q1.3.3, A1.3.3, Q1.3.4, A1.3.4	Class	y	9	Q1.3.7, A1.3.7	Indiv	x_i
4	A1.3.2	Class + Teams	y, X_j	10	A1.3.7	Teams	X_j
5	A1.3.2	Teams + Class	X_j	11	A1.3.7	Teams + Class	X_j, y
6	Q1.3.5. A1.3.5	Class	y, x_i	12	A1.3	Teams + Class	X_j, y

The table shows that the teacher acted as main agent with a lot of active participation in most of sessions. However, an important characteristic of this project that is crucial in the paradigm of questioning the world is that all the new information, tools and pieces of knowledge introduced by the teachers were studied and activated by the students because they needed them to answer the question. The new knowledge was at the service of the project, not the other way round.

Concluding remarks

To analyse the constraints hindering the development of this teaching experience, we will consider two specific aspects. On the one hand, the experience was developed in response to a generic proposal, such as the announcement of a contest. The contest invites statistical work in the context of secondary education, as it is a topic included in the curriculum. The initial motivation of the contest is to influence the value given to statistics, especially its usefulness, to motivate students and get them interested in statistics. The generic recommendations and previous examples offered by the organisation of the contest include the case of formulating a question, a hypothesis or to do an experiment from which questions can be formulated. However, no detailed guidelines are given nor a specific PBL approach suggested; it is an open setting, passing the responsibility to the participating teachers, which leaves them alone and requires much more dedication. It also gives them more flexibility and allows more creativity.

On the other hand, although it may be influenced by instructional formats that are in vogue, defined independently of the content, the teacher did not have guidelines to follow. The implementation of projects in class was not a requirement of the school. It appeared as the teacher's response to the demotivation detected in a group of students, with the aim to show the usefulness of statistics. The teacher worked alone to prepare the project questions and answers, provide the tools to be used and guide the students' inquiry. The result was clearly an excessive burden of time that puts sustainability at risk. The analysis of the project through the ATD approach shows some characteristics of the project that could have been organised differently, for instance in the management of the questions-answer dialectic and the sharing of responsibilities between teacher and students: what was explicitly stated, what remained implicit; what was done by the teacher, what by the students and why, etc. Collaborative work between teachers and researchers can help identify the constraints that hinder the long-term sustainability of project-based teaching in statistics and, the most important, implement new conditions to overcome them.

Infodemiology and COVID-19: Using big data analytics to enhance secondary students' statistical thinking in an artificial intelligence era

Orlando González

Assumption University, Graduate School of Human Sciences, Thailand; ogonzalez@au.edu

The goal of this article is to illustrate how two Grade 12 Thai students, working together on an activity using Google Trends and COVID-19 open data from the Department of Disease Control of Thailand, engaged in the six phases of the framework for statistical thinking for the era of big data and artificial intelligence developed by González, Isoda and Araya (2020). The obtained results provide empirical evidence that senior high school students can successfully engage in infodemiology, a multidisciplinary field through which it is possible to observe the health-seeking behaviors of people involved in social media and their attitudes toward health and illness. This study documents the feasibility of enhancing secondary students' statistical thinking and literacy through the engagement in big data analytics to monitor new infectious diseases such as the COVID-19.

Keywords: Statistical education, COVID-19 data, statistical thinking, big data transnumeration.

Introduction

The interest in big data has been growing in many areas of today's society, including education. Big data (i.e., data that are too big for standard database software to process; Manyika et al., 2011), represents a paradigm shift in the ways that we understand and study our world, and at the very least, it is seen as a way to better use and creatively analyze information for public and private benefit. In order to make sense of big data, it is necessary to explore large, complex and seemingly unrelated sets of raw data, looking for significant correlations and new and unanticipated connections among them, using artificial intelligence (AI)-driven data analytics platforms, powerful enough to handle data sets with sizes in the order of terabytes, petabytes and zettabytes (Claverie-Berge, 2012; Glaser, 2018). These platforms are IT environments in which raw big data sets can be transnumerated under user request (i.e., converted into a new type of representation, within the platform restrictions, standards, and degrees of access) by AI (Ferguson, 2012). For example, search engines like Google and Google Trends use AI algorithms to analyze vast amounts of text online and determine, as quickly as possible, the most appropriate result for a particular search.

The concept of big data "refers to datasets whose size is beyond the ability of typical database software tools to capture, store, manage, and analyze" (Manyika et al., 2011, p.1). Additionally, big data is often associated with key characteristics that go beyond the question of size, namely the 5 Vs: volume, velocity, variety, veracity and value (Storey & Song, 2017). Big data is dispersed among various platforms that operate with different standards, providers and degrees of access (Ferguson, 2012). For example, a lot of work in big data focuses on Twitter, the blogosphere, and search engine queries. All of these activities are not undertaken equally by the whole population, which raises concerning issues around the question of whose data traces will be analyzed using big data.

Big data is opportunistic data (i.e., data already collected by others, not through personally-planned processes conducted by the user, and hosted somewhere). One way in which big data can be converted into a new type of knowledge is through machine learning, which is an automated process that extracts patterns from data using AI algorithms (Kelleher et al., 2015). This approach to data analysis, the big data analytics, is an iterative and exploratory process of using advanced technologies and analytical techniques on big data to reveal critical information, such as hidden and/or meaningful data patterns, trends and associations, which are data-first answers, and then users will work backward to find the questions that should have been asked (Claverie-Berge, 2012; Cumming et al., 2017; Glaser, 2018).

The big data analytics approach to data analysis is rarely, if ever, dealt with at school level (Wild et al., 2018). Instead, statistical thinking frameworks using a question-then-answer approach (e.g., such the PPDAC cycle), are commonly used when teaching statistics in the school. These question-then-answer approaches focus on data gathered systematically for a purpose, using planned processes, and chosen on statistical grounds (e.g., random sampling) to justify certain types of inferences and conclusions. This is one of the most relevant criticisms to current statistical thinking frameworks, because analyzing opportunistic data requires statistical thinking processes that do not necessarily follow the line of thought sketched by models such as the PPDAC cycle (Wild et al., 2018).

A framework for statistical thinking for the era of big data and AI

Addressing the aforementioned weakness of statistical thinking frameworks using a question-then-answer approach was one of the aims of the "Inclusive Mathematics for Sustainability in a Digital Economy" (InMside) project, supported by the APEC Secretariat[1]. One of the outcomes of the InMside project was a six-phase framework for statistical thinking for the era of big data and AI, describing how a big data user engages in statistical thinking with the support of an AI-driven platform (González et al., 2020). This framework understands statistical thinking as a cognitive process comprised of the following six phases[2].

- Big data quality assessment: Before engaging in creative discovery with big data, users must assess the quality of the big data at hand, in order to establish, among other things, from where the data came, how they were collected, and what instrument or questions were used to collect such data. In other words, this is a step in which the users assess big data's veracity (i.e., the assurance of quality or credibility of the collected data for the intended use).
- Patterns and relationships from data: Iteratively look for trends within big data sets, such as patterns and linear or nonlinear relationships between variables, with the support of an AI-driven data analytics platform (e.g., Google Trends), based on a particular interest.
- Questions: Pose critical and worry questions, in order to find plausible explanations to the patterns and relationships found. These questions are not digging into data searching for specific metrics, as in the traditional data handling approach.
- Objectives: Set objectives related to the posed questions, in order to analyze the data.
- Data mining: In order to achieve the objectives previously set, the user re-examines the data in the light of the objectives, explore old and new data sources, or introduce new variables for

[1] For more information, please refer to https://aimp2.apec.org/sites/PDB/Lists/Proposals/ DispForm.aspx?ID=2247

[2] For detailed information on this framework, the interested reader may consult the article by González et al. (2020).

consideration, using AI, machine learning and statistics.

- Designing: Provide ideas for new searches for trends within big data sets, based on the understanding of the past and present, and design plans and strategies for the future, based on the results from the data mining.

Using big data analytics to engage in infodemiology

Big data analytics allows data users and scientists to engage in a new research field known as infodemiology, which is the study of big data generated during a pandemic or other significant event that may impact public health, using web-based resources, in order to repurpose such data to inform public health and health policymaking (Kurian et al., 2020). During these times of COVID-19, using health-related data in a statistical investigation allow students to put into practice statistical thinking and big data analytics in the context of a real-life problem, as well as to fully experience statistical processes such as acknowledging, modelling of and reasoning about variability, data representation, data-driven argumentation, and informal inference (González et al., 2020; Watson et al., 2018).

Research methodology overview

Participants and data gathering procedure

For this study, a task named “Use Google Trends to tell a data story” was developed by the author, with the support of a Grade 12 mathematics teacher working in a large public high school in Bangkok, who administered the task to her 24 students (9 boys, 15 girls) via Zoom in real time on September 13, 2021, in two 50-minute-long consecutive sessions. This task required students to look for stories told by COVID-19 data using Google Trends (https://trends.google.com). All the participants were already familiar with using Google Trends and Excel, stating the “what” and the “why” while making charts with the application, using the six phases of the framework for statistical thinking for the era of big data and AI (González et al., 2020), and using and interpreting the COVID-19 Dashboard data from the Department of Disease Control of Thailand (https://ddc.moph.go.th/ covid19-dashboard). The students, arranged in pairs, were placed in breakout rooms and engaged in solving the task after being instructed by the teacher. Students were not assisted in any way as to influence their responses. When the task was completed, each group submitted their stories in a Word document to the teacher, including captures of Google Trends charts and any additional graphical representation or calculation made for the activity. A qualitative interpretive micro-analysis was used to analyze the data.

Summary of results: Yai and Nan’s answer

In order to illustrate the potential of this activity to enhance secondary students’ statistical thinking and literacy through the implementation of the six-phase framework for statistical thinking for the era of big data and AI (González et al., 2020), this paper presents, as a case study, a description of the answer given by one pair of students (two girls nicknamed Yai and Nan). This was due to the rich answers that occurred in this pair and the fact that these answers were deemed to be typical of the ones that occurred in the other pairs. The analysis of the collected data will be presented in terms of the six phases of the aforementioned framework for statistical thinking (González et al., 2020).

Big data quality assessment

The veracity of the big data to be used in this task was assessed by the researcher and the classroom teacher, who provided students with data from a trustful source (i.e., the Department of Disease Control of Thailand). Also, students were previously instructed to approach to big data analytics posing worry questions such as “Who created the source?” “What methodology did they follow in collecting the data?” “Did the data creators, or anyone else, summarize, edited or modified the data? Answers to these questions are necessary to assess and determine the veracity and quality of the data.

Patterns and relationships from data

Browsing news and media reports on the Internet, Yai and Nan found the date of the first confirmed case of COVID-19 in Thailand (January 12, 2020) and China (December 8, 2019). Then, they decided to set January 12, 2020 as the “Day Zero”, and created a data set from December 8, 2019, until April 4, 2020, the date in which all commercial international flights were suspended in Thailand, and lockdown measures were implemented in varying degrees throughout the country. When asked why they named January 12 as “Day Zero”, they answered that they learned from the movies that the first person infected by a disease is usually called “Patient Zero”.

Using Google Trends, this group chose three keywords to observe the online health-seeking behaviors of Thai people involved in social media, in relation to COVID-19, over the selected time period. The keywords were the following: flu, fever, coronavirus. Figure 1 shows the evolution of the online search trends for these three keywords in Thailand during the chosen timeframe.

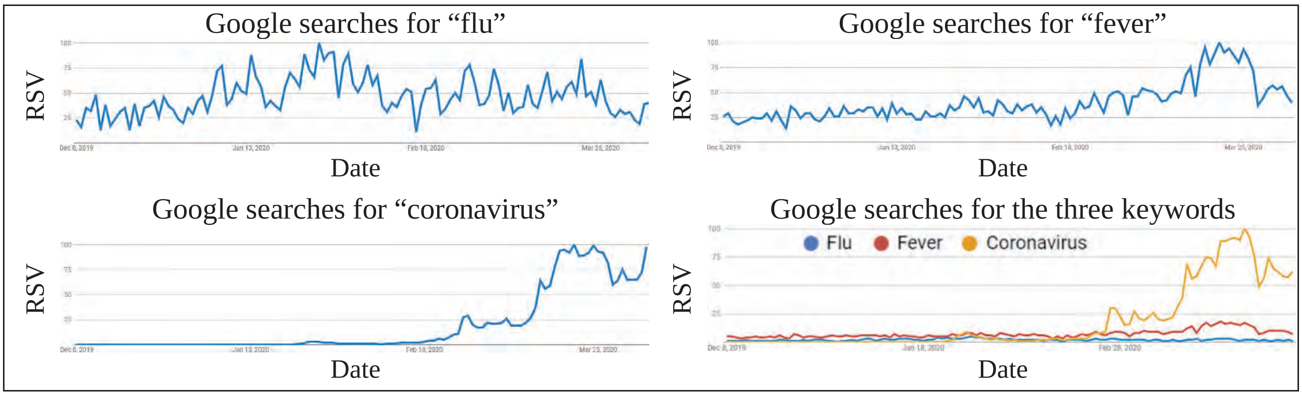

Figure 1: Relative search volumes (RSVs) of the Google queries “flu”, “fever”, “coronavirus”, and their simultaneous comparison, during December 8, 2019 to April 4, 2020 in Thailand

Making a naked eye analysis of the graphs depicted in Figure 1, Yai and Nan mentioned that the general trends of the Google searches for each of the keywords of interest changed after the “Day Zero”. In relation to this idea, they wrote the following:

> Yai and Nan: General trends on each graph show that interest in Thailand for searching “flu” and “fever” in Google spiked in “Day Zero”, but not for “coronavirus”. The Google Trends graphs for “flu”, “fever” and “coronavirus” were nearly parallel until January 26, 2020, when the searches for “coronavirus” started to increase, and more clearly from February 22, 2020, when the Google searches for “fever” and “coronavirus” increased in comparison to the searches for “flu”.

So, in order to write their data story, Yai and Nan explored sets of raw big data using Google Trends looking for patterns and connections, instead of digging into data searching for specific metrics. This approach provided them with data-first answers to questions they had not yet thought to ask.

Questions

Some of the questions posed by Yai and Nan, based on the patterns and relationships they found from their interpretation of Google Trends graphs depicted in Figure 1, are shown below.

- Why did the interest in Thailand for Google searching “coronavirus” started late in January 2020, almost two weeks after “Day Zero”?
- Why did the Google searches for “fever” and “coronavirus” start to show a noticeable increase after February 22, 2020, in comparison with the Google searches for “flu”?
- What happened in Thailand from March 13 to 25, 2020, that there was a common increase in the Google searches for “flu”, “fever” and “coronavirus”?
- Is there a relationship between the volume of Google searches for “flu”, “fever” and “coronavirus” and the number of daily new COVID-19 cases reported in Thailand during that time period?

Then, from the data-first answers generated in the previous phase, Yai and Nan worked backward to find the questions that should have been asked. These questions can lead to the creation of more data representations in order to find explanations to the patterns and relationships previously found.

Objectives

After posing questions to arrive at insights about the patterns and relationships previously found, Yai and Nan, were able to set clear objectives to continue their data analysis, such as the following:

- To identify the reasons why the interest in Thailand for Google searching “coronavirus” started late in January 2020, almost two weeks after “Day Zero”.
- To identify the reasons why Google searches for “fever” and “coronavirus” started to show a noticeable increase after February 22, 2020, in comparison with the Google searches for “flu”.
- To determine what happened in Thailand from March 13 to 25, 2020, that there was a common increase in the Google searches for “flu”, “fever” and “coronavirus”.
- To determine whether there is a relationship between the volume of Google searches for “flu”, “fever” and “coronavirus” and the number of daily new COVID-19 cases reported in Thailand during that time period.

Data mining

In order to address the objectives previously set, Yai and Nan engaged in data mining. Data mining is the process of finding and extracting relevant data, previously unknown but potentially useful, in a heterogeneous data repository, using AI, machine learning and statistics (Cumming et al., 2017). In order to exemplify this phase in Yai and Nan’s work, let us briefly address the objectives stated above.

Any verbal statement can be considered to be a hypothesis. Therefore, in the context of data mining, a hypothesis is an explanation of some phenomenon (e.g., a cause-effect relationship or a trend in data) that can be argued by the means of data analysis. Then, Yai and Nan hypothesized, in relation to the first objective, that the term “coronavirus” was not on most Thai people’s health radars by that time. Yai and Nan confirmed this hypothesis when they found, through Google searches, that the terms “novel coronavirus” and “2019-nCoV” were mentioned by the World Health Organization (WHO) in their first situation report, published in January 21, 2020.

In relation to the second objective, Yai and Nan surfed the Internet to find plausible answers. They concluded the following:

Yai and Nan: It is very likely that the noticeable increase in Google searches for “fever” and “coronavirus” that started in Thailand after February 22, 2020, was due to the news of the 10 towns locked down in Italy, which was released on February 23, 2020, after as the number of reported cases in Italy grew from fewer than five to more than 150. Also, the Ministry of Public Health and the Department of Disease Control of Thailand had a daily broadcast to instruct population about COVID-19, and by that time thermometers were placed in most public spaces, so people were watching their temperature, since people knew that “fever” was one of the most common symptoms of COVID-19.

In relation to the third objective, Yai and Nan concluded, after surfing the Internet, the following:

Yai and Nan: We think that the noticeable spike in Google searches for “flu”, “fever” and “coronavirus” that happened in Thailand from March 13 to 25, 2020, was mainly because of the state of emergency to control COVID-19 declared by the Thai Prime Minister and Cabinet on March 17, to become effective on and from March 26 to April 30, 2020. This measure prohibited entering into Thailand, entering in crowded areas and places at risk of COVID-19 infection, gatherings of many people, and only certain businesses were allowed to open. Also, on March 22, Thailand reported 188 new COVID-19 cases, the largest single-day rise until then, and the first time that more than 100 new cases were reported. Another possible reason could be the announcement of the death by COVID-19 of four Thai nationals on March 24. Before that, only one person had died of the virus in Thailand.

In relation to the last objective, Yai and Nan used the data from the Department of Disease Control of Thailand to obtain the number of daily new COVID-19 cases reported in Thailand from “Day Zero” to April 4, 2020, and plotted them in Excel against the RSVs for each of their Google queries, which they downloaded from Google Trends. The results are depicted in Figure 2.

Pearson correlation coefficients were calculated between each Google query’ RSV and the daily new COVID-19 cases in Thailand. On this matter, Yai and Nan wrote the following:

Yai and Nan: The Excel scatterplots revealed a moderate to strong relationship between the volume of Google searches in Thailand for “fever” and the daily new COVID-19 cases reported from “Day Zero” to April 4 ($r = \sqrt{0.363} = 0.602$). A strong relationship was found between the volume of Google searches in Thailand for “coronavirus” and the daily new COVID-19 cases reported during the chosen period ($r = \sqrt{0.6756} = 0.822$). We interpret these results as evidence that, as the number of COVID-19 cases increased, Thai people’s interest in searching information on “fever” and “coronavirus” also increased. However, the relationship between the volume of Google searches in Thailand for “flu” and the daily new COVID-19 cases reported during the chosen period was negative, because of the decreasing linear trend, and moderate ($r = -\sqrt{0.094} = -0.307$). We think that when more was known about the nature of COVID-19, so agencies and Thai people got to know that COVID-19 wasn’t a flu variety, then the volume of Google searches in Thailand for “flu” wasn’t as large as the volume of Google searches for “coronavirus” or “fever”, one of the most common symptoms of COVID-19.

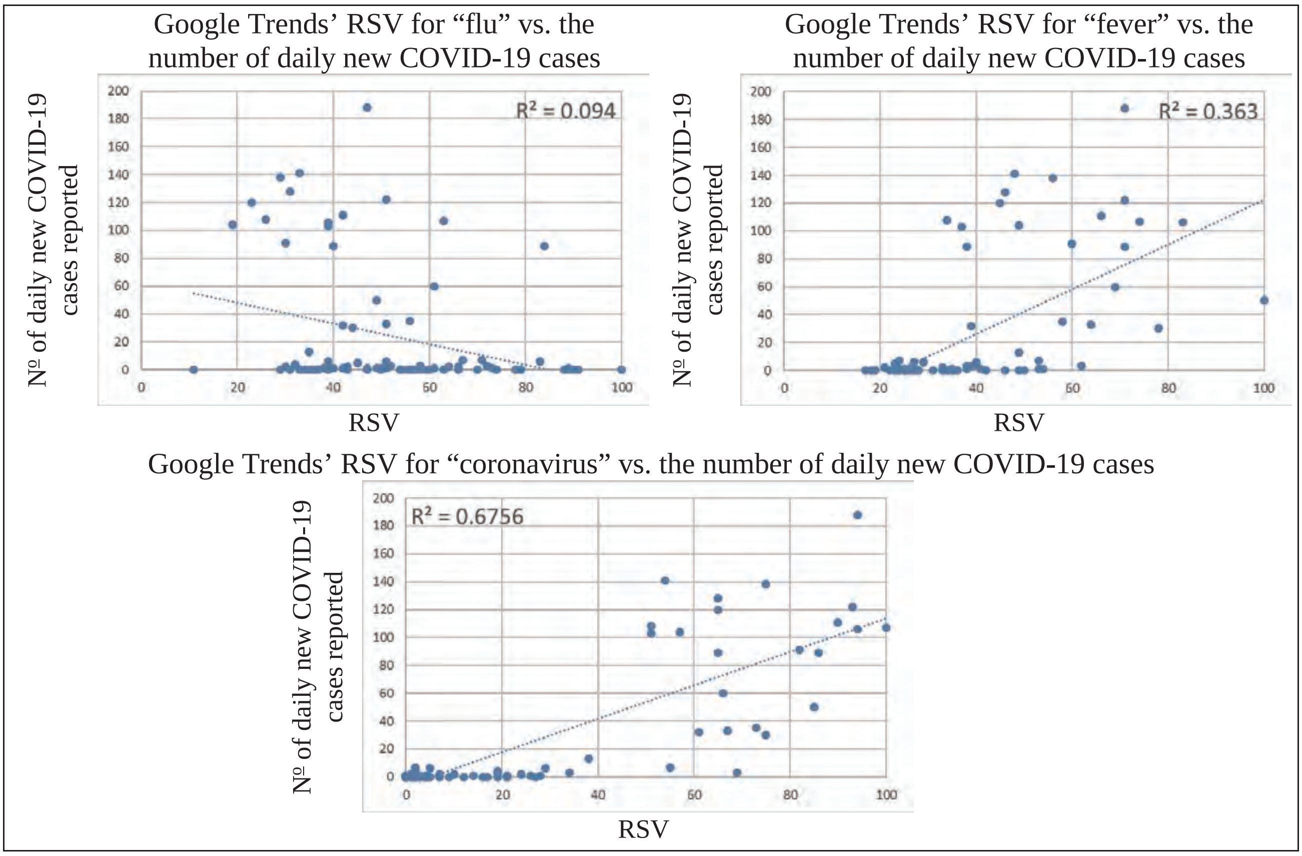

Figure 2: Scatterplots of the daily new COVID-19 cases reported in Thailand from January 12 to April 4, 2020, as a function of the RSVs of the Google queries "flu", "fever", and "coronavirus"

Designing

From all the insight and valuable knowledge Yai and Nan gained through engaging in the data mining phase (e.g., Thai people learning that COVID-19 was not a flu variety), they were able to design plans and strategies for the future, to generate value of some sort. For example, they suggested the creation of health education campaigns about COVID-19 using music and animated cartoons, so Thai people avoid considering COVID-19 as a flu variety, self-medication, and underestimating its symptoms.

Summary and implications

Google Trends is a proven AI-driven tool for evaluating people's information-seeking activities. If Google Trends is used to describe interest on health issues or health-seeking behaviors of people involved in social media, then we are engaging in infodemiology, which is the area of scientific research that focuses on scanning the Internet, publicly available data (e.g., public health and government databases) and other sources for user-contributed health-related data. This study reveals the benefits of engaging secondary students in infodemiology, through big data analytics using Google Trends, for their development of statistical thinking in this era of big data and AI. In fact, while engaged in data mining, Yai and Nan provided answers similar to those by Kurian et al. (2020).

Although this short description is far from exhaustive, the findings reported in this paper have practical implications for the teaching and learning of statistics, suggesting how an activity designed to engage students in infodemiology and big data analytics is particularly suited to support the development of statistical thinking for the era of big data and artificial intelligence through the implementation of the six phases of the big data analytics approach identified by González et al. (2020). Even though the traditional question-then-answer approach can still be used to find answers when we have specific needs, when it comes to finding the most impactful ways to reveal stories from big data, people that let the data provide the questions first, as in the approach described by González et al. (2020), Claverie-Berge (2012) and Glaser (2018), will get the best and more insightful results.

Data science and especially machine learning issues are currently the subject of lively discussions in society. Many research areas now use machine learning methods, which, especially in combination with increased computer power, has led to major advances in recent years. One example is natural language processing. A large number of technologies and applications that we use every day are based on methods from this area. For example, students encounter these technologies in everyday life through the use of Siri and Alexa but also when chatting with friends they are supported by assistance systems such as predictive text systems that give suggestions for the next word. This proximity to everyday life is used to give students a motivating approach to data science concepts. In this paper we will show how mathematical modeling of data science problems can be addressed with students from tenth grade or higher using digital learning material on predictive text systems.

Keywords: mathematics education, Jupyter Notebooks, natural language processing, mathematical modeling, data science.

Motivation and classification of the research area

The use of mobile devices has increased enormously in recent years. This results in a high demand for fast and reliable input methods. One of these assistance systems for typing is word prediction. It makes suggestions for the next word based on expressions already written to save the time of the user when typing. But how does this assistance system know what the user wants to write next? How can word suggestions be generated in such a way that they suggest the desired word with high probability? Answering these questions is the goal of the interactive workshop.

Word predictions are predictive text systems, which are developed within the scientific field of natural language processing. The main goal of natural language processing is to study, how humans understand and use language in order to develop software programs, that allow computers to simulate human behavior (Chowdhury, 2005, p. 51). Predictive text systems also attempt to mimic the language of the user. Specifically, they involve the prediction of letters, words, or even entire word sequences. However, predictive text systems are not only used in typing, but also in speech recognition, spell correction, machine translation, and handwriting recognition (Ghayoomi & Momtazi, 2009, p. 5233). Predictive text systems are thus “one of the important tasks in most natural language processing applications” (Ghayoomi & Momtazi, 2009, p. 5233) and are encountered by students in their everyday life. This makes it an authentic and relevant topic.

In order to give predictions for a text, predictive text systems work with large text data to extract knowledge from it. The N-gram concept, which is a simple decision tree model, is used in the workshop to bild suitable word suggestions out of the text data (Bahl et al., 1998, p. 1002). This makes it a typical problem in the field of machine learning and data science.

Since data now play a central role in all areas of our lives, it is necessary to give learners an understanding of data science issues and to train them in the critical use of data (Gould, 2021; Opel et al., 2019). Therefore, based on the mathematical and technical knowledge in the modeling of data science questions, digital learning material for high school students should be developed and tested on real problems. The topic of predictive text systems was seen as a particularly suitable example to convey machine learning and data science concepts in an easily accessible way in school lessons. In a design-based research approach, learning material on this topic should be designed, developed and improved in cycles of implementation and redesign with systematic feedback from students.

Background information on the learning material

In the workshop, high school students work out how occurrence frequencies of word sequences can be estimated using large data sets and how they can be used to generate word suggestions. On several worksheets, they collect first ideas for developing a prediction model and then develop different basic models for generating word suggestions. Finally, they apply these models to a large training data set.

The learning material is suitable for students from tenth grade and higher. The workshop assumes prior knowledge of relative and absolute frequencies, as well as prior knowledge of the concept of functions. In addition, students should understand and be able to calculate probabilities and perform and evaluate simple multistage random experiments. Programming skills are not required. The learning material can be used in a compact one- or two-day workshop or divided into several lessons of a teaching unit, both in presence but also in online classes.

A problem-oriented workshop

The developed learning material uses the example of word prediction to show how real-world problems solved using big data can be prepared for students. It approaches the topic in a problem-oriented manner and introduces mathematical content when it is needed to find and understand the solution of the problem. Thus, the problem is the focus and mathematics is experienced as a tool that helps to understand the world, so that the students do not only learn mathematical methods but can recognize the usefulness of mathematics for everyday life. This strategy is part of all workshops that are created within the CAMMP (Computational and mathematical modeling program) project of the Karlsruhe Institute of Technology[1] and the RWTH Aachen University[2]. The overall goal of the project is to promote competencies in mathematical modeling among learners through a variety of learning opportunities and to highlight the importance of mathematical modeling and simulation science for society. CAMMP aims to achieve this goal by providing education and training for teachers in mathematical modeling and by continuously developing and testing new learning material. All workshops created in the project are implemented as digital learning material.

Digital learning material

Digital learning material in school context is already a much discussed topic due to the advancing technological development of society and is currently gaining even more importance for schools teaching due to the Covid-19 crisis and the distance learning associated with it. For mathematical modeling, digital learning material has a special significance, as it enables the solution of real-world problems with large amounts of data in school context and can be a useful support for learners, especially in complex reality-based problems (Geefrath & Siller, 2018, p. 9-10).

This learning material is therefore implemented in the form of digital worksheets, so-called Jupyter Notebooks (see Figure 1), which can be accessed via a cloud platform hosted by the Karlsruhe Institute of Technology. The material can thus be edited directly in the web browser. The login process to the platform is described at www.cammp.online/english/214.php. The digital working material contains many different building blocks clearly arranged in a single file. Instructions, formulas, illustrations, but also code fields can stand directly next to each other and facilitate the learners work in the workshop. Digital differentiation material, such as staged help as fold-out text or in the form of a link to a separate file, as well as consolidation tasks, make the learning material very suitable for heterogeneous learning groups. Additional differentiation is provided by information sheets that are linked to the worksheets and can be called up by the learners if required. For example, learners who have no experience in programming are supported by information about for-loops or if-statements. The subdivision of the problem into smaller tasks as well as adaptive, automated feedback on the solutions enable the learners to work through the material very independently. A more detailed description of the form of the learning material can be found in Gerhard et al. (in press).

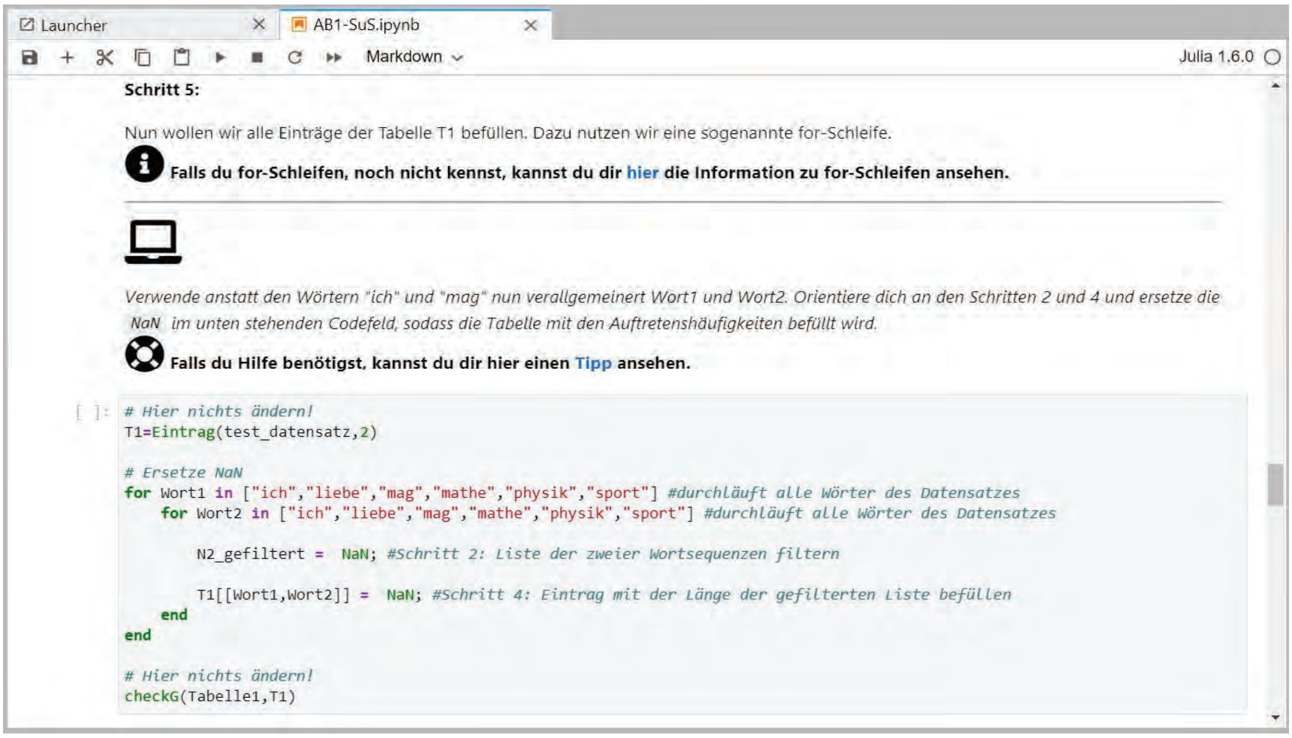

Figure 1: Screenshot of a digital worksheet from the learning material on word predictions

Didactic preliminary considerations

In the development of the learning material, particular attention was paid to the independent implementation of the prediction model by learners. At the end, the solution of the problem should not only be understood theoretically, but also worked out practically. Only minor technical details, which are less relevant for the basic mathematical understanding, are executed in the background.

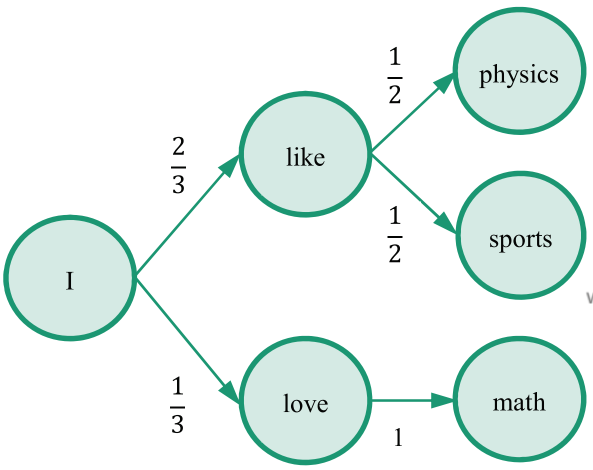
Furthermore, care was taken to avoid unnecessary technical terms, like “Markov chain” or “matrix”. Merely the nth-order Markov assumption is relevant for the workshop. Students will only learn about the applied assumption to the word prediction example. Here it means that the frequency of occurrence of words depends only on the n previous words. In the workshop the assumption thus simplifies the estimation of the occurrence frequency. Also, the term matrix, since it is not known by some learners depending on their previous schooling, is circumvented by paraphrasing it with tables. Since the matrix is only used as a storage form, this can be done without problems in the workshop.

Detailed description of the material

Worksheet 1: A first prediction model

To understand how word predictions are generated, the workshop will first look at a small example. As data basis, which will be used later for comparison, the three sentences "I like physics. I like sports. I love math." will be used. This represents the so-called training data of the prediction model and, in contrast to the training data sets used in practice, which comprise several thousand words, is chosen to be very small in order to be able to clearly illustrate the principle of word prediction. With the help of this data set, the word that the user would most likely write next should be suggested, if possible. It is first assumed that the user has already typed the word "I". Ideas and thoughts about possible suggestions for the next word and how to build them based on the data set, are first collected in a short brainstorming session in plenary. So far, the students always discovered independently that one possible strategy for generating the word suggestions is to compare the already typed word sequence, in our case the word "I", with the data set. In this way, we can determine which word has already been typed in the past after this word sequence and use this information for our prediction.

In our small training data set, the word "I" is found in three places. Now the words which follow can be identified. These are the words "like" and "love". One can therefore assume that these are popular



word2

word1	I	love	like	math	physics	sports
I	0	$\frac{1}{3}$	$\frac{2}{3}$	0	0	0
love	0	0	0	1	0	0
like	0	0	0	0	$\frac{1}{2}$	$\frac{1}{2}$
math	0	0	0	0	0	0
physics	0	0	0	0	0	0
sports	0	0	0	0	0	0

Figure 2: Transition graph (left) and transition table (right) of the bi-gram model

subsequent words after the word "I" and thus also represent meaningful suggestions for the next word. The word "like" follows the word "I" more often than the word "love". The probability of the word "like" occurring after the word "I" should thus be estimated as higher according to our training data. Quantitively, this so-called transition probability of the word "like" occurring after the word "I" $\mathrm{P}(\mathrm{I} \rightarrow \text{like})$ can be estimated via the occurrence frequency of the two-word sequence (I, like) as well as the occurrence frequency of the two-word sequence (I, any word) and results in

$$\mathrm{P}(\mathrm{I} \rightarrow \text{like}) = \frac{\mathrm{N}(\mathrm{I}, \text{like})}{\mathrm{N}(\mathrm{I}, \mathrm{I}) + \mathrm{N}(\mathrm{I}, \text{like}) + \mathrm{N}(\mathrm{I}, \text{love}) + \cdots} = \frac{2}{0 + 2 + 1 + 0 + 0 + 0} = \frac{2}{3}.$$

These two-word sequences are also named bi-grams, which explains, why the corresponding model is called the bi-gram model. In order to display and store the different transition probabilities in a suitable form, the students learn two different possibilities. The visual representation as a transition graph (see Figure 2, left side) serves mainly as a visual support for the learners, while the transition table (see Figure 2, right side) is especially suitable for a larger data set as a storage location for the transition probabilities. The row of the transition table represents the already typed word (word1), the so-called word history, and the column represents the following word (word2). If a word is now typed, the next word with the highest probability can be found in the corresponding row and indicated as a suggestion.

Based on this, learners develop a general strategy for estimating transition probabilities from a training data set using the occurrence frequencies of two-word sequences and automate the process for all possible transitions so that the calculations no longer need to be done by hand. Now the model can be tested on a larger data set. A larger data set is important so that meaningful suggestions for the next word can be made for as many already typed words as possible. As soon as the already typed word does not occur in the training data set, no suggestion can be made using the bi-gram model. The training data set used for this purpose consists of the German-language texts of the corpus "What's up, Switzerland" (Stark et al., 2014-2020) and the texts of the category "Belletristik" of the corpus "LIMAS" (Research group LIMAS, 1970-1971). The training data set contains more than 300,000 words. From this, part of the data is retained for later testing of the model.

The model is first trained with the help of sample texts, the so-called training data set. Subsequently, the correlations detected from these can be used for prediction on an unknown data set. Bi-Gram models therefore use typical machine learning strategies.

Worksheet 2: Uni-gram and tri-gram model

When testing the bi-gram model with different word histories, learners are tasked with identifying various problems of the model and coming up with possible model improvements. Among other weaknesses of the model, learners recognized that the prediction model uses only the last word for word prediction and that the word history needs to be extended to more than one word for more context-based suggestions. To do this, students use the learning material to develop a tri-gram model that takes the last two written words into account to build a suggestion.

Another problem, which learners will identify through examples in the workshop, occurs when the word already typed does not appear in the data set. In this case, there is an option to suggest the words that occur most frequently overall in the training data set. This model is called a uni-gram model, because the occurrence frequencies of one-word sequences are determined instead of two-word sequences, as in the original model. The transition probability is calculated by dividing the occurrence frequency of the single word by the total number of words at

$$\mathrm{P}(\text{word 2}) = \frac{\mathrm{N}(\text{word 2})}{\mathrm{N}(\text{every word})}.$$

In the workshop, learners now collect advantages and disadvantages of the three n-gram models, to finally realize that all models have different strengths and weaknesses and that they need to be combined for the best possible prediction of the next word.

Worksheet 3 and 4: Combined models and model evaluation

The combination of the n-gram models makes it possible to realize the probability estimation more reliably and at the same time context-based. For the combination of the models, the back-off procedure or the interpolation are mainly used in natural language processing (Wendemuth et al., 2004, p. 30-31). The back-off procedure is a fall-back strategy. In the case of an unseen bi-gram as a word history, the tri-gram model does not give any suggestions for the next word. Therefore, the bi-gram model is used. If the last word in the word history also does not appear in the training data set, the uni-gram model is used and the words that appear most frequently in the data set are suggested. The students implement the back-off procedure with the help of a simple if statement. As a result, the students learn different combinations of possible n-gram models, while they are improving their basic programming skills.

However, with the back-off procedure, the model may count on the tri-gram probability, which is often not as reliable. This is because there are much more tri-grams than bi-grams or uni-grams. Therefore, many tri-grams do not appear in the training data set, or appear only very rarely. This means that the tri-gram likelihood is often based on very little data compared to the bi- or uni-gram model. It is therefore always best to use all transition probabilities of the individual models and combine them with a weighted sum to produce an overall transition probability. The new estimator of the transition probability of word2 with word history (word0, word1) is thus given by

$$\widetilde{\mathrm{P}}(\text{word 0}, \text{word 1} \rightarrow \text{word 2}) = \mathrm{g}_1 \cdot \mathrm{P}(\text{word 2}) + \mathrm{g}_2 \cdot \mathrm{P}(\text{word 1} \rightarrow \text{word 2})$$
$$+\mathrm{g}_3 \cdot \mathrm{P}(\text{word 0}, \text{word 1} \rightarrow \text{word 2}).$$

The interpolation weights g_1, g_2 and g_3 are initially determined by the learners in a range selected by logical considerations. Later, the weights can be optimized by minimizing an error measure. In this context, the distinction between training data, which are used to estimate the transition probabilities, and test data, which are used to determine the goodness of the language model, but also the weights of the interpolation, is important. Here, the students have the opportunity to independently develop an optimization procedure for minimizing the error measure as a function of the weights or, guided by another worksheet, to learn about one possible procedure.

At the end of the workshop, the initially qualitative considerations regarding the advantages of combining the n-gram models compared to a single n-gram model can also be confirmed quantitatively by calculating an error measure.

Additional tasks

Another optional task for learners is to use the prediction model, they have developed, to generate whole texts. Learners can choose different prediction models (a combined model or a single smoothed n-gram model) and observe differences in text generation. The higher the n-gram length is chosen, the better the generated text will be in both grammatical and contextual terms. At higher orders, the generation is comparable to copying individual sentence strings from the training data set.

Furthermore, the workshop is followed by some social questions about the benefits and dangers of these assistance systems, which can be debated with the learners in an open exchange. Questions such as "Do assistance systems, like word prediction, influence writing behavior?" or "How do biased word suggestions arise and what are their effects?" are particularly suitable for critical discussion. On the one hand, dealing with these questions serves to dive deeper into the topic. On the other hand, it shows a second perspective on the problem from a socio-scientific point of view and, by critically illuminating the assistance systems in plenary, it contributes to empowering the students to form independent critical judgments. The learning material is therefore suitable for application in interdisciplinary lessons, for example in a seminar or a project week on natural and social sciences.

In addition, another worksheet is in progress, which will give students the opportunity to use different data sets as training data for the prediction model. In this way, the influence of the training data on the language model can be highlighted and thus attention can be drawn to the importance of a suitable training data set.

Experience and summary

Data science in school is desirable and possible. This is demonstrated by the learning material described above, but also by other projects such as ProDaBi (Opel et al., 2019), in which a data science curriculum was developed and tested in high school, or the experience of Narges Norouzi et al. (2020) with learning material in machine learning and natural language of the COSMOS Summer School for high school students.

In this workshop, students learn how knowledge can be generated from data and used to support decisions when typing. In doing so, they use typical machine learning strategies. The learning material has already been conducted in an online workshop with 28 learners and will be tested more frequently and continuously improved in the future. The conduction took place as a two-day event during the summer vacations with students from grades ten to thirteen. Additionally, the workshop was conducted and examined from a didactic point of view with 29 teacher trainees of the RWTH Aachen University in one day as part of a didactic seminar. Especially the independent work of the high school students on the open tasks to optimize the interpolation weights and to generate their own text using the prediction model on the second workshop day shows how quickly the students were able to familiarize themselves with a topic that was new to them. After conducting the online workshop with students from grades 10 to 13, the students were asked to fill out an online questionnaire in order to use the results and past experiences to iteratively improve the workshop. The students named machine learning, mathematical modeling, as well as programming basics, among others, as areas in which they could see an increase in learning after the workshop. The workshop was rated with an average grade of two (good).

During the conduct, the learners contributed interesting ideas to the mathematical model, but also to the socio-critical discussion. The high oral participation of the learners shows how interested they are in understanding and solving the problem and the positive feedback from the learners also speaks in favor of the project: “I found the insight into generating word suggestions very interesting and it was a very good example of how mathematical modeling is applied in everyday life.” (Participant’s answer in the evaluation of an online workshop, personal communication, August 27, 2021).

Task design to foster informal statistical inference in upper secondary school: focusing on correlation with multivariate data

Koki Hosoda

University of Tsukuba, Graduate School of Comprehensive Human Sciences, Japan;

hosoda.koki.wy@alumni.tsukuba.ac.jp

Keywords: Informal statistical inference, correlation, multivariate data.

Introduction

Recent statistical education research has focused on informal statistical inference (ISI), without using formal inferential statistical procedures to understand the concept of uncertainty (Makar & Rubin, 2018). Kazak et al. (2021) focused on the relationship between multivariate data and ISI, and identified students' difficulties about the relationship between correlation and uncertainty. On the other hand, there is a few studies related to the task of improving students' understanding with correlation and uncertainty, and promoting ISI. Accordingly, this study discusses the instructional guidance needed to resolve them and the task promoted ISI with multivariate data. This study develops a task to promote ISI, by focusing on correlation with multivariate data.

Method

In this study, the principles of the task designed from a theoretical perspective are based on collaboration with researchers and teachers. Makar and Rubin (2009) defined ISI as comprising three elements — "generalization beyond the data at hand," "use of data as evidence of generalization," and "representation of uncertainty with probabilistic language." Further, Engel and Sedlmeier (2011) pointed out the importance of understanding the concept of correlation as distinct from that of regression, and the need to understand data as a construct of signal and noise, whilst also considering the role of variability. The principles of the task design for this study, based on previous literature, are presented in Table 1. Subsequently, a tentative task, the "Decathlon Data Project," was developed based on the principle of the presented task design.

Principle	Description of the principle
Principle 1	Researchers and teachers should develop problems that enable students to use correlations to identify the relationship between variables through real multivariate data and to, subsequently, make generalized predictions.
Principle 2	Teachers should plan their instructional guidance to enable students for technological modeling and making generalizations based on evidence on the relationship between various variables.
Principle 3	Teachers should encourage students to reflect on the process and conclusions of data analysis, as well as account for the explanations (Signal) and unexplained variations (Noise) in the data.

Table1: The principles of task design in this study

Results and Conclusion

The developed task pertains to the Olympic Decathlon (Figure 1).

The "King of Athletes" is a decathlon in athletics, in which the participants' ranking is determined by their total score from ten different events. In the 2021 Tokyo Olympics, two Japanese athletes, who competed in the previous Rio Olympics (Keisuke Ushiro and Akihiko Nakamura) could not participate because they were unable to achieve the participation standard score of 8350 points. Thus, based on the score data of the 23 athletes who participated in the Tokyo Olympics and the two Japanese athletes, what events would you suggest to the Japanese athletes to practice and participate in, in order to win a medal in the next Olympics?

Figure 1: The task of the "Decathlon Data Project"

Principle 1: This task aims to predict the events that the Japanese athletes should focus on for the next Olympic Games, by considering the relationship between the total score and each event and between the events based on real data of the decathlon. *Principle 2*: This task was designed to enable students to predict the events that the athletes should focus on by determining the correlation coefficients between the total score and the points or records of each competition, using CODAP (Finzer, 2017) and Excel, and by creating scatter plots. *Principle 3*: In this task, the teacher encouraged students, through reflection, to recognize the need to further analyze data about world competition, since the proposed events are only based on the characteristics and trends of the Tokyo Olympics. It is expected to help students understand the relationship between correlation and uncertainty, and promote ISI. After this study, the author and the teacher will collaborate to validate the effectiveness of the task from a practical perspective and elaborate the principles of task design.

Allgemeinbildung and Statistical Reasoning with Digital Technologies

Stine Gerster Johansen

Aarhus University, Danish School of Education, Copenhagen, Denmark; sgj@edu.au.dk

University College Copenhagen, Department of Teacher Education, Denmark

Keywords: Allgemeinbildung, statistical reasoning, digital technologies, distribution.

The historical development of the Danish school is deeply influenced by the German *Bildung*-tradition. Through all periods, the curricular aims were formulated both in terms of *Allgemeinbildung* and education (Børne- og Undervisningsministeriet, 2022). *Allgemeinbildung* addresses the need for a democratic society to have enlightened and empowered citizens. Mathematics teaching must, as well as all other school subjects, contribute to students *Allgemeinbildung* (Niss, 2000). Heinrich Winter (1995) offers a specification of how mathematics education should contribute to this aim. He determines three basis experiences, which mathematics teaching should allow students to create.

In today's data-rich society, all citizens should be familiar with statistical ideas. Statistical reasoning is a way of moving back and forth between the particular and the general and the purpose of statistical investigations are to learn new about the context (Zieffler et al., 2018). Because of the embedded connection to the context, statistics teaching seems to comprise potentials particularly for Winter's first basis experience: "to perceive and understand the phenomena of the world around us in nature, society and culture in a specific way" (translated in Biehler, 2019, p. 153).

The inclusion of digital technologies (DT) in statistics teaching comprises some potentials, for example by liberating students from routine calculations and drawing of graphs and making instant shifts between different representations and simulations possible (Biehler et al., 2013). The question is, however, if statistical reasoning with the use of DT comprises new potentials for *Allgemeinbildung*. The research question for this project is: How can statistics teaching in lower secondary school be designed so that students' statistical reasoning with digital technologies can serve as contributions to their *Allgemeinbildung*?

Distribution is a central statistical idea and is a way of moving from seeing data as individual values to interpreting distribution as a conceptual entity. It is difficult for middle-grade students to liberate their view on data from the measurement value of an object to see data in terms of distributions. A conceptual understanding of distribution is, at the same time, a prerequisite for developing the ability to choose appropriate statistical measures. The inclusion of DT can support the development of an informal understanding of distribution (Bakker & Gravemeijer, 2004). The development of students' conceptual understanding might give rise to experiencing the world around them in new ways. Their interaction with DT while reasoning about data in terms of distribution might be essential in creating the opportunity for such experiences. To conceptualize students' interaction with digital technology and investigate how the inclusion of DT affects the ability to articulate their reasoning, the Theory of Instrumental Genesis (TIG) is included in the project. TIG conceptualizes the role of an artefact when humans carry out a task. Drijvers et al. (2013) describe TIG in three dualities. The artefact-instrument-duality describes the process where a person builds an instrument out of an artefact. The instrumentation-instrumentalisation-duality is bilateral and addresses how a student knowledge forms the building of an instrument, and, at the same time, the artefact forms the students thinking. The scheme-technique duality addresses the duality between the students thinking and gesture. In this project, the focus will be on the process where students build an instrument for reasoning about distribution from educational software for statistics, but also on how the software forms their conceptual understanding about distribution.

This PhD project is expected to connect *Allgemeinbildung* and the use of digital technologies and develop teaching principles for statistics teaching in lower secondary school. The methodological approach is Design-Based Research (DBR), which is anchored in authentic learning situations through iterative processes. Each iteration comprises preparation, experiment and retrospective analysis (Bakker & van Erde, 2015).

Preservice mathematics teachers' experiences of acquiring and organizing image-based data

Sibel Kazak

Pamukkale University, Turkey; skazak@pau.edu.tr

There is a growing interest in engagement with non-traditional data generated from a variety of sources, such as sensory devices, smartphones/watches, and social media tools. This paper reports on experiences of a group of pre-service mathematics teachers in acquiring and organizing image-based data to analyze categorical data as part of a course assignment. To identify the actions pre-service teachers took to transform observations of butterflies' photos to cases to answer statistical questions related to categorical data, the data from retrospective interviews and artifacts generated during the data exploration and organization were analyzed. The findings suggest that data handling and structuring became an important component of the statistical investigation before formulating statistical questions. While the use of hierarchical tables in structuring data by hand appeared to be intuitive, it could be challenging to use such a structure already built in a data organizing tool.

Keywords: Statistical inquiry, data acquiring, data organizing, image-based data, categorical data.

Introduction

Understanding and reasoning with data become increasingly essential part of our everyday lives as we need to handle information related to global issues on health, environment and so on, such as the COVID19 pandemic and wild fires due to extreme weather conditions. The nature of data also evolves with the advanced digital technologies. Large quantities and different forms of data are generated from a variety of sources, such as sensory devices, smartphones/watches, social media tools etc., every day. To analyze and make predictions from these data require new skills. Therefore, an important goal of statistics education is to develop necessary data skills starting from early school years.

Statistics is typically taught as part of school mathematics curriculum and there has been a shift from simply computing numerical and graphical representations of data to an inquiry-based approach (Watson, Jones, & Pratt, 2013). In this approach to the teaching of statistics, the focus is on the statistical problem-solving process (Franklin, Kader, Mewborn, Moreno, et al., 2007; Bargagliotti, Franklin, Arnold, Gould, et al., 2020). According to *the Pre-K–12 Guidelines for Assessment and Instruction in Statistics Education II (GAISE II): A Framework for Statistics and Data Science Education*, the purpose of this process is "to collect and analyze data to answer statistical investigative questions" (Bargagliotti et al., 2020, p. 13). As seen in Figure 1, it has four components that are interlinked: (1) Formulate statistical investigative questions, (2) Collect/consider the data, (3) Analyze the data, and (4) Interpret the results.

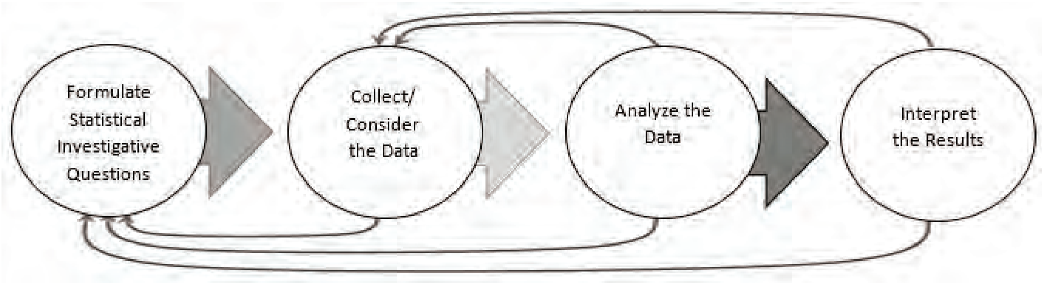

Figure 1: Statistical problem-solving process (reproduced from Bargagliotti et al., 2020)

Traditional statistical education focuses on data from random samples and making inferences from a sample to an unknown population. In today's digital age, however, data come in various forms (big, messy, unstructured data, repurposed data, image/text/sound-based data etc.) and do not necessarily comply with the structure required for statistical inference in the traditional sense (Gould, Bargagliotti, & Johnson, 2017). Along with the emerging field of data science, statistics education tends to focus more on the engagement with such non-traditional data sets.

Image-based data, i.e., the use of photographs as data, becomes increasingly common in daily encounters. The GAISE II report (Bargagliotti et al., 2020) acknowledges the use of this kind of non-traditional data as part of the statistical problem-solving process and helping students to make sense of these non-traditional data. As an example, Bargagliotti et al. use data from Dollar Street website as part of the Gapminder Foundation project (www.gapminder.org/dollar-street). The Dollar Street website displays the world as a street ordered by monthly income per person in the family from different countries and continents, and currently uses 43685 photos of 422 families in 66 different countries. Using these image-based data, students are expected to investigate "How are people's concepts of family and living spaces similar or different across the world?" (Bargagliotti et al., 2020, p. 63). The guidelines in the GAISE II report offers some instructional ideas with regard to the use of these image-based data through each four components of the statistical problem-solving process mentioned above. Bargagliotti et al. (2020) suggest that this kind of non-traditional, multivariate data sets requires a great amount of data exploration time to make observations and wonderings to analyze data. Engagement with other types of non-traditional (large and complex) data from secondary data sources, such as participatory sensing data (Gould et al., 2017) and public data sets (Wilkerson, Lanouette, & Shareff, 2021), also appears to require more emphasis on considering data and data preparation phases in statistical investigation process. As seen in these studies, such existing multivariate data sets are constructed and made publicly available by others with a particular purpose and investigators often repurpose them to explore new questions. To do so, data handling and structuring becomes an important part of statistical investigations.

The Collect/Consider the Data component of the statistical problem-solving process involves recording/acquiring, measuring and organizing the data to answer statistical questions with the acknowledgment of variability in data (Bargagliotti et al., 2020). Konold, Finzer, and Kreetong (2017) call attention to this important process of transforming observations into data and focus on table format as a typical means of data recording and structuring either by hand or using software. Two common table formats in statistics are case-data table and summary table as called by Konold et al. (2017). While case-data tables are mainly used for collecting and storing raw data, summary tables usually include only some of the information gathered and are organized in a way to compare groups or detect trends in the data. The data analysis software, such as TinkerPlots (Konold & Miller, 2011) and CODAP (https://codap.concord.org/), uses attribute-based structure for recording data where each column includes a variable and each row holds one observation, called a 'case', as described by Konold et al. (2017). However, entering the information collected to organize the data in such a format can be challenging for the learners. Konold et al. point out the need for thinking of data based on attributes which requires considering properties of the observations along with their values case by case. Their study revealed that students and adults tended to create two types of case tables, flat and hierarchical, when they were asked to construct data sheets to record and organize the data by hand from the pictures showing traffic along two road segments (including information about the vehicle type, speed, direction etc.) in a given time and date. Compared to the flat tables (attributes as columns and cases as rows) as seen in most data analysis software, the hierarchical tables include the cases at more than one level created by nested structure. This type of hierarchical structure of observations is available in CODAP and allows exploration of multilevel data sets.

Given the scarce of research on how students/adults come to record and organize data, especially with non-traditional image-based data, as part of a statistical problem-solving process, the aim of this paper is to present a case of three pre-service mathematics teachers who chose to use photos of butterflies as data to analyze categorical data. More specifically, the following question will be investigated in this exploratory study: What actions did pre-service teachers take to transform observations of butterflies' photos to cases to answer statistical questions related to categorical data?

Method

As part of 3rd year course, Teaching of Statistics and Probability, in the mathematics education program, the pre-service teachers were given a group assignment to design a statistical investigation activity that is aligned with the learning outcomes in the middle school mathematics curriculum. Two of the groups were expected to focus on analyzing categorical data and comparing two or three groups using existing data sets available in publicly available internet sources. One of these groups, including Arya, Yelda and Hale (pseudonyms), chose image-based data using "Kelebek-Türk" (Butterflies-Turk) group's website (https://www.kelebek-turk.com/) while the other group designed their data investigation activity involving data collected through survey questions on readings books.

Due to the uniqueness of transforming image-based data into a statistical analysis of categorical data with group comparisons, an interview was conducted with these three pre-service teachers to gain insights into their approaches when acquiring and organizing information from photographs of butterflies. Other artifacts, such as the documents created during the data exploration and organization, were also collected for analysis to answer the research question. Recordings of group interview and the student artifacts were analyzed using the perspectives on collect data/consider data suggested by Bargagliotti et al. (2020) and Konold et al. (2017).

Findings

Preservice teachers began with considering possible data appropriate for analyzing categorical data with comparing groups, which was given in the course assignment. Due to the difficulty in finding at least three categorical variables in data sets using publicly available data sources, such as Turkish

Statistical Institution website, they stated that some of the data explored during the course, such as the ladybug data (Bargagliotti et al., 2020, p. 32), inspired them to consider similar data about other animals. Yelda came up with the idea of searching butterfly data on the internet and found the group of Kelebek-Türk that provides photographs and observational data provided by their members from different age and occupation groups. After reading the "About us" information on the website, the pre-service teachers got their initial information about how the data were collected. Then they decided to use some of these photographs to construct their own observations involving categorical data.

According to the Kelebek-Türk website, there are 416 types of butterflies under nine different families in Turkey and their members have photographed 393 of them. As seen in Figure 2, there are nine butterfly families with different number of types, such as the Family Hesperiidae has 43 types, observed in Turkey and Figure 3 shows a sample of photos of different butterfly types belonging to the Family Hesperiidae.

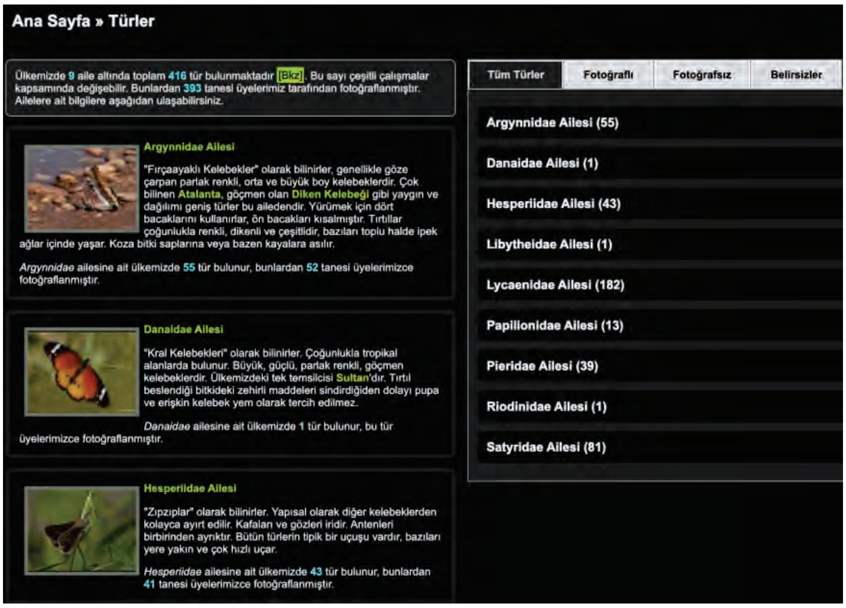

Figure 2: Screenshot of the website displaying the information about all nine different butterfly families

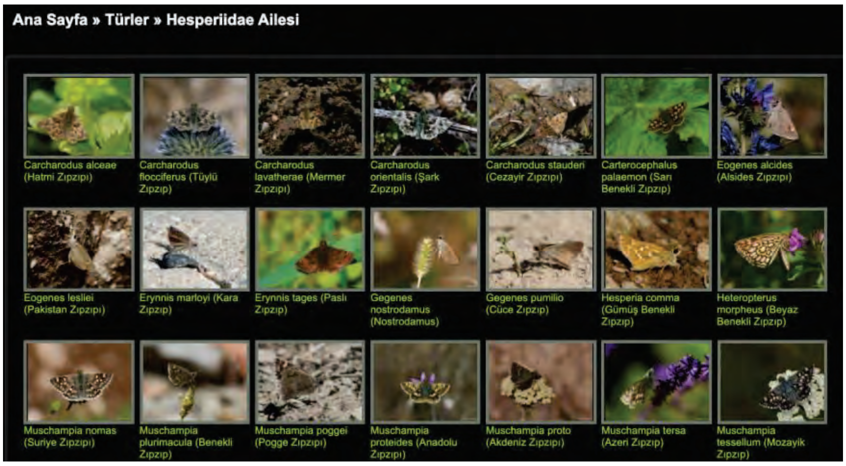

Figure 3: Screenshot of the website displaying the photographs of the butterfly types belonging to the Family Hesperiidae

Following the exploration of the information given in these pages, the pre-service teachers decided to focus on two families with a similar number of butterfly types (the Family Hesperiidae with 43 types and the Family Pieridae with 39 types) for comparison purposes given in the assignment. To collect information about these two families, they then began to click on each photo as seen in Figure 3. For example, Figure 4 shows various information about Muschampia poggei from the Family Hesperiidae, including numerical (frequencies of photographs by cities), geographic (distributions of butterflies across Turkey), photographic (captured images of butterflies with/without identified gender), tabular (months they were seen) and graphical (distribution of altitudes seen by months) representations. From this information, they selected to focus on the image of butterfly with unidentified gender (since not all types had gender information) to generate attributes, such as wing color and wing appearance which were considered as distinguishing characters of butterflies, and the seasons the butterflies seen, which involved grouping of months data given on the website.

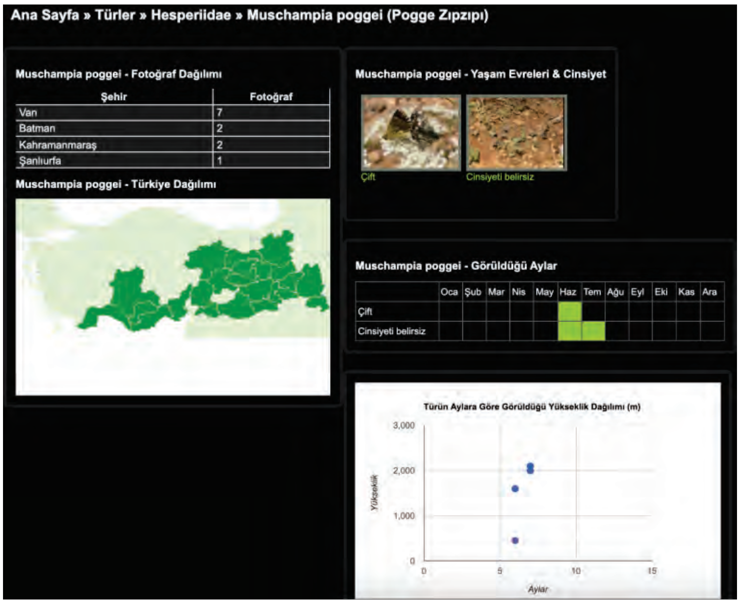

Figure 4: Screenshot of the website displaying various information about Muschampia poggei from the Family Hesperiidae

After this extensive exploration on the website, the pre-service teachers began to make an ordered list for each type of butterflies in both families, including the name of the butterfly, its photo, and the season it is seen, on a Word document. As part of the course assignment, they needed to use CODAP to analyze the data to answer questions considered in the Formulate statistical investigative questions phase of the statistical problem-solving process in Figure 1. Three questions emerged during this exploration: 1) What colors are the wings of the Family Hesperiidae and the Family Pieridae? 2) How do the appearances of the wings of the Family Hesperiidae and the Family Pieridae look like? 3) What seasons do the Family Hesperiidae and the Family Pieridae tend to be seen? Then they constructed a table, as seen in Figure 5, displaying the family name, type name, wing color, wing appearance, and season seen in columns respectively and case values in rows.

Kelebek Aileleri	Kelebek türleri	Kanat Rengi	Kanat görünümü	Yaşadıkları Mevsimler
Hesperidae (Zıpzıplar ailesi)	Pyrgus cinarae (Güzel Zıpzıp)	Siyah	Desenli	Yaz
	Pyrgus serratulae(Zeytuni zıpzıp)	Kahve	Desenli	İlkbahar-Yaz
	Eogenes alcides (Alsides Zıpzıpı)	Beyaz	Düz	Yaz
	Pyrgus sidae (Sarıbandlı Zıpzıp)	Siyah	Desenli	İlkbahar-yaz
	Pyrgus jupei (Kafkasya Zıpzıpı)	Kahve	Desenli	Yaz

Figure 5: Part of the table created for organizing the data

Organizing the data as shown in Figure 5 made entering them into CODAP table relatively easier due to its case-based structure. One difficulty the pre-service teachers encountered in this process was having more than one value for season variable for some cases, such as Pyrgus serratulae seen in both spring and summer. Therefore, they chose to create two different data sets, one including 70 cases of butterflies in two families with family names, wing color and wing appearance variables (Figure 6, table on the left) and the other including 120 cases with season variable for two families (Figure 6, table on the right). Due to the repeated cases for each season a butterfly seen, the number of cases was increased in the second data set. The pre-service teachers decided to separate multiple seasons since they wanted to answer their third question: What seasons do the Family Hesperiidae and the Family Pieridae tend to be seen? In either of the data sets, they also did not include type name which was displayed in the table in Figure 5 as they considered that having the type names would not allow to see two categories (the families) which were compared in the data analysis.

Figure 6: The data set tables created in CODAP

Concluding remarks

This paper presented insights from a group of pre-service teachers’ experience of acquiring and organizing image-based data to analyze categorical data by comparing two groups as part of a course assignment. As pointed out by Bargagliotti et al. (2020), the pre-service teachers spent a great deal of time to explore the non-traditional data involving photographs and other types of data collected by others for specific purposes as mentioned in the Kelebek-Türk website. In accord with the findings of Gould et al. (2017) and Wilkerson et al. (2021), data handling and structuring became an important component of the statistical investigation before formulating statistical questions. They needed to consider attributes/variables and criteria for identifying categoric values for them, such as assigning values, plain or pattern, for wing appearance based on the dots or lines seen in the photos of butterflies. The pre-service teachers did not seem to have any issue with preparing the data for the analysis in CODAP as they were able to consider the data as attribute-based. This could be due to their prior experiences with using CODAP for data analysis during the Statistics course taken in the previous semester. However, transforming the initial table created by hand (Figure 5) into a single data set table in CODAP was challenging for them. Since their initial table included subsets of data within the season variable, the flat table did not work. Instead, they needed to create hierarchical data sets, which is possible in CODAP, but this feature was not used in the course before. It was also evident in the work of Konold et al. (2017) that the use of hierarchical tables in structuring data by hand was more intuitive, but it could be challenging to use such a structure that is already built in CODAP environment.

This work is part of a wider investigation conducted in Italy, which aims to explore the effects of instruction in combinatorial reasoning of secondary school students. Two groups of students with and without instruction were given a questionnaire adapted from Navarro-Pelayo's research in order to analyze the students' performances and strategies used in the solutions, as well as the effect of instruction. In this work we present the results found in three combination problems. The students did not generally present particular difficulties in solving problems of combinations even though students who received instruction showed an improvement in their performances. In the no instruction group enumeration was the main strategy while the group of instruction used a more heterogeneous distribution of strategies.

Keywords: Combination problems, strategies, secondary students' performance.

Introduction

The study of combinatorics is an important component of mathematics, especially within discrete mathematics and in the school curriculum, where often plays a key role in the teaching of probability. For instance, combinatorial reasoning is needed to form the sample space in probability problems, as well as to understand some discrete distributions (e.g., the binomial distribution). However, not much attention has been given to the teaching of this topic, especially in the Italian school system. Moreover, some previous research, such as that by Navarro-Pelayo (1994) have described the students' difficulties in solving combinatorial problems, and this justifies an interest toward this field of research.

Piaget and Inhelder (1951) considered that combinatorial reasoning is a pre-requisite for a full understanding of the notions of randomness and probability. In addition, combinatorics is an area where students can both develop and train problem solving strategies, as well as mathematical processes such as generalization and recursive thinking (Kapur, 1970). Although there has been previous research on students' strategies in solving combinatorial problems, most of this research have been carried out with small children (e.g., English 1991; 2005) or university students (Godino et al., 2005) and none of this research considered Italian students.

The aim of this research was exploring the Italian students' combinatorial capacity and its change with instruction, as well as describing strategies developed by secondary school students before and after teaching. In this paper we present a part of the results of the global project; more specifically we analyze both performances and strategies used by a sample of secondary school students in solving three combination problems, also comparing the results obtained by the students with and without instruction.

Background

We based our research on the work by Fischbein and Gazit (1988), who analyzed the combinatorial capacity of children since 10th year of age and proved that they can learn to solve combinatorial problems when they receive a specific instruction. They suggested as main variables affecting the difficulty of the tasks the type of combinatorial operations (suggesting that permutations are the hardest), the type of element to be combined (numbers and letters are easier than objects or people) and the total number of combinations to be formed (a variable that we will describe as the dimension of the problem). Concerning secondary school students, Batanero et al. (1997) showed on a sample of 720 14-15-years-old students the effect on the difficulty of combinatorial problems of the implicit combinatorial model (together with the type of elements to be combined, the type of combinatorial operations and instruction). This variable was firstly described by Dubois (1984) who stated that every elementary combinatorial problem (that is a problem that could be solved through the application of a single combinatorial operation) could be classified through one of three possible schemes, implicitly present within the problem: selection, distribution or partition, depending on the combinatorial operation suggested in the text. Henceforth, we will refer to a problem by saying that it belongs to a particular model depending on its combinatorial scheme.

Regarding combinatorial strategies, English (2005) described enumeration used by small children in combinatorial problems and considered both a-systematic (consisting in a random or incomplete selection of elements) and systematic enumeration. Systematic enumeration involves repeating the selection, fixing an element (for example the first element in a permutation) and combining it with all the other elements, and then repeating the procedure with the remaining elements until all the configurations are listed. Lockwood and Gibson (2016) worked with 42 undergraduate students concluding that even creating partial lists of the set of outcomes led to significant improvements in the students' performance in solving combinatorial problems; the authors also suggested that instruction should facilitate systematic enumeration processes in the students. In a case study with university students, Godino et al. (2005) found that some students still used enumeration at this educational level and described other strategies such as use of a formula, use of the sum or product rule, posing new problems related to the original or breaking down the problem into simpler subproblems. In our investigation we will analyze all the strategies used by the students in the sample and its effectiveness to get a correct solution, as well as the differences between students with and without instruction.

Method

The sample consisted in 115 secondary school Italian students from different school grades and specialties, 64 of which had not received instruction on combinatorics and 51 students who received instruction on the subject. Although the sample of students was not random, because we depended on the availability of schools and teachers, we included classes of different schools and with different teachers, in order to obtain a sample of students as heterogeneous as possible. The group of students who did not received instruction was formed by classes of grade 10, 11 and 12 (i.e., second, third and fourth year of secondary school with students aged between 15 and 18). On the other hand, most of the students who received instruction on combinatorics belonged to grade 12 (fourth year of secondary school with age 17-18). There were also three students belonging to grade 10 (second year of secondary school) who received instruction on combinatorics in extracurricular courses and who were, then, included in this group. The instruction was mostly formal, based on the use of formulas to solve combinatorial problems, with the exception of one class of 12 students who approached the topic in a constructivist way, mostly through exercises and examples, constructing combinatorial rules before being taught a formula. The students were given a questionnaire of 13 open-ended problems (in an Italian translation) adapted from the one used in Navarro-Pelayo (1994) and Batanero et al. (1997) and proposed in two different versions presenting the same problems with an inverted order, aiming to cancel a possible effect of time on the data collection and obtaining a sufficient amount of data on every item of the questionnaire. Depending on the availability of the school, students had 60 or 90 minutes to complete the questionnaire. We remark, though, that time did not represent an issue, considering that most of the students were able to complete the questionnaire widely before the smaller time limit.

In this work we will focus on three items taken from the whole questionnaire and corresponding with combination problems:

> **Item 1**. Supposing we have three identical letters, we want to place them into four different colored envelopes: yellow, blue, red and green. It is only possible to introduce one letter in each different envelope. How many ways can the three identical letters be placed into the four different envelopes? For example, we could introduce a letter into the yellow envelope, another into the blue envelope and the last one into the green envelope.
>
> **Item 2**. School students must elect their representatives. Five students are the candidates: Elisabeth, Ferdinand, George, Lucy and Mary. In how many different ways can three of the five candidates be chosen? For example, Elisabeth, Mary and George could be elected.
>
> **Item 3**. Mary and Cindy buy four lipsticks of different shades, numbered from 1 to 4. They decide to share out the lipsticks, two for each of them. In how many ways can they share out the lipsticks? For example, Mary could hold lipsticks with shades 1 and 2 and Cindy those with shades 3 and 4.

All the three items are small dimensional, meaning that the solution requires less than 10 combinatorial configurations. Item 1 is a problem belonging to the distribution model (Dubois, 1984) in which students are requested to distribute some objects (the letters) in three containers (the envelopes), and whose solution is $C_{4,3} = \frac{4!}{3!(4-3)!} = \frac{4!}{3!} = 4$. Item 2 belongs to the selection model and students are asked to select 3 people from a group of five and the solution is $C_{5,3} = \frac{5!}{3!(5-3)!} = 10$. Finally, item 3 belongs to the partition model and students are asked to form two subsets from a set of numbers and the solution is $C_{4,2} = \frac{4!}{2!(4-2)!} = \frac{4!}{2!2!} = \frac{4!}{4} = 6$.

Once the written responses of each student were collected, a content analysis (Neuendorf, 2017) was performed. Every solution has been codified through numerical vectors including all the information related to the problem (e.g., ID of the student, group, class, correctness of the resolution, strategy of resolution). We also included qualitative information on the strategy used; for example, when a student employed a formula but not enumeration in a problem the respective entries of the vector include a number identifying how the formula has been used (e.g., correct formula, wrong formula, correct formula with arithmetical mistake, correct formula introduced with a wrong name, etc.) and a zero in correspondence of enumeration. After the codification of the students' responses to the questionnaires, we proceeded with a quantitative analysis focusing mainly on two variables: on one hand the correctness (or not) of the problem solution and on the other hand, the strategy used by the student (in this work we focused only on the bare use of a strategy and not on how a particular strategy is used). The solution to a problem was considered correct if the student either identified the total number of combinations by using a formula or correct arithmetic operations or else if he or she provided a complete list of all the possible configurations. Regarding the strategies, we observed all the procedures of the students considering all the strategy appearing in a solution, even when one strategy was used as a support for another one.

Results

In Table 1 we present the percentages of correct solutions to each item in both groups. We note that in both groups item 3 (partition of a set of numbers into two disjointed subsets) was significantly easier than the other two problems and that, generally, there was an improvement in students' performances after the instruction, even though some students in the instruction group were still not able to solve the problems.

Table 1: Percentages of students in each group correctly solving the items (above) and comparison with results in Navarro-Pelayo (below)

Item 1 $C_{4,3}$ Distribution	Item 2 $C_{5,3}$ Selection	Item 3 $C_{4,2}$ Partition	Item 1 $C_{4,3}$ Distribution	Item 2 $C_{5,3}$ Selection	Item 3 $C_{4,2}$ Partition
No instruction (n=64)			Instruction (n=51)		
39,1	12,5	51,6	51,0	54,9	66,7
No instruction (n=348) [Navarro-Pelayo, 1994]			Instruction (n=352) [Navarro-Pelayo, 1994]		
26,9	22,5	31,0	26,7	46,0	37,2

We observe that despite the small dimension (only 10 different configurations), item 2 was difficult for students with no instruction. We suppose that this is due to the fact that the students were not used to deal with the selection of people (while they were more familiar to work with numbers, that are used in item 3, and letters, appearing in item 1). We can observe that mistakes mostly derive from either not considering that the ordering of elements does not have an influence in the problem or considering as different elements that are identical instead; for example, in item 3 many students provided a solution that considered different the permutations of a same solving configuration or in item 1 students assumed that different letters should be distributed in the envelopes. This error was described both in Batanero et al. (1997) and Fischbein and Gazit (1988) as linked to combination problems. Comparing our results with those in Navarro-Pelayo (1994) – see Table 1 – we can observe a similar trend of improvement for Spanish students. While, on one hand, the percentages are different from those obtained in our sample, probably because of the different sample size (115 students in our research and 720 in Navarro-Pelayo's), on the other hand we observe a similar pattern of results: students globally improve after the instruction and they perform better on item 1 and item 3 (with the latter as the best performing item), but it is in item 2 where can be noted the best improvement after instruction.

Students' strategies

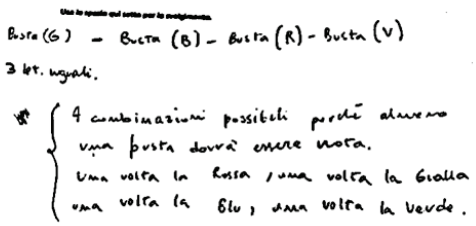
In analyzing the solutions, the following strategies were considered: a) *Enumeration*, found in previous research (Batanero et al., 1997; Godino et al., 2005; English, 2005; Lockwood and Gibson, 2016) with students of different ages and consisting in the explicit listing of all the possible combinations to be formed, according to the problem statement. b) *Tree- diagram*: the student builds a tree diagram as a help in producing all the configurations; according to Fischbein and Gazit (1988) the resolution of the problem is facilitated with the involvement of this tool. We also considered the following strategies, as described in Godino et al. (2005): c) *Formula*: the student recognizes the combinatorial operation of combination (or another operation, when the students proceed changing the combinatorial model or refers to another problem that he or she found equivalent) as a solution to the problem and remembers its formula. d) *Reference to other problem*: the student transforms the problem in another equivalent which is used to obtain the solution. e) *Sub-problem decomposition*: the original problem is divided into several combination problems of smaller dimension and the resolutions of which are combined to get the solution to the initial problem. f) *Sum, product or quotient rules*: the student does not remember the formula of combinations and tries to solve the problem using the elementary arithmetical rules of sum, product or quotient. g) *Other strategies*, generally giving a wrong answer with no justification.

In Table 2 we present a summary of the results obtained from the analysis of strategies, with the percentage of use of every strategy considered together with the percentage of students getting to a correct solution. We observe how students without instruction mostly relied on an enumerative strategy in every item, even though this did not always lead to a correct resolution, especially in item 2. The majority of enumerations were systematic, probably due to the reduced dimension of the problem, that allowed students to better control their listing procedures. We remark how students proceeding through enumeration failed in reaching the correct answer due to different reason: on one side, in item 1 and item 3 their mistakes were mostly connected to a misunderstanding of the problem (i.e., considering objects different/identical or taking/not taking into account the importance of order) rather than something imputable to the chosen procedure. However, in these items students tended to overestimate the number of configurations.

A different situation is observed in item 2 where students mostly produced an incomplete list of configurations, underestimating the solution of the problem, providing a partial resolution to the problem (a solution which does not contain procedural mistakes but that fails to reach a correct solution). In fact, we observed how most of the enumerations end with a list of 9 out of 10 configurations.

Table 2: Percentages of global and correct use of each strategy in the no instruction group (n=64) and in the instruction group (n=51, percentages in brackets)

	Item 1		Item 2		Item 3	
Strategy	Global	Correct	Global	Correct	Global	Correct
Systematic enumeration	45,5 (21,3)	30,9 (19,1)	75,4 (17,0)	12,3 (8,5)	75,9 (39,6)	53,4 (33,3)
A-systematic enumeration	5,5 (10,6)	(6,4)	1,8 (4,3)	(2,1)	(4,2)	(4,2)
Tree diagram	16,4 (2,1)	5,5	1,8 (2,1)		8,6 (2,1)	3,4
Formula	(29,8)	(19,1)	(57,4)	(46,8)	1,7 (31,3)	(25,0)
Reference to other problem	(6,4)	(6,4)	(6,4)	(4,3)	1,7 (6,3)	(4,2)
Sub-problems decomposition	7,3		10,5 (2,1)		6,9 (4,2)	3,4 (2,1)
Sum rule	10,9 (8,5)	9,1 (8,5)	5,3		(4,2)	(2,1)
Product rule	25,5 (29,8)		21,1 (14,9)	1,8 (2,1)	20,7 (16,7)	3,4 (2,1)
Quotient rule	(6,4)	(6,4)	(10,6)	(6,4)	(12,5)	(8,3)
Other	3,6	1,8	(2,1)		(4,2)	(4,2)



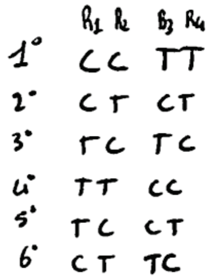


Figure 1: (a, left) Resolution of item 1 through the implicit use of the sum rule

(b, right) Resolution of item 3 through enumeration

Some of the students also developed different solving strategies but there were very few cases in which they were able to get to a correct solution. Most of these were reached through the use of the sum rule, by changing the model of the problem from distribution to selection: an example of this resolution is presented in Figure 1a, where the student explains that, instead of distributing letters he can choose the envelope to be left empty and so there are four possibilities (basically, every sub-problem is represented by a single configuration of the envelope that is discarded so that the global solution is reached by summing up the results obtained in the four subproblems). A change of model can be also observed in Figure 1b, where the student distributed people instead of partitioning lipsticks and proceeds by listing all the possible configurations. We also notice how in the group of students with instruction – see Table 2, percentages in brackets – the choice of strategy shifted from a majority of enumerations to a more heterogeneous use of strategies. In fact, most of the considered strategies appeared in the solutions of the whole group with the exception of the sub-problems decomposition and tree diagram, that were scarcely used. The most frequent strategies were formula, enumeration and product rule, even though the latter was mostly connected to a non-resolution of the problem. Students of the instruction group who applied a formula mostly got to a correct solution, even though we can observe some students using a wrong formula due to, we suppose, a misunderstanding of the statement of the problem.

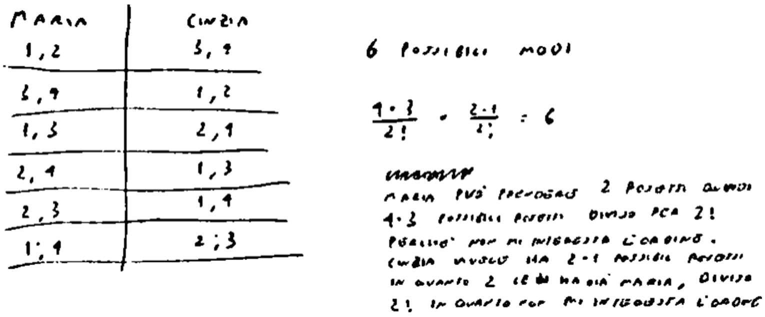

Figure 2: Resolution of item 3 through the double use of enumeration and quotient rule

We observe how part of the students used enumeration; we suppose, also considering results of the whole questionnaire, that this is due to the fact that the problem is a small-dimensional, so students easily produce a complete list of configurations. This strategy led to a correct solution nearly in most of the cases for item 1 and item 3 while, similarly to what was observed for the group of no instruction, students were not always able to get to the complete list of enumerations in item 2, for which resulted more effective the use of the formula. We suppose that the reason is that the formulation of item 2 is very similar to usual combination problems one can find in textbooks. Finally, we notice that some of the students who received instruction solved the problem using multiple strategies within the same resolution; for example, we can observe in Figure 2 a resolution of a student involving both enumeration and quotient rule. On one hand, on the left of the figure, the student properly produces the complete list of solving configurations and then provides an argument involving the arithmetic rule of quotient explaining how the result of the problem is 6. We suppose that students that provided a double solution proceeded in this way in order to justify their calculations, in case they were not sure about the formula or the rule they were using. In conclusion, instruction was found to be useful to increase the competence of the tested students to solve combinatorial problems, in agreement to what stated by Fischbein and Gazit (1988). Students' performances (in terms of correctly solved problems) increased significatively after the instruction, even though some difficulties remained, and the students were not always able to get to the correct solution. In spite of a (mostly) formal instruction based on the learning of formulas it is worth observing that even after acquiring new procedures some of the students of the group with instruction continued to rely on enumeration, even though sometimes they used it together with formulas and arithmetical rules, providing a double solution to a problem. Comparing our results with the ones presented in Godino et al. (2005) for university students, we notice that the distribution of strategies for secondary school students is different, shifting toward a higher use of enumeration. On the other side, focusing only on the results of the group with instruction, we can observe that the distribution of strategy was more similar to what observed in university students with higher mathematical preparation that, consequently, does not seem to play a key role in the development of solving strategies.

Conclusions

Despite the small dimension of the tested sample, this explorative research provides new insights on the solving strategies students activate when solving combination problems. Most of the correct answers come from the use of either enumeration or formulas even though students also developed other different procedures. We underline the fact that knowing the strategies that the students activate would allow the teacher to better implement a teaching activity, for example introducing different techniques. However, further and deeper steps would be needed in order to proceed with this research; for example, widening the dimension of the sample and including more focused qualitative analysis, aiming to better understand the mechanisms that lay behind the choice of a solving strategy.

Digital learning environments for mathematics education – A workshop on stochastic paradoxes

Preconditions and motivation

Digital technologies can support and benefit mathematical learning processes, especially the development of students' statistical reasoning, but also have their limitations (Thurm, 2020, Biehler et al., 2013). In order for student teachers to reflectively use digital technologies at an early stage of their teacher training, the seminar "Digitalbasierte Lernkontexte des Mathematikunterrichts" (Eng. Digital learning environments for mathematics educations) was developed. There, student teachers develop, test, evaluate, and reflect on digital learning environments for relevant, authentic applications of mathematics in a Design-Based research approach (Bakker & Eerde, 2015). Below, we present a workshop developed by students who pursued the initial research question: How can we profitably employ digital technologies in teaching stochastic paradoxes?

Storyline

The 90-minute workshop starts with a joint introduction to the situation via radio recording. The state "Tralien" is struggling with the serious disease "Frost" as well as with substantial financial problems. A pharmaceutical company presents two drugs to cure the disease. However, due to a lack of financial resources, a decision has to be made in favour of the production of one of the drugs. Furthermore, when aid money is put up, it is discovered that "Tralien" is missing large amounts of tax money. This causes the financial problems and leads to a second task: tax evaders must be exposed. Upon this introduction, students form two expert groups who work on the problems almost independently guided by GeoGebra books and additional material in Excel and R. The first group learns about the Simpson paradox and how it relates to the choice of one of the two drugs. The second group deals with Benford's law and applies it to expose tax evaders. Finally, each group presents the findings.

Didactic considerations and digital tools

A statement is judged as paradoxical, if it conflicts with another self-evident statement. Hence, a reason for working with stochastic paradoxes is that students conflict with their intuition and have to correct misconceptions. In doing so, existing conceptions must be recognized as incorrect, underlying errors must be understood and then a correct conception can be formed. This process of understanding errors and building new conceptions is common in many learning areas (Winter, 1992). Simpson's paradox (Meyer, 2018) and Benford's law (Humenberger, 2018) offer many starting points here. Another reason to choose stochastic paradoxes is their relation to students' everyday life. Students are exposed to statistics of large data sets and their interpretation. Thus, they should internalize the relevance of proper handling of statistical results as well as how to evaluate and interpret data sets.

To further emphasize the relevance of the content, the workshop is based on real, publicly available data and students are introduced to software used in data analysis (R, Excel). These tools allow the demonstration of the processing of large amounts of data as well as its visualization, while reducing schematic operations. Currently, however, students do not program themselves. Instead, the focus is on the discussion and interpretation of the finished code and relevant diagrams. In further revisions, we plan to enable students to complete programming tasks too, using Jupyter Notebooks. For now, GeoGebra books guide through the workshop. The many different tools in GeoGebra enable a diverse design and a clear structure of learning tasks, as well as visualisation and change of representation to promote comprehension. GeoGebra serves as an information and presentation tool, so students can work on the materials almost independently and are not bound by space or time. In addition, GeoGebra Classroom provides a virtual classroom, where teachers can view students' answers and identify potential problems and misunderstanding, allowing for individualized learning guidance.

maritzamendez@pensadoresmatematicos.com, soledad.estrella@pucv.cl

Developing statistical thinking at the early school levels is a challenge that in-service primary school teachers must face. One of the actions that would achieve this goal is aimed at generating teaching proposals from the teachers themselves in their schools, from contexts that give meaning to the analysis of data in situations of uncertainty from an informal perspective. This report presents how collaboratively, a group of preschool and primary school teachers and researchers participated in a Lesson Study Group on the Informal Statistical Inference (ISI) approach for nine weeks. This allowed them to move in a cycle of goal setting, planning, implementation and evaluation of a lesson plan, acquiring knowledge of the content and pedagogical knowledge of ISI reflecting on their professional learning and the teaching of ISI.

Keywords: Early statistics, primary education, informal statistical inference, lesson study, pedagogical content knowledge.

Introduction

Statistical thinking makes it possible to more accurately analyze the world and overcome the fallibility of intuition. The use of statistics allows decisions to be made about phenomena in which uncertainty is present and facilitates the establishment of inferences in situations that we try to foresee according to the behavior of the data. It is necessary to incorporate at the school level experiences that allow students to face critically various information sources that provide data, such as those related to epidemiological phenomena, scientific findings, electoral results, weather forecasts, economic models, among others. In turn, they are required to be able to recognize variation and understand the randomness present in many daily activities. Given this scenario, teachers could use informal statistical inference (ISI) as a theoretical and pedagogical approach that contributes to developing in their students' ways of reasoning in situations of uncertainty, understanding ISI as "a generalized conclusion expressed with uncertainty and evidenced by, yet extending beyond, available data" (Ben-Zvi, et al., 2015, p. 293).

On the other hand, preservice teachers and in-service teachers, require a pedagogical content knowledge of the informal inferential reasoning (IIR) around central concepts of ISI, so that they understand key ideas in statistics, anticipate the difficulties and errors of students and can build tasks that provide opportunities for the development of inferential reasoning (Leavy, 2010). In this sense, the present study addresses early statistical education with preschool and primary educators and investigates their pedagogical content knowledge (PCK) by planning a learning sequence on ISI in early childhood education designed collaboratively within a lesson study group (LSG), and by researching their lessons in the classroom.

Lesson study for the transformation of teaching

To initiate a Lesson Study cycle, a team of 3 or more teachers is needed to form a LSG, which meets periodically to establish a lesson plan. Through Lesson Study cycles, understood as a process of instructional improvement, teachers can transform traditional ways of teaching mathematics into an instance of teacher professional development. Research has shown that it is a way for teachers to develop their work collaboratively and understand how their students learn. Lesson Study (LS) focuses attention on teamwork and shared responsibility around a lesson plan, its implementation, and its improvement. Thus, one or more teachers prepare the lesson, selecting the materials needed to achieve the objective stipulated in the lesson plan. Subsequently, one of the teachers involved in the planning implements the lesson, which in some cases is observed by other teachers or researchers. Once the lesson is completed, the teachers and observers meet in a session in which the implemented lesson is reviewed and analyzed, which will allow for the improvement of the lesson plan and its subsequent dissemination. According to Isoda et al. (2021), LS allows the development of teachers' Content Knowledge and Pedagogical Knowledge, promotes their ability to observe students' productions in class, motivates the improvement of their teaching proposals and allows the establishment of collaborative relationships among colleagues.

Teachers' knowledge and Informal Statistical Inference

Since the 1980s, Shulman (1987) stated that teaching begins when the teacher reflects on what needs to be learned and how students will be taught. In these reflective processes, beliefs, implicit theories, and other forms of thinking interact with context variables to shape actions that take place in the classroom. The PCK construct seeks answers that contribute to specifying the professional knowledge needed in teaching to intensify student learning (Shulman, 1987).

The framework presented in Table 1 (Chick et al., 2006), accounts for the components of PCK that are evident in teaching and the way pedagogical and content knowledge are intertwined. This framework considers three components: Clearly PCK (involves aspects that are more of a mixture of content and pedagogy); Content knowledge in a pedagogical context (involves aspects drawn more directly from the content); and Pedagogical knowledge in a content context (includes knowledge drawn more directly from pedagogy).

Table 1: Framework for analyzing Pedagogical Content Knowledge (Chick et al., 2006)

PCK Category

Content knowledge in a pedagogical context	Profound Understanding of Fundamental Mathematics (PUFM)
	Deconstructing Content to Key Components
	Mathematical Structure and Connections

PCK Category	
	Procedural Knowledge
	Methods of Solution
Pedagogical knowledge in a content context	Goals for Learning
	Getting and Maintaining Student Focus
	Classroom Techniques

The research in which this report is framed, involves characterizing the progression of the IIR from kindergarten through fourth grade attending, in turn, to the development of the PCK of the teachers when designing and implements a lesson plan in an LSG. In this sense, it is considered that the PCK accounts for the knowledge of teachers to understand the concepts, problems or emerging difficulties adapted according to the interests and skills of the students (Estrella et al., 2015).

This framework is combined with the informal statistical inference components characterized by Makar and Rubin (2009) for the generation of teaching proposals that seek to promote IIR in students at the school level. Various frameworks have been proposed when characterizing the ISI and the reasoning that it supports, whose common components correspond to using data as evidence requiring to assess and consider the available data to establish arguments associated with a question or problem, privileging certain evidence that they provide over personal experiences or opinions; generalizing beyond the data accounts for the ability to communicate conclusions derived from particular data, generating inferences that apply to a broader set; and expressing uncertainty implies manifesting the uncertain in generalization, being aware that statements are not certainties, but consider a margin of error.

In this way, one of the purposes of this study focuses on how the work in a LSG that seeks to promote ISI can contribute to the development of the PCK of the teachers linked to the experience. Although the work with the teachers included stages of planning, execution and improvement of a lesson plan, this report focuses on the following question: How does a teacher's PCK manifest itself when planning a lesson plan on ISI at the preschool to fourth grade levels?

Methodology

To answer this question, -and based upon consensus among the authors-, a qualitative, descriptive-interpretative approach is adopted, analyzing the dialogues transcribed from nine video recordings: seven working sessions within the LSG and two lessons of implementation of the lesson plans of each teacher, according to the categories adapted from the PCK components of Chick and collaborators (2006), integrating the key components of the IIR.

Participants

The LSG consisted of six teachers (three primary school teachers, one preschool educator, two special educators) and three researchers with expertise in statistics education, two of them with LS research experience. Regarding their years of professional experience, three of the teachers in this school had more than 15 years of teaching experience, two of them had between 10 and 15 years of experience and one had less than 10 years of teaching experience. The teachers work in a municipal educational establishment located in the Metropolitan Region of Chile and carried out the execution of the lesson plans with a total of 70 students distributed in grades K-4.

The LS cycle for generating a lesson plan that promotes IIR.

The LSG met weekly for 2 hours during 9 weeks. The activities of the LS cycle in which the teachers had to go through were delineated by the team of researchers based on four work axes: A. Authentic experiences of informal inferential reasoning; B. Planning a learning sequence; C. Implementation, revision and adjustment of the lesson plan that promotes IIR; and D. Analysis and reflection of the LS process.

In Table 2, although the activities are presented sequentially, some actions are carried out cyclically throughout the process, for example implementation of the lesson plan, review and adjustment of the lesson, identify student needs, reformulate objectives, propose new possible teaching interventions, among others.

Table 2: Overview of the activities according to the LSG work

Week	Activity
1–2	**Authentic experiences of informal inferential reasoning: Exploring content knowledge in a pedagogical context** •Task 1. How will Tom get to school tomorrow? •Task 2. Which car would he choose to win the race? What elements characterize IIR: Comparing responses of LSG teachers and some other teachers in the country, in light of the components: Using data as evidence, expressing uncertainty, and generalizing beyond data.
3–4	**What do we expect from the IIR of K-4 students? - Planning a learning sequence** Identify student needs, formulate objectives, set a task to promote IIR, anticipate student difficulties and responses, outline possible teaching interventions, and determine aspects to assess.
5	**Implementation of the lesson plan** The planned lesson plan is implemented, some teachers and researchers observe and record, in videos and/or field notes, what happens.
6	**Review and adjustment of the lesson plan according to post-session analysis** The experiences of the teachers in the implementation are shared, the LSG reviews and adjusts the lesson plan considering some suggestions and recommendations that arise in the post-session analysis.
7	**Implementation of the adjusted version of the lesson plan** The lesson plan is implemented in light of the proposed adjustments and the LSG's recommendations.
8 - 9	**Analysis and reflection of the LS process** Video records and field notes are reviewed to identify strengths and aspects of the intended lesson plan, and group reflection on all activities of the process describing the LS experience, professional learning and challenges, socioemotional aspects and some discoveries.

ISI tasks proposed to the teachers in the first LS stage

In the first LS stage, the teachers had two experiences that triggered their RII (see Table 3). The first situation is from the inferential domain and is based on one of the items reported by Watson and Callingham (2003). The second situation belongs to the probability domain and is related to a randomized experiment with dice. After its realization, the in-service teachers were able to know the elements that have been characterized at the research and pedagogical level of the ISI approach, with the purpose of integrating these elements in the lesson plan that would be formulated, implemented and evaluated in the following stages.

Table 3: ISI tasks proposed to the educators and teachers in the first stage of the LS

Situation	Concepts	ISI Ability	Resources

Reading a data representation with a missing data to make a prediction in a scenario of uncertainty.	Variable, categories of the variable; data; majority; prediction.	Predicting the variable category in which the missing data correspond beyond the data provided in the representation.	
Conducting an experiment of throwing two dice simultaneously, advancing on game board according to the sum of the results of the dice faces.	Random variable; sample; population; random experiment; variability; sample size; prediction.	Predicting the greatest chance of winning by considering various samples.	
The lesson plan and the core task proposed within the LSG

The lesson plan was jointly designed based on previous LSG discussions on IIR and was intended to be implemented transversally with K-4 students. This plan considers a central statistical task of a playful type involving the randomized coin-tossing experiment, called "the frog race".

The game, whose instructions are illustrated in Figure 1, favors the manipulation of the material and the recording of data on a game board. Before starting the game, each player must choose the frog that he/she thinks can reach the goal before the other two. The game ends when one of the frogs has reached the goal. The game can be repeated as many times as desired, although three or more completed games are recommended.

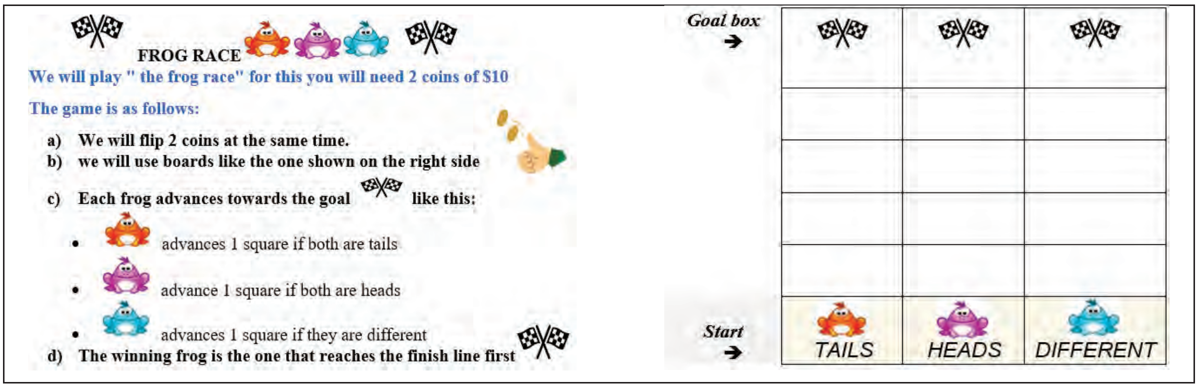

Figure 1: Board and game instructions “Frog race” (Estrella et al., 2022)

After completing several games with the data recorded on the boards, students are encouraged to establish generalizations beyond the data, using arguments based on the samples obtained (their own and those of their classmates) and to express uncertainty about which of the frogs is more likely to win; the guiding question was "If you had to give someone advice, which frog would you advise them to choose? Why?". Each teacher gave two lessons on ISI in two groups of the same course.

Results

To account for teachers' PCK when generating, implementing, and improving a lesson plan that promotes IIR, some illustrative episodes were selected from the categories proposed by Chick et al. (2006). Given the limitation of this paper, we chose to show only the lesson planning stage and the categories used to analyze the teachers' interventions (each teacher is labeled with T1 to T5, and the researchers as R1 and R2).

Conformation of a lesson plan

As an instance prior to the planning of the lesson plan, the teachers faced IIR eliciting tasks, as an authentic experience that not only allowed them to activate their content knowledge on ISI, but also enabled them in a subsequent exercise, to analyze their own and other colleagues' answers, considering the IIR components brought into play. At the same time, they learned in parallel some aspects of the ISI approach as an alternative that makes possible the teaching of contents associated with uncertainty prior to the use of formal inference techniques. These actions were key in the formulation of a central task of the lesson plan.

Some manifestations of teachers' PCK according to the categories (1) Clearly PCK, (2) Content knowledge in a pedagogical context and (3) Pedagogical knowledge in a content context, when participating in an LSG are illustrated in Table 4 below.

Table 4: PCK manifestations of two teachers according to PCK categories

Stage of the LS cycle	**PCK Category**		
Planning	1	2	3
T1: The central problem of the class... considering K to 4th grade, What scenario... evidence... express uncertainty...	X	X	X
T2: It would have to be something like the car race thinking that something super meaningful and known to the kids...			X
T1: You can think of the generalization in the fact that if they see that a car is winning... When they are doing the game ...If a partner asks them	X	X	
T1: A visual question to see who is winning... visually they realize who is winning... and when the children realize that they are winning... they will immediately say "yes", I experience this daily with my students. They want to get to the winning situation, yes or yes!	X		X

In this episode, T1 points out in his intervention key aspects to promote in his students, identifying components of the IIR that are fundamental for students to understand and establish ISI, in particular the use of data as evidence and the establishment of expressions with uncertainty. T2 proposes to the LSG to involve playfulness as a fundamental feature of the task, so that students can become emotionally attached to its development. Then T1 points out to his colleagues that employing a visual representation could allow students to reason through identifying patterns in the data, and analyze the results more favorably. Finally, T1 discusses strategies for engaging students.

Table 5: PCK manifestations of five teachers according to PCK categories

Stage of the LS cycle	**PCK Category**		
Planning	1	2	3
R1: Regarding the car race, in kindergarten I think there would be difficulty with the sum of the dice, ... there would be too much prominence of the teacher, 2 dice are going to be slower (e.g. 6 and 6).	X		
T1: Maybe the children could roll [roll the dice] and one [teacher] could count.			X
T2: But T1, that has to be done [live and direct with the students] how do you plan to do it with Kindergarten in this [Pandemic] scenario?			X
T1: A of course .... I was thinking about that... how do you apply it? It has to be something we can apply now [Pandemic] right?			X
T3: With R2 we thought of a race, but with colored frogs, and that, instead of rolling dice, you would roll a coin 2 times or 2 coins at the same time. The frogs would advance, for example, the orange one if the two coins go "tails", the pink one if the two coins are "heads"., and the blue one if different [head and tail].		X	

R1: Given the level of the children it could be 2 coins. I want to know which frog you would vote for.	X		
T4: I'm leaning...I have no prior training ...but I think there's a better chance of 1 or 1 [heads and seal]. R1: and why? T4: I don't know... Thinking it's harder for [both] 2 heads and 2 tails to fall out. R2: Do you have 2 coins? let's toss them 10 times!		X	
T5: I already did it, I got 2-times [both] head, 1-time tails [both], and 7-times tail and head T4: I won!		X	
T1: Playing the game I feel it's super practical, because the parents could pull or the children, and helping them to advance. We [teachers] wouldn't have to do it, my kids could do it.			X
T4: It could be playing as a family and completing a register...	X		

In the episode (see Table 5), R1 invites to anticipate certain difficulties of the students in the operation of a randomized experiment of throwing two dice simultaneously given the limited numerical scope of the kindergarten through fourth grade students. Some LSG members propose alternatives to reduce its complexity, in this case using two coins (three non-equiprobable events) instead of dice (six equiprobable events; or 36 non-equiprobable events). On the other hand, teachers discuss some pedagogical strategies that can be adjusted regarding their management in an online learning environment given the pandemic. In turn, R1's intervention provokes teachers to bring into play their content knowledge in the pedagogical context of task planning vis-à-vis possible predictions, the operation of the randomized experiment, and possible outcomes.

Discussion

It is recognized that teachers face challenges in teaching statistics, as many lack experiences in school or in their initial teacher training, particularly on aspects specific to early statistics (Estrella et al., 2020). Although research regarding teachers' PCK about ISI and ways of preparing to teach ISI is scarce (de Vetten et al., 2017), it is also recognized that teacher professional development experiences conducive to promoting PCK on ISI and associated reasoning can be generated. In this perspective, the manifestation of K-4 teachers' PCK was analyzed when planning, executing and improving the lesson plan on ISI.

Authentic informal inferential reasoning experiences (Table 3) helped to foster in teachers, an awareness of the uncertainty inherent in the outcomes presented in the situations, which led to proposing a central task for K-4 students to develop their IIR early; in turn, allowed teachers to analyze their own IIR, and to delimit future actions regarding the planning, management and evaluation of a learning sequence that could develop the IIR of their students. The planned learning sequence considered the materials, motivation, online education context, and students' prior knowledge and experiences, delineating possible teaching interventions, in the core task promoting IIR. During the implementation, review, and adjustment of the lesson plan, teachers were able to reflect on the achievement of the lesson objectives, providing feedback leading to the fine-tuning of the lesson. Finally, the instance of reflection of the LS process allowed teachers to make explicit the professional challenges, the perceived socioemotional aspects and some discoveries.

Although this report shows part of the comprehensive analysis of teachers' PCK in only one of the stages of the LSG cycle, the categories employed can be considered relevant to analyze in detail the manifestation of aspects of PCK in relation to IIR. The generation of statistical learning sequences created with the expertise of the teachers themselves together with LSG collaborating researchers in an LS that lasted several weeks, hold promise for the promotion of statistical thinking at the early school levels. It is projected that the spirit of improvement of the LS methodology will permeate both the learning sequence constructed and the experience and teaching of this group of teachers.

Game-variation to support probabilistic reasoning

Per Nilsson

School of science and technology, Sweden; per.nilsson@oru.se

This study investigates game-variation as a means for supporting reasoning on the bi-directional relationship between underlying probability distribution and data. A teaching experiment where students in Grade 5 (11-12 years old students) are playing three games of the Color-run constitutes the context of investigation. The study shows how variations in the sample space between the games can pull students into probabilistic reasoning about chance, random variation and sample space. The study also shows how probabilistic reasoning can face challenges from deterministic reasoning.

Keywords: Probabilistic reasoning, deterministic reasoning, random variation, sample space, inferentialism.

Introduction

This study intends to contribute to the call for increased attention on how learning environments can be designed to support students' statistical and probabilistic reasoning (Ben-Zvi et al., 2018; Langrall et al., 2017). This is approached by the research question:

> How can variation in sample space between games be used to support reasoning on the bi-directional relationship between underlying probability distribution and data?

A teaching experiment where Swedish grade 5 students are playing three games of the Color-run (Nilsson, 2020) constitutes thew context of investigation.

Theoretical background

The present study takes an inferentialist perspective on reasoning. This means that reasoning is understood to be a constructive process, taking place as students participate in and contribute to the practice of giving and asking for reasons (GoGAR) (Brandom, 2000). Think of the concept "probability", in the claim, "The probability of an outcome of six is 1/6 when rolling the die." Being an act of reasoning in GoGAR, the claim implies the assumption of a fair die, that the relative frequency of sixes stabilizes around 1/6 as we increase the number of trials, and that the probability of not having a six is 5/6. This example involves many reasons related to the concept of probability, of which only a few have been made explicit here. The main point, however, is to show that reasoning consists of knowing what follows from a claim and what it follows from, what would be evidence for it and what is incompatible with it (Brandom, 2002). For the learning of probability, this implies teaching where students are invited to make claims (take a stand) and are challenged to ask and give reasons for claims, in explorative practices of experimenting with data, making connections, explaining, inferring and generalizing (Nilsson, 2019).

Understanding the bi-directional relationship between underlying probability distribution and data implies understanding how the sample space is mapped in data, taking into consideration the effect of chance (Nilsson, 2014). On this issue, research shows some contradicting results.

Lecoutre (1992) for instance, shows that students often fail to use information of sample space when an element of chance is involved. Students argued that outcomes of a random experiment are equiprobable, no matter of the composition of the sample space, because the experiment is just a matter of chance. Noll and Shaughnessy (2012) and English and Watson (2016), on the other hand, show that students tend to stress proportional reasoning between sample space and frequency outcomes. Several studies also show that students tend to appreciate contextual, material and idiosyncratic explanations (Nilsson et al., 2018; Watson et al., 2007) over probabilistic and data-centered reasons when asked to predict or explain the distribution of data.

Method

The teaching experiment

This study is part of a small-scaled teaching experiment over three lessons in a Swedish grade 5 class (11–12 years old) with the purpose of exploring informal hypothesis testing in a probability context. The present study concentrates on the first of three lessons, with the aim of introducing the students to reasoning on random variation and sample space in the context of the Color-run (Nilsson, 2020). Three bottles with three different sample spaces were design. After shaking the bottle, the color of the marble that appears in the neck of the bottle is recorded. The color first recorded seven times wins the game.

Figure 1 shows the bottle used in the first game and the results of the three games. The entire lesson was in the format of whole-class teaching. One camera was placed at the back of the classroom to capture the whole-class discussions. In the two first games there were 15 students in the class. Another student joined in during Game 2.

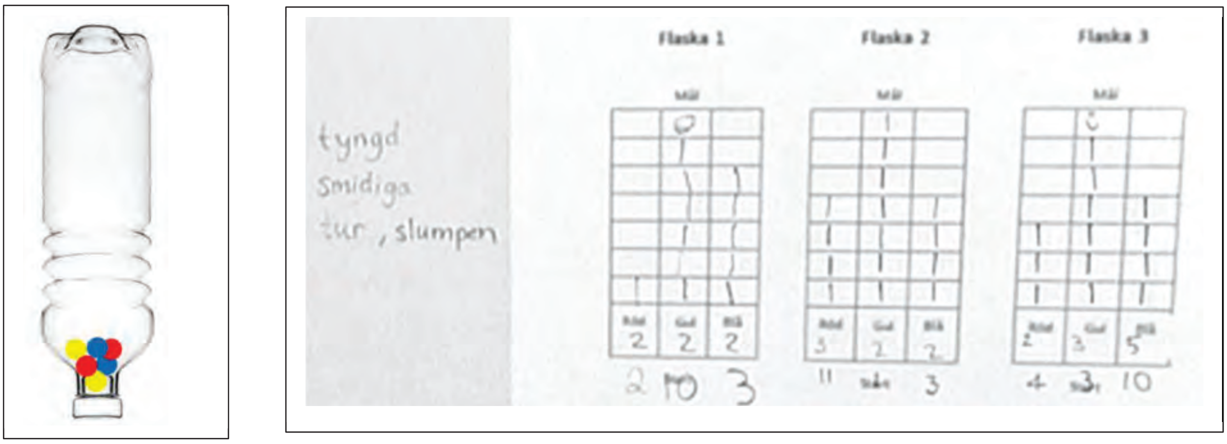

Figure 1: The bottle and the three games. The order of the three games moves from left to right. A list of reasons is to the left of Game 1. At the top of the list is 'weight', then 'agilent' and at the bottom 'luck, chance'. The row at the bottom of the playing-boards tells the colors – red to the left, yellow in the middle and blue to the right - and the number of each color in the bottle. At the very bottom are the students' votes on each game.

The rationale of the design of the game

The teaching experiment was designed by me, the researcher and author of the paper. Sara[1], the class-teacher, run the lessons and was supposed to act as she was used to. She was used to elicit and build discussion on students' ideas. If no student made connections between the win of a game and the sample space, Sara should take some careful initiatives to support such connections.

Each game was structured in three phases: predicting-playing-reflecting. First, the students were asked to predict which color they think will win and to provide reasons for their predictions. Second, the game was played. Third, the students were asked to reflect on the outcomes of the game, connecting back to their predictions. It was expected that a game both would ask for reasons and give reasons. It would ask for reasons if a game outcome was different from students' expectations. Experiences from previous games would help in giving reasons for predicting a subsequent game.

A principal idea of the variation theory is that we can only discern an aspect of a learning object if we experience a variation in that aspect (Runesson, 2006). In the present study the bi-directional relationship between sample space and data was an aspect students were supposed to discern. On this account, the sample space was changed between the three games. The game should also incite reflections on random variation. This raised questions on the length of a game. A long game would stress the regularity between sample space and data but mask random variation. A short game would stress random variation but mask the relationship between sample space and data. In preparing the lesson, I played the game of different length and decided to use a seven-step playing board (Figure, 1).

Method of analysis

In the analysis I looked for signs of taking a stance and of asking and giving reasons for a stance taken. Taking a stance (expressing a claim) on an outcome, was initiated by the teacher asking, "Who do you think will win?". Taking a stance was also made explicit in voting on a color. Signs of asking for reasons are 'why-questions" or questions like, 'how are you thinking?'. Signs of giving reasons come with signal words like, 'because' and 'since'. The results are structured according to the phases of predicting-playing-reflecting in each game.

Analysis and Results

Game 1

The sample space in Game 1 was, 2R, 2Y and 2B (Figure, 1).

Predicting on Game 1

After introducing the game and making all aware of that it is two marbles of each color in the bottle, Sara asked, "Which color do you think wins?". The votes from the students were two on

[1] Sara is a pseudonym for the teacher's real name.

red, ten on yellow and three on blue. The students gave both deterministic and probabilistic reasons for their votes.

Of the deterministic reasons were an idea of distance the most emphasized. When Sara asked the students to vote, she held the bottle horizontally and a yellow marble was closest to the bottle top. The students noted that the yellow was “At the front”. Hence, being at the front, the yellow marble has the shortest distance to the bottle top and so, most likely be first to the top when turning the bottle around. Sara did not shake the bottle to challenge the idea.

Probabilistic reasons are reasons that take into consideration sample space and random variation. For instance, when Sara asked Marcus why he voted for blue he said, “I don’t know. One should pick one and it doesn’t matter which one”. We can interpret Marcus as if he considers the win of the game to be just a matter of chance, since each color has as many favorable outcomes.

Playing Game 1

Sara turned the bottle each time. One of her students helped her at the whiteboard to mark the outcomes in the race. Sara moved around in the classroom to engage all students in reporting on outcomes. The first game ended with one on red, seven on yellow and five on blue.

Reflecting on Game 1

Sara asked, “Do you have any ideas why yellow won?” Students still argued for the distance to the bottle top. Now, Sara challenged this, “But I shook the bottle. I thought I was shaking a lot” [Sara shakes the bottle]. No student responded, probably because the shortcomings of their idea became obvious to them. Another deterministic reason that came up was, “Maybe because it is heavier? [giggling] They [the yellow] look bigger”. Sara looked close to the bottle, and responded with a long yes, which can be interpreted as if she wanted to tell that all marbles are exactly the same, without dismissing the student’s contribution. In general, Sara struggled between an attitude that no answer is wrong and trying to turn the students away from deterministic reasons towards probabilistic reasons.

Albin explained the win of yellow by, ”Yellow has luck”. After Albin’s suggestion Sara made a list on the whiteboard of the reasons students came up with (Figure, 1). Noting ‘weight’ and ‘at the front’, she asked if she had missed anything. One student repeated luck. Sara revoiced luck but with hesitation in the tone. She also expressed, “Lucky color maybe”. Sara added ‘Luck’ to the list. It seems as if Sara considered luck not a characteristic of randomness but a material property of the yellow color. Why Sara made this interpretation might be because Albin said, “Yellow has luck” and not “Yellow had luck”. The former signals that yellow possesses luck as a property. Regardless of if Sara made this interpretation or not, the situation shows how important it is to make inferences explicit in teaching, so the participants know they are talking about the same thing.

Game 2

The sample space in game 2 was, 3R, 2Y and 2B (Figure, 1).

Predicting on Game 2.

Sara made explicit the number of colors in the bottle. Eleven students voted on red, one on yellow and three on blue (Figure, 1) and Sara asked, "Yellow was a color of luck, it had the weight for winning, but now we do not believe in yellow anymore, it is only one that believes in yellow? Why do we believe most in red this time?". Daniel articulated, "It is most of them". Several students agreed with Daniel. Mario, who claimed that yellow won Game 1 because they looked bigger (heavier) now claimed that red looks bigger. However, when Sara claimed the marbles are exactly the same he moved to probabilistic reasoning:

Mario:	But, it can be because, it is more, it is greater, like, 65% percent chance that red wins as they are one more than the other".
Sara:	Where did you get the 65% chance from?
Mario:	Sorry, I say 60% chance. 60% chance and the other have 20% chance, because, yes red, because, last time it was 50, 50 50.

Mario seems to confuse two ways of quantifying the probabilities. He ended with, "last time it was 50, 50 50", which implies that he connects equally likely outcomes to a 50-50 situation. When he articulated 65% chance on red, we do not know if he changes the chance also of the other two colors or if he ends up in the triplet 65-50-50. However, Mario's change to 60% can be understood as if he discovers that the total probability needs to be 100%. Nevertheless, extending on Daniel's sample space reasoning, Mario tries to give reasons for the probabilities of the three outcomes by making connections to the underlying sample space. Being able to compare between different games helped him in making this connection.

Sara held the bottle horizontally also when the students were predicting the second game. However, this time, no student expressed they vote on a color because it is at the front.

Playing Game 2

After five observations in Game 2, there were three yellow, one red and one blue. When the third yellow appeared in the fifth observation one student voiced, "What?". Sara picked up on that, asking, "Anyone who has any thoughts now when yellow has run away with three?". Following his previous line of reasoning, Albin responded, "They (yellow) are lucky!"

Sara stopped the game again after nine observations. Now there were six on yellow, two on red and one on blue. Sara asked, "How can this be?". Reasons given were that it is something with yellow; that yellow is closes to the bottle top most times and that yellow won last time.

Next come five observations with no yellow. One student claimed yellow got tired and another that yellow wants to create a thrill. Since these answers are accompanied with a laugh, I interpret them more as jokes than as real reasons. No student referred to luck or chance. The next observation is yellow, and the game ended with four on red, seven on yellow and four on blue.

Reflecting on Game 2

Sara initiated reflections on Game 2 by connecting the game-variations to the list of reasons posted on the whiteboard. She asked, "Do we still think it is about these things [moving her hand over the list] or is it something new, something we should delete, because we are going to play another game with another bottle, so we need to have some thoughts before". The students negotiated on deleting the social reason 'Most votes' and the distance reason 'At the front'.

They kept weight and added that yellow is agilent and bouncy. However, most students raised their hand for “luck” as a reason for why yellow won. There is reason to believe that this was stimulated by how Sara was pausing the game, highlighting aspects of random variation.

No student referred to the role of sample space, which was probably because the situation was about explaining why yellow won. The sample space did not answer to why yellow won.

Game 3

The sample space in Game 3 was, 2R, 3Y and 5B (Figure, 1).

Predicting on Game 3

In Game 3 it was evident that the sample space is a strong reason for many students. In Game 3 there are 16 students but, there are 17 votes, distributed as, four on red, three on yellow and nine on blue. From the video it is hard to figure out where the extra vote comes from. However, most likely it is an extra vote on yellow, because it appeared some confusion when Sara counted the votes on yellow. Most students voted on blue, because there are most blue in the bottle. So, even if the students did not receive empirical evidence in Game 2 for the role of the sample space, most students put forward properties of the sample space as the strongest reason for why it is highest chance that blue wins Game 3.

Charles took a specific turn on the sample space. He voted for red because there are two red marbles in the bottle. He shaped this reason from the two first games, “It is always two marbles that win”. Sara responded, “Okay, it is always those [colors] with two marbles, yes it was two yellow [looking at the playing-board of Game 2] and two yellow also there [looking at the bottle of Game 1]. Okay, so when it is two of the same sorts, it wins!”. Another student, Albin, challenged this by noting that there were two of each color in Game 1 and that there were also two blue in Game 2. Sara’s first reaction to Albin was to silence him but, almost immediately she acknowledged his objection:

Sara: “But now it's Charles who ..., here you're [talking to Sven] talking about there are two. Yes, here it was two of each [pointing to Game 1]. Here then [looking at Game 2]? Yes, there were two blues as you said. Yes, hmm [nodding her head from side to side].

Even if Sara did not move further on this contradiction, the episode shows how game-variation can invite for reasoning on sample space in relation to exploring patterns between games.

Playing Game 3

Again, the game provided students opportunities to experience random variation in short series. After seven observations Sara made a short break. She did not ask for any reflections or thoughts. She just let the student take in that there is one observation on red, two on yellow and four on blue. No more blue appeared in Game 3. Yellow won again. In the last seven observations it appeared six yellow and two red. The game ended by, three on red, seven on yellow and four on blue.

Reflecting on Game 3

Several students thought that the yellow marbles are heavier and therefore drop down to the bottle top faster than the other. It is probably unlikely to many students that yellow wins over blue only because of chance, since there were so many more blue than yellow marbles in the bottle. In terms of hypothesis testing, we can say they consider the result of seven yellow out of a total of 14 observations so extreme that they reject the null hypothesis P(yellow)=3/10. The result on yellow is rather unlikely, but not significant on the level of 0,05 (two-sided test). However, we need to take into account that yellow won all three games. This experience most likely further support that chance does not tell the whole story for the results on yellow, compared to the other colors, within and between the games.

Chance was also highlighted in reflecting on Game 3. When Sara asked for other ideas on why yellow won, Albin again answered “luck”. Charles then added “the chance”, which Sara added to the list of reasons, after luck (Figure, 1). The meaning of luck or chance was not given any further consideration. The class negotiated on deleting bouncy and keeping agilent in the list of reasons.

Concluding discussion

How can variation in sample space between games be used to support reasoning on the bi-directional relationship between underlying probability distribution and data? The present study answers to this research question by reporting on a teaching experiment where students in Grade 5 (11-12 years old students) were playing three games of the Color-run (Nilsson, 2020).

In line with previous research (e.g., Nilsson et al., 2018; Watson et al., 2007), this study shows how probabilistic reasoning can face challenges from deterministic reasoning. Deterministic reasoning was manifested as distance reasoning and reasoning on material properties of the random generator. Distance reasoning relates to the perception that random experiments can be controlled (Pratt, 2000): you can control the outcomes by ordering them in a certain way. Distance reasoning neglects the random process, which, in the present study, took place in shaking the bottle. Reasoning on properties took place in reflecting of material difference between the colors in the bottles. Material differences were manifested as differences in weight, bounce, and agility. Reasoning on material differences does not need to neglect the random process, where students predict too narrow ranges of variation (Noll & Shaughnessy, 2012). After Game 3, for instance, material differences were given increased attention. The result of yellow in Game 3 was almost significant for rejecting the parameter value, according to sample space. Hence, it was reasonable to reflect on if it could be something more to the situation, beyond sample space and chance, to explain the strongly deviating result of Game 3.

In contrast to Lecoutre (1992), the present study shows that students can express strong commitments to the role of the sample space. In Game 3, for instance, even though the number of favorable outcomes was not decisive for the outcome of Game 2, most students used the number of favorable outcomes to give reason for why blue would win in Game 3.

Several students referred to luck, to explain the outcome of the games. What students mean by luck, is not always easy to tell. Does it refer to a property of an outcome or is it synonymous to chance? However, it would not be inferentially possible to substitute “Yellow has luck” with

“Yellow has chance”. Hence, the present study suggests further research on the meaning of luck. Taking an inferentialist perspective (Brandom, 2000), the study particularly suggests investigating situations in which students are supported to develop GoGARs of many inferential relationships that include the concept of luck.

Keywords: Education for sustainable development, data collection, processing data.

Introduction

Important decisions in politics, economics, health, and society are based on statistics. In order to participate in society as a responsible citizen, data management is an essential skill (e.g., Nichelson et al., 2018). For students growing up in a data-driven world, it is crucial to not only know how to analyse data, but also to think about how data are generated and what data can or cannot tell us (Wild et al., 2018). The present study follows the work of Andre et al. (2020), aiming to re-design their learning trajectory towards a student-centred approach on data collection and processing of data.

Theoretical background

Wild et al. (2018) list key statistical ideas important to understand at a deeper level including data collection, statistical modeling, covariance, and others. Student-centred methods lead to deeper understanding of concepts and the use of technology when exploring real datasets is crucial therefore (e.g., Wild et al., 2018). The PPDAC-cycle (Wild et al., 2018) describes such statistical investigation processes. Moreover, many studies emphasize that a context meaningful for students contributes to their development of competences (e.g., Makar und Ben-Zvi, 2011). Andre et al. (2020) take sustainability issues as such a context for students' statistical investigations. With the doughnut economy, Raworth (2017) presents an economic model for describing sustainable development (see figure 1), where social thresholds should be fulfilled while ecological boundaries should be obeyed.

Methods and Implementation

Following design-based research approaches (Bakker, 2018), a learning trajectory was generated to guide students of the 'Secondary School Centre' of Vipiteno in the district of South Tyrol through their own statistical research on sustainable development of their school's community. The aim of the study was to identify opportunities and challenges that arise during their statistical investigations.

31 students of two grade 12 classes participated in this study. They completed 12 lessons of 45 minutes each. In the first part, students were asked to identify factors contributing to a good and equitable life in the school community. Based on these results, basic ideas of the doughnut model (Raworth, 2017) were introduced, and a *school doughnut* was assembled containing students' ideas of their schools' sustainable development including issues such as energy consumption, CO_2-emissions on their way to school, political voice, mental health and many more. Subsequently, students were guided in their working processes of collecting and analysing data on these issues. Currently, results of the assignments and video recordings of the lessons are analysed qualitatively.

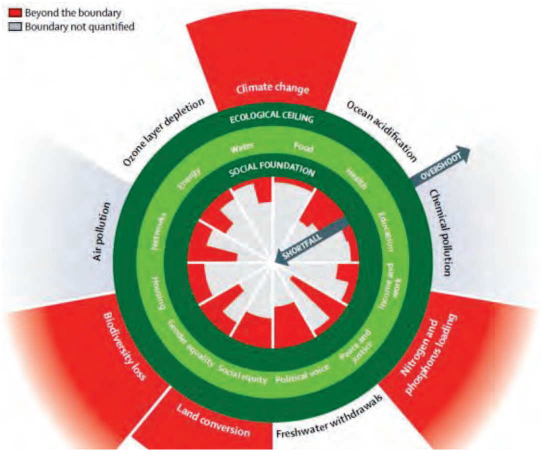

Figure 1: Doughnut Model (Raworth, 2017, p. e48)

First Results

Following the PPDAC-cycle, students managed to generate a doughnut model of their schools' sustainable development integrating several crucial topics. Thus, students could develop a deeper understanding of how to describe a phenomenon with statistical procedures. Two main categories of our data analysis are processes of data collection and generating statistical questions where we found major difficulties. Moreover, a third main category were students' struggles when defining specific boundaries and thresholds to classify the results of their investigations. These results are used to re-implement an improved learning trajectory in order to support students to overcome these difficulties.

How secondary school students build frequency tables?

Jocelyn D. Pallauta[1], María M. Gea[1], Carmen Batanero[1] and Pedro Arteaga[1]

[1]University of Granada, Spain; jocelyndiaz@correo.ugr.es; mmgea@ugr.es; batanero@ugr.es; parteaga@ugr.es

The ability to build and read statistical tables is part of statistical literacy and its teaching is included in the Spanish curriculum. We present results of an evaluation study carried out with 128 students in the 3rd grade of Compulsory Secondary Education (14-16 years old) who were asked to construct a distribution table with absolute and relative frequencies from a data list. About half of the sample performs a correct construction and calculation of absolute frequencies and 15% of relative frequencies. Based on the ontosemiotic approach, semiotic conflicts such as confusion of relative, percentage and absolute frequencies and erroneous procedures in the calculation of these frequencies are identified.

Keywords: Statistical education, statistical tables, student evaluation.

Introduction

Statistical tables are an important tool for summarizing and communicating information both in the media (Estrella, 2014) and in the scientific field (Feinberg & Wainer, 2011). Consequently, the ability to read, interpret and build statistical tables should be a component of statistical literacy for all citizens (Gal, 2019). Taking into account this goal, different curricular guidelines, including the Spanish documents (MECD, 2014) propose working with statistical tables throughout primary education (6 to 11 year-olds) to record and classify qualitative and quantitative data, as well as to build absolute and relative frequencies tables. Although statistical tables are considered easy by teachers, due to their wide use (Koschat, 2005) and their high presence in textbooks (Pallauta et al., 2021), research shows the need to reinforce its teaching, given that tables require specific cognitive skills for their understanding and construction (Martí, 2009). The aim of this study is analysing the construction of one-variable distribution table and identifying the semiotic conflicts that may arise in the process of organizing and summarizing a data list in a group of Spanish secondary education 3rd grade students.

Fundamentals

Theoretical framework

We base on the Onto Semiotic Approach to mathematical knowledge and instruction (OSA; Godino et al., 2007; 2019), which assumes that mathematical objects emerge from the mathematical practices (actions or operations) put into play to solve problem-situations. In this theoretical framework, the mathematical object can be considered from an institutional (e.g., a teaching institution) or personal (a person) perspective. The following types of mathematical objects are distinguished: problem-situation, language, concepts, propositions, procedures, and arguments. In the OSA the understanding of a mathematical object involves a synchrony between the institutional and personal meaning attributed to that object, which should be built progressively during the teaching-learning process (Godino, 2002). Furthermore, when there is a discrepancy between both meanings, a *semiotic conflict* is produced and may be classified according to the type of mathematical object involved. A conflict is conceptual if it refers to a misunderstanding of concepts or properties, and procedural when the students confuse a procedure.

Background

Research analysing the students' performance in the construction of statistical tables is scarce, despite this type of representation is widely used in the classroom (Estrella & Estrella, 2020). Such construction, according to Chick (2004), among other processes, requires the ordering and classification of data, their grouping and calculation of frequencies, which implies high cognitive demand, especially for elementary school students (Nisbet et al., 2003). Pfannkuch and Rubick (2002) point out that students are unaware of the need to summarize information, and it is complex for them to establish classification criteria when they analyse a large list of data. In this sense, Marti et al. (2011) suggest that the construction of tables requires segmentation processes along with deciding the variable(s) to be represented, the frequencies to be computed and adjusting such information in the spatial structure that characterizes the table. Research with primary school children confirms these difficulties: it is not easy for them to translate graphs to frequency tables (Díaz-Levicoy et al., 2018), or find criteria to organize data in tables (Estrella & Estrella, 2020). As regards adolescents, Álvarez et al. (2020) conducted an investigation with 100 Colombian students aged 15 to 18 years to analyse their difficulties in constructing frequency tables. The authors observed errors in the construction of tables with grouped data; confusion of different types of frequencies with the variable values and arithmetic errors in compute different types of frequencies. We note that most of research developed with secondary school students has focused on the two-way tables, so our work intends to contribute knowledge of these students' difficulties when constructing a one-dimensional frequency table.

Method

The study involved 128 Spanish students just beginning the 3rd grade of Compulsory Secondary Education from two schools in the same region, which split in a total of 70 males and 58 females ranging in age from 14 to 16 years. The participants had worked with statistical tables throughout primary education and their knowledge had been reinforced in 1st and 2nd grades of secondary education in accordance with a common standard for learning of the Andalusian curricular guidelines: "Organises data, [...] of qualitative or quantitative variables in tables, calculates their absolute and relative frequencies". (Consejería de Educación y Deporte, 2021, p. 785, p. 788). To these students we proposed a situation to be solved individually during the mathematics lesson, with paper and pencil (Figure 1), which is part of a wider questionnaire aiming to analyse the secondary students' knowledge on statistical table and to identify the semiotic conflicts that may arise in their answers. The task was adapted from a textbook (Kheong et al., 2017), and selected by suggestion of a panel of experts among three possible items. This type of table is frequently used in secondary school in Spain. Although the structure of the statistical table is provided in the task, no example was provided to complete it so, firstly, the student must identify the different modalities of the variable; no order of the categories is required because the variable is qualitative. Secondly, he/she had to find the absolute and relative frequencies associated with each modality, and finally calculate the corresponding totals. A similar activity was used by Díaz-Levicoy et al. (2020) with Chilean primary school students in the 3rd grade (8 years old), who had to translate a data list to a table, where a column was provided to record the count and absolute frequency of each modality and no relative frequencies were requested.

Claudia is very fond of insects and one morning she made a list of those she could observe in her garden:

ant - butterfly - ant - bee - ant - ant - mosquito - mosquito - bee - mosquito - butterfly - ant - ant - mosquito - ant - ant

Complete the table with the data collected by Claudia:

Insect	Absolute frequency	Relative frequency
Total		

Figure 1: Task proposed to the students

A content analysis (Bisquerra, 2019) was carried out to analyse the students' productions, in which the authors systematically reviewed the categories established in the previous analysis, and in the discordant cases a consensus was reached to ensure the reliability of the coding. Thus, the evaluation of the productions around the construction of the table were discussed in two rounds and were classified into three categories: correct, partially correct and incorrect; and additionally various semiotic conflicts that arose in this process were identified according to our knowledge and results of previous research in three rounds.

Results

This section presents firstly the results of the evaluation of the tables constructed by the students and then the different cognitive semiotic conflicts identified along with their distribution.

Statistical table construction

The criteria for classifying the construction of the table were as follows:

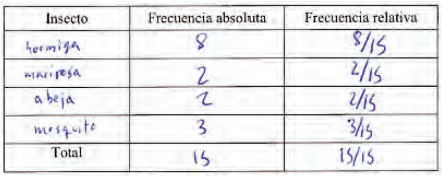
Correct table. The student adequately completes the columns corresponding to the absolute and relative frequency of each modality, using the information given (Figure 2), where the relative frequency can be represented through decimal numbers or fractions (simplified or not).

Insecto	Frecuencia absoluta	Frecuencia relativa
Hormiga	8	$\frac{8}{16}$
Mariposa	2	$\frac{2}{16}$
Abeja	2	$\frac{2}{16}$
Mosquito	4	$\frac{4}{16}$
Total	16	$\frac{16}{16}$

Figure 2: Correct construction of the statistical table (student E16)

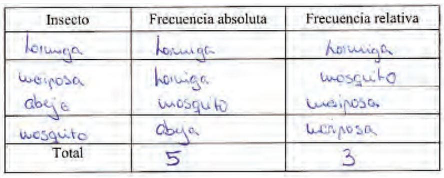
Partially correct table. In this category we classified the answers in which most of the cells were filled in with correct values, but there were some errors or blank cells. An example, with a counting error in one absolute frequency, which affects the calculation of the total, is presented in Figure 3 (left hand side).

Incorrect table. The table records values that make no sense, showing a lack of knowledge of the concepts of absolute and relative frequency, such as the example shown in Figure 3 (right hand side).



Insecto	Frecuencia absoluta	Frecuencia relativa
hormiga	8	8/15
mariposa	2	2/15
abeja	2	2/15
mosquito	3	3/15
Total	15	15/15

Partially correct construction of the statistical table with conflict in data classification (student E9)



Insecto	Frecuencia absoluta	Frecuencia relativa
hormiga	hormiga	hormiga
mariposa	hormiga	mosquito
abeja	mosquito	mariposa
mosquito	abeja	mariposa
Total	5	3

Incorrect construction of the statistical table (student E5)

Figure 3: Partially correct and incorrect construction of the statistical tables

The results on the building of the statistical table according to its correctness are presented in Table 1. A high percentage of students incorrectly computed the frequencies (absolute: 23.4%; relative: 62.5%) or did not compute them (absolute or relative: 18.8%). This result indicates that the task of classifying the values of the variable and forming the distribution was not simple. In the study developed by Díaz-Levicoy et al. (2020) with primary education 3rd grade students, most participants computed absolute frequencies correctly (68.4%); however, they were given a column to complete the counting, and the modalities were previously given, which facilitated task. The authors did not ask to complete the total. In our study, a low percentage computed the relative frequencies successfully (14.8%), while results were better for absolute frequencies.

Table 1: Frequency (percentage) of tables according to its correctness and frequencies computed

Table	Frequencies computed	
	Absolute	Relative
Correct	63(49.2)	19(14.8)
Partially correct	11(8.6)	5(3.9)
Incorrect	30(23.4)	80(62.5)
Not calculate	24(18.8)	24(18.8)
Total	128	128

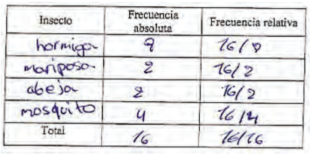
Semiotic conflicts in the construction of the table

A second analysis of the responses containing partially correct and incorrect construction of the statistical tables led to the identification of some semiotic conflicts, which are described below according to whether a concept o procedure is misunderstood. Some students showed more than one of these conflicts, and consequently the percentages in Table 3 do not add up to 100%. The conflicts were classified as procedural or conceptual.

Procedural semiotic conflicts

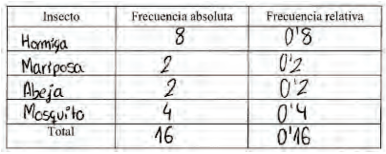
- P1. *Confused or incorrect classification of values*. Some data are classified incorrectly, leading to an error in the calculation of frequencies, as in the example shown in the left-hand side of Figure 3, which alters the total.
- P2. *Conflict in the computing relative frequencies*, which were classified in three different types:
  - P2.1. *Inverting the numerator and denominator* in the calculation of the relative frequency (Figure 4), which evidences a confusion in the definition of this concept, as well as misunderstanding the part-whole relationship (Álvarez et al., 2020).
  - P2.2. *Multiplying or dividing by a power of 10 to calculate the relative frequency,* instead of

using the total number of insects in the sample (Figure 5). An explanation is that the student tries to incorrectly obtain the relative frequencies from the percentage.



Insecto	Frecuencia absoluta	Frecuencia relativa
hormiga	9	16/9
mariposa	2	16/2
abeja	2	16/2
mosquito	4	16/4
Total	16	16/16

Figure 4: Construction of the statistical table with conflict P2.1 (student E249)



Insecto	Frecuencia absoluta	Frecuencia relativa
Hormiga	8	0'8
Mariposa	2	0'2
Abeja	2	0'2
Mosquito	4	0'4
Total	16	0'16

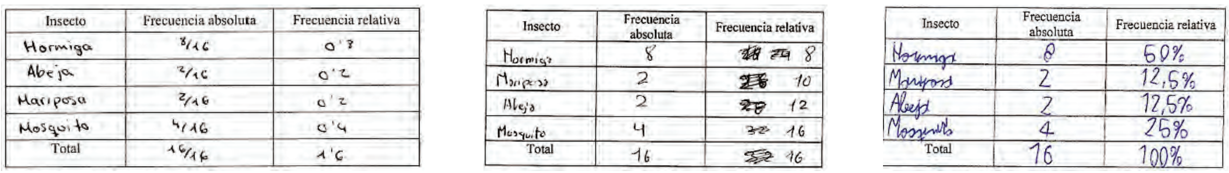
Figure 5: Construction of the statistical table with conflict P2.2 (student E58)

- P2.3. *Not computing the relative frequencies.* When the student leaves the column provided to record the relative frequencies incomplete.

- P3. *Conflict in computing totals (of absolute or relative frequencies).* These are the answers in which the total of the frequencies is not calculated, or show confusion in the addition algorithm.

Conceptual semiotic conflicts

- C1. *Confusion of different types of frequencies*, which found in previous research (Álvarez et al., 2020; Batanero & Godino, 2001; Fernandes et al., 2019) and can be classified into several types:
  - C1.1. *Confusing absolute and relative frequencies.* An example is given in Figure 6 (left hand side), where E23 completed the absolute frequencies using the formula for relative frequencies; this conflict was also presented inversely, that is, some students record absolute frequencies both in the absolute and relative frequencies columns.
  - C1.2. *Confusing relative and cumulative frequencies.* Similar to the conflict described above, some students provided cumulative frequencies in the column of relative frequencies (Álvarez et al., 2020) as can be seen in Figure 6 (centre, answer of E130).
  - C1.3. *Exchanging relative frequencies and percentages.* This response was less common, and includes the students recording percentages instead of relative frequencies for each modality of the variable as can be seen in the response of E248 in Figure 6 (right hand side).



Insecto	Frecuencia absoluta	Frecuencia relativa
Hormiga	8/16	0'8
Abeja	2/16	0'2
Mariposa	2/16	0'2
Mosquito	4/16	0'4
Total	16/16	1'6

Conflict C1.1 (student E23)

Insecto	Frecuencia absoluta	Frecuencia relativa
Hormiga	8	8
Mariposa	2	10
Abeja	2	12
Mosquito	4	16
Total	16	16

Conflict C1.2 (student E130)

Insecto	Frecuencia absoluta	Frecuencia relativa
Hormiga	8	50%
Mariposa	2	12,5%
Abeja	2	12,5%
Mosquito	4	25%
Total	16	100%

Conflict C1.3 (student E248)

Figure 6: Students' construction of the statistical table with conflict C1

- C2. *Not understanding the table content and meaning of the concepts involved in its structure.* This type of answer is uncommon and is shown in Figure 3 (right hand side), where the student records in the cells combinations of three insects, instead of computing absolute and relative frequencies. The concepts of variable, modality and frequency are not understood.

The semiotic conflicts presented in the construction of the statistical tables according to the content analysis made and whether they refer to absolute or relative frequencies are showed in Table 2. It should be noted that some answers showed more than one conflict (total percentages exceed 100%).

Table 2: Frequency (percentage) of conflicts in the tables according to the frequencies computed

Type of semiotic conflict	Abs. Freq.	Relative Freq.	Total (n=128)
P1. Misclassification of values	25(19.5)		25(19.5)
P2. Miscomputation of relative frequencies			
P2.1. Inverting numerator and denominator		8(6.3)	8(6.3)
P2.2. Dividing or multiplying by 10		11(8.6)	11(8.6)
P2.3. Not computing the relative frequencies		46(35.9)	46(35.9)
P3. Incorrect or not computing the total	39(30.5)	84(65.6)	123(96.1)
C1. Exchanging different frequencies			
C1.1. Absolute and relative	4(3.1)	6(4.7)	10(7.8)
C1.2. Relative and cumulative		5(3.9)	5(3.9)
C1.3. Relative and percentages		1(0.8)	1(0.8)
C2. Not understanding the table meaning and structure	7(5.5)	6(4.7)	13(10.2)

The most frequent semiotic conflict was P3 (96.1%) consisting of errors or absence of totals, particularly in the relative frequency (65.6%) that may be due to the lack of knowledge in the properties associated with the table (e.g., sum of total relative frequency is 1). It was followed by P2.3 (35.9%) linked to not computing the relative frequencies, giving evidence of the lack of proportional reasoning; then P1 (19.5%) corresponding to misclassification of values; and C2 (10.2%) lack of knowledge in the table structure and the concepts involved in its construction. Infrequent conflicts were P2.2 (8.6%) in which the relative frequency is obtained by dividing or multiplying the absolute frequency by powers of base 10, or C1.1, consisting in exchanging absolute and relative frequencies (7.8%). In absolute frequencies there were few conflicts (P3: 30.5%, P1: 19.5% and C2: 5.5%).

Discussion

The analysis of students' productions suggests that the process of building a statistical table is not simple, which coincides with other studies (Estrella & Estrella, 2020; Marti et al., 2011). It is striking that given the age of the students and their educational career, some of them lack minimal knowledge of the process of building a one-dimensional frequency table. Thus, a wide variety of semiotic conflicts in this process was detected, the most recurrent being the absence or incorrect calculations of the total, followed by the absence of calculation of relative frequency. Other students who tried to complete it, confused frequencies or showed a confusion of the concept manifested in procedural conflicts. These results confirm the need to make the teaching statistical table construction explicit (Martí, 2009), as well as further research within different educational levels and various situations to that described in our study such as showing the structure of the table completely, partially or not at all (e.g., Gea et al., 2020), and the translation between different representations (graphs, statistical measure, etc.), among others.

An example of rich, real and multivariate survey data for use in school

Susanne Podworny[1], Yannik Fleischer[1], Dietlinde Stroop[2] and Rolf Biehler[1]

[1]Paderborn University, Germany; podworny@math.upb.de

[2]District government Detmold, Germany

Data exploration and getting new insights from data is more important today than ever before. Exploring data is an important part of data science and can be a fruitful topic in middle school. New insights can be gained from rich data, but this requires a good data basis. Therefore, we present multivariate and rich data of over 1200 young people who answered an online survey on more than 150 questions. Several examples of possible data explorations of this data are presented. A short glimpse is given to a corresponding teaching unit for grade 8-10. With a suitable data science tool, students can handle and analyze such rich data. Students' presentations at the end of the teaching unit show the insights students get from the data but also, show challenges when exploring multivariate data.

Keywords: Data science, multivariate data, statistics education, CODAP.

Introduction

Statistics and data exploration have a long tradition and is fortunately also getting more attention in the classroom. With the rise of the new field of data science in recent years, its importance is once again increased (Ridgway, 2016) and gets new perspectives from computer science and special domain knowledge. In a data science project (Rubin & Mokros, 2018), various skills can be acquired and used that are helpful for good data exploration. On the one hand, this requires having rich, real data for students to draw real insights and conclusions that are important and motivating to them (Garfield & Ben-Zvi, 2008). On the other hand, a tool is needed that provides easy access to data analysis (Biehler, Ben-Zvi, Bakker, & Makar, 2013). In this paper, we present an example of such data which were collected as part of the ProDaBi project (https://www.prodabi.de/en/) and use the CODAP tool for exemplary explorations.

Background

The Project Data Science and Big Data in Schools (ProDaBi) aims at investigating in which way and with what topics data science can be implemented in the school curriculum. The project was initiated by Deutsche Telekom Stiftung and is conducted by an interdisciplinary team with members from statistics and computer science education. In this context, we collaborated with a media education research association[1] that conducts representative surveys among young people. We received an elaborated questionnaire for telephone interviews about media use of young people (so called "JIM-study"; JIM=Youth, Information, Media) and adapted this as an online survey. Since 2019, many young people participated in this online survey, so that we got rich and real data on young people's media use, which we call *JIM-PB*, based on the official JIM study and our regional reference

[1] https://www.mpfs.de

(PB=Paderborn). Please note, in contrast to the official data from the JIM-study, our data does not claim to be representative.

The data is used in different teaching settings. At first, it is used as an introduction in a project course on data science in grade 12 (Frischemeier, Biehler, Podworny, & Budde, 2021). This project course consists of three modules: (1) basics of data analysis and statistical thinking, (2) algorithmic thinking and machine learning, and (3) application in a comprehensive project.

Second, adapted from these modules 1 and 2, we have developed a teaching unit for grades 8-10, which also introduces statistical reasoning and machine learning. Here, students work entirely with the CODAP tool, both for data exploration and for creating decision trees based on data. This entire unit makes use of the JIM-PB data. Enhancing statistical thinking as proposed by Wild and Pfannkuch (1999) and introducing predictive modelling (Ridgway, Ridgway, & Nicholson, 2018) with the use of decision trees are the two main purposes of the teaching unit.

Rich data that allow multivariate explorations consist of many variables of different types to motivate creative investigations. How the JIM-PB data fulfils this is shown in the next section.

The data “JIM-PB”

The JIM-PB data is based on an online survey that contains various thematic blocks. The first block contains questions on age, sex, grade, type of school. The following blocks contain question in the style “How often do you…”

- … do leisure activities (e.g. meeting friends, playing an instrument, etc.),
- … use classical and digital media (e.g. newspapers, radio, etc.),
- … use media devices (e.g. tablet, gaming console, PC, etc.),
- … use social media (e.g. Facebook, Twitter, WhatsApp, etc.),
- … watch different YouTube videos (e.g. on product tests, letsplays, sports, etc.),
- … play different electronic games (e.g. car racing, shooter, adventure, etc.),
- … use specific apps (e.g. for news, public transport, school, etc.).

Values for all the corresponding questions on the frequency range from “daily”, over “several times a week”, “once a week”, “once in a fortnight”, “once a month”, “less often” to “never”.

Some questions are posed concerning the weekly time in minutes e.g. on watching TV, playing electronic games or using a PC for school at home. Additionally, questions are asked about availability or owning devices for media use (e.g. PC, Laptop, Tablet, WiFi, etc.). Questions are like “Is the device available at your home?” with values “available at home” or “not available at home” and “Do you own such a device?” with values “I own it myself” and “I do not own it”.

This leads to 161 different questions, resp. variables. 1287 young people fully answered the survey, so the data contains as many cases from September 2020 until June 2021. A list of variables lists the original questions and the variable’s names in the data. Data handling is done in advance. Variables are defined and little data cleaning like correction of German umlauts is necessary.

This results in rich and multivariate data with numerical and many categorical variables. In particular, the large number of variables makes it possible to develop and investigate very creative questions.

The Jim-PB data in a teaching unit for middle school

The idea of using the Jim-PB data in school is mainly to introduce reasoning about data in the frame of a data project. The PPDAC-cycle (Wild & Pfannkuch, 1999) frames the teaching unit and

> [w]orking with SP [statistical projects] thus represents a strategy that can enrich curricula because each phase involved in developing a project entails the use of various statistical concepts and processes that go beyond the topics normally included in curricula (Gómez-Blancarte & Ortega, 2018, p. 5)

For use in school, we created two versions of the data. The "standard" version is didactically reduced and contains 50 variables. A selection was made for this based on content criteria. For example, all questions about "owning" a device and playing different games were abandoned. We recommend using this version in grade 8-10. The "large" version contains all 161 variables.

The selection of a tool is crucial for doing data science in middle school. We selected and applied our JIM-PB data to the online data exploration platform CODAP (https://codap.concord.org), which is a free and online software that allows an easy and quick start of data exploration for beginners. For a detailed description of CODAP see for example Haldar, Wong, Heller, and Konold (2018).

For the teaching unit in middle school, we have chosen personalized advertising as the context. This has a motivation and an everyday relevance for students. The students are asked to explore the data with regard to four topics: user groups of TikTok, online newspapers, Youtube Letsplay videos and use of game consoles. Eight lessons with 45 minutes each can be used to enhance students' statistical skills when exploring Jim-PB data with CODAP in the first part. Additional eight lessons then build on findings from the first part to create and understand the method of decision trees for predictive modelling within CODAP. For the first part, three lessons can be dedicated to introducing basic terms, the data and tool, and concepts like row, column and cell percentages. Posing statistical questions (Arnold, 2013) and preparing group work can happen in lesson 4. The following two lessons can be used for students' own data exploration and preparation of a presentation. That results in a following presentation lesson. Reflections on the data, the PPDAC cycle and the conclusions can happen in the eighth lesson of the first part.

Explorations of the Jim-PB data with CODAP

What's in the Jim-PB data? At the beginning of an analysis, it is worth taking a brief look at one-dimensional distributions to characterize the sample of respondents.

Figure 1: Distribution of sex and age in the Jim-PB data

A little more female (56%) than male (44%) students participated in the survey, aged 10-20 with peak at age 15 (Figure 1). For example, 78% have a game console available at home and a tablet is used by slightly less than half for gaming (Figure 2).

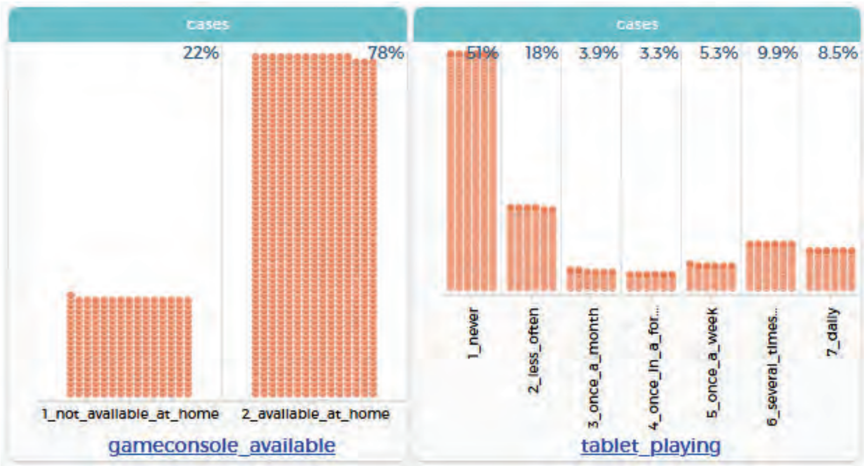

Figure 2: Distribution of game console available at home (left) and playing on a tablet (right)

Exemplarily, we look at a typical distribution of how often the participants use a tablet or Instagram (Figure 3). Such an "u" shape often occurs in these data, which means that the students can be split in two major subgroups ("rarely" and "frequently").

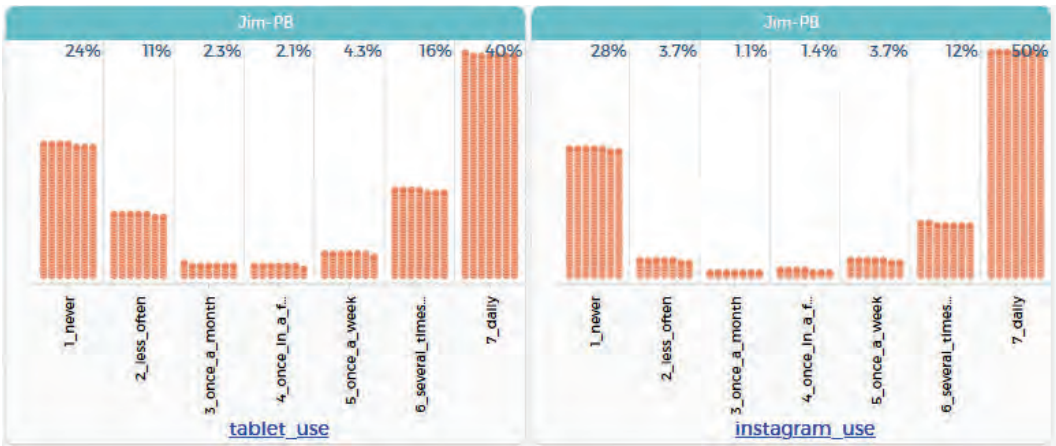

Figure 3: Distribution of tablet use (left) and Instagram use (right) in the Jim-PB data

Who belongs to those who daily use a tablet? Are those, who use daily a tablet those who use Instagram daily? For answering questions like this, two-dimensional diagrams are necessary like in Figure 4.

The challenge of interpreting complex diagrams like the one in Figure 4 is to use the correct percentages. This is often difficult for students (Watson & Callingham, 2014) and must therefore be well addressed in class. In Figure 4, row percentages are shown. A correct interpretation of the value 53 % at the top right corner is: Of those who use a tablet daily, 53 % use Instagram daily. But this is the same for those who never use a tablet (lowest right value in Figure 4)! Now we look at those who use a tablet daily.

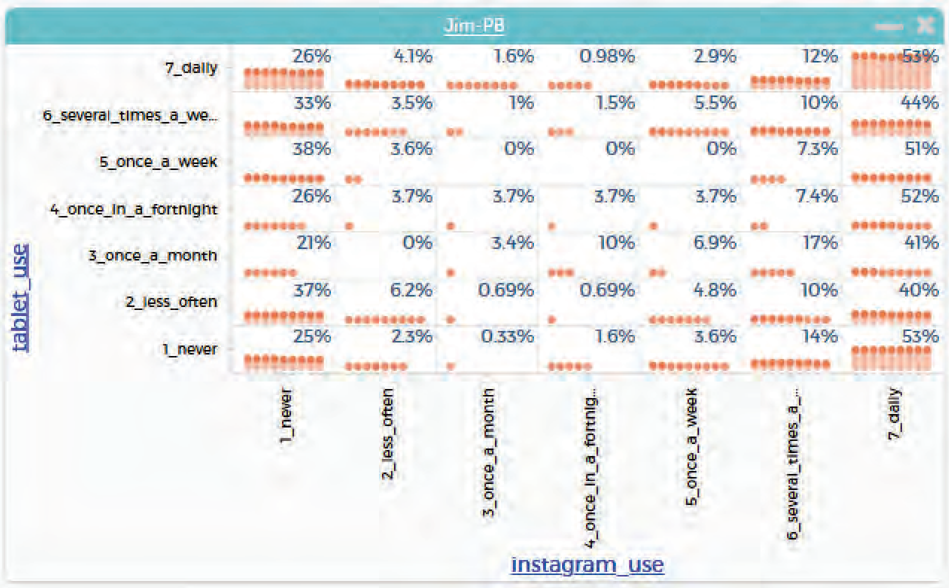

Figure 4: Do those who daily use a tablet those who daily use Instagram? (with row percentages)

7x7 tables like in Figure 4 are quite complex and hard to interpret not only for middle school students. By using data moves (Erickson, Wilkerson, Finzer, & Reichsman, 2019) like filtering with the "eye" function in CODAP, one can concentrate on a subgroup of the participants by selecting the corresponding cases and hiding all other cases (Figure 5).

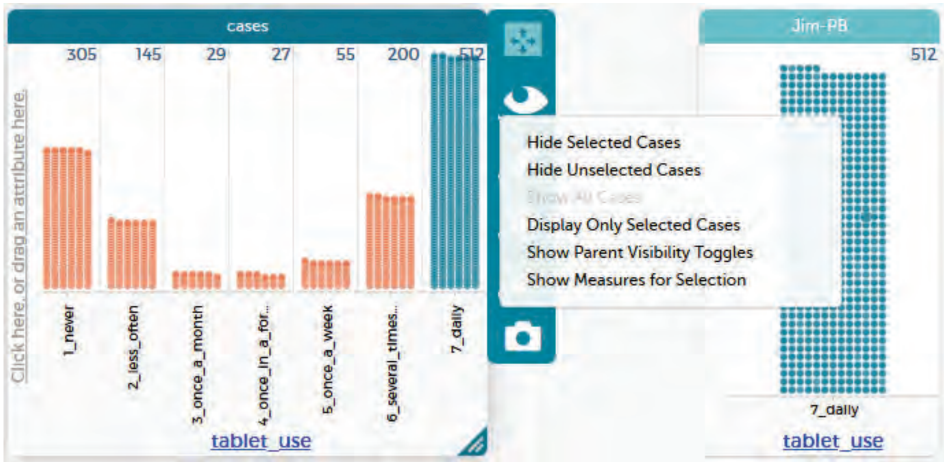

Figure 5: Filtering the data by selecting a subgroup (left) and the subgroup only (right)

Now the analysis can be focused on the subgroup of participants of those who use a tablet daily. For example, in this subgroup two third are female (Figure 6 left) in contrast to all participants (56%, Figure 1); distributed over all grades (Figure 6 middle) like in the whole group. 38% play often with the tablet (Figure 6 right, values for 'several times a week' plus 'daily') in contrast to the all participants, of whom less than 20% play tablet often (Figure 2 right). As a story, daily-tablet-user are more often female than male and use a tablet for playing more often than the whole group.

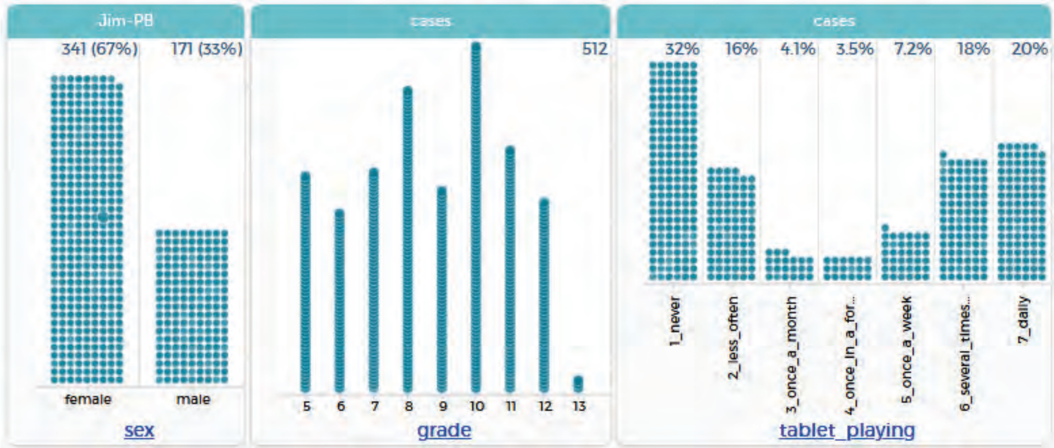

Figure 6: Subgroup displays of those who use a tablet daily

This is a small impression of an analysis of the Jim-PB data that can be done with CODAP.

Students' explorations of the JIM-PB data: some impressions

The first part of the teaching unit was implemented in four different classes in different schools in 2020, once in grade 9 and 10 and twice in grade 11. This includes a total of 77 students aged 13 (grade 9) to 17 (grade 11). All students had nearly no previous knowledge in statistics and data analysis. We collected their final presentations from lesson 7 and analyzed their diagrams and written interpretations. Student groups had between two and six members, we collected n=15 presentations because one group did not hand in their presentation.

Here we give a short overview of the 15 students' presentations, the diagrams used and written interpretations. Major differences between the three grades could not be identified, but the groups differed greatly in their work, independently of the grade. There were great and poor presentations in every grade. So, we analyzed on all presentations without taking the grade into account.

The number of slides and diagrams varied much between the presentations. The number of slides varied between two and 37, with an average of 13. Many slides of a presentation had only little or no text, except one presentation that was like a report. Every group stated their topic at the beginning.

The number of diagrams per presentation varied between two and 16 with an average of six. One group did not include any diagram, they only reported several percentages (that must have been figured out with diagrams in CODAP). The presentations often had no written explanations in the slides but were explained orally during the presentation lesson. Three groups used column percentages, all other used row percentages which are the default setting in CODAP. For these groups it is not clear whether they also considered using column percentages to answer their underlying question. Of course, a rearrangement of the variables would be equivalent to changing row and column percentages. Using and interpreting percentages was often challenging for students. The use of row percentages did not always go along with the interpretations, several times column or cell percentages would have been appropriate for the written statements. This is similar to results found by Watson and Callingham (2014). Two groups used the filtering function to focus on subgroups like in Figure 5.

A nice example is from a group from grade eleven that looked at how the frequency of reading online newspapers is changing with age. They computed the average age of readers in the different groups as shown in Figure 7.

Figure 7: Students' exploration of age and online newspaper reading

As an interpretation they wrote "For each 'reading frequency' you can see the average age indicated by the blue line. Newspapers are read online from the age of about 15, while the average age of non-online newspaper readers is 13. Therefore, it can be said that the target group of online newspapers has the age of more than 15 years, while the largest and most active part of the readers is represented by people aged 16 years and older."

Students' investigations were rich and showed interesting relationships in the data. Diagrams created and used for presentation by the students offered great opportunity to tell many stories about the data. Nevertheless, only few detailed descriptions like the one for Figure 7 occurred and these were not yet completely satisfactory due to inaccuracies in the explanations. Cultivating interpretations turned out to be a challenge.

Conclusion

The JIM-PB data provides rich exploration opportunities and is suitable for students aged 13 and up. For students, the version with 50 variables is sufficient to make interesting discoveries and looking for many relationships in the data. CODAP has proven as an appropriate tool for an easy entrance to explorations.

Such rich data not only brings advantages, but also challenges. The type of the data means that variables with seven values have to be related to each other. This results in 7x7 matrices with a total of 49 entries. In class, it became apparent that the interpretation of 7x7 matrices was challenging for students and patterns were rarely well described and interpreted. As an implication, we added a lesson on data preparation in the teaching unit, where the seven values can easily be merged so that only the values "frequently" and "rarely" remain by using the "hierarchize" function in the CODAP's table. Then only four-field tables occur, which are much easier to interpret than the 7x7 matrices.

Additionally, modelling aspects of such a data preparation with relation to possible interpretations can be discussed in class. As another implication, data moves (Erickson et al., 2019) like filtering (easily done in CODAP with the "eye" function) are a useful concept that can enrich students' data science projects in middle school.

During the last year, governments around the world used statistics data to keep people informed about Covid-19, to stress the importance of managing this disease and to encourage to adopt preventive behaviors. In this study, we investigated a mechanism underlying intentional non-precautionary behaviors during the COVID-19 lockdown. We hypothesized that the comprehension of COVID-19 risk statistics information had a central role in mediating the relationship between probabilistic reasoning ability and perceived statistics value (the antecedents) and the intention to act non-precautionary behaviors. Participants were 141 university students enrolled in an online study. Results revealed that probabilistic reasoning ability and perception of statistics value had a role in reducing the likelihood of engaging in transgressive behaviors through their impact on the ability to adequately reason with statistics data referred to the COVID-19 epidemic.

Keywords: Probabilistic reasoning, COVID-19 risk statistics information, statistic value, statistical literacy.

Introduction

The 2019 coronavirus disease (COVID-19) outbreak, caused by the novel coronavirus SARS-CoV-2, has become a global health threat, which has prompted the scientific community to question how to deal with it and mitigate its impact. It has been reported for the first time in Wuhan, Hubei Province (China) in late December 2019 and it has rapidly spread around all the five continents. As of 30 April 2020, the number of totals confirmed cases worldwide has exceeded 3 million (World Health Organization, 2020). On 20 February 2020, Italy identified its first case of local transmission and since March 20, Italy had surpassed China as the country with the highest amount of people who died from COVID-19 in the world (World Health Organization, WHO, 2020a). The number of deaths in Italy remained the highest worldwide until April 13, when the USA has become the nation with the highest number of deaths (WHO, 2020b). Even though governments around the world adopted different response strategies to tackle the pandemic, at some stage most countries either enforced or encouraged policies targeting preventive behaviors such as social distancing. However, these measures of containment have requested citizens a limitation of their activities and a modulation of their behaviors.

In medical decision-making, it has been widely demonstrated that adherence to health behaviors is influenced by risk comprehension related to the medical issue/problem. For example, risk comprehension has been found to influence risky decisions related to sexual behavior (Patel et al., 2007), substance use (Lundborg & Lindgren, 2002) and tobacco consumption (Lundborg & Lindgren, 2004). In a systematic review about poor risk comprehension's health outcomes, it has been found that a lower comprehension of health information was associated with more hospitalizations, less mammography screening and influenza vaccination (Berkan et al., 2011).

Several studies about risk comprehension were then carried out to investigate what improves or hinders it. In this regard, as much of health-related information is expressed numerically (Reyna et al., 2009), a growing body of literature has sought to determine how health numeracy skills, the ability to understand and make use of health-related statistics (Låg et al., 2014), can improve people's risk comprehension. Health numeracy, intended as the ability related to probabilities, proportions, and percentages in the health domain, is low in the general population (Lipkus et al., 2001; Peters, 2012). However, it seems to have important impact on risk comprehension (Låg et al., 2014; Rolison et al., 2020).

Anyway, numeracy is a complex concept, encompassing several functional elements. Numeracy skills can be defined along a continuum that goes from elementary arithmetic skills to higher levels that encompass the ability to master probabilistic information and risk estimates (Reyna et al., 2009). Among these numerical skills, a growing interest has been recently posed on *probabilistic reasoning abilities* (Donati et al., 2014; Donovan et al., 2017; Hertwig et al., 2008; Primi et al., 2017). Probabilistic reasoning can be defined as the ability to think statistically about uncertain outcomes, and to make decisions based on probabilistic information. Probabilistic reasoning ability represents an important skill to correctly understand information related to risks. Interestingly, it has been highly documented that the majority of people have an inadequate comprehension of probabilities (Gigerenzer et al., 2005), even if they are highly educated (Lipkus et al., 2001). In the health domain, risk comprehension demands people to face uncertain outcomes and, therefore, with probabilities. For example, it has been demonstrated that the inadequate comprehension of risk and probabilities is critical in many areas, as the understanding of diagnostic tests (Gigerenzer et al., 2007) and drugs' side effects (Gigerenzer & Galesic, 2012). Specifically referring to COVID-19 related risks, it has been shown that when introductory statistic course students had higher probabilistic reasoning ability, they were more proficient in understanding COVID-19 risks (Primi et al., 2021). Additionally, probability reasoning ability, reflective ability and statistics interest had a role in reducing the likelihood of engaging in transgressive behaviors through their profitable impact on the ability to adequately reason with statistics data referred to the COVID-19 pandemic.

In line with this premise, we were interested in investigating the relation between probability reasoning ability and Covid Statistic Risk Comprehension in graduate students with more experience in statistics. We hypothesized that people who properly understand probability would be better in understanding and evaluating Covid Statistic Risk information. Additionally, as mass media communication about COVID-19 has been based on statistical concepts, such as "frequency", "shape of the curve", "flattening the curve", "positive rates", we hypothesized that a fundamental prerequisite to personally engage in data understanding would be the perception of the statistics value. It represents the usefulness, relevance, and worth of statistics in personal and professional life (Schau et al., 2003). Finally, as individuals who perceived risk related to COVID-19 as higher declared are more likely to implement protective behaviors (de Bruin & Bennett, 2020, we included intentional non-precautionary behaviors during the COVID-19 lockdown as dependent variable.

In sum, our research question was to investigate the role of the probabilistic reasoning ability and the perceived value of statistics (positively related to each other) as antecedents of risk comprehension of COVID-19 statistics and this variable was hypothesized as the intermediary variable (mediator) between its antecedents and the dependent variable, that was conceptualized as intentional non-precautionary behaviors during the COVID-19 lockdown.

Method

Participants

Participants were 141 students attending graduate programs (60% female; mean age = 23.4; *SD* = 4.83) at the University of Florence (Italy). Introductory stats courses are compulsory in all the programs. For the pandemic all the programs were online. All students participated on a voluntary basis after they were given information about the general aim of the investigation. Participants completed an online survey on April 2020, during the first Italian lockdown.

Measures and Procedure

The *Probabilistic Reasoning Scale* (*PRS-B*; Primi et al., 2019) consists of 9 multiple-choice questions. The items include questions about simple, conditional and conjunct rule in probability, and the numerical data are presented in frequencies or percentages. A single composite score, based on the sum of correct responses, was calculated.

The *Value* subscale of the *Survey of Attitude towards Statistics* (*SATS-36*; Schau, 2003) is one of the subscales of the instrument measuring the six components of attitude toward statistics. The specific subscale consists of 9 Likert-type items using a 7-point scale ranging from *strongly disagree* to *strongly agree*. A single composite score was computed based on the sum of the responses, with higher ratings representing a higher perception of the Statistic Value.

The *Statistics Risk Comprehension Scale-Covid 19* (*SRCS-Covid 19*) was developed for the purpose of this study. In detail, we constructed a scale aimed at investigating people's understanding of the statistics about the epidemiological situation regarding the COVID-19 epidemic that was spreading in Italy in that specific historical period. Eight multiple-choice items with three response options (among which only one was the correct one) were created with the aim of covering the most debated issues in the Italian mass media concerning the COVID-19 at that time (e.g., cases of infections, dead cases out of infections, prevalence rates of positive COVID-19 tests). A single composite score, based on the sum of correct responses, was calculated. An example of item is: "*On 19 March 2020, in Italy there are about 40,000 infections and about 33,000 people who are still positive for the virus. This means that: a) As of that date, there are about 73,000 cases of infections; b) As of that date, there are about 7,000 cases between deceased and recovered; c) As of that date, there are about 7,000 cases of healed*".

In order to investigate the intention to act not precautionary behaviors put in place during the lockdown period, we developed a brief questionnaire through which participants were asked to indicate whether they have intention to act the listed behaviors. Behaviors were defined as not precautionary on the basis of the restrictions imposed by Italian government through the Decree of President of the Council of Ministers (DPCM) issued on March 9, 2020 (https://www.gazzettaufficiale.it/eli/id/2020/03/09/20A01558/sg). An example of not precautionary behavior was "*Take a walk with some friends*". For each of the ten listed behaviors, participants had to respond "*no*" (scored as 0) if they had not the intention to engage in that behavior, or "*yes*" (scored as 1) if they had the intention to do that behavior, by specifically referring to the lockdown period. Among the listed behaviors, four were classified as not precautionary. In order to obtain a measure of intentional not precautionary behaviors, a total score was computed by summing responses given to the items investigating those kinds of behaviors.

After giving the informed consent, each scale was briefly introduced, and instructions for completion were given. All participants completed the *PRS-B*, *Value* subscale of the *SATS-36*, *SRCS-Covid 19* and the scale investigating intentional precautionary behaviors during the Covid 19 lockdown period. Time administration was about 30 min.

Results

To analyze the relationships between COVID19-related statistics risk comprehension and the scores relative to probabilistic reasoning ability, perception of statistics value, and intention to engage in not precautionary behaviors, correlations among the variables were calculated (Table 1).

	1.	2.	3.	4.
1. COVID19-related statistics risk comprehension	-			
2. Probabilistic reasoning ability	.46***	-		
3. Perception of statistics value	.33***	.36***	-	
4. Number of intentional not precautionary behaviors during the Covid 19 lockdown	-.22**	-.13	-.22*	-
M (*SD*)	5.09(1.52)	6.43(1.72)	46.71(8.36)	1.94(1.71)

*p<.05, **p<.01, ***p<.001

Table 1: Summary of intercorrelations, means, and standard deviations for scores of COVID19-related statistics risk comprehension, probabilistic reasoning ability, perception of statistics value, and intention to engage in not precautionary behaviors during the Covid 19 lockdown

As expected, the SRCS-Covid 19 score significantly and positively correlated with probabilistic reasoning ability and perception of statistics value. It was also significantly and negatively correlated with the number of not precautionary behaviors that are likely to take be placed. Moreover, probabilistic reasoning ability and perception of statistics value were positively inter-related, and the number of intentional not precautionary behaviors were significantly and negatively correlated with both probabilistic reasoning ability and perception of statistics value.

In order to investigate our hypothesis on the mechanisms underlying the relationships among these variables, we conducted a path analysis employing the maximum likelihood (ML) method using AMOS 16 software (Arbuckle, 2007). The model included probabilistic reasoning ability and perception of statistics value as COVID-19 statistics risk comprehension's antecedents (positively related to each other). In turn, statistics risk comprehension was hypothesized as the intermediary variable (mediator) between the antecedents and the dependent variable, that was conceptualized as the number of intentional not precautionary behaviors during the Covid 19 lockdown.

The presence of the mediated effect was investigated through the test of indirect effects (Cheung & Lau, 2008). In AMOS the Bootstrap confidence interval method is used to define the confidence intervals for indirect effects (MacKinnon et al., 2004). In mediation analysis, bootstrapping is used to generate an empirically derived representation of the sampling distribution of the indirect effect, and this empirical representation is used for the construction of a confidence interval for the indirect effect. The 90% bias-corrected confidence interval percentile method was implemented, using 2,000 bootstrap samples. Confidence intervals for the indirect effects which do not contain 0 are considered as indicative of significant indirect effects, thus meaning the presence of a mediated effect. Several goodness-of-fit indices were used to test the adequacy of the model: Comparative Fit Index (CFI) (Bentler, 1990), the Tucker-Lewis Index (TLI) (Tucker & Lewis, 1973) and the Root Mean Square Error of Approximation (RMSEA) (Steiger & Ling, 1980). CFI and TLI values equal to .90 or greater and RMSEA values of .08 or below are considered as indices of adequate fit. The model showed a good fit to the data (CFI = .976, TLI = .927, RMSEA = .074). All coefficients were statistically significant in the expected directions. Specifically, results revealed that probabilistic reasoning ability and perception of statistics value – positively inter-correlated – had a significant direct and positive effect on COVID-19 statistics risk comprehension. In turn, COVID-19 statistics risk comprehension was directly and negatively related to the number of intentional not precautionary behaviors during the Covid 19 lockdown. Results also showed significant and negative indirect effects from the independent variables on the number of intentional not precautionary behaviors during the Covid 19 lockdown, indicating that probabilistic reasoning ability and perception of statistics value had a role in reducing the likelihood of engaging in transgressive behaviors through their profitable impact on the ability to adequately reason with statistics data referred to the COVID-19 epidemic (Figure 1).

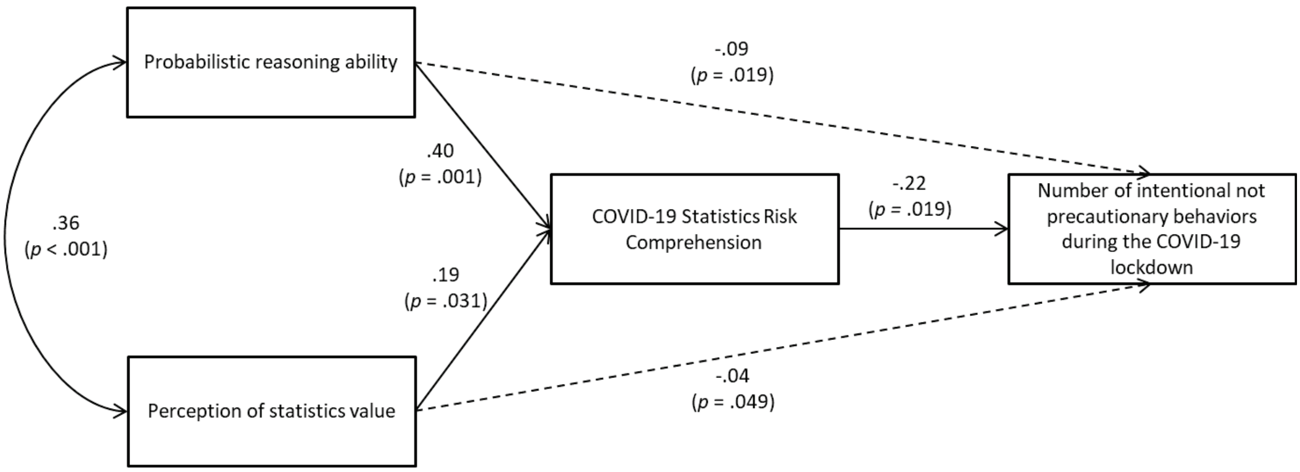

Figure 1: Path model among the variables. Straight lines indicate direct effects. Dotted lines indicate indirect effects. All the coefficients are standardized

Conclusion

The emergency caused by coronavirus disease 2019 (COVID-19) has led to a surge in interest in trustworthy statistics and a greater number of people accessing statistical information about their own communities. Results showed the role of mediator of the statistics risk comprehension confirming the need to have a deep understanding of statistics, especially in the context of a global pandemic such as Covid-19. We found that probabilistic reasoning ability and perception of value in statistic had indirect effects on the intention to act non-precautionary behaviors through statistic risk comprehension. This result is in line with other studies concerning diverse health contexts, that showed that numeracy (in its different components) has consistently been related to risk perception, more accurate understanding of risks, and better decisions (Garcia-Retamero et al., 2019), and with explanation models related to behavioral conducted in the pandemic (Primi et al., 2021). More generally, our findings show the importance of statistical literacy as an essential skill for all citizens, especially in the context of a global pandemic such as Covid-19**.**

Onto-semiotic competence in the statistics content of early childhood education of recently graduated teachers

Maria Ricart[1] and Assumpta Estrada[2]

[1]University of Lleida, Spain; maria.ricartaranda@udl.cat

[2]University of Lleida, Spain; assumpta.estrada@udl.cat

This paper presents a training action with ten recently graduated teachers who are taking an advanced training Master's Degree in Spain. The objective of the action is to develop their didactic-mathematical competences and, in particular, the onto-semiotic competence in the field of statistics in early childhood education. To achieve this competence, the teachers identified the emergent objects in a real videotaped mathematical practice. The results obtained from a qualitative analysis indicate that the participants have difficulties in recognizing the properties and the arguments, as well as some statistical concepts, whereas they identify the procedures quite well. It is concluded that the competence development requires increasing the temporal suitability of the action and also dedicating more hours to the initial training of teachers in statistical content.

Keywords: Teacher education, instructional design, onto-semiotic competence, statistics, early childhood education.

Introduction

The development of statistical literacy should begin in early childhood education (NCTM, 2000). Carrying out small statistical studies with a qualitative variable is suitable for this. However, in Spain, there is still some reluctance to do so. One of the causes of the statistics teaching and learning processes implementation slowdown in the early ages is that statistical content is not well integrated into the Spanish educational curriculum for early childhood education. But this is not the only reason.

In the last decade, there has been a warning that, in the initial training of teachers at this stage, not enough hours are dedicated to statistics (Alsina & Vásquez, 2016; Franklin et al., 2015; among others). Along these lines, Alsina (2020) reviews the study plans of the Degree in Early Childhood Education of seventeen Spanish universities and concludes that most of them dedicate only 6 credits to the whole didactic-mathematical training and that only three of these universities, allocates between 6 and 9 credits to strictly mathematical or statistical content. Consequently, there is an immediate need to improve the didactic-mathematical skills and knowledge in statistics of kindergarten teachers. In this sense, Batanero (2019) suggests that research on the teacher's statistical knowledge focus on training actions that favor the development of their specialized knowledge and professional competence.

This work is part of a larger investigation whose aim is to explore and develop the didactic-mathematical skills and knowledge about statistics in early childhood education of a group of recently graduated teachers after a training action designed for this purpose. This paper addresses the onto-semiotic competence and it is motivated by the question of which mathematical objects identify the participants in a statistical practice of early childhood education.

It is dedicated the following section to expose the theoretical framework and describe the methodological approach, as well as the training action, in the third point. In the fourth section, the main results regarding the onto-semiotic competence are collected and, finally, the conclusions of the work and some final reflections are presented.

Framework

In recent decades, the field of mathematical education research has focused on determining the knowledge of the mathematics teacher. In this sense, the Schulman model (1987) and the Mathematical Knowledge for Teaching model (MKT) (Hill et al., 2008) stand out internationally. Different approaches have also been interested in teacher skills, such as Lesson Study (Fernandez & Yoshida, 2004) or Noticing (Mason, 2002).

This research is developed within the Teacher's Didactic-Mathematical Knowledge and Competence (DMKC) model (Godino et al., 2017) of Onto-semiotic Approach (OSA) (Godino et al., 2007) theoretical framework, because it offers detailed categories of knowledge and skills.

This model considers that the mathematics teacher must have three types of knowledge. The mathematical knowledge includes the common knowledge of the content of MKT; the didactic-mathematical knowledge comprises the specialized knowledge of MKT and also cognitive, affective, interactional, mediational and ecological aspects and, finally, the third is the meta didactic-mathematical, which includes knowledge about the norms that condition a teaching and learning process, as well as on the didactic suitability assessment criteria (Pino-Fan & Godino, 2015). Likewise, the DMKC determines that the mathematics teacher's main competence is the general competence of didactic analysis and intervention. This competence is made up of five different competences: global meaning analysis competence, onto-semiotic analysis competence of mathematical practices, didactic configurations analysis and management competence, normative analysis competence and didactic suitability analysis and assessment competence (Godino et al., 2017).

Specifically, in this work, we focus the attention on one of them, on the onto-semiotic analysis of mathematical practices competence. This competence consists in carrying out an onto-semiotic analysis, that is, in identifying the objects (situation-problem, concepts, linguistic elements, procedures, properties and arguments) and processes involved in a mathematical practice (Godino et al., 2017). To achieve the development of this competence, current research (Burgos et al., 2018; Godino et al., 2018; among others) is committed to specific training actions in which it is necessary, first, to produce an evolution of the personal meanings; then, introduce the tools of the OSA and put them into practice and, finally, institutionalize the acquired knowledge through discussions.

Method

Methodological approach

This research is framed within the exploratory qualitative approach and the design research paradigm (Kelly et al., 2008), which pursues the development of knowledge about an educational reality that is desired to be improved through the design of an innovative intervention in it, while researching on the said design (Cobb et al., 2003).

Context and participants

The training action was carried out with the ten students of the Master's Degree in Advanced Training of Early Childhood and Primary Education Teachers of a Spanish university. All of the participants are recently graduated teachers with no work experience. In particular, two of them have dedicated 6 ECTS of their initial training to didactic-statistical content for the teaching and learning of statistics in primary education and, the other eight, 0.5 ECTS to statistics in early childhood education. The teachers worked in pairs throughout the training action.

Video material and implementation

In the formative experience of this research, video is the main material used. Its use of scaffolding coincides with that indicated by various authors (Coles, 2014; Gaudin & Chaliès, 2015) in teacher training, since it is used to develop analysis and reflection skills, such as competence in onto-semiotic analysis. Specifically, two real teaching and learning processes videotaped are used in this action.

The main video shows the mathematical practices of an early childhood education class (5-6 year-old) when carrying out a statistical study. Children want to discover "What is the game that the class likes the most?". First, they collect the data. Each child has a paper with five pictures that represent a class' game (building game, cars, doctors, hairdressers and jigsaw puzzles) and has to cut the one he likes the most. Then, children all together build a single pictogram with the pictures they have cut. Finally, they compare frequencies and identify the mode. In the following sessions, the transnumeration is worked, since they build a graphic experientially and another, with Lego pieces.

The other video is about geometry in 5th grade (10-11 year-old) and it is used as a preliminary practice with the OSA.

Implementation

The action designed and implemented consists, principally, of two content blocks (Figure 1). In the first block, of provocation and exploration of personal meanings, the participants assessed, according to their criteria, the statistical teaching-learning process of the main video. Then, they shared their impressions and ideas. This block is completed with an oral game about the personal meanings of the training teachers about the mathematical processes defined by NCTM (2000). The second block focuses on onto-semiotic competence. First, the lecturer introduced some theoretical notions of OSA, such as the kinds of mathematical objects and onto-semiotic analysis. Then, in Task 1, the teachers searched for mosaics and then identified the emergent objects in them. In Task 2, they watched the geometry video and recognized the mathematical processes underlying in the video. Afterwards, they shared their work. Finally, in task 3, they had to identify contextualized examples of each type of mathematical object and process that emerged in the statistical teaching-learning process videotaped.

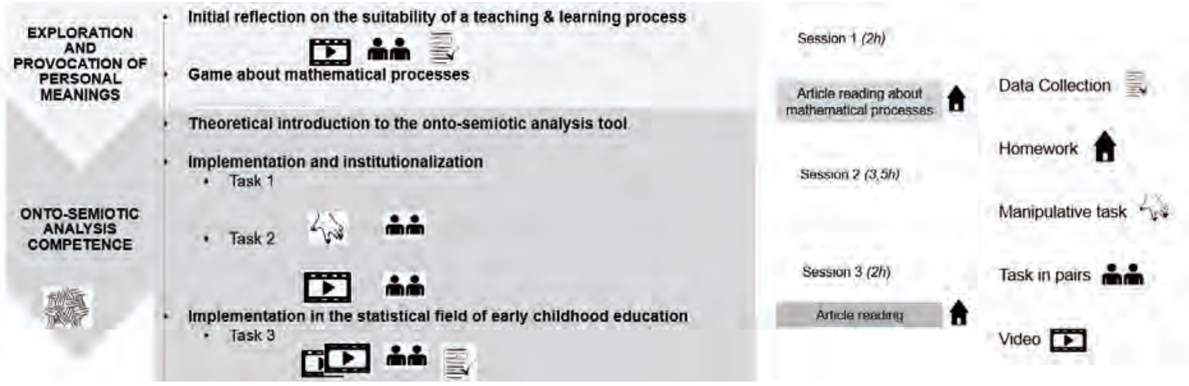

Figure 1: Characteristics of designed and implemented formative intervention

Data collection and analysis

In this paper, it is analyzed the information collected from the teacher's pairs written responses corresponding to task 3 applying the onto-semiotic analysis techniques. Specifically, first, an expert onto-semiotic analysis of the emergent objects in the videotaped was carried out and then, based on the content analysis, the onto-semiotic analysis of each pair was compared with the expert.

Results and discussion

As far as concepts are concerned, certain difficulties have been detected. Some of them have also been observed in other training experiences with primary and secondary school teachers and with other mathematical content. For example, not all the elements that the participants present as a concept are, really, a concept. Likewise, not all the mathematical concepts identified are actually mathematical concepts that emerge in the teaching and learning process, since some of them do not emerge in the videotaped process or, simply, as Beltrán-Pellicer et al. (2020) suggest, do not respond to an operational need, such as "statistics" or "reasoning". Another aspect observed is that some couples confuse the curricular contents with the concepts. For example, one of the pairs presents as a concept "the identification of the numerical symbols". Similarly, another couple does the same with "writing the number symbols." As highlighted by Beltrán-Pellicer et al. (2020), the teachers in training include in mathematical concepts, concepts that, from the didactic-mathematical perspective, are rather linguistic elements, such as "tie" to refer that two categories of the variable have the same absolute frequency or "drawing", to symbolize the iconic figure of a category. Another remarkable characteristic is that teachers have difficulty seeing concepts that emerge from a routine situation in the early ages classroom. In the videotaped process, and specifically, for data collection, a child has to distribute scissors to each partner, so that they make a correspondence. Only two couples have been able to detect this correspondence.

In the process, mainly numerical and statistical concepts emerge. It should be noted that the teachers in training recognize the first quite well. However, the results are not good in terms of statistical concepts. Table 1 shows the statistical concepts that emerge and the number of pairs that identifies each of them. As can be seen, the concepts that they mostly recognize are mode and pictogram, although it is surprising that, since mode is the main concept, it is not explicitly recognized by all the groups. Likewise, concepts so elementary as variable or absolute frequency have not been identified by the teachers in training. This result is in line with that obtained by Gea (2014), in which the percentage of identification of the measures of central tendency by prospective secondary school teachers is higher than that of the statistical variable.

Table 1: Number of pairs that identifies each statistical concept

Statistical concepts	Number of pairs
Absolute frequency	0
Categories	0
Graph	2
Mode	3
Pictogram	3
Population	0
Qualitative statistical variable	0
Sample	0

With regard to linguistic elements, the mathematical videotaped practice brings into play four types of language: verbal expressions, numerical, graphic and iconic language. Now, while four pairs identify verbal and graphic language, only one of these four also recognizes numerical and iconic language. One of the pairs only identifies graphic language.

It should be noted that in the videotaped, the children represent the data in three ways. However, only one of the couples is able to refer to the experiential graph and the Legos graph. This result is worrying given the importance of experiential and manipulative mathematics in the early ages.

Regarding the procedures, most teachers recognize the data collection and the graphs construction, but, on the contrary, do not identify the data reading. An important fact observed in the analysis of this kind of object is that, in some cases, the teachers' personal meaning of the mathematical procedure coincides with that of the mathematical process. In fact, Beltrán-Pellicer et al. (2020) point to certain coincidences between both constructs that make it difficult to differentiate them. This could explain why teachers do not view level 2 of data reading as a procedure, but as a reasoning process. This level requires interpretation of the data from the comparison or ordering, typical entities of the reasoning. Finally, with regard to the statements and arguments, the level of competence shown by the teachers in training has been very low.

In the videotape, eleven emerged properties or propositions are considered informal and, most of them, are linked to the data reading. Three couples identified only the following: "The game with the most votes was hairdressers." The remaining, none of them. As for the only formal property that is put into play, "the mode represents a group, so it provides information on the entire set and not on specific elements", it should be noted that no one recognized this property. We believe that there are two reasons for the low number of correctly identified properties and propositions. The first lies in a lack of understanding of what is a mathematical proposition, property or statement (Giacomone et al., 2018). The second is that most of the properties of the videotaped process are justified from informal deductive arguments based on a graph; consequently, the properties and propositions do not emerge accompanied by their arguments.

The result is not better in the case of arguments. Four of the five couples have not been able to correctly identify any argument. In fact, it has been observed that training teachers confuse arguments and properties and propositions, that is, they can present an argument as a property and a property as an argument. Or, they, simply, do not separate the proposition to be justified from the argument itself, that is, they present a justifying statement (Beltrán-Pellicer et al., 2020) with a proposition-conjunction-argument structure.

Conclusions

The competence development of the teachers has not been uniform for all the objects. The level of recognition of linguistic elements and procedures is sufficient, but that of properties, propositions and arguments is insufficient. As far as concepts are concerned, the level is beginner, but not sufficient, since they recognize numerical concepts well, but not statistical ones.

In our opinion, in addition to the aspects indicated in the previous section that hinder the development of competences, we point out the early childhood context. Specifically, we refer to the fact that common verbal expressions abound in early age mathematical practices and that the mathematical name of the concepts in them is not institutionalized. This requires a higher cognitive effort on the part of the teacher to identify mathematical objects, because there is a "camouflage" effect. Therefore, it is necessary to educate the professional noticing of kindergarten teachers in this regard.

We emphasize that the level of recognition of the procedures shows that the mathematics with which the participants have been trained has been basically algorithmic, rather than constructive. Moreover, they identify most of the procedures involved, but do not distinguish the reading and interpretation of the data, to which it seems that they are not so used.

Finally, it is necessary to add that the didactic suitability of the formative action is quite high, but for possible replications it is suggested to leave more time for the discussions and institutionalizations of the mathematical objects, even for the assimilation of their meanings. However, it is difficult to increase the degree of cognitive suitability of the action if the teachers have not previously received an initial training that favors, at least, their common content knowledge.

It is evident, now more than ever in the reality that we live as a consequence of the pandemic, that statistics are necessary for society and science to advance. Therefore, it is a good time to push for a change in university curricula.

Subjective probability in use: reasoning about a chess game

Luis J. Rodríguez-Muñiz, Lorena Rodríguez-Suárez and Laura Muñiz-Rodríguez

Universidad de Oviedo, Spain; luisj@uniovi.es

Subjective probability is often left aside in elementary school curricula, despite it is often used in daily-life. In this paper, we expose a didactic experiment with 5th grade students (10-11 years old) in which they were asked to handle subjective probability. Findings show how students were able to make probability judgements even without a numerical support, they changed their initial judgements when more quality information was provided, and they refrained from state a founded judgement when they considered available information was not enough. Results endorse the importance of introducing this type of probabilistic reasoning in elementary school.

Keywords: Elementary school, Probabilistic reasoning, Subjective probability, Verbal communication.

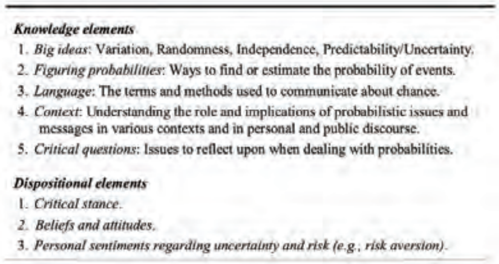
Introduction

The notion of chance is polysemic and, often, controversially interpreted in common contexts, including scientific ones. This affects how probability is understood in our society, and how it is perceived in school contexts. Despite the axiomatic approach solved the formal mathematics obstacles, “there are still controversies over the interpretation of basic concepts and about their impact on the practice of statistics” (Batanero et al., 2005, pp. 15–16). Classical and frequentist (or experimental) approaches are the most common in elementary school when teaching probability, being the subjective (or Bayesian) approach often barely mentioned, or totally ignored (Carranza & Kuzniak, 2008; Gómez-Torres et al., 2014). However, subjective probability is largely present in daily-life, where events cannot be simplified into counting possible outcomes of the random experiment, or repeating it under the same conditions, as when predicting sport results or assessing the risk of being infected by a virus (Muñiz-Rodríguez et al., 2020).

At early school ages, the subjective meaning of probability is strongly related to the use of verbal reasoning and, particularly, chance language (Kazak & Leavy, 2018). This conceptualization is often described as the intuitive meaning of probability (Batanero, 2005), in which the use of linguistic quantifiers and terms about chance helps children making qualitative probabilistic judgements. In this paper, the results of a didactic experiment developed with 5th grade students (10-11 years old) in a Spanish school, consisting of probabilistic reasoning about a chess game, are described.

Theoretical framework

The intimate relationship between probabilistic reasoning and the notion of chance produces a greater space for intuition (and for counterintuition) when learning and dealing with probability. Handling this intuition and making it coherent with the mathematical development of probability is a challenge in probabilistic education at the elementary school, as Fischbein (1975) already pointed out. Even when subjective probability has not been a trending topic on probabilistic education research literature, the didactic experiment described here can be framed within the general paradigm of probability literacy (Gal, 2005), due to its link to the basic probabilistic instruction at elementary school. Gal's framework includes five knowledge and three dispositional elements (see Figure 1). This research study focuses on figuring probabilities (estimates), language (of chance), and context (a chess game), and mainly dealing with beliefs and attitudes.



Knowledge elements

1. *Big ideas*: Variation, Randomness, Independence, Predictability/Uncertainty.
2. *Figuring probabilities*: Ways to find or estimate the probability of events.
3. *Language*: The terms and methods used to communicate about chance.
4. *Context*: Understanding the role and implications of probabilistic issues and messages in various contexts and in personal and public discourse.
5. *Critical questions*: Issues to reflect upon when dealing with probabilities.

Dispositional elements

1. *Critical stance.*
2. *Beliefs and attitudes.*
3. *Personal sentiments regarding uncertainty and risk (e.g., risk aversion).*

Figure 1: Elements of probability literacy (Gal, 2005, p. 51)

De Finetti's claim (1974) "probability does not exist" illustrates the subjective meaning of probability, neglecting the objective existence of "one" probability, and assuming it as the degree of belief about the occurrence of a given event. Such a personal judgement about the outcome of a random experiment is necessarily based on the information about the experiment or similar experiments that the involved person has. Thus, estimating the probability is dependent not only on the quantity of information but also on its quality. Different people have different type of information, and process it into very different ways, depending on his/her knowledge of the problem/context, experiences, and beliefs. And when new information is provided, people revise their initial probability assignment (the formalization of this revision process should be made in terms of Bayes' formula, which led to alternatively use Bayesian for this subjective approach). The subjective theoretical approach differs from the classical one, based on Laplace's rule, which is only applicable under equiprobability of the elementary events in a finite sample space, and assumes the existence of a real/certain value of probability for a given event. Nevertheless, subjective does not mean ungrounded: the probability elicitation depends on the person, but in obvious situations, as simple random experiments with games (coins, cards, dice, etc.), the subjective probability assignment of a minimally informed person should converge with the classical one, unless evidence from the running experiment is opposed (for instance, an unfair dice). Hence, Pratt and Kazak (2018, p. 206) discussed "the dual notion of probability" as a degree of belief and as the stable frequency in a long run.

Going into the elementary school framework, probability is introduced in different countries by means of the language of probability (Vásquez Ortiz & Alsina, 2019). Some experiences can be found in the research literature to promote a proper probabilistic reasoning by linguistically labelling, interpreting, and ranking the probability of certain events (e.g., Alsina et al., 2020; Kazak & Leavy, 2018). But, after this linguistic approach, most national curricular guidelines go directly to the formal definition of probability based either on Laplace's rule or on the experimental probability (Batanero et al, 2005). These guidelines rarely move towards the subjective definition, despite many daily-life situations are not suitable to apply Laplace's rule, neither experimentation is possible (either similar conditions are not reached, or repetition is impossible).

This paper addresses Pratt and Kazak's claim (2018, p. 222): "there is still a scarcity of research […] in the area of subjective probability at the school level". By means of a didactic experiment based on a chess game, we aim at analyzing 5th grade students' probabilistic reasoning in a context of uncertainty without conditions for applying Laplace's rule nor for experimenting by repetition. Previous research (Helmerich, 2015; Huber & Huber, 1987; Kazak, 2015; Pratt & Kazak, 2018; Vásquez Ortiz & Alsina, 2019) showed that students can deal with the language of probability and produce qualitative probability estimates, and that, under certain conditions, they mobilize their personal knowledge and beliefs to confront with experimental information. However, these studies considered situations which could be analyzed in combinatorial terms, that is, counting cases, even when they were not undertaken by using that strategy. The task that we present here is not suitable for determining probabilities by counting cases and, therefore, the cognitive demand is greater. Thus, we raise the following research question: How do 5th-graders integrate contextual information to deal with probability estimates not based on counting cases?

Methodology

Context

The didactic experiment was carried out in April 2021, at an elementary school in Oviedo (Spain). Thirty-one students (20 boys and 11 girls) in 5th grade (10-11 years old) participated, 4 of which played chess (3 boys and 1 girl). Curricular guidelines in 5th include to identify random situations and to make estimates on some game results (coins, dice, cards). In previous years, students worked with probability language (impossible, likely, certain), whereas the definition of probability based on Laplace's rule is to be studied in 6th grade. The experiment was conducted by one of the researchers.

Experiment

The didactic experiment consisted of a chess-based situation about a game between two elite players, organized into three steps:

1st step: In Grenke's chess tournament Anish Giri (white) will face the current world champion, Magnus Carlsen, in black. Of all the games that Anish Giri has played (908) almost half (456) were drawn. By contrast, Magnus Carlsen lost just three games in the last two and a half years. What do you think the result will be? Will Anish Giri win the world champion with white? Justify your answer. Would Giri be less likely to win if he played black?

2nd step: Due to the COVID-19 pandemic, both players spent several months without playing slow games. The three games that Carlsen lost in the last two and a half years were after pandemic lockdown. Meanwhile, Anish Giri did not lose any games after the lockdown. Do you think confinement was more beneficial for one than the other? After knowing these data, would you change the answer in the previous section?

3rd step: If that game had happened before the pandemic, when Carlsen had 120 games without losing, what do you think would be Giri's probability of winning?

A sheet with the wording of the situation was given to each student. First, each student individually wrote down his/her answer to each question on the sheet. Then, students orally shared their answers in a group discussion (due to COVID-19 restrictions personal contact was limited).

Obviously, in this situation the probability cannot be determined by using Laplace's rule, as there are too many variables involved (pieces color, opening preparation, level of concentration, etc.).

Information from previous matches can help to make an estimate but, clearly, not the repetition of the same random experiment under similar conditions. Moreover, the data provided for both players refer to different periods. Students must mobilize their knowledge about the context and handle their beliefs about games. There was not a right or wrong answer, but a better or worse reasoning based on the way students integrated and aggregated information and beliefs, and how they handled possible biases in probabilistic reasoning. Depending on the amount and quality of information, students could critically analyze the situation and produce an argued answer. During the didactic experiment, some explanations about chess had to be provided regarding the supposed advantage that the player with white pieces has. Also, a brief profile of Giri and Carlsen was required by students, explaining why they are considered world top players. Even being a complex argumentation, this task can be framed within the aforementioned Gal's three knowledge elements in probabilistic literacy, combined with beliefs and attitudes as a dispositional element.

Data collection and analysis

Students' written answers were considered as the primary unit of analysis. One of the researchers acted as teacher during the didactic experiment. She gave some instructions at the beginning about how to tackle the task. During the group discussion, she asked few questions to prompt students to justify their answers and took observation notes. Data was analyzed using a mixed technique, with a frequentist analysis and also a qualitative content analysis (Krippendorff, 2018) to find evidence of the use of probability language, the estimation of probabilities from a subjective point of view, and changes in the initial estimates when new information is provided. Considering that students' answers were rather brief and not too elaborated, data was first examined using a grounded theory approach. Each of the emerging categories was later analyzed in relation to the aforementioned Gal's knowledge and dispositional elements. For instance, students' answers to the 1st step questions were classified into blank or unclear justification supporting that Giri wins, justifications based on Giri's trajectory, justifications based on Carlsen's trajectory, and justifications supporting a draw between both players. Later, each category was reviewed to understand how students build their justifications using probability language, estimates, and information from the context (knowledge elements) together with their beliefs and attitudes (dispositional element).

Results

Table 1 shows the answers to 1st step questions. Justifications about Giri's win with white were based on players' trajectories: "Anish Giri would win because he has not lost a game, while Carlsen lost three", "Carlsen is the champion", or "Carlsen only lost 3 games in one year and a half". There were unclear justifications ("Giri is going to be lucky"). Those who supported the draw argued that both players are excellent. When asked if Giri would be less likely to win if he played black, 6 students agreed, and the rest (25) said there would be no difference. One of the arguments supporting the less likelihood was expressed with probability language ("The piece color matters because there are higher probabilities of winning when playing white"), while the rest were mainly based on students' beliefs ("Black pieces give worse luck"). Most students supporting there was no less probability argued that the color did not matter. Between the first and the second step, the teacher conducted a discussion with the students about their answers. Many of the students who did not know too much about chess waited to hear the argumentation provided by those who played chess, looking for endorsement or extra information. Key points of such discussion are stressed in the next section.

Table 1: Answers to "Will Giri win with white? Would Giri be less likely to win with black?"

	With white				With black	
Type of answers and justifications	Giri wins, blank or unclear	Giri wins, based on his trajectory	Carlsen wins, based on his trajectory	Draw	Less likely	No difference
Frequency	14	5	9	3	6	25

The 2nd step of the experiment was about reasoning if the confinement was more beneficial for Carlsen or Giri and checking how students integrated the related information. Table 2 shows the answers. Most who agreed that the confinement was more beneficial for Giri ("He did not lose any game after it") kept their initial answer about Carlsen's favoritism, based on his role as champion ("I trust in Carlsen, he is the champion"), but there were three answers providing an intuitive probabilistic reasoning (for instance, "Maybe Carlsen just had a bad run"). There was one student supporting the confinement was not beneficial for any of the players, who noted that the provided information was about the number of losses, but nothing was said about the number of draws (where Giri had much more than Carlsen), so it justified keeping Carlsen as the favorite player to win. We did not find solid argumentations among those changing their initial view.

Table 2: Answers to "Do you think confinement was more beneficial for one than the other? After knowing these data, would you change the answer in the previous section?"

Type of answers	For Giri, not changing	For Giri, changing	To any of them, not changing
Frequency	18	4	9

In the 3rd step of the experiment, students were asked about Giri's probability of winning if the game had been held before the pandemic. Table 3 shows the types of arguments used by students. Some recognized the difficulty of estimating a probability ("I do not know how to measure probabilities, but I think it would be around 45%"), others simply provided a value ("From 1 to 10, an 8"). Some other reasonings were based on Carlsen's apparent superiority, eliciting a low estimate for the probability ("Very low, 2 out of 10, 20%, because Carlsen was undefeated", "About 33% or very low, because Carlsen was undefeated during 120 games"). Two answers explicitly based the argument on the previous results: "Giri would draw, because he usually draws", and "Giri is going to win because he was never the champion and Carlsen started losing games".

Table 3: Answers to "If that game had happened before the pandemic, […] what do you think would be Giri's probability of winning?"

Type of arguments	Blank	No reason	Verbal	Numerical	Verbal and numerical
Frequency	3	2	11	14	1

Discussion and conclusions

Results revealed different examples of probabilistic heuristics, as well as some biases in students' reasoning. In the first step, students used their previous knowledge about the context (a knowledge element in Gal, 2005) to guess the possible result of the game, but their beliefs (a dispositional element in Gal, 2005) were also involved. Since previous knowledge differed from one student to another, we found answers based on a proper integration of previous information and knowledge about chess ("Anish Giri would win because he did not lose a game, while Carlsen lost three") and also other answers built on maximum uncertainty ("There will be a draw because both players are excellent"). There were also some mistakes regarding information processing or reading comprehension, getting confused between Carlsen having lost three games and having won all but three (that is, not considering draw as a possible result). Thus, this illustrates how students differently integrate and process the contextual information in terms of deciding what is the most probable event.

In the second step, extra information was added, so the students had to decide whether they keep or change their initial decision, again within a meaningful context (Gal, 2005). It was striking how most of the students integrated the information about the confinement and the players but decided to keep their initial decision, because most answers were supported by the personal belief on Carlsen's quality as player, and also a poorly explained favoritism to him (Batanero, 2005; Vásquez Ortiz & Alsina, 2019). There was also an interesting answer trying to find a rationale between Carlsen's category as world champion and the three games he lost after confinement ("Maybe Carlsen just had a bad run"). Also remarkable was how students used personal experience regarding chess (for instance, the one arguing that whites have greater chances to win was one of the students playing chess and he used his records to support this idea). In line with Kazak and Leavy (2018), we confirmed how the meaning of subjectivity is used when dealing with previous and added information and personal experiences and beliefs to estimate a probability, stressing in this experience the importance of beliefs as an attitudinal element (Gal, 2005).

In the third step, the difficulties to estimate a probability without a counting or experimental situation were revealed. Nevertheless, students were able to find a rationale supporting their linguistic or numerical assignments (knowledge elements in Gal, 2005). Rather curious was how students expressed probability in many different scales (percentage, 1-10 scale, linguistic quantifiers, etc.), and how they were able to compare even without a numerical assignment. Besides numerical language, half of the students used verbal language to express such probability using different terms ("impossible", "very low", "none"). In some cases, a wrong understanding of the probabilistic language was reflected when considering an improbable or unlikely event as impossible. Students also used different approaches to integrate the information from previous games: some used it to find a trend in terms of experimental probability ("He usually draws"), others reasoned by using a version of gambler's fallacy ("Giri is going to win because he was never the champion"). The latter shows the outcome approach described by Konold (1989): when asked about a probability there are students answering about the outcome of the next trial.

Regarding research question, the development of the discussion between the first and second steps became particularly crucial. We witnessed how students who were not familiar with the context (chess game) started from a total uncertainty (even ignorance) about the answer, but when they heard their colleagues who regularly play chess reasoning about the situation, they started either totally following them or modifying their opinions in terms of what was expressed by experts. That is, they acknowledged the quality of the information provided by others and modified their initial beliefs about the probability in an informal Bayesian reasoning. As stated by Kazak and Leavy (2018), such reformulations seem rather intuitive for children of this age.

The implications on this didactic experiment are rather promising for future research and practice. Despite the difficulties encountered on probabilistic reasoning, students are able to quite naturally handle probability in informal and even numerical terms. Evidence pointed to the use of Bayesian procedures to integrate added information about the experiment. Choosing a chess-based situation instead of a more popular sport (as football or basket) made students felt too much apart from the context and impeded arguing about their reasonings. Thus, to promote students' probability literacy, particularly probabilistic reasoning, it seems necessary to widely implement similar contextualized situations that are relevant to students and help them to understand the different meanings of probability. Similar experiences, with an increasing complexity in the situations and the cognitive demand, could be also designed for secondary education, where the use of the subjective meaning of probability is also usually omitted (Blanco-Fernández et al., 2016; Rodríguez-Muñiz et al., 2019). More precisely, the presence of didactic experiments about subjective probability should be increased by teachers making use of daily-life situations instead of archetypical examples, such as urns, coins, dice, cards, or lottery.

Causal inference for beginners: designing a massive open online course

Julia Rohrer[1] and Karsten Lübke[2]

[1]Leipzig University, Institute of Psychology, Leipzig, Germany; julia.rohrer@uni-leipzig.de

[2]FOM University of Applied Sciences, Dortmund, Germany; karsten.luebke@fom.de

Keywords: Causal inference, data literacy, curriculum development, instructional materials.

Data literacy and causal inference

It takes much more than the ability to insert numbers into formulas to be data literate. According to Schüller (2020), data literacy includes behaviors and attitudes that allow us to create value or make decisions with the help of data. In the age of "big data", the basis for decision making is often observational in nature and contains many variables, which increases the necessity to "think clearly about correlation and causation" (Rohrer, 2018). As causal conclusions are ubiquitous, we should provide a framework to discuss the necessary assumptions (Rohrer et al., 2021). Several authors advocate for the inclusion of causal inference in the curriculum, at least in post-secondary education (Cummiskey et al.; 2020, Lübke et al., 2020). The presented course therefor aims at introducing basic concepts of causal inference to improve data literacy and foster understanding of sources of bias. Ignoring these has led to many incorrect conclusions in, e.g., Covid-19 research (Herbert et al., 2020).

Massive open online course

The course "Introduction to causal inference" is designed as a self-paced online course and will be hosted by https://ki-campus.org/, a project funded by the German Federal Ministry of Education and Research (BMBF) focused on developing the prototype for a digital learning platform specifically geared towards AI.

Interactive modules and videos provide learning opportunities on the potential outcomes framework and causal effects. Correlations based on confounding as well as collider bias are presented and explained with the help of basic elements of causal diagrams (chain, fork, inverted-fork). With these diagrams direct, total and indirect effects are introduced as well as the consequences of (not) adjusting for covariables when estimating causal effects. The mathematical foundations provided include conditional probabilities, conditional and unconditional independence as well as Bayes theorem. Within this framework, design principles like random sampling and allocation are explained and motivated. Probability and statistics are used to explain everyday phenomena as well as "paradoxes" like the ones attributed to Simpson and Berkson. The course is published with the CC BY-SA 4.0 license and can be integrated in existing curricula, as questions for summative assessment are provided.

Technology

Computer-based tools are used and integrated to support learning. The R package learnr is used to provide course participants a web-based opportunity to explore data with R or to run simulations to investigate how different assumptions about the data generating process affect conclusions. Furthermore, assignments and quizzes with automatic feedback are provided. Embedded videos give additional motivation and illustration by e.g. interviews of researchers and practitioners in the field.

Thanks to R/exams, it is possible to generate randomized tests which can be integrated in different learning management systems. The flexible modules of this course allow for assessment of up to 1 ECTS.

Evaluation plan

A major concern with massive open online courses is that most participants never finish. Who does and who does not finish furthermore depends on individual characteristics (such as motivation, background knowledge), raising the possibility that a large number of people who could, in principle, profit from a course are left behind. To improve our understanding of how well different materials work for participants with different backgrounds, future participants of the course are encouraged to take part in a longitudinal evaluation alongside the course. This evaluation contains quantitative but also qualitative assessments of the provided learning materials as well as obstacles encountered by participants. It will be realized with the help of the survey framework formr.

Data Science and Machine Learning in mathematics education: High-school students working on the Netflix Prize

Sarah Schönbrodt[1] and Martin Frank[2]

[1]Karlsruhe Institute of Technology, Germany; sarah.schoenbrodt@kit.edu

[2]Karlsruhe Institute of Technology, Germany; martin.frank@kit.edu

One goal of contemporary mathematical modeling classes in schools should be to include up-to-date problems or interesting, new technologies from the everyday life of students - especially if these allow the didactical reduction to elementary (school-)mathematical knowledge and thus have the potential to enrich mathematics education. Data Science and Machine Learning is applied in numerous areas of science and technology and used in many applications in our everyday life. Using movie recommender systems and the so-called Netflix Prize as an example, this paper discusses how mathematics education can be enriched by modeling real-world, student-centered problems from the field of Machine Learning in school. For this purpose, we describe tested digital learning material from guided modeling projects and share our experience with giving the problem of developing a recommender system as a completely open problem to upper secondary students.

Keywords: Data Science, Machine Learning, mathematical modeling, recommender system, digital learning material.

Motivation

Many technologies and applications that students use in their everyday life are based on methods from the fields of Data Science (DS) and Machine Learning (ML). An important tool for answering questions from these areas is (mathematical) modeling. Therefore, DS problems offer a great opportunity to design mathematical modeling activities on student-oriented, up-to-date problems. In this way, not only modeling competencies but also the handling of data can and should be trained. Especially in today's world, it is essential to deal with data in an understanding, responsible and critical way. Some profitable approaches to implement problems from the field of DS and ML in the classroom are advanced by the Paderborn project ProDaBi (Opel et al., 2019). In addition, Sube (2019) and Schönbrodt et al. (2021) already worked out how mathematical modeling lessons on DS questions can be designed using real-world problems.

We developed digital learning material in which upper secondary students can acquire an understanding of essential steps in solving data-heavy problems based on methods from DS and ML by actively working on an authentic, and relevant problem (Schönbrodt & Frank, 2021). The learning material presented in the following can be implemented within a mathematical modeling day or be distributed over several school lessons.

The problem – Authentic and relevant

Netflix, Amazon, and many other e-commerce companies that the students encounter every day mainly rely on one thing for customer loyalty: personalized recommendations for new products, movies, etc. For this purpose, recommender systems are developed, which should predict what the respective user might like. The developed learning material is based on the Netflix Prize which

Netflix launched in 2006 to further improve their own recommendation system: The team, that could predict at least 10% more accurately than Netflix's system, which movies a user would like had a chance to win the grand prize of one million USD (Feuerverger et al., 2012, p. 203).

Mathematical modeling days – Guided digital learning

The key questions of the developed learning material are: "How can we model user preferences by exploiting given user ratings?" and "How can we predict unknown user ratings in the best possible way to then use the predicted ratings to suggest relevant new movies to users?" (Schönbrodt et al., 2021).

In the learning material the students work with the original dataset of the Netflix Prize. On digital worksheets they explore the dataset and collect their own ideas for the development of a recommender system. Afterwards, they develop a mathematical model and apply it to the Netflix dataset. The implementation of the data exploration and the modeling process is discussed in more detail below. The digital tool used to develop the digital worksheets is Jupyter Notebook[1]. Jupyter Notebooks are widely used in numerous branches of industry, research, and economy. Thus, not only the learning content but also the digital tool provides an authentic insight into current problem-solving strategies and technical implementations in applied mathematics or more generally in STEM fields. Put in simple terms, Jupyter Notebooks are digital documents which can be used to write text, execute code (to compute mathematical terms), and can be edited interactively by the students. Also, Biehler & Fleischer (2021) and Opel et al. (2019) highlight the possibilities of Jupyter Notebooks for designing learning material on ML methods. In these papers the focus is stronger on statistics and computer science teaching whereas we focus more on the process of mathematical modeling and related competencies.

The developed learning material exemplifies how data-heavy problems from the students' everyday life can be prepared and carried out in the context of modeling projects, both in distance and face-to-face learning. The material is available on a cloud-platform of the Karlsruhe Institute of Technology for direct use in class and can both be accessed and edited in a web browser (see www.cammp.online/english/214.php). The material can be used in heterogeneous learning groups by means of digital differentiation material (scaffolded tips, optional tasks for more advanced students) and individual, automated feedback on the students' solutions. The dataset and the main modeling steps of the learning material are briefly described below.

For the processing of the learning material, it is assumed that the students are familiar with mean values and standard deviations. In addition, an understanding of functional relationships is also central. Knowledge of vectors and the scalar product is preferable. Matrices, however, are not a prerequisite for the comprehensible processing of the learning material. They are rather introduced in a problem-oriented manner as explained below. Furthermore, no programming knowledge is required on the part of the students. Instead, a fill in the gap approach is implemented. The students simply need to replace a placeholder within the code (specifically *NaN*, which stands for Not a Number) with

[1] For further information see https://jupyter.org, last accessed: 05 August 2021

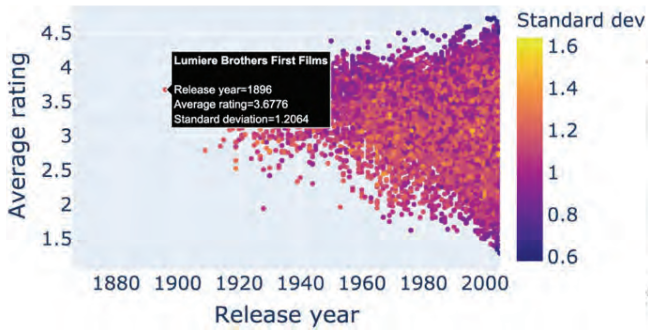
the relevant solution to the task (a number, formula, or function). They receive task-specific feedback on their input and, if necessary, a tip on how to correct their solution.

Unit 1: Understanding and analyzing the data

The starting point of the learning material is the Netflix dataset. This consists of 17,700 movies, 480,189 (anonymized) users, and 100,480,507 ratings from one (worst) to five (best) that users gave to the movies (Feuerverger et al., 2012, p. 204). The title and release year of the movies are known.

Figure 1: Rating matrix / table containing users' ratings for the movies

The students examine the dataset using various forms of representation such as the rating matrix / table (see Figure 1) or interactive scatter diagrams and tables (see Figure 2). In doing so, they answer questions such as "For which movie do the ratings differ the least from the mean rating?" or "Which conclusions can you make regarding the distribution of the data over time?". The students can modify the interactive plots shown on the worksheets to answer the questions. For example, they can zoom into the scatterplot or sort the table in Figure 2 by any column. They decide independently which representation of the data is suitable for answering which questions.



Titles	Number of ratings	Average rating	Standard deviation	Release year
Miss Congeniality	232944	3.3613	1.1117	2000
Independence Day	216596	3.7242	1.0391	1996
The Patriot	200832	3.7839	1.097	2000
The Day After Tomorrow	196397	3.4422	1.0993	2004
Pirates of the Caribbean: The Curse of the Bla...	193941	4.1539	0.9071	2003

Figure 2: Visualizations of the Netflix dataset on the digital worksheets

When introducing the tabular representation of the rating data (see Figure 1), the concept of a matrix is avoided at first, as this should not be a prerequisite for the processing of the learning material.

Unit 2: Developing a mathematical model

After exploring the data, a brainstorming takes place. Whilst discussing with their fellow students the students collect their own ideas on how to use the known ratings in the rating table to predict the unknown ones. During the lessons conducted with secondary students so far, the students mentioned diverse approaches. Among them:

- Find similar users and then find the movies the similar users liked.

- Identify users' areas of interest, such as a specific genre.
- Determine the genre of the movies a user liked. Then suggest movies from that genre.

Next, using small rating tables, the students start with the development of a selected mathematical model: the decomposition of the rating table into a user-feature table (short user table) and a movie-feature table (short movie table, see Figure 3). The core of the described model is a matrix factorization. This was also the basis of the model used by the winning team of the Netflix Prize (Koren et al., 2009, p. 32). Thus, not only the problem but also the mathematical methods used are authentic (Vos, 2011). The user table indicates how much a user likes certain properties, such as the action or comedy genres. The movie table specifies the extent to which a film contains these features (see Figure 3). The students independently develop a formula to calculate the known ratings from the rows of the user table and the columns of the movie table and transfer this to the calculation of unknown ratings. This is basically achieved by the scalar product of the row vector of the user table and the column vector of the movie table.

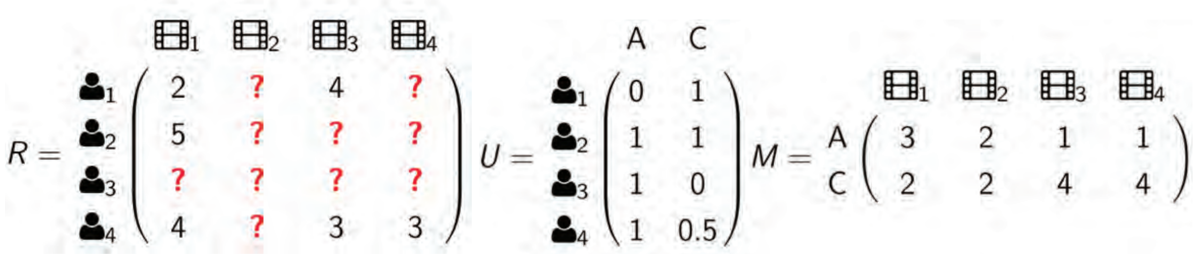


Figure 3: Exemplary rating table R and corresponding user table U and movie table M. The user and movie tables reflect the interests of the users and the characteristics of the movies regarding the features "action" (A) and "comedy" (C)

Motivated by the fact that the Netflix dataset does not provide any information on the features of the movies and thus both the user and the movie table must be calculated appropriately, the students should first determine a suitable decomposition for a 2x2 rating table themselves using pen and paper.

Note: Another modeling approach for which learning material for guided modeling projects was developed and tested is the modeling of similarities - either between users or between movies. Students can be creative in their choice of similarity measures, but also learn about common similarity measures such as (adjusted) cosine similarity and Pearson correlation (Sarwar et al., 2001, p. 287). This approach falls in the class of so-called neighborhood methods.

Unit 3: Error measure and optimization

Calculating a decomposition "by hand" is not feasible for large rating matrices. Therefore, the goal is to leave the calculation to the computer. For this purpose, a step-by-step optimization procedure is applied, which provides a sufficiently good decomposition. The students first define an error measure by which they (and later the computer) can evaluate whether a found decomposition is already sufficiently good. The error measure is defined by looking at a small example of a given rating table R and predicted ratings given in the table P (see Figure 4).

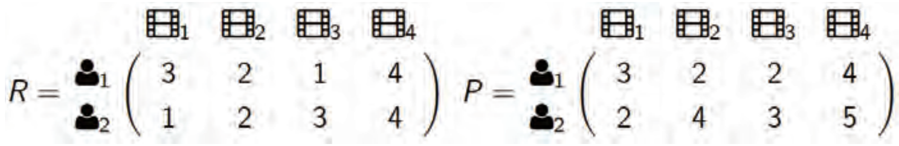

Figure 4: Exemplary rating table R and table P containing the predicted ratings

The self-defined error measures are then compared with the mean absolute error and the mean squared error. Then an alternating optimization algorithm is used to compute a decomposition that leads to the smallest possible error on the known data. The algorithm does not have to be developed by the students themselves. Instead, an optimization package of the used programming language, in our case Julia (Python would also be possible), is applied as a black box.

Unit 4: Application to the Netflix dataset and critical discussion

So far, we have only evaluated how well a found decomposition is suited to represent known ratings, but unknown ratings are to be predicted. We apply an essential strategy of supervised ML: Dividing the known rating data into those used to compute a decomposition (training data) and those used to afterwards validate how well the prediction works on "unknown" data (test data). Students apply this strategy to the Netflix dataset. Finally, they conduct a parameter study (varying the number of features considered) and try to improve the results on the test data.

In a final discussion, limitations of the developed model are discussed, such as: "How do we deal with new users who have not yet submitted ratings?". A critical discussion on the possibilities of manipulating recommender systems, the problems that could arise from de-anonymizing[2] users, and the extent to which so-called filter bubbles could be problematic takes place. The opinions and the students' experiences with recommender systems are particularly included in this discussion.

Experiences with students

The digital learning material was already implemented with more than 90 students from Grade 10 to Grade 13 (this corresponds to an age range of approx. 15 to 19 years) within school lessons (4-5 lessons 90 minutes each) or in the framework of a mathematical modeling day (approx. 5 hours) in Germany. During the implementations, the diverse ideas of the students for the development of a recommender system but also the numerous arguments in the critical reflection of such systems stood out. The very lively discussions also showed that the students were highly interested in solving the problem.

While working with the learning material numerous school mathematical contents are used; among them mean values, standard deviation, vectors, scalar product, and functions. Therefore, the problem setting is not only extremely student-centered but especially real and authentic and thus provides an answer to the question "What's the point of math?".

[2] In 2008, two researchers at the University of Texas showed that de-anonymization of the dataset was partially possible by combining it with another publicly available film dataset (Narayanan & Shmatikov, 2006).

Open modeling within a mathematical modeling week

The Netflix Challenge was given to a group of six upper secondary students within a so-called modeling week. The task of the students was to develop a movie recommender system for a smaller subset of the Netflix dataset from scratch. The students developed the recommender system and thus the mathematical model all by themselves. In contrast to the more guided modeling days described above within the modeling week the students did not receive any learning material with pre-structured subtasks. They only received a description of the datasets and the problem as well as a short introduction in using Jupyter Notebook. The students implemented code themselves and filled the Notebooks with content on their own. They worked on the problem for four full days and were supported by a scientific advisor. The advisor only helped with programming related questions but did not intervene in the modeling process of the students at all. The students not only developed a recommender system but also documented their modeling process in a report and gave a presentation on their results at the end of the modeling week. The core idea of the model the students developed was to measure similarities between users by computing the mean absolute deviation of the ratings of different users. Once they determined the similarity measure and computed the similarities between any pair of users the students predicted the rating of a specific user by taking a weighted sum of the ratings of the most similar users to the selected one. The model developed by the students without any guidance, can be linked to the class of neighborhood methods mentioned above. These are methods that are used by experts in this field (Sarwar, 2001, p. 285).

During the modeling process, the students discovered a relevant trade-off in the field of ML:

“Furthermore, we concluded that the more data we use in the algorithm, the more accurate our result will be. One problem that arose was the long, very rapidly increasing, computation time that the program needs to get results with the large amount of data” (quote from the students’ report).

Summary and Outlook

Through the learning material, secondary students collect experience in dealing with large amounts of data and gain an active insight into essential strategies of mathematical modeling and ML. We already implemented the learning material on the Netflix Challenge with numerous learning groups as part of stronger guided modeling projects (modeling days). Jupyter Notebooks were used as a digital tool to structure and guide the modeling process through smaller subtasks. The feedback from the students on the modeling activities, which were so far only carried out virtually, showed that there is a great interest in this type of problem.

On top, the Netflix Challenge was posed as a problem in the context of an open modeling project (modeling week) once. The results of the students at the end of the modeling week showed that they were indeed able to work independently in a small team and to develop and validate a recommender system on a real-world dataset. To make a more general statement about the extent to which this problem is suitable for open modeling projects, further testing with a more heterogeneous student group would be necessary. Here, the participating students were interested in mathematics and some of them already had programming skills.

The tool Jupyter Notebook provides different design possibilities, variability of the programming language and the neat combination of code and text in one document. Nevertheless, it would also be feasible to provide the data (or a part of the data) in the form of CSV files and to have the neighborhood methods described above developed with the help of a table calculation program.

In addition to the problem presented here, various other applications based on ML methods offer a good opportunity to design modeling activities on real and up-to-date problems. The following are examples of possible ML methods which can be reduced to school-mathematical concepts: The so-called support vector machine (SVM), which is widely used for classification problems. The SVM is based on minimizing distances between points and hyperplanes. Vectors, straight lines, and planes as well as the scalar product can find an authentic application (Schönbrodt et al., 2021). Starting from a classification problem with two- or three-dimensional data, the method could first be developed with students in the visual case using rich visualizations implemented in Jupyter Notebooks. After that the method can be abstracted and applied to higher dimensional problems (e. g., for the classification of images with faces). Another example is represented by so-called n-gram models, which are used to predict words when typing a message on a smartphone. In this case conditional probabilities and absolute and relative frequencies play a central role. Finally, Neural Networks, which are the basis for countless applications in our everyday life (Schlichtig et al., 2019), rely on various school mathematics contents such as the chain rule, vectors, and the scalar product.

It seems important to prepare a selection of these methods to give meaning to (school) mathematical content and to offer students an insight into methods and problem-solving strategies that increasingly influence technologies and our society now and in the future. Therefore, the development of a curriculum that precisely addresses these kinds of methods and meaningfully combines content from mathematics and computer science education is necessary. Important steps in this direction are already accomplished by the projects ProDaBi and the International Data Science in Schools Project (Biehler et al., 2018; IDSSP, 2019). These projects as well as the learning material on the Netflix Prize presented in this paper underline that addressing problems from DS and ML with high-school students is feasible and necessary.

In Brazil, as in many other countries, there is a gap between the type of statistics preservice teachers learn in graduate programmes and what they will teach at compulsory education. This paper presents the design of a study and research path for teacher education (SRP-TE) as a tool to reflect, develop, analyse, and experience teaching proposals in statistics for the final grades of the lower secondary school. The investigation is based on some principles of the Anthropological Theory of the Didactic and its proposals to locate teacher education within the paradigm of questioning the world. The proposed SRP-TE starts from a school activity about the water distribution in Brazil and its extension to incorporate dimensions of the statistical work that tend to be absent from secondary education, such as the search, collection, cleansing, and representation of data.

Keywords: Anthropological Theory of the Didactic, study and research path for teacher education, statistics teaching, secondary school, working with data.

Introduction – Research context and aim

In this paper, we present a PhD investigation developed at the *Universidade Federal de Mato Grosso do Sul* (Brazil) in partnership with the *Universitat de Barcelona* (Spain). The question motivating the research project came from a perceived limitation in the preservice teacher education process followed by the first author during her degree in mathematics education. In the case of statistics, it seems that the double discontinuity described by Klein (Isaev & Eichler, 2017) appeared there with even greater prominence. The subject *Probability and Statistics* did not provide future mathematics teachers with a practical vision of the area. It is then common to hear reports from new mathematics teachers expressing difficulty working with this theme in Brazilian compulsory education[1] when they take up a classroom, as happened with the first author of this article. A significant gap is perceived between the education received and the teaching practice, and the situation is not limited to Brazil. According to Martignon (Batanero et al., 2011):

> […] the gap between disciplinary statistics and school statistics has to be taken seriously into account when preparing future school teachers of statistics who have to be aware that they will be providing future citizens with "statistical literacy". In other words, future citizens need to be endowed with tools for interpreting statistical information in the media, for dealing with relative and absolute risks, and for understanding the effect of base rates on the predictive accuracy of medical tests" (Batanero et al., 2011, p. 34)

[1] In Brazil, the compulsory education is composed by preschool (for children between four and five years old); primary and lower secondary education (for children between six and fourteen years old), that is also known as elementary education; and upper secondary education or high school (for teenagers between fifteen and seventeen years old).

In her master's thesis, Verbisck (2019) focused on the case of probability and the teaching proposals of different textbook collections from grade 1 to grade 12. In all cases, only a small part is devoted to probability and statistics, with a tendency to locate it in the last chapters of each book. More than ten years ago, Lopes and Ferreira (2004, p.12, our translation) stated that "until the implementation of [...] PCNs[2] (MEC, 1998), the teaching of statistics at elementary and high school grades was very restricted and marginal. The topics covered were included in the mathematics discipline, in the most advanced grades and, generally, it was one of the last topics in the textbook [...]". However, this persists today, at least in more than half of the textbooks approved by the Brazilian ministry of education in 2017.

There is an agreement in the international research community on the importance of adopting a broad view of statistics that includes aspects such as searching for and collecting data, cleaning and organising data, visualising data, using specific software, preparing reports, all within a perspective of solving open questions and studying variability. These perspectives are described in terms of: "statistical reasoning" (Garfield & Ben-Zvi, 2008), "statistical literacy" (Watson, 2006), "statistical thinking" (Wild & Pfannkuch, 1999), "informal inferential reasoning" (IIR) (Leavy, 2010) and "informal statistical inference (ISI)" (de Vetten et al., 2019).

How to transpose this perspective in teacher education is still an open problem. Statistical investigations are often taken as a basis for enlarging teachers content knowledge while providing them with new pedagogical resources (Makar & Fielding, 2011, Pfannkuchm & Ben-Zvi, 2011, Santos & da Ponte, 2014). Our PhD research proposal follows this line of research, focusing on lower secondary school teacher education. We aim to investigate the possibilities and contributions of implementing a teacher education proposal to focus their reflections on current statistical practice and literacy. The proposal should also provide teachers with experience in carrying out statistical inquiries. Thus, the broad research question framing the development of the thesis is: *What educational proposal is it possible to implement with a group of preservice mathematics teachers in Brazil and how this proposal contributes to providing future teachers with tools to design, analyse and implement new didactic processes for the teaching of statistics in lower secondary school?* This question is approached within the Anthropological Theory of the Didactic (ATD) and, more particularly, a specific teacher education proposal called "study and research paths for teacher education" (SRP-TE). After presenting the theoretical approach, we will describe the design of an SRP-TE that will be implemented during this academic year 2022, with a pilot version during the last term of 2021. The SRP-TE starts from an open question taken from a Brazilian textbook. We will illustrate in this paper how the inquiry promoted by an SRP-TE can highlight the different dimensions of the statistical work and also be used as a tool to analyse curriculum and textbook proposals.

Theoretical framework: Study and research paths for teacher education

Chevallard (2015) states that, in our societies, teaching mathematics—and teaching in general—participates from what he calls the *paradigm of visiting works*. In this paradigm, the role of students is to study ready and finished knowledge organisations built in topics, areas, domains, and disciplines. It is up to the students to "look and admire" these works without necessarily questioning their validity or value. So, in this paradigm, topics and subjects are like monuments: students cannot change them; they do not need to know their *raison d'être*; they just have to study them. At most, questions about knowledge value and validity are posed by the teacher, characterised as "the one who knows".

[2] *Parâmetros Curriculares Nacionais* (National Curriculum Parameters), official documents used in Brazil as a curricular tool for educators and educational institutions. These curriculum documents were published in 1997 and 1998 and have recently been replaced by the document: BNCC, *Base Nacional Comum Curricular* (Common National Curriculum Base). The BNCC was approved by the Brazilian Education Minister on December 20, 2017. With this document, "school systems and public and private educational institutions now have a mandatory national reference for the preparation or adaptation of their curricula and pedagogical proposals" (Brasil, 2017, p. 5, our translation).

In contrast to this first paradigm, Chevallard describes the *paradigm of questioning the world* in which knowledge organisations change into *questions*. Teaching and learning processes become inquiry processes aiming at answering the questions. In other words, students are the inquirers of the generating questions *Q* proposed by the teachers (or by the students themselves). There may be times when visiting works is required in the search for answers to a question, but with a specific *raison d'être* (answering *Q*). They also have to search for answers in medias (as the internet, books, experts, etc.), and they have to validate these answers and check their utility to answer *Q*. This paradigm creates significant changes in the teachers' and students' roles. The first ones are no longer the "holders of knowledge", and the students raise questions, investigate, search or elaborate answers and even validate them. To study the conditions needed to transition to this second paradigm, Chevallard (2015) proposes a general inquiry format called *study and research paths* (SRP). The interplay between questions and answers plays a crucial role in the dynamics of SRPs. Students, helped by teachers, address an initial question *Q*, display *Q* into derived questions Q_i, search or elaborate answers A_i, find new questions during the process which, in turn, call for new answers, etc. Bosch and Winsløw (2015) point at the importance of such a dialectic between questions and answers to ensure the dynamics of SRPs, which is usually represented using *questions-answers maps* (Figure 1).

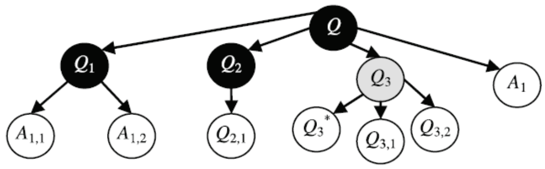

Figure 1: Example of Questions-Answers maps (Q-A) (Winsløw et al., 2013, p. 271)

Barquero, Bosch and Romo (2015) argue that teacher education proposals also need to be conceived within the new paradigm of q*uestioning the world*. Thus, they consider implementing *study and research paths for teacher education* (SRP-TE) "as a way to provide teachers with pertinent (theoretical and practical) tools to nourish and sustain their professional development" (Barquero et al., 2015, p. 810). An SRP-TE consists of five modules, which will be described below.

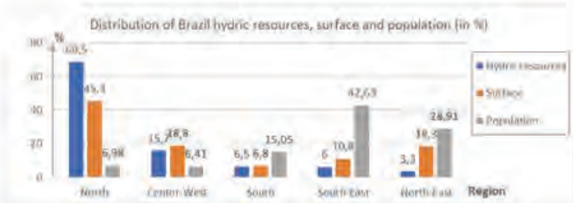
Module 0 is to propose the open question (generating question $Q_{0\text{-TE}}$) related to the subject to be discussed. In our case, our $Q_{0\text{-TE}}$ is: "How to teach statistics in the final grades of lower secondary school?". Other derived questions will appear, such as: What statistics should we teach at these levels according to the curriculum? What kind of activities are proposed by official textbooks? What other proposals can exist? Partial answers to $Q_{0\text{-TE}}$ will appear during the entire SRP-TE (and hopefully also afterwards), making it a transversal module of the educational process. *Module 1* consists of proposing the group of teachers an SRP with a relevant question that could be approached in a real classroom as students. With this, the group of teachers will be introduced to an inquiry process, a strategy also suggested by Makar and Fielding (2011). *Module 2* is the moment for teachers to analyse the experienced SRP using epistemological and didactic tools spontaneously accessed by the students or provided by the educators. In *Module 3*, teachers design and implement (if possible) an SRP for the schooling level under discussion. The new design is carried out based on the analyses made in the previous module, adapting, adding, or excluding (if necessary) didactic tools that seem necessary – or at least useful – for the implementation of this new SRP. Finally, *Module 4* consists of the teachers sharing their experiences through an a posteriori analysis. Again, the mathematical and didactic tools used in modules 2 and 3 are present here and have great importance, "not only to provide some provisional answers to the question that was at the origin of the whole process (e.g., "How to teach …?"), but also as a means to analyse other possible alternative answers" (Barquero at al., 2015, pp. 810-811), as those answers found in Module 0.

These modules structure the SRP-TE. We present below an exercise identified in a Brazilian textbook of the eighth grade of secondary school that gave us the initial idea of a generating question to be studied in the SRP when developing module 1 with the group of teachers.

Designing a teacher education proposal

The proposed SRP for the teachers starts from a school activity about “the water distribution in Brazil”. Looking at the approach to statistics in some textbooks from the eighth and ninth grades of secondary school, we find the exercise below:

Brazil has about 13.7% of the total fresh water in the world, being considered a territory rich in water terms. However, the country is experiencing serious problems related to both the degradation of water quality, especially in the urban areas' proximity, and the lack of control of excess and lack of water, which affect several Brazilian locations. Not just the floods affect Brazilian cities: water scarcity also imposes serious restrictions and high costs on economic and social development of large cities. Looking at the chart below, answer in your notebook:



Information obtained in: Ministério do Meio Ambiente <http://wwww.mma.gov.br/estruturas/ sedr_proecotur/_publicaco/140_publicacao09062009025910.pdf>. Accessed: 1st July 2018.

a) What kind of chart is this?
b) Indicate the Brazilian region:
- with the largest surface;
- with more water resources;
- with the second lowest population concentration.

c) Which region has the lowest percentage rate of water resources in our country?
d) In which region is there the greatest concentration of population?
e) Can it be said that the larger the surface of the region, the greater the number of inhabitants? Justify your answer.
f) How many percent of the world's fresh water is in the Southeast region of Brazil? Explain how you elaborate your answer.
g) Can it be said that the region with the most water resources is the one with the largest population?

Figure 2: Brazilian exercise (Giovanni Júnior & Castrucci, 2018, p. 26, our translation)

This type of exercise shown in Figure 2, and which is relatively common in the textbooks, is clearly located in the paradigm of visit works. Although it presents a relevant topic to be discussed (and even includes a link to the source of the data), it does not pose any open question, nor does it encourage students to search the data, organise and summarise them, and investigate other issues related to the topic. The questions raised in the textbook only require students to look at the graph, identify the largest or smallest bar, and perform some simple percentage calculations. If we look at the official curriculum guidelines, we can observe that this is not the kind of activity that encourages students to develop the skills assigned to this level of education, which are:

- Assess the suitability of different types of charts to represent a survey dataset.
- Classify the frequencies of a continuous variable of a survey into classes so that they summarise the data in a way that is suitable for decision making.
- Obtain the values of measures of central tendency of a statistical survey (mean, mode and median) with an understanding of their meanings and relate them to the data dispersion, indicated by the range.
- Select reasons of different natures (physical, ethical, or economic) that justify conducting sample and non-census surveys and recognise that sample selection can be done in different ways (simple random, systematic, and stratified sampling).

- Plan and execute a sample survey, selecting an appropriate sampling technique, and write a report that contains the appropriate graphs to represent the data sets, highlighting aspects such as measures of central tendency, range, and conclusions. (Brasil, 2017, p. 315, our translation)

Despite the limitations of the exercise proposed, the topic presents many interesting questions that could generate a potential SRP within and SRP-TE. For this, we need to move from the paradigm of visiting works to the paradigm of questioning the world and *question* the piece of information given. At the same time, we will see how the inquiry process it generates can incorporate dimensions of the statistical work that tend to be absent from secondary education, like the search, collection, cleansing and representation of data, together with a critical reading of quantitative information. Thus, for the SRP to be developed with the group of preservice teachers in Module 1, we propose to start with Q0 and initiate a questioning that can lead to the following derived questions (starting from the same text and graphical information as before):

Q0: How can we explain the contradiction between the abundance of water resources and the water problems (scarcity, quality degradation, lack of control, etc.) of Brazilian locations? How are hydric resources distributed in Brazil compared to the population and surface?

Q1_Water: What do we know about water distribution in Brazil?

Q1.1. Are there studies about the water problem in Brazil? Where can we find them?

Q1.2. What disciplines are involved in the studies: geography, politics, geology?

…

Q2_Graph: What information can we draw from the graph?

Q2.1. What variables appear in the graph? What others could it be interesting to consider?

Q2.2: What are hydric resources? How are they measured?

Q2.3: Why are the variables in percentages? How are these percentages calculated?

Q2.4: How will be the graph if we use units instead of percentages?

Q2.5: Can we improve the graph using another type or adding/omitting information?

…

Q3_Data: What data is used to make the graph?

Q3.1 Is it available? Where? [The presented link does not work.]

Q3.2. Is the data available also reliable? How is it obtained?

Q3.3. What are the units of the different variables in the data source?

Q3.4. Can we use the available data to reproduce or update the graph?

Q3.5. Are there other interesting variables with available data to consider?

...

Q4_Working with data: How to download the data to start working with it?

Q4.1. How to clean the table of data to make it ready to use?

Q4.2. What tools are available for data processing, and which ones can we use?

Q4.3. What types of numerical and graphical summaries are appropriate?

…

We started from the main subject of the text presented in the textbook exercise and elaborated a relevant open question (Q0) that could be worked on in a classroom. The exercise presented a graph with the distribution of water in Brazil and the population and surface area by region. This graph will also serve as a possible answer for a derived question since its source is the Ministry of the Environment. In this initial work to list our generating question and possible derived questions, we identified two large groups of questions: those related to the topic “water” (Q1, Q1.1, Q1.2, ...) and those related to the topic “graph” (Q2, Q2.1, Q2.2, ...). Still, within the topic “graph”, another large group of questions appears, which is the topic related to “data” (Q3, Q3.1, Q3.2, ...). By raising the questions related to “data”, we entered the topic “working with data” (Q4), which also made us think of derived questions (Q4.1, Q4.2, ...). With this, we obtain an a priori questions-answers map (Figure 3) that is part of SRP-TE.

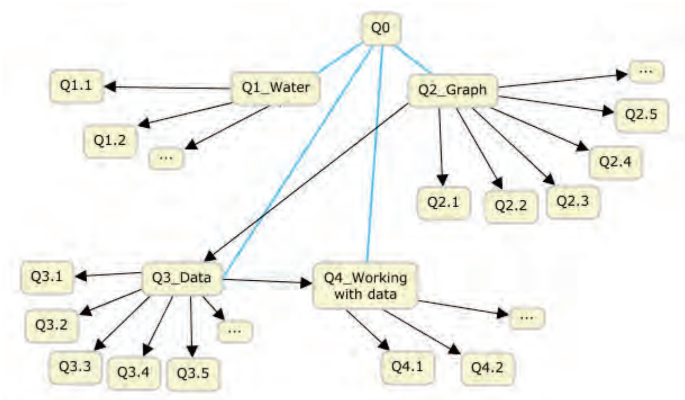


Figure 3: Questions-answers map about water distribution in Brazil

We started from an exercise proposed in a Brazilian textbook and reworked it to display the initial and derived questions that may arise during the inquiry process. This questions-answers map serves as a possible SRP to be developed with the group of preservice mathematics teachers. The answers are still being developed since we have not yet worked directly with the group. It is an a priori study about the proposed theme: distribution of water in Brazil and, with this SRP in development, we believe it will be possible to work with dimensions of the statistical work that tend to be absent from the final grades of the lower secondary education, as the search, collection, cleansing and representation of data. The inclusion of provisional answers will likely enrich the map with more questions and potential maps to follow. It will also introduce more connections between the derived questions and the different branches they form.

Conclusions

The a priori questions-answers map shows the productivity of changing attitude from *visiting works* to *questioning the world*. It first gives visibility to many interrogations that are usually hidden in the way school tends to present (quantitative and qualitative) information, giving no room for doubts or questioning. It also shows how these interrogations go beyond the strict statistical reading and analysis of data to merge with other disciplines or areas concerned by the question addressed. This is not specific to statistics, even if it plays a crucial role there. Teaching modelling also suffers from the same phenomenon of disciplinary confinement. It makes many connections between different topics of statistics that tend to be presented separately even if they nourish each other (like the definition and measurement of variables, the reliability of data, the ambiguity of percentages, the pertinence of the type of graphs chosen, etc.). Finally, it provides future teachers with a broader and more realistic vision of statistics that can help them detach from the narrow perspective proposed by textbook exercises and facilitate the introduction of engaging statistical activities in the classrooms. We hypothesise that the design and implementation of an SRP-TE in statistics will provide students with tools to reflect, develop, analyse, and implement new statistics teaching proposals when working in lower secondary school and develop a critical posture when acting in their profession. The change of paradigms proposed by Chevallard (2015) seems particularly appropriate in the case of statistical inquiries for the specific descriptive tools it provides (Markulin et al., 2021). It also makes us, researchers, adopt a critical stance towards the social, educational, political and epistemological dimensions that involve the themes of teacher education and statistics teaching.

Exploring the statistical practices in classroom: STEM teachers' experiences using dynamic data analysis technology.

Defne Yabaş[1], Batın Örene[1] and M. Sencer Corlu[1]

[1]Bahçeşehir University, Faculty of Education, İstanbul, Turkey; defneyabas@gmail.com, batinorene@gmail.com, sencercorlu@gmail.com

In the 21st century, schools have been increasingly expected to raise students prepared for a world of quantities and uncertainty. As statistical practices become an important skill for every individual, researchers and educators work on ways to translate the methodologies of professional statisticians in the teaching and learning environments. Technological tools are helpful in translating statistical investigations into the classroom. The purpose of our research is to understand teachers' experiences about integrating statistical practices into their STEM lesson plans by using LabStar, a dynamic data collection and data analysis tool. Findings were investigated under four categories: personal development, in-class implementation, views about the mobile application and the tool, and statistical investigation environment. Future research was recommended to investigate teachers' professional development opportunities to integrate meaningful statistical practices in their lesson plans.

Keywords: Statistics education, statistical investigation, dynamic data analysis technology.

Introduction

In the Big Data era being competent in making data driven decisions in all aspects of daily life is inevitable. Many decisions in politics, economics and social sciences are based on thorough analysis of data. The omnipresence of data requires individuals with strong analytical and reasoning skills who can base their decisions on their inferences beyond the data in the way that professional statisticians do (Frischemeier, 2020). However, international reports point out the lack of individuals, who demonstrate necessary skills to cope with Big Data even at the tertiary level (Manyika et. al., 2011; Puang-Ngern, Bilgin, Kyng, 2017). From this point, practice of statistics became a crucial element to integrate in primary and secondary school curricula.

In 21st century, schools have been increasingly expected to raise students prepared for a world of quantities and uncertainty. With the availability of data from variety of sources and in a variety of formats students are required to manage the complexities to reach data driven conclusions (Makar & Rubin, 2009). Statistics, therefore, has become an essential element of school mathematics curricula of many countries (e.g., Australian Curriculum, Assessment and Reporting Authority, 2015; Common Core State Standards Initiative, 2010; Ministry of National Education, 2018).

As statistical practices become an important skill for every individual, researchers and educators work on ways to translate the methodologies of professional statisticians in the teaching and learning environments. Statistics education is becoming an agenda across many levels of schooling. Debates about how to help students gain an understanding about statistics requires us to think about the nature of statistics. Statistics is about carrying out statistical investigations on a specific statistical question to understand a phenomenon. Statistical investigations are based on exploring the variation, by engaging data collection, data representation, data reduction, level of certainty and informal inference practices (Watson et al., 2018).

Statistical investigation is recommended to be the focus of the statistics teaching-learning activities in classroom contexts. The parts of the investigation process have been also included in mathematics curricula starting from elementary grades. As the practices of statistical investigation become a part in mathematics curriculum, the role of the teachers comes forth. Teachers are expected to design authentic contexts where students can engage in data collection, analysis, and informal inference processes. Research also underlines the importance of teacher knowledge on statistics and statistical thinking to design effective learning experiences for their students (Rodrigues & de Ponte, 2020).

Technological tools are helpful in translating statistical investigations into classroom. Dynamic technologies that allow students to experiment with data collection and analysis techniques were started to be researched in terms of the opportunities they provide for statistical practices (Meletiou-Mavrotheris et al., 2008).

COVID-19 caused schools to get shut off, which made STEM and statistics education to be conducted on online portals. This probably led to changes in the teaching method and the environment. The aim of creating statistics literate students that use statistics tools, software, and can interpret the data became the priority. In order to fulfill this aim, collaboration, communication and multidisciplinary studies that involves data science and education must be addressed.

Based on this rationale the purpose of our research is to understand teachers' experiences about integrating statistical practices into their STEM lesson plans by using LabStar, a dynamic data collection and data analysis tool. Teachers were provided with educational videos about integration of statistical investigations into STEM lesson plans and the use of LabStar tool. After watching all the videos teachers implemented the STEM lesson plans, designed with authentic statistical investigation tasks. Our aim is to explore the lived experiences of teachers about the implementation of these lesson plans. Our research questions are:

- How STEM teachers contextualize statistics and mathematics into daily life problems using STEM integration?
- How STEM teachers perceive their roles in terms of integration statistical investigation in STEM education?
- How STEM teachers evaluate the educational videos in terms of designing and implementing statistical investigations in STEM lessons?

Methodology

The research used a phenomenological method among qualitative research designs. The study group is four STEM teachers who used statistical investigation practices in their classrooms during 2020-2021 Spring Semester. T1 was a middle grades mathematics teacher, T2 and T3 middle grades science teachers, and T4 was a high school physics teacher. They implemented STEM lesson plans integrated with statistical investigation in various grades and with different disciplines in the center of the lesson plan. They used LabStar as a dynamic data analysis technology. LabStar is a dynamic data collection and analysis tool. It works with the physical tool and the mobile application. The mobile application can be used also separately from the tool by analyzing open resource data. All teachers and students had the LabStar mobile application, one of them (T4) had both the physical data collection tool and the mobile application. Teachers used data from open resources to analyze in their in-class implementations. Before the implementation they were provided with training videos regarding ways of using dynamic data analysis technology in their STEM lesson plans.

For data collection we conducted face-to-face interviews with the teachers. To ensure a prolonged relationship, interviews lasted at least 60 min. Audit groups were formed within the research group and member check processes were planned to ensure trustworthiness. Researchers are also using peer-debriefing during data collection and analysis phases. STEM lesson plans and field notes of the teachers were used as data sources to ensure triangulation in data collection. For data analysis, interviews were transcribed, and thematic analysis was conducted by using constant comparative method. Because multiple coders will analyze the transcripts, the methods for ensuring intercoder reliability were used. Documents of teachers (lesson plans and notes) will be analyzed by content analysis. Data analysis will be finished in November 2021.

Findings

Analysis of the interviews and the documents revealed myriad findings about the experiences they had during integration of STEM education into their classes. Findings were investigated under four categories: personal development, in-class implementation, views about the mobile application and the tool, and statistical investigation environment.

Personal Development

This theme emerged as the participants mentioned about the training they have received and research they have done before and/or during applying a STEM activity in the class. All teachers expressed that the educational videos that they have watched before attending to the classes, helped them to learn and grasp the nature of the application before introducing the software to the students. One of the teachers, T1, commented that "With the help of the videos, especially the fourth one, we were able to lead the students in the right direction". T2 added that: "The videos were sufficient, I received STEM education last year, I knew nothing. In a year I learnt about STEM education and some of the questions were given to us that are in the videos."

Furthermore, some of the teachers had to get help from various resources because they felt that they did not have sufficient knowledge.

> I am a science teacher, when I was studying on it, I got help from my husband who is a mathematician, (I asked about) upper quartile, lower quartile etc. I taught students with the information I got from him too. I also got tremendous help from the educational videos. (T3)

This view also showed that teachers also had an opportunity to discover knowledge related to other disciplines. A teacher had sufficient technological knowledge and even integrated STEM education to work with a software simultaneously.

> I thought about what I could do, I set up a meeting with the students from 9th and 10th grades. A student said that we should test its (LabStar's) accuracy. We tested it and it was accurate. We conducted two experiments, firstly

> we created sound waves and measured its decibel. We have a software called Scratch; we created the sound waves then integrated it with LabStar. The data were almost equal. We used it to compare the sound waves, their wavelengths. I found it usable for advancing in physics. It is a nice software (T4).

The teachers started their lessons with introductory activities to motivate students. T1 stated “We asked the students about number of cases of covid-19. Then we led them to the relevant website.”. T2 added “I asked the properties of microscopic life forms. With the feedback I have received, I mentioned about the bacteria then gave the table”. Although T2 did not ask anything before the lesson, she let the students explore by themselves. This allowed the students learn by discovery.

> I did not ask anything, I let them do experiments because I was experimenting too. When I asked what do you see, they told me that the wave is increasing, I asked how a wave can increase? Is it on the direction x or y? Then we got data, but now they tell numbers instead. Are they increasing or decreasing? We call them data. As the waves increase, the numbers increase, what do we call it? Wavelength. (T4)

Some teachers worked as a group to put out the lesson plan.

> We worked as a group. I usually build interdisciplinary relations with mathematics, but I always get help from the biology. We do gas pressure, sound waves, they are all about biology. There were machines in STEM laboratory, I used the distance sensor there. (T4)

The teachers explained that they plan to apply their knowledge into their other lessons too.

> Maybe it is not possible to apply it to all topics, since physics, chemistry and biology are different. But for velocity, race, order of the velocity, density of a matter, there can be data and it can be commented on. I think that it could be integrated depending on the area. (T2)

T4 also asserted that, “I will use it to explain illumination density. I have the topic movement on 10th grade, location, distance, translocation, I will use graphs. It is fun to make students active in 9th and 10th grades.”

In-class implementation

This theme has emerged as the teachers expressed their experiences about the application of a STEM lesson in a class. A problem occurred because of the mismatch between the current grade’s curricula and the statistical terms in the tool. T1 claimed that “Some terms were troublesome since they did not fit to my class”. T2 added that “In my opinion it was not suitable for 5th graders, the terms mode, median in the graphs”. T1 further explained that: “The students didn’t know the terms and their meanings since the terms do not fit to fifth grade’s curriculum. They did not understand it because they did not learn it, and I did not pre-teach the terms.”

Some teachers had problems because of the students’ technological skills being insufficient. T1 claimed “Some students found it hard to transfer data to an Excel sheet”, She further said “At first they found it hard to create a table. There were students who did not know the shortcuts”.

The teachers explained that they were not able to hold the attention of the whole class nor make all students participate in the activity. T2 claimed that “If you have 50 students, only 10 students give positive feedback. There were students who did not download the mobile application or participate in the lessons”.

The teachers who had the mobile application but not the physical tool claimed that they could have reached to more students if they had the physical tool to collect real time data. Some teachers observed that some students were interested in the lesson:

> There were many students who were interested in the lesson. There was data related to basketball, it drew the attention of male students. If the topics were different there could be different things. But I received positive reactions, some students asked if they could collect and analyze another data. (T2)

Views about the mobile application and the tool

This theme has emerged as the teachers stated their views about the mobile application and the tool that they have used to carry out their STEM lesson plans.

Another challenge was born because of the language of the application being English. This was a common problem amongst all teachers. T1 stated "The only problem was the application being in English, it could be in Turkish. If they don't know English, they need to use translation". Some schools did not receive the physical tool, but they only had the mobile application. The teachers believe that they need the tool itself.

> It would be better if we had the tool. For instance, in a 7th grade, I have conducted a lesson about darker colors absorbing light thus being colder. I used heat and light sensor simultaneously to observe the graph. It was a brilliant lesson. I did not have such fun in any lesson before. So, it would be better if we had the data collection tool. (T3)

T2 claimed that. "It is vague for 5th graders, for a fifth grader, the tool being here and the process of collecting the data is necessary. It needs to be concrete". There were some problems that originated from the application and technology use. Overall, the teachers were satisfied with the experience they had with LabStar. T2 claimed "The teachers can use LabStar easily and create STEM lesson plans.", T4 added "LabStar can analyze data, it is accurate and fun".

Statistical Investigation Environment

The teachers have different expectations about the statistical terms that the students must know and express in a statistical investigation environment.

> It is crucial to be able to read the graphs, where is the peak, what is the increment this month, being able to comment, creating a cause-and-effect relationship is important for science. Mathematical interpretation, peak point, outliers. I believe that LabStar application is related to mathematics at most. (T2)

> The students do not know how to read the graphs, they cannot even read tables. They have learnt how to do it; I believe that that is the significant contribution. (T3)

The teachers claimed that STEM integration made observing statistical terms easy.

> In the topic waves, there are fundamental notions. Frequency, amplitude, and wavelength. You can create a sinus wave, you can observe the wavelength, then we can measure it. We talked about range and modes, we created 2-3 waves, x wave and y wave then we compared them. At first, they talked about their image, then we compared them as data. (T4)

Some students were not interested in terms related to statistics. When teachers were asked if the students asked about statistical terms, T2 said “No, they did not ask. In 6th and 7th grades the activities would be more efficient. However, since the total number of lessons are less in 5th grades, it limits us.” T1 added that, in online environment, only the students who are passionate about mathematics asked, but we did not have a whole-class discussion. Since the number of curious students were low, they contacted us through private messages. (T1)

Discussion

The teachers reported that by seeing the graphs live, students grasp the concepts of mathematics and statistics in a fun and interactive way. This may be because in most cases formal statistics teaching leaves students in a confused state as most of the time they are not able to apply the theoretical knowledge into real life (Bakker et al., 2017), whereas the fun factor comes into play with the activities. The teachers worked together with other teachers to set up a multidisciplinary context, this is because developing mathematics, and integrating it with the other disciplines in STEM is the main aim in STEM education (Li & Schoenfeld, 2019). Even though context integration should be used to teach STEM (Kertil & Gurel, 2016), the teachers most of the time failed at integration of STEM with other disciplines, they mostly worked on their own disciplines. Therefore, creating statistical investigation environments was evaluated to be essential (Anderson & Li, 2020).

Teachers used real data from various resources to analyze with the mobile application and believed that real life situations are shown with excellence by using the tool and mobile application. it is probable that go prepare students to real world and its requisites, they feel that real life problems should be the main scope of the curriculum and the lessons in the schools to provide problem solving skills in which they need to provide a solution, a model to achieve the goals clearly (English & Watters, 2005). The teachers preferred experimenting with the students mostly because In the 21st century, using computers and being proficient is necessary and in STEM education, for the most of the educators experimentation is the preferred way rather than the computation (Li et al., 2020). The teachers dealt with problems that arise from the statistical terms, but they were caused from the curriculum not including the related terms, and the teacher’s lack of self-awareness to do a pre-teach session. Future research was recommended to investigate teachers’ professional development opportunities to integrate meaningful statistical practices in their lesson plans.

Introduction

The thematic working group TWG6 takes on the importance of exploring the role of mathematics when it is used and applied in the study of real-world phenomena in educational contexts. TWG6 considers the interplay between empirical research results and theoretical approaches to the teaching and learning of applications and mathematical modelling, in mathematics and other subjects, at primary, secondary and tertiary school levels, as well as in teacher education. It started at the fourth ERME Congress (CERME4) in 2005 and has since then continued to be an active thematic working group in the following nine congresses. In total, more than 200 papers and posters have been presented in the TWG6. In CERME12 the TWG6 received 36 submissions, resulting in a total of 25 papers and 5 posters presented. See Figure 1 for a summary of the TWG6 contributions in the different CERMEs. At CERME12, we have discussed theoretical, methodological, and empirical research contributions aiming to address a variety of topics, such as application, modelling and simulations in connection to other subjects, the use and impact of technology and other resources to support modelling, teacher education for applications and modelling, and assessment practices for mathematical modelling, among others. The contributions discussed at the congress revealed a strong and fruitful diversity in the research questions considered, the school levels addressed, the theoretical approaches chosen and their methodological development.

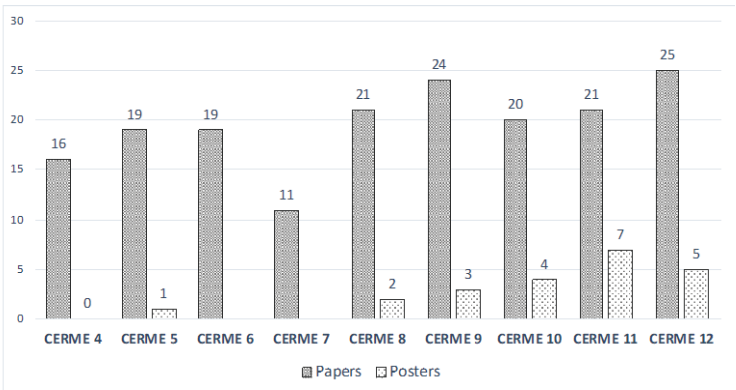

Figure 1: Evolution of the papers and posters presented in TWG6

A total of 45 participants participated in the online CERME12, representing 14 countries –most of them from Europe, but also from South and Central America, Israel, South Africa and Japan. The papers and posters were divided into six leading themes (see Table 1), so that in each session papers and posters were discussed on one of the themes.

Table 1: Leading themes (LT) defined and number of contributions in the proceedings

Leading themes	Papers	Posters
LT1. Theoretical and methodological developments in modelling	3	
LT2. Modelling in STEM topics and extra-mathematical topics	3	2
LT3. Design and analysis of modelling tasks and processes – Learning modelling at primary or secondary school education	6	2
LT4. Design and analysis of modelling tasks and processes – Teaching and learning of modelling at tertiary education	6	
LT5. Teacher education for mathematical modelling and application	4	1
LT6. Technology and other resources in mathematical modelling	3	

In the first leading theme, the reader can find papers focusing on theoretical and methodological developments of tools for the analysis of the modelling tasks and practices. The second theme focuses on the interplay and connections between mathematical modelling and other subjects, referring to the STEM topics and/or engineering context. The third and fourth themes address different strategies to support the design and analysis of modelling tasks and of the strategies to foster students' work on modelling tasks. These contributions are organised into two sub-topics according to the educational level the research contributed to: primary or secondary school education (LT3), or university education (LT4), the latter also including university students who are being prepared to become teachers. This last sub-topic links coherently with the fifth one, which covered teacher education for modelling and its applications, presenting several instructional proposals for preservice and in-service teacher education for application and modelling. Finally, the sixth theme focuses on the use of technology and other resources in mathematical modelling, mainly about how to combine different resources with technology in concept development by means of real word contexts. Table 2 summarizes the papers and posters included in the proceedings of CERME12, which we elaborate on in this introductory report discussing the leading themes.

Leading themes and overarching questions

LT1: Theoretical and methodological developments in mathematical modelling

This first theme focuses on proposing research tools and methodologies to analyse modelling practices beyond the cognitive aspects and to discuss the rationale and specificities of mathematical modelling in comparison to other domains or disciplinary approach to modelling. Firstly, *Vos* and

Frejd present a suggestion for extending the modelling cycle by the dimensions of metacognitive strategies, tool use and social norms. Secondly, the paper of *Ärleback* and *Frejd* considers a dual integrated modelling approach to the teaching and learning of mathematics and the teaching and learning of mathematical modelling at the same time. Thirdly, *Kawakami* and *Ärleback* present a review on the characterization and comparison among the rationales of statistical modelling and mathematical modelling. In all three contributions it became clear that the teaching of modelling and the analysis of modelling processes should not be limited to modelling competencies but should also include other aspects such as mathematical concepts, metacognition, affect, social norms, group work and tool use. Some questions for discussion emerge for future developments on this topic:

- What might a modelling cycle as an analysis tool look like, that includes aspects such as metacognition, affect, tools, social norms or group work, in addition to the analysis of sub-competencies?
- What would a concept for teaching look like, in which modelling competencies and mathematical concepts or knowledge about the context can be taught at the same time?
- To what extent is it necessary to distinguish between mathematical modelling and, for example, statistical modelling? Does statistical modelling represent a sub-form of mathematical modelling?

LT2: Modelling in STEM topics and extra-mathematical topics

The LT2-papers study the role of mathematical modelling in extra-mathematical, engineering, and STEM contexts. The paper by *Kacerja* and colleagues presents an analysis of teachers' discussions on the modelling involved in the body mass index (BMI). *Vásquez* and colleagues discuss a study and research path (SRP) for the teaching of modelling in secondary school in relation to the evolution of COVID-19, which connects to the poster from *Donner* and *Bauer* on a modelling project about the pandemic for grades 9 and 10. The poster by *Fleischmann* and colleagues presents the design of an SRP about modelling climate change. Finally, *Pablo-Díaz* and *Romo-Vazquez* present the design of a didactic activity for engineering education based on the Hazen-Williams model. The main areas and driving questions of the discussion with respect to LT2 can be summarized and highlighted as:

- The complexity of realistic and real-world (ill-defined) problems. How to deal with and conceptualize the extra-mathematical domain? How to transpose complex real-world modelling problems into different grade classrooms without losing authenticity, relevance and richness? How to support or motivate students to validate their results with the real context?
- Critical perspective, ethical considerations, and sensitivity towards students. How to support a critical perspective on the use of models in society (e.g. when addressing issues related to Covid-19, BMI)? How to consider in classrooms the potential implications of using the models for decision-making?
- Implications of using real data in modelling activities. How to foster a critical stance towards, and thinking about, data in students? Starting from the given data: what questions can be answered? Starting from questions: what data is needed in order to provide an answer?
- The role and importance of various aspects of posing questions. What is the role of problem posing in the context of applications and mathematical modelling? What can students learn

from posing questions with respect to modelling and extra-mathematical questions? How to support students in posing productive and answerable extra-mathematical questions?

- The nature of the models used and developed: To what extent are STEM contexts and activities providing new and different types of models to explore?

STEM and other extra-mathematical contexts provide rich sources for modelling problems but introduce new types of challenges and demands for students, teachers and researchers. We need to conceptualize and theorize about how to design activities and learning environments (including technology) that fundamentally connect to, and use, knowledge from other disciplines and extra-mathematical domains.

LT3: Design and analysis of modelling tasks and processes – Learning modelling at primary or secondary school education

The papers related to this topic refer to different strategies to support students when solving modelling problems, teachers when guiding their implementation and strategies for the design and analysis of modelling activities. As one of the themes that are grouping more contributions, we can distinguish different focuses and issues raised.

Firstly, *Elias* and colleagues focus on examining the notion of the rate of change in modelling problems. The authors examine which aspects of the notion of rate of change are prone to subjective reasoning by learners, due to their structure or due to missing information, and which aspects are objective. Secondly, some contributions focus more on some particular steps of the modelling process and analyse, for instance, the influence of students' beliefs about modelling or the interest in the context of modelling tasks. *Geisler* focuses on the steps of validation and investigates how students validate their models within modelling tasks with experiments. Additionally, *Kanefke* and *Schukajlow* focus on the difficulties of students noticing when data are missing from some modelling problems. They aim to analyze the extent to which students noticed missing data while processing modelling problems with missing data. Furthermore, the poster from *Kaemmerer* presents a comparison between students' work on modelling tasks when they have an interest (or do not) in the real-world context where the task is proposed. The poster from *Surel* discusses strategies for a better comprehension of modelling tasks related to students' engagement. Some common questions for discussion linked to these contributions are about:

- What impact do students' beliefs about the nature of mathematics (e.g., exactness of mathematics) have on students' approaches to working with (missing) data? How can we influence students' beliefs, so they are able to be more flexible with their models (adaptations/reformulation/validation)?
- Are students' affective reactions dependent more on the type of modelling task or the phase in the modelling process? Are there important differences in students' affective reactions?

Thirdly, other papers are more focused on the proposal of analytic tools for the ideal, individual, or collective modelling routes. The paper from *Schneider* and colleagues investigates whether and to what extent knowledge about ideal-typical modelling processes have an influence on phase transitions in individual modelling. *Göksen-Zayim* and colleagues present an observation instrument to study collaborative modelling. The authors use three main components: collaborative learning, mathematical modelling and the language that students use while working together. Moreover, *Bassi* and *Brunetto* are interested in the affective factors, cognitive and motivational, that can be associated with the different modelling activities. Some common questions about these contributions refer to:

- To what extent does group work condition the modelling process? How to take into consideration the aspects related to group work conditions?
- Which tools are more useful for the systematic analysis of the influence of interactions on the resolution process?

LT4: Design and analysis of modelling tasks and processes – Teaching and learning of modelling at university

This fourth leading theme, closely related to the previous and the next ones, is now focused on the design and analysis of mathematical modelling at university level. Most of papers on this topic choose the university students who are in fact preservice teachers.

Zhou and *Hansen* investigate how the introduction of the pedagogical method "mathematics in three acts" to preservice teachers influenced their mathematical modelling. *Hartmann* and colleagues investigate the modelling activities that take place when posing problems that are based on given real-world situations and the extent to which modelling activities occur with different problem-posing activities. *Segura* and *Ferrando* aim to categorize the different types of errors when university students solve some modelling tasks involving estimations and to inquire into the efficient use and learning from errors to improve initial teacher training. *Sevinc* and *Ferrando* analyze the commonalities and divergences in the resolution of a group of Turkish and Spanish preservice mathematics teachers' ways of modeling approaching a Fermi-based modeling problem. The contribution from *Andresen* aims to inquire about learning trajectories in the context of modelling with differential equations. Textual analysis of the reports from teachers in a masters' program implied the marking of notions and terms related to progressive, horizontal and vertical mathematising,

We can divide the main topics into three areas. They are school-university transfer, modelling processes and modelling tasks. In the *school-university transfer*, the importance of the transfer of studies from school to university, was discussed. Here, the question arises, how to compare the conditions under which the implementation runs and the results. Another question discussed is for example: How to take into account the university context and the institutions to which some modelling tasks are to be transferred?

In the *context of modelling processes*, the question of understanding reality and mathematics in the modelling process as "part of the world" was discussed. Modelling is seen, especially at university, as a way to learn new advanced mathematics rather than just using familiar university-level content. The connection between mathematical modelling and problem posing and the importance of their relationship was also pointed out here.

The discussion of *modelling tasks* for university students includes criteria for evaluating the "quality of the problem" (for example openness and complexity). Fermi tasks also have great potential as modelling tasks at the university. They provide an opportunity to analyse possible errors in more detail. Modelling tasks examples at university, if used in teacher education, should also be considered in terms of their pedagogical significance. Looking to the future with respect to this fourth topic, questions arise about:

- What differences between engineering students and preservice teachers are relevant to the construction of modelling opportunities?
- What are the main differences between mathematical modelling in university and mathematical modelling in the school?

LT5: Teacher education for mathematical modelling and application (professional content knowledge and competencies)

This fifth theme is focused on teacher education, based on the acknowledged need for preparing preservice and practicing teachers for the teaching of applications and modelling. Papers on this leading theme are closely related to the previous ones. As mentioned before, papers in LT4 present the analysis of preservice teacher activity (considered as university students) and, in the current one, the focus is on professional content knowledge for mathematical modelling, pedagogical knowledge for modelling and simulation, and/or on teachers modelling skills.

On the one hand, *Greefrath* and colleagues consider the professional content knowledge of mathematical modelling as a competence facet of teachers to present and discuss the development and use of a test instrument. In this same direction, but referring more to pedagogical knowledge, *Gerber* and colleagues propose a theory-based model and subsequently present items of an associated test instrument to measure the preservice mathematics teachers' professional knowledge for teaching simulations and mathematical modelling with digital tools. On the other hand, *Montejo-Gámez* and colleagues present the characterization and the analysis of the kinds of assumptions made by a group of preservice teachers on the models considered and the impact on modelling outcomes and teachers' skills. The poster presented by *Ulbrich* and colleagues focuses on developing mathematical modelling skills for mathematics teachers through 3D Modelling and 3D Printing. Some main issues and questions related to this leading theme are about:

Content knowledge (CK) and Pedagogical content knowledge for mathematical modelling (PCK): Considering the specificities of the knowledge domains (mathematics, stochastics, grade level, ...), how can we describe mathematical, technological and modelling knowledge involved in PCK in order to design assessment tools for measuring PCK?

Noticing mathematical modelling processes: How is teachers' noticing competencies and knowledge (regarding metacognition) in modelling and its development related to one another?

Validity and replicability of research in teacher education: How do we deal with the question about validity and replicability in our field of research (in particular, in teacher education for mathematical modelling)? What might be the impact of teacher education for modelling on teachers' practice? How can we replicate studies in light of the diversity of conditions (and limitations) under which teachers can act? In the future development of our field of research, questions arise about what knowledge on technologies (which tools, when to use tools, black boxing, instrumental genesis, ...) might also be involved in the discussion of teacher knowledge for mathematical modelling and of teacher education.

LT6: Technology and other resources in mathematical modelling

This theme focused on the use of technology and digital resources in mathematical modelling. *Touma* and *Olsher* explore the design principles of computer-based modelling activities. From design-based research, the results show that technology plays several relevant roles, namely simulation, investigating scenarios, and simplifying procedures. In her study, *Jessen* aims at characterising the roles of digital resources in mathematical modelling, by using the Anthropological Theory of the Didactic in terms of media-milieu dialectics. The digital tools are seen both as media and milieu. *Lieban* and *Bueno* examine students' use of 2D and 3D resources to find out how ideas from the Three Worlds of Mathematics come into play. They conclude that connections result from experimentation, exploration, understanding, and manipulation, in physical or digital environments. Some of the matters largely discussed were:

Contributions of digital tools to the modelling activity: What is the relationship between simulation and modelling? In considering the different roles that digital tools can play in the modelling process, to what extent does technology define the modelling activity? How does technology trigger students' creativity in the modelling process?

Design of technology-based tasks and environments: How can we find a balance between the teacher's and the students' intervention in a modelling task? How to design good tasks that foster the students' modelling competencies using digital tools? How to develop modelling tasks considering the diversity of students' knowledge of technology in a class? How to promote student's self-confidence on the use of technology for modelling?

Teachers' knowledge on mathematical modelling with digital tools and STEM practices: Is there a specialized PCK concerning the implementation of mathematical modelling with technology? How can technology be used as a communication tool and a collaboration tool in modelling activities? Is it possible to establish a relationship between a modelling task and the technology that is more effective to carry out some or all the steps of the modelling process?

In the future development of our field of research, we need more studies on technology-based modelling activities. New conceptualizations and theoretical approaches concerning mathematical modelling with technology are also necessary. The design of modelling activities with digital tools is important in feeding the research on this theme.

Concluding remarks and perspectives

The leading themes addressed by the TWG6 show again the variety of research approaches and questions the papers dealt with (Carreira et al., 2019; Kaiser & Sriraman, 2006). Furthermore, the educational levels spanned from primary to tertiary education, also covering preservice and in-service teacher education. With the overview presented in the previous section, we now focus on each of the six leading themes central in CERME12 and summarize the main driving questions of the discussion, as well as some remarks and questions, looking ahead for future research with respect to each leading theme.

The first leading theme (LT1) discusses research tools and methodologies to analyse modelling practices beyond the cognitive aspects, suggesting extending the modelling cycle by considering metacognitive strategies, social norms, affect, group work and tool use. Moreover, this discussion is complemented by the comparison between mathematical modelling with modelling in other domains, such as statistical modelling, to discuss their possible meeting point in terms, for instance, of their rationale or conceptualisation. The second theme (LT2) argues the role of mathematical modelling in extra-mathematical, engineering and STEM contexts (or more in general, interdisciplinary contexts). There is a long tradition in TGW6 of discussing examples under this theme. The discussions highlight the need to conceptualize and theorize about how to design activities and learning environments that connect disciplinary knowledge, in particular mathematical and mathematical modelling knowledge, to other disciplines and extra-mathematical domains.

The third and fourth themes are more associated with the design and analysis of modelling tasks and processes in primary and secondary education (LT3) and tertiary education (LT4). These two themes group about half of the contributions. LT3 groups the papers that refer to different strategies to support students when solving mathematical modelling problems and strategies to design and analyse modelling activities at primary and secondary school levels. Closely related to the previous one, LT4 is focused on the design and analysis of mathematical modelling at tertiary education. Most of the papers choose the university training of preservice teachers to analyse what future teachers do when they are being trained (as students) at university.

The fifth theme (LT5) focuses on teacher education, based on the need of preparing preservice and in-service teachers for the teaching of applications and modelling. LT5, with the previously mentioned LT4, included many papers, continuing with the dynamics initiated in the previous CERME11. Teachers and their initial and continuous professional development are crucial for the integration of mathematical modelling into mathematics education at all school levels. Some questions about the linkages and replicability of teacher education and its impact on teachers' practice remain open for future research. Finally, the sixth theme (LT6) is focused on the use of technology and digital resources in the teaching and learning of modelling. Questions about the need for theoretically-based designs of modelling activities with digital tools or the need for extending research on teacher education for the use of simulations and modelling remain highlighted for future development of our field of research.

Acknowledgment

We want to thank all the participants of TWG6 at CERME 12 for their presentations and participation in the discussion and for working together in the online intensive sessions.

Learning trajectory as a complex cluster of activity

Mette Andresen

University of Bergen, Norway; mette.andresen@uib.no

This paper presents a study of students' learning mathematics by modelling. In the study learning was conceptualized in terms of emergent modelling following the four-layer model by Gravemeijer et al. (Gravemeijer, 2020). Aim of the study was to inquire learning trajectories in the context of modelling with differential equations in 21 students' reports. Textual analysis of the reports implied the marking of notions and terms related to progressive, horizontal and vertical mathematising, followed by the linking of them with the four layers. The paper focuses on one case of students' modelling in one report. It demonstrates how the students' learning trajectory was identified and determined, for interaction between populations as an emergent sub-model of a differential equations model. Thereby it contributes to the discussion of i) conceptualizations of modelling and its relations to learning, and ii) methods for research in students' learning.

Keywords: Mathematical models, learning processes, active learning.

Introduction.

The issue of this paper is to interpret students' learning mathematics from modelling with differential equation (DE) systems in terms of emergent models, by vertical and horizontal mathematising (Gravemeijer & Stephan 2002). The study's students do not build up the model from scratch. The study's conceptualization of learning from modelling is in contrast with cases of 'learning by modelling' that refer to learning about/developing competence in modelling (see Blomhøj & Ärlebäck, 2018). The present study was part of a more comprehensive study of data, consisting of the 21 reports described below. In the presentation of the larger study by Andresen (2021) the methods used in the present study were described and discussed. The larger study also encompassed another case study, going into details about the interplay between the DE model, the problem modelled, and the tool used for modelling, presented in Andresen (2020).

Theoretical framework

In this section the basic idea of emergent models is presented and operationalized into a tool for textual analysis, following the larger study by Andresen (2021). Whereas the presentation in (Andresen, 2021) concentrated on conceptualizations of learning in terms of emergent modelling, the aim of this paper's study was to trace and identify the students' learning trajectory for cyclic interaction between populations in the predator – prey DE model as an example of learning about a mathematical concept by modelling.

Emergent mental models of mathematical concepts and relations

Gravemeijer and Stephan (2002) expressed modelling in terms of emergent models. The notions of emergent models and modelling originated in Realistic Mathematics Education (RME) which sees mathematics as a human activity (see Freudenthal, 1991). One of the basic principles of RME was students’ horizontal and vertical mathematising, described by Gravemeijer and Stephan (2002) as the passing of four levels of activity where a new mathematical reality is created at each level. The levels of activity were:

1. situational level with descriptions in natural language and own wording,

2. referential level where a ‘model of’ is created and inquired. A ‘model of’ is identified by the students’ use of situation related terms and half-way formalized explanations, for example, that ‘the number of sick persons will grow exponentially over time’,

3. general level with creation and handling of a ‘model for’. A ‘model for’ is identified by the students’ use of general expressions and terms with no visible relation to the situation, for example, that ‘We find that the graph of I(t) hits the maximum value if the parameter has a value of 0.259’,

4. formal level with general reasoning and considerations. For example, considerations and reflections about modelling with DE.

Horizontal mathematising is described as the passing from first to second level, vertical mathematising as passing further up. This four-layer model was the basis for the design heuristics of emergent models that aim to support the students’ processes of emergent modelling (Gravemeijer & Stephan, 2002). Gravemeijer (2020) described emergent modelling as an incremental process in which models and mathematical conceptions co-evolve. Central to the emergent modelling design heuristic is the use of a series of sub-models. Together they substantiate an overarching model which develops from a model of informal mathematical activity to a model for more formal mathematical reasoning. The overarching model is mental, with Gravemeijer (2020) mentioning, for example, the concepts of ‘distribution’ and ‘function’. In this view, modelling is not separated from mathematics nor from ‘reality’. The two goals, modelling for the sake of mathematics and mathematics for the sake of modelling, mentioned by Niss and Blum (2020), are here intertwined.

According to Cobb (2002, p. 193) the four-layer model might ‘facilitate (…) the analysis of mathematical learning in instructional situations (…). The explication of a mapping between a situation and a model might then be viewed as a description of the way that the situation became structured during modelling activity’. Based hereon, the four-layer model was in this study operationalized into a tool for textual analysis of reports to interpret the students’ mathematical concept formation. Signs, displayed by the wording in reports, of students’ activity were stratified regarding the levels. The progressive mathematization, then, was detected as progressive variation between the levels and interpreted as steps of the students’ concept formation, in the form of sub-models evolving into an emergent model. Accordingly, the mathematical learning outcome was conceptualized as emergent models of essential mathematical concepts, following Cobb (2002). This paper’s case study of modelling with DE was focused on sub models in the form of details of the interaction between populations. The overarching (mental) model was the mathematical idea to model interaction between two populations, namely foxes and small rodents, by the predator – prey differential equations model (Figure 1).

Students’ mathematical modelling

The modeling took place in a group of Norwegian teachers in a masters’ program that requires 60 ECTS in mathematics and two years of professional practice as a mathematics teacher. The teachers, in the following called students, attended the course ‘Modelling in and for mathematics teaching and learning’ which is a 15 ECTS course in a masters’ program in mathematics education.

The DE part of the course was based on Blanchard et al. (2002) which progressively build up the DE models and examples, and balance between qualitative, quantitative, and numerical methods. Hereby inspired, groups of students (2-3 persons) under sparse supervision were asked to formulate, complete, and present a project that encompassed a simple DE model, and to report the project. Each group choose what DE model they wanted to study. The course’s individual examination included an interview about this project (10 minutes). The students were expected stepwise to establish an overarching DE-systems model in a process, contrasting with bare application of a model, i.e., contrasting with picking out a ready-made model and fit its parameters with data. However, the students would not be able to establish a model stepwise from scratch, purely based on progressive mathematising and formation of sub-models. Therefore, they were free to involve and build on ready-made models like the predator-prey model and its modifications.

$$\frac{dx}{dt} = \alpha x - \beta xy,$$
$$\frac{dy}{dt} = \delta xy - \gamma y,$$

Where x is the number of prey, y is the number of some predator,

dx/dt and dy/dt represent the instantaneous growth rates of the two populations, t represents time, and α, β, ɤ, and δ are positive real parameters describing the interaction of the two species

Figure 1: The predator prey DE model

Methods

The research question was formulated in terms of a goal, i.e., the aim of the study was to identify the students’ learning trajectory for cyclic interaction between populations in the predator – prey DE model. The research question, hence, was: *What appearance can a learning trajectory have in a modelling process?* The study’s case was picked out of 21 reports prepared in 2014–2020 and evaluated by the author. The students were not familiar with De-models nor modelling in advance. For this presentation the cyclic interaction between populations was used as the example of an emergent sub-model. In the case, the students’ collective learning processes were documented by their own descriptions of the mathematical modelling activities, and by the reflections reproduced in the reports. The descriptions and reflections were reported in a convincing way: they used a first-person perspective in their writings in the report which is mentioned as a sign of being an active learner by Ju and Kwon (2007). This impression of validity was supported by the interviews under the individual examinations. The reliability of the analysis rested on the condensation of meaning from units of the convincing texts in accordance with the qualitative methodology described in Kvale (2001). The meaning of each unit was interpreted in accordance with the emergent modelling framework.

The textual analysis, presupposing that the students’ mental activities were reflected by the wording in their reports, served to stratify the mathematical learning process in terms of passing through the four levels, situational, referential, general, and formal. Each appearance of a mathematical concept or its related notions in the text was assigned to a level of activity in the four-layer model (Gravemeijer & Stephan 2002). Thereby, the marking served to stratify the signs of mental activity concerning the emergence of sub-models into the four levels of progressive mathematising. These signs constitute the study's documentation of the students' learning path or learning trajectory in the example.

Data

During the textual analysis all elements were coded and subsequently sorted by their (related) mathematical content. This case considers emergence of the sub-model cyclic interaction. The result, hence, of the textual analysis was a cluster of signs of activity at different levels concerning interaction between the populations of foxes and small rodents in the predator – prey DE model. Table 1 displays, chronologically, some of the excerpts in the cluster concerning (cyclic) interaction. The numbers in Table 1's most left column refer to the complete cluster. The level of activity refers to the four-layer model by Gravemeijer and Stephan (2002).

Table 1

Number	Excerpt, translated from Norwegian by the author	Level of activity
1	In the work with our model, we start from a simple model, and on the basis of the changed model, we study what happens to the prey population and the predator population. We will then expand the model and look at factors that are significant for prey-predator interaction. (…).	*Situational -> referential*; Horizontal mathematising
3	(…). It turns out that the number of mountain foxes varies in step with the number of small rodents (…). At population peaks of lemmings and other small rodents, we see that there is a large increase in mountain foxes. Correspondingly, there is a significant decline in the population of mountain foxes when the population of small rodents declines. In other words, reproduction increases for the arctic fox when the supply of prey increases. (…).	*Referential level*; number of foxes and number of small rodents are half-way formalized but still linked with the situation. The same goes for the peaks of lemmings and other small rodents, and the large increase in foxes.

5	 Figur 2: Tallmaterialet presentert i Geogebra. Figure 2	*General level*; Except for the figure text the graphs have no connection with the situation
9	Cyclic oscillations It is often the case that predator populations and prey are interdependent and that populations fluctuate depending on the number of the other species. If there is one species that eats another species, then we have two sizes that vary with time. In such a model, we will thus have two dependent variables, both of which are a function of time.	*Situational -> referential level* (horizontal mathematising)
12	Two of the factors are important to clarify the sign of: • $-\boldsymbol{\beta BR}$ will always be negative, except if $\boldsymbol{B}$ and / or $\boldsymbol{R}$ is equal to zero, because $\boldsymbol{\beta}> \mathbf{0}$ • $+\ \boldsymbol{\delta BR}$ will always be positive, except if B and / or R are equal to zero, because $\boldsymbol{\delta}> \mathbf{0}$ This means that if the prey population increases, then the growth rate of the predators will increase. A solution of this first-order system will be two functions, B (t) and R (t). • $\boldsymbol{B}\ (\boldsymbol{t})$ describes the prey population as a function of time. • $\boldsymbol{R}\ (\boldsymbol{t})$ describes the predator population as a function of time.	*General -> referential level* The first two bullets are at general level (no links with the situation), the text and the last two bullets interpret / link them with the situation
24-26	We perform the calculations using spreadsheets and draw the curve in Geogebra:  Figur 5: Løsningskurve for byttedyr-rovdyrsystem med initialbetingelser $(B_0, R_0) = (1, 0.5)$ We see that this curve has a characteristic oval shape that reflects that the number of individuals in the populations changes cyclically.	*General level*, *General -> referential level* Interpretation of the shape of the curve in the referential level (number of individuals changes cyclically)
36	(…) Phase diagram for different values of α: Initial conditions: (B0, R0) = (1, 0.5)	*General level.* The phase diagrams, though, are interpreted

	(…) What happens when a = 1?  *Figur 13: Fasediagram for a=1* See that there will be nice, smooth cyclical fluctuations. Predators (red curve) depend on prey (green curve). Can imagine that there are limited external factors that affect. What happens when a = 2?  *Figur 13: Fasediagram for a=2* See that there are smooth, cyclical oscillations. The peaks of the curves are higher than the peaks of the curves when a = 1. These curves are more similar to our starting point. (…)	and linked with the situation: The activity at general level is followed by experiments at *referential level* with different values of α (the model's parameter) in graphic representation, and then followed by interpretation into the situation of the results of the experiments

Comments to Table 1

Ad 1: Prey population and predator population and their interaction are at the situational level. The simple model is seen by the students as a means for study of the interaction between them on the one hand, and the study is intended to enrich and develop the model on the other hand.

Ad 3: Here the sub-model emerges; Peaks of small rodents give large increase in foxes and decline of small rodents give decline in foxes. Reproduction increases for the fox when the supply of rodents increases.

Ad 5: The emergent sub-model in a new graphic representation, re-produced by the students using GeoGebra.

Ad 9: The mentioning of two dependent variables is (cyclic) interaction at an early stage

Ad 12: Increase in prey population gives increase of growth rate of predators; this is initial characterization of interaction.

Ad 24-26 Solution curve, reproduced by the students. The number of individuals in the populations changes cyclically in accordance with the sub-model.

Ad 36: The cyclic interaction is identified in the graphs.

Results

The aim of the case study was to identify the students' learning trajectory for cyclic interaction between populations in the predator – prey DE model. As illustrated by Table 1, the report displayed signs of activity at situational, referential and general level and, in total in the report, shifts in both directions between these levels. Besides, the students' demonstrated representational literacy by shifting between plain language and wordings, formal language and formulars, and graphic representations in the report. In contrast with an (ideal?) smoother passing up through the four levels from situational to referential and further up to general, their learning trajectory can be identified as the complex cluster of their activities.

Learning trajectory for cyclic interaction as a cluster of activities

A brief sketch of the activities starts with the introduction in plain language (3) based on observations of population curves from a Norwegian official web site. Next, the students reproduce population curves in GeoGebra (5) and compare these. Then they introduce models for growth of populations in general terms. This introduction is detached from the graphs and from the plain language description. After the presentation of the general predator – prey model the students mention cyclic interaction for the first time (9) before they proceed to discuss qualitative and quantitative methods. They use Euler's formula and GeoGebra to prepare a curve that illustrate the cyclic interaction (24-26). Finally, they prepare a series of graphic representations (36) to compare with their initial data to control the cyclic interaction.

Perspectives

This cluster of activities can be seen as the result of the rich environment for the students' modelling. They had the general predator – prey model, series of authentic data, tools in the form of GeoGebra and others, and their own prior mathematical experiences as the resources to include. The students' initial task was open, and they had little guidance during their project and preparation of the report. At a first glance, the process and the report might appear messy with no clear goals and direction. In a classroom context, such unstructured student activities could easily trigger the teacher to act and make an intervention like, for example, asking the students' leading questions and guide their process. Taking the students' evident learning outcome into account in the present study, as it was evaluated in informal conversations and in the interviews at the oral examination, though, the process in which the students to a high degree worked without guidance from the lecturer showed to be fruitful. There seems to be a paradoxical discrepancy between the messy and unstructured process documented in the report on the one hand, and the learning outcome on the other hand.

Conceptualization of learning in terms of emergent modelling and models seems to be one promising way to explain this apparent paradox. In particular, the idea of learning trajectories as clusters of activity in these terms, may contribute to widen and nuance the discussion of the relations between mathematics modelling and the learning of mathematics. Metaphorically speaking, the non-linear learning fits well with the non-linear modelling represented not only in the four-layer model but also in the traditional modelling circle by Niss and Blum (2020).

Besides, the study presented in this paper can give inspiration to the development of research methods for inquiry of students' learning: the tool for textual analysis presented in this paper may be useful for studies based on data in the form of students' written reports and other materials.

Possible strategies to enhance students' learning and achievement in mathematical modelling teaching experiences

Caterina Bassi[1] and Domenico Brunetto[1]

[1]Politecnico di Milano, Department of Mathematics, Milan, Italy; caterina.bassi@polimi.it, domenico.brunetto@polimi.it

In the present work preliminary results about strategies to enhance students' learning and achievement in mathematical modelling teaching experiences are presented. The results confirm the importance of employing real world problems which are perceived as important by students. Moreover, they also suggest that the design of teaching experiences in which the initial steps of the modelling cycle can be carried out with a few or even any mathematical language could enhance students' perception of self-efficacy, thus providing a motivational push also for the subsequent steps, where specific disciplinary language must be employed. Finally, also the use of ICT and mathematical tools which are perceived by the students as belonging to the university and employment world can increase students' perception of value.

Keywords: Real-world problem, enjoyment, self-efficacy, modelling cycle.

Introduction and theoretical background

In the last decades mathematical modelling (MM) has been recognized as relevant both by scholars and educational policies for teaching mathematics (Barquero et al., 2019). However, bringing MM within the mathematical curriculum is demanding both for teachers and students, so that in everyday mathematics teaching practice, there is still relatively few genuine modelling (Blum, 2015). Indeed, MM requires mathematical and extra-mathematical knowledge, as well as appropriate beliefs and attitudes, especially for more complex modelling activities (Blum, 2015; Niss, 2003). We agree with the scholars that claim the relevance of affect factors for teaching and learning mathematics exploiting MM. In particular, we agree with the fact that using MM to deal with real world situations increases students' enjoyment and interest, motivates them and makes them retain longer what they learned. The research *problematique* of the present paper frames within two of the five leading themes emerged during the discussion of the thematic working group TWG6 at CERME 11 (Barquero et al., 2019), namely *T1. Analysis of modelling process when solving modeling problems* and *T3. Strategies to support design and implementation of modelling.* To that end, in this work we present the findings of a preliminary study about MM in high school.

Mathematical modelling and modelling cycle

The term *mathematical modelling* indicates the process of translating between the real world and mathematics in both directions (Blum & Borromeo-Ferri, 2009). More precisely, *a mathematical model* is a "deliberately simplified and formalized image of some part of the real world" (Blum, 2015, p. 77), such as nature, society, everyday life and other disciplines. The purpose of building and making use of a model is to understand how to tackle problems related to the real world (Niss et al., 2007). For our purpose, we focus on the modelling cycle (Blum, 2015; Greefrath, 2011), which is composed of seven steps within and between reality and mathematics (see Figure 1).

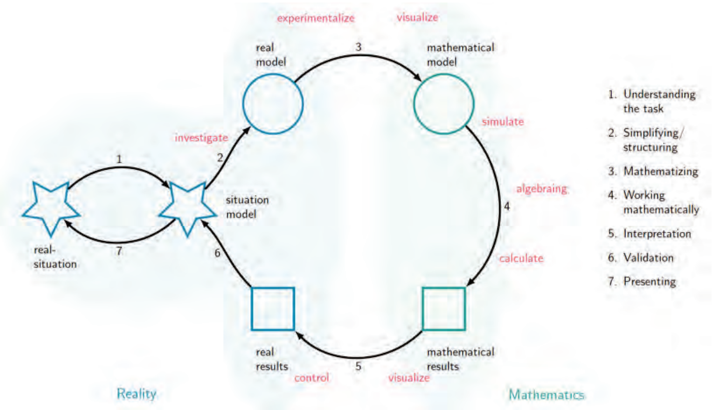

Figure 1: Blum's modelling cycle with added influence of digital tools (red terms)

The first two steps are within the reality and allow to move from the real situation to situation model (understanding) and to the real model (simplifying); the third step (mathematizing) bring to the mathematical model within the mathematics domain, where it is possible to work mathematically (step 4) reaching a mathematical result. The further two steps allow to go back to reality interpreting (step 5) and validating (step 6) the results. In the last step, the results (if any) are presented in the real situation. According to Greefrath (2011), we share the importance of digital tools along such a cycle. For instance, a digital tool may support the learner to calculate in step 4. Teaching mathematics using MM means to carry out all steps of the modelling cycle and drive students through them. To achieve that, certain competencies or sub-competencies are required (Niss, 2003), for instance understanding a given real world situation or interpreting mathematical results in relation to a situation (Blum, 2015). Modelling competency means the ability to construct, to use/apply mathematical models by carrying out appropriate steps as well as to analyze or to compare given models (Blum, 2015). Moreover, non-mathematical and extra-mathematical knowledge are required for MM. As a result this activity is highly demanding: several studies (see Blum (2015) and the references within) have shown that each step can be a cognitive barrier for students, even the first one "understanding the situation and constructing a situation model".

Affect framework

The role of affect factors, such as "emotions", "beliefs" and "attitudes", is pivotal in learning mathematics, also when students deal with problems (Schukajlow et al., 2012; Hannula, 2012). The characterization of affective factors is challenging for the researchers, because affective variables tend to form a cluster (Liljedhal, 2018). But in one of the possible classifications, Hannula (2012) identifies three types of affects: i) *cognitive* (e.g., beliefs), ii) *motivational* (e.g., values), and iii) *emotional* (e.g., feelings). *Cognitive* type refers to the affect variables that concern the beliefs towards the learning process and the achievement. We dwell on the self-efficacy belief (Bandura, 1977), which is the engine for mathematical thinking and doing (Andrà et al., 2020). More precisely, self-efficacy is a major factor in whether students will attempt a given task, how much effort they will put on it, and how resilient they will be when difficulties arise. Self-efficacy beliefs can be represented with the variable "I can", that range continuously from zero (lack of) to a maximum (strong) (Andrà et al., 2020). *Motivational* type concerns value and interest. The value is the perceived importance attributed to something (Eccles & Wigfield, 2002), while the interest concerns a specific relationship between a person and something in one's "life-space" (Krapp, 2000, p.111). Value and interest are nuances of motivational factors, for instance one can recognize that mathematical skills are valuable for obtaining a specific job but has not any interest in developing mathematical skills because that job is not part of one's "life-space". Finally, *emotional* types are all those feelings which do not belong to the previous ones. Emotions prepare our actions, accompany these actions, and influence reflection about their outcomes (Schukajlow et al., 2012). Among them, we distinguish positive and negative emotions (Pekrun et al., 2002), that can be task- and self-related or social related. For instance, *hope*, *boredom* and *anxiety* are task- and self-related emotions, while *sympathy* and *antipathy* are social related. In this paper we strongly focus on the emotion *enjoyment*, since it has been proven that there is a positive correlation between students' enjoyment and academic achievement (Pekrun et al., 2002). The levels of enjoyment can be seen as nuances of the variable "like" (Di Martino & Zan, 2015), that can range continuously from zero (boredom) to a maximum.

Research questions

We recall that the rationale behind the present study is the problematique of finding possible strategies which can be employed in the design of mathematical modelling teaching experiences in order to enhance students' learning and achievement. In particular, due to the strong connection between learning process and affective factors, we formulate the following specific questions: RQ1. Which activity carried out during the project the students enjoy the most? And RQ2. Which affective factors, cognitive and motivational, linked to the emotion enjoyment, can be associated to the different activities of the project?

Methodology

The research context

The present study, which is part of a wider MM project, involved two researchers (the authors), 18 students (grade-11) and their teacher. The data analyzed in this work has a peculiarity because the didactical situation stems from a real-world problem posed by a stakeholder. The alderman to the culture of a small town wanted to know how young people use and what they would like to find in the municipal library. The stakeholder involved the local high school for answering her question. The project was carried out through eight meetings of two hours each. The first three meetings, delivered as frontal lessons by statistics experts, aim at providing some fundamental statistical instruments. The remaining five meetings, delivered by the authors of the paper, had a student-centered approach such as group work and classroom discussion and focused on the mathematical modelling process. Such methodologies have been used since they have proven to be particularly suited for modelling activity: they are able to activate students both cognitively and metacognitively (Blum, 2015) and they have a positive impact in terms of enjoyment, interest and self-efficacy (Schukajlow et al., 2012). Since the question posed by the stakeholder is open-ended, as highlighted in (Blomhøj et al., 2003), this could generate in the students a feeling of "perplexity due to too many roads to take and no compass given". For this reason, the students have been guided through the modelling process by means of the activities described in the following subsection.

The mathematical modelling activities

The question posed by the stakeholder (how young people use and what they would like to find in the municipal library) has been investigated by means of a survey which has been built and successively analyzed by the students using statistical and ICT instruments. In the last part of the experience the students wrote a scientific report which has been delivered to the stakeholder. The activities were designed to allow students to pass through all the steps of the Blum's modelling cycle, but the ones considered in this work are related to steps 2, 3, 4 and 5. More precisely, during activity A1 (*Proposing the more relevant questions*) students were asked to work in groups and propose questions for the survey, suggesting them to take inspiration from surveys to which they answered in the past and from the internet. Then, they were asked to identify which dimensions (e.g., frequency of attendance, reason for attendance) of the phenomenon "library" their questions aim at exploring. Finally, the questions were classified according to such a criterium. Therefore, students discarded the questions which were not relevant with respect to the stakeholder's request. Thus, A1 is related to the "step 2. simplifying/structuring" of the Blum's modelling cycle. While activities A2 (*Formulating the questions for the survey*) and A3 (*Formulating the answer options for the survey*) are linked to "step 3, mathematizing". Indeed, during such activities, the students were asked to work in groups on the formulation of questions and answers to make them as clear as possible for the participants to the survey, to reduce possible ambiguities in their answers and to answer effectively to the initial stakeholder's question. The main part of such activities concerns the characterization of variables beyond the identified dimensions. Roughly speaking, the students decided which form to give to a particular question (e.g., Likert scale, open question, multiple choice). Even if it isn't written in mathematical language, the survey produced by the students is the mathematical model of the initial problem posed by the stakeholder. Activities A4 (*Using the statistics software R*) and A5 (A*nalyzing the results of the survey*) are strongly intertwined. In activity A4, a lesson-tutorial about the software R has been delivered to the students and the students were asked to practice with the software, with given datasets and with some preliminary data coming from the first draft of the survey. While during activity A5, the students were asked to work in groups with the software R to analyze and to interpret the results of the survey. We can then relate both activities A4 and A5 to step 4 ("working mathematically") and 5 ("interpreting"). In particular, the software R support the students in "calculate" and "visualize" (Greefrath, 2011).

Data gathering and method of analysis

The participants of this study are 18 high school students (grade-11), 4 male and 14 female. The average grade of the class in maths is good (6.9 over 10), according to their last report card. To address the above research questions, one survey has been developed and administered online by google form the day after the last meeting. The survey is composed of a set of Likert (5 levels) questions and a set of open questions, according to the narrative analysis (Di Martino & Zan, 2015). Question Q1 and Q2 investigate the "like" and "can" variables, respectively. They ask students to rank each of five activities according to their level of "like" and "can", more precisely: *Q1. Consider the following activities you took during the project and indicate how much you liked them from 1 (I didn't like it at all) to 5 (I liked it very much). Q2. Consider the following activities you took during the project and indicate how much you perceived it as easy from 1 (Not easy at all) to 5 (Very easy).*

For questions Q1 and Q2 and for each activity the mean of the answers has been computed. Cognitive, motivational and emotional factors related to the emotion enjoyment have been investigated more in detail by means of the following two open questions: *Q3. Choose the activity that you liked MOST among the options of the previous question and describe what you liked of that activity and why. Q4. Choose the activity that you liked LESS among the options of the previous question and describe what you DIDN'T like of that activity and why.*

The answers to both questions have been qualitatively analyzed based on the affective types which can be retrieved in them. These types have been identified in students' answers by means of keywords and sentences. For example, the answer *"Formulating the questions for the survey because we had interesting discussions and it was also easy"* is labelled as both motivational type (interest) and cognitive type (self-efficacy). Finally for each activity, the frequency of a particular type has been computed.

Data analysis and findings

Figure 2 (left) summarizes the analysis of the responses to question Q1 and Q2. For each activity, we employed the mean of the score assigned for the level "like" and "can". In this way each activity can be seen as a point in the cartesian plane. We can notice that the activities which have been enjoyed the most were activities A2 (Formulating the questions for the survey) and A3 (Formulating the answer options for the survey), closely followed by activity A1 (Proposing the most relevant questions). We then find at an intermediate level activity A5 (Analyzing the results of the survey), while activity A4 (Using the software R) has been considered as the less enjoyable one. Figure 2 is also a first indication about the fact that, as expected, high levels of enjoyment (I like) correspond to high levels of perceived control and self-efficacy (I can), even if for all the activities the "I like" level is greater than the corresponding "I can" level.

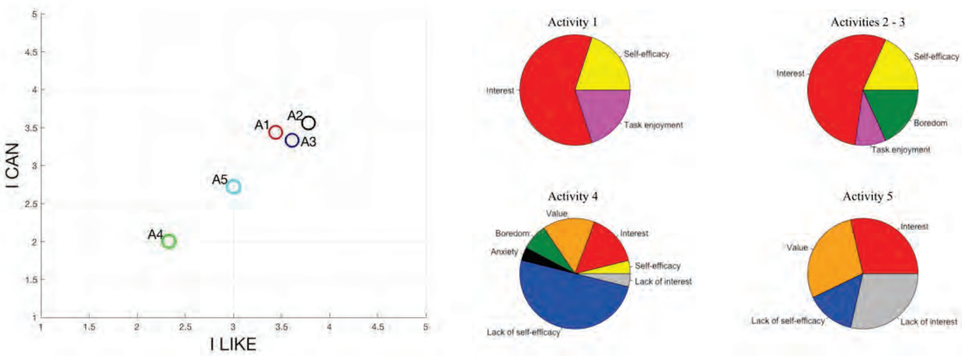

Figure 2: Left: Graphical representation of the dimensions I can – I like. Right: Frequencies of emotional, motivational and cognitive types for the different activities

In order to identify which cognitive, motivational and emotional factors, related to the emotion enjoyment, are reported by the students when carrying out different activities (RQ3), we analyze the answers to the open questions Q3 and Q4. Figure 2 (right) shows the overview of such an analysis, and in the following we report detailed examples of the students' responses.

Considering activity A1, 5 students have indicated it as the preferred one. Analyzing their answers, we notice that the motivational factor (interest) is the more frequent justification for their enjoyment, as can be seen from the following answer: *"thinking about the questions because they are tightly bound to reality"*. In other answers we can retrieve the emotion of task related enjoyment and the self-efficacy: *"because in general I like sharing my point of view with other people and discussing points of view different from mine [...]"* and *"We have been challenged in finding questions inherent to the project which had to be carried out"*. Activities A2 and A3 have been indicated as the most enjoyable ones by 6 out of 18 students. Also for these activities interest was the most popular justification. Moreover, confirming the trend highlighted in Figure 2, also the self-efficacy and perception of control emerge: *"[...] because we had interesting discussions and it was also easy"*. As we can notice in Figure 2, even if activities A1, A2 and A3 have been appreciated by the majority of students, their score in terms of "I like" is not the maximum possible. Analyzing the open question Q4, we can infer that these activities have sometimes triggered negative emotions, like boredom: *"[...] because, for what I am, I didn't find this activity exciting and sometimes boring"*. We now consider activity A4, using the statistics software R, which has been chosen as the less enjoyable activity by 15 out of 18 students. Confirming the trend reported in Figure 2, we can notice that the lack of control and self-efficacy is the most frequent reason for their choice, as can be seen from the following answer: *"I wasn't able to use the software as I would have to"*. In other cases, the activity also triggered negative emotions, as anxiety and boredom: *"Using R needs precise codes and high attention in every little detail of them otherwise an error is computed"* and *"The initial approach was difficult and, since we spent many hours using R, the activity seemed quite repetitive to me. Overall, it was however interesting learning this new language"*. Notice that in the last few lines of the previous answer also the interest factor comes out. Even if activity A4 was the less preferred activity for the majority of students, 3 students out of 18 have indicated this activity as the preferred one. Also in their answers we can recognize the types of interest and value: *"Using the statistics software R is the activity I enjoyed the most because it was a new experience and mostly because it can be useful for my future studies"*. Activity A5 was preferred by only 3 out of 18 students, due to value and interest: *"To me it seemed the most useful and interesting thing among the different activities"*. Summing up, for activities A1, A2 and A3, which have been considered as the most enjoyable, enjoyment is mainly associated to positive types such as interest and, to a lesser extent, task related enjoyment and self-efficacy, even if also the negative emotion of boredom emerges. Activity A4, which has been evaluated as the less enjoyable, triggers mainly negative types. The most frequent one is the low self-efficacy. However also positive motivational types, such interest and value, come out. Finally, in activity A5, which has received an intermediate score with respect to enjoyment, positive and negative types are more balanced: we find in similar proportions value, interest and lack of self-efficacy and lack of interest.

Discussion and conclusions

This study focuses on the relation between the emotion enjoyment and mathematical modelling activities. More precisely, we wonder which activity the students enjoy the most and which cognitive and motivational types can be associated to the different activities. Briefly, we were able to identify self-efficacy and lack of self-efficacy, concerning the cognitive factor; value, interest and lack of interest for the motivational factor; task enjoyment, boredom and anxiety for the emotional factor. Back to the MM, in Section 4 we argue the correspondence between activities and steps of the Blum's modelling cycle. Focusing on "Simplifying" step (activity A1), Blum (2015) argues that this step is usually challenging for the students since they are not used to making assumptions by themselves. However, in our case students show a high sense of self-efficacy. An explanation could be the strong link with reality of activity A1, which could have enhanced students' interest. This is a confirmation of the fact that the employment of real-world problems felt as important by students is fundamental in order to make students interested. Also for the "Mathematising" step, a potential cognitive barrier, students' answers show high levels of self-efficacy. In this case an aspect which could have impacted is the fact that this step has been realized without employing explicitly specific mathematical language. In fact, in activities A2 and A3 only common language was employed. The design of teaching experiences in which a few specific mathematical language is employed in the "Mathematising" step, could increase students' perception of self-efficacy, thus providing them a motivational push also for the following steps of the modelling cycle. On the contrary, in activities A4 and A5, associated to the Blum's step of "Working mathematically" and "Interpreting", the students' difficulty in dealing with mathematical language and problems linked to instrumental genesis strongly come out: the lack of self-efficacy is the cognitive factor more frequently reported in their answers. However, also for these steps, which have been perceived as difficult, the students reported positive motivational types such as interest and value. In particular, value was instead absent in the students' answers referring to the "Simplifying" and "Mathematising" steps. An explanation for this could be that students perceived the statistical and ICT tools as close to the university and employment world, thus contributing to raising the perceived value of the "Working mathematically" and "Interpreting" steps. The use of such tools could be important to enhance the value students attribute to the modelling experience. In order to verify the hypotheses just exposed we are planning to extend the present study by involving more students and by designing additional modelling teaching experiences based on different real-world scenarios.

Towards a dual integrated modeling approach to the teaching and learning of mathematics: Challenges and tensions in implementation

Jonas Bergman Ärlebäck[1] and Peter Frejd[1]

[1]Department of Mathematics, Linköping University, Sweden;
jonas.bergman.arleback@liu.se, peter.frejd@liu.se

This paper elaborates on the theoretical conceptualization of a so-called dual integrated modeling approach to the teaching and learning of modeling and the teaching and learning of mathematics through modeling. Departing from a sociocultural perspective on teaching, the models and modeling perspective, and using the previously developed theoretical constructs of the Teaching Triad and the Expanded Mediated Triangle, we discuss modeling in terms of (i) micro modeling in which modeling is used as a vehicle to teach and learning other curricula content; and (ii) macro modeling in which modeling is a self-standing mathematics curricula goal. We illustrate this dual integrated approach by analyzing and discussing a lower secondary teachers' implementation of a modeling activity focusing on a simple statistical investigation and measures of central tendency in statistics.

Keywords: Dual integrated modeling approach, expanded mediational triangle, measures of central tendency, models and modeling perspective, teaching triad.

Introduction

There are different goals and rationales for implementing modeling tasks in the teaching and learning of mathematics (Blum & Niss, 1991; Kaiser & Sriraman, 2006). One way to broadly characterize these is to draw on Julie and Mudaly's (2007) discussion of modeling as either *a self-standing mathematical content* or as *a vehicle for learning other more specific (mathematics) ((curricula)) objectives* (see also Niss & Blum (2020)). By enabling the option to put 'mathematics' and 'curricula' in brackets in the last sentence, "*(mathematics)*" and "*((curricula))*", the latter category then includes socio-critical and discursive perspectives on modeling (cf. Barbosa, 2006) as well as ethnomodeling (Orey & Rosa, 2021). There are plenty of examples of research studying modeling as understood more or less exclusively in one or the other of these two categories. In the case of modeling as a self-standing mathematical content much research focusing on the development of students' modeling competencies qualifies, see Cevikbas et al. (2021) for examples. Regarding modeling as a vehicle for learning other more specific (mathematics) ((curricula)) content, Barbosa (2006) and Orey and Rosa (2021) illustrate this strand of research, as do much of the research carried out based on the realistic mathematics education (RME) programme (cf. Gravemeijer, 1999). However, theoretical and empirical research on integrated modeling approaches, combining both rationales and goals outlined above and given close to similar emphasis on both, is to our knowledge spares. Even in the so-called *educational modeling perspectives* (cf. Kaiser & Sriraman, 2006), which potentially have pedagogical as well as subject-related goals, are commonly divided into two strands focusing either on *didactical modeling* or *conceptual modeling*.

In this theoretical paper, we seek to start building and elaborating on a theoretical foundation for a dual integrated modeling approach based on the models and modeling perspective (MMP) (Lesh & Doerr, 2003). We use the MMP to at the macro level of teaching focus on modeling as a self-standing mathematical content in its own right (*macro modeling*), as well as at the micro level of teaching using modeling as a vehicle for teaching more specific mathematical content matter (*micro modeling*). In terms of Blum and Niss' (1991) six basic approaches to include applications and modeling in mathematics teaching and learning, our conceptualization of this dual integrated modeling approach is akin to what they term "*[T]he interdisciplinary integrated approach*" (p. 61, italics in original).

As part of our initial work and ongoing thinking, we in this paper outline our current theoretical conceptualization of this dual integrated modeling approach. We also report on a first attempt to apply this framework as an analytical lens, to discern its adequacy to capture aspects and challenges of teaching that arises when the dual approach is implemented in the classroom. The question guiding our theoretical exploration in this paper is: *What teaching challenges come to the fore in the initial phase of when a teacher tries to adapt a dual integrated modeling approach in his/her teaching?*

To further theorize, we use a sociocultural perspective on teaching to try and capture and describe teaching challenges on both the micro- and macro level of the teaching and learning of, and through, modeling, when a lower secondary teacher implements a modeling activity involving a simple statistics investigation focusing on measures of central tendency in statistics.

Theoretical considerations

We now elaborate on the notion of the dual integrated modeling approach adapted in the paper, and how we conceptualize modeling at both a micro- and macro level (*micro*- and *macro modeling*) using the Teaching Triad (Jaworski, 1994) and the Expanded Mediational Triangle (Engeström, 1998).

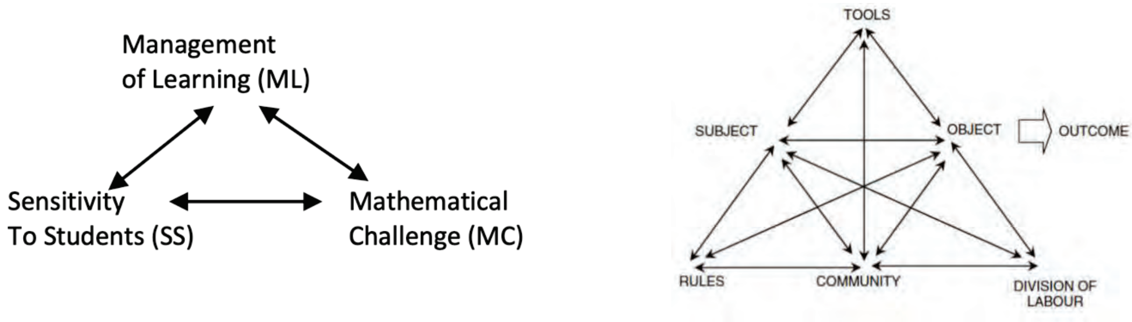
The models and modeling perspective

The perspective on modeling adapted in this paper is the *models and modeling perspective* (MMP), in which a model is defined as a general system consisting of elements, relationships, rules and operations that can be used to describe, predict, make sense of, or explain some other system. A mathematical model focuses on the structural characteristics of the system at hand (Lesh & Doerr, 2003). Learning from a MMP is understood as developing useful and generalized models consisting of a set of concepts and procedures. The concepts are used to describe or explain the mathematical objects and aspects in the context relevant to the phenomenon studied using or re-using the procedures to engage in or create goal-directed constructions, manipulations, or predictions (Lesh & Harel, 2003). In the MMP three different types of structurally related activities organized in so-called *model development sequences* can be used to purposefully support students' learning towards a given learning goal: *model eliciting activities* (MEAs) which aim to elicit the students' ideas they bring to the activity; *model exploration activities* (MXAs) that focus on the underling mathematical structure elicited by students; and *model application activities* (MAAs) were students apply their models in similar or new contexts (Lesh et al., 2003). In all three types of activities students iteratively engage in expressing, testing, revising, and developing their models (Lesh & Doerr, 2003; Lesh et al., 2003).

The Teaching Triad and the Expanded Mediational Triangle

Following Jaworski and Potari (2009) and Jaworski et al. (2017) we in addition stress the sociocultural aspects of teaching as a mediating process connecting the content of mathematics, students, and teachers. In particular, we elaborate on the notions of *micro*- and *macro modeling* from both an institutional perspective and the nature of more local interactions between teachers and students engaged in modeling activities.

The Teaching Triad (TT) captures three interdependent and interlinked dimensions of teaching (see Figure 1a): *Management of Learning (ML)* aims at describing the organization of the learning environment by the teacher such as the planning and orchestrating of tasks and activities, use of resources, and forms of working in the classroom; *Sensitivity to Students (SS)* focuses on students' affective-, cognitive- and social needs and the ways in which these are considered by the teacher in interactions; and *Mathematical Challenge (MC)* on what mathematical content, thinking and activities are offered to students in the learning environment including for example posed questions, sets and sequences of tasks, and metacognitive demands and processing.



(a) (b)

Figure 1: (a) The Teaching Triad (Jaworski, 1994); and (b) The Expanded Mediational Triangle (Engeström, 1998)

The Expanded Mediational Triangle (EMT; see Figure 1b) by (Engeström, 1998) models the structure of human activity built around Leont'ev's three levels of human activity where the concepts *activity*, *action* and *operation* are central and dialectical theoretical constructs. An *activity* is described as a complex evolving structure of mediated and collective human agency connected to specific *motive* that both distinguishes activities from each other and gives the activity directionality. Activities are constituted by *actions* directed toward specific and conscious *goals* that realize and sustain the activity. Actions in turns are constituted of *operations* that realize the actions in the activity and are carried out under the premises determined by the *conditions* of the activity and the environment in which the activity takes place (Leont'ev, 1979). In the EMT, the *subject* transforms the *object* into an *outcome* using *tools* and artifacts. However, the mediation facilitating this transformation is both supported and conditioned by the culture and *community* carrying out the activity. Here, the *rules* account for norms, conventions and regulations within a community or activity, whereas the *division of labour* highlights both the actual division of labour and responsibility for achieving the goal/motive of the actions/activity and status- and power relations within the community (Engeström, 1998).

The dual integrated modeling approach: micro- and macro modeling in terms of TT and EMT

In terms of EMT, we consider the activity in the dual integrated modeling approach to be the teacher teaching mathematics with the overall motive of the activity for the students to learn mathematics within the boundaries of the teacher's and students' school setting. The actions that constitute the activity are the actions of the teacher as s/he based on her/his set goals interact and engage with the students to support their learning. One of the goals in the dual integrated modeling approach is for the teacher to draw on and implement the ideas and principles of the models and modeling perspective, and indeed to for the students to learn modeling, meaning for the teacher to make the students cognizant about the modeling processes that inherently comes with the way of working based on the models and modeling perspective and with model development sequences (macro modeling). In realizing the actions, the teacher carries out various operations conditioned by the conditions manifested in the activity and the institutional and cultural setting in which the activity is carried out. In other words, and analogous to Jaworski et al. (2017), we conceptualize the teacher as the *subject* in the activity with the *objective* to teach and support students to learn and make sense of mathematical content (such as modeling as a self-standing mathematical content – macro modeling). The teacher does this using various *tools* in mediating the mathematics – including pedagogical and didactical strategies and theories – and in particular the elements of the models and modeling perspective and micro modeling (modeling as a vehicle). However, the mediation of mathematics is in addition supported as well as conditioned by the cultural norms of the schooling (*community*), the school's norms and regulations (*rules*), and status- and power relations between actors in the classroom (*division of labour*).

In the dual integrated modeling approach this framing using the EMT is complemented by the TT framework to really focus in on the acts of teaching and how the teachers' actions and managing of the learning are related to the mathematical content and the students' learning – and in particular the role and function of all aspects related to micro modeling (the use of modeling to teach other content) and how these relate and support developing macro modeling as a mathematical content to be learnt.

An example of the use of the dual integrated modeling approach

The example we will now discuss and theorize on comes from a grade 7 classroom of 22 students of which the majority was girls (86%). The class was considered to be somewhat loud and challenging to keep on track in order to not lose focus on the topic at hand and the work needed to be done (providing clues about governing behavioral- and interactional norms in the class (community) as well as the power- and status relations in the classroom (division of labour)). The teacher had taught the class for almost a year at the time when the modeling activity, The Paper Helicopter Activity, was implemented.

The teacher participated in a project aimed at developing the teaching of statistics using the MMP, and he was familiar with, and had some prior experiences with, the fundamental philosophy and ideas of this perspective. In the context of this paper, the adoption of the MMP as the framework guiding and supporting the design of the learning opportunities for the students, induced principles for how to implement micro modeling in terms of model development sequences. With respect to the content matter of statistics being in focus in the project, simple statistical investigations and measures of central tendency in statistics, macro modeling in the context of this paper is (somewhat artificially) equated with the whole statistical (model) investigating process.

In addition, one of the goals the teacher expressed for participating in the project was to be able to work more independently from the textbook used in the school (breaking an established rule) and for his students to be comfortable in not relying on the textbook all the time as the sole source for mathematical knowledge and truth, and hence wishing to change the epistemic status of the textbook (a community norm) as well as its authoritative status (shifting the division of labour).

Within the project focusing on the teaching of statistics, the teacher and the two authors together developed a sequence spanning 12 lessons of on average 60 minutes covering the statistical content prescribed in the curricula; mainly descriptive statistics, simple statistical investigations, and measures of central tendency (mean, median and mode). The allocated amount of time and predefined mathematical subject-matter content establish natural conditions on what actions and operations were feasible to implement and enact to support the students mathematical learning. To document the teaching, the classroom was videotaped using two cameras: one following the teacher's movement and actions in the classroom which in addition picked up all his interactions and conversations (using a small portable microphone); and a fixed camera in the back of the classroom facing front to capture the dynamics of the classroom. The teacher also recorder short pre- and post-lesson audio-memos to document the teachers thinking regarding the goals and plans made before the lesson, and then the teacher's reflections on what happened in the classroom in relation to these goals and plans during the lesson. All audio-memos were collected, as were all the written work done by the students. In the account provided here we only draw on the video and audio data. Next, we use data from this project in a first attempt to apply and evaluate the outlined dual integrated modeling approach as a lens to identify and teaching challenges that surfaced during an implementation of a modeling activity involving a simple statistical investigation and focusing on measures of central tendency in statistics.

Identifying of teaching challenges applying the dual integrated modeling approach as a lens

As part of the sequence of the 12 lessons on statistics the teacher introduced an adapted version of the paper helicopter activity originating from the work by Box (1992) who used it to teach experimental design to engineering students. The activity has also recently been used as a modeling activity involving conjecturing, experimenting, and evaluating 10-11-year-old students' ideas about statistical distributions (Kawakami, 2017). In the activity, the students were presented with a scenario to evaluate three competing designs of airdrop devices by conducting a small statical investigation of miniature replicas of the designs in terms of paper helicopters (see Figure 2). The aim for the students were to decide which helicopter (a) had the longest flying-time; and (b) which was the more accurate in terms of coming closets to the airdrop target – and also considering if difference in the loaded weight might influence the decisions. The class worked on the activity on and off during four consecutive lessons (lessons 6-9 in the sequence), whereby we will focus on the first two lessons.

Figure 2. Helicopter

In the first lesson, the teachers used 20 minutes to introduce the activity using a by the researchers pre-prepared PowerPoint presentation (a new tool) aimed at raising the students' interest and provide a meaningful as well as motivating framing for the activity. This had the effect that the class fell dead silent and focused all their attention on the teacher's introduction. This behavior was atypical for the class in question, indicating that the use of this type of presentations might be an effective strategy in managing the learning (ML) to tackle this class' students' attitudes toward mathematics and what it means to do mathematics in a, for the students, intriguing and inspiring way (SS), and hence make them better prepared to engage in the mathematical challenges (MC) to come. The introduction ended with the teacher leading a MEA-inspired whole class discussion around the questions *What features of the paper helicopter affects its (a) precision (how far from the intended target it lands)? (b) travel time (time spent in the air after being released?* and *How do you think these different features affect the precision and travel time of the helicopter?* The features suggested by the students to affect the precision were wind, distance to fall, air pressure and gravitational force. Features suggested to affect the travel time were the size of the rotor blades, the weight of the helicopter, the body-shape of the helicopter, and the falling velocity. Note that all the features related to precision are about external factors that might affect the behavior of the helicopter rather than actual features *of* the helicopter.

The second lesson (70 minutes) began with the teacher recapitulating and discussing the students' suggested ideas of what factors might influence the paper helicopter. The teacher explained that the class were to evaluate three competing paper helicopter designs by collecting and analyzing data to determine which design is the best. In addition, the teacher also qualified the explicit goal of the activity to in addition investigate (i) if heavier load decreases the travel time? (ii) if heavier load increases the precision? (iii) if larger rotor blades increase the travel time? and (iv) if larger rotor blades increase the precision? After having established these goals, the teacher turned to illustrate an airdrop with a prepared cut out paper helicopter, explicitly showing how to fold the rotors of the helicopter to form a suitable angle relative to its body, how to hold it to minimize interference on its trajectory, and from what height to drop the helicopter (the edges of the ceiling lamps). In doing this, the teacher also multiple times explicitly stressed the need for the students to be consistent in their experiment procedure and data collection. Initially, this way of managing the learning (ML) was interpreted as being over-sensitive to the students' needs (SS) just to get them to understand the mathematical challenge at hand (MC). However, this later turned out to be an important clarification act by the teacher to eliminate misconceptions, as the students' following discussions revealed that some of the student had the impression that the task dealt with real maneuvering helicopters.

Most of the time in the second lesson were spent on collecting and analyzing the data in groups. The students took measurement series of 10 values using either 0, 1 or 2 paperclips as helicopter wight. At this point the students were not totally free to explore the data and think about how their data set could be used to answer the posed questions. Rather, they were implicitly prompted by the semester overall planning listing the content for the week as "mean, median and mode" as well as explicitly by the teacher's statements like "I wonder what the mean, median and mode of that data will tell us about which helicopter is best?!". Here, a tension between two conflicting goals came to the fore: the teacher's goal for the students to engage in realistic statistical investigation and to freely explore the data set (macro modeling) on the one hand, and to use the activity as a context for the students to learn more about (and apply) mean, median and mode (micro modeling). This tension was then accentuated when the nature of the students' collected data not in all cases was suitable for determining the mode of the data.

In summary, the first attempt to apply the dual integrated approach as a lens on a teaching sequence provided information on teaching challenges related to establishing student's autonomy for learning both micro and macro modeling simultaneously. The teachers' role, highlighted by our theoretical analysis, of directing students on what to learn and at the same time leave enough space and time for students' own experience in both micro and macro modeling is at the core of the teaching challenges.

Discussion and conclusions

This paper provides the first steps of theorizing toward a theoretical conceptualization of a so-called *dual integrated modeling approach* to the teaching and learning of (i) modeling; and (ii) mathematics through modeling. In this initial work, a potentially fruitful interplay between what is discerned from the TT- and the EMT-related framing of the ongoing teaching has come to the fore. On the one hand, the EMT provides a background helping to contextualize and deeper understand the relationships and dynamics revealed in the TT-based analysis of students' learning as mediated by the teacher's actions in managing of the mathematical challenges (MC) while being sensitive to students' various needs (SS) given the organized and planned management of learning (ML). An example of how the EMT elevates the effect of the teacher's actions, is the effect the use of the introductory PowerPoint had on focusing the students and making them more susceptible and ready to engage with the mathematical content. On the other hand, challenges for the teacher in obtaining the learning goal revealed by the TT-based analysis highlight conflicts and tensions between the micro level of teaching as constrained by institutional and cultural aspects manifested at the macro level provided by the EMT. As such, the TT-based analysis might be helpful in pointing at more systemic oriented changes needed in the EMT to improve the teachers' possible actions to increase the students' opportunities to learn mathematics in the classroom. This could for example be introducing a new tool such as a pedagogic strategy or assessment tool that facilitate the teacher in transforming his/her objectives for the students to learn mathematics toward the desired outcome, or to pin-point where measures need to be taken, such as replace dysfunctional power relationships (division of labour) or classroom behavioral norms (rules).

The development of the dual integrated modeling approach is just in its infancy, and all notions and concepts still need to be further concretized and elaborated. However, our analysis shows that the dual integrated approach as a lens provides some useful information for developing teaching practice, and we hope that what we have presented in this paper can spark an interesting discussion and result in productive suggestions for how to continue develop this line of thinking and theorizing.

A topic-specific design research approach for modelling Covid-19 in grade 9 and 10

Lukas Donner[1] and Sebastian Bauer[2]

[1]University of Duisburg-Essen, Essen, Germany; lukas.donner@uni-due.de

[2]Georg-August-Universität, Göttingen, Germany; sebastian.bauer@uni-goettingen.de

Keywords: design research, iteration, epidemiology.

Method and Description of the research topic

In the framework of topic-specific design research, see e.g. Gravemeijer and Prediger (2019) and the literature cited therein, we consider dynamical systems both from content and design perspective. We report on the introductory two steps of the design research cycle according to the FUNKEN model by specifying and structuring the content and discussing initial ideas for design development. As a result, we outline a first teaching-learning arrangement dealing with discrete epidemic models. Design experiments are to follow in a next step.

Specifying and structuring the content, design principles

On a formal level (Gravemeijer and Prediger, 2019, p.47), Epidemiology is both an interdisciplinary field and highly relevant for understanding the global issues in treating the Covid-19 pandemic and therefore chosen as underlying topic. The professionally recognised basic model is the SIR model according to Kermack and McKendrick (1927), which is used both in a discrete and in its continuous variant. Our design goal is a teaching-learning arrangement for grades 9 and 10, so for curricular reasons only discrete models can be considered. On a semantic level the proposed arrangement is intended to tie in with exponential growth, the idea of iteration and simultaneously to enable a wide range of modelling activities. As a design principle, we use the four-step model "Mathematise → Mat. Work → Interpret → Validate" (Blum, 2015, p. 82). Our second design principle is visualisation to support structuring. Students are asked to work with the aid of flow-charts throughout the intended tasks, which is an excellent tool for clarifying complex iterative processes by providing a stringent pictographic representation (Sommer and Venke, 2020). For an example of a possible flow-chart see Figure 1. The teacher should focus on supporting students by translating the flow-charts into formal difference equations. The use of a spreadsheet program (e.g. Excel) and the graphical representation of the results scaffolds mathematical working.

Sketch of the developed design

We organise the modelling activities according to runs of the modelling cycle. In each step, a difference equation is set up (mathematisation), implemented with help in a spreadsheet programme (inner-mathematical work), the result is displayed graphically, interpreted and validated.

Exponential model: $I_{n+1} = I_n + \alpha I_n$. Focus in this step lies on the *effective contact rate* α giving the average rate of contacts of an infected person leading to a new infection. Problem: Exponential growth. After a while there is nobody left, who could be infected.

SI-model: In addition to the class of the infected I, the class of susceptibles S is introduced. The probability that the contact person of an infected is susceptible is modelled by the Lagrange probability $\frac{S}{N}$ where N is the size of the whole population $N = S + I$ leading to the difference equations $S_{n+1} = S_n - \alpha \cdot I_n \cdot \frac{S_n}{N}$ and $I_{n+1} = I_n + \alpha \cdot I_n \cdot \frac{S_n}{N}$. Compared to the formulation of the infection term as aSI (Ableitinger, 2011), the parameter α retains its meaning here in the transition from the exponential model to the SI-model. Problem: In the end all people are infected. There is no recovery and immunisation.

SIR-like model: The group I is split into several groups, depending on the number of days a person is already infected. After a few days, the exact number has to be specified – here we assume 8 days –, the infected recover. The final model is depicted in Figure 1.

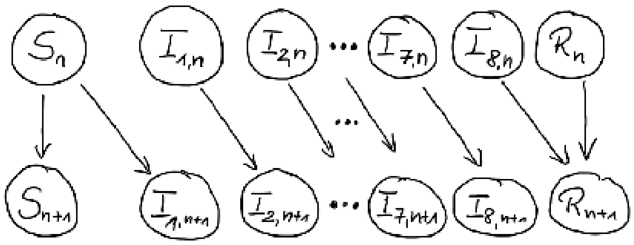

Figure 1: Flow-chart of a discrete SIR model with age structure

In subsequent modelling runs, contact restriction measures, testing and quarantine strategies, vaccinations and different virus variants can also be taken into account. Initial experiments show that students can arrive at sensible models here, at least at the pictographic level.

As a next step, this proposal is going to be empirically studied and further specified and improved. Our first questions are: To what extent 1) do students form a semantic understanding of the terms and parameters involved, 2) are students enabled to translate flow-charts in difference equations, and 3) are students enabled to break down complex real-life situations in epidemiological contexts into easier sub-problems through this teaching-learning arrangement?

Objective and subjective aspects of mathematics and context - the case of rate of change

Dafna Elias[1], Tommy Dreyfus[2], Anatoli Kouropatov[3] and Lia Noah Sella[4]

The concept of Rate of Change (RoC) is often presented in an Extra-Mathematical Context (EMC) which evokes subjective judgments due to interpretations of the described real-life situation and of the missing information in the problem. In this study, we investigated different learners' interpretations of several EMC problems involving RoC, with the aim to examine which aspects of the notion of RoC are prone to subjective reasoning, due to their structure or due to missing information, and which aspects are objective. We found that while the problems raised subjective thoughts for different learners, analysis of both the EMC and the mathematical concepts can help predict which aspects of the mathematics are prone to be subjective, and which are not.

Keywords: Rate of change, context, calculus, missing information.

Introduction

Mathematics is often regarded as a domain in which students do not have much room to express their opinion, but rather one in which they need to find the correct answer. Problems that are based on Extra-Mathematical Context (EMC), offer an opportunity in this sense: the interpretation of the described real-life situation and of the missing information in the problem may allow for personal interpretation, and as a result, the problem may have several correct answers. Among other rationales for using EMC, Rubel and McCloskey (2021) claim that it motivates students to learn mathematics, supports learning mathematics, as well as how to solve everyday problems.

EMC based problems assume students have some factual knowledge and experience with the context of the problem. This, together with the need for reading comprehension, may lead to missing information situations. These situations require interpretation, which is necessarily subjective. Furthermore, the content of EMC problems may bring into play students' subjective thoughts and experience about the given context. These characteristics give EMC based mathematical problems a subjective shade that must be taken into consideration.

Personal thoughts, subjective by nature, may be based on objective or subjective considerations. Objective considerations include agreed paradigms, whereas subjective considerations include personal life experience. It seems that mathematics students have learned that only objective considerations are acceptable by the system, but in EMC problems, students react differently than in "pure mathematics" problems.

The concept of rate of change (RoC) is a central concept in calculus. A central issue for mathematics educators is how to make fundamental ideas of calculus, such as RoC, meaningful for students. From a mathematical point of view, in the concept of RoC (and in many other mathematical concepts) there are aspects that are prone to subjective judgments. The study presented here aims to examine which aspects of the notion of RoC are prone to subjective reasoning, due to their structure or due to missing information, and which aspects are objective.

Missing information and subjectivity in word problems

Word problems found in textbooks are typically well-defined with all the necessary information given. This is because such problems are explicitly designed to provide a way for students to practice the mathematical procedures they have just learned. De Lange (1995) introduced categories of context, one of which is referred to as “camouflage context”. These "artificial" word problems are situations where the context is used only to “dress-up” the mathematical problem. The frequent use of "dressed-up" word problems has caused students to develop restricted beliefs about word problems. Specifically, such beliefs are that all of the relevant information is given and that every problem has a single precise numerical answer (Reusser & Stebler, 1997). Thus, in these problems, students usually do not apply subjective ways of thinking.

Problems with missing information are an important part of mathematics education as well as real life (Blum, 2015). Solving problems with missing information requires skills and solution strategies that are different from the ones required to solve well-defined problems (Jonassen, 2000). For example, Fermi problems are what Ärlebäck (2009) defines them as "open, non-standard problems requiring the students to make assumptions about the problem situation and estimate relevant quantities before engaging in, often, simple calculations" (p. 331). For example: How long would it take to count to a million? Or: How many cups of water are there in a bathtub? Ross and Ross (1986) recommend teachers present such problems, because it gives the students a more nuanced picture of mathematics, showing that doing mathematics is not always about executing well-defined procedures.

Krawitz et al. (2018) compared students' performance in solving word problems that are problematic from a realistic perspective versus quantitative problems with no numerical information, such as Fermi problems. They found that students did not notice the missing data in the word problems and as a result developed unrealistic solutions. In Fermi problems, when no numerical data are given but a numerical answer is required, the missing information is obvious. On the other hand, in questions in which students fail to notice the missing information, this may prevent them from arriving at a realistic response. An example for a question that is problematic from a realistic point of view: "A man wants to have a rope long enough to stretch between two poles 12 m apart, but he has only pieces of rope 1.5 m long. How many of these pieces would he need to tie together to stretch between the poles?". In this question, students have to notice that some length of rope will be used to tie knots, and this has to be taken into account. How much rope exactly is needed for a knot, is not given in the problem, although other numbers are given. Thus, with problems that have missing information, a student needs to first notice the missing information and then deal appropriately with the situation.

Missing information in a problem brings into play different subjective ways of thinking that students use to fill in what they don't know. These subjective thoughts are important to understand when teaching different mathematical concepts with EMC.

Rate of change

The concept of RoC, a central concept in calculus, describes how one quantity changes in relation to another quantity and is expressed as a ratio between a change in one quantity relative to a corresponding change in the other. Herbert & Pierce (2011) state that while rate is an important mathematical concept with many everyday applications, it is commonly misunderstood. Thompson (2013) made the point that the notion of RoC "entails a complex coordination of understandings of quantity, variation, relative change, accumulation, and proportionality" (p. 60).

From a mathematical-epistemological analysis of the concept of RoC, the following aspects seem vital for the existence of RoC in an extra-mathematical situation: (1) RoC always involves the measures of two quantities; (2) The quantities involved are varying ; (3) The change is continuous (or at least intuitively perceived by the student as continuous); (4) The nature of the relationship between the variables is relevant - The notion of RoC is closely related to that of function. A function describes a relationship between two quantities, while the RoC describes how one quantity changes with respect to the other. Not any relation between two quantities can be described by a function. There needs to be some specific sort of relationship between two variables for their connection to be fit to be described by a function, and thus potentially have a RoC of one with respect to the other. The definition of that relationship is relatively simple when we talk about pure mathematics but is not straightforward when the real world comes into play.

Some of these aspects seem to be objective (for example: in a situation in which one variable is described, it can be concluded without using personal judgment, that there aren't two variables in the situation) and other aspects seem to be subjective (for example: the nature of the connection between the variables). Others maybe objective at times, and subjective at other times, depending on the familiarity with the described situation (for example: whether the variable is discrete or continuous).

Methodology

The aim of our research study was to investigate which aspects of RoC tend to elicit subjective reasoning and which aspects tend to elicit objective reasoning, in an EMC based discussion. In the instrument used in this study, various situations were selected according to the aim mentioned. These situations differ in the sort of information which is given, the sort of information which is missing, and the characteristics of the situation: the number of quantities involved in the situation, the kind of quantities involved, whether the quantities vary and how they vary (continuous vs. discrete), and whether they co-vary or not (in our opinion). While these are not classic Fermi problems, since they require no numerical estimations, they are of the same character: open problems requiring the students to make assumptions about the problem situation. Based on the analysis of pilot trials, the situations as well as the formulation of the questions were repeatedly modified.

The final situations and questions have been used as base for semi-structured task-based interviews (Goldin, 2000). The interviewees were students and prospective teachers that were asked whether, in their opinion, it made sense to talk about RoC in these situations. The interviews were recorded and transcribed. When analyzing an interview, we identified which aspects of RoC were judged as relevant for each situation by the interviewee. We needed to establish which utterances are indicative of an interviewee's subjective considerations. To do this, we identified several relevant criteria, which helped us tag utterances as subjective considerations: (1) Statement of opinion – utterances explicitly qualified by the interviewee as their own belief, opinion or interpretation; (2) Non institutionalized (mathematically) argumentation – the utterance contains non-general arguments that are determined by personal life experiment or/and non-formal personal interpretations; (3) Adjustment completion – the utterance contains interviewee's use of concepts and ideas that were not a part of the given situation, which make the situation more logical and complete for the interviewee. The interviews were analyzed by the authors using content analysis methods (Smith, 2000) using the above mentioned criteria of subjectivity.

Findings and their discussion

Here, we present the preface to the final version of the interview, and three of the situations, as they were presented to the students. For each situation, a few representative student answers are given. The students were interviewed one by one, but the answers are presented here together. The quotes in this chapter symbol that the text is presented as was presented to the interviewees.

Preface

"Students learned in class about rates of change of quantities in different situations. Two situations were discussed in class: (1) A car that drives on a road. In this situation, they agreed that the distance driven by the car changes with time and it makes sense to talk about the RoC of the distance with respect to time. This RoC is the speed of the car. (2) Water flows into a tank. In this situation, they agreed that the volume of water in the tank changes with time and it makes sense to talk about the RoC of the volume with respect to time. After class, the students continued discussing this topic for other everyday situations."

Boris' situation

"Boris said: I am thinking of the rate of the dollar to the shekel and the temperature of the Mediterranean Sea. Does it make sense to talk about rate of change in Boris' situation? If it does – what is that rate of change? If it doesn't – why doesn't it make sense?"

Boris describes two variables, with a questionable connection between them. In this situation there is missing information regarding the nature of the connection between the two variables, meaning that the aspect of RoC which may be considered subjective, the type of connection between the two variables, is at the core of the situation. We ignore potential continuity issues of the exchange rate. The following are responses to Boris' situation (translated from Hebrew):

Tina	There is no connection between these two variables. One does not influence the other. It isn't possible to treat one as a function of the other.
Rob	The temperature of the Mediterranean Sea doesn't influence the rate of the dollar, so there's no rate of change.
Oliver	They're asking me how the rate (of the dollar to the shekel) influences the temperature? […] In this case it doesn't make sense to talk about rate, because it's difficult to find something that connects them. Maybe there's an oil company that works in the Mediterranean, and if the exchange rate goes up, the company will work harder, I don't know. […] Maybe in the summer the rate of the dollar

goes up and in winter it goes down? But no, I don't think so. [After discussing different situations, Oliver returned to Boris' situation] You can talk about a rate of anything. The question is if it makes sense… If there is some benefit in it for me. […] If there's no connection, then one doesn't influence the other; then the rate of change will be zero, because it isn't having an influence.

Typical for this type of open-ended questions, the respondents gave answers at different levels of complexity. Tina and Rob both stated that one variable has no influence on the other, but each of them drew a somewhat different conclusion. Rob drew the immediate conclusion that if there is no influence then there is no RoC. Tina answered indirectly, and considered one not being a function of the other a satisfactory answer to the question she was asked, about the existence of RoC. Oliver, on the other hand, gave the impression that he was fearing that he lacked some knowledge regarding the connection between the two variables. Tina and Rob made an assumption regarding the connection between the variables, maybe without being aware that this is an assumption, since obviously they may lack some unknown knowledge regarding the situation. Oliver tried to "find the answer", although it is an impossible mission. Later on, Oliver reached two surprising conclusions. The first is that for a situation to have a RoC, there needs to be some benefit to the discussion of RoC in the given situation. The conclusion regarding the benefit of the discussion, is the effect of basing a mathematical problem on EMC. The second surprising conclusion is that no connection means the RoC equals zero. This is a confusion. Zero RoC means no change, rather than no connection.

All students characterized the connection between the variables (or rather the lack of such a connection) as the criterion for the inability to talk about RoC in this situation. Oliver's response was labeled as subjective due to the 'non-institutionalized (mathematically) argumentation' expressed by the issues raised (oil company, summer-winter).

Anat's situation

"Anat said: While I am driving to the Dead Sea, I am thinking of my height above sea level and my distance from the Dead Sea. Does it make sense to talk about rate of change in Anat's situation? If it does – what is that rate of change? If it doesn't – why doesn't it make sense?"

Anat describes two continuously changing quantities which are closely related. This is a situation in which RoC is objectively relevant (or at least, it may be assumed that all the vital aspects for RoC are present), if the student is familiar with it. The following are two responses to Anat's situation:

Tina	Yes. You can talk of the rate of change of the distance in relation to the height.
Tanya	If the speed is constant then the distance and the height will change accordingly. Speed multiplied by time equals distance. So if I want to know the rate of change then I will divide the distance by the time. The distance changes here, and so does the time [variable]. The magnitudes here are changing all the time but I don't know if you can estimate the rate of change. The question is how you define rate of change. No, I can't estimate the rate of change. As time goes by, the distance changes and so does the height above sea level. […] You can talk about the speed in respect to distance and height. Maybe the height changes with respect to the distance I've traveled. I think that there is a time parameter here, a distance parameter and a height parameter.

While Tina immediately stated her answer, Tanya had trouble talking about the RoC of distance with respect to height (or height with respect to distance). In this situation, “time” isn’t explicitly involved and Tanya imposed it, presumably because she found quantities that “change over time” to be easier to discuss, than two non-temporal quantities changing one with respect to the other. This is what Jones (2017) called “invoking time”. This is a tendency for some students to insert time into what are otherwise time-less contexts. “For some students, invoking time seemed to be beneficial since it helped them to organize the covariation between the two quantities and to reach those higher covariational reasoning levels in which changing rates of change are considered.” (p. 107). Due to the 'adjustment completion' used to invoke time, which was not part of the described situation, Tanya's reply was labeled as subjective.

Hadas' situation

"Hadas said: I am thinking about the fact that nurses at baby-care centers weigh the babies, and each baby has its own weight. Does it make sense to talk about rate of change in Hadas' situation? If it does – what is that rate of change? If it doesn't – why doesn't it make sense?"

Hadas describes one magnitude only, which is, objectively, a situation in which RoC is not relevant. The following are responses to Hadas' situation:

Rob	Every baby has his or her own weight. In rate of change we talk about rate between two things, right? […] I don't understand – the weight in respect to what?
Oliver	I see only one variable here. […] You can talk about rate of change but it would be… There's no connection between the babies. It [the RoC] would be difficult to measure and it wouldn't give me anything. Would I be numbering the babies? […] You can talk about rate of change but it would be degenerated. You can talk about change, but not about rate of change because it's not continuous. […] If you weigh 10 babies every hour then you can force the rate in here.

While both students understood that this is a situation with only one variable, Rob was quick to determine that one variable is not enough to talk about RoC. Oliver, on the other hand, expressed some confusion, although he stated clearly that he only sees one variable in the situation. We witness him trying to find a second variable (numbering the babies) and reasoning why this wouldn't solve the problem. Of the aspects which are vital for the existence of a RoC of one variable with respect to another, the one which is relevant in this situation is that two quantities need to be involved. This aspect was considered objective by the researchers and witnessed in practice as objective. Although subjective thoughts have been raised (for example "numbering the babies" which uses 'adjustment completion') the criterion remains central and valid.

It is interesting that Oliver talks about the number of babies that are weighed per hour, since it has to do with the influence of language. In Hebrew, the words 'rate', 'rhythm' and 'pace', are the same word. Oliver talks about the pace of work that the nurses manage as an option to insert rate into the situation. This has nothing to do with the mathematical concept of RoC which is not relevant in this situation.

In general, our findings in this study include notions which are considered necessary for the notion of RoC. Some of these were considered objective, which have one "correct" judgment (having 2 quantities involved in the situation or having quantities that “change” – related to as quantities that takes on different values). The findings demonstrate how, in objective situations, students still bring in their subjective ways of thinking (such as invoking time or completing a missing variable by numbering a single variable).

Other notions are subjective, and different interviewees had different opinions, none of which were incorrect. The first is "A connective relationship" – Students argued that in order to talk about RoC, two quantities need to be connected, meaning that one influences the other: “There’s no RoC because there’s no connection between the two variables”. This is a subjective judgment, and different interviewees found different levels of relationships in the same given scenario. The second subjective notion is "Having a benefit" – Students stated that in real-life scenarios, some benefit must come out of talking about RoC: “you can talk about RoC, but the question is what you get from it”.

Conclusion

It seems that, in the case of the concept of RoC, EMC has a considerable influence on students’ interpretation of the concept and on their decision-making process. Interviewees based their decisions on their own life experience and their personal ways of thinking. Regarding the different aspects of RoC, even aspects that the researchers thought to be objective proved to elicit subjective thoughts when the design of the task was based on real-life situations. Missing information played a significant role when the two described variables had a vague connection. While some students assumed (without stating the assumption) that no connection exists between the variables, others tried to fill in the missing information with imaginary connections.

Viewing mathematics as a basis for many engineering and scientific fields makes working with EMC vital for a proper mathematical education. But working with EMC elicits subjective ways of thinking, which are difficult to foresee and not easy to analyze. Understanding which knowledge elements are more prone to be objective, and which inherently propose a situation in which there is missing information, may enable mathematics educators to combine EMC in a more constructive manner. As a benefit, students learn that assumptions must sometimes be made, in order to solve a mathematical problem, sometimes there is information which is missing in the problem, and sometimes there is more than one correct answer - doing mathematics is not always about getting exact answers by means of well-defined procedures.

Modelling climate change through Study and Research Paths

Yael Fleischmann, Frode Rønning and Heidi Strømskag

Norwegian University of Science and Technology, Trondheim, Norway;
yael.fleischmann@ntnu.no, frode.ronning@ntnu.no, heidi.stromskag@ntnu.no

Keywords: Herbartian schema, mathematical modelling, paradigm of questioning the world, Study and Research Paths, the Anthropological Theory of the Didactic.

Research topic

The upcoming research accounted for in this poster is related to CiviMatics, an Erasmus+ funded project involving Austria, Germany, Norway (NTNU), and Romania (see https://www.civimatics.eu). CiviMatics aims to combine approaches of mathematics education and political education by offering educational tools to enhance the competences of citizens, especially regarding the interaction with global issues facing our societies. A societal issue dealt with in this project is climate change, currently one of the most urgent problems requiring an initiative. At NTNU, the course MA3001 (see https://bit.ly/3DDy0df) has been designed for the sake of CiviMatics to conduct experiments with the modelling of climate change through so-called *Study and Research Paths* (SRPs; Chevallard, 2022). MA3001 will be taught in the spring 2022 as part of a master's programme for Grades 8–13, "Natural Science with Teacher Education". The accompanying research will be centred on the following questions: *What are the main constraints related to implementing SRPs? What is the student teachers' learning outcome? What are the successful points associated with conducting SRPs?*

Theoretical framework and methodology

The didactic design to be employed and the research to be conducted in MA3001 are rooted in the *Anthropological Theory of the Didactic* (ATD; Chevallard, 2022). Our conceptualization of modelling is based on the notions of *system* and *model* as explained by Strømskag and Chevallard (2021): A system $\mathcal{S}$ is any entity subject to laws of its own. Given a system $\mathcal{S}$, a system $\mathcal{S}'$ is said to be a model of $\mathcal{S}$ if, by studying $\mathcal{S}'$, one can answer certain questions Q about $\mathcal{S}$. In practice, given a question Q relating to $\mathcal{S}$ which one wants to answer, one tries to build up a model $\mathcal{S}'$ of $\mathcal{S}$ (or choose an existing one) whose study with respect to Q is easier, safer, quicker than by a "direct" study of $\mathcal{S}$.

The modelling activities to be conducted in MA3001 are based on the new didactic paradigm proposed by ATD, that of *questioning the world* (Chevallard, 2022). In this paradigm, the point is to create a didactic system $S(X; Y; Q)$ that inquiries into a question (or a set of questions) Q. A praxeological function that studying a question Q assumes is to lead to studying all sorts of works (including derived questions Q_i). How can we describe what happens in a didactic system S when a class X studies a question Q under the supervision of a teacher/teachers Y? The model provided by the ATD is the *reduced Herbartian schema* (Chevallard, 2022): $S(X; Y; Q) \Rightarrow A^{\heartsuit}$. The heart hints at the fact that the answer A to Q will be "at the heart" of the didactic system, at least for some time.

The next step in building up a model of the inquiry is the introduction of the didactic *milieu*, M, which is the set of tools that the class gathers in order to carry out their inquiry into question Q. This results in the *semi-developed* Herbartian schema (Chevallard, 2022): $[S(X; Y; Q) \Rightarrow M] \Rightarrow A^{\heartsuit}$. Here, the didactic system is seen to *create* (denoted by ➡) the milieu M and to *generate* (denoted by ➥) the answer $A^{\heartsuit}$ by drawing upon the milieu M. In the quest for an answer A to the question Q, three main components stick out: (1) The search in the literature (including Internet queries) for *existing answers* $A^{\lozenge}$ offered by other persons or institutions. (2) To draw upon the answers $A_i^{\lozenge}$, the didactic system has recourse to *works* W_j of various kinds, like theories, experiments, essays, etc. (3) To use these works, the student needs to study them. This involves studying a number of *questions* Q_w about the work under study. Hence, the milieu M takes on the following appearance: $M = \{A_1^{\lozenge}, A_2^{\lozenge}, \ldots, A_m^{\lozenge}, W_1, W_2, \ldots, W_n, Q_1, Q_2, \ldots, Q_p\}$. We will use the Herbartian schema as a tool to regulate and analyse inquiries.

An SRP in MA3001 will be organised as follows: The generating question Q of the SRP will be presented by the teacher who is supervising the SRP. Student teachers (hereafter 'students') work in teams to study and answer the question Q. The teams and the teacher meet regularly to review the teams' work on Q and to confirm, adjust or extend the SRP for a specific period. In addition, seminars will be arranged where the teams present preliminary progress reports and receive feedback from each other and from the teacher on the condition of the answer under construction.

This is the generating question Q_1 (with subquestions $Q_{1.1}$ and $Q_{1.2}$) that the students will be given:

Q_1. How is future climate change caused by long- and short-term pollutants modelled in the scientific literature?

$Q_{1.1}$. What assertions and simplifications are made in these models?

$Q_{1.2}$. What knowledge seems indispensable to understand these models (focusing on mathematics, but also considering civic education, chemistry, biology, physics)?

At present, the focus is on an a priori analysis of SRPs which involve inquiring into Q_1 and its subquestions. We will draw on the many SRPs reported on by the ATD research community (e.g., Barquero et al, 2018; Bartolomé et al., 2018). Data to answer the research questions for the follow-up research presented in the first section, will include observations of students' team work, students' reports from the SRPs, and questionnaires about the functioning of the didactic systems at work.

Students’ approaches concerning model validation and model improvement when solving modelling tasks with experiments

Sebastian Geisler

University of Hildesheim, Germany; geisler@imai.uni-hildesheim.de

Mathematical modelling is important yet challenging. Especially the validation step is a hurdle for many students. One approach, discussed in the literature, for fostering students’ validation competence is to use modelling tasks that use data gathered in experiments. Analyzing the validation of 71 students in two modelling tasks with experiments, we found that many students struggle with validation. In particular, most students seem to put more trust in their model than in their experimental data and therefore suggest to improve experiments instead of working on an alternative model. Stimulated recall interviews show that students’ lack of mathematical knowledge as well as a lack of understanding of the relation between data and model can be the reasons for these findings.

Keywords: Experiments, mathematical modelling, model-validation.

Introduction

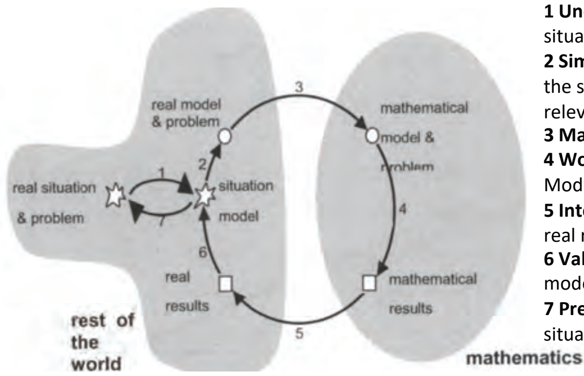
Mathematical modelling is a central mathematical competence, which is reflected in several curricular documents around the world (e.g., National Governors Association Center for Best Practices and Council of Chief State School Officers, 2010). Nevertheless, modelling remains complex and challenging for students. Previous studies have shown that especially the validation of one’s models is a hurdle in the modelling process for many students (e.g. Blum & Leiß, 2007). Therefore, supporting students when validating their models is necessary. According to Engel (2010) real data is needed for authentic modelling and validation, since real data usually does not fit perfectly to an intended model. In contrast, using already smoothened or unrealistic data that fits well to an intended model, leads to a modelling process in which the relevance of validation is not stressed (Engel, 2010). One approach to integrate real data into the modelling process is to use modelling tasks with experiments in which students first perform experiments and gather data that can be used for the subsequent modelling (cf. Zell & Beckmann, 2009). This approach is frequently discussed in practical teaching literature (e.g. Ludwig & Oldenburg, 2007) but little empirical evidence for the anticipated positive effects on students’ validation competence exists.

The project *Mathematical Modelling with Experiments* (MaMEx) follows the objectives to design and evaluate modelling tasks with experiments and to gather insights into students’ validation processes. In a pilot study, Geisler (2021) used a modelling task with experiment concerning the decay of beer-froth and analyzed students’ validation approaches. Students in this pilot study still struggled with validation. Moreover, there was confusion among students, whether the mathematical model should be fitted to the data or vice versa in the sense that the measurement of the data should be improved in order to fit better to the mathematical model. In this contribution, we present an extension to the aforementioned pilot study to get more insights into students’ validation approaches.

Theoretical Background

Mathematical Modelling

Mathematical modelling is usually described as a circular process (e.g. Galbraith et al., 2010). In this contribution, we follow the modelling cycle proposed by Blum and Leiß (2007) describing seven steps in the modelling process (Figure 1). According to Niss (1994), the validation step is the most important step in the modelling-process. In this step students evaluate whether the real results obtained in the modelling process and the used mathematical model itself are adequate with respect to the real situation. As a consequence of this step, the model itself could be revised if it is not found suitable. Unfortunately, validation is very challenging for many students and some students do not see validation as a necessary step (Hankeln, 2020). When students work on modelling tasks, the validation is often absent (Blum & Leiß, 2007) and those students who validate their models often rely on a rather intuitive feeling that their model might be suitable or not (Borromeo Ferri, 2006). In accordance with these results, Borromeo Ferri et al. (2013) report that students scored weakest concerning their validation competence compared to the other modelling sub-competences. Furthermore, within their intervention-study they showed that fostering students' validation-competence is possible even with short interventions like modelling project days.



1 Understanding/Constructing (understanding the real situation and setting up a (mental) situation model)
2 Simplifying/Structuring (simplifying and structuring the situation model into a real model focusing on the relevant information)
3 Mathematising (setting up a mathematical model)
4 Working mathematically (working with the math. Model to obtain mathematical results)
5 Interpreting (interpreting the math. results to obtain real results)
6 Validating (validating the real results and the whole modelling-process with respect to the situation model)
7 Present (present real results with respect to the real situation)

Figure 1: Modelling-Cycle following Blum & Leiß (2007)

Fostering validation with modelling tasks with experiments

In the literature, there exist several concrete teaching ideas for combining experiments and modelling tasks (e.g., Ludwig & Oldenburg, 2007). Halverscheid (2008, p. 226) sees a natural link between experiments and modelling as experiments "represent the *rest of the world* for which mathematical models are built." Ludwig and Oldenburg (2007) emphasize benefits of experiments for the whole modelling process and especially the validation step, because students can validate their models based on real data instead of theoretical considerations. According to Zell and Beckmann (2009, p. 2216) experiments offer good occasions for validation: "Because of measurement errors the formula is never correct. So it is natural to talk about the correctness and the limitations of the model and its results."

Even if these considerations propose a high potential of modelling tasks with experiments for validation, empirical research in this field is scarce. So far only a few qualitative studies with small samples have dealt with validation in the context of modelling tasks with experiments. Zell and Beckmann (2009) used modelling tasks in combination with physics experiments and interviewed secondary students after working on these tasks. Students struggled with accepting the imperfection of their models due to measurement errors at first but eventually were able to validate their models. In contrast, Maull and Berry (2001) observed undergraduate students who worked on a modelling task concerning the cooling off of tea and found that many students were not able to validate their models without help of the lecturer. It seems that using experiments can even hinder the validation process: Carrejo and Marshall (2007) report about an undergraduate course in which students experimented with motion. When talking about the validation of their models, students attributed even systematic shortcomings to measurement errors instead of unfavorable model specifications.

In a pilot study of the MaMEx-project, Geisler (2021) implemented a modelling task concerning the decay of beer-froth in two upper secondary classes. Students performed an experiment and used their gathered data to model the decay by exponential functions. Analyzing students written solutions, Geisler (2021) found that students' acceptance or rejection of a model was very subjective, in the sense that models identified as adequate by the students as well as models that students judged as inadequate showed the same systematic shortcomings (e.g. systematically over- or underestimating the data). These shortcomings have often been justified via measurement errors by the students which is in line with Carrejo and Marshall's (2007) findings. Furthermore, being asked how to improve the fit between data and function, most students stated that they would improve their experimental procedures instead of searching for an alternative model. It seems that students put more trust into their mathematical model than in their data and therefore try to improve data in order to fit the data to the model instead of improving the model with respect to the data. However, the analyzed sample ($N = 19$) in this pilot study was rather small and all students came from the same school.

The current study

Objectives and Research Questions

In this paper, we present an extension to the aforementioned study. We implemented two modelling tasks in four secondary classes to determine whether results are comparable within a larger as well as more diverse sample and with different modelling tasks. Furthermore, we wanted to understand students' ideas behind their approaches to improve their models. Our guiding research question was:

How do students validate their models within modelling tasks with experiments with respect to their gathered data and which approaches to improve models do they propose?

In the following, we give an overview of the used modelling tasks before describing the methods of data collection and analysis.

Design Principles of the Modelling Tasks

All modelling tasks with experiments used in the MaMEx-project follow four design-principles (cf. Galbraith et al., 2010): P1) The contexts of the task should be realistic and use only those physical quantities that are already known by the students. P2) The mathematics should be foregrounded in the whole process. Therefore, experiments should be easy to conduct and take only a few minutes. P3) It should take not too much time to set up a mathematical model but the task should offer relevant occasions for validation. P4) A validation prompt should be implemented since many students do not validate their models spontaneously.

The task “Cold Coffee” (in the following named “CC”) is adapted from Ludwig and Oldenburg (2007). The following served as an introduction to the task:

> After brewing, coffee needs some time to cool off in order to be conveniently drinkable. The desired drinking temperature differs from person to person. Model the temperature decrease and evaluate at which time the coffee can be delightfully drunken.

The context is familiar to students. Students are asked to formulate a hypothesis concerning the decrease of temperature before performing an experiment. Students measure the temperature of freshly brewed coffee every minute for 10 minutes. Only well-known quantities (time and temperature) are used in the experiment (P1) and it can be done with everyday material and takes only 10 minutes to perform (P2). After performing the experiment, students were asked to model the cooling using a function. No hint was given which kind of function is suitable. However, setting up a mathematical model is not to complicated (P3) since the temperature can be modelled using an exponential function of the form $f(x) = b \cdot a^x + c, b > 0, c > 0, 0 < a < 1$ with x as the time in minutes after brewing the coffee. The parameters can be calculated by using the data from the experiment: c can be estimated as the room temperature and b can be calculated as the difference between the temperature at the beginning of the experiment and the room temperature. One possibility to estimate a is to use two consecutive measured values, e.g. $a = \frac{\text{temp (1 min)} - b}{\text{temp (0 min)} - b}$. Students could use GeoGebra to plot graphs of functions and compare them with their data. There are several occasions for validation, since the decrease is not perfectly exponential. Furthermore, students sometimes forget to consider that the coffee cannot cool down under the room temperature, so that their first attempt to model the decrease is often not adequate. As a validation prompt (P4) serves the following subtask:

> Compare your function with your measurement-data. Does your function describe the data accurate enough? How could your model be improved?

Besides the CC task, a second modelling task “Stale Beer” (“SB” in the following) was used. In this task students were asked to model the decay of beer-froth and to evaluate the beer quality based on their results (Geisler, 2021). The SB task had the same structure as the CC task, in the sense that the same subtasks (e.g., the same validation prompt) were used. However, the SB task can be considered to be a little easier. The decay of beer-froth can be modelled using an exponential function of the type $f(x) = b \cdot a^x$ and therefore less parameters have to be computed. A detailed description of this task and the related experiment can be found in Geisler (2021).

Methods

Both modelling tasks were implemented in four upper secondary classes (all in year 10) from three different German schools. 71 students (age between 15 and 17 years, 54 % female) voluntarily participated in the study. Based on their last mathematics grades, the students represent a large variety of achievement levels reaching from grade 1 (very good) to grade 6 (not sufficient) (mean: 3.1 – sufficient). All classes had covered exponential functions as well as the calculation of the function’s parameters based on given values some month prior to the implementation of the tasks. Students were not informed that exponential functions could be used to solve the tasks. In every class, half of the students worked on the CC task whereas the other students solved the SB task during a 90 minutes lesson. Students performed the experiments in pairs of two. Students' answers to the validation prompt served as data in order to answer the research question. Since not all students answered all subtasks, data is available for 64 students. Furthermore, we conducted stimulated recall interviews with six students after working on the task to better understand students' validation ideas and ideas for model improvement. We chose students for the interviews based on their answers to the validation prompt, to achieve a certain variety of students' approaches. Accordingly, we used their answers to the validation prompt as a stimulus in the interviews. Interviews have been recorded and transcripted.

Students' answers have been analyzed using qualitative content analysis (Mayring, 2010). We used an inductive coding guide. All answers were first coded regarding students' judgement whether their model was adequate with respect to their data. Second, students' ideas to improve their models were coded. All answers have been coded independently by two raters and Cohen's kappa has been calculated indicating a very good interrater-reliability of $\kappa = 0.9$.

Results

Since both tasks are very similar in structure, we do not discuss the results divided by tasks. However, numbers concerning the different approaches related to the tasks are provided in brackets. Except of two (SB: 1, CC: 1), all students were able to set up an exponential function as a model for the decay of beer-froth respectively the decrease of the temperature of the coffee. However, most students working on the CC task did not consider the room temperature and set up functions of the form $f(x) = b \cdot a^x$ resulting in models that mostly only describe adequately the temperature during the first minutes of the experiment, as can be seen in the solutions in Figure 2.

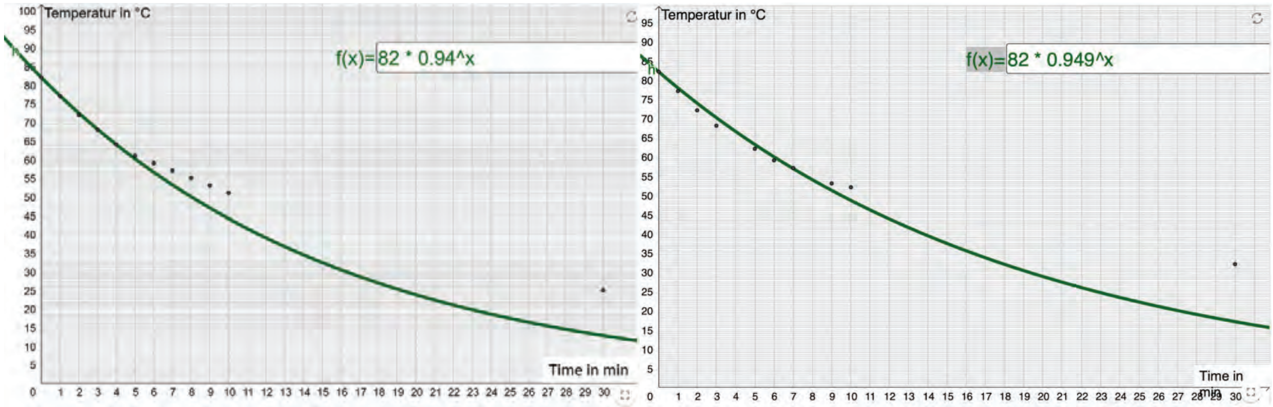


Figure 2: Screenshots of students' GeoGebra files with measured data and related functions – CC task

Model Validation

28 students (SB: 16, CC: 12) stated that they see no or minimal deviations between their model and data, indicating that they consider their model to be adequate (e.g., "*The function describes our measured values quite exact*", CC). In contrast, 25 students (SB: 13, CC: 12) see substantial deviations between their data and their model and therefore judge their model as not adequate (e.g., "*No, the function is decreasing more steep than our measured values*", SB). Two of these students wrote that they are satisfied with their model but that they consider their measured values to be "*very imprecise*". It seems that these students attribute deviations between model and data to their data instead of the specifications of the model. 11 students (SB: 6, CC: 5) gave a more sophisticated

evaluation, stating in which timespans the model is useful to describe their data (e.g., "*The measured values deviate a little bit from the function especially at the beginning. At the end the values match with the function*", SB). In these answers, first ideas concerning the limitations of models become apparent. These judgements are nearly equally distributed among the two tasks. Furthermore, students' judgements are very subjective, as can be seen in the solutions in Figure 2. While both models show similar shortcomings (good fit during first minutes but clear deviations later), the left model was considered to be not adequate by students and the right model was considered sufficient.

Approaches for Model Improvement

Five students did not answer the question concerning the improvement of their models. Moreover, ten students (SB: 4, CC: 6) explicitly stated that they have no concrete idea for improving the fit between model and data. The majority of the students (n = 39, SB: 22, CC: 17) only gave ideas to improve the experimental procedure instead of working on the model itself. Most of these ideas contain only simple improvements like taking more measurement values or measuring the values more precisely. However, two students argued that one should repeat the experiment several times with partly different materials ("*Take more values for a longer timespan for a more precise model, repeated experiments with different bottles of the same beer*", SB). Only ten students (SB: 4, CC: 6) wrote ideas for an alternative model for their data, like calculating the parameter "a" in another way (e.g., "*It would be helpful to calculate a for all measured values and to take the mean for it*", CC).

It seems that many students have no concrete idea how an alternative model based on their already measured values can be set up. Furthermore, some students seem to put more trust in their model than in their data. This impression is supported by students' answers in the stimulated recall-interviews. Out of the six students interviewed, only two (we call them student *A* and student *B*, both worked on the CC task) offered ideas how to improve the function. Student *A* offered the idea to use more than one function (in the sense of a composite function) in order to adequately model different parts of the data: "We recognized that beginning with a certain value it [the coffee temperature] remained constant. […] Perhaps one can split it into two functions: one for the first part and one for the constant part". Student *B* followed a different idea that involved using all measured values to set up a function:

Interviewer: You have thought about how one can improve your function and you wrote "one could calculate *a* for every single value and take the mean then." What do you mean by every single value?

Student *B*: We have values for every timepoint and we could calculate an *a* for every timepoint and calculate the mean of these *a*s.

Interviewer: And what would happen if you do so?

Student *B*: Then one value would lie exactly on the function and it would be consistent what lies over and under the graph.

Student *B* seems to be aware that not all measured values will lie exactly on a function and that it is desirable that a similar number of values lies over and under the function, that is the function does not systematically over- or underestimate the measured data.

All other students said that they have no idea how to further work on their functions. Two students argued that the model depends heavily on the experimental data and that the experiment should be improved accordingly. These students are aware that measuring new data will result in a slightly different function, as becomes apparent in the dialogue with student *C*, who worked on the SB task:

Interviewer: Do you have ideas how to improve your model if you already have the measured values? […]

Student *C*: So I think the analysis is really dependent on the experiment and so it is more relevant what values we gather from the experiment to have the right analysis.

Interviewer: Ok, so you say it depends on the data. What would you say would happen to your function if you gather other data, if you measure more often or more precisely?

Student *C*: I think nothing. It would be the same. It would just be more detailed and one could better see how the function…

Interviewer: So if you would have measured more precisely it would be the same function but everything would fit better?

Student *C*: So maybe there would be a different number [for the parameter] but basically it would be the same.

The last two interviewed students, one is student *D* who worked on the SB task, stated that improving the experiments will lead to the same function they already have:

Interviewer: You wrote that one could use a better measuring cylinder to better measure the change [of the beer-froth]. These are ideas that set in during experimentation. Do you have also ideas how to improve your function if you already have the values and you cannot change them? […]

Student *D*: I have no idea!

Interviewer: And if you would have a better measuring cylinder and you measured the values more precisely, do you think at the end you would have a function that fits better to the measured values?

Student *D*: I think we would have the same function then, but eventually the measured values would fit better to it.

Discussion

All in all, the results of the study at hand are similar to those of the pilot study of the MaMEx project (Geisler, 2021) and support the findings of Carrejo and Marschall (2007): Most students seem to attribute deviations between their model and the experimental data to measurement errors and primarily suggest to improve the experimental procedure instead of considering alternative models. This is even the case, if systematic shortcomings of the models exist. These results show that integrating experiments in lessons does not guarantee successful validation but experiments could be used as a starting point for fruitful discussions on validation in the classroom. Regarding students' statements in the interviews, two main problems can be identified: 1) Students seem to have not enough knowledge about exponential functions to reconsider their model and 2) there seems to be a lack of understanding concerning the relation of the reality (data) and the model (function) which has to be addressed in mathematics lessons. The latter problem might be due to the perception that the model is solely determined by the data and that gathering good data is the most important step in the whole process. This is remarkable since ones' model depends on both: the data used and the decisions made (e.g., type of function) in order to set up the model. However, in the answers of student *D* a real misconception concerning the relation between data and model comes apparent. Student D seems to see his function as the "right" model and rather independent from the actual data. It remains uncertain where this trust in his model comes from. One possibility could be that many students believe that mathematics is always precise and mathematics tasks have only one right answer. These beliefs are quite common among students and have been proven to influence their approaches to mathematics tasks (Schoenfeld, 1992). Measuring students' beliefs concerning the nature of mathematics prior to their work on modelling tasks with experiments might shed light on this hypothesis.

Pre-service teachers' pedagogical content knowledge for teaching simulations and mathematical modelling with digital tools

Dealing with simulation and modelling tasks with digital tools in mathematics lessons puts high demands on teachers when it comes to the preparation and implementation of lessons. These must be met in teacher education. To measure the pre-service mathematics teachers' professional knowledge for teaching simulations and mathematical modelling with digital tools, we propose a theory-based model and subsequently present items of an associated test instrument. Using a one-parameter Rasch model, we show that the underlying model can be confirmed empirically and discuss the potentials and limitations of the results.

Keywords: Mathematical modelling, simulations, digital tools, pedagogical content knowledge, measurement.

Introduction

Large-scale studies – such as Kunter et al. (2013) and Blömeke et al. (2014) – have shown how the pedagogical content knowledge of mathematics teachers can be described theoretically and empirically. Wess et al. (2021b) were able to use these conceptualizations and other research results from recent years to examine the pedagogical content knowledge of pre-service mathematics teachers specifically for mathematical modelling. Due to the increasing importance of digitalization in teaching and learning, it now seems sensible to integrate digital tools into this existing concept and to reinterpret the construct of Wess et al. (2021b). Based on this, the first results of the development of a test instrument that focuses on the professional knowledge for teaching simulations and mathematical modelling with digital tools will be presented in the following. The main question is: *To what extent can the pre-service teachers' pedagogical content knowledge for teaching simulations and mathematical modelling with digital tools be empirically captured as a construct?*

Theoretical Background

The term **mathematical modelling** describes the investigation of extra-mathematical processes and relations with mathematical tools. This includes the structuring of the extra-mathematical situation, the well-justified construction of a model to describe the reality, translation processes between the extra-mathematical and intra-mathematical world (in both directions), mathematical considerations, and the interpretation and validation of the results obtained (Niss et al., 2007). These modelling processes can sometimes be carried out several times as well.

If a mathematical model, which can be used for experimentation, of a reality-related situation is already available, **simulations** can also contribute to the exploration of reality. Simulations then enable dynamic, experiment-like processes that provide insights into the real system represented in the model (Greefrath & Siller, 2018). Simulations can also help to validate and optimise the mathematical model (Greefrath & Vorhölter, 2016).

Digital tools that are used in mathematics education represent a subcategory of digital media. While digital media are used, among other things, to communicate and document information, digital mathematics tools specifically support mathematical learning processes and the investigation of mathematical relations (Drijvers et al., 2016; Hillmayr et al., 2020). For example, they can generate and process larger amounts of data, visualize interrelationships dynamically, take over calculation processes, reduce complex function terms and offer new possibilities for information research (Greefrath et al., 2018). Thus, on the one hand their use therefore enables – especially in simulation and modelling processes – the treatment of previously inaccessible content. On the other hand, other focal points in mathematical considerations are now made possible (Greefrath & Siller, 2018). Examples of digital mathematics tools (we will speak of "digital tools" in the following) are Computer Algebra Systems, Dynamic Geometry Software, spreadsheets, and function plotters.

Several authors, such as Molina-Toro et al. (2019), investigated the integration of **digital tools in modelling processes**. They showed that digital tools can be used to support various processing phases and sub-competencies of mathematical modelling. Communication with the digital tool is essential here: on the one hand, mathematical descriptions must be translated into the language that the digital tool can understand and process and on the other hand, the results of the digital tool have to be translated back into the mathematical terms and operations. Greefrath et al. (2018) therefore extend the modelling cycle of Blum and Leiss (2007) by a technological world that takes into account the translation processes with the digital tool (Figure 1).

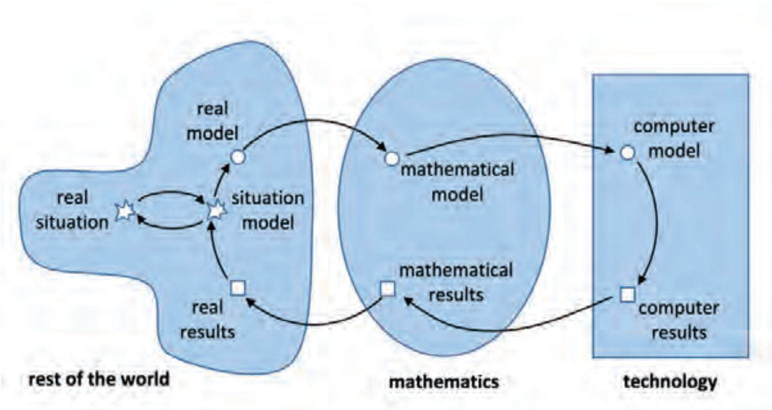

Figure 1: Extended modelling cycle (cf. Greefrath et al., 2018, p. 235)

Concrete functions of the digital tool can be implemented in different modelling phases: investigate, experimentalize, visualize, simulate, calculate, control (Greefrath et al., 2018). As mentioned above, mathematical simulation fits into reality-related contexts as an experiment-like process with the already existing mathematical model.

To investigate **professional knowledge for teaching mathematical modelling**, Wess et al. (2021b) developed a structural model of professional competence for teaching mathematical modelling. It serves as the initial basis of our test instrument and uses the model of Kunter et al. (2013) and research by Borromeo Ferri (2018). Therefore, the pedagogical content knowledge for teaching mathematical modelling includes a *theoretical dimension* (e.g. knowledge about modelling cycles as well as aims, perspectives and criteria for the use of modelling tasks), a *task dimension* (e.g. knowledge about solution processes, analyses and development of modelling tasks), a *diagnostic dimension* (e.g. recognition of modelling phases and difficulties in the modelling process) and an *instruction dimension* (e.g. knowledge about interventions during students' modelling processes) (cf. Borromeo Ferri, 2018; Wess et al., 2021b).

For the current test development to **measure the pedagogical content knowledge for teaching simulations and mathematical modelling with digital tools**, mathematical simulation is included in this structural model at the above-mentioned intersection with mathematical modelling. Additionally, the four teaching competencies are focused on the use of digital tools (cf. Figure 2).

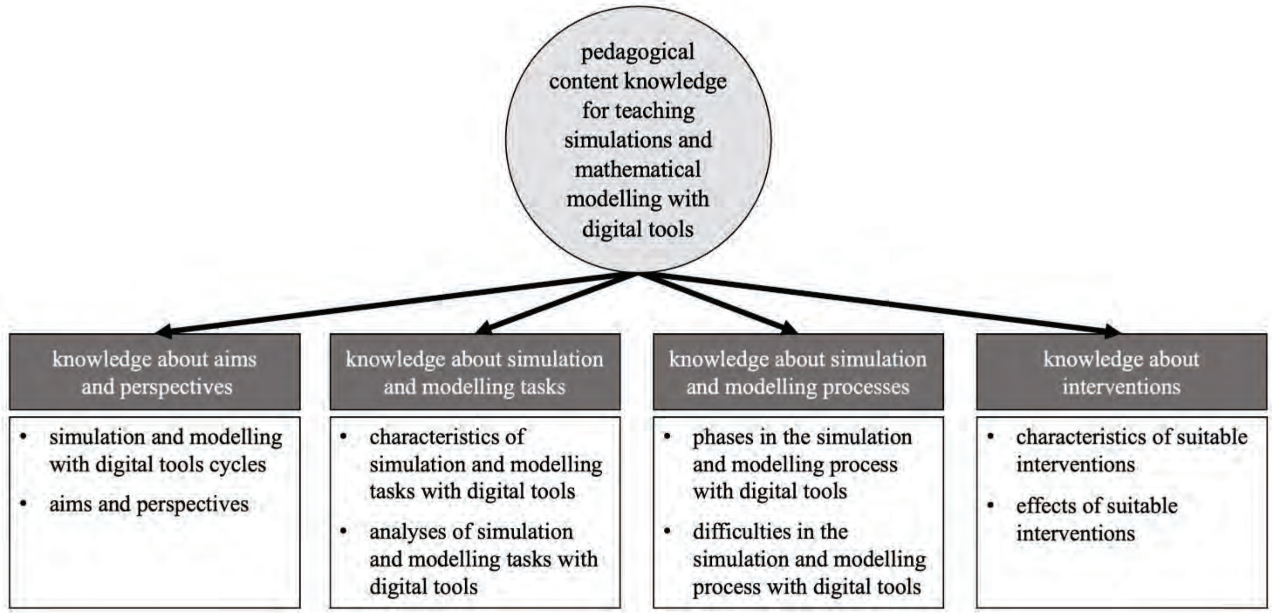

Figure 2: Pedagogical content knowledge for teaching simulations and mathematical modelling with digital tools (following Wess et al., 2021a)

Test construction

Based on the model shown in Figure 2, we developed 84 items in a deductive test construction to empirically (quantitatively) capture the construct described above in four dimensions. The preliminary test design was first qualitatively pre-piloted with experts on simulation, modelling, and digital tools ($N = 11$). Based on their feedback and edits, the content of the test draft was revised. We then presented the test draft to ten pre-service mathematics teachers at the University of Muenster and the University of Wuerzburg for further qualitative pre-piloting. Using think-aloud and verbal probing methods, items that were difficult to understand were identified and then revised or eliminated. Finally, a test draft with 79 closed items in the four theoretically derived dimensions *aims and perspectives* (13 items), *tasks* (10 items), *processes* (28 items) and *interventions* (28 items) was developed. As an example, we would first like to present one item each from the dimensions *aims and perspectives* (Figure 3) and *tasks* (Figure 4):

5.3	The use of digital tools …	
	… requires a standardized approach to mathematical modelling.	☐
	… in mathematical modelling is only possible in calculation.	☐
	… makes it possible to work on mathematical models with complex function terms.	☐
	… is not helpful in understanding the factual context.	☐

Figure 3: Example item of the dimension *aims and perspectives*

6.3	Modelling tasks with digital tools in pre-built configurations (e.g., dynamic worksheets) ...	true	false
	… prevent different ways of solving the problem.	☐	☐
	… enable a targeted reduction of task complexity.	☐	☐
	… enable students to use the digital tool independently right from the start.	☐	☐

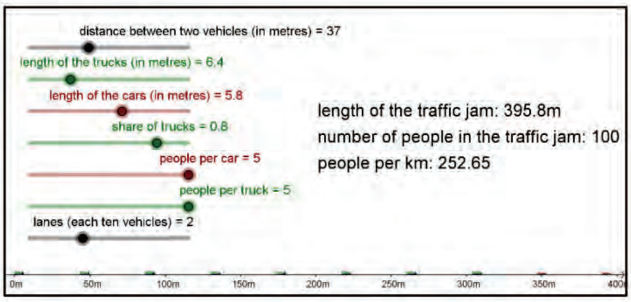
Figure 4: Example item of the dimension *tasks*

Following Wess et al. (2021b), the scales consist of multiple-choice and combined-true-false formats, which are to be evaluated dichotomously. Both items (as well as the following) were initially constructed in German and then translated into English for this paper.

The dimensions *processes* and *interventions* are captured with case-based text vignettes. The text vignettes each contain a simulation and/or modelling task and associated conversations between students in a concrete processing phase of the task with digital tools. The text vignette "Traffic Jam" serves as an example here (cf. Figure 5, task, and Figure 6, conversation).

7.4 Traffic Jam (9th grade)

At the beginning of the summer vacations, traffic jams often occur. Christina is stuck in a 20 km traffic jam for six hours. She thinks about how many people are in the traffic jam with her.
Estimate the number of people in the traffic jam.
Also use the GeoGebra applet on the right.



[The simulation shows a traffic jam with ten vehicles per lane. The students can make different assumptions for the traffic jam using the sliders. The simulation then calculates the length of the traffic jam, the number of people in the traffic jam and the number of people per kilometer in this traffic jam.]

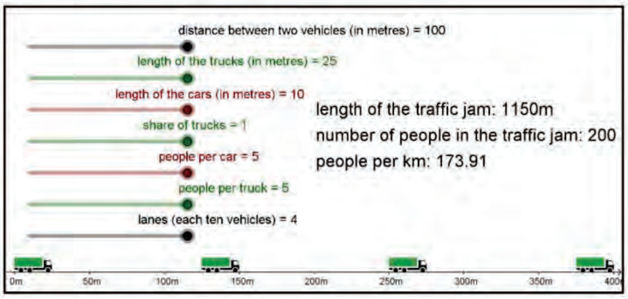
Figure 5: Task "Traffic Jam" (following Maaß & Gurlitt, 2011; Wess et al., 2021b)

STUDENT 1: First, we need to know how many cars and how many people are even in the traffic jam. Or rather in an average traffic jam. Otherwise we can't estimate.

STUDENT 2: Exactly. In the simulation, by the way, you can also adjust the trucks. There are fewer people in them, or at least they are longer than a normal car.

STUDENT 3: I'll set everything so that the traffic jam is as big as possible.

STUDENT 3: [Sets the maximum distance and the maximum vehicle length, among other things, on the sliders, see right].



STUDENT 3: Huh? I don't even get to 20 km. The traffic jam is always shorter in the simulation. We can't even solve the problem with that.

STUDENT 2: I have no idea how to do that.

Figure 6: Conversation of the students while solving the task "Traffic Jam"

Based on the task and conversation, the participants should subsequently diagnose the students' problem in the solving process (cf. Figure 7) and derive suitable interventions (cf. Figure 8) in these situations by answering the corresponding items.

7.4.2	Which function of the digital tools do the students **mainly** use in this situation? Please place <u>**one**</u> mark.	
	investigate	☐
	simulate	☐
	visualize	☐
	control	☐

Figure 7: Example item of the dimension *processes*

	Please mark whether each of the following interventions is suitable for the autonomy-oriented promotion of modelling or simulation competencies in this situation. Please place <u>**one**</u> mark for <u>**each**</u> intervention.	suitable	unsuitable	do not know
7.4.5	"Check that the simulation allows you to make statements about at least part of the problem."	☐	☐	☐

Figure 8: Example item of the dimension *interventions* (following Wess et al., 2021b)

Evaluation methods and results

To make the quantitative evaluation of the test design in the context of ongoing item revision and selection possible, the test was presented to a suitable sample under standardized conditions. The sample consisted of $N = 128$ pre-service mathematics teachers from the University of Muenster, the University of Wuerzburg and the University of Erlangen-Nuremberg.

The four dimensions were each scaled with a one-parameter Rasch model (cf. e.g., Rost, 2004). For the calculations, the software R with the packages TAM (Robitzsch et al., 2021) and eRm (Mair & Hatzinger, 2007) was used. Following PISA (OECD, 2012), items with a discrimination index under 0.2 were removed from the test. In line with Bond and Fox (2007), we only left items with adequate mean square fit (MNSQ) statistics in the test. Thus, items whose infit and outfit values were not between 0.8 and 1.2 were gradually eliminated. We made an exception for two items from the dimension *interventions*. The two items show an overfit that, however, is not significant at a level of five per cent. Since the two items are of great importance from a didactic point of view, they remain in the test nonetheless and only their phrasing is revised. In future evaluations, they are to be critically examined again.

After selection and revision, the test contains 54 items in the four dimensions. The one-dimensionality of the scales was tested globally with the help of Andersen tests (cf. e.g., Rost, 2004). According to Lienert and Raatz (1998), the EAP reliabilities of the individual dimensions are sufficient for group comparisons. The results of the tests are summarized in Table 1.

Table 1: Results of the analyses

<table>
<tr><th>Scale</th><th>Number of items</th><th>EAP reliability</th><th>Andersen test</th><th>MNSQ</th><th>Pt.-bis. corr.</th></tr>
<tr><td>Aims and persp.</td><td>9</td><td>.57</td><td>1</td><td rowspan="4">0.82* to 1.15
* Exception: Two items are closely below 0.8 (overfit).</td><td rowspan="4">> 0.22</td></tr>
<tr><td>Tasks</td><td>9</td><td>.56</td><td>.95</td></tr>
<tr><td>Processes</td><td>18</td><td>.62</td><td>.26</td></tr>
<tr><td>Interventions</td><td>18</td><td>.78</td><td>.16</td></tr>
</table>

Summary and Outlook

This article focused the extent to which the pre-service teachers' pedagogical content knowledge for teaching simulations and mathematical modelling with digital tools can be empirically captured as a construct. Based on the structural model of professional competence for teaching mathematical modelling (Wess et al., 2021b), items were constructed using a deductive test theory. It was found that – in the studied group – pedagogical content knowledge for teaching simulations and mathematical modelling with digital tools can be adequately captured as a construct using the developed test instrument. The data collected confirms the four scales *tasks*, *aims and perspectives*, *processes* and *interventions*. Nevertheless, the scales *tasks* and *aims and perspectives* need to be focused on separately in the further course of the investigations due to the comparatively poorer EAP reliabilities. It needs to be checked whether a multidimensional approach, which takes into account correlations between the latent traits, increases the EAP reliabilities.

Combined with the results obtained from the Andersen test and in the Mean Square Fit (MNSQ) statistics for the two scales, the developed test in its current form seems to enable the measuring of pedagogical content knowledge for teaching simulations and mathematical modelling with digital tools. At the same time, the results are to be confirmed again in cross-validation.

The promising results must be viewed – analogously to Wess et al. (2021a) – against the background that the dichotomous item construction has to allow for definitive true or false answers. Particularly in the field of reality-based tasks, this leads to an additional narrowing of an already very narrow construct, so that many items and text vignettes had to be excluded at the outset. In addition, the scalability and meaningfulness of the current test instrument have so far only been demonstrated for the participating universities. Although we have taken into account the representativeness of the sample according to objective parameters (e.g., study progress, subject combination, previous achievements if applicable) in our evaluation, differences in teacher education in the area of reality-based tasks cannot be ruled out. The question of generalizing the present results therefore remains open for the time being.

In addition to the previous results, pedagogical content knowledge, beliefs and self-efficacy will now also be evaluated and presented in a structural equation model. The complete test instrument will then be used in the coming semesters in courses at the University of Muenster and the University of Wuerzburg in a pretest-posttest control group design.

An observation instrument to analyze the collaboration between students while solving mathematical modelling problems

Sevinç Göksen-Zayim, Derk Pik and Carla van Boxtel

University of Amsterdam, The Netherlands

s.goksen@uva.nl; d.r.pik2@uva.nl; c.a.m.vanboxtel@uva.nl

Collaborative learning is a well-established approach to elicit reasoning. The ability to solve mathematical modelling problems depends much on the ability to reason, because mathematical modelling problems are usually presented to students through texts. Decisions have to be made at all stages of the mathematical modelling cycle, for instance on assumptions, simplifications and feasibility of the model. In this paper we present an observation instrument to study collaborative modelling. There are three core components: collaborative learning, mathematical modelling and the language that students use while working together.

Keywords: Mathematical modelling, collaborative learning, observation, language proficiency.

Introduction

In the Netherlands, mathematical modelling has become a small but obligatory part of the upper secondary curriculum. However, it is missing in the greater part of lower secondary education. To improve the vertical coherence in the curriculum, our research focuses on modelling assignments in lower secondary education.

The purpose of our larger research is to determine whether the open-ended group assignments we developed promote collaborative mathematical modelling. In this study, we aim to construct an observation instrument. The research question we address is: How do we examine the quality of students' collaborative learning in tasks that aim at mathematical modelling?

Theoretical framework

Many studies have shown that collaborative learning has a positive effect on students' mathematics learning (e.g. Dekker & Elshout-Mohr, 1998, 2004; Pijls, 2007; Webb, 2009; Webb et al., 2020; Yackel et al.,1991). Discussions in small groups can also promote the development of modelling competencies (Maaβ, 2006; Galbraith & Clatworthy, 1990). We discuss three features of the interaction between students, that - based upon the literature - can be considered relevant when aiming at mathematical modelling with group tasks: (1) collaborative learning, (2) mathematical modelling and (3) the language that students use while working collaboratively on the modelling task.

Collaborative learning: Various researchers have shown that collaborative learning in heterogeneous groups raises the level of abstract reasoning as suggested by van Hiele and Freudenthal when the task enhances students to verbalize their understanding, to explain their thinking to one another and to criticize one another's way of thinking (Calor et al., 2019; Dekker & Elshout-Mohr, 1998; Palha, 2013; Pijls, 2007; Yackel et al., 1991).

Dekker and Elshout-Mohr (1998), for example, defined four key activities in their Process Model for structuring small group discussions of students when working at a mathematical task. Initially the students are working individually on the same mathematical task. Their works will be different. After some time, they compare the findings: they show their own work, they explain their own work, they justify their own work and eventually reconstruct their own work.

Collaborative learning activities that have been identified as key activities for mathematical level raising, such as explaining and justifying, have also be mentioned by scholars who focus on features of productive collaborative learning (Mercer, 2006; van Boxtel et al., 2000; van der Linden et al., 2000). According to Mercer (2006) three types of talk can be discerned: disputational talk, cumulative talk and exploratory talk. Disputational talk is characterized by disagreement and individualized decision making, cumulative talk takes place when students share knowledge but contributions are uncritically accepted by the group. In exploratory talk students engage critically and constructively with each other's ideas.

Mathematical modelling: In the field of mathematical modelling various definitions of the modelling cycle are found. The modelling cycle starts with a situation or problem in the real world. Thus is it important to understand the situation. Blum and Leiβ (2005) define this understanding of the original situation as the situation model. Then, the given situation has to be simplified, structured and made more precise, which results in a real model (Blum & Leiβ, 2005). In the first step of the modelling cycle it is essential to become aware of the meaning of the problem. Furthermore, modelling encompasses various activities that are carried out consecutively, including mathematising, working mathematically, interpreting, and validating (Blum & Leiβ, 2005). Maaβ (2006) identifies specific sub-competencies related to the mathematical modelling process and argues that modelling competencies include more than the steps of a modelling process. Assumption making is one of these sub-competencies to understand the real problem and to set up a model based on reality.

The use of language: The language used at school often forms an obstacle to learning mathematics (Van Eerde & Hajer, 2009). Plath and Leiβ (2018) point out that a low language proficiency may result in comprehension problems and a low performance on modelling tasks.

Mathematical modelling problems are usually presented to students through texts in context-rich assignments. In the context of modelling tasks, it is important to examine what language students use while modelling. Cummins (2000) distinguishes between Basic Interpersonal Communicative Skills (BICS) for communication every day and Cognitive Academic Language Proficiency (CALP) for communication in education. During collaboration, students may explain difficult words to each other, and use mathematical terminology during their collaborative work. Webb (1991) classifies this as the explainer: the learner who translates unknown vocabulary into language that is known to other students. Especially for modelling tasks is it important to understand the situation of the given problem (Blum & Leiβ, 2005).

Method

In this study, a series of five different modelling tasks for the domains algebra and geometry have been developed for grade eight students (age 13-14). In the Netherlands, grade eight is part of lower secondary education. The modelling tasks were developed according to design principles that we derived from Galbraith (2006) and Geiger et al. (2021) and literature on collaborative learning.

For collaborative learning, a task should be complex and rely on multiple skills (van Boxtel et al., 2000; Cohen, 1994). Furthermore, the designed modelling tasks are open-ended problems that require making the necessary assumptions, are linked to the real world and motivate students (Galbraith, 2006; Geiger et al., 2021). The tasks were improved using feedback from educational experts, mathematics teachers and a pilot with grade eight students.

In total, five secondary schools with ten classes and seven mathematics teachers, located in an urban environment participated in this research. The collaborative learning groups consisted of three students. Each group worked on one task during one lesson. Three or four randomly selected groups in each class were video-taped and audio-recorded, and the written group products of all groups were collected. In each class, the tasks were introduced with the same introduction and brief information about mathematical modelling.

To analyze students' verbal interaction while collaborating on mathematical modelling tasks, we need a valid and reliable observation instrument. This observation instrument was designed in three steps: (I) development of the instrument based on theory about collaborative learning and mathematical modelling and recordings of three randomly selected groups; (II) a pilot study in which we used six randomly selected video-recordings of group conversations to further operationalize the categories in the instrument and to investigate the reliability of the instrument; (III) adjustment of the instrument.

Results

First design of the observation instrument: Recordings from three randomly chosen groups were selected to design a first version of the observation instrument. A variety of two tasks was included. We defined three main categories of student interaction while working collaboratively on mathematical modelling tasks, that can be considered relevant: (1) collaborative learning, (2) mathematical modelling and (3) the language that students use while working collaboratively on the modelling task. In addition, to improve the designed open-ended group assignments, it is important to examine questions students ask the teacher about the modelling task. This additional category is named questioning. Furthermore, for each subcategory, we added space to note comments.

Collaborative learning: It is important to discern whether students work primarily individually or together at our tasks. Therefore, the first subcategory in the main category collaborative learning is collaboration. The second subcategory is critical considerations focused on the solution strategies (critical considerations and strategies). The next four subcategories are the four key activities of Dekker and Elshout-Mohr's (1998) Process Model. The last sub-category is the type of discussion. According to Mercer (2006) three types of talk can be discerned: disputation talk, cumulative talk and exploratory talk.

Mathematical modelling: Mathematical modelling encompasses various activities that are carried out consecutively. For these activities we make use of the modelling cycle of Blum and Leiβ (2005). The steps in the modelling cycle are sequentially added as subcategories to the main category mathematical modelling of the observation instrument. In the first step of the modelling cycle it is essential to get aware of the meaning of the problem. Therefore, we first focus on whether students have understood the problem by observing whether students clarify the purpose of the modelling task (clarifying). In the second subcategory we observe if students discuss how to tackle the problem (addressing). In the third subcategory, we observe whether students understand the problem and if they transform the problem for reasoning (transforming). The fourth subcategory, we observe whether students simplify or structure the problem (simplifying). In the next subcategories we observe the assumption making, mathematizing, working mathematically, the way students are solving the problem (solving strategies), interpretation of the solution (interpreting) and whether students validate (in between or at the end) throughout the modelling process (validating).

The use of language: In the first subcategory we observe the use of everyday language (BICS). To find out whether the designed tasks contain difficult words for the students, we observe whether students explain certain words to each other while collaborating on the modelling task. In the second subcategory we observe the extent to which students use mathematical terms (CALP). To support coding, a list has been added with the most common mathematical concepts for the designed modelling tasks. In the third subcategory we observe whether students explain the mathematical concepts to each other (CALP to BICS). The last subcategory focuses on students' use of modelling language. We investigate whether students formulate their solution in the context of the modelling task (formulating) and whether they use specific modelling language in the solution process.

Questions about the task: The last category is added to examine if the students are asking the teacher a question and to write down the question(s) asked (questioning).

Results of the pilot study: Six randomly chosen video-recordings were coded by two researchers (the first two authors). The percentage of agreement between the researchers are shown in Diagram 1. For the main category collaborative learning the subcategories with the least agreements are: explaining their own work, justifying their own work and reconstructing their own work. For the main category mathematical modelling the subcategories with the least agreements are: clarification of the purpose, assumption making, mathematization and validation. For the main category use of language the agreement is acceptable. This is also for the additional category: questioning.

Revision: As a result of these findings, the categories with a low percentage of agreement, were revised. Clarifications have been added to the key activities. For example, what is meant with to show, to explain, to justify and to reconstruct. The fourth category, with subcategory to explain, of the observation instrument is shown in Table 1.

Table 1: Fourth subcategory of the observation instrument for main category collaborative learning

Collaborative learning	☒	Notes
4. To Explain Explaining or clarifying the way of working or thinking		
A. No student explains his way of working or thinking to the rest of the group		
B. One student explains his way of working or thinking to the rest of the group		
C. Several students explain their way of working or thinking to the rest of the group		

An explanation has also been added to the main category mathematical modelling, subcategories making assumptions and validating. In the main category collaborative learning, critical considerations focused on solution strategies have been adapted into two subcategories. Critical considerations students make with each other while collaborating is still a subcategory of collaborative learning. Solution strategies have been moved to the category mathematical modelling, because it fits more in the processes for solving modelling problems. With this category we examine whether students apply one or more strategies to solve the modelling problem.

We also adjusted the sequence of the subcategories in the main category mathematical modelling. In the revised instrument, we started with the subcategory clarification of the purpose of the task, followed by addressing the problem, understanding and simplifying the problem, and assumptions making. After that, the findings of a mathematical model or mathematization were noted, followed by mathematical solution, interpretation and validation. As discussed above, another subcategory had to be added, namely the solution strategies. As a result, the revised observation instrument included ten subcategories for mathematical modelling. By choosing an order that best suits how students work through the task, it becomes easier to observe.

No adjustments were made for the components: language proficiency and question to teacher.

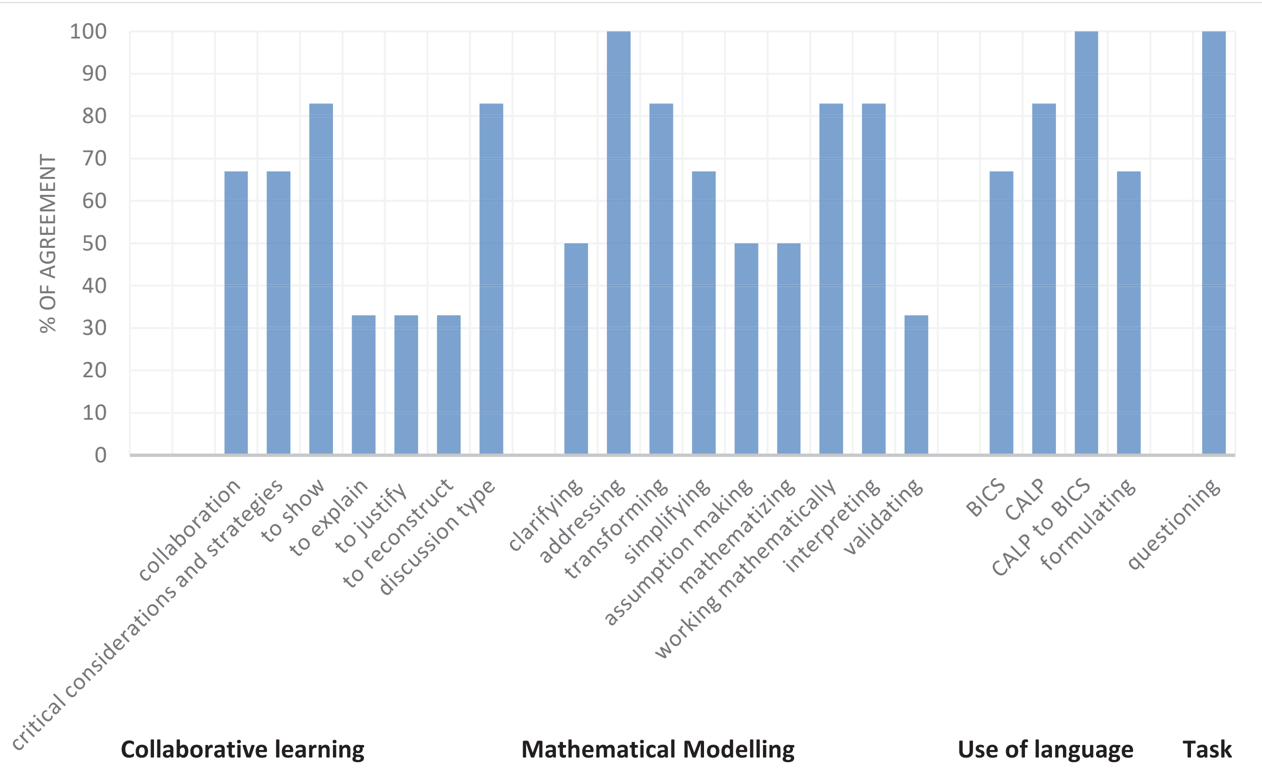

Diagram 1: Percentages of agreement in each subcategory for the pilot with the observation instrument (six collaborative learning dialogues)

Conclusion and discussion

In order to evaluate the quality of students' conversation, we have developed an observation instrument with which we can analyze the students collaborative learning while solving mathematical modelling problems. We observe the data on basis of three main categories. The first category is collaborative learning of students. We are using the Process Model (Dekker & Elshout-Mohr, 1998) to observe how students work together to increase their mathematical understanding. The second category is mathematical modelling, using the phases of the modelling cycle (Blum & Leiβ, 2005). The last category is the language that students use while working collaboratively on the modelling task. We observe the way students explain difficult words to each other, the use of language related to mathematics and modelling.

For the main category collaborative learning, the least agreement has been reached for the key activities of Dekker and Elshout-Mohr's (1998) Process Model. One reason for this could be that these key activities are applied by Dekker and Elshout-Mohr to students who initially work individually on the same task and then compare it with each other. While the students in our study work together on the tasks throughout the modelling process. For the main category mathematical modelling, subcategories have also been identified in which a low agreement has been reached. These subcategories, have been supplemented with an explanation that has been added or adjusted. Therefore, the revised observation instrument should be retested.

Successful solving of a mathematical modelling problems requires modelling competencies (Maaβ, 2006), but also metacognitive strategies in solving complex modelling problems in groups (Vorhölter, 2019). In the instrument we focus on the students' multiple solution strategies, but we do not observe whether students are (collaboratively) engaged in task orientation or planning. It is difficult to include that, because we want to use the observation instrument to know whether the developed modelling tasks are suitable. If there is a lot of regulation during collaboration, it can mean that the task is too open or complex, but it can also mean that students discuss this well. In addition, the developed assignments were performed in groups without teacher guidance and this can lead to confusion of students' thinking (Goos et al., 2002). A more qualitative analysis would then be necessary to gain more insight into this. Follow-up research could focus on how these metacognitive activities and teacher guidance could be included in the observation instrument.

In our next study, we will apply this observation instrument to investigate the quality of student interaction in order to evaluate the suitability of the group tasks we developed in order to develop students' mathematical modelling competencies.

Professional content knowledge of mathematical modelling of pre-service teachers: First considerations for a new test instrument

Gilbert Greefrath[1], Rita Borromeo Ferri[2] and Hans-Stefan Siller[3]

[1]University of Münster, Germany; greefrath@uni-muenster.de

[2]University of Kassel, Germany; borromeo@mathematik.uni-kassel.de

[3]University of Würzburg, Germany; siller@dmuw.de

Modelling competence is a central concept in research on teaching and learning mathematical modelling. Numerous studies support the theoretical foundation of modelling competence as well as the existence of tested and already modified test instruments for different age levels. In addition to other aspects of professional competence, such as pedagogical content knowledge, pre-service teachers must also possess modelling competence themselves. Even though test instruments for modelling competence already exist, the aspect of professional content knowledge of mathematical modelling as a competence facet of teachers has received less attention thus far. In this theoretically oriented paper, first theoretical considerations for the development of such a test instrument are presented on the one hand, and on the other hand, ideas for further development are discussed based on sample items.

Keywords: Professional competences, content knowledge, test instrument, mathematical modelling.

Introduction

The importance of pedagogical content knowledge in mathematical modelling teacher education has already been highlighted as significant, but only more systematically in recent research. Therefore, a focus will now also be placed on the content knowledge of modelling. In this paper, we mainly present theoretical considerations regarding the content knowledge of modelling in the overall context of teacher education on modelling. In addition, we present examples of concrete items. Accordingly, we would like to address the challenge of developing a test instrument, which will differ from already existing tests in the still pending development process.

Therefore, we first review the following theoretical foundations, which form a theoretical framework for us as a basis for the systematic construction of items. This concerns professional competence in the models of Kunter et al. (2013) and Shulman (1986). Especially regarding Krauss et al. (2013), we derive our considerations of levels of mathematical expertise, which we concretise with respect to calculus, with which we start as a mathematical subject area with item construction. Relevant aspects of modelling sub-competencies follow, as well as a discussion of existing test instruments. Finally, the item examples illustrate first considerations and show the challenge of construction. The main goal of this paper is to demonstrate we need a new test instrument for the content knowledge of mathematical modelling in teacher education, including which aspects of test construction need to be considered.

Professional competence

The professional competencies of mathematics teachers and pre-service mathematics teachers have been extensively studied (e.g. Blömeke & Delaney, 2012; Kunter et al., 2013). The concepts of professional competence developed in these studies share key commonalities. In particular, professional knowledge is seen as consisting of different knowledge domains: content knowledge, pedagogical content knowledge and pedagogical–psychological knowledge (Shulman, 1986). In addition to these cognitively oriented knowledge dimensions, affective aspects are also considered. Further conceptions of pedagogical content knowledge for mathematics teachers, some of which also include content knowledge and pedagogical–psychological knowledge, are relevant (Depaepe et al., 2013). The importance of teachers' content knowledge is highlighted in various studies (Blömeke & Delaney, 2012). The high correlation of content knowledge and pedagogical content knowledge is well known (Krauss et al., 2008; Yang et al., 2021), highlighting the importance of the content knowledge of pre-service teachers in particular.

Levels of mathematical content knowledge

Mathematical content knowledge can be described using different models. Based on Shulman (1986), Krauss et al. (2013) proposed four levels to describe mathematical content knowledge. They distinguish everyday mathematical knowledge, the mastery of school-level mathematical knowledge, a deep understanding of the content of the secondary school mathematics curriculum and university-level knowledge (Krauss et al., 2013, p. 155). This classification begins with a first level of mathematical content knowledge that all adults must possess. The second level is school knowledge. At this level, we consider competence to use mathematics in the context of the knowledge usually taught at school. This *school mathematical competence* goes beyond everyday mathematical competence and includes, for example the competences required to complete a task in the Abitur examination (KMK, 2012). A third level describes the mathematical content knowledge required for a deeper understanding of the subject content at the secondary level. We refer to this level as *in-depth school mathematical competence*. This includes elementary mathematics from a higher standpoint (Klein, 2016) as taught at university. The fourth level can be called *university competence.* This includes mathematical knowledge taught at university with virtually no connection to the school curriculum, for example algebraic number theory (Krauss et al., 2013). Depending on the course of study, *in-depth school mathematics competency* or university mathematics competency are achieved at university in a teaching degree with mathematics as a subject. Content knowledge, as conceptualised in COACTIV, lies between the second and the third level, as shown in the published example item 'Is $2^{1024} - 1$ a prime number?' (Krauss et al., 2013, p. 152).

Modelling cycle and sub-competencies of modelling

Mathematical modelling processes can be illustrated by a modelling cycle that depicts the sub-processes or sub-competencies of simplifying, mathematising, interpreting and validating. Former research describes many cycles that vary mainly in the number of individual sub-processes (Borromeo Ferri, 2006). The modelling cycles from applied mathematics (Pollak, 1977) describe the processes deterministically in three or four phases. In didactically oriented discussion, there are four-phase, but also six- and seven-phase cycles (Blum & Leiß, 2007) or extended cycles concerning the use of technologies (Greefrath et al., 2018). Regardless of the number of sub-processes, modelling competence is required. In this context, modelling competence is understood as the ability to identify a real-world problem in a given situation, translate it into mathematics and interpret and validate the solution to the corresponding mathematical problem about the given situation (Niss et al., 2007). *Global modelling competence* refers to the entire modelling process and to general competences, such as a structured and goal-oriented approach to tasks, reasoned argumentation and independent reflection on the modelling process (Kaiser & Brand, 2015). The *sub-competencies of mathematical modelling*, however, refer to the sub-processes in the modelling cycle mentioned above or identified in the various cycles (Maaß, 2006).

The assessment of students' modelling competencies using tests has already been empirically demonstrated in many studies for different age groups (Haines et al., 2001; Hankeln et al., 2019; Kaiser & Brand, 2015). Two basic principles can be distinguished. On the one hand, there are items that focus on the sub-processes of modelling (atomistic approach) and, on the other hand, items that require the complete pass through of a modelling cycle (i.e. a holistic approach; Blomhøj & Jensen, 2003). In our test construction, we prefer an atomistic approach and limit ourselves to the sub-competencies simplify, mathematise, interpret and validate.

Mathematical modelling and analysis

In his characterisation of applied mathematics and modelling, Pollak (1977) attributed early special importance to analysis. To work on a modelling task, a knowledge of mathematical content is required in addition to process-related competences, which are described within the framework of the German educational standards for the Abitur examination. The central subject here is calculus (KMK, 2012).

Textbooks often contain examples from calculus as modelling tasks, for example for modelling growth processes. These tasks are particularly suitable for students because of their accessibility through a reference to real life and use of a well-known mathematical topic. With the help of differential calculus, many real or application situations can be modelled, such as topics in the context of traffic (Siller, 2013). Simultaneously, calculus is a central subject area in the German Abitur examination and in mathematics teacher education; it is receiving special attention in research (Rach & Heinze, 2017).

Development of a test instrument

Previous test instruments on university students' modelling-specific mathematical content knowledge use either rather clear Level 2 mathematical content knowledge for modelling, that is the school level (Yang et al., 2021), or Level 3 to Level 4, that is university knowledge or knowledge clearly beyond the secondary level (Czocher et al., 2021; Haines et al., 2001). While Level 2 may seem too low for pre-service teachers in higher semesters, Levels 3 to 4 may overwhelm some pre-service teachers. Sample items from the test of content knowledge from COACTIV could be used as a guide for items on modelling specific content knowledge between Levels 2 and 3.

Based on the previous considerations, we design an *atomistic* test instrument for the modelling-specific content knowledge of pre-service teachers with subject-specific content at *Levels 2 to 3* from the subject area of *calculus* and the focus on one of the four *selected sub-competencies*: simplify, mathematise, interpret and validate. Four example items will illustrate this direction in the following.

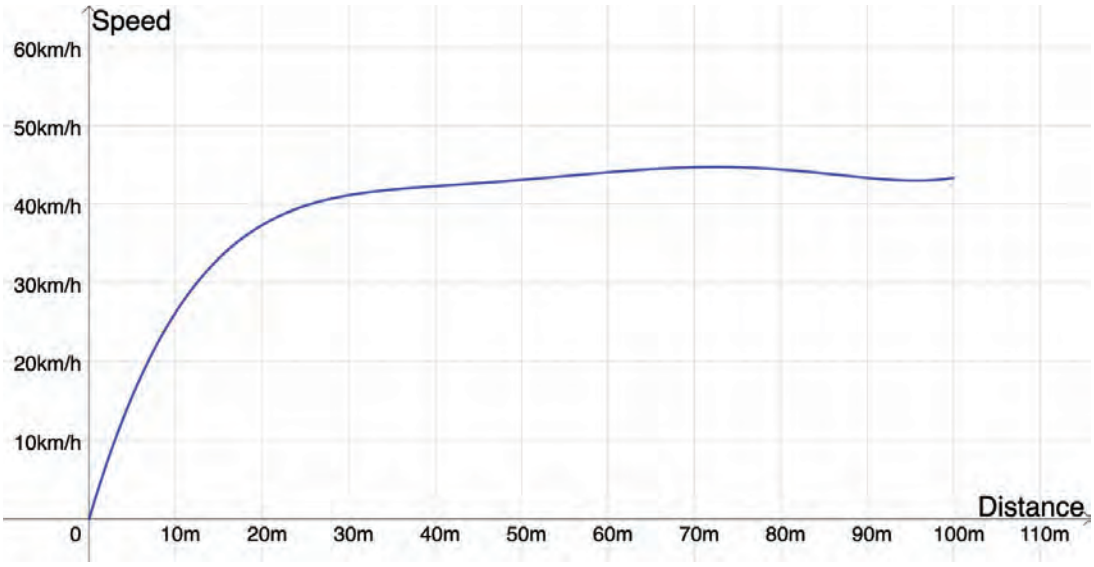
Example item 1 (mathematising)

Spruces represent an important timber species in Germany. The temporal development of the thickness of spruces is modelled by a function d. The planted seedling has a diameter of 0.04 m. After 160 years, a spruce has typically reached a diameter of 0.96 m. Which of the following mathematical models best fits the problem described?

$d(t) = \frac{1}{1+e^{-0,04\,(t-80)}}$	$d(t) = 0,00575\,t + 0.04$	$d(t) = 0,04\,e^{\frac{1}{50}t}$	$d(t) = \frac{1}{e^{-0,04\,(t-80)}-1} + \frac{t}{80}$
●	●	●	●

Example item 2 (interpreting)

In 2009, Usain Bolt set a new world record over 100m running with a time of 9.58s. In the figure, the course of his speed during the world record race is approximated.



Describe the progression of Bolt's speed during the race, considering the real-world context of the record run.

Example item 3 (interpreting)

Tim and his friends are standing on a federal highway in the slow-moving traffic that has seemingly formed 'out of nowhere'. Caro is annoyed: 'These damn 70 zones! If they would lift the speed limit here, then everyone could drive faster, there wouldn't be so many vehicles piling up, and we'd get there sooner!'

Tim has come up with the following 'half-speed rule': $d = \frac{v}{2}$:

v = speed
l = vehicle length
d = distance between two vehicles
S = route of the convoy
D = vehicle throughput per hour

$$D = \frac{S}{l+d} = \frac{1000 \cdot v}{l+d} = \frac{1000 \cdot v}{6+d} = \frac{1000 \cdot v}{6+\frac{v}{2}}$$

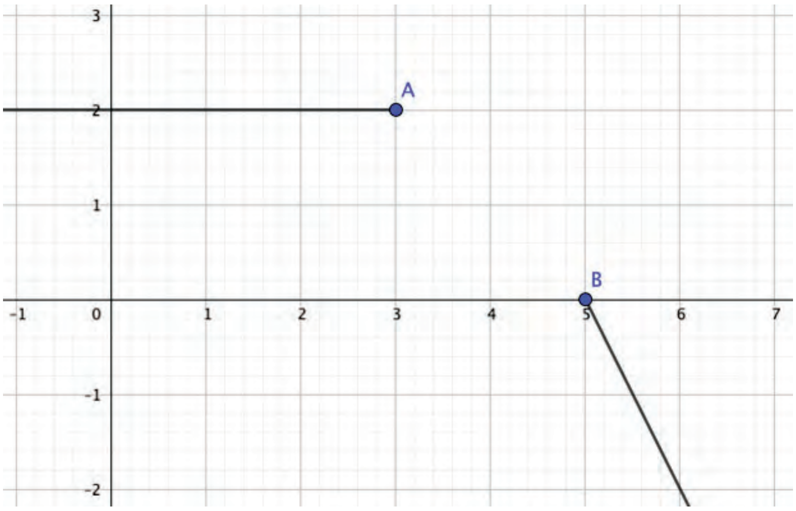
Tim achieves an approximate vehicle throughput of 1,600 vehicles per hour.

What did Tim calculate with his result?

a) The throughput grows infinitely with increasing speed.
b) The risk of rear-end collisions increases due to a guideline speed of 50km/h.
c) The throughput grows limited with increasing speed.
d) The maximum vehicle throughput is only achieved at a higher speed.

Example item 4 (validating)

The shape of a road between two existing roads should be modelled mathematically. The roads can be presented in the coordinate system as follows.



The missing piece of the road between A and B should be modelled mathematically. The model chosen was the appropriate arc of the function $f(x) = \sqrt{4-(x-3)^2}$. Explain why this result would not be used by engineers in reality.

Discussion and Conclusion

Previous research shows that there is a need for a special test instrument on professional content knowledge in mathematical modelling, which is, on the one hand, more demanding in content than average modelling tasks for school students and, on the other hand, below the level of university students who study mathematics as a major (cf. tests by Czocher et al., 2021; Haines et al., 2001). Furthermore, it is desirable that sub-competencies of modelling are considered atomistical, so a separate consideration of sub-competencies becomes possible. In this case, there is already experience with modelling tests for students (e.g. Hankeln et al., 2019; Kaiser & Brand, 2015), whereas in Haines et al. (2001), there is a focus on the first steps of the modelling cycle and no aim at a distinction between sub-processes. Another aspect concerns the common mathematical content of teacher education. Here, several items from the well-established test instrument of Haines et al. (2001) seem less suitable, as they mainly target linear optimisation. Therefore, we focused on calculus as a well-known subject area from upper secondary education and developed items for (pre-service) teachers that go beyond the content of lower secondary education, such as in Yang et al. (2021).

Example item 1 refers to finding a suitable mathematical model in the context of exponential functions. Hence, it is an important sub-area of calculus that is also covered in school. Not all the models given (e.g. logistic growth) are typically school subjects, but go beyond this. Therefore, this test item is to be placed between Levels 2 and 3 of mathematical knowledge. Basic experience with (plant) growth is sufficient to identify the appropriate mathematical model. Based on the problem, the participants can consider which type of growth is appropriate for this problem. The possible answers include linear growth, exponential growth, and logistic growth. A backward validation by inserting values is not necessarily goal-oriented because the terms available for selection correctly represent the boundary points in each case. The mathematical properties of the function must therefore be recognised from the properties of the real problem. The item, then, targets mathematising. For an objective evaluation, a multiple-choice task is recommended here. The task format is like well-known tasks by Haines (2001), but the level of difficulty is adapted to the target group.

Example item 2 describes a world record race using a graph of a function. This graph represents speed and needs to be interpreted. This belongs to the subject area of calculus and can be assigned to secondary level II. Like example 3, it belongs to interpreting, because the results of a mathematical model need to relate to the respective situation. In example item 3, the mathematical content goes beyond the school material. Example item 4 addresses validation. Students must critically examine the mathematical model used (Item 4) in the context of the real-world situation. Item 4 addresses a familiar high school context with a functional equation not usually used in that context. Further additional items for simplification can be taken from the test by Haines et al. (2001), if necessary. A broad coverage of sub-competencies seems important to us to obtain a valid measurement instrument that considers all steps of the modelling cycle for pre-service teachers.

All items, therefore, can be assigned to the subject area of calculus and use school material from upper secondary school or surpass it. The mathematical requirements, then, are implicit. It should be discussed whether explicit items on working mathematically should also be included. In various test instruments for students (Hankeln et al., 2019), this has not been done. The reason in this case was that the processes of modelling were the focus of the study and the test length should remain within certain limits. The question of the test length is also to be discussed here. Other test instruments (Kaiser & Brand, 2015), however, consider holistic tasks and implicitly include mathematical work. However, we also consider it attractive for teacher educators to use items precisely for certain sub-competencies, so that a very focused diagnosis is possible.

Some of the items developed thus far can be objectively coded using multiple choice items, while others are evaluated using criterion-guided coding manuals in the partial credit model. In addition to the items presented here, further items for a complete test of professional content knowledge for modelling need to be developed and empirically tested. A prerequisite is a discussion of the competencies to be tested (atomistic or holistic), level of difficulty, item format and mathematic subject area.

Modelling while problem posing – A case study of preservice teachers

Luisa-Marie Hartmann[1], Janina Krawitz[1], and Stanislaw Schukajlow[1]

[1]University of Münster, Department of Mathematics, Germany; l.hartmann@uni-muenster.de

Because problem posing might enhance activities that are necessary for solving real-world problems, it has the potential to foster modelling. However, systematic research on the connection between problem posing and modelling is largely missing. Therefore, in the present study, we investigated (1) the modelling activities that take place when posing problems that are based on given real-world situations and (2) the extent to which modelling activities occur with different problem-posing activities. To address these questions, we asked seven preservice teachers to first pose a problem based on a given real-world situation and then to solve their self-generated problem. A qualitative content analysis revealed that modelling activities that are close to the real-world situation (e.g., understanding, simplifying, and structuring the given pieces of information) are involved in problem posing. This result indicates that problem posing has the potential to foster mathematical modelling.

Keywords: Problem posing, modelling, teaching approach, preservice teachers.

Introduction

Modelling is one of the key competencies of mathematical learning as it enables students to understand their environment with the help of mathematics (Niss & Blum, 2020). However, modelling is a demanding process for both students and teachers alike (Schukajlow et al., 2018). Therefore, beneficial approaches for fostering mathematical modelling are needed (Schukajlow et al., 2018). Problem solving research has indicated that problem posing has a positive influence on problem solving because problem posing has been claimed to trigger important problem solving processes, for example, analyzing the given situation in an in-depth manner (Cai & Leikin, 2020). As modelling can be characterized as real-world problem solving and begins with a given real-world situation that has to be understood, simplified, and structured, it is possible that problem posing based on given real-world situations (i.e., modelling-related problem posing) is beneficial for fostering mathematical modelling. Surprisingly, there is only a little research on modelling through problem posing. To investigate the potential of problem posing for modelling, we aimed to analyze the connection between problem posing and modelling from a cognitive perspective in this study (Schukajlow et al., accepted).

Theoretical Background

Mathematical Modelling

Mathematical modelling can be characterized by a demanding process of translating information between the real world and the mathematical world with the goal of solving a real-world problem with the help of mathematics (Niss & Blum, 2020). The modelling process can be described as idealized in a circular theoretical model consisting of various activities (Blum & Leiß, 2007). The process begins with activities that are located in the real world. The given real-world situation, which is often presented as a textual description, first has to be *understood* by reading the text and supplementing the information with experience, thus ending up in the construction of an individual situation model. In the next step, the situation model has to be transformed into the real model by *simplifying and structuring* the given situation. Through *mathematization*, the translation from the real world into the mathematical world begins. The real model is translated into a mathematical model or problem. By *working mathematically*, a mathematical result can be calculated, and then it has to be *interpreted* with respect how it applies to the real world so that a real result is achieved. Finally, the real result must be *validated* with respect to whether the existing models and results are appropriate for describing the given situation.

Each of the activities described above can be demanding for students and may represent a potential barrier in the solution process (Blum & Leiß, 2007; Schukajlow et al., 2018). Especially the activities located in the real world (understanding, simplifying, and structuring) are challenging as real-world aspects are often neglected (Krawitz et al., 2018). Therefore, there is a need for approaches that can help overcome these barriers.

Problem Posing

In recent years, problem posing has become an important topic in mathematics education as it has great potential for both the teaching and learning of mathematics (Cai & Leikin, 2020). Problem posing includes a variety of processes. In addition to the generation of new problems, it also comprises the reformulation of given problems that can take place before, during, or after problem solving (Silver, 1994). Further, different stimuli can initiate problem posing. In addition to the categorization of these stimuli on the basis of the structure of the given situation (Stoyanova, 1997), the stimuli can also be differentiated on the basis of their connection to reality. With regard to the differentiation of real-world problems (Blum & Niss, 1991), problem posing can be initiated by situations with and without a connection to reality. In our study, we define problem posing as the generation of new problems on the basis of given real-world situations before problem solving and refer to this type of problem in the following as modelling-related problem posing. An example of a given real-world situation is depictured in Figure 1. An exemplary question that can be posed based on the "Cable Car" situation is a question about the length of cable needed for the new cable car.

Cable Car

For more than 90 years, the *Nebelhorn* cable car has taken numerous guests up into the heights. Now it can go into well-earned retirement. Beginning in the summer of 2021, a new cable car will transport enthusiastic outdoor fans to the Nebelhorn mountain. The aim of the project is to avoid long waiting times, to provide seated transportation with an optimal view from every seat, and to increase carrying capacity.

Technical data of the old cable car:

Model:	Großkabinen-Pendelbahn
Weight empty cabin:	1,600 kg
Weight full cabin:	3,900 kg
Height valley station:	1,933 m
Height top station:	2,214.20 m
Horizontal difference:	905.77 m
Speed:	8 m/s
Carrying capacity:	500 person/h
Power unit:	120 PS

Figure 1: Real-world "Cable Car" situation

Mathematical Modelling in Problem Posing

The connection between mathematical modelling and problem posing can be regarded from two perspectives. On the one hand, questions can be raised during modelling (e.g., Barquero et al., 2019). On the other hand, modelling activities can be already involved in posing a problem. In the following we want to focus the latter connection. In out-of-school modelling scenarios, even though discovering or generating a problem typically takes place before the problem is solved, not much research has investigated the relationship between problem posing and modelling. On the basis of theoretical considerations, generating one's own problems can have a positive influence on the subsequent modelling process. To pose problems that are based on given real-world situations, the given situation has to be *understood* and *explored* with regard to possibilities for posing a problem by distinguishing relevant from irrelevant information and establishing relationships between the relevant information (Bonotto & Santo, 2015). Based on these relationships, possible mathematical problems can be *generated* and *evaluated* with respect to whether or not the given information is coherent and sufficient for solving the problem (Bonotto & Santo, 2015). The associated in-depth analysis of the situation might therefore already involve the modelling activities that are needed to construct an adequate real model and have benefits for the solution process (Hartmann et al., 2021). Empirical research on modelling-related problem posing has supported this assumption. Bonotto and Santo (2015) showed that students included real-world aspects in their solutions when solving self-generated problems using real-world artefacts as problem-posing stimuli (e.g., supermarket bills, restaurant menus). Further, empirical results indicate that the sequence of posed problems is guided by the problem-solving strategies that are typically employed (Cai & Hwang, 2002). Therefore, it is possible that problem posers are involved in *problem solving* while posing a problem that is based on given real-world situations by planning possible solution strategies. As part of planning a possible solution strategy, students might therefore already be engaged in the activities (e.g., structuring and mathematizing) that are needed to solve the self-generated problem. However, an open question is which modelling activities are already taking place during problem posing.

Research Questions and Method

The goal of the study was to analyze the connection between problem posing and modelling by investigating the occurrence of modelling activities in problem posing process. Therefore, we focused on the following research questions:

1. Which modelling activities take place when posing problems based on given real-world situations?
2. With which problem posing activities do the modelling activities co-occur?

Sample

To find an answer to these research questions, we conducted a study with seven preservice mathematics teachers from a large university in Germany (3 men, 4 women) between the ages of 20 and 26 years old (M = 22.86, SD = 1.95). Five of them participated in a program for a higher track secondary school teachers' degree and two of them for a middle track secondary school teachers' degree. All of them already had experience in solving modelling problems and six of them in problem posing. We used heterogeneity sampling to select preservice teachers with different mathematics performance levels, with different levels of experience in problem posing and solving, and who were participating in different university programs.

Procedure and Instruments

To collect the data, we used a qualitative design that included thinking aloud and stimulated recall in order to get deep insights in cognitive processes. The preservice teachers were given three real-world situations and were asked to first pose a problem that was based on the given situation and after posing it to solve their self-generated problem while thinking aloud. We recorded both processes. To supplement the thinking aloud data, we conducted a stimulated recall for every posing and solving process. We used the recorded videos of their posing and solving processes, including their writing, speaking, gestures, and facial expressions, to stimulate the processes. As stimuli for problem posing, we used real-world situations as they are described in modelling problems and extended them by adding further authentic information to allow them to pose a variety of problems. An example of a real-world situation is displayed in Figure 1.

Data Analysis

For data analysis, we first transcribed the videos that had been recorded of the problem posing and stimulated recall and paraphrased the transcripts into sequences, each describing an activity in the process. Then, we analyzed the transcripts by using Mayring's (2015) content analysis. The coding scheme is based on the problem posing and modelling activities described in the literature, and the problem-posing activities were extended on the basis of the given material. The coding schema for the problem-posing activities and the modelling activities are presented in Figure 2. The activity of understanding is included in both coding schema and conceptualized in the same way.

Problem-Posing Activities		Modelling Activities	
Understanding	Comprehending and understanding the given situation and information using the description that is given about the situation.	Understanding	Comprehending and understanding the given situation and information using the description that is given about the situation.
Exploring	Discovering/ gathering relevant information to develop possible questions and organizing the information.	Simplifying/ Structuring	Simplifying and structuring the given real-world situation by differentiating between relevant and irrelevant information, identifying missing information, making assumptions on the basis of this information, and identifying possible solution steps.
Generating	Raising and formulating possible questions and defining a question.	Mathematizing	Translating the selected information into a mathematical model (e.g., table, term, diagram).
Problem Solving	Planning a more or less concrete way to solve the generated problem.	Working Mathematically	Performing the mathematical operations to generate a mathematical result.
Evaluating	Evaluating possible questions on the basis of individual criteria (solvable, meaningful, complete, appropriate formulation, difficulty, suitable for a particular target group).	Interpreting	Interpreting back the mathematical result with respect to the real-world situation and question.
		Validating	Checking models/results for plausibility and appropriateness with respect to the situation.

Figure 2: Coding Schemes for Problem Posing and Modelling Activities

All data were coded by the first author, and over 50% of the data were coded by a second well-trained rater. Interrater reliability was at least moderate for problem posing (Cohen's Kappa between κ =.81 and κ =.95) and for modelling activities (Cohen's Kappa between κ = .76 and κ = .92). To gain an overall picture to which extent the modelling activities are already involved in the problem posing process, we analyzed the transcripts regarding the duration (time of sequences) and the frequency (number of sequences) of the sequences assigned to individual modelling activities.

Results

To assess the occurrence of modelling activities in problem posing, we analyzed the frequency and duration of the sequences in which modelling activities took place while participants posed a problem (see Figure 3). The figure shows that all modelling activities except validation took place during the problem-posing process. However, there were strong differences in the frequencies of the individual activities. Simplifying and structuring could be identified most frequently in problem posing. Second most, understanding could be identified during problem posing, whereas mathematizing, working mathematically, and interpreting could be identified only rarely in the problem-posing process.

Regarding the duration of the individual activities, the overall picture was similar, but it was noticeable that the duration of understanding was significantly higher when compared with the number of sequences. Accordingly, the sequences to which understanding was assigned included a long duration. Overall, participants spent most of their time understanding, simplifying, and structuring, whereas they addressed the activities of mathematization, working mathematically, and interpreting for only very short periods of time.

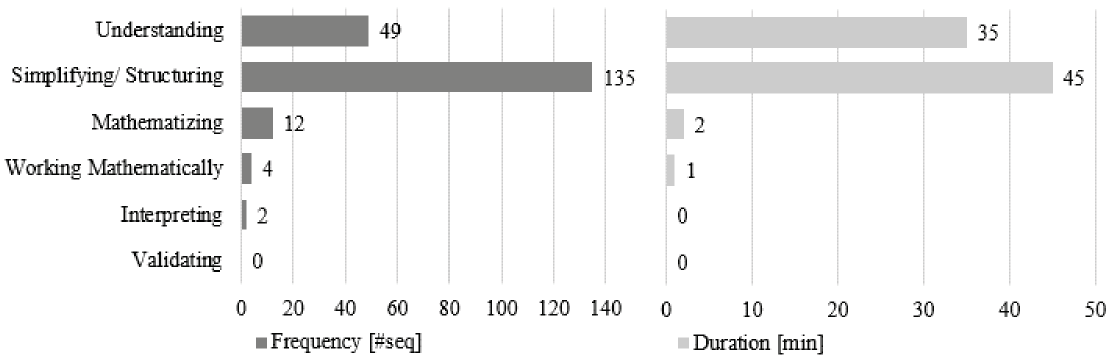

Figure 3: Frequency (left) and duration (right) of modelling activities during problem posing

To understand the connection between mathematical modelling and problem posing, it is important to analyze the co-occurrence of modelling and problem-posing activities. Table 1 presents an overview of the co-occurrence of these activities.

Table 1: Co-occurrence of problem posing and modelling activities

Problem Posing **Modelling**	**Understanding**	**Exploring**	**Generating**	**Problem Solving**	**Evaluating**	**Σ**
Understanding	49	0	0	0	0	49
Simplifying/ Structuring	0	94	6	14	21	135
Mathematizing	0	0	0	12	0	12

Working math.	0	2	0	2	0	4
Interpreting	0	1	0	1	0	2
Validating	0	0	0	0	0	0

Overall, the results revealed that the modelling activity of understanding exclusively occurred with the problem posing activity of understanding. Simplifying and structuring took place most often when participants were exploring the given situation. In the following excerpt, Max is exploring the given real-world situation by filtering relevant from irrelevant data.

Max: Let's take another look at the data for the old Nebelhornbahn. Um, I find the large-cabin aerial tramway rather irrelevant now. Weight empty cabin 1,600 kg and full cabin 3,900 kg.

However, simplifying and structuring also occurred during generation, problem solving, and evaluation. In the context of generation, simplifying and structuring occurred while participants were making assumptions or mentioning relevant information for solving the problem in the formulation of the self-generated problem. For example, in the following excerpt, Nina supplemented her self-generated problem (*What is the best way to shorten the waiting time for the new cable car?*) with the information that the number of people and the speed should be taken into account when solving the problem.

Nina: *(Supplements problem)* Consider the number of people and speed. Something like this.

During problem solving, simplifying and structuring occurred when participants were planning the solution steps they would follow to solve the self-generated problem. In the following excerpt, Max is planning a possible solution for his self-generated problem.

Max: But then we also have the travel speed of 8 m/s. This means that one could theoretically also determine the travel time if we have the length of the route. How long the cable car needs from one station to the next. That would be the next solution step so to speak.

In the context of evaluation, the possibility of solving the self-generated problem is evaluated by checking whether all the information is given. For example, in the following excerpt, Lea evaluated her posed problem by identifying the information that was relevant for checking whether all the information needed to solve the problem was given in the situation.

Lea: Because we know how fast it is, we know where it starts, we know how it's going, and we can say that it's just going straight, so it's kind of going up as a linear function; Then you could/This is a nice question.

Mathematizing came up exclusively for problem solving and working mathematically, and interpreting occurred during exploration and problem solving.

Discussion and Conclusion

In the present study, we investigated the connection between problem posing and mathematical modelling and in particular the occurrence of modelling activities during modelling-related problem posing. The analysis of the problem-posing processes of seven preservice teachers revealed the involvement of nearly all modelling activities. We found that especially the modelling activities of understanding, simplifying, and structuring were already involved in posing a problem that was based on given real-world situations. Understanding was involved in problem posing because it is an essential part of both conceptualizations (problem posing and modelling). Simplifying and structuring are similar to the problem-posing activity of exploring as they are aimed at analyzing the given situation in an in-depth manner, and they typically co-occurred with this activity. Hence, while posing a problem, a situation and real-world model might already be developed. Mathematizing is less involved in the problem-posing process, but it typically co-occurred with the problem-posing activity of problem solving. Problem-solving activities while posing a problem may help problem posers to plan possible solution steps by creating a partial mathematical model. The other modelling activities (i.e., working mathematically, interpreting, and validating) occurred only rarely or not at all, and therefore, these activities might not be triggered by posing a problem.

Our results indicate that especially the modelling activities located in the real world occur while posing a problem. Consequently, problem posing might stimulate an in-depth analysis of the context, something that is important to do for modelling. This result contributes to a theoretical model of the relationship between problem posing and modelling, and it needs to be examined in future studies. As the modelling activities in the real world represent a major cognitive barrier (Krawitz et al., 2018), posing a problem with respect to a real-world situation might help problem solvers overcome these cognitive barriers. Some indication about the importance of problem posing for modelling activities in the real world comes from results in a study by Bonotto and Santo (2015) who found that after problem posing, students often considered real-world aspects of the problem. Further research should investigate how self-generated problems are solved and whether problem posing can affect modelling performance. As a practical implication, our results suggest that modelling-related problem posing could be an innovative and fruitful approach for teaching modelling activities that are located in the real world.

Our study has some limitations that we want to acknowledge. We used a qualitative research approach with a small sample to describe the connection between problem posing and modelling in an in-depth and detailed manner. Due to the design, we could make only hypothetical generalizations, which must be verified in future studies. Further limitations result from the real-world situations we used. These limitations should be kept in mind when interpreting the results of the study. Despite the listed limitations, the study allowed us to contribute to research on modelling by qualitatively exploring the connection between problem posing and modelling. We conclude that there is a close relationship between problem posing and modelling and that, therefore, modelling-related problem posing has great potential for fostering modelling.

Characterising the roles of digital resources in mathematical modelling

Britta Eyrich Jessen

Department of Science Education, University of Copenhagen, Denmark; britta.jessen@ind.ku.dk

Over the last decades digital resources of various kinds have entered mathematics education including mathematical modelling. In this paper we present the a priori analysis of a modelling activity based on Study and Research Path using the notions of media-milieu dialectic and Herbartian schema from the Anthropological Theory of the Didactic. We use these notions to differ between resources: digital tools, textbooks, data and to differ between the pragmatic and epistemic value of the resources. Finally, we discuss how task design can benefit from addressing the potential roles resources can play in modelling processes.

Keywords: Mathematical modelling, media-milieu dialectics, Herbartian schema, digital tools, study and research paths.

Introduction

Through computers, with numbers of digital tools, and smartphones students have access to numerous resources potentially supporting their mathematical work including modelling. Initially, emphasis has been put on Dynamic Geometry Software (DGS) and Computer Algebra Systems (CAS), but other resources emerge continuously. The presence of the resources affects the objects, techniques and practices, students are engaging with in mathematics. Artigue claims that “mathematical objects are not absolute objects but are entities which arise from the practices of given institutions” (2002, p. 248). Thus, when institutions allow the use of more resources it changes the practices for example within mathematical modelling and during the last CERME, the following questions were raised:

> ”How can digital and physical tools change ways of approaching modelling problems? How do they change the meaning of “working mathematically” today? Do we need to rethink the definition and conceptualizations of the steps of the modelling processes when using technology and simulations?” (Barquero et al., 2020, p. 1108)

Though still open, the questions are not new. Previously, Siller and Greefrath (2010) have argued how the merger of modelling and technology might serve both pedagogical, psychological, cultural and pragmatic aims for the teaching of modelling where more advanced calculations and realistic problems can be addressed. They have described the modelling process with an addition (an extra cycle) to the modelling cycle representing the role of computational media (Greefrath et al., 2011). Doerr, Ärlebäck and Misfeldt challenge this representation of the merger arguing that this approach does not capture the potentials of the new resources: “computational media both empower the mathematical processes involved in modelling activities by providing new “worlds” to explore and potentially shape the world we try to model.” (Doerr et al., 2017, p. 79). In other words, emphasis must be put on epistemic values just as much as pragmatic values. Though more realistic problems, requiring more advanced calculations, and larger amounts of data might favour the pragmatic value of computational media. Hence, the role of computational media should be central in our studies.

Greefrath et al. examined this in a study where performances by students who employed GeoGebra compared to those using pen and paper, did not differ. Though students' attitudes towards GeoGebra and self-efficacy related to the program, were predictors for their modelling competence. They conclude that technological tools "cannot simply be seen as a facilitator of learning mathematical modelling, at least not if the tasks are not changed." (Greefrath et al., 2018, p. 243). Thus, the need for analysing and understanding how we can design learning environments providing high-quality modelling education, which draw on "experimental materials and technology in modelling" (Carreira et al., 2019, p. 48) is still an open question. Schukajlow et al. (2018, p. 11) recommend authors in the future to "[...] take into account how technologies can be used for modelling or more generally what interaction between humans and media are meaningful […]". This aligns with the claim of Artigue (2002) and the notion of instrumental genesis, which she argues works in two directions: instrumentalization and instrumentation. Trouche formulates the processes as: "the instrumentation process is the tracer of the artifact on the subject's activity, while the instrumentalization process is the tracer of the subject's activity on the artifact" (Trouche, 2020, p. 410), where the artefact can be DGS, CAS or others. In other words, when tools are used for pragmatic purposes, the students operate the tools to gain certain answers, which can be considered instrumentalization. When we identify instrumentation, it is often linked to more epistemic purposes, where students' thinking is shaped by the tool and the explorations done within the tool. Thus, to capture the needs formulated by Schukajlow et al. (2018) and Carreira et al. (2019) we might need to link instrumental genesis with mathematical modelling, as done by Geiger (2017). He discusses the role of instrumental genesis and teachers' orchestration through a technology rich modelling task capturing traits of authenticity, open-endedness and connectivity as characteristics of high-quality modelling education. He concludes that "by improvising and revising his approach to orchestrating students' learning the teacher promoted changes in students' schemas of instrumented action related to both the digital tool and also the task" (Geiger, 2017, p. 299). He continues by stating the need for further research on requirements for designing modelling problems, where technology acts as enabler for other design principles, implementation, and the learning of mathematical modelling.

To address the challenge of designing and implementing modelling activities, where technology acts as enabler, we propose to explore the potentials of the Anthropological Theory of the Didactic (ATD) in terms of media-milieu dialectics and the Herbartian schema when designing Study and Research Paths (SRP).

The media-milieu dialectics and Herbartian schema

Below we present a generating question, Q, initiating a SRP modelling total income for persons with different levels of education. The question invites students to study of the extra-mathematical and mathematical domain further. Thus, we consider the modelling activity a driver for learning mathematics as seen in (Jessen, 2017). This paper presents the a priori analysis of the design. This is one of the four main components of didactical engineering from the perspective of ATD (Barquero & Bosch, 2015). The a priori analysis explore the potential role of digital resources for modelling and afterwards we discuss how this might inform design principles. From an ATD perspective, the modelling activity unfolds as a dialectic between study and research processes initiated by Q. Students pose derived questions, which leads them to study some media. The new knowledge gained from the media is reworked into partial answers to the derived, and hereby the generating question. This is the research process or reconstruction of knowledge, which takes place in the milieu (Jessen, 2017). The quality of the reconstructed knowledge is validated against the milieu. In ATD we use the Herbartian schema (Chevallard, 2008) to explain the media-milieu dialectic and identify factors affecting the dialectic. The schema describes the didactic system S working together for the development of an answer to the modelling problem Q:

$$S(X; Y; Q) \Rrightarrow A^{\heartsuit}$$

X represents the group of students (which can be a singleton), Y represents the group of teachers supporting X's study of the question Q. Y can be a group, a single teacher, y, or $\emptyset$ in case of self-study. The ➥ indicates that the system of $X; Y$ and Q bring into being a personal answer $A^{\heartsuit}$ to the modelling question. $A^{\heartsuit}$ is different from answers found in any resource, as it is the result of the personal or joined modelling process of a class. The modelling process in ATD is characterised as X and Y's interaction with the milieu M, which is "a fuzzy and changing set of didactic "tools" of different kinds that X, acting under the supervision of Y, has to bring together (➡)" (Chevallard, 2008, p. 2). The entire process can be depicted as:

$$[S(X; Y; Q) \Rightarrow \mathrm{M}] \Rrightarrow A^{\heartsuit}$$

$$M = \{A_1^{\Diamond}, A_2^{\Diamond} \dots, A_l^{\Diamond}, W_1, W_2, \dots, W_m, D_1, D_2 \dots, D_n\}$$

The elements of the milieu are media which "designate here any representation system of a part of the natural or social world addressed to a certain audience" (Chevallard, 2007, p. 1, our translation). The $A_i^{\Diamond}$ denote existing answers being students' previously learned knowledge. This includes instrumented techniques and ability to draw on different digital resources. The W_j cover resources to be studied during the modelling process. This can be a page of a textbook, web searches of different nature (Khan Academy, encyclopaedia etc.). The D_k denotes data in various forms. Chevallard (2019) argues that data can be of quantitative or qualitative nature. Students might generate data (from experiments or simulations), they can be found in databases, or they can be part of the formulation of the modelling problem. Thus, the milieu of the Herbartian Schema is the media brought together with the purpose of nurturing the study of the modelling problem Q. Note that the milieu can have an element of a-didactic potential as known from the work of Brousseau (1997), where "a system of objects acting as a fragment of "nature" for Q, able to produce objective feedback about its possible answers" (Kidron et al, 2014, s. 158). Thus, for modelling problems, their real-world contexts become objects to be studied by students when developing and validating an answer $A^{\heartsuit}$.

We consider the notions of media-milieu and Herbartian schema tools for designing the rich environments for high-quality modelling education as suggested by Carreira et al. (2019). Below we draw on elements of didactical engineering from the perspective of ATD when we address the research question of this paper: How can media-milieu dialectic and Herbartian schema support the characterisation of the potential roles played by digital resources in the SRP on modelling?

A modelling problem on total income

The generating question for the SRP has been designed to introduce the notion of piecewise linear functions in Danish upper secondary mathematics in grade 10 building on the notion of linear function from lower secondary mathematics. In Denmark the students are allowed to use CAS-tools for their written exit examination and to visit webpages previously used in class (Danish Ministry of Education, 2017). Therefore, the students are used to search all sorts of information online and familiar with basic uses of CAS-tools. The problem is formulated as:

Three friends completing lower secondary school in Denmark discuss their plans for further education. One is planning to get a job without pursuing further education. The two others plan to become a nurse (bachelor degree) and upper secondary teacher (master degree) respectively. They discuss when each of the different strategies have given the larges total income? Below you find a table of average income in Danish kroner (DKR), as result of years of completed education.

Table 1: The table of average income corresponding to years of education

Years of education	9	12	14	16	18	21
Average Income/year	210.000 DKR	310.000 DKR	365.000 DKR	370.000 DKR	490.000 DKR	520.000 DKR

The entries correspond to completing lower secondary, upper secondary, short further education, bachelor's degree, master's degree, and the PhD degree. The idea behind the problem is to create the need for piecewise defined functions and the specific notation linked to this. The teacher can enlarge the milieu by the end of the modelling process, introducing a work, W_j, presenting the notation. The idea of enlarging the milieu with intentions of the a-didactical situations has been reported on by Grønbæk & Winsløw (2015). Striving to promote self-study element on complex numbers for first year students, they designed media and milieus for students to explore. They argue for their design choice by stating "when students study and encounter an inference they do not follow, they are supposed to consider the text as a milieu that resources and constraints their efforts to fill the gab" (Grønbæk & Winsløw, 2015, p. 2132). The same idea has been explored by Jessen (2017), who explicitly designed a repository offered to the student to consult, when and if they encountered shortcomings of their existing knowledge and techniques. We will return to this idea later.

An a priori analysis of the SRP

As Grønbæk & Winsløw (2015) we here present the potential paths of students working with this SRP, not having a repository. We present the potential strategies, which serve as an argument for generating power of Q. Not all strategies require the use of digital resources. Basic pen and paper methods allow students to add income for each person. This requires knowledge about educational length for nurse and upper secondary teacher. This can be found online through webpages or educational guides. This represents data, D_i, brought into the milieu by the students. The strategy can be eased using spreadsheets as indicated in figure 1, where blue fields mark the years where the nurse's total income is largest, the orange is when the teacher exceeds both. This strategy draws on existing answers, $A_i^\lozenge$, in terms of arithmetic, and instrumented techniques if using spreadsheets.

Some students might consider the spreadsheets tables, they can create scatter plots from. Some might experiment with linear regression using Excel, GeoGebra, etc. Both instrumented techniques and existing answer, $A_i^\lozenge \ldots$The tables can be considered self-generated data, D_l. When the digital tool plays the role of media it provides the students with answers. When exploring what function fits data, we consider the digital tool the milieu for exploration. Thus, the scatter plot might be yet another answer or experiments with different types of function. It depends on the context and the students discourse regarding the problem of fitting data. If new knowledge is reconstructed, we consider it research and the digital tool is the milieu supporting this.

Other students might recall the notion of linear functions, $A_j^\lozenge$, identify the average income as the slope of a linear function. The x-axis represents time measured in years. When the linear function is expressed as $f(x) = ax + b$, where f is total income in thousands of DKR, they need to determine the constant b. For the person without further education, we have $b = 0$. In this scenario the students need to determine b for the nurse, where $f(6.5) = 0$, since it takes 6.5 years to complete nursing school. The slope of the function is 370, and students should solve the equation $0 = 370 \cdot 6.5 + b$. Which means $b = -2405$. This reasoning requires several notions and formulas (known answers, $A_1^\lozenge, A_2^\lozenge, \ldots,$) put together in new ways. The students' interaction with the milieu provides the students with new answers and further practiced for the teacher.

Figure 1: spread sheet solution

Some students might choose to use CAS-tools and the 'solve' command to do the same. Depending on their instrumental genesis, this might affect their conception of the models developed. The pragmatic use of the CAS-tool provides them with an answer to be studied, W_i, and incorporated with the models they are building. From here the intersection points can be found solving the equation where two functions are equal or using apps in the CAS-tool. This leads to the construction of different mathematical knowledge. The simple models of total income are presented at the left side of figure 2. When shared with classmates, the models become new answers brought into the milieu by students for their classmates to study. The different approaches will provide them with broader perspective on choices made during the modelling process.

For some students the real world will drive them to elaborate their models. Most students know that Danish government provide financial support to students after turning 18. The amount depends on whether you live at home or away from home, and the parents' income. These data, $D_i \ldots$, are to be found online and to be use in the models describing the nurse and the teachers' total income. Other income from student jobs might also be included providing new pieces in each model.

This can be modelled by adding numbers by hand or in spreadsheets as an elaboration of the strategy shown in figure 1. Again, students might choose to experiment with scatter plots and linear regression for certain domains. Here the digital tools have epistemic value, when students' partial answer becomes objects to be explored further using notions, works and existing answers. Alternatively, they might try to use the strategy of being able to find the slope of each part of the function using the potential amounts of income (financial support, student jobs etc.).

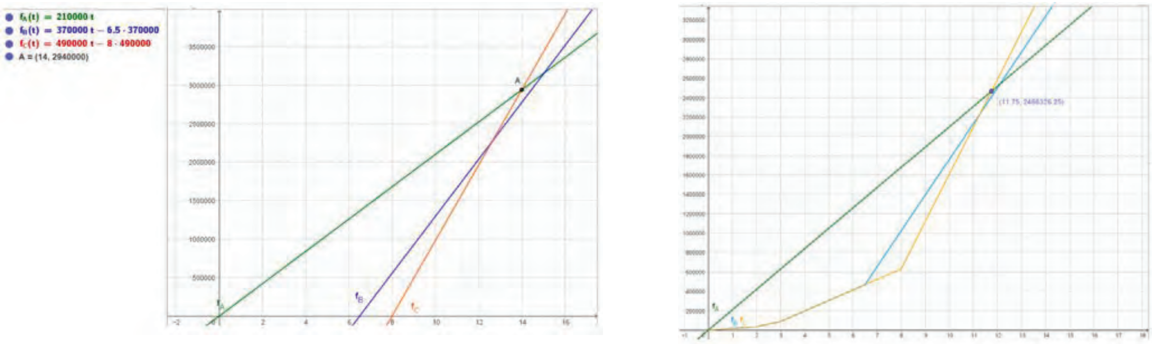

Figure 2: Two different solutions with linear and piecewise linear functions respectively

Then the strategies will be like those used to produce the models of the left side of figure 2 taking each domain into consideration. For this strategy the digital tools will mainly have pragmatic value. Though the tools allow the development of still more elaborate models to be done faster, using CAS-tools. This is valuable, when engaging students in continuously improving their models against the extra-mathematical context. Finally, when the teacher elaborates the milieu by introducing the notation for piecewise linear function and syntax for this using CAS-tools, the teacher provides the students with the a-didactical potential of formalising their previous work. Simple examples of models based on this new knowledge is presented at the right side of figure 2.

Not all students will be able to use this notation, why it is important to orchestrate validation of the different models by asking the students to compare and contrast their answers, helping them to realise which piece of the scatter plot is representing the blue fields from the spreadsheet and how is this represented in the formal notation of piecewise linear functions?

Discussion and concluding remarks

From the a priori analysis we can argue that media-milieu dialectic and Herbartian schema allow us to identify the roles played by digital resources in the SRP on modelling as being the provider of data, and new answers or work to be studied. In some cases, the tools might function as reminders of notions or tools taught previously. Also, the digital resources represent the perceived reality against which hypotheses, notions, newly constructed answers, and still more elaborated models are explored and validated. Moreover, SRP and the media-milieu dialectic seem to provide the students with the autonomy to enlarge the milieu or to choose known methods and answers as starting point for their modelling process. We can argue that SRP based modelling activities where the media-milieu dialectics are explicitly considered in the design process offers a richness in terms of number of strategies, students might pursue depending on previous learning. It allows students to experiment with data from various resources, and different uses of technology. We consider this the outset for high-quality modelling education as requested by Carreira et al., 2019. The notion of Herbartian schema naming resources as answers, works or data, which all can shift between being media to be studied or milieu employed in research processes can highlight changing roles that enrich modelling and enable us to harvest the pedagogical, psychological, cultural, and pragmatic aims of merging modelling and digital tools as Siller and Greefrath (2010) argued for. Jessen (2017) draw on media-milieu dialectics and Herbartian schema for the a posteriori analysis. If we do the same for technology rich modelling activities, we might be able to describe the potential meaningful interaction between humans and media as asked for by Schukajlow et al. (2018). This resonates with the instrumental genesis approach adopted by Geiger (2017), though his framework does not capture episodes where the digital tools provide new knowledge in terms of search for data or works to be studied. The study process might be the most novel contribution to modelling activities: to explore the potential of small elements of direct instructions, brought into the milieu by the students. Therefore, when Doerr et al. (2017); Geiger (2017) and Greefrath et al. (2018) argue that the presence of technologies in mathematics education calls for a change of tasks designed for modelling activities to capture new potentials. We propose to consider the digital tools and technologies both as media and milieu facilitating students' exploration of modelling as a dialectic study and research processes. Thus, from a task design perspective, we need to experiment with ways to nurture both study processes and research processes. We need to explore how technology and different tools can nurture those processes. What is gained, what is lost in the shaping of mathematical modelling? And if the modelling functions as driver for learning mathematics, how does this approach shape the mathematical object constructed through the modelling process?

Prescriptive modelling – mathematics teachers' discussions of the BMI

The study presented in this paper focuses on primary school teachers engaging with the Body Mass Index (BMI) as part of a university course. The BMI is seen as an example of prescriptive modelling where mathematics is used to keep track of the obesity phenomenon. Four categories are developed to characterize the teachers' discussions: the mathematical aspects of the BMI formula, meta-validation, the consequences of the use of the BMI and other indices in society, as well as on their teachability in the classroom. The results can contribute to developing an understanding of prescriptive modelling processes from a critical perspective.

Keywords: Prescriptive modelling, teachers' discussions, critical perspective.

Introduction

In this paper, we investigate the processes some in-service teachers go through when they discuss a task about a mathematical model like the BMI and its inclusion in mathematics education. Blum (2015) highlighted four purposes for using mathematical modelling in education: helping students to use mathematical knowledge to make sense of extra mathematical situations (pragmatic); developing argumentation and modelling competencies (formative); exploring the relationship of mathematics to real life and the mathematics' role in shaping society (cultural); and affective issues such as students' interest in mathematics (psychological). The study presented here is particularly situated in the cultural perspective, with a specific focus on a critical view of mathematics' role in society.

In mathematics curricula around the world, such as in the Department of Basic Education (2011) in South Africa, in the Common core state standards initiative (2010) in the USA, and in the Australian curriculum, assessment and reporting authority (2015), modelling and applications play a key role. Similarly, in the mathematics curriculum in Norway, *modelling & applications* is one of six core elements and concerns students' insight on how mathematical models are used to describe everyday life, work-life, and society, as well as students' competence to solve problems from reality by using mathematics (Ministry of Education and Research, 2020). *Democracy & citizenship* is an interdisciplinary topic in mathematics, aiming at students' awareness of the prerequisites and premises of the mathematical models used in society by giving them opportunities to work with real data sets from different fields. Modelling and models are seen as a possibility for students to understand the role of mathematics in society, which is the focus of socio-critical modelling and connected to the cultural arguments for using mathematical modelling in education (Blum, 2015). Barbosa (2006) defined this perspective as modelling as critic, where students' ability to criticize the mathematical models is achieved through the learning of mathematical concepts and modelling competencies.

Niss (2015) distinguished between two types of modelling. In descriptive modelling, the aim is to find a model that can be the answer to a problem from extra-mathematical domains. In prescriptive modelling, the aim is "to pave the way for taking action based on decisions resulting from a certain kind of mathematical considerations, in other words 'to change the world' rather than just 'to understand the world" (p. 69). The differences between the two types of modelling centre around the process of modelling. While examples of research in mathematics education focus mainly on descriptive modelling, Niss (2015) called for research on prescriptive modelling because of the impact such modelling has on society. Indices, like the BMI, are examples of prescriptive use of models in our society. We consider the term *index* as a measure of one or several chosen variables connected to a relatively large sample taken from a population or set. BMI is computed as the ratio between the weight (m) of a person in kilogram, and the squared height (h) in meters: m/h^2. The BMI values should be between 18.5 to 24.9 kg/m^2 for an adult to be considered of normal weight. The model is used extensively e.g. in medical contexts, in keeping track of obesity in individuals and populations, even though it has known limitations (e.g. Hall & Barwell, 2015; Kacerja et al., 2017).

Given the emphasis on modelling in the curricula, mathematics teachers across the world have the task to make mathematical modelling an integral part of students' learning of mathematics and connect it to students' development of critical competence and critical citizenship. Following Niss' (2015) call to focus on prescriptive modelling, we have used the BMI with in-service primary school teachers (grades 1.–7.) to facilitate discussions about the mathematical models' impact in society. The novelty in our study consists in the use of prescriptive modelling examples in teacher education settings and in collecting empirical data from teachers' discussions about indices. According to Niss, little is known about the processes when people engage with prescriptive modelling. In this paper, we address this gap by exploring the research question: what characterizes teachers' discussions about indices and how they, the BMI in particular, can be used in mathematics education? We include a critical mathematics perspective to provide insights into teachers' understanding of indices' roles in education and society.

Theoretical considerations

Several researchers have described processes involved in mathematical modelling. Niss (2012) defined the mathematical modelling cycle as the process that starts with "some extra-mathematical domain, moving into some mathematical realm so as to obtain mathematical conclusions and translating these back to the extra-mathematical domain" (p. 50). A model of the modelling cycle which is often referred to is the one by Blum and Leis (2007) with two connected worlds: the mathematics and the real world. Even though there are different modelling cycles presented for descriptive modelling, there are some common elements we find in all of them. An extra-mathematical problem is the starting point. Then through discussions, the problem is translated into a mathematical problem, and mathematical concepts and processes are used to find one or several models as solutions to the problem. An important phase of the modelling process is the de-mathematization of the solution, choosing the best solution (model) while interpreting it in relation to the original problem. If the solution does not make sense for the problem at hand, then a new modelling process must start.

In the socio-critical perspective in modelling, Rosa and Orey (2015) emphasized that "students are expected to understand, reflect, comprehend, analyze, and take action to solve problems taken from their own reality" (p. 390). They presented a social-critical mathematical modelling cycle, where the real problems are environmental, political, social etc. This focus is in line with the purpose that the socio-critical perspective applies for mathematical modelling, where students should understand the role of mathematics in society, and develop tools for their social-critical efficacy, which they can further apply in other cases as well. In the modelling process, the emphasis is on the individual modeller, and it includes action since the aim is for students to be able to act upon reality.

Doerr, Ärlebäck and Misfeldt (2017) underlined the necessity to have several representations of mathematical modelling to capture the multiplicity of perspectives in mathematics education. The modelling cycles such as the ones by Blum and Leis (2007) and Rosa and Orey (2015) are different and capture different aspects of modelling. They are however not enough to describe students' working processes when involved with prescriptive modelling (Niss, 2015). By exploring three examples, one of which is the BMI index, Niss argued for some of the limitations of the existing modelling cycles that "become very rudimentary when applied to the BMI model" (p. 71). In our study, while exploring an existing model such as the BMI index, the processes of idealizing the extra-mathematical situation and mathematizing the question posed, become trivial in the sense that the index already exists. As Niss (2015) discussed, the mathematical treatment reduces into replacing the weight and the height of a person into the BMI formula and the de-mathematization process reduces into finding the interval in which the person can be placed based on the number obtained (p. 70–71). Niss (2015) argued that two aspects of the modelling cycle that need to be more developed in existing models to adapt it to prescriptive modelling are meta-validation and critique of the model. Meta-validation requires looking critically at three points: how the modelling results influence the discourse around the problem that was modelled; how the obtained model is compared to other potentially relevant alternatives; and how a change in the requirements influences the modelling and its outcomes. An important contribution from our study is the attention towards teachers' reflections upon the possible uses of BMI and other indices in their classroom teaching. In this paper, we analyze the teachers' discussions to characterize how they talk about including the BMI in their teaching and which of these three, and other processes, they go through. This can be seen as a first step in developing an understanding of prescriptive modelling processes and their use in school settings.

Method

The participants in our study were twelve in-service primary school teachers who attended a course on Numeracy across the curriculum. After a teaching session in which one teacher educator presented some uses and misuses of mathematics and the idea of an index, the teachers were divided into two groups and given 60 minutes to work with the BMI task. The task had three sets of questions: the first included questions about what BMI is, the formula and purpose of the BMI, what it measures, and how it could look differently; the second concerned the use of the BMI in different contexts in society and the meanings of the use; and the third focused on the teachers' thoughts on using indices in their teaching of mathematics, possible reasons for including or excluding such topics in schools, as well as thoughts about similar index-related examples they have used. A picture of a muscular rugby player with a high BMI value was included. The purpose of the BMI task was to structure and guide the discussions towards the mathematics in the indices, the role that indices have in our society, and how teachers see possibilities and challenges in using indices to promote critical thinking with their students. There were two teacher educators present, one in each group, to observe the discussions and provide a better understanding of what the teachers said, and make sure that the teachers addressed all three sets of questions of the BMI task. After a few minutes of discussion, the groups were given the BMI formula and the cut-off points for six weight categories. The teachers did not follow the structure of the question sheet, they jumped back and forth, but in the end, they had covered all the questions. The discussions were audiotaped and transcribed.

All the authors of this paper worked together through several cycles to analyze the data applying a thematic analysis approach (Braun & Clarke, 2006). The three sets of questions from the question sheet were used as initial, overarching codes, combined with the recommendations by Niss (2015) on meta-validation and critique of the model. The teachers' utterances were analyzed within the framing of the question sheet. We went systematically through some initial parts of the data as a whole group and analyzed the teachers' utterances according to the different codes. Then we continued the coding process in smaller groups to complete the first coding before we as a group compared and refined the coding to generate the final categories. The initial analysis was based on the question sheet, but the succeeding code and retrieve process was based on what the teachers said. The analytical process was therefore twofold in which the main part of the categories and subcategories were generated inductively from the data. We also used premade categories deductively, but also these categories were refined based on what the teachers said.

Results

In Table 1 below, we present the results – the categories developed from the analysis of the teachers' discussions:

Table 1: The categories (underlined categories are generated from the data, the others are premade)

A Investigating the index (BMI) concept and formula A1 What is an index (BMI) A2 What does it measure? <u>A3 Variables</u> A4 Reflections about previous knowledge	**B Evaluating alternatives (meta-validation)** B1 Formula - how could it look differently <u>B2 Challenges (neglected variables, measurement inaccuracy etc.)</u> <u>B3 Point out existing alternatives, compare with alternatives</u>, adapt the index
C Influence and use in society <u>C1 Pros of using BMI</u> <u>C2 Cons of using BMI</u> <u>C3 Seeking/giving information</u> <u>C4 Critical</u> <u>C5 Examples</u>	**D Teachability** <u>D1 Reflections, appropriateness mathematically and thematically</u> <u>D2 Reflections, appropriateness ethically</u> <u>D3 Reflections on own knowledge about indices to use them in teaching</u>

Categories A (investigating the index) and B (evaluating alternatives) include the teachers' utterances when addressing mainly the first set of questions from the question sheet. Here the meta-validation questions by Niss (2015) are integrated as part of category B to characterize the discussions when teachers look at alternative formulas and point out challenges of the existing formula. Category C (influence and use in society), including critique, stems mainly from the teachers' discussions of the second set of questions. Here the notion of critique by Niss (2015) is found on discussions where the inappropriate use of the model is criticized (cons) and the results of such use on the discourses around the obesity problem are brought forward. Category D (teachability) is connected to the third set of questions from the question sheet.

Investigating the index (BMI) concept and formula (category A)

The following discussion takes place at the beginning of the discussion in group 1, where the teachers have not yet seen the formula of the BMI (the teachers are anonymized and numbered like this: T1, T2 …). One of the groups starts the discussion with T1 reading aloud the first question: "What is BMI?" T2 answers "it has something to do with the body", focusing on what the index measures (an A2 category utterance). T3 includes variables, "it has to do with height and weight" (A3) and adds "it is a ratio" (A2). The teachers search for answers together by saying what they think BMI is and what they seem to remember concerning body, height, weight, and ratio. They have not yet seen the formula, but they are closing in as the ratio is between the weight and the square of height.

Towards the end of the group discussions, when talking about how to teach about something like indices, the teachers go back to their initial reflections trying to make sense not only of the BMI but also of what an index is or can be. The question by T4, "When we measure temperature and rainfall, do we work with indices?", is such an example, where the teachers are trying to find out what qualifies to be an index. Similarly, T5 asks: "if you some days in advance get a considerable increase in the air pressure, you quite often see an improvement of the weather […]. Is that an index?" In this category, the teachers focus on what they know about BMI: what an index is and BMI in particular (A1); discussions about what it actually measures, usually related to different uses of BMI they know about (A2); the variables used to measure it, such as the weight and the height (A3); and in addition, they talk about their previous knowledge (A4) about BMI. The categories from A1-A3 are nuances of teachers' investigations of the BMI as they try to make sense of it. It is difficult to distinguish between the three subcategories as the answers are often intertwined, but they are valuable for being able to nuance the discussions.

Evaluating alternatives, meta-validation (category B)

Another question in the first part of the question sheet asks if the formula could look differently. This question is connected to the meta-validation process as introduced by Niss (2015). To answer the question, the teachers present examples of the different uses of the BMI they know about. One such example is the picture of a rugby player on the question sheet with a muscular body, but with a BMI of 35.98 kg/m2 is placed in the obese class II according to the cut-offs provided by the BMI model. T4 compares the rugby player with a person "who does not train, that has eaten too much, right. It does not say they are in the same shape; it just says they have the same weight". There is a discussion of muscles weighing more than fat, and how this is not taken into consideration in the BMI formula. This aspect is categorized as a challenge (B2) in terms of neglected variables in the formula.

Other examples, such as the use of weight and height graphs for small children, which even though they are not direct examples of the use of BMI, are referred to in the discussions. These graphs monitor children's development to ensure they grow as they should by comparing a child's measures to the curves of the average children at the same age. In these examples, the teachers focus more on how the BMI or other indices are used, sometimes without considering geographical factors. Other challenges of the BMI are taken into the discussions, such as measurement inaccuracies (B2) and the effect these can have on the results of the formula. The teachers point out existing alternatives such as waist circumference as a better measure that in some respects takes into account the fat vs muscles issue. They often express the need to combine those two measures to get a better picture of someone's health. These discussions are categorized as B3, as adaptions or alternatives to the BMI.

Use and influence in society (category C)

When the teachers in group 2 discuss the question "What do you think about BMI's role and use in society?", they use examples to illustrate their answers (C5). Examples vary from personal ones about themselves or their family members, to examples of extreme cases where the formula does not fit. A representative example is T6 saying "I am worried about who shall decide what is right about weight". T6 gives an example about a 14-year-old girl who was told her weight was a little high, but T6 did not agree with this at all. The example is personal (C5), and T6 is critical (C4) towards the uncritical use of BMI, without considering other factors besides the number from the BMI formula. The critique is also directed to the ones who use the formula and have decision power. The example can also be seen as being against the use of BMI (C2). Among the examples that support the use of the BMI (C1), we find: "I think, from a society perspective and when used sensible, that this is a good tool. What else shall health nurses or I use … if we don't have standards?" The reasons for accepting the use of the BMI are often connected to the need of having standard tools. In these discussions, the teachers often elaborate on the examples by arguing for why the formula is necessary (C1), or on the contrary, giving reasons for why the formula should not be used (C2). They often ask questions seeking for information or giving information (C3), and it is usually when taking into consideration the different examples that they are critical towards the use of the index (C4).

Teachability (category D)

The last section on the question sheet is connected to the participants' work as teachers and their thoughts about the possible use of indices in school teaching. In the following example from group 2, the participants are trying to make sense of the BMI formula, and T7 says, "I think it is very difficult to think that one also measures area", and T8 adds, "yes, surface area". At the same time, the teachers are thinking about their students, and T7 says: "Talking with the students about this and then you take kilos and then you divide it by the area of the body". T7 is thinking aloud about how to present the topic so that students can make sense of it from a mathematical point of view, which is an example of discussions of the mathematical appropriateness of the BMI (D1). T7 adds immediately after "hm ... there is something wrong, isn't it?" showing uncertainty on how to present it since the teachers themselves are having problems with figuring out how to talk about this with the students (D3).

In the teachers' answers, we identified several reflections about the BMI and other indices' appropriateness to be used in teaching. They discuss both thematic appropriateness in terms of the mathematical level (D2) and ethical appropriateness in terms of BMI representing obesity that can be a sensitive topic for their students (D1). All of these aspects came in addition to their discussions of teachers' knowledge about indices to include them in their teaching (D3). At this point, they often ask themselves the question: what is an index?

Discussion and concluding comments

In this paper, the focus has been on in-service primary school teachers' discussions of the BMI and the use of indices in education. We have looked at the discussions from a critical perspective where the aim is to facilitate an understanding of and criticize the role of mathematics in shaping society. As we found through the categories in the study, the teachers engaged in discussions about the mathematical aspects of the BMI formula and their knowledge of it (A); about alternatives to the BMI and its limitations, or meta-validation processes (B); about the BMI's use and influence in society (C) as well as about teachability of BMI and indices in general (D). These categories were also nuanced with subcategories that capture different aspects of teachers' discussions.

Like in several of the mathematical modelling cycles (e.g. Blum & Leis, 2007; Rosa & Orey, 2015), the starting point of the discussions in our data is an extra-mathematical situation, the BMI and its use in society. However, the discussion of the mathematics in prescriptive modelling is different from the aforementioned descriptive modelling cycles, as also Niss (2015) pointed out. In our data, teachers discuss an existing mathematical formula (categories A and B), by comparing it to alternative models (B3) and pointing out weaknesses such as missing variables (B2). Similarly to the socio-critical modelling cycle (Rosa & Orey, 2015), the teachers discuss the role of the BMI model in society (category C). At this point, our data allowed us to nuance the way teachers did this by weighing pros and cons for using BMI (C1 and C2), by being critical (C4), by seeking further information (C3) and by providing examples (C5). The categories and subcategories made it possible to further develop the aspects of meta-validation (B) and critique of the model (B and C) as processes of the prescriptive modelling cycle that Niss (2015) called for. Our study adds the teachability aspect (D) to prescriptive modelling. Since we work with teachers and their competence to engage students with examples of the uses of mathematics in society, it is important for us as teacher educators to know the teachers' challenges and possibilities for working this way. This adds another perspective for understanding ways of implementing these examples in teacher education and school mathematics.

The categories and subcategories are a step towards finding ways to represent working processes in prescriptive modelling. The importance of such representations was emphasized by Doerr, Ärlebäck and Misfeldt (2017) and Niss (2015). The representations can be used in further research about prescriptive modelling and socio-critical perspectives in modelling, but also for teaching about the mathematics' role in society. The categories show that the teachers were given the possibility to engage in critical discussions of BMI and indices in general, from different angles. Given this possibility, indices can be a starting point to develop a critical perspective in mathematics. As Niss (2015) and Hall and Barwell (2015) also recommended, focusing on such models allows for developing insights both into the mathematical and the societal aspects of the models and their consequences, which lies at the heart of the critical mathematics perspective.

Comparison of the working on modelling tasks when students have or do not have personal interest in the real-world context of the task

Melanie Kämmerer[1]

[1]University of Muenster, Germany; melaniekaemmerer@uni-muenster.de

Keywords: Modelling task, real-world context, personal interest.

Motivation

Modelling means solving a real-world problem with the help of mathematics. A modelling process can be analyzed using an ideal modelling cycle with the steps: understanding, simplifying, mathematising, working mathematically, interpreting, validating and exposing (Greefrath & Vorhölter, 2016). Consequently, dealing with modelling tasks not only entails dealing with a mathematical problem, but also with the real-world situation described in the task. In a classroom there are children with a variety of personal interests. Thus, the question arises to what extent these personal interests influence the working on a modelling task. This study therefore compares the use of the real-world context by individual students when working on two modelling tasks in which students have much/little personal interest in the real-world context.

Theoretical framework

The person-object conception of interest differentiates between two types of interest: 1) Situational interest which is aroused by the conditions of a situation. 2) Personal interest which is a longer lasting characteristic of a person that goes along with a high subjective esteem, positive emotions for the content (Krapp, 2000) and a lot of knowledge about it (Renninger et al., 2002).

Ainley et al. (2002) identified a connection between interest in the topic of a reading task and persistence and learning outcome. When working on mathematical word problems in a context of high or low developed personal interest, Renninger et al. (2002) found out, that the influence of the context can be different depending on the interest in mathematics itself and the mathematical ability. The way of dealing with the real-world context of a modelling task can be very individual and variable. However, Busse (2011) was able to distinguish between “four different ideal types of dealing with the real-world context: reality bound, integrating, mathematics bound, ambivalent” (p. 38). Concerning mathematical application tasks Stillman (2000) showed that prior knowledge of an application task context can help students to engage with the task or check results for reasonableness. Nonetheless, the prior knowledge might still have negative or neutral effects as well. Krawitz and Schukajlow (2018) examined the impact of prior mathematical knowledge on the solution of modelling tasks. They discovered that it depends on the appropriateness of the activated knowledge, whether the prior knowledge promotes or interferes with the solution process. Since personal interest is often accompanied by a lot of knowledge, it could be interesting to investigate, whether the effects of prior knowledge are applicable in a similar way for personal interest.

Research questions and Methods

As there are hints to both positive and negative effects of interest on the working on a mathematical or reading task, the present study aims to investigate the impact of personal interest in the context of a modelling task on the working progress. The following research questions are examined:

- At which points in the working process do students refer to the real-world context of the modelling task when they have much or little interest in the context?
- At which points is personal interest mentioned by students when working on a modelling task in which they have a personal interest in the real-world context?
- To what extent does the personal interest in the real-world context of a modelling task have an impact on the working on the task?

The study consists of two parts: First, a class of 7th grade is presented an interest questionnaire. Based on the results students are selected for participation in the next step. Second, 10-15 students work individually on three modelling tasks using the “think-aloud” method. One task with a high personal interest in the context and one with low interest, respectively. In between there is a buffer task as a distraction. The tasks are followed by a short interview about the working process.

Outlook

Data collection is currently being carried out. Using a qualitative content analysis, the working process will be divided in the steps of the modelling cycle. For each student, a comparison is made of whether the points, at which the context is considered in the work, differ depending on whether there is much or little interest in the context. Also, the points, where interest or prior knowledge is used, are coded, so one can see if there are differences for tasks with much/little interest in the context.

Students' processing of modelling problems with missing data

Jonas Kanefke and Stanislaw Schukajlow

University of Münster, Münster, Germany

jkanefke@uni-muenster.de, schukajlow@uni-muenster.de

The problems that are found in the real world, mathematics, and science are usually ill-defined problems. By contrast, the problems given in classrooms tend to be well-defined. It can be useful for students to solve modelling problems so they can learn how to deal with ill-defined problems. In a qualitative study of ninth to eleventh graders (N = 12) in different secondary school tracks in Germany, we investigated how students process modelling problems with missing data. We found that students have difficulties noticing when data are missing from some problems. When students notice the missing data, they notice it at the very beginning of their processing, after understanding the problem, or while validating the mathematical results. After noticing, either the students were able to make a realistic assumption about the missing data using various strategies, or they made no assumption at all. The theoretical and practical implications of the study are discussed.

Keywords: Mathematical modelling, ill-defined problems, missing data.

Introduction

Having students solve problems is an integral part of mathematics teaching all over the world. The problems that are typically given in school have a clear structure, include all relevant data, do not include any superfluous data, and have exactly one solution. This type of problem is known as a well-defined problem. By contrast, the problems encountered in everyday life and at work are often ill-defined and have multiple solutions. Consequently, their solution processes differ from the processes needed to solve well-defined problems. In mathematics education, ill-defined problems are defined as problems situated in a specific context, where one or more aspects of the problem are not well specified, the problem description is not clear, or all the data needed to solve the problem is not provided in the description (Jonassen, 2000). One important type of ill-defined problem is a problem with a connection to reality (e.g., a modelling problem). Modelling problems are characterized by a demanding process of transferring information between the real world and mathematics. Modelling problems can be ill-defined in different ways, for example, when the initial state of the problem is unclear and the initial data are missing, so-called modelling problems with missing data or open (-ended) modelling problems. Modelling problems as ill-defined problems have rarely been the focus of research yet. In this study, we aimed to analyze how students process modelling problems with missing data and how they overcome the difficulties that occur while solving these problems. The theoretical foundations of this research are theories about the processes involved in solving modelling problems (Blum & Leiss, 2007) and problems with missing data (Krawitz et al., 2018).

Theoretical background and research questions

Modelling problems

Mathematical modelling is an important competency that is part of mathematical literacy and is included in many national curricula and in mathematics teacher education. Modelling problems have been found to be difficult for students to solve due to the cognitive complexity of such problems. In order to describe which activities students need to engage in to solve modelling problems, several approaches and numerous theoretical models of the solution process have been developed in previous research (e.g., Blum & Leiss, 2007; Galbraith & Stillman, 2006). An idealized process for finding a solution to a modelling problem proposed by Blum and Leiss (2007) is the following: The first phase involves understanding the problem and constructing an individual situation model. Second, the students have to construct a real model by simplifying and structuring the situation model. Afterwards, the real model is transformed into a mathematical model. The mathematical model allows the student to apply mathematical procedures to compute a mathematical result. Then the mathematical result is interpreted with regard to reality in order to obtain a real result that should be validated with respect to the real situation. The validation can lead to the need to revise the solution and the constructed models by applying the modelling cycle again. There are various types of modelling problems with different characteristics (Maaß, 2010). An important characteristic of modelling problems that is particularly relevant to this study is that they often do not contain all the data needed to find an accurate solution (i.e., the initial state of the problem is unclear). Following Maaß (2010), such modelling problems will be titled modelling problems with missing data. An example of a modelling problem with missing data is the "Fire Brigade" modelling problem (see Figure 1). Missing data for this modelling problem include the position in which the fire engine is parked or the height of the fire engine where the ladder is attached.

Fire Brigade

There is great happiness at the fire brigade! The authorities have approved a request for a new turntable ladder vehicle. Now, the fire brigade can rescue people from great heights using a basket attached to the end of the ladder. The vehicle has an engine with over 250 hp and has space for 3 firefighters. The length of the turntable ladder is 30 meters. In addition, the firefighters were informed that some safety rules must be observed when using the new vehicle. The vehicle must maintain a safe distance of 7 meters when firefighting a burning house. In addition, care must be taken to ensure that the operation is not obstructed by power lines. Furthermore, in the event of a storm, the vehicle should not be operated as a matter of principle when wind speeds reach 100 km/h.

From what maximum height will the fire department be able to rescue people from danger with this new vehicle?

Figure 1: The "Fire Brigade" modelling problem, modified from Schukajlow and Krug (2014)

Characteristics of modelling problems with missing data

In ill-defined problems, the data, goals, and operators are not clearly specified (Jonassen, 2000). Modelling problems with missing data share these important characteristics with ill-defined problems, including the opportunity to develop different solutions to the same problem. From a normative point of view, the ability to solve modelling problems with missing data can be useful for students' actual and future lives because most of the problems that occur in their daily lives and at work are ill-defined. Schukajlow and Krug (2014) identified benefits of prompting students to find multiple solutions to modelling problems with missing data on students' interest, experiences of competence, and autonomy. In another study, a feeling of autonomy that came from solving modelling problems with missing data was found to be one of the important sources of students' interest in these problems (Schulze Elfringhoff & Schukajlow, 2021). In previous research, many studies have used modelling problems with missing data without emphasizing that data were missing, which is an important feature of the problem. A typical class of modelling problems with missing data are Fermi problems, where a large amount of information is missing, and reasonable assumptions and a series of estimates are necessary for finding a solution (Ärlebäck & Bergsten, 2013), much more than in the problem presented in Figure 1. Therefore, the special type of problem used in this study is characterized as unique because it is missing relatively little data, but the data that are missing are crucial for the solution with respect to reality.

In order to solve modelling problems with missing data, such as the one in Figure 1, three steps seem to be crucial from a theoretical point of view (Krawitz et al., 2018): (a) Students must identify the problem as an ill-defined problem by noticing that the numerical data given in the problem is not sufficient to solve the problem adequately; (b) they must identify which quantities have to be estimated; and (c) after noticing which data are missing, they have to make assumptions about how to deal with the missing data. In order to make assumptions, students need to conceptualize the real-world situation, which requires realistic considerations and extramathematical knowledge. Further, estimation skills and strategies, such as the reference point strategy, are necessary. For the "Tree Track Adventure Park" modelling problem (Figure 2), students must notice during their processing that Mr. Meier needs enough rope so that the rope that will connect the two trees can be securely attached to each tree. Thus, students must estimate how many meters of additional rope will be needed to securely attach the rope to each tree by wrapping the rope around the trees. To make an assumption, students can either just estimate how much rope will be needed, or they can compute the amount of rope that will be needed after estimating how thick the trees are and how many times the rope will be wrapped around them.

Tree Track Adventure Park

Mr. Meier is the owner of a tree track adventure park. He opened this attraction for young and old guests 12 years ago. Now he has to replace the steel ropes to which the safety lines are clipped. These steel ropes are very expensive. To replace them, Mr. Meier needed more of the steel cable than originally planned. He has only 22 m of steel rope left for the last zip line between two trees. The two trees are 17 m apart. So that visitors can then slide from one tree to the other, the steel rope is attached to the starting tree at a height of 10 m and to the ending tree at a height of 8.5 m.

Does Mr. Meier have to buy more steel rope or is the existing steel rope sufficient?

Figure 2: The "Tree Track Adventure Park" modelling problem, modified from Schukajlow and Krug (2014)

If the students neglect the real-world aspect of attaching the rope, they can still calculate how many meters of rope are needed between the trees and give this as an answer, thus concluding that Mr. Meier has enough rope, but this is in fact an unrealistic answer. The rope that is available is not enough because Mr. Meier needs more rope to attach the rope to the trees, so he needs to buy more rope.

No or inappropriate assumptions in a modelling problem can also result in an inadequate situation model and an inadequate mathematical model for the problem situation (Chang et al., 2020). Thus, it is important for students to master the steps needed to solve modelling problems with missing data. Previous studies have pointed out that students have trouble solving modelling problems with missing data because they seem to separate their knowledge of the real world from their mathematical knowledge and tend to ignore the context of the problem (Galbraith & Stillman, 2001). However, in-depth research on students' individual work and thinking with respect to the demands of such problems is rare.

Research questions

In this study, we addressed students' processing of modelling problems with missing data. Thereby, we first analyzed the extent to which students noticed missing data while processing modelling problems with missing data. Second, we investigated whether students made assumptions about the relevant missing data in the modelling problems used in this study. Thus, we posed the following research questions:

1. How do students process modelling problems with missing data?
    a. To what extent do students notice that data are missing?
    b. Did students make assumptions about the missing data?

Method

Participants

Participants were 12 students (seven girls and five boys) from different secondary school tracks in Germany. Participants came from high-, middle-, and low-track classes. They were between the ages of 14 and 16 and were in Grades 9 to 11. All students participated voluntarily in the study with their parents' permission. To select the participants, we followed the principle of maximum variation. Thus, we chose students who varied in gender, age, and mathematical performance. To assess students' mathematical performance, we considered students' math grades, the types of classes they were taking, and the types of schools they were attending. Students' grades ranged from very good to deficient. It was ensured that all participating students had already covered the unit on the Pythagorean theorem, which was required to solve the problems in the study, in previous mathematics lessons.

Procedure

In order to address the research questions, we conducted a three-step procedure that combined the methodological approaches of thinking aloud, stimulated recall, and interview. The procedure began with instructions for the think-aloud method, where students watched a video with a demonstration of the think-aloud method and practiced the method to solve a nonmathematical task. After the instructions, first, all students worked individually on the same given modelling problems with missing data using the think-aloud method. Students were videotaped as they processed the modelling problems. Second, after solving all the given problems, the stimulated recall was conducted. Video recordings of students working on all the problems administered in the study were shown to the students immediately after they finished working on the problems. Students were asked to pause the video recordings whenever they wanted to add something that was going through their minds about the situation that was shown on the screen. If the interviewer thought that the situation shown in the video recording was relevant to the research question, and the students did not pause the video recording, the researcher could pause it too. By doing this, the insights from the first step could be intensified. In the third step, the students were administered a semi-structured interview with in-depth questions about their work on the three problems. In particular, questions were asked about how students handled the missing data from the problems.

Modelling Problems

In this study, we used two modelling problems with missing data. Both problems could be solved by applying the Pythagorean theorem, which is part of national and international curricula. The two problems—"Fire Brigade" (Figure 1) and "Tree Track Adventure Park" (Figure 2)—were modified from prior studies (Schukajlow & Krug, 2014). For our study, the relevant data that was missing was always numerical. Thus, students needed to make assumptions about the missing quantities in order to solve the problems correctly. All problems were developed so that students were also able to perform calculations without noticing that important data were missing. For the "Fire Brigade" modelling problem, the height of the fire engine, and for the "Tree Track Adventure Park" problem, the additional rope needed to attach the rope to the trees were considered the relevant pieces of missing data.

Data Analysis

The transcripts of students' responses were analyzed using a qualitative content analysis (Mayring, 2014). The deductively developed coding scheme was used to code the sequences with regard to modelling activities from the modelling cycle by Blum and Leiss (2007). Another coding scheme was used to code how the students dealt with the characteristic demands of modelling problems with missing data (Krawitz et al., 2018). More specifically, we coded whether students had noticed the relevant missing data from the modelling problem and had made a realistic numerical assumption.

Results

We analyzed whether the students noticed that relevant data was missing from the problems (Research Question 1a). In the solutions given by 7 of the 12 students for the "Fire Brigade" problem, the students noticed that the height of the fire engine was missing (Figure 3). Among other objects, Anton's mathematical drawing included the fire engine with its height (Figure 3, left).

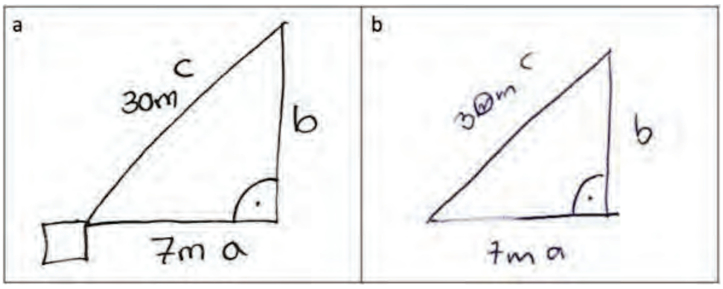

Figure 3: Excerpts from students' solutions to the "Fire Brigade" modelling problem

In the sequence presented below from Anton's processing while thinking aloud, he commented:

Anton:	Okay. (…) Here is a house wall, I don't know how big it is yet. (...) The safe distance must be seven meters. Seven. (…) And the height of the fire/the turntable ladder is thirty meters. (...) The turntable ladder is not completely on the ground.

By contrast, in the drawing made by Paula (Figure 3, right), data about the height of the fire engine was not considered. The sequence presented below illustrates that she was not thinking about the missing data while making her drawing.

Paula:	The turntable ladder is thirty meters and uhm (…) the safe distance of seven meters. So that's seven meters. And then (…) the ladder would have to be angled so thirty (…) thirty meters. And that is then (…) the height.

For the "Tree Track Adventure Park," students were less likely to notice the relevant missing data (only 2 out of 12 students noticed). For the "Fire Brigade" problem, we investigated how students' noticing of the missing data interacted with their modelling process by analyzing when (i.e., between which sequences of modelling activities) the students noticed that the height of the fire engine was missing. Figure 4 illustrates Anton's modelling process with its modelling activities (Blum & Leiss, 2007), and the arrow indicates when he noticed the missing data. It took Anton four minutes and 17 seconds to process the "Fire Brigade" modelling task.

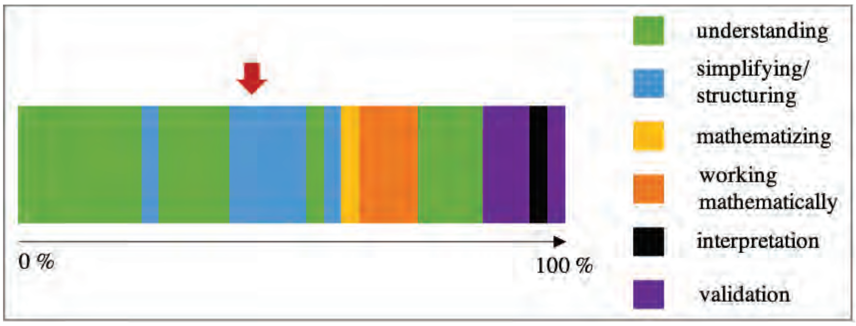

Figure 4: Anton's modelling process

Anton noticed the height of the engine between sequences in which he was simplifying/structuring. Students usually noticed the missing data in one of two different phases in the modelling process. First, the relevant missing data were noticed at the beginning of the modelling process after an initial understanding and after or during simplifying/structuring, but usually before working mathematically. An example of this case is Anton. Second, some students noticed the missing data after they had completed the modelling cycle activities (i.e., after mathematizing and working mathematically and usually between the validation sequences). These students noticed the missing data after they had already obtained an initial mathematical result. In the validation phase, students noticed that the answer they had calculated was not appropriate for the problem situation. In this case, some students began to correct their previous solution by considering the missing data, whereas other students stuck with their inadequate solution without making any changes. Further, noticing the missing data was not related to the activities of mathematizing or working mathematically. After students noticed that the height of the fire engine was relevant data, they should make a numerical assumption about the missing data and consider this assumption in the next steps of their modelling process. However, only five of the seven students who noticed the missing data also made a numerical assumption. The other two of the seven students did not make any assumptions. An illustration of this can be seen in a sequence of Julius' solution while thinking aloud.

Julius: Although, (…) the vehicle height, but I think it doesn't matter.

Julius does not see the height as being particularly important for solving the problem. In order to answer Research Question 1b, we analyzed the extent to which the students made appropriate reality-based numerical assumptions. Comparing the students' numerical assumptions with the real data, we found that all the students' assumptions were within an acceptable range around the real data. Different strategies for making a numerical assumption were found. For example, how Berta made her numerical assumption is described in the following sequence from the stimulated recall.

Interviewer: How did you do that?

Berta: I (…) when you look outside, you can see the trees, and then I thought to myself, or in the climbing forest, there are sometimes trees like that, and then I thought to myself that (…) yes, if you just put an arm around it, I don't know, then that's (…) usually a meter or two, if you, if those are thicker trees.

Summary and Discussion

We investigated students' processing of modelling problems with missing data (i.e., real-world problems where the initial state of the problem is ill-defined). In this study, we analyzed whether students noticed relevant missing data and whether they made realistic assumptions about the missing data. An important finding of the study was that students seem to have trouble noticing the relevant missing data in the modelling problems. One possible explanation for this finding could be that students fail to think about the real-world situation of the modelling problem and just take the quantities given in the problem description and then work mathematically with these quantities. This idea would contribute to previous research on mathematical modelling by pointing out that students do not appropriately consider the real-world context of a problem when they process problems with missing data. The modelling problems used in this study were designed to analyze how students deal with missing data and to make it possible for students to perform calculations without noticing the missing data. However, ignoring the missing data in these tasks leads to unrealistic answers. As the necessity of noticing missing data can easily be overlooked, an intensive consideration of the real-world context was essential for solving these problems. As the number of students who noticed the missing data varied considerably between the modelling problems, this finding suggests that whether students notice missing data depends on the specific characteristics of the task. These characteristics might be the context of the problem or the use and nature of the missing data. With respect to the modelling cycle (Blum & Leiss, 2007), we found that some students noticed the missing data directly after reading the problem description, indicating that these students try to develop a more in-depth understanding of the given situation before continuing to process by mathematizing and working mathematically. In the other cases in which students noticed the missing data, the in-depth understanding of the real-world context took part at the end of the processing, after mathematization and working mathematically. Another important finding of our study is that students who noticed the missing data did not always make a numerical assumption, but when students did make an assumption, the assumptions were realistic. This indicates that measurement skills or estimation strategies are not the key obstacle to making assumptions. One possible explanation for the results regarding difficulties in including assumptions in processing might be that problems with missing data and the ability to make assumptions might not be a part of students' mathematics classes. Another possible explanation may be students' conceptions and beliefs about mathematics.

A practical contribution of our study is that students need practice processing modelling problems with missing data in school. Therefore, teaching methods should address students' ability to notice missing data and make assumptions. As the results of our study show, close attention should be paid to the phases of simplifying, structuring, and validation that were particularly relevant for the noticing of missing data. Teaching methods need to stimulate these phases intensively.

Characterising rationales for using statistical modelling in education research from a mathematical modelling perspective: A review

Takashi Kawakami[1] and Jonas Bergman Ärlebäck[2]

[1]Utsunomiya University, Japan; t-kawakami@cc.utsunomiya-u.ac.jp

[2]Linköping University, Sweden; jonas.bergman.arleback@liu.se

This study developed and discussed a framework for characterising rationales for using statistical modelling from a mathematical modelling perspective based on a systematic literature review. We used this framework to provide an overview of the distributions of these rationales in the analysed studies, focusing on statistical modelling. The results identified three categories of rationales for using statistical modelling, namely, competency, content, and socially oriented types. This work discussed how the conceptualised rationales for using statistical modelling in the teaching and learning of statistics can guide the initial step in task design and curriculum development related to statistical modelling. These rationales may also serve as a common point of departure for discussions and collaboration between the mathematics and statistics education communities on the use of models and modelling.

Keywords: Statistical modelling, mathematical modelling, rationale, systematic review.

Introduction

Research on the teaching and learning of statistical modelling (SM) has increasingly gained attention in the statistics education community (e.g. Langrall et al., 2017; Pfannkuch et al., 2018) and mathematics education communities (e.g. Ärlebäck & Frejd, 2021; Frejd & Ärlebäck, 2021; Kawakami & Mineno, 2021). This trend owes its rise to the advent of data science and the need for models to address uncertainty, and underpinned by the worldwide growth of mathematical modelling (MM) in education research (e.g. Kaiser, 2017; Niss et al., 2007) and the rapid technological development.

The present study is part of an overall research goal to elaborate on the connections, boundaries, and boundary-crossing approaches between the teaching and learning of MM and statistics or SM. In this study, MM refers to the generic modelling process involving back-and-forth transitioning between the extra-mathematical world and mathematics (Niss et al., 2007). SM refers to 'any one of a number of practices: the development of a distribution (empirical or descriptive model) from data; the process of creating a theoretical (probability) model from an empirical model; and the practice of sampling from a theoretical model (simulation)' (Langrall et al., 2017, p. 502). MM and SM both include the generation, use, evaluation, and revision of models, and both emphasize the real-world context. However, a characteristic of SM that is not always found in MM is that of making uncertainty and variability central aspects of modelling (Langrall et al., 2017).

Pfannkuch et al. (2018) highlighted interpretations of SM and frameworks for describing students' reasoning with SM in statistics education literature. However, the design guidelines for SM tasks and curriculum components related to SM have not been identified and elaborated. As with MM in mathematics teaching and learning (Niss et al., 2007), such guidelines are essential for including SM as a significant component of statistics teaching and learning at all levels of education. This study examined the rationales for using SM, given the particular significance of rationales in designing SM tasks and curricula related to SM. Studies on teaching and learning SM have employed various rationales for using SM (Kawakami, 2019; Pfannkuch et al., 2018), but these rationales have yet to be systematically organised and structured. To facilitate the work of researchers, teachers, and curriculum developers in systematically designing purposeful SM tasks and to position SM practices appropriately within the statistics and mathematics curricula, this study aimed to (i) develop and discuss a framework for characterising the rationales for using SM from an MM perspective based on a systematic literature review; and (ii) provide an overview of the distributions of these rationales in studies focusing on SM.

Theoretical framework

Commonalities between rationales, goals, theories, and practices in research focusing on MM and SM have been noted and broadly pointed out (Frejd & Ärlebäck, 2021; Langrall et al., 2017). To investigate some aspects of these commonalities in more detail, we used the rationales for using MM in mathematics education to clarify the characteristics of SM from an MM perspective.

Rationales for using MM in mathematics education

The reasons for including the teaching and learning of MM in mathematics education have been discussed from at least two perspectives. Niss and colleagues (2007) introduced dual rationales for using MM: *modelling as a means for developing competency in applying mathematics and building mathematical models* and *modelling as a means for learning mathematics*. The former uses MM to develop a general MM competency (analysing and constructing mathematical models of extra-mathematical contexts and situations) by focusing on the use of mathematics in real-world contexts and problem solving. The present work referred to this rationale as *competency oriented*. The latter, modelling as a means for learning mathematics, uses MM to support the learning of mathematical contents through modelling activities 'by offering motivation for its study as well as interpretation, meaning, proper understanding and sustainable retention of its concepts, results, methods and theories' (Niss & Blum, 2020, p. 28). Our work referred to this rationale as *content oriented.* Niss and Blum (2020) stressed that these two rationales are not dichotomous but can be pursued simultaneously. However, the priority of either can change the aims and designs of mathematics lessons. In addition to these two rationales, Barbosa (2006) proposed a third rationale from a critical mathematics education perspective, namely, *modelling as a means for reflecting on the nature and role of mathematical models in society*. This perspective uses MM to 'emphasize critical thinking about the role of mathematics in society, the role and nature of mathematical models, and the function of mathematical modeling in society' (Kaiser, 2017, p. 274). We referred to this rationale as *socially oriented*.

Three potential rationales for using SM in the teaching and learning of statistics

Pfannkuch et al. (2018) noted and listed four distinct educational purposes for using SM in the teaching and learning of statistics: (P1) enculturating students engaged in the discipline with an approximation of professional statistical practice and reasoning, thinking, points of view, and beliefs; (P2) instructing students in key statistics knowledge and concepts; (P3) developing students' notions of the power, nature, role, purpose, and utility of SM; and (P4) enabling students to gain insights on particular situations. However, these four objectives have not been elaborated upon, nor are their relations discussed systematically. In this study, we sought to elaborate on the rationales for using SM by relating these four purposes to rationales for MM.

P1 employs SM as a means for developing students' statistical competency. In statistics education, such a statistical competency is often framed and discussed in terms of statistical literacy, statistical reasoning, or statistical thinking (Garfield & Ben-Zvi, 2008). According to Garfield and Ben-Zvi (2008), statistical literacy is the ability to interpret, evaluate, and communicate statistical information and messages; statistical reasoning is the ability to connect statistical concepts and explain statistical processes and results; statistical thinking is the ability to use statistical models, methods, and applications in advancing statistical investigation, such a PPDAC cycle (Problem–Plan–Data–Analysis–Conclusion) (Wild & Pfannkuch, 1999). In terms of the rationales for using MM, P1 can be described as *competency-oriented SM*. P2 and P3 employ SM for promoting the learning of statistical contents, such as statistical knowledge and concepts (e.g. variability, distribution, sample, and sampling) as well as knowledge and concepts related to statistical models and modelling. Employing the rationales for using MM, P2 and P3 can be described as *content-oriented SM*. Lastly, P4 employs SM for decision making in the real-world, social, and societal contexts, in which data are embedded and, in some cases, for developing a critical understanding of the use and role of statistics, statistical models, and modelling in these contexts. In terms of the rationales for using MM, P4 can be described as *socially oriented SM*.

In summary, we have elicited three potential rationales for using SM in the teaching and learning of statistics: (R1) *competency-oriented SM*, (R2) *content-oriented SM*, (R3) *socially oriented SM*. These three rationales for using SM, as well as the rationales for using MM, are not in opposition to one another. Indeed, multiple ones may merge within a single practice. As the priority of any of these rationales can influence the aims and design of statistics lessons, we make a distinction among these three rationales. The present study addressed two questions: (i) How can rationales R1–R3 be further elaborated and understood based on the use of SM as also done in empirical research? (ii) What is the use distribution of rationales R1–R3 in empirical research on SM?

Methodology

We conducted a systematic literature review of peer-reviewed research on SM in mathematics and statistics education. Research papers from the following influential mathematics education journals were identified: *Educational Studies in Mathematics* (ESM) (May 1968–July 2021), *ZDM: Mathematics Education* (ZDM) (1997–July 2021), *Mathematical Thinking and Learning* (MTL) (1999–July 2021), *Journal for Research in Mathematics Education* (JRME) (1970–July 2021), and *Journal of Mathematical Behavior* (JMB) (1995–July 2021). Research papers from the following internationally recognised journals in statistics education were also included: *Statistics Education Research Journal* (SERJ) (2002–July 2021) and *Journal of Statistics Education* (JSE) (1993–July

2021). The paper selection process is illustrated in Figure 1. As part of the systematic review process, we read all identified 63 papers, and then coded the rationales for using SM in the papers by assigning them into the three categories R1, R2, and R3. The coding was determined based on the explicit description(s) of the rationale(s) for using or investigating SM or modelling in the papers by focusing on the (1) purpose and position of the study; (2) intentions and purposes of the used teaching materials, curriculum, and teaching practices; as well as (3) research questions in the papers. Examples of such descriptions and their coding are shown in Table 1. The first author conducted the first analysis, which included classification, and the second author independently checked the assigned papers and the first analysis. Where discrepancies occurred, the authors discussed and resolved these issues.

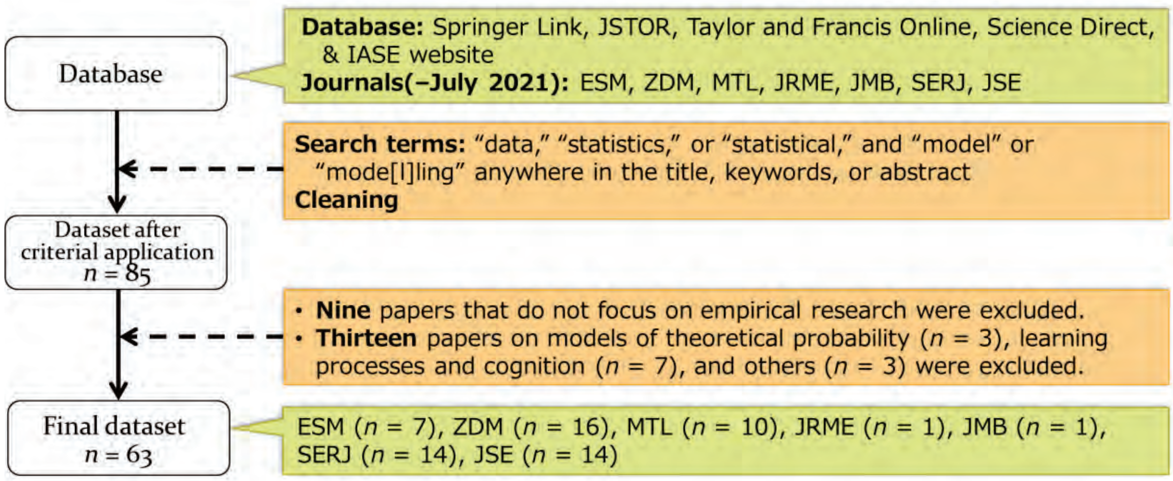

Figure 1: Paper selection process

Table 1: Examples of the descriptions from which categories R1–R3 were determined

Category	Examples of the description in the papers
R1	In this article, we have examined one approach to developing primary school students' statistical literacy, namely, through modelling with data. (English & Watson, 2018, p. 113)
R2	The study relied on classroom video and student artefacts to analyse aspects of the students' modelling experiences which exposed them to powerful statistical ideas, such as key repeatable structures and dispositions in statistics. (Makar & Allmond, 2018, p. 1139)
R3	Statistical modelling needs to become a tool for critical democracy. (Zapata-Cardona, 2018, p. 1220)

Results

Table 2 presents the identified rationales for using SM in the analysed literature with the frequency and examples within each category.

Table 2: SM rationales in the literature in terms of categories R1, R2, and R3 (*n* = 63)

Category	Freq. (%)	Examples (listed by author only given space constraints)
R1	19 (30)	Doerr & English (2003)$_{\text{JRME}}$, Biehler et al. (2017)$_{\text{SERJ}}$, Doerr et al. (2017)$_{\text{SERJ}}$, Noll & Kirin (2017)$_{\text{SERJ}}$, Dvir & Ben-Zvi (2018)$_{\text{ZDM}}$, Leavy & Hourigan (2018)$_{\text{ESM}}$
R2	13 (21)	Prodromou & Pratt (2006)$_{\text{SERJ}}$, Lesh et al. (2008)$_{\text{ESM}}$, Ainley & Pratt (2017)$_{\text{SERJ}}$, Büscher & Schnell (2017)$_{\text{SERJ}}$

Only R1 rationale: Competency-oriented SM

Papers in which R1 was the only rationale used comprised the second largest category of papers, accounting for about 30% (*n* = 19). These studies typically used SM to develop statistical competencies (e.g. statistical literacy, reasoning, and thinking) as well as statistical processes (e.g. *statistical inquiry* in the sense of Wild and Pfannkuch [1999] and *informal statistical inference* in the sense of Makar and Rubin [2009]). These studies emphasised the role of statistical models and modelling in developing statistical competencies; for example, '[m]odels are important concepts in statistics and key components of learning to think statistically' (Noll & Kirin, 2017, p. 213). Exclusively, R1-coded papers often described SM as applicable for real-world problem solving and stressed the applied nature of statistics, emphasising the use of actual and authentic data in the educational setting.

Only R2 rationale: Content-oriented SM

Papers in which R2 was the only rationale used comprised the third largest category of papers, accounting for about 21% (*n* = 13). These papers used SM to elicit, develop, and deepen the understanding of a wide range of statistical contents, including an aggregate view of data, measures of distribution, signal and noise, variation, population, sample and sampling, theoretical distributions, statistical models, SM process, causality, and statistical inference. These papers tended to reframe statistical concepts and knowledge as models or modelling constructs in support of the notion of *emergent modelling* (Gravemeijer, 1999) and *model-eliciting activities* (Lesh & Doerr, 2003); for example, 'measures are understood as models, which can either be used to make sense of a given situation or to reason about the statistical measures themselves' (Büscher & Schnell, 2017, p. 144). Exclusively, R2-coded papers often expressed SM as an epistemic practice of statistics and a pedagogical tool.

Combined R1 and R2 rationales: Competency- and content-oriented SM

The largest category of papers employed both R1 and R2 (approximately 33%, *n* = 21). These papers used SM to combine and integrate statistical competencies (R1), such as statistical reasoning and informal inference, and statistical contents (R2). In these papers, the emphasis was not only on real-world problem solving, transiting between the real (data) and model (data) world, but also on conceptual developments within the model world. Some papers considered statistical literacy and reasoning as competency to carry out SM, comparable to MM competency. For example, Patel and Pfannkuch (2018) framed *SM reasoning* as the ability to transit between the physical and model worlds involving the following activities: starting with understanding of the real-world problem, applying structure to it toward a transition to the model world, refining the model and analysing simulated data, and interpreting the results back into understanding regarding the original real-world problem. R1-and-R2-coded papers often used SM as an integrator between statistical methods and statistical content.

R3 rationale: Socially oriented SM

R3 was the least commonly discerned rationale in literature (approximately 16%, n = 10). None of the papers used it as the sole rationale, only using it in tandem with R1 and/or R2. These studies used SM to enhance critical thinking on real-life, social, and societal contexts and to examine the power and limitations of statistical models and modelling. In some cases, the discipline of statistics embedded in these contexts were examined using the notions of authenticity, critical citizenship, ethics, and publicity. These papers focused on the role of statistical models and modelling in thinking critically about life and society. For example, Zapata-Cardona (2018, p. 1220) observed that '[s]tatistical modelling needs to become a tool for critical democracy' and '[m]odelling activity should focus on the functions of the applications in society'. R3-coded papers often described SM as a means and object of social criticism and decision-making based on data. They also emphasised the use of social issues and contexts in education.

Discussion and conclusion

Our analysis showed that all three rationales for using SM in research on the teaching and learning of statistics were used to various extents in empirical studies. In other words, SM is seen as a multifaceted means of achieving applied, epistemic, and social critical-related goals in the teaching and learning of statistics. However, based on the results of the systematic review in terms of R1 to R3, SM can also be understood more holistically: (i) R1 can be seen as stressing *SM as a component of statistical competencies*, i.e. the use of statistical models/modelling as a key element for promoting real-world problem solving and statistical inquiry (e.g. Noll & Kirin, 2017); (ii) R2 can be taken to promote *SM as integrating aspects of statistical contents*, meaning that the structure of statistical content is rooted and reflected in statistical models/modelling (e.g. Büscher & Schnell, 2017); and (iii) R3 portrays *SM as shaping and influencing real-life, social, and societal decision making*, indicating that statistical models/modelling form the basis for data-driven decision making (e.g. Zapata-Cardona, 2018). Figure 2 summarises these three conceptualised rationales for using SM in the teaching and learning of statistics. In each rationale in Figure 2, the goal–means relation is depicted with arrows. Inclusionary relations between the goal and means are shown by the ellipses.

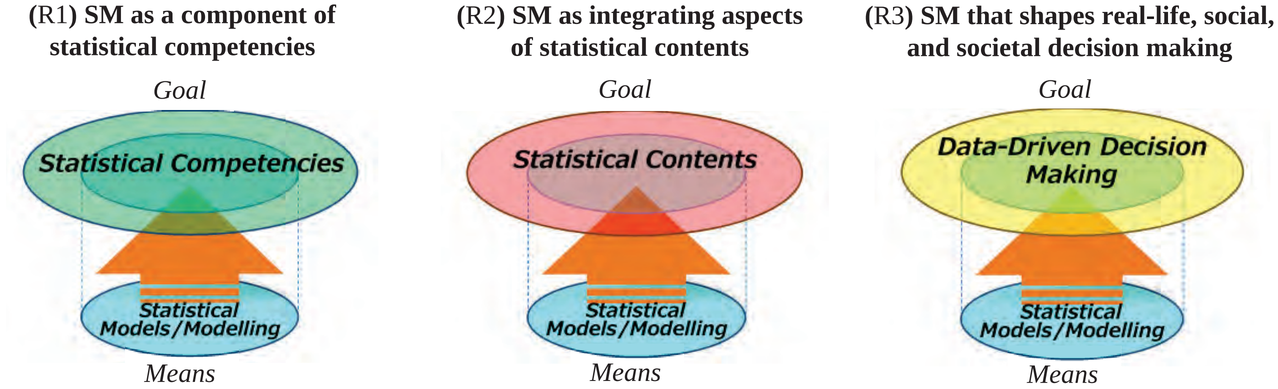

Figure 2: Three conceptualised rationales for using SM in the teaching and learning of statistics

The review results also revealed that these three rationales can be used together in one lesson, unit, curriculum, or project. Indeed, the exclusive use of R3 was not found in any of the 63 analysed papers. This is in contrast to the research on MM, where the lone use of the socially oriented rationale is common (cf. ethnomodelling). The combination of R1 and R2 was the most common category, with three papers using all three rationales (R1–R3). Hence, combining rationales is common in the context of SM, in contrast to much of the research on MM. These results may be related to the nature of statistics, which pertains to statistical methods, statistical content, and data with context (Wild & Pfannkuch, 1999). However, a more detailed review of MM literature is needed to establish further the viability of these differences between SM and MM.

The goal–means relations in Figure 2 support the hypothesis of the learning trajectory of SM. For example, learners can advance competency-oriented SM (R1) using contents constructed through content-oriented SM (R2). They can then perform socially oriented SM (R3) by making full use of competency and contents acquired through the other types. The inclusive relations in Figure 2 also suggest that different rationales have different domains and assumptions in which statistical models and modelling are placed and that, in practice, the functions/roles of statistical models and modelling can be changed dynamically. Therefore, it is also necessary to review the meaning of statistical models, modelling, and the description of SM specified in each study.

The conceptualised rationales for using SM in Figure 2 can guide the initial step in task design and curriculum development related to SM for researchers and teachers. It can also serve as a common lens for shared discussion and collaboration between the mathematics and statistics education communities on issues related to the teaching and learning of models and modelling (e.g. English & Watson, 2018; Langrall et al., 2017). However, to provide more concrete design guidelines, additional research is needed to identify and elaborate on more aspects and characteristics of SMs. The review results specifically demonstrated the applicability of the findings of MM education research to SM education research in terms of goals and rationales. A natural next step is to clarify the similarities and differences in teaching and learning SM and MM. It is also necessary to clarify to what extent we need to distinguish between MM and SM, or whether SM is a sub-form of MM. These, in turn, will shed light on the nature and role of models and modelling, and the underlying assumptions and hypothesis in, and for, MM research.

Acknowledgement

This paper is a revised and extended version of a short presentation at ICME14 (Kawakami & Ärlebäck, 2021). This version included more studies in the analysis. The results and conclusions are likewise revised and updated versions of the short presentations.

An exploratory modelling task by slicing 3D shapes: the Three Worlds of Mathematics through an historical and technological approach

Diego Lieban[1] and Rafael W. Bueno[2]

In this work, high school students were assigned to investigate a problem which involves the transition from 2D to 3D interpretation using the method of exhaustion, one of the cornerstones ideas of Calculus. For this approach, the authors sought to develop the study through an exploratory modelling task, under the lens of the Three Worlds of Mathematics theory. In this scenario, the students were supported by an initial discussion based on Calculus early ideas and with the use of current technologies, such as GeoGebra and laser cutting machines. The data collected in this study came from a video recording of this initial discussion and from the portfolios of three students who explore the volume of the solid generated by the rotation of a cycloid, comparing it with classical results in two dimensions.

Keywords: Three worlds of mathematics, method of exhaustion, cycloid, GeoGebra.

Introduction

In this work, high school students were assigned to investigate a question which involves the transition from 2D to 3D interpretation using some of the cornerstone ideas of Calculus. For this approach, the authors sought to develop the study through an exploratory modelling task, under the lens of the Three Worlds of Mathematics theory (Tall, 2013). In this scenario, students were supported by an initial discussion based on Calculus early ideas and with the use of current technologies, such as GeoGebra and laser cutting machines. In this regard, dynamic simulations were digitally represented based on a physical model to initialize the discussion and enhance students' mathematical ideas. Observing the interactions during an online meeting and students' portfolios, the authors of this paper aimed to identify (or not) the benefits coming from either physical and digital prototypes and how they can support one another. Based on these ideas, the following research question emerged: *how do students understand and combine ideas from the Three Worlds of Mathematics while using 2D and 3D resources and prototypes to build basic ideas of Integral Calculus?*

Motivation

The nature of slicing a 3D shape to develop mathematical concepts goes back to Archimides, who resorted to the method of exhaustion in order to have a more rigorous proof of his theorems, particularly following his goal to determine the volume of a sphere (Bueno, 2020). Nevertheless, it is not hard to identify such a technique in day-by-day contexts and this can be a natural reason to connect 2D and 3D representations in geometric studies and working with modeling. These practices take part of the Conceptual Embodied world (Tall, 2004), which is developed by students' perceptions and actions in manipulating such shapes and its slices. The examples in Figure 1 illustrate some possibilities in this sense. While the tomato and sheets of paper easily connect to daily life contexts, the artcraft lighting shows an example developed by students in a Calculus undergraduate course.

The central picture is a physical model developed through the integration of GeoGebra and laser cutting techniques and it was used to spark the discussion with the students in this study.

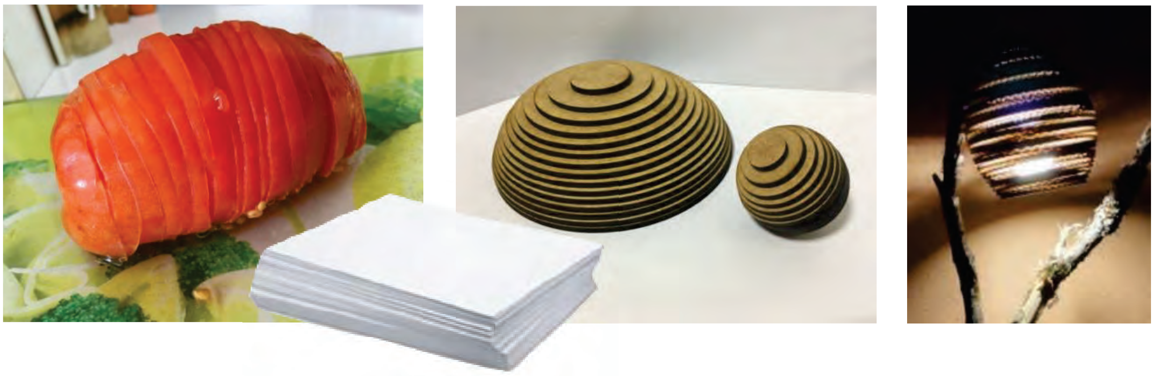

Figure 1: Conceptual Embodied world through shapes sub-divided by slices

Once the math behind the strategy to obtain the right volume of solids of revolution might rely on Integral Calculus, the problem posed to high school students was to approximate such volume based on geometrical concepts and supported by GeoGebra. Particularly, the task was to estimate the volume of the solid generated by the revolution of a Cycloid when it is turned around its symmetrical axes. The challenge is to investigate whether there is, or not, a straight connection with the circle that generates the Cycloid, since there is a known result in the 2D version of this problem, regarding their areas (Toffolo et al., 2020). To support the students' ideas, and in addition to the physical model that was shown, GeoGebra applets[1] were shared and discussed with student participation during an online meeting, when the problem was presented.

Theoretical Framework

David Tall, aiming to understand how mathematical thinking is built, developed the Three Worlds of Mathematics theory, which involves early perceptions about counting and arithmetic, reaches algebraic symbolism and goes on until mathematical border research. By creating the Conceptual Embodied, Operational Symbolic and Formal Axiomatic worlds, Tall (2013) brought ideas capable of supporting important thoughts about mathematics teaching and learning.

In this regard, Tall (2013) highlights that mathematical thinking development is more complex than the simple sum of new ideas to a fixed structure of pre-existing knowledge. Mathematical thinking is built, in fact, by a continuous rearrangement of mental conexions that evolve to reach, in time, knowledge structures more and more sophisticated.

Geometry study, for instance, starts with real objects manipulation. These objects have their physical particularities described by students in an informal way using the common spoken language. With time and development of news ideas, these particularities start being defined in a more accurate way and evolve until reaching more formal ways, like Euclidean Geometry. Some students who go to college to study exact sciences can go further and learn even more complex ideias, like Differential Geometry, for instance.

[1] https://www.geogebra.org/m/hacg6ex6 and https://www.geogebra.org/m/tykauqhp.

Arithmetics knowledge grows in a different way, because it is related to actions done with objects and not just with its embodied particularities, like shape or size. Therefore, the focus of arithmetics is counting, grouping and ordination, for example. These activities occur, inicialy, on the perceptual world and evolve until the use and manipulation of mathematical symbols that arise from operations and go further until its manipulation without great conscient cognitive effort.

Algebra arises from the generalization of the perceptions built with arithmetics. New rules are understood and fill out the blanks of previous studies until the moment that equations and functions start being used as cognitive resources to solve problems. With this gradual mathematical thinking sophistication, functions can be understood, for instance, by visualizations of the cartesian plane. In the long term, some algebraic structures can be formulated with axiomatic systems, generating fields, rings or groups.

According to Tall (2004) theory, ideas of the Conceptual Embodied world are developed by perceptions and actions that happen in the real world and evolve until the creation of mental images becomes more and more sophisticated. Conceptions that don't belong to this real world are built in an abstract way, like a perfect straight line.

The idea of embodiment, as stated by Lima (2007), is related to observation, action and thought about situations with physical objects, but that evolve until the development of mental experiences. In this case, with abstract thoughts, objects (reals or imaginary) start being manipulated and observed by using only thoughts, generating new ways to perceive these actions.

A relevant alternative for this embodiment complexification can be the use of digital resources to manipulate objects. Therefore, with tools like GeoGebra it is possible to develop actions and, in a blink of an eye, verify its implications on the screen. Beyond that, with 3D printers and laser cutting machines, many mental constructions can be brought to life in the real and physical world and help teachers in their class, illustrating important ideas and supporting individual and collective mathematical perceptions.

Tall (2003) understands that educators should use new technologies to help them to build more meanings in Mathematics studies. With GeoGebra, 3D printers, laser cutting machines and other resources it is possible to change ways to teach and learn mathematics, going beyond algebraic manipulation and static graphics and reaching discussions and learnings from embodyments made possible by digital technologies.

The Operational Symbolic world, as highlighted by Tall (2013), arises from symbols used in arithmetics, algebra or even Calculus. It begins with actions that, with some time and thoughts, can evolve and until it is perceived as mathematical processes or even as mathematical concepts. In this regard, some people reach only the process idea while others go further and understand symbols as processes to do and also as concepts to think about.

Discussing this duality of mathematical symbols, Gray and Tall (1991) brought the idea of "procept", understood as the amalgamation of process and concept. According to Lima (2019), if some individual understands symbols as "procepts" he/she will end up developing "proceptual" thinking.

The Formal Axiomatic world, as suggested by Tall (2004), can be characterized by axiomatic developments that generate definitions, theorems and corollaries (among others) that have its ideas deduced from mathematical demonstrations. In this mathematical environment thoughts are not restricted to embodiment objects and thoughts are expanded to reach mental experiences even more sophisticated that end up with constructs that provide mathematical abstract structures such as an abelian group. Even knowing that this world begins to be studied only in college it is important to perceive that "in any mathematical activity formal mathematics ideas can be found, because a student doesn't understand new mathematical concepts without some presence of its formal characteristics" (Lima, 2019, p. 8).

According to Tall and Mejía-Ramos (2004), each one of the Three Worlds of Mathematics has its ways to warrant the truth. In the Conceptual Embodied world the truth is built from human intuition to, on a more advanced level, be grounded in mental experiments. In other words, something is proved right if it seems to be true or if some experiments end up occurring in the expected way.

In the Operational Symbolic world a formula is proved right because it can be developed by a sequence of algebraic manipulations. In the Formal Axiomatic world a theorem is proved right if it can be built by formal logical developments based on axions and mathematical definitions.

To an individual to trill his/her journey through the Three Worlds of Mathematics and develop knowledge, some previous ideas are necessary. Some of this previous knowledge leads to increasing progress while others lead to alternative paths that can, in some cases, lead to erroneous conclusions.

Tall (2013) calls this previous knowledge as *met-before* and uses this term to describe how new situations can be understood from the perspective of previous experiences. *Met-before*, although, can't be restricted only to experiences because it is linked also to any memories generated by those previous experiences and held on into the brain and that can affect new cognitive constructs.

Methodology and Methods

The explorative nature of the study demanded an interpretative approach comprising qualitative methods such as observation, data collection, and analysis (Cohen et al., 2011). Our experiments were carried out with high school students through an online course in Brazil and lasted a period of three months with meetings in every second week on average, to follow the students' progress. At the phase of the course when the problem was proposed, all participants had already been introduced to GeoGebra and it is important to highlight that students were free to choose which problem they would work with, among three alternatives. Beyond the cycloid problem, the other two were related to combinatorial studies (applied in a logical game) and fractals. From 19 students who achieved this investigative and exploratory task, 3 of them chose the cycloid problem (12 chose the game task and 4, the fractal task). Nevertheless all problems were introduced and initially discussed with the whole group.

The data collected in this research came from two different sources: i) a video recording from the initial session (~30min) when the problem was introduced and discussed with the whole group, and ii) the portfolios of the three students who dealt with the cycloid problem, in which they extended the discussion started at the whole group session and developed their ideas, research and calculation. During the online session with students, the mediator (one of the authors of this paper) emphasized that despite this problem could be tackled using Calculus techniques, the main goal would be to explore the basis of these techniques, it means, the math ideas behind the Calculus (or supporting it).

From this point, the mediator asked if the participants had seen anything about cycloid before and one of the students mentioned some animations with a circle generating the curve that she had already seen online (in a math blog and also in a GeoGebra applet). These animations as well as some experiments that give the cycloid its known alternative names – brachistochrone and tautochrone – were then shared and mentioned some reasons why this curve has an important role in the field of sciences. Some short math videos (from the Portuguese Mathematics show “That is Mathematics”[2]) was also recommended. Finally, the problem was presented, with an important remark that it had been motivated by the genuine curiosity of a former student a few months earlier.

Data Analysis and Results

The starting point for this problem, as mentioned in the previous sessions, was the initial online meeting, when the physical model composed by the slices of the solid obtained by the cycloid rotated was shared. Therefore, the discussion was introduced from ideas of the Conceptual Embodied world. In the same class, the mediator shared with the students two digital applets.

Before sharing such physical (through the cam, only) and digital representations, nevertheless, an introduction about the relevance of the Cycloid and some of its characteristics were explained and this step was crucial to attract students’ attention and contributions. Despite the fact that online communication has been challenging in general, some students did not hesitate to express their guesses when they were asked about the ratio between the solid generated by the rotation of the cycloid and the correspondent sphere. At this moment, they already had seen that the area under the cycloid was three times the area of the correspondent circle through the first shared applet. After discussing some free guesses, they looked suspicious and uncertain (some guesses suggested the ratio would be kept as the planar situation). Then, the second applet was shared, with a 3D interactive representation, so they could rotate the cycloid and visualize the final shape of the generated solid. This second applet allowed users to approximate the solid by a set of slices, starting with a cone, through the interaction with two sliders and facilitate the comparison between the original shape and its approximation by the set of truncated cones. Such interaction supported students’ interpretation regarding the strategy to approximate the unknown volume (adding up slices as thin as desirable, they will tend to infinity), but their task was still open.

From this point and based on the group discussion, three students developed their digital representations, shown on Figure 2, to approximate the volume, but the analysis of their portfolio shows they had slightly contrasting approaches.

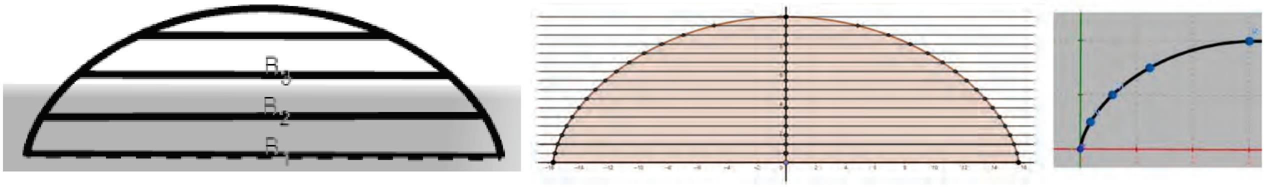

Figure 2: Shapes sub-divided by slices leading to ideas from the Conceptual Embodied wor

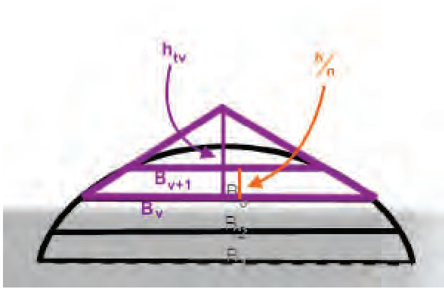
[2] https://www.youtube.com/istoematematica

Despite all three strategies arose from the Conceptual Embodied world, their goals were not exactly the same. Whereas one of them (student 1) sought to generalize an expression based on an arbitrary number of slices, the other two concerned to calculate the volume based on a particular example. In these last two cases, one of them (student 2) sought to determine the unknown ratio as accurately as possible, while the other one (student 3) tried to convince herself whether such a ratio was three, or not, since this was the ratio in the planar case, regarding the areas of the figures (cycloid and circle). These students' approaches indicate how the participants were able to recognize 3D shapes' properties and compare 3D shapes (in this case, solids of revolution), as well as understanding and visualizing the internal structure of the solid to calculate the volume of solids in the sense of 3D geometry abilities described by Pittalis et al. (2009).

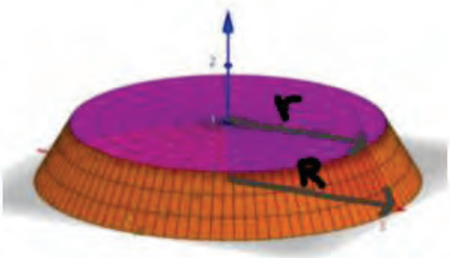
Considering the case of student 1, who tried to generalize the formula of the volume, it seems that he reached Operational Symbolic world ideas once he used digital algebraic descriptions to understand how developed ideas could be extended to more and more cases. Even though he did not obtain a final formula, he was able to generalize in some steps. In Figure 3 (right side), it is shown how he started defining the *height related to the basis B_1*, to obtain the height (named h_{tv}) related to an arbitrary basis B_v using similarity of triangles, understood by the authors as a met-before. The colorful remarks on the left side were added by the authors to illustrate the idea described in digital symbolic language by the student.



"h_t1 = Altura do triângulo de base B_1
*h_t1 = (-B_1*h)/n(B_2-B_1)*
*h_t1 = (-B_1*2r)/n(B_2-B_1)*
*h_tv = (-B_v*2r)/n(B_(v+1)-B_v)"*

Figure 3: Similarity of triangles to generalize a formula in the Operational Symbolic step

The other two students, as already mentioned, focused on calculating the volume of the truncated cones, also considering the radii from consecutives slices as their bases. In this case, news ideas arrived from this met-before (truncated cones). Particularly, student 2 used an online calculator to obtain the volume of the truncated cones and organized all data in a spreadsheet, as shown below, in Figure 4 (right side). The representation on the left side (Figure 4) is from one of the applets shared, but the notes (r and R) are from student 3.



Raio maior	Raio menor	Altura	Volume
15.7	15.6	0.62	477
15.6	15.4	0.62	468
15.4	15.1	0.62	453
15.1	14.8	0.62	435.3
14.8	14.4	0.62	415.2
14.4	14	0.62	392.8
14	13.4	0.62	365.6
13.4	12.8	0.62	334.3
12.8	12.2	0.62	304.4
12.2	11.4	0.62	271.3
11.4	10.5	0.62	233.7
10.5	9.5	0.62	195
9.5	8.4	0.62	156.2
8.4	7	0.62	115.8
7	5	0.62	70.8
5	0	0.62	16.2
	VOLUME TOTAL:		4704.6

Figure 4: Calculating the volume of the truncated cones

Despite both pictures above came from different students, they reveal the same strategy, with different number of slices. The ratio obtained by student 2 and student 3 were, respectively, 8,99 (with 16 slices) and 7,71 (with 4 slices), which are rather close to the real ratio, 9,10.

Conclusions

Physical and digital resources were combined in this research to support students in an exploratory modelling task, which the aim was to investigate the volume of the solid generated by the rotation of a cycloid around its symmetry axis. As motivation for the task developed in this paper the authors considered the interpretation from daily contexts of slicing and historical aspects that retrieve Archimedes' studies and the method of exhaustion, an important and cornerstone topic of Calculus. Using the Three Worlds of Mathematics as theoretical framework, the study intended to observe how the connections with such resources that use current technologies (GeoGebra and laser cutting machines) might help students on their journey through the Three Worlds of Mathematics – Conceptual Embodied, Operational Symbolic and Formal Axiomatic. Based on students' interaction during an online meeting and the portfolio of three students, the researchers found evidences that connect the conceptual embodied and operational symbolic in this task, specially connecting ideas from classical geometry, understood as met-before, to introduce seminal ideas of calculus.

In addition, this study is in line with Carreira (2019), who consider that modelling problems require a certain kind of mathematical thinking that could be called modelling thinking. For her, such thought aims to establish connections, analogies, similarities and relationships between different systems, among which mathematics is obviously included. These connections, according to the author, as well suggested by the evidences in this work, arise as a result of experimentation, exploration, understanding, conceptualization and manipulation of reality (in different environments, whether physical or digital). Although the problem in this study is sparked by the exploration of a mathematical object – the cycloid curve – the strategy applied might be naturally adapted for (and motivated by) other solids of revolution coming from the real world, such as illustrated in Figure 1. Thus, as highlighted by Carreira, the processes of mathematization, prototyping, experimentation and simulation take place in a cycle that involves the construction of a model (based on mathematics) that becomes multidimensional as the relationships among its variants (real model, physical model, mathematical model, computational model) are strengthened and consolidated.

The outlined examples are part of a set of experiments and activities developed in our practices. In future papers, we hope to report additional insights into connecting physical and digital modeling approaches, seeking to align with related and pertinent theories and pedagogies.

Acknowledgment

This work was supported partially by the Federal Institute of Education, Science and Technology (IFFAR and IFRS), Brazil, and by the Johannes Kepler Universität (JKU), Austria. The activities developed in this study also takes part of the PIPA IFmakeRS project.

On the information that prospective teachers assume when modelling and its impact on the modelling outcomes

Jesús Montejo-Gámez[1], Elvira Fernández-Ahumada[2] and Natividad Adamuz-Povedano[2]

[1]University of Granada, Education Sciences Faculty, Granada, Spain; jmontejo@ugr.es

[2]University of Cordoba, Education Faculty, Córdoba, Spain; elvira@uco.es; nadamuz@uco.es

This paper characterises the mathematical models that prospective elementary teachers develop to solve a modelling task, as well as its dependence on those information and assumptions that students use without justification when developing the model. For this purpose, a sample of 74 prospective elementary teachers (45 women) was chosen to estimate the distance a ship is from shore when it sees the lighthouse on the horizon. The use of an analysis tool specific to characterize models and the analysis of those statements that individuals use in their models without justification showed a wealth of models. The relationship between individuals' awareness of certain information and the validity of such information was also suggested. Several assumptions on the curvature of the earth's surface or on the height of the ship resulted to had an impact on the models analysed.

Keywords: Mathematical models, educational research, prospective elementary teachers.

Introduction

Nowadays, mathematical educators in general and researchers in mathematics education in particular acknowledge the benefits of modelling at all levels of education. In the scope of teacher education, particularly, several authors point out the potential of the modelling activity to provide prospective teachers with challenging experiences allowing to explore mathematics content, serve as examples of teaching and help to manage students' beliefs (see Fernández-Ahumada & Montejo-Gámez, 2019 and references therein for a discussion on the benefits of modelling in teacher education). This makes modelling a field of great interest to researchers in mathematics education and teacher educators. One of the most relevant and differentiating skills of mathematical modelling is linked to taking actions that facilitate the application of mathematical tools to obtain knowledge about real systems, which are usually complex. In other words, modelling implies simplifying or organising a real system, in order to bring it closer to a mathematic formulation. Within Ärlebäck and Albarracín (2019) activity-based approach, for instance, those actions devoted to facilitate the application of mathematics are encompassed in the "Modelling" sub-activity. Under a modelling-cycle approach, on the other hand, they are included in the Simplifying/Structuring transition.

The role of assumptions in the transition of Simplifying/Structuring

Previous research has emphasised that difficulties in modelling are especially obvious when real-world situation has to be simplified (Dede, 2016; Kaiser et al., 2010), and there are studies describing the actions involved in the simplifying/structuring process of a real system (see e. g. Czocher, 2016; Maas, 2006; Montejo-Gámez & Fernández-Plaza, 2021). These include drawing/sketch of such real system, identifying and naming variables, operationalising relationships or patterns, introducing outside knowledge and estimating data, carrying out systematic experiments and using and formulating assumptions. In particular, there is consensus among the different authors on the importance of the management of assumptions within the modelling activity. However, some studies suggest that much of the difficulty in the simplification process arises when making assumptions (Dede, 2016; Hidiroğlu et al., 2014 cited by Dede, 2016), and the focus of teaching is hardly focused on the formulation, use or discussion of the assumptions of a model. On the other hand, Wozniak (2012) highlighted the importance of prospective teachers being able to explicitly express the actions carried out during the modelling activity. Consequently, it is appropriate to help students to become aware of the information they apply when modelling.

Research on the impact of this information on the modelling activity is not very extensive. Fernández-Ahumada and Montejo-Gámez (2019) introduced the term premises to refer to mathematical statements used in a model without prior justification. The analysis of this type of statements allowed the detection of difficulties in the modelling activity. Other studies made emphasis on the formulation of the assumptions. At this respect, Wozniak (2012) found 'mute praxeologies' when analysing prospective elementary teachers' activity: they used hypotheses, but generally did not formulate them. These studies suggest the usefulness of making visible the information that prospective teachers may assume when solving a modelling task and measuring the influence that this may have on the modelling outcomes. This leads to the following research question: what information do prospective elementary teachers assume as valid when approaching a modelling task and what is its impact on the models developed? To give an answer, this study aims to analyse written productions in order to access the assumptions made during the transition simplifying/structuring. The methods used are explained below.

Methods

A qualitative methodology was used for the development of the research. The sample used was made up of N = 74 students of the degree in Primary Education at the University of Granada (45 women and 29 men). The participants were organised according to the usual working groups in class for them: 1 group of two people, 12 groups of three people and 9 groups of four. The 22 groups worked for an hour and a half, without interactions between groups, to solve the following task, adapted from Kaiser (2014): *The Cabo Mayor lighthouse is situated at the North of Santander. The focus of this lighthouse is situated 91 m above sea level; thus, it is useful to warn ships that they were approaching the coast. How far, approximately, is a ship from the coast when it sees the lighthouse for the first time?* The work of the groups generated 22 written productions that reflected the models proposed by the students.

Analysis procedure

The research question was approached on the basis of a three-stage analysis. (1) The first one was to characterise and categorise the models developed. For this, the instrument and procedure presented by Montejo-Gámez et al. (2021) were used, which are schematised in Figure 1. The procedure starts by deciding what is to be considered mathematical content. Next, per each written production, the representations used in such production were identified, categorised and then analysed: On one hand, the questions of the system and the mathematical questions of the model were identified (depending on whether or not they contained mathematical content). On the other hand, the statements involved in the representations drove to identifying the relations of the system (those without mathematical content) and mathematical results (those with mathematical content) of the model. Then, the entities referred to in the relations were identified as the objects of the system, whereas the relevant quantities involved in the results were identified as the variables of the mathematisation. Finally, the underlying mathematical properties from the results were abstracted, and hence, the concepts involved. In this way, the system and the mathematisation that made up the mathematical model in the written production were obtained. The synthesis of the differentiating elements provided a summary characterisation which gives an overall idea of the model developed and highlights its main attributes (see Table 1 below). Once this was done with all the written productions, models were organised into emergent categories, according to such attributes and the validity of the models (to provide a reasonable answer to the task).

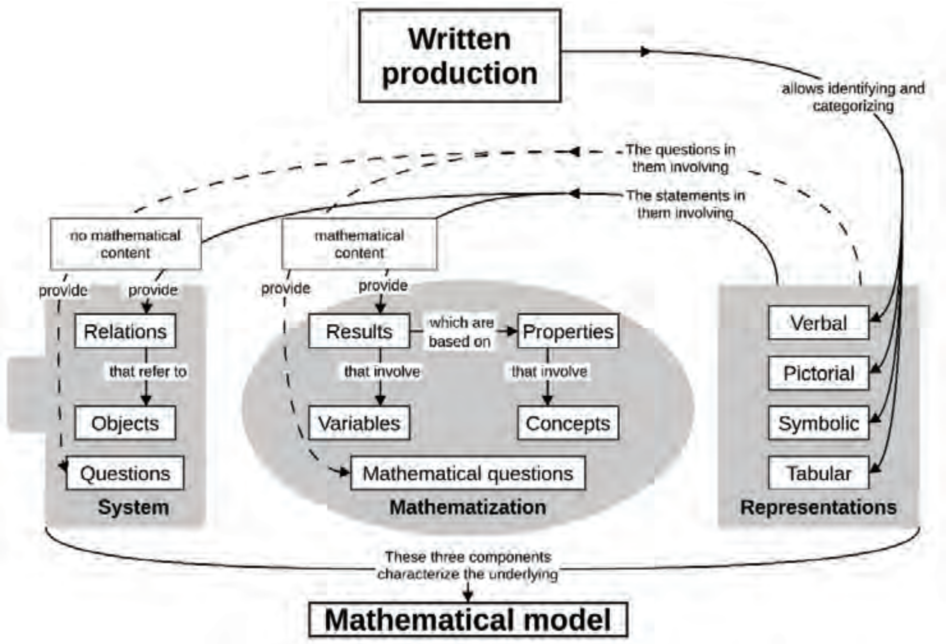

Figure 1: Flux diagram of the procedure used to characterise the models from the written productions in the first stage (Montejo-Gámez et al., 2021, p. 6)

(2) The second stage of the analysis consisted of identifying the information that students assume to be valid in their models, which was based on Fernández-Ahumada and Montejo-Gámez's (2019) notion of premise. In this way, the relations and the results and properties of the models analysed in the first stage were retrieved, and those statements that were used without prior justification were selected. Note that such statements were obtained from the representations of the models. For example, the first pictorial representations in Figure 2 below (from a to e) indicate that students assume as valid the flatness of the earth's surface. Once the statements assumed as valid were recovered, they were organised into emerging categories with a common meaning, and each category was assigned a synthetic formulation that summarises this meaning. These categories were obtained by two of the researchers independently and then discussed and reviewed by the third researcher. In order to find out the incidence of each category, the following variables were quantified: frequency of appearance in the productions, contextuality (percentage of statements in that category that were represented without any reference to mathematical content), awareness (percentage of statements in

that category that the authors recognise as assumptions in an obvious way) and validity (percentage of statements that have been used in an acceptable way in the context in which they were used). For example, the 82.4% validity shown in row S6 in Table 2 indicates that 82.4% of the times students used the Pythagorean theorem it was to apply it to right-angled triangles (on the remaining occasions they used it in situations where it does not apply). (3) Finally, in the third stage, the distribution of the statements that students considered valid according to each type of model was obtained. These data made it possible to visualise the impact of the information students assumed to be valid on the models produced.

Results

The characterisation and categorisation of the models developed by the students (first stage of the analysis) started from the choice of what was to be considered mathematical content: arithmetic operations, units of measurement, geometric properties of the circle and the Pythagorean theorem, content that belongs to the syllabus of the university course in which these students were enrolled. This first stage resulted in six categories, which are summarised in Table 1 and illustrated in Figure 2. The most repeated models (11 of the 22 models analysed) were those based on a right-angled triangle with the sea surface (flat) and the lighthouse. Nine of these constitute the M1 category and the remaining two make up the M2 category. M1 consists of the models that correctly identified the height of the lighthouse. None of them were valid for solving the task, as four of them assumed ad hoc data on the angles (Figure 2, a and b) and four others assumed values for the sides of the triangle (Figure 2, c and d). A final group gave no answer after considering the right-angled triangle.

Table 1: Summary characterisation and validity of the models developed by students

Model	*Frequency*	*Summary characterisation*	*Valid?*
M1	9	A right-angled triangle whose base is the Earth's surface (considered to be flat). The lighthouse height datum is correctly identified (Figure 2a-d).	No
M2	2	A right-angled triangle whose base is the Earth's surface (considered to be flat). The lighthouse height datum is incorrectly identified (Figure 2e).	No
M3	1	Circle of radius 91 m (Figure 2f).	No
M4	5	Right-angled triangle whose legs are the radius of the Earth and the lighthouse-horizon line of sight. The height of the ship is neglected (Figure 2g).	Yes
M5	3	Triangle whose legs are the radius of the Earth plus the height of the ship and the lighthouse-ship line of sight. The triangle is assumed to be right-angled (Figure 2h).	No
M6	2	Two right-angled triangles with common leg the radius of the Earth, and uncommon legs the ship-horizon and lighthouse-horizon lines of sight, respectively (Figure 2i).	Yes

M2 is made up of the models based on a right-angled triangle that misidentified the 91 m height datum (Figure 2e). The remaining categories use the circumference to address the task. In particular, category M3 has been assigned to a single model that interpreted the range of the lighthouse as 91 m and described the situation using a circle, which could not lead to an answer to the question posed (Figure 2f). In turn, category M4 encompasses the 5 models that used the curvature of the Earth's surface to model the situation and disregarded the height of the ship, which allowed them to obtain close-to-reality solutions (Figure 2g). Category M5 includes models that did not disregard the height of the ship but considered right-angled triangles that are not really right-angled, which was the case for two of the groups (Figure 2h). Finally, M6 comprises models that considered the ship's height and used two right-angled triangles to calculate the ship-to-horizon and horizon-to-lighthouse distances (Figure 2i).

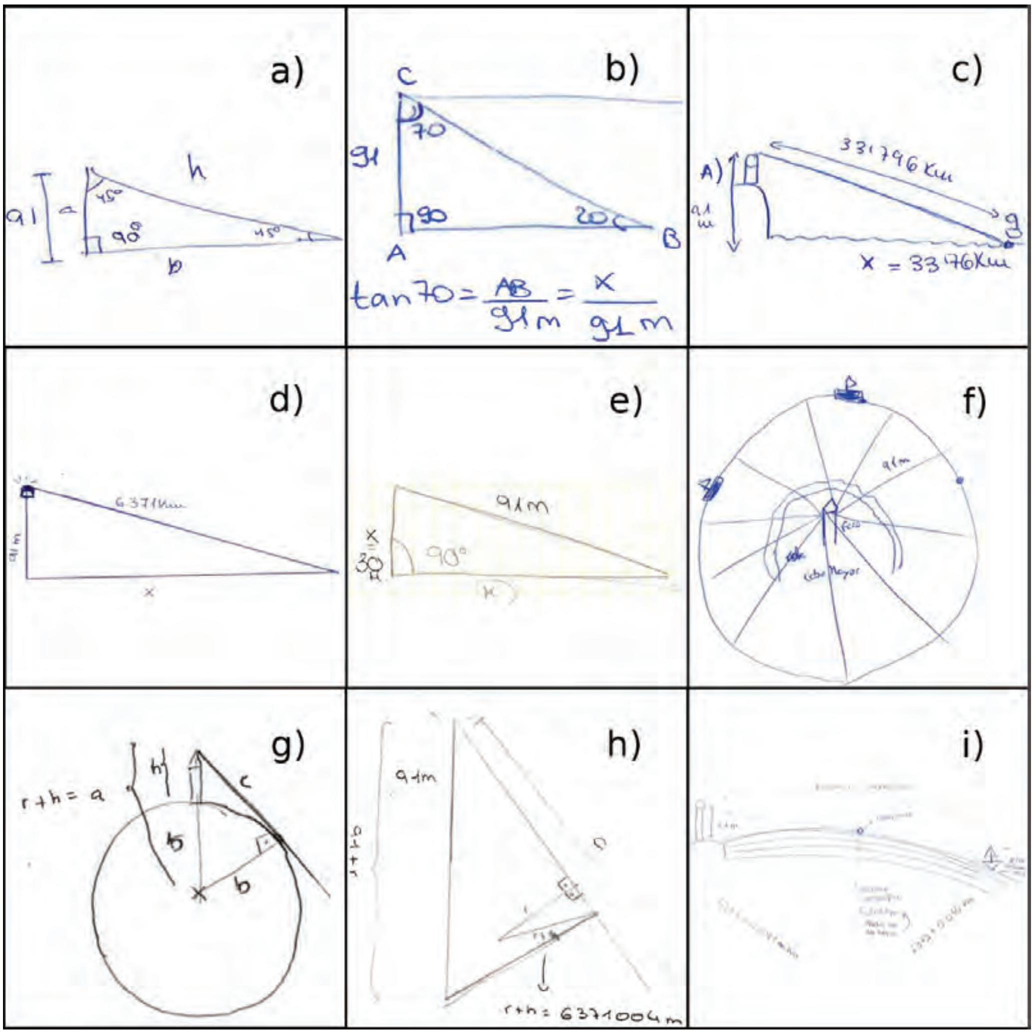

Figure 2: Pictorial and symbolic representations corresponding to the models found

Table 2, regarding the second stage of the analysis, summarises the information that students considered valid for the development of the models without the need for justification. There were 116 such statements, which were organised into seven categories. Four of them included statements expressed with hardly any mathematical content (rows S1-S4 in Table 2), and the remaining three were mostly expressed in mathematical language. In the case of S1-S4, we found hypotheses that students used without showing evidence that they were making assumptions. Of particular note were the assumptions of the flatness of the Earth's surface, the assumption that the height of the ship can be neglected, and different approximations to useful numerical parameters (angles in the M1 models, triangle side lengths in the M1, M2 and M3 models, and the radius of the Earth in M4, M5 and M6). In contrast, those models that used the curvature of the Earth or the height of the ship showed a higher degree of awareness. Furthermore, data indicate that statements with a higher degree of awareness have higher validity within the corresponding model. With regard to the last three categories (rows S5-S7 in Table 2), which describe applied mathematical knowledge, it is observed that students generally use valid mathematical content (the Pythagorean Theorem in most cases) without justifying it, and that they assume its applicability as a matter of course. However, about a quarter of the statements in S5 expose that the students show explicit awareness of having identified a variable whose numerical value provides the answer to the task.

Table 2: Categories of statements that students considered valid in their models

Synthetic formulation		*Frequency*		*Contextuality*		*Awareness*		*Validity*	
S1a. The Earth's surface is flat	S1b. The Earth's surface is curved	12	10	100%	100%	8.3%	80%	0%	100%
S2a. The height of the ship is negligible	S2b. The height of the ship is not negligible	18	4	100%	100%	0%	50%	100%	100%
S3. A variable has a certain numerical value		21		90.4%		28.6%		57.1%	
S4. There are no clouds or haze		2		100%		100%		100%	
S5. Calculating certain information answers the problem (identification of the unknown).		22		4.5%		22.7%		81.8%	
S6a. Pythagorean Th. is applicable to solve the problem	S6b. Trigonometry is applicable to solve the problem	17	2	0%	0%	0%	0%	82.4%	100%
S7. When the ship starts to sight the lighthouse, the ship-lighthouse line is tangent to the Earth.		8		0%		12.5%		100%	

Regarding the impact of the statements that students used without justification, Table 3 shows the distribution of these statements in the different models. In particular, row S1 shows that the use of the curvature of the Earth was decisive in the development of the models, so that M1, M2 and M3 are based on the flatness of the Earth's surface, while the remaining three types of models are based on taking advantage of its curvature. Among the latter are also concentrated the claims related to the tangency of the ship-lighthouse line of sight (line S7 in Table 3), although it seems reasonable that these claims are a consequence of using the curvature of the Earth, rather than a cause of the development of the models. In contrast, the use of ship height does discriminate between M4, which disregards it, and M5 and M6, which introduce it as a model parameter (row S2 of Table 3). As for the rest of the statements, the applicability of certain mathematical contents such as trigonometry could be a differentiating feature of the models (especially with regard to mathematics), but it has not been considered as such due to its residual nature in the context of pre-service education. Finally, it is observed that statements related to the adoption of values for the parameters and the identification of the unknown are evenly distributed across the different models, so that they did not exert any relevant influence on the students when constructing their models either.

Table 3: Distribution of the statements that students considered valid according to each type of model

Synthetic formulation		*M1 (9)*		*M2 (2)*		*M3 (1)*		*M4 (5)*		*M5 (3)*		*M6 (2)*	
S1a. The Earth's surface is flat.	S1b. The Earth's surface is curved.	9	0	2	0	1	0	0	5	0	3	0	2
S2a. The height of the ship is negligible	S2b. The height of the ship is not negligible	9	0	2	0	1	0	5	0	1	2	0	2

S3. A variable has a certain numerical value	7	3	1	5	3	2
S4. There are no clouds or haze	0	0	0	1	1	0
S5. Calculating certain information answers the problem (identification of the unknown).	9	2	1	5	3	2
S6a. Pythagorean Th. is applicable to solve the problem	6	1	0	5	3	2
S6b. Trigonometry is applicable to solve the problem	2	0	0	0	0	0
S7. When the ship starts to sight the lighthouse, the ship-lighthouse line is tangent to the Earth.	0	0	0	4	2	2

Note: The number in brackets next to M*i* indicates the number of models that fell into the *i-th* model category

Discussion and conclusion

This paper characterises the mathematical models developed by prospective elementary teachers when dealing with a task in which a property of the reference system, which is not explicit in the task but known to all participants, is key to finding a valid answer. The aim of this study was to analyse the information that prospective elementary teachers put into play without justifying it and its impact on the models developed. The main novelty of this paper is the analysis strategy used for this purpose and the first results found about this impact.

Analysis of the statements that prospective elementary teachers assumed to be true without justification revealed a large volume of information that was used in the models without obvious justification, with a balance between mathematical and extra-mathematical information. These results are aligned with those of Wozniak (2012), who found a large amount of mute praxeologies during modelling activity of prospective elementary teachers. In addition, it was observed that statements that students consciously impose are more valid for the model than those that are assumed without obvious awareness. As for the impact of these types of statements on the models developed, it was found that the use of the flat or curved character of the earth's surface was decisive. Indeed, all three types of models that assumed the flatness of the Earth led to non-valid answers, while two of the three types of models based on the curvature of the Earth did provide reasonable answers. The use of ship height was not decisive for the validity of the models, but it did differentiate them. On the other hand, data or information on the applicability of certain mathematical content had less impact on the models developed.

In brief, it has been found that the information that students use without justification when developing a model (especially in the simplification and structuring of the initial contextualised situation) can determine the modelling outcomes. Therefore, knowing this information is useful for understanding their models, finding difficulties (Fernández-Ahumada and Montejo-Gámez, 2019) and accounting for the contextual mathematical knowledge of prospective elementary teachers. The present study highlights the usefulness of written productions when studying this information that is used without justification and provides an analysis strategy for this purpose. The instrument developed by Montejo-Gámez et al. (2021) has been used, although tools for analysing written productions such as that of Ferrando et al. (2017) could also be used for this purpose. The didactic implication that emerges from this study is the relevance of expressing the mathematical knowledge that is activated during the modelling activity, which is especially necessary in prospective elementary teachers. Tools such as the Study and Research Paths (Barquero et al., 2019) or the implementation of modelling tasks focused on the specific activities of using, formulation or detection of hypotheses could be useful in this sense. Exploration of these possibilities will be developed as future work.

Design of a didactic activity based on the Hazen-Williams model for engineering education

Esteban Pablo-Díaz[1] and Avenilde Romo-Vazquez[2]

[1]Instituto Politécnico Nacional, CICATA, Mexico; estebanpablo@yahoo.com.mx

[2]CINVESTAV, Mexico; avenilde.romo@cinvestav.mx

The research presented is focused on engineering education, framed in the Anthropological Theory of Didactics (ATD), whose objective is to design a didactic activity of mathematical modelling. For this purpose, didactic engineering is considered. The starting point is the analysis of a civil engineers' workplace. A praxeology based on the Hazen-Williams model to design pipelines is identified using notions of hydraulics, topography, and mathematics. A didactic transposition on this praxeology is performed. A mathematical modelling activity is designed and implemented with students in the fluid mechanics' course. The central task is to determine the diameter of the pipe and ensure a water flow rate of 50lts/s. The handling of the mathematical model requires a qualitative analysis of the variables at stake and to relate knowledge of various kinds.

Keywords: Mathematical models, higher education, engineering education.

Introduction

Linking the mathematics that engineers use at work with the mathematics they study at university is a social demand, highlighted by Pollak (1988). Indeed, some research has been conducted in the workplace to identify the mathematics being used (e.g., Frejd & Bergsten, 2016; Gainsburg, 2007). Their results show the fundamental role of mathematical models, the management of which requires other knowledge, such as computational, practical, and engineering, and particularly, from experience, which is fundamental in decision-making, what Gainsburg (2007) calls the engineer's judgement. These types of mathematics can occur in training through didactic proposals that are inspired or based on the analysis of mathematics in the workplace, as suggested by Frejd and Bergsten (2016). In this line, this research was carried out within the framework of the Anthropological Theory of Didactics (ATD), in proposing to relate the workplace and specialised training as a first step for designing didactic proposals for the mathematics classroom. We mainly raise two research questions: What kind of activities of engineer's workplace can be transposed to engineering courses through mathematical modelling teaching proposals? Furthermore, what institutional conditions make it possible to integrate these proposals into engineering courses?

Some elements from ATD

The ATD proposed by Chevallard (1999; 2019) defines a model for analysing human activity in its institutional dimension. The praxeology $[T, \tau, \theta, \Theta]$ is a minimal unit of analysis of human activity. Its four components are the task type (T), the technique (τ), the technology (θ), and the theory (Θ). The 'task' refers to what is to be done; the 'technique' is how it is to be done; the 'technology' is a discourse that produces, justifies, and explains the 'technique'; while the 'theory' produces, justifies, and explains the 'technology'. Doing mathematics is a human activity closest to mathematical modelling because doing mathematics in this frame consists of and acting (produce, teach, uses) on mathematical models, as stated in Barquero et al. (2019). Institutions offer resources and conditions that allow their subjects to develop specific activities and establish restrictions. There are different types of institutions, and a subject may belong to several institutions, occupying various positions (e.g., teacher, student, parent, citizen). According to Chevallard (1999), praxeologies can circulate between institutions, undergoing, in effect, transpositive processes, i.e., transformations. To analyse this phenomenon in the case of the training of future engineers, Romo-Vázquez (2009) classified institutions according to their relationship with knowledge into three types: production, teaching and use. Production (or research) institutions are those that produce praxeologies, such as disciplines (e.g., mathematics, hydraulics); teaching institutions are in charge of transmitting praxeologies (e.g., school mathematics, school hydraulics) and using institutions are those in which praxeologies are used (e.g., industry, workplace). This classification is made considering the primary vocation of each institution. Still, it does not mean that praxeologies are not created or taught in the workplace or that no praxeologies are taught in the disciplines. However, when a disciplinary praxeology is taught, it undergoes a didactic transposition. It means that it is transformed to become an object of teaching. Thus, mathematical praxeologies become school mathematical praxeologies (Chevallard, 1991). The didactic transposition process is illustrated by Bosch & Gascón (2006, p. 56) as follows (figure 1):

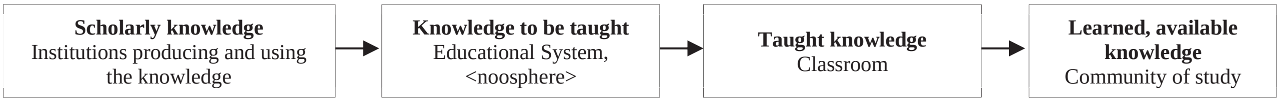

Figure 1: The didactic transposition process

In the case of training of future engineers, specific didactic transpositions can be performed. For example, transposing mathematical modelling praxeologies from the workplace to mathematics or engineering education, as suggested by some research (e.g., Frejd & Bergsten, 2016; Romo et al., 2017), as represented in figure 2.

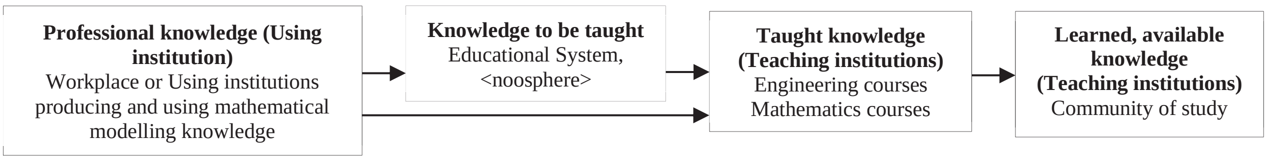

Figure 2: Transposing mathematical praxeologies from the workplace to teaching institutions

Performing this kind of transposition from Workplace to Engineering education demands identifying a local[1] mathematical modelling praxeology in a specific workplace of engineers W: $[T^e, \tau^{em}, \theta^{em}, \Theta^e] \leftarrow Pw$. Here, T^e is an engineering type task and the technique τ^{em} to perform this type of task has mathematical and engineering elements. The technology θ^{em} that justifies the technique is a mathematical model used in engineering, whereas the theory is from engineering. Praxeology Pw is then transformed into a school mathematical modelling praxeology Ps that can be constructed in engineering teaching (ET) as illustrated in figure 3.

[1] Praxeology with the same logos block for different practical blocks. It corresponds metaphorically to a modelling topic composed of various sub-topics.

$$\begin{bmatrix} T^{e} & \tau^{em} & \theta^{em} & \Theta^{e} \\ T^{se} & \tau^{sem} & \theta^{sem} & \Theta^{sem} \end{bmatrix} \begin{matrix} \leftarrow W \\ \leftarrow ET \end{matrix}$$

Figure 3: Scheme of transposition workplace praxeology to teaching praxeology

The process of transposition demands considering the institutional conditions: workplace and teaching, and the way of the original praxeology can be transformed to live in the teaching institutions. Likewise, *Pw* is conceived like an *epistemological model reference* in the sense proposed by Barquero, Bosch and Gascón (2019). Thereby, *Pw* must be a local modelling praxeology.

Methodology: Didactic engineering

Didactic engineering constitutes a solid research methodology (Artigue, 2020), which allows the design of tasks. Its four phases are preliminary analysis, activity design and a priori analysis, experimentation, and a posteriori analysis. Based on this, we design and analyse a didactic activity of mathematical modelling for engineering education, as illustrated below.

Phase 1. Preliminary analysis: Civil engineers' mathematical modelling praxeology of hydraulics. This analysis focused on characterising a mathematical modelling praxeology of hydraulics used by civil engineers to design pipelines in their workplaces. It was carried out jointly by a mathematics education researcher and a civil engineer with 29 years of experience, who is also a university professor (first author) of mathematics and engineering courses and a PhD student in mathematics education. Analysing his professional practice is a difficult task because some knowledge is no longer recognised, then a researcher in mathematics education questioned and asked for explanations. Civil engineers' mathematical modelling praxeology of hydraulics is represented as $[T^{h}, \tau^{hm}, \theta^{hm}, \Theta^{h}] \leftarrow Pw$, where *h* represents hydraulics and *m* mathematics. Thus, task type is T^{h}: Design a pipeline to transport water between two points taking advantage of the effect of gravity. Technique τ^{hm} and technology θ^{hm}: Step 1. Recognise the project's requirements and the minimum initial data to calculate the difference in level between the supply and distribution reservoirs and the total length of the pipeline path. Step 2. Determine the whole length of the pipeline path (L) using an established reference system (see figure 4). Step 3. Determine the hydraulic head of the system (ΔH), calculating the difference between supply and distribution reservoirs. ΔH is always greater than zero since the level of the distribution reservoir is lower than that of the supply reservoir, ensuring that the effect of gravity generates the flow of the fluid (figure 4).

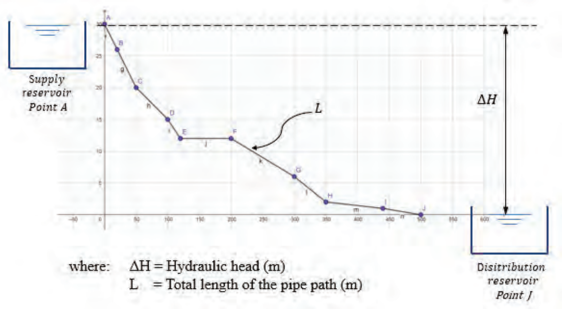

Figure 4: Schematic illustration of the pipeline path

Step 4. Select the material of manufacture of the pipe, considering the roughness of materials employing the Hazen-Williams coefficients (C)[2]. A material with high roughness will have a lower coefficient and a lower flow rate for the same pipe diameter. In contrast, the lower roughness of the material will have a higher coefficient and a higher

[2] See for example Alegret & Martínez (2019, p. 45).

flow rate. Step 5. Determine the flow rate (Q) using the Hazen-Williams mathematical model: $Q = 0.2785C\ D^{2.63}\ S^{0.54}$ where: Q = Flow rate at the pipe (m^3/sec); C = Hazen-Williams coefficient (dimensionless); D = Diameter of the pipe in meters (m) and S = hydraulic head loss per length of pipe (dimensionless factor) obtained with the following formula: $S = \Delta H/L$ where: ΔH = hydraulic head, expressed in meters, L = Total length of the pipe path interconnecting both reservoirs. The applicable limits of this formula are debatable; in the third edition of Hydraulic tables by Williams & Hazen (1933), the pipe diameters to be used were limited to 0.05 m (2 in.) < D < 1.85 m. (6 ft.). Furthermore, it is recommended to be used for flow velocities values below 10 ft./sec (3.05 m/s) and is valid only for water flowing at ordinary temperatures (5 °C - 25 °C) (Alegret & Martínez, 2019). It is worth mentioning that, in the case of not complying with the described parameters, the mathematical model could give results different from reality. Step 6. Verify that the flow rate (Q) obtained is the closest (approaching from a higher value) to the project's required flow rate (Q_p); Step 7. Check the water velocity (v) at the pipeline, which should be less than 10 ft/sec (3.048 m/sec). Step 8. Report the pipeline design results. To perform these eight steps requires that engineers properly use the Hazen – Williams model, recognising the mathematical relationship of the variables involved and how they can be satisfied from experimental conditions. Sometimes it is necessary to adjust data and, above all, to contrast the results obtained by the model with the existing pipe diameters on the market. The theory Θ^e is hydraulic engineering.

Phase 2. Didactic transposition of the civil engineers' mathematical modelling Pw, design of the didactic activity and a priori analysis. A didactic transposition was performed on the Pw, obtaining a school praxeology Ps. The task type is the same; the technique is organised in Ps through three stages using subtasks *Tn.m*. The technology in both praxeologies is the Hazen-Williams mathematical model, and the theory is hydraulic. However, in school praxeology, the fluid mechanic's course is also involved, see figure 5.

$[T^h, \tau^{hm}, \theta^{hm}, \Theta^h] \leftarrow Pw$		$[T^h, \tau^{shm}, \theta^{shm}, \Theta^{sh}] \leftarrow Ps$
T^h Design a pipeline	→	T^h Design a pipeline
τ^{hm}	→	τ^{shm}
Step 1		Stage 1 (3 subtasks): T1.1, T1.2., T1.3
Step 2 -7		Stage 2 (5 subtasks): T2.1, T2.2, T2.3, T2.4, T2.5, T2.6
Step 8		Stage 3 (1 subtask): T3.1
θ^{hm} Hazen-Williams mathematical model	→	θ^{shm} Hazen-Williams mathematical model
Θ^{shm} Hydraulic	→	Θ^{shm} Hydraulic– Fluid mechanics course

Figure 5: Scheme of didactical transposition from *Pw* to *Ps*

Thus, the school praxeology is described in this way. T^h: Design a pipeline to transport water between two points taking advantage of the effect of gravity. The technique has three stages. In stage 1, the requirements and initial data of the project are recognised through three subtasks. Firstly, T1.1. Identify the required flow rate (Q_p) at the distribution reservoir. This is the project's main datum, for example, 50lts/sec; T1.2. Analyse the topographic data (see Table 1), draw up a scheme and visualise the general conditions of the system to be designed. This is a first approach to the establishment of the reference system: location of the supply point as an initial point of the system, establishment of scales to use and labels to identify the implicit elements in the system. Finally, T1.3. Drawing up the topographic profile for recognising the natural terrain and identifying key points for the design of the pipeline. Civil engineers usually use the software like AutoCAD, favouring parameter manipulation for better visualisation and detailed analysis. Students can use GeoGebra, which provides an elevation view and elements necessary in a simplified two-dimension drawing to apply the Hazen-Williams model (see figure 6). Stage 2: designing a pipeline to transport water between two points by taking advantage of the effect of gravity involves five subtasks. T2.1. Determination of the pipeline's total length is important for calculating the hydraulic head loss per length of the pipe. The lengths of the pipe sections are calculated from point to point where the changes of direction in the path occur and add together. Students can perform these calculations in GeoGebra. T2.2. Calculation of the hydraulic head, a dominant factor for the natural movement of the fluid through the pipe. This is the difference in level between the point of supply and the point of distribution calculated in meters. T2.3. Selection of the type of pipe considering three main conditions: 1) installation needs, 2) cost of the pipe, and 3) the related Hazen-Williams coefficient, depending on the material of manufacture. The students do not have information on conditions 1 and 2, so they should focus on the efficiency of the material for fluid conduction, evaluating the Hazen-Williams coefficient. T2.4. Determine the flow rate. *This is the central task* and consists of the application of the Hazen-Williams mathematical model. Although their use is not identified in professional praxeology, it is considered that students could propose an initial value of the pipe Diameter using the continuity equation $A = Q/v$, where v is the limiting velocity of the water in the pipe, Q, the flow rate for which the design is made and A, the cross-sectional area of the pipe. Considering the formula of the area of a circle, it is feasible to obtain an initial datum for the Diameter. For the students to perform this same procedure, avoiding an initial random proposal of Diameter, they will be provided with a table that favours the qualitative analysis of relationships between variables. T2.5. and T2.6. Verification of compliance with limitations or restrictions of the method, guaranteeing the correct operation of the mathematical model to obtain results following reality. 1) Pipe Diameter limited to 0.05 m (2 inches) < D < 1.85 m. (6 ft.); 2) Design flow rate greater than or equal to that required in the project [$Q \geq Q_P$]; 3) Fluid velocity in the system must be less than 10 ft. per second (3.05 m/s). To verify it, the formula $v = Q/A$ is used again. Suppose any of the restrictions are not met. In that case, students are expected to propose another diameter, develop the procedure, checking whether all the restrictions are met again, i.e. an iterative process is generated until the pipe Diameter that meets the restrictions of the method is found. As a means of verification (immediate feedback) and approaching the professional reality, students can use "Epanet", specific software for the design of piping systems in which the Hazen-Williams mathematical model is encapsulated or implicit. Stage 3) Report the pipeline designed results. A T3.1 subtask is proposed to elaborate a report of the pipeline designed results.

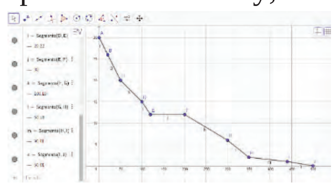

Figure 6: Topographic profile in GeoGebra

The objective of the didactic activity is to allow students to construct or reconstruct the school praxeology *Ps* in the classroom. For this purpose, a situation similar to those faced in workplace practice is proposed: "A team of engineers has to connect two reservoirs for the supply of water for domestic use in some town, whose flow rate average required is 50 lts/sec, according to the results of previous studies carried out by specialists. The topographic study carried out on the path of the pipeline that will connect these reservoirs yields the following data on the obligatory points (Table 1), to carry out the least amount of excavation possible."

Table 1: Topographic data of pipeline

Punto	Coordenadas		Punto	Coordenadas	
	X	Y		X	Y
A (supply)	0	30	F	200	12
B	20	26	G	300	6
C	50	20	H	350	2
D	100	15	I	440	1
E	120	12	J(distribution)	500	0

Phase 3. Experimentation. The study was developed at the Universidad Cristóbal Colón, Veracruz, Mexico, in engineering education. The didactical activity was implemented in a fluid mechanics course. The participants were 37 students of the fourth semester, from majors of Industrial Engineering and Petroleum Engineering.

Phase 4. A posteriori analysis. The analysis was performed on the basis of the students' worksheets and the teacher's notes on this activity. Three teams were chosen to analyse their praxeologies and, mainly, how they used the mathematical model, chose the Diameter and justified their solution to the project. The criteria for selecting the teams were the clarity and coherence of their reports and the students' commitment to the development of the activity (according to the teacher's notes).

Some results

This section presents a first analysis of the praxeologies developed by three teams of students, particularly in three subtasks: the determination of the Diameter and flow rate (T2.4) and the verification of compliance with limitations or restrictions of the method (T2.5 and T2.6), which were vital in the development of the didactic activity. When the students were faced with subtask T2.4, they had calculated the value of S and identified the material for their pipe and the Hazen-Williams coefficient C. So, they still had to determine the value of the Diameter D and Q (flow rate) by using the Hazen-Williams model: $Q = 0.2785CD^{2.63}\,S^{0.54}$. The students had no previous experience selecting pipe diameters; then the teacher provided them with a table with different diameter values. So that they could evaluate it in the mathematical model and, depending on the results of the flow calculation, continue with the proposal of diameters until they found the one that would provide the closest flow to that required by the project. Thus, we tried to avoid using the mathematical model as a formula and favour qualitative analysis and the relationship between the variables at stake. The students determined the Diameter and verified that it was as close as possible (approaching from a higher value) to the flow rate required by the project (Qp = 50Lts/s). (See Tables 2a, 2b, and 2c, corresponding to samples of work achieved by the teams 1, 2, and 3, in that order).[3]

Table 2a: Work by team 1

Diameter (in)	Diameter (mm)	Diameter (m)	Flow rate (m^3/sec)	Flow rate (Lt/sec)
5.7	144.78	0.14478	0.049066	49.0661151
5.8	147.32	0.14732	0.051363	51.3625321
5.9	149.86	0.14986	0.053724	53.7244023

Table 2b: Work by team 2

Diameter (in)	Diameter (mm)	Diameter (m)	Flow rate (m^3/sec)	Flow rate (Lt/sec)
3 3/4	95.25	0.09525	0.0543	54.3
3 1/2	88.9	0.0889	0.0453	45.3
4	101.6	0.1016	0.0644	64.4

Table 2c: Work by team 3

Diameter (in)	Diameter (mm)	Diameter (m)	Flow rate (m^3/sec)	Flow rate (Lt/sec)
5.75	146.05	0.1463	0.050431	50.4331434
5.744	145.8976	0.1459	0.050033	50.0334106
7	177.8	0.1778	0.5053	50.53

[3] These tables were made by the authors, considering some rows of the original tables. The green highlighted was also made by the authors.

Team 1 selected a Diameter of 5.8 inches; it is observed that for this selection, they started evaluating diameters from the table they were provided (2, 3, 5) until they found values close to the required project's flow rate, then by 0.1-inch diameter approximations (5.7, 5.8, 5.9). They found the closest value, approaching from a higher value to the project flow rate (see table 2a). *Team 2* selected a diameter of 3¾ inches. This team presents errors in the operation of the mathematical model, it obtains higher flow rates using smaller diameters; the process of selecting the pipe diameter is very similar to that carried out by team 1, with the difference that they use approximations of 1/4 of an inch. (see table 2b). *Team 3* selected a diameter of 5.744 inches. It can be seen that they used the same procedure for diameter selection as teams 1 and 2; in this case, the approximation of the diameter proposals is 0.001 inches, trying to obtain the value of the project flow exactly equal to that required (see table 2c). The mathematical model worked as a technology that allowed them to control the technique, not considering whether the Diameter obtained corresponds to existing pipes in the market. This knowledge is constructed in the engineer's workplace. Moreover, we could ask students to verify the pipe's existence in a new redesign of the modelling activity. Thus, they would have another element to validate the Diameter obtained with the Hazen-Williams model. Concerning the verification of the obtained flow rate to be the most adjusted (approaching from higher values), it was observed that in all cases the students selected the Diameter that provided the closest magnitude to the required project flow rate, always considering values higher than this one. T2.5 Regarding the review of the water velocity at the pipeline using the continuity equation: $v = Q/A$ (where A is the cross-sectional area of the pipe). It was observed that some teams did not perform it. Where this was done, they only indicated that the parameter was not met. However, they did not make any proposal to establish a design that meets this requirement.

As an extra activity, and as a possibility for future research, it was proposed to the students to work with more specialised software –used in the workplace–, which allows them to check their results and receive immediate feedback, favouring reflection on the work carried out, proposals for improvement and connection with reality. Modelling the system in Epanet allows inserting geometric data of the system (obtained from the topographic profile in GeoGebra, figure 6), characteristics of the pipe (diameter, length, material of manufacture), accessories and equipment (e.g., valves, pumps) with the corresponding characteristics obtained from the manufacturer. The software also allows an immediate validation of the results by consulting the design parameters; these are flow rate and fluid velocity. This can be seen on the screen by moving the pointer to the desired element (figures 7 and 8).

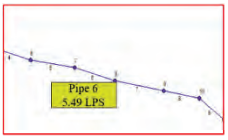

Figure 7: Epanet fluid flow rate

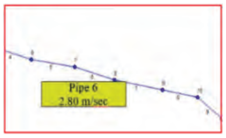

Figure 8: Epanet fluid

Conclusion

This research shows an avenue to design mathematical modelling activities for the training of engineers that connect using and teaching institutions. Didactic engineering allows performing a didactical transposition on the workplace's mathematical modelling praxeology. In this case, the analysis of the Civil engineers' mathematical modelling praxeology of hydraulics is developed by a subject of a using institution and a teaching institution. He analysed his workplace activity, identified a mathematical modelling praxeology, transposed it, generated a didactic activity and implemented it. His professional experience as an engineer and as a teacher was fundamental in all stages of didactic engineering. The students have no difficulties carrying out this activity, but their lack of experience limits the proposed solutions: expensive materials, non-existing pipe diameters, lack of practical verifications. The use of GeoGebra allows an approach to mathematics courses in the first semesters. In contrast, the possibility of using Epanet's software allows an approach to professional practice, guiding the student in the consideration and analysis of parameters and the relationship between them for the generation of the solution with elements very close to reality. From the teacher's perspective, the software used is complementary since GeoGebra provides relevant geometric data for modelling the project in Epanet. It is considered that this didactic activity can also be adapted to be implemented in a mathematics course, and even more, it can be proposed to be developed by students from different semesters with different backgrounds and experiences.

How knowledge about ideal-typical modelling processes affects phase transitions in individual modelling routes

Working on mathematical modelling tasks is usually challenging for students: several studies have shown, that students do not knowingly and consciously apply solution strategies when working on modelling tasks. In an empirical study, we investigate whether and to what extent knowledge about ideal-typical modelling processes has an influence on phase transitions in individual modelling routes. The individual acquires this knowledge in the form of an instruction that contains information about the modelling process, e.g. in form of a modelling cycle and a solution plan. In this article, the phase transitions of students who received an instruction about modelling processes are compared to those of students without such an instruction. The data for the study were collected, presented, and analysed using the Modelling-Activity-Interaction-Tool (MAI-Tool), which is based on quantitative methods to capture and analyse structures of modelling processes.

Keywords: Individual modelling routes, knowledge about ideal-typical modelling processes, phase transitions, MAI-Tool.

Introduction

Studies have already shown that knowledge about mathematical modelling has a positive influence on the modelling process (Stillman & Galbraith, 1998). This knowledge is often provided to students in the form of a solution plan (Beckschulte, 2019). Schneider et al. (2021) found out that individuals who received knowledge about the modelling process engaged intensely with mathematics and rarely deviated from the solution process.

In an empirical study, we compare individuals who have received knowledge about ideal-typical modelling processes (referred to as *the instructed*) with those who have not (*the non-instructed*). Knowledge about ideal-typical modelling processes is provided to students as an instruction in the form of the five-step modelling cycle of Kaiser and Stender (2013) (cf. Figure 1) and the corresponding solution plan of Beckschulte (2019).

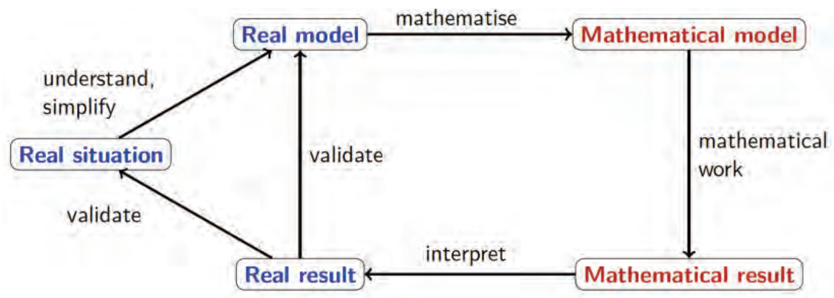

Figure 1: The modelling cycle of Kaiser and Stender (2013)

In addition, the solution process of a modelling problem is discussed using the problem of colouring the map of Germany (Leuders, 2007). The instruction is based on the fundamentals of Vorhölter and Kaiser (2016) and took about 20 minutes.

The aim of our research is to analyse how knowledge about ideal-typical modelling processes affects the structure of individual solution processes. Not only the phases, but also the phase transitions provide information about the influence of an instruction on the modelling process: especially with regard to the phases that are outside the modelling cycle (*summary solution process* and *miscellaneous*), the phase transitions can be used to show which phases occur before or after these phases. This particular view of individual modelling routes requires a tool that can represent structures of modelling processes and algorithmically evaluate them as numerical data: the MAI-Tool. In this article, we examine individual modelling routes for differences in the relative frequency of phase transitions, i.e., we investigate whether the relative number of the two cohorts differ significantly from each other.

Theoretical framework

Analysis of individual modelling routes

Methods for the representation and analysis of individual modelling processes already exist and have been applied in empirical studies. The modelling cycle is not passed linearly and there is a switching back and forth between the phases. This is what Borromeo Ferri (2007) calls an individual modelling route: Successive phases are connected by numerical arrows in the modelling cycle. Thus, the modelling cycle is not only suitable for representation, but also serves as an analysis tool for individual modelling processes.

The Modelling-Activity-Diagram (MAD) is another concept for representing and analyzing modelling processes (Ärlebäck and Albarracin, 2019): in a linear representation, activities of an individual are shown over time. The activities describe what is done in the phases of the modelling cycle.

The MAI-Tool is a newly developed tool for capturing, representing, and evaluating modelling processes (Ruzika & Schneider, 2019; Schneider et al., 2021): the tool is based on observable interactions within the group as they work on a modelling task. Following qualitative methodology, interaction units are entered into the MAI-Tool with the following information: interacting person(s) and content of the interaction. The content is assigned to a phase of the modelling cycle. A timestamp is automatically assigned to each interaction unit so that the duration is also stored. Individual modelling routes are automatically extracted from the group process. The evaluation is quantitative, as modelling processes are described with numerical data. Since the data are available digitally, they are evaluated by algorithms, so that an objective evaluation is given. This results in the advantage that the numerical data can be applied in a statistical test. The individual modelling routes are displayed graphically in the tool – depending on the focus of the evaluation.

Knowledge of mathematical modelling

Solving mathematical modelling problems is challenging for students (Blum, 2015): empirical studies have found that students rarely consciously follow a strategy and do not know how to proceed when they encounter difficulties (Kaiser et al., 2015). Therefore, it is important to provide students with strategies that can assist them in the solving process. In the form of a solution plan that includes the modelling cycle, the phases as well as their transitions are described in detail using activities. A solution plan belongs to the general strategy aids, as no specific help is given for the task (Borromeo Ferri, 2006). By describing the entire solution process in the solution plan, knowledge about the ideal-typical course of a modelling process can be acquired: "[the] solution plan is not meant as a schema that has to be used by the students' but as an aid for difficulties that may occur in the course of the solution process" (Blum & Borromeo Ferri, 2009, p. 55).

Schneider et al. (2021) showed in an empirical study that knowledge about ideal-typical modelling processes affects the structure of individual modelling routes: individual modelling routes of the instructed were compared with those of the non-instructed for differences in the relative number and relative duration of phases in the modelling process. In particular, the phases of the *mathematical world* (*mathematical model* and *mathematical solution*) occur more frequently and for longer for the instructed compared to the non-instructed students. In addition, two phenomena were discovered that have not been considered before: non-instructed students summarise their solution process more often and longer. Moreover, they digress more often from solving the modelling task. On the basis of these analysis, they concluded that the non-instructed students lack knowledge about ideal-typical modelling processes: since they do not know how to solve a modelling task in a structured way, they are not interested in an improved solution and are satisfied with their first solution found.

Classification of phase transitions in the modelling process

To investigate differences in individual modelling routes between the instructed and the non-instructed students with respect to phase transitions, we assign the possible phase transitions to different categories.

In a first step, we divide the phases into two phase types. Phases within the ideal-typical modelling cycle (INPHASE) are *real problem*, *real model*, *mathematical model*, *mathematical solution*, *real solution*, and *validating*. Phases outside the ideal-typical modelling cycle (OUTPHASE) are not part of the modelling cycle: *summary solution process* and *miscellaneous*.

Phase transitions are characterized by their start and end phases. We distinguish between typical and atypical transitions. Typical transitions include adjacent phase transitions (APT). An APT corresponds to an ideal-typical transition in the modelling cycle with INPHASES. There is a total of three atypical transitions that do not correspond to an ideal-typical transition in the modelling cycle: The adjacent backwards phase transition (ABT) is a phase transition in which the start and end phases are reversed compared to APT. ABT are not typical phase transitions because they do not follow one another in an ideal-typical manner as in the modelling cycle. The ABT as well as at the jumps (JUMPS) consist of INPHASES: JUMPS are neither APT nor ABT. The third atypical phase transition includes at least one OUTPHASE and is called phase transition outside the modelling cycle (PTOUT). Start and/or end phase of the phase transition is an OUTPHASE. An illustration of the phases can be found in Figure 2.

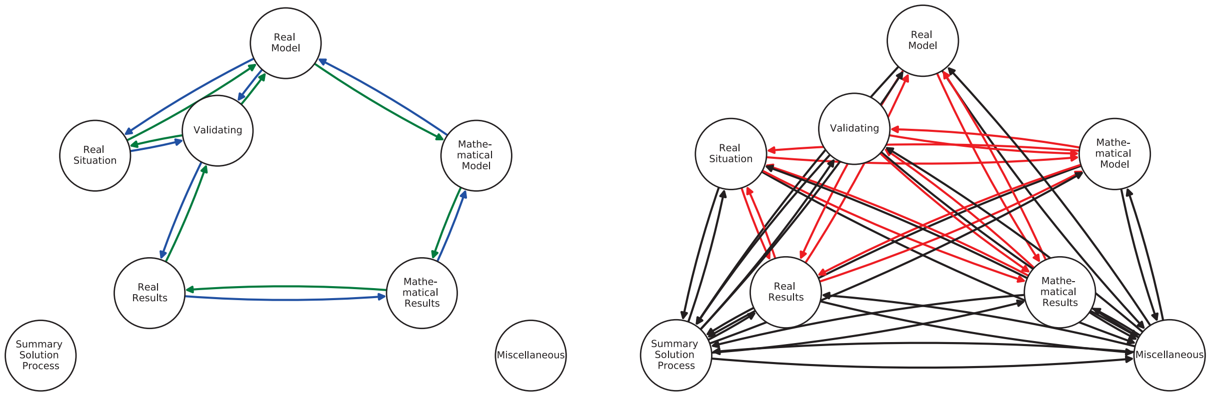

Figure 2: An overview of the phase transitions: APT (green), ABT (blue), JUMPS (red) and PTOUT (black) – illustrated on the modelling cycle

Research question and hypotheses

Based on the theoretical framework as well as on the classification of phase transitions in modelling processes, we formulate the central research question in this article:

To what extent does knowledge about ideal-typical modelling processes affect phase transitions in individual modelling routes, in particular: for which phase transitions does the relative number of individuals with instruction significantly differ from those without instruction?

Following the results of Schneider et al. (2021), we formulate hypotheses that are tested for significant differences in the phase transitions between the instructed and the non-instructed students. The instructed students engage with the mathematical world more frequently and more often during the solution process compared to the non-instructed students. From this, we derive the following hypothesis:

(H1) The instructed students have a significantly higher relative number of the APT *mathematical model* to *mathematical solution* (MM → MS) than the non-instructed students.

In particular, Schneider et al. (2021) highlighted the long duration and frequent occurrence of OUTPHASES for the non-instructed students. We hypothesize that this also affects phase transitions, especially PTOUT. Since the non-instructed students have not engaged as intensively with the *mathematical world*, it can be conjectured that they often switch from the *real model* to OUTPHASES. The following hypotheses emerge:

For the instructed students, the relative number

(H2) of the PTOUT,

(H3) of the PTOUT *summary solution process* to *miscellaneous* (SSP → MISC),

(H4) of the PTOUT *miscellaneous* to *summary solution process* (MISC → SSP),

(H5) of the PTOUT *real model* to *miscellaneous* (RM → MISC) and

(H6) of the PTOUT *real model* to *summary solution process* (RM → SSP)

is significantly lower than for the non-instructed students.

Methodological framework

The study uses a mixed-methods design, with data collection being qualitative and data analysis being quantitative. Tenth grade students from different Gymnasien (German Grammar School) were selected for the study. Only those who had indicated in a questionnaire that they had no previous experience in modelling and had not acquired knowledge about modelling were included in the study. Thus, we excluded the influence of previous experience in modelling. Working in groups of five, they complete the "filling-up" task in 30 minutes (Blum & Leiß, 2006). The sample includes 40 students (20 instructed, 20 non-instructed). The group work was videographed.

Interactions were recorded using the MAI-Tool: Grounded Theory (Strauss & Corbin, 1996) was used to qualitatively code the interaction units. Each interaction unit contained information on who interacted (with whom), which phase of the modelling process could be assigned an when the interaction began and ended. To guarantee reliability in the coding, two people coded the data. The interrater reliability was calculated using Cohen's Kappa (Cohen, 1960) and is $\kappa= [.72, .90]$ for each individual. Phase transitions are evaluated by absolute and relative frequencies in the MAI-Tool. The relative frequencies of both cohorts are analysed for significant differences using the Mann-Whitney U test. In contrast to t-tests, this non-parametric test requires fewer prerequisites. The significance level is set at $\alpha=0.05$. The effect size δ is calculated according to Fritz et al. (2012) and interpreted according to Cohen (1988). The Mann-Whitney U test and the calculation of the effect size was done using the software R. Because multiple hypotheses are tested from one data set, analyses are corrected using the Benjamini-Hochberg method (Benjamini & Hochberg, 1995).

Results of the study

The hypotheses are tested using the Mann-Whitney-U-test. The results are shown in Table 1. All hypotheses are accepted because the *p*-values for the respective variables are always below the significance level of $\alpha=0.05$. Thus, significant differences between the two cohorts can be measured for each variable. The effect size is at least weak for each hypothesis; this underlines that an effect is measured in each case.

Table 1: Results of the Mann-Whitney-U-test for group 0 (non-instructed) and group 1 (instructed) with the mean values (mv), standard deviation (sd), *p*-values and effect size δ (rounded to 3 decimal positions)

variable (corresponding hypothesis)	mv cohort 1	sd cohort 1	mv cohort 0	sd cohort 0	*p*-value	effect size δ
relative number MM → MS (H1)	0.024	0.027	0.006	0.014	0.006	0.351
relative number PTOUT (H2)	0.213	0.166	0.411	0.262	0.006	0.349
relative number	0	0	0.042	0.051	<0.001	0.53

SSP → MISC (H3)						
relative number MISC → SSP (H4)	0.001	0.004	0.025	0.045	0.032	0.259
relative number RM → MISC (H5)	0.027	0.036	0.08	0.089	0.007	0.343
relative number RM → SSP (H6)	0.01	0.012	0.002	0.006	0.007	0.343

Interpretation of the results

An overview of the phase transitions in the solution process of both cohorts can be found in Figure 3: the thicker an edge, the higher the relative number of the respective phase transition. In particular, the significant differences shown by the statistical test are evident in this figure.

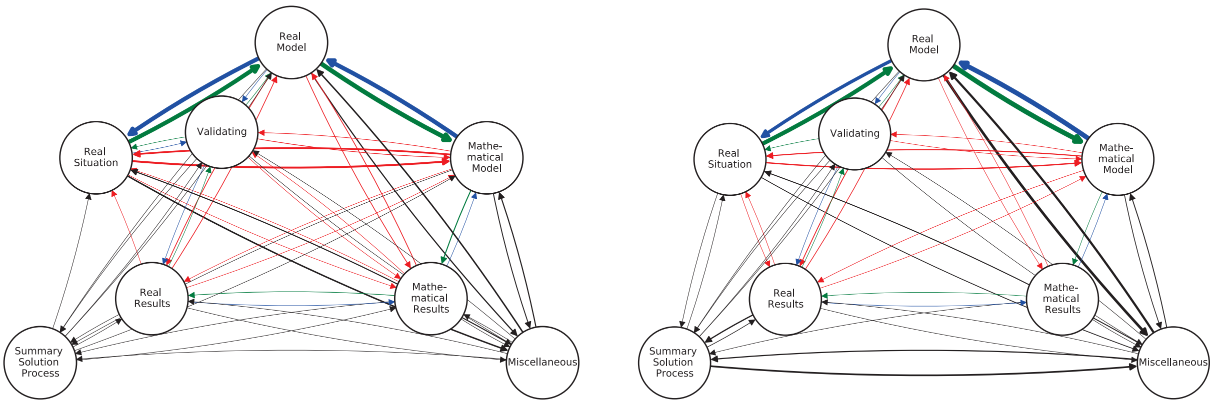

Figure 3: Overview of the phase transitions of the instructed (left) and the non-instructed (right)

The APT *mathematical model* to *mathematical solution* occurs often for the instructed in the solving process compared to the non-instructed students: when creating (and improving) the *mathematical model*, an attempt is made to translate reality into mathematics in the best possible way. From the instruction, students know that a *mathematical model* as well as its solution with mathematical concepts is relevant to solve the modelling task. In contrast, the non-instructed students have problems working mathematically: besides forming the *mathematical model*, there are also difficulties in applying mathematical concepts to solve the problem. Above all, solving the problem is a challenge for them, which is why the switch from *mathematical model* to *mathematical solution* rarely occurs.

Especially in the OUTPHASES the influence of the instruction becomes clear: the non-instructed students often switch between the OUTPHASES, which is reflected in the high relative number of PTOUT. Thus, they often stay outside the modelling cycle, i.e. also outside the processing of the modelling task. The instructed students proceed in the solution process more goal-oriented and follow the phases of the modelling cycle, which they learned in the instruction. Therefore, they deviate less often from the solution process when working on the modelling task. Since the non-instructed students lack knowledge about modelling processes, they move away from the problem (OUTPHASES) and/or summarize their previous solution. By switching between the two OUTPHASES, they again gather new ideas on how to proceed in the solution process. The frequent switches from *real model* to an OUTPHASE and vice versa show that the non-instructed students have problems forming the *mathematical model*. Either they switch to topics that have nothing to do with the processing of the task or they recapitulate their solution process. This can be related to the phase transition *mathematical model* to *mathematical solution*: the influence of an instruction mainly affects those phase transitions that are related to the *mathematical world*. Without knowledge about the formation of the *mathematical model*, individual modelling routes are less structured and often outside the ideal-typical modelling cycle.

Further research

We have shown that individual modelling routes of the instructed and non-instructed students differ with respect to the relative number of certain phase transitions. In the next step, we build on these results: using the MAI-Tool, we will examine individual modelling routes with respect to the sequence of phases. For this we will develop a concept to describe them more precisely on the basis of patterns.

Comparing pre-service teachers' errors in individual and group resolutions of modelling tasks involving estimations

Carlos Segura and Irene Ferrando

Universitat de València, Spain; carlos.segura@uv.es, irene.ferrando@uv.es

Real-context estimation problems are useful for introducing modelling in primary school classrooms, although teachers have difficulties associated with the modelling process and also with measurement and estimation senses that may hinder their implementation. Based on a specific categorization, this work analyses the errors of N= 224 pre-service teachers when they draw up individual resolution plans for a sequence of modelling tasks involving estimations, and when they subsequently solve the same sequence in groups and on-site. Individual and group resolutions are compared with two objectives: the first is to determine whether working at the problem site and in groups helps to reduce the number of errors; the second is to find out whether the types of errors that are made are different. This would help to efficiently use learning from errors to improve initial teacher training in solving modelling problems.

Keywords: Fermi problems, errors, measurement, estimation, pre-service primary teachers

Introduction

Real-context estimation problems, also known as Fermi problems, are modelling tasks accessible to primary school students (Ärlebäck, 2009). Hagena (2015) argues that measurement sense and estimation are necessary to successfully solve many modelling tasks. Different studies have found that prospective teachers have difficulties and make many errors when solving modelling problems (Wess et al., 2021; Moreno et al., 2021). Furthermore, deficiencies have been found in the estimation skills of prospective teachers (Castillo-Mateo et al., 2012), especially when they have to reason about estimation and measurement in complex situations (Baturo & Nason, 1996). A previous work (Segura & Ferrando, 2021) developed a specific error categorization for one type of Fermi problem: those that require estimating a large number of elements on a delimited surface. This paper analyses errors in the productions of N = 224 pre-service primary school teachers when they are confronted with a sequence of this type of Fermi problems, whose statement is contextualized around the Faculty of Education building. The experience consists in two phases: firstly, individually and in-classroom, they have to make a resolution plan for each problem, secondly, they have to solve the sequence again in groups (N = 62) and perform measurements and estimations at the problems' site.

A comparative analysis allows us to answer the following research questions: Q1. Does group and on-site work help to reduce the number of errors made by prospective teachers when solving Fermi problems? Q2. Do error types evolve from individual resolution plan to group resolution at the problem site?

Theoretical framework

Lesh and Harel (2003) define a *mathematical model* as a system consisting of mathematical concepts, symbolic representations of reality, relationships, regularities or patterns, as well as the procedures, mathematical or otherwise, associated with their use. The development of a mathematical model is made up of phases, and these phases form a cycle (Borromeo Ferri, 2018) that starts from a real and open situation that has to be *simplified* and *structured*. This process leads to the *real model*, a representation that prefigures the mathematical model. In order to build the *mathematical model*, the real model must be *mathematized*. The next phase requires *working mathematically* within the model to find a solution to the problem in mathematical terms. Finally, the mathematical result must be *interpreted/validated* in the real situation.

Estimation tasks can be used as a means of initiation into mathematical modelling (Borromeo-Ferri, 2018). A specific case of estimation tasks are Fermi problems: these problems present a situation where little concrete information is known, forcing students to make assumptions and estimates to obtain a solution to the initial question (Ärlebäck, 2009, p. 331). In this study we will use a subset of Fermi problems, those that consist of estimating a large number of elements in a delimited surface. Ferrando et al. (2020) categorised the productions of prospective teachers when solving these problems into four types of resolution (counting, linearization, base unit and density). Productions that did not reflect a clear process for arriving at the estimate were classified as *incomplete*.

Studying errors made by pre-service teachers can be useful to understand with what competence and how they solve modelling tasks. Wess et al. (2021) provide a comprehensive categorization that provides an overview of the difficulties at each stage of the modelling cycle. Moreno et al. (2021) established a categorisation of errors (simplification error, mathematization error, resolution error, interpretation error) that has been one of the bases of the categorisation we have developed for Fermi problems. The other basis for establishing a specific error categorisation for Fermi problems consisting of estimating a large number of elements on a surface is the work of Castillo-Moreno et al. (2012). Their research analyses errors of measurement and estimation of length and area, which helps them to establish a categorisation of these errors, both conceptual (errors in perception or meaning of the magnitude; errors in the internalisation of the referents) and procedural (errors in the conversion of units of measurement or incorrect calculations). Basic understanding of quantity management poses difficulties that hinder reasoning about estimation and measurement in complex situations (Baturo and Nason, 1996).

Experimental design

The starting point of this work is a sequence of four problems. The four problems are contextualised in rectangular enclosures located in areas close to the Faculty of Education:

P1-People. How many students can stand on the faculty porch when it rains?

P2-Tiles. How many tiles are there between the education faculty building and the gym?

P3-Grass. How many blades of grass are there in this space?

P4-Cars. How many cars can fit in the faculty parking?

The sample is formed by N = 224 prospective teachers. The experience includes two parts: in-class individual work, on-site group work.

In-class individual work

We provided each prospective teacher the written statements of the four problems of the sequence and a little image for each problem. They worked individually for 90 minutes on solving the sequence. The following aspects were emphasized: in each problem they should raise a possible solution plan indicating the measures they would need to obtain the estimation; the work should be done individually; they should explain their procedures in written form and may use drawings or diagrams; and, finally, they were not expected to obtain a numerical estimate but rather to explain how to get the requested estimate. We have called this schematic solution a *resolution plan*.

On-site group work

Pre-service teachers were again confronted with the same sequence of four estimation tasks one week later, but they were randomly grouped into N = 62 groups of between 3 and 5 people, and they were taken to the real spaces in the Faculty of Education's environment where the problems are located. They were also provided with measuring instruments to take data and carry out the necessary calculations to obtain a numerical estimate. The session lasted 90 minutes.

Errors categorization

The following categorisation of errors (Table 1), specific to the Fermi problems which require estimating a large number of elements in a delimited surface, is based on a previous analysis of the resolution plans of prospective teachers (Segura & Ferrando, 2021) and on the background review. It is organized following the phases of the modelling cycle and also considers essential processes of estimation and measurement sense.

Table 1. Error categories and associated error types for modelling problems involving area and length estimates

➢ *Simplification error:*
E1. Incomplete real model associated with the lack of consideration of elements of the real situation.
E2. Incorrect real model due to error of perception of the magnitude.
E3. Incorrect real model due to inadequate internalisation of referents of the magnitude to be estimated.
E4. Does not build a real model.
➢ *Mathematization error:*
E5. Mathematical model incoherent with the real model due to an error in the meaning of the terms of the magnitude.
E6. Mathematical model incoherent with the real model due to inadequate internalisation of units of measurement of the S.I. of the magnitude to be estimated.
E7. Mathematical model incoherent with the real model due to the use of unsuitable units of measurement.
E8. Mathematical model is not constructed or is incomplete because elements of the real model are not quantified.
➢ *Mathematical working error:*
E9. Use of incorrect calculation procedures or calculation errors.
E10. Error in conversion of measurement units.

E11. Incomplete resolution procedure.
➢ *Interpretation error:*
E12. Absence of measurement units in the results.
E13. The estimate is clearly incompatible with the real situation.

Results and discussion

The analysis of the N = 224 resolution plans and the N = 62 group resolutions combines descriptive and qualitative analysis of categories and types of errors. Using the categorisation presented in Table 1, Table 2 show the overall results of the analysis of the N = 224 individual resolution plans and the N = 62 group resolutions.

Table 2. Frequency comparison of each type of error in individual resolution plans and group resolutions

Error type/ Category	Frequency in the N = 224 individual resolution plans	Frequency in the N = 62 group resolutions
E1	27 (5,86%)	5 (4,17%)
E2	100 (21,69%)	7 (5,83%)
E3	4 (0,87%)	5 (4,17%)
E4	41 (8,89%)	0
Simplification error	**172 (37,31%)**	**17 (14,17%)**
E5	66 (14,32%)	7 (5,83%)
E6	7 (1,52%)	25 (20,83%)
E7	24 (5,21%)	5 (4,17%)
E8	87 (18,87%)	3 (2,50%)
Mathematization error	**184 (39,91%)**	**40 (33,33%)**
E9	44 (9,54%)	7 (5,83%)
E10	1 (0,22%)	13 (10,83%)
E11	49 (10,63%)	1 (0,83%)
Mathematical working error	**94 (20,39%)**	**21 (17,49%)**
E12	2 (0,43%)	3 (2,50%)
E13	9 (1,95%)	39 (32,50%)
Interpretation error	**11 (2,39%)**	**41 (35%)**
Total	*461*	*120*

Among the 224 prospective teachers who participated in the in-class individual experience, 166 made at least one error, representing 74.11% of the total. The results show that pre-service teachers made a large number of errors (461) in their individual resolution plans, giving an average of 2.05 errors per solver. In particular, 166 pre-service teachers who made errors had an average of 2.78 errors per solver. On the other hand, when these prospective teachers were confronted with the same problems in groups and on-site, they made a total of 120 errors, an average of 1.9 errors per group. 51 of the 62 groups made errors, or 82.26% of the total. The 51 groups that made an error had, therefore, an average of 2.35 errors per group. Thus, a higher proportion of groups made errors when they had to find a numerical estimate for each problem, but they made fewer errors than when, individually, each group member had to come up with a resolution scheme.

It is observed that the proportion of errors for each category and for each associated error type is different for individual resolution plans and for group resolutions. In the individual in-class experience 37.31% of the errors belong to the category of *simplification error*, when the real model has to be constructed from the simplification and structuring of the real situation. Specifically, error *E2. Incorrect real model due to error of perception of the magnitude* is the most frequent (21.69%). Qualitative analysis of the individual resolution plans shows that most of these errors are due to confusing length and area. It appears especially in problem P2-Tiles, where the surface area between the gymnasium and the Faculty of Education is confused with the distance between the two. It also appears in P1-People or P3-Grass; in which the width of a person or width of a blade of grass is confused with the surface area they occupy. However, simplification errors are drastically reduced in the on-site group resolutions, accounting for only 14.17%, the category with the lowest error frequency. It is relevant that there is no group resolution that has not developed a real model (E4, leading to incomplete productions) while in the individual resolution plans the number was high (41).

Regarding the category *mathematization error*, number of errors is very high both in the individual in-class experience (39.91% of the total number of errors) and in the group and on-site experience (33.33%). However, the nature and severity of these errors are very different. The most frequent errors in the individual resolution plans (E5 and E8) are the least frequent in the group resolutions. Indeed, *E5. Mathematical model incoherent with the real model due to an error in the meaning of the terms of the magnitude* is a type of error related to the inappropriate use of different quantities in a procedure, mixing them without respecting dimensional homogeneity. A qualitative analysis shows that many errors of this type appear in individual resolution plans which, in order to obtain the number of elements, divide the magnitude measurements of different dimensions. For example, in P1- People, dividing the total area of the porch by the width of a person. We also find other examples of E5, such as the confusion of the concept of area and the concept of perimeter. On the other hand, *E8. Mathematical model is not constructed or is incomplete because elements of the real model are not quantified* relates to resolutions that do not develop the mathematical model sufficiently to know which strategy would give the estimate. There are numerous examples of this error in the individual resolution plans: for example, in P4- Cars it is mentioned that "the car is measured" and that "the parking is measured" but it is not stated precisely what magnitude is plan to be measured are, nor is it written with what mathematical procedures the number of cars would be estimated from these "measurements". There is a lack of definition of relevant variables for the resolution of the problem and the dependencies between these variables, which indicates difficulties in understanding the mathematical concepts involved in the real model of the situation. Errors E8 and E5, numerous in individual resolution plans (18.87% and 14.32%, respectively) are the most serious in this category. They denote important conceptual shortcomings, especially E8 is often linked to resolutions categorised as incomplete. In contrast, in on-site and group resolutions, the most frequent type of *mathematization error* (20.83% of the total number of errors) is *E6. Mathematical model incoherent with the real model due to inadequate internalisation of units of measurement of the S.I. of the magnitude to be estimated*. This type of error is caused by assigning a value to an estimation reference in conventional units of measurement that does not correspond to reality. We find many examples in group resolutions: for example, in P2-Tiles, those who consider that one foot is equivalent to one metre. Another example: in P3-Grass, a solver estimates that the dimensions of a blade of grass are 1 metre wide and 3 metres long. It is clear from these examples that the conventional measures for the length of a foot or the area of a blade of grass are not well internalised by the solver. These are errors that denote shortcomings in the measurement sense, but do not hinder the development of a mathematical model to obtain an estimate. In group resolutions only 2.50% presented incomplete mathematical models (E8).

Regarding the category *mathematical working error*, number of errors is similar for individual resolution plans (20.39%) and group resolutions (17.49%). However, the associated error types also change drastically. In the individual resolution plans the most numerous are E9 and E11. For *E9. Use of incorrect calculation procedures or calculation errors*, a qualitative analysis shows that, in individual resolution plans, this error is due to the use of the inverse algorithm (Ivars and Fernandez, 2016), that is, make a multiplication in a situation with a measure division structure. For example, the procedure $surface\ area \div element\ area = number\ of\ elements$ is inverted to $surface\ area \cdot element\ area = number\ of\ elements$. Errors of type *E11. Incomplete resolution procedure* are due to the fact that, in many individual resolution plans, the solver has not explicitly written that, in order to find the number of elements of a surface using the area of the surface and the area occupied by the element, he/she must divide these data. Solvers do not write down the process because, perhaps, it is taken for granted. In contrast, in the on-site group experience the most numerous error in this category is E10, which only appears once in the individual plans. E9 and E11 hardly appear at all. Thus, in group resolutions, numerous errors of type *E10. Error in conversion of measurement units* are made, especially when converting units of area (for example, from cm^2 to m^2 by multiplying by 100).

Finally, the most important change is observed in the *interpretation error* category: from representing only 2.35% of the total errors in individual resolution plans, it becomes the most frequent in group resolutions (35% of the total). This is not because working in a group and on-site makes it difficult to interpret and validate the results, but because the schematic nature of the resolution plan, which did not require a numerical estimate, meant that there was no solution to interpret, as most plans only point out how they would get there. In group resolutions, the most frequent error is *E13. The estimate is clearly incompatible with the real situation*, representing 32.50% of the total errors. In fact, it is the most frequent error made in all phases of group resolutions. A qualitative analysis shows that most of these errors occur because the numerical nature of the result is incompatible with reality. For example, a decimal number is given as an estimate of the number of cars that fit in a car park, or people that fit on the porch. This error is because the solvers have not checked the mathematical result and have presented it as a solution without first interpreting it in the real situation.

Conclusions

The discussion of the results above allows us to answer the two research questions:

Q1: *Does group and on-site work help to reduce the number of errors made by prospective teachers when solving Fermi problems?*

Working in groups and on-site does not reduce the proportion of participants who make errors, but increases slightly. This may be because the group resolution is more comprehensive than the individual resolution plan, as it requires measurements and numerical estimations. A larger number of processes may allow more errors to be made. However, working in groups and on-site does slightly reduce the number of errors made and, above all, their seriousness. Errors that prevent the development of a real model (simplification errors, especially E4) and those that prevent the development of a mathematical model (especially E8) are drastically reduced. This explains, from the point of view of errors, a previous work (Segura et al., 2021) which shows that, for this same sample, the percentage of incomplete productions drops from 15.6% in the individual experience to 2% in the group productions. Working in groups and on-site, therefore, is a scaffolding tool that, although it does not reduce the number of errors committed, it does drastically reduce their relevance. Errors made in groups do not impede the development of a model and the achievement of a reasoned estimate, even if it may be wrong.

Q2: *Do error types evolve from individual resolution plan to group resolution at the problem site?*

The nature of the errors indeed differs from individual resolution plans to group and on-site resolutions. The evolution at each stage of the modelling process is as follows: in group resolutions there is a sharp reduction of error rates of the simplification phase compared to individual resolution plans. Working in the place of the problem improves the perception of space and, therefore, of the magnitudes involved in the real model and which will be quantified in the mathematical model. This allows for a low number of incomplete or incoherent real models, when in the resolution plans this number was high.

In the mathematization phase overall proportion of errors does not change much, but their nature does. The types of errors associated with this phase in individual resolution plans were mostly serious conceptual errors that often impede the development of a mathematical model and result in incomplete productions. However, in group resolutions most errors in this phase denote a lack of skills in the measurement sense, but do not prevent the development of a mathematical model to reach an estimate. Again, working in groups and on-site helps in the modelling process, although the detailed measurement work brings out errors in the sense of measurement and estimation.

The proportion of errors in the mathematical working phase is similar in the individual in-class experience and in the on-site group experience. But the types of error are different in each experience. In the individual resolution plans there is a majority presence of errors of a structural type in the estimation calculation procedures (use of the wrong algorithm, or lack of calculations). However, in the group resolutions, most of the errors in this phase are due to failures in the conversion between units of measurement, which implies a poor understanding of the concept. This difference is due to the schematic character of the individual resolution plan: it is not required to execute the numerical operations, only to explain them, which may lead to errors in the choice of algorithms that would not be made if actually executed, but avoids making numerical errors (such as in conversion).

The change in the proportion of errors of the interpretation phase is drastic: these errors increase considerably in group resolutions. The explanation is obvious: the schematic nature of the individual resolution plan makes it unnecessary to interpret the result, as it only explains how to get an estimate, and very few solvers provide a numerical estimate. However, in the group resolution they have to reach a numerical estimate, and many groups do not reflect on the nature of the result obtained: they use decimal numbers to express the number of cars or people, or give clearly implausible estimates (e.g. estimating that there are 30 blades of grass in a garden).

Turkish and Spanish Prospective Mathematics Teachers' Solutions to a Fermi-Based Modeling Problem

Serife Sevinc[1] and Irene Ferrando Palomares[2]

[1]Middle East Technical University, Faculty of Education, Turkey; sserife@metu.edu.tr

[2]University of Valencia, Facultat de Magisteri, Spain; irene.ferrando@uv.es

This study presents a part of a larger project investigating Turkish and Spanish prospective mathematics teachers' ways of modeling in Fermi-Based Modeling Problems. In this particular study, we focused on 10 Turkish and 10 Spanish prospective teachers' models to solve Toilet Paper Rolls Problem. We collected their written responses to the Fermi-based modeling problems. The data analysis process involved series of coding and categorizing the characteristics of the solutions. We presented the models of prospective teachers from two countries separately and articulated the commonalities and divergences in their ways of approaching a Fermi-based modeling problem. Although most models indicated a numerical approach, we observed that some models were pedagogically more powerful than others.

Keywords: Fermi-based modeling problems, Prospective mathematics teachers, real context.

Introduction

In this study, we focused on open-ended and ill-defined Fermi-based modeling problems. Fermi-problems involve situations that people may face in their daily lives and engage in making strategic estimations to identify quantities (Ärlebäck, 2009). Therefore, researchers found Fermi problems useful to integrate into a modeling perspective and investigated students' ways of thinking from the modeling perspective (e.g., Albarracín et al., 2019; Albarracín & Gorgorió, 2014, 2019; Gallart et al., 2017). Considering Fermi problems as a base for modeling is a very recent approach, and much needs to be known. For instance, there is still little known about the pre-service or in-service teachers' modeling process in Fermi-Problems (e.g., Ferrando et al., 2021). To address this gap, we designed a project to investigate prospective mathematics teachers' ways of modeling in Fermi-Based Modeling Problems that incorporated a global real context, Covid Pandemic. We used such context because it was experienced somehow similarly all over the world. Researchers investigating the models in Fermi problems argued that the familiarity of the context played a role in problem-solvers' models (e.g., Ferrando et al., 2021). We therefore conjectured that the context of the problem would not intervene the models that was produced by the prospective teachers in both countries and so we could attend prospective teachers' ways of mathematical thinking that were provoked by but not depend on the Covid Pandemic context. In the larger project, we aimed to articulate the commonalities and divergences in Turkish and Spanish prospective teachers' ways of approaching Fermi-based modeling problems. This study, however, presents our initial exploration of Turkish and Spanish prospective teachers' approaches to one Fermi-based modeling problem through an in-depth content analysis of their work. Through this exploration, we expect to see a range of solution approaches that the prospective teachers might develop in a Fermi-based modeling problem situation.

Theoretical Framework

There are various modeling perspectives addressing different epistemological assumptions (Kaiser & Sriraman, 2006). Still, they share a common understanding that modeling involves a transition between the real-world and mathematical world, and this transition embraces a series of modeling cycles (Sevinc & Brady, 2019). Hence, the modeling process involves a series of express-test-revise cycles where the problem-solvers express the real-life situation mathematically, develop and test mathematical solutions, and revise the solutions until they satisfy the real-life problem (Lesh & Doerr, 2003). Since the nature of Fermi problems are “directly related to the daily environment” and therefore “offer more pedagogical possibilities” (Sriraman & Lesh, 2006, p.248), they have been considered as effective situations to initiate a modeling process.

Some examples of Fermi problems ask for the time needed to get into the top of the Empire State Building using the stairs (Ärlebäck, 2009), estimate the number of elements in a specified area (see Albarracín & Gorgorió, 2014 or Ferrando et al., 2021). As seen, these problems are realistic, open-ended, and do not often involve a numerical value and therefore ill-defined. Due to these characteristics of the Fermi problems, researchers considered that they had the potential to initiate and develop a model in response to the given problematic situation. Models refer to

> (a) a conceptual system for describing or explaining the relevant mathematical objects, relations, actions, patterns, and regularities that are attributed to the problem-solving situation; and (b) accompanying procedures for generating useful constructions, manipulations, or predictions for achieving clearly recognized goals. (Lesh & Harel, 2003, p. 159)

According to this definition, models present one’s ways of thinking about a situation. However, those ways of thinking needed to be useful for a particular situation and therefore required a goal-directed conceptual reorganization.

In this study, we focused on a Fermi-based modeling problem that was given a realistic context and not bounded by cultural issues (see Figure 1). In other words, our Fermi-based modeling problem addressed a global situation that people experienced all over the world. Modeling this realistic problem required one’s analysis of the situation, making relevant and realistic assumptions, producing a solution that will be useful in that situation. Although the problem did not explicitly state, the ill-defined nature of the problem requires problem-solvers to produce a general model (e.g., a formula or a list of steps and/or procedures) that will be applicable in similar situations. In this respect, we expect prospective teachers to engage in a series of conceptual reorganizations and produce a model that is shareable and re-usable, one of the identifying characteristics of a model (Lesh & Doerr, 2006).

Methods

This study presents a small portion of a larger project involving a set of Fermi-based modeling problems and 30 Turkish and 34 Spanish prospective mathematics teachers as participants. The participants in both countries were senior college students. Particularly, Turkish prospective teachers were in their last semester of a four year-long teacher education program. They have been trained to teach mathematics in middle schools (i.e., grade 5-8). Similarly, Spanish participants were in the second term of the compulsory professional master's degree for secondary school mathematics teachers. Since we are still at the initial phase of data analysis, here, we focused only on 10 Turkish and 10 Spanish prospective teachers' solutions that were randomly selected from the entire data set.

We collected prospective teachers' written responses to the problems and, in this study, analyzed their responses to one of the Fermi-based modeling problems called the Toilet Paper Rolls Problem (see Figure 1).

Toilet Paper Rolls

It has recently been one year since the declaration of the global pandemic by COVID19. In the first months after the start of the pandemic, most governments decided to place citizens in strict home confinement for a couple of weeks. In most of our homes, products were stockpiled to avoid unnecessary trips to the supermarket, and one of the most stockpiled products in our homes (all over the world) was toilet paper rolls.

Based on the picture, how many rolls of toilet paper do you think can be accumulated in this wardrobe?

Figure 1: The Toilet Paper Rolls Problem

The data analysis process involved series of reading the responses, coding the characteristics of the solutions, and categorizing the solutions and characteristics. Data-driven coding process characterizes our data analysis process: we did not start with a code list but constructed the one as codes emerge from the data. Two authors also met to articulate and refine our interpretations of teachers' models.

Findings

In this section, we present Turkish and Spanish prospective mathematics teachers' models separately and, in the following section, discuss the commonalities and divergences in their way of approaching a Fermi-based modeling problem. As we communicate about their ways of solutions, we use T# (e.g., T1, T2, …) for Turkish participants and S# (e.g., S1, S2, …) for Spanish participants.

Turkish Prospective Mathematics Teachers' Models

The participants first identified what information was needed to solve the Toilet Paper Rolls Problem. Depending on the approach they took, they either identified the needed information with literal symbols or numerical values, which were not provided in the problem. For instance, T4 made a list (Figure 2a) with estimated numerical values. Not only T4 but five other prospective teachers listed them and assigned estimated values to conjecture a solution for the problem. Prospective teachers who approached the problem algebraically also listed the same items (Figure 2b), but they listed their labels with literal symbols instead of the numerical values.

Numerical Approach	Algebraic Approach
Width of the cabinet: 32 cm Depth of the cabinet: 30 cm Height of the cabinet: 40 cm } Only for one shelf of the cabinet Height of the toilet paper roll: 12 cm Radius of the toilet paper roll: 5 cm	*To formulate a general formula, I label the height of the cabinet (a), width of the base of the cabinet (b), length of the base (c), diameter of the toilet paper roll (R), and height of the toilet paper roll (h).*

Figure 2a and 2b: The list of information made by T4 (left) and T1 (right) to solve the problem

We observed that five of the ten prospective teachers preferred estimating numerical values and those estimations were mostly blind guessing. Only one of them stated that she relied on the picture provided in the problem and showed her marking on the given picture. There was one prospective teacher who showed both an algebraic solution and a numerical solution and one who provided a description of a solution but did not produce an algebraic expression or a numerical value.

Those seven of the ten prospective teachers considered a regular arrangement of toilet paper rolls. The regular arrangement that they described was involving four steps: finding the number of rolls that would fit along with (i) the length, (ii) the width, and (iii) the height of one shelf the cabinet, and (iv) multiplying that result by 2 to find the total number of rolls that would fit into two shelves of the cabinet. Not only the prospective teachers who approached numerically but also the ones who approached algebraically considered this regular arrangement. Figure 3 below presents both cases.

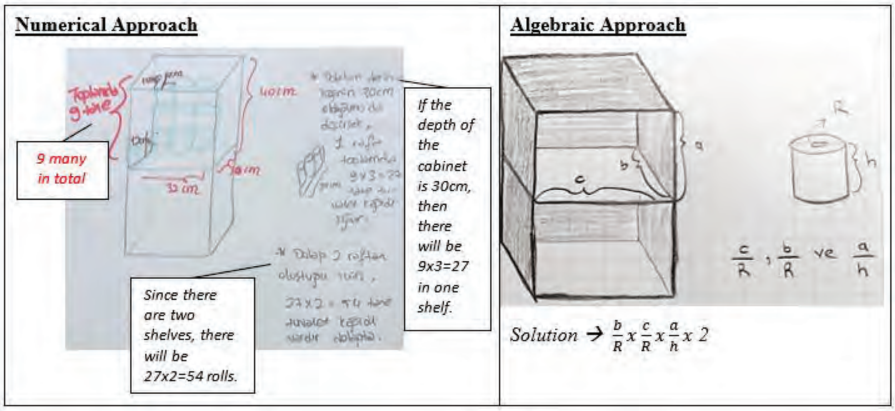

Figure 3a and 3b: Numerical and algebraic solutions based on a regular arrangement

Another algebraic solution was produced by T9 without referring to the arrangement of the rolls. Her solution involved a ratio of the volume of the cabinet to the volume of the toilet paper rolls.

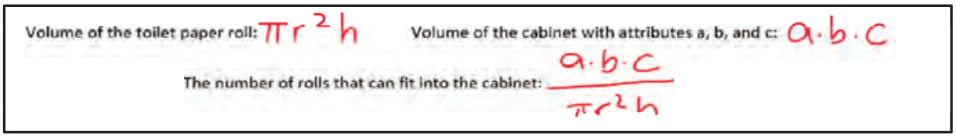

Figure 4: Algebraic solutions without a particular arrangement consideration

Although the prospective teachers expressed that the problem was different from stereotypical textbook problems, these solutions indicated they followed a procedural prescription of their curricular knowledge. There was only one prospective teacher, T6, who considered realistic and contextual assumptions and a variety of (regular and irregular) arrangements. In this sense, his model was more detailed than other prospective teachers' models (see Figure 5).

T6 stated that, for the arrangement in Solution 2, he was inspired by his mother's arrangement of cans in a cellar, and this solution resulted in one more row to put toilet paper rolls. For Solution 3, he stated that he needed to consider a realistic need – the need for storing as many rolls as possible during the pandemic lockdown period – and therefore, he would not care about the shapes of the rolls in such a case. So, he decided to distort the shapes of some rolls to fit more into the cabinet.

Spanish Prospective Mathematics Teachers' Models

Similar to Turkish prospective teachers, we observed that in all the productions the variables necessary to address the problem were identified and, in most cases, these were initially presented literally (except in the case of S7, which, as shown in Figure 6a, directly gives values to the variables). For example, S2 states: "To solve this problem, I would need to know the dimensions (width, height, and depth) of each of the two shelves of the cabinet. In addition, I would also need to know the diameter and height of each paper roll", while S6, as shown in Figure 6b, with the help of a graphical representation, indicated the quantities he needed to know.

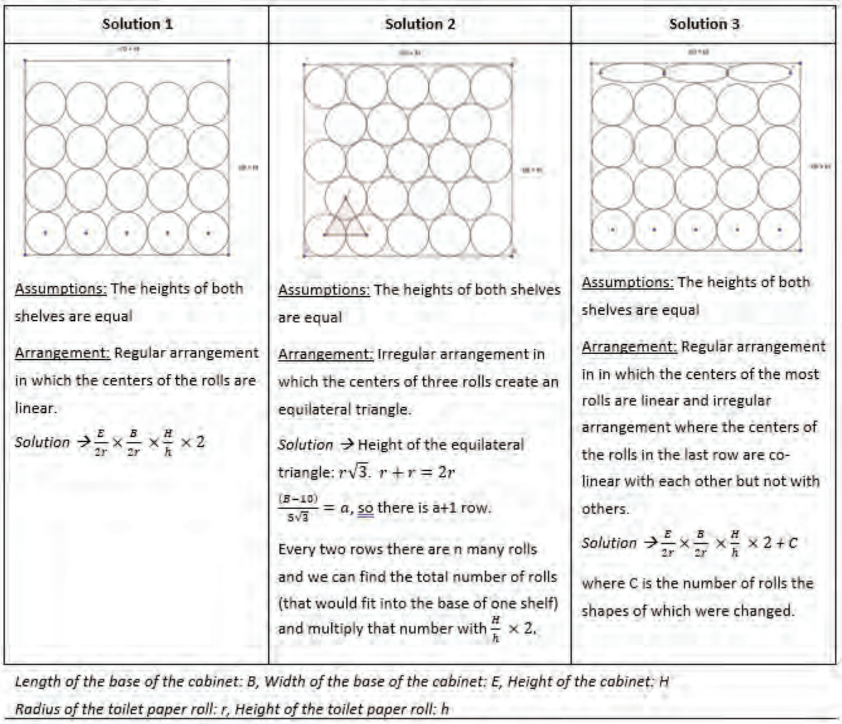

Figure 5: Three algebraic solutions with various arrangement considerations

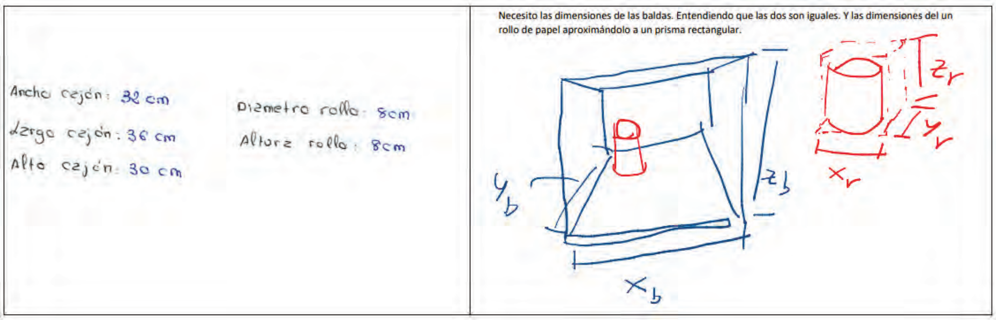

Figure 6a and 6b: The list of information made by S7 (left) and S6 (right) to solve the problem

Most of the productions did not include indications on how to obtain values of the variables; as we will see later on, these productions presented, in almost all cases, algebraic resolutions. However, some participants introduced estimated values to the magnitudes involved, sometimes in an unjustified way (such as S7 in Figure 6a). In other cases, relying on the image accompanying the statement, S3 noted that "From what can be seen in the image, the maximum height per shelf seems to be four rolls. We can make an estimate of the maximum depth, also assuming that there are four rolls. Finally, we can also get the length of the wardrobe, which seems to be three rolls".

The statement of the problem suggests that the rolls are organized in the cabinet, and this is how it has been interpreted in practically all the resolutions that propose one or more models for the arrangement of the rolls.

Only S4 avoided indicating a specific arrangement of the rolls; however, he explained the following: “I first thought that we could reason directly from the volumes of the paper roll and the cabinet, but I discard this option because we would not have enough information to know how many could be correctly arranged.” As we have already seen in the analysis of Turkish prospective teachers’ productions, in some cases, they proposed more than one possible arrangement, both in the way the rolls were placed and in the way they were oriented on the shelf (see Figure 7).

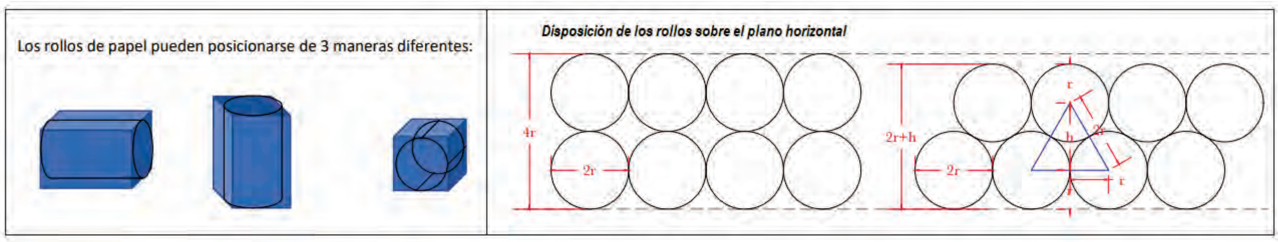

Figure 7a and 7b: Different orientation of rolls on the plane (S1) and different arrangements (S5)

Once the variables were fixed (and, in some cases, their values estimated) and the arrangement(s) defined, there were two possible procedures to arrive at the solution. Starting from the estimated number of rolls that would fit in rows, columns, and shelves, a final estimate could be obtained. One of the prospective teachers defined this as “finding the volume by taking the rolls as the unit of measurement.” Another less direct way of arriving at the solution was to reason from the dimensions of the elements (the rolls and the cabinet) according to a fixed arrangement.

Finally, the proposed solutions were categorized according to the language used, following the same criteria as in the analysis of the previously described Turkish productions. However, in the case of Spain, there was no production that presented the solution both in numerical and algebraic language. In relation to the introduction of elements of reality in the resolutions, we have identified two prospective teachers who considered particular characteristics of toilet rolls in their resolutions: both S4 and S9 commented that it was necessary to determine whether or not the roll could be deformed.

Conclusion

As we presented in the previous section, the prospective teachers approached the Toilet Paper Rolls Problem in different ways, but they all did make sense of the problem situation. Below, we summarized the characteristics of Turkish and Spanish prospective mathematics teachers’ models in the Toilet Paper Rolls Problem. As our analysis of the Fermi-based modeling problem indicated, there were similarities in prospective teachers’ ways of thinking (see, for instance, Table 1).

Actually, a considerable number of Turkish and Spanish participants approached the problem numerically. We interpreted that those who operated with estimated numerical values did not feel comfortable with indeterminacy in the problem and transform the problem into a one that is manageable. Although those prospective teachers estimated numerical values to conjecture a solution, their solution process involved systematic steps of finding the number of rolls on each attribute and multiplying them.

Table 1: Characteristics of prospective mathematics teachers' models

</table>

In this sense, the models relying on the numerical approach – and the algebraic ones – indicated ways of reasoning that were useful in the situation and are re-usable in similar situations, aligned with Lesh and Doerr's remark of model's being sharable and re-usable (2006). In addition, we observed a few prospective teachers considered realistic and contextual assumptions that influenced their solutions (e.g., T6 considering the different arrangements and S1 considering the different orientation of rolls), consistent with the research found that students tended not to consider realistic assumptions while solving real-life problems (Verschaffel, de Corte & Lasure, 1994; Verschaffel et al., 2000). However, even though they were a few, we found these models more sophisticated than others because their assumptions and approaches resulted in more than one solution. We believe that such models are pedagogically more powerful to develop solid mathematical reasoning for both teachers and students because they allow problem-solvers to think different aspects of the situation, which resulted in a different solution. In our presentation, we will further address these pedagogical implications. Our analysis involved only written responses and therefore hindered us to observe prospective teachers' modeling process. Although it is not in the scope of this particular study, in the data analysis of the larger project, we seek for the ways of which final models might signal possible shifts in problem-solvers' mind.

Written engagement with modelling task situations as a strategy to enhance the comprehension process

Anna Surel

University of Münster, Germany; anna.surel@uni-muenster.de

Keywords: Modelling task, situation model, comprehension process.

Motivation

When it comes to mathematical modelling tasks, students often have difficulties when working on them (Blum & Leiss, 2007). A high proportion of the occurring errors are errors in the comprehension process (Wijaya et al., 2014). These errors lead to further errors in subsequent modelling steps and to incorrect solutions. Although understanding the context of a modelling task and forming a suitable situation model is so important, it is often not focused on in mathematics lessons (Prediger & Krägeloh, 2015). In order to help students to solve modelling tasks correctly, it would be advisable to focus on the comprehension process. One way to integrate this into regular mathematics lessons could be to guide students to engage with the situation of a modelling task. In more detail one option could be to have students retell the given task situation in writing before solving the task.

Theoretical framework

According to the modelling cycle by Blum and Leiss (2007), the first step in solving a modelling task is to understand the task text and the situation described in it. In this step, a mental model of the given situation, the so-called situation model, is formed. A situation model is a mental representation of the given situation that is built in the mind while understanding a task and is influenced by variables of process-, person- and task-related characteristics (Leiss et al., 2019). Since the context of modelling tasks is not interchangeable, modelling tasks cannot be solved without considering the context (Leiss et al., 2010). The comprehension of the task and the associated formation of a suitable situation model is crucial for the further processing of the task. Nevertheless, when working on modelling tasks in mathematics lessons, the focus quickly shifts to mathematizing or to directly working mathematically (Prediger & Krägeloh, 2015). This makes it difficult for students to form a suitable situation model.

To counteract this, it would be advisable to focus more intensively on the given situation when working on modelling tasks. One possibility would be to encourage students to do this by retelling the given task situation in detail. In order for all students to have the opportunity to engage with the task situation individually by retelling it, this could be done in writing. The argument in favor of a written engagement is that the thinking process is slowed down during the writing process, which allows students to deal with the situation more intensively (Kuntze & Prediger, 2005). Therefore, this strategy could help students to form a suitable situation model. However, text production requires certain writing skills, what might bring new hurdles that need to be overcome (Bossé & Faulconer, 2008). It is therefore unclear to what extend an engagement with the task situation of a modelling task in the form of written retelling is beneficial for the processing of a modelling task.

Research questions and method

With the theoretical background, the following research questions arise:

1) To what extend does an engagement with the situation of a modelling task influence the success of solving a modelling task?
2) How does the processing of a modelling task differ when students retell the task situation in writing before solving the task?

To investigate the research questions, a quantitative study is planned. Seventh graders are given two modelling tasks to solve. The first task is to be solved by each student without further instructions. For the second task, the students receive further instructions in which they are asked to retell the given task situation in writing. Afterwards, they are asked to solve the task as well. The order of the tasks will be permuted over all students.

The students' written solution paths are then analyzed. For the evaluation of the results, first the number of correct solutions will be compared for the processing with and without applying the presented strategy. Subsequently, some details, such as the number and type of errors made, can be focused on in more detail. For example, it could be analyzed whether certain errors are made less frequently when retelling the task situation before solving the task instead of directly solving the task. These analyses should help to determine whether written retelling of the task situation as a strategy to engage with the task situation is beneficial for solving a modelling task. Data collection will begin in the spring of 2022.

Designing computer-based modeling activities in mathematics

Muna Touma[1] and Shai Olsher[2]

[1]University of Haifa, Faculty of Education, Israel; munatouma89@gmail.com

[2]University of Haifa, Faculty of Education, Israel; olshers@edu.haifa.ac.il

In the present study, we asked: what are the design principles of computer-based modeling activities in mathematics? Using a design-based research approach, we formulated our essential components for computer-based modeling activities according to the literature. Next, based on enactment of the activities, we redesigned it and formulated five design principles. We describe a four-phases study demonstrating the "Head-to-head dice competition" activity.

Keywords: Task design, mathematical modeling, technology, simulation.

Theoretical background

A main challenge in learning mathematics is the students' difficulty in making connections between reality and mathematics, and in realizing that math is important and useful for understanding and solving reality-related problems. For this reason, one of the goals of the mathematics curriculum worldwide is to provide opportunities for developing an understanding of mathematical models, structures, and simulations applicable to many disciplines (NCTM, 1989), which should infuse students' mathematical interest with meaning.

This paper conceptualizes a model as a system of elements and the relations between them, which can be used to describe, explain, or predict the behavior of some other familiar system (Doerr & English, 2003). This definition is consistent with Shternberg and Yerushalmy's (2003) definition of a didactic model as "a collection of objects that are familiar to the learner, and operations defined on them which support the construction of an understanding of more formal reasoning about mathematical concepts and about their essential properties". The model serves as an accessory to thinking and a testbed for alternate assumptions, considering that the predictions of the model depend on the accuracy of its input data (Wilensky & Rand, 2015). Schwartz (2013) claimed that mathematics education is about teaching people how to build and use effective models of phenomena, therefore, education should also focus on formulating the relations between the elements of the models, which are referred to as measures.

Modeling problems are authentic, complex, and reality-related situations, in which students connect their extra-mathematical knowledge (or knowledge of the context) with the mathematical ideas to which they have access (Ferri, 2018). To deal with these reality-related problems, many researchers agree that students need to go through a modeling cycle which starts with simplifying and understanding the situation of a given problem and ends with interpreting the mathematical results in the real world as real results. This process includes getting through constructing a real model of the situation, transforming the real model into a mathematical model by working mathematically, getting mathematical results, and validating it (Ferri, 2018; Greefrath, 2011).

Schwartz (2013) stressed that the formulation of measures is an important first step in the act of modeling, and that in order to have a model students must be able to predict the values of a measure they are interested in. Modeling problems often involves two steps: selecting an already formulated model that describes the phenomena given in the question, then selecting the “correct” relation between the relevant aspects of the situation and evaluating it quantitatively (Schwartz, 2013).

In recent years, technology has been a great assistance for teachers and learners alike, by offering dynamic forms of mathematical representation such as models and simulations, which facilitate access to previously unfathomable concepts (Chance et al., 2007) and assist in building students’ understanding, facilitating their thinking about the domain by promoting a visualization approach to learning (Konold & Lehrer, 2008). Indeed, some researchers claim that technology can play a pivotal role in supporting and promoting mathematical modeling (Greefrath, 2011), especially that it illustrates the relationships between the different components of the given model, enabling students to investigate different contexts and to submit more than one correct solution for various input data (Wilensky & Rand, 2015). Greefrath (2011) claims that technology can be utilized at several steps in the modelling cycle such as for investigating, experimenting, visualizing, simulating, and calculating (see Figure 1). In the present study, we are interested in exploring design principles of computer-based modeling activities in mathematics that includes models and simulations.

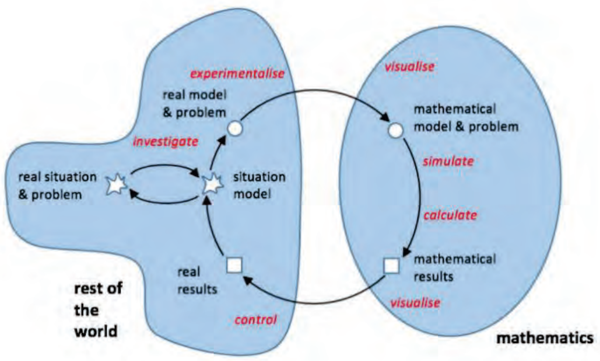

Figure 1: Modelling cycle with added influence of digital tools (Greefrath, 2011)

Methodology

The present study is part of a larger research project on the design principles of modeling activities in a digital environment, in which we ask which design principles of computer-based modeling activities support students’ modeling processes. The project is carried out in Israel. In the present study, we asked: what are the design principles of computer-based modeling activities in mathematics that includes models and simulations? We focused on principles related to activity structure, given tools, and teacher role.

Research settings

The design of new educational materials is a crucial part of design-based research in education, and it is interwoven with the development and testing of theory through iterative cycles (Bakker, 2018). To explore the design principles of computer-based modeling activities, we conducted design-based research, focusing on the “Head-to-head dice competition” activity. The research was conducted in four phases. In the first phase, we explored the design principles of modeling activities in the literature, and formulated our essential components for modeling activities. According to the design principles we articulated in the first phase, we designed new modeling activities. One of the designed activities, “Head-to-head dice competition”, is demonstrated in the research tools section. In the second phase, we presented, implemented, and consulted about the designed activities with a team of mathematics education research and development professionals, and two teacher educators and mathematics teachers. During the second phase, we further clarified and consolidated the design principles. In the third phase, we implemented the activity in mathematics lessons. As a result of this phase, 5 design principles were formulated. In the fourth phase, we examined and redesigned the activities according to the outcomes of the third phase. In this way, we integrated the design and the enactment insights derived from the research into the activities.

Population

To clarify and consolidate the design principles, in the second phase, we presented the designed activities and consulted with three groups: (a) our research team, which included graduate students, post-doctoral fellows, content developers, and researchers; (b) two teacher educators with expertise in accelerated mathematics teaching; and (c) 30 secondary mathematics teachers who participated in a professional development program and were furnished with pedagogical tools for using modeling activities in their mathematics lessons. For the third phase, we used a population of accelerated 9th grade students who were taught by two teachers in two schools, and who participated in a preparatory session to familiarize themselves with the digital environment. Both classes performed the Head-to-head dice competition activity.

Research tools

We used questionnaires, class observations, lessons’ recording, and modeling activity designed in a digital environment. The Head-to-head dice competition activity includes six tasks, and it deals with probability. This activity focuses on the students' strategies for assigning numbers to two fair six-sided dice, an orange and a yellow one, to create situations of equal and different probabilities of winning the game for each die. This activity deals with head-to-head competition in which two players play against each other. After asking students to write randomly the numbers 1 to 12 on the sides of the dice (Figure 2a), the first player selects randomly a die. Next, the players roll their own die. The player who gets the higher number wins a point. The winner of the game is the player with the most points. The activity includes a simulation that enables students to model how many times to roll the dice, and presents a histogram showing the relative frequency with which each number appeared, and the total points for each die (Figure 2b). In addition, tasks 2-6 include two-dimensional matrix model in which the first yellow row represents the six sides of the yellow die and the left orange column represents the six sides of the orange die (Figure 2c). When writing numbers on the sides of the dice, the squares in the matrix are colored according to the winner of the outcome of the roll. For example if the orange die shows 1 and the yellow die shows 5 then the square will be colored yellow - which means that the player with the yellow die is the one who wins in this case. This model allows students to look at the probabilities through an interactive area model.

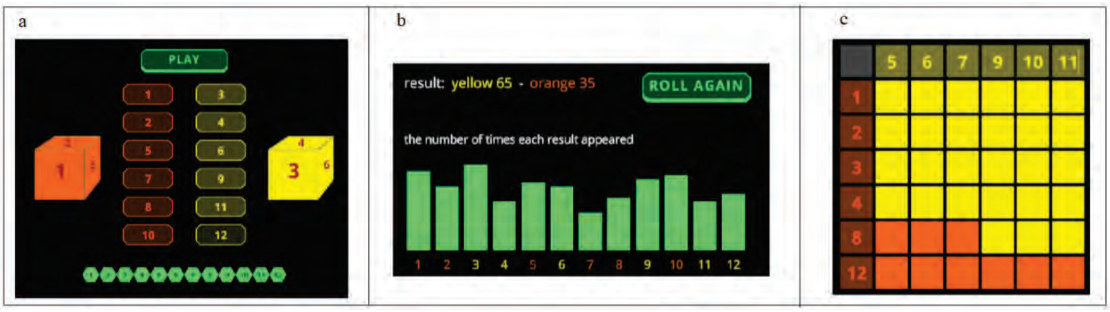

Figure 2: Head-to-head dice competition activity (a) writing numbers on the dice model (b) histogram of the frequency (c) the two-dimensional matrix model

This activity is considered a modeling activity as it deals with playing a simple game, a head-to-head competition, which helps students to understand the difference between probability and statistics by presenting probability quantitatively through the two-dimensional matrix model, while the statistics are inferred after simulating rolling the dice and interpreting the data obtained from the simulation.

Data sources

Data for this report consist of students' responses (from questionnaires, submissions and observation), comments by our research team, reviews of the two teacher educators and the mathematics teachers, and field notes of the first author taken during the various phases. Because of the COVID-19 epidemic, learning and meetings were conducted virtually. The lessons were recorded: the screen was video-recorded and the students' voices were audio-recorded. In the course of the meetings, all of the participants worked on the activities as students, asked questions, and discussed the various aspects of each activity with the designers. The authors took notes and documented the suggestions.

In the third phase, we implemented the activity in mathematics lessons: each class was asked to solve the dice activity during a mathematics lesson. Students worked individually and submissions were collected automatically by the digital environment. The students' notes and conversations were audio-recorded and correlated with the collected data. During the class observation of the virtual classes, we focused on the students' comments as they were interacting with the modeling activities, and later followed up their interaction with the teacher in the class discussion.

Data analysis

To answer our research question, in the first phase, we explored the design principles of modeling activities reported in the literature (Ferri, 2018; Schwartz, 2013; Greefrath, 2011). To design our computer-based modeling activities, we began by formulating our own design principles. We defined our designed activities as literacy activities that describe authentic and complex situations related to reality, which require students to understand the context, collect data, make assumptions, and evaluate their answers. Similar to Schwartz's (2013) approach, our activities involved formulating measures using the given data of the phenomenon we want to describe, arranging the data and describing how it is related. According to the design principles we articulated in the first phase, we designed new modeling activities. In the second phase, we gathered notes and comments of professionals, and then we coded and categorized it according to its relation to the activity structure, the tools for students and teachers, and the teacher role while students interact with the activity. In the third phase, we gathered the questions that students asked while they were working on the activity, their comments during the class discussion, and their responses to a questionnaire concerning the activity. We summarized all these data, coded it and categorized it according to how common is each phenomenon. Then we analyzed submissions to elicit evidence for common phenomena. In the fourth phase, we classified the design principles of modeling activities according to the categories we formulated in the second phase, after incorporating the insights derived from the third phase.

Results

The present study focuses on the design principles of computer-based modeling activities. In this section, we describe the four design phases. For each phase, we explain and demonstrate the design principles that were developed.

First phase: First attempts at formulating design principles

After exploring the design principles of modeling activities reported in the literature (Ferri, 2018; Schwartz, 2013; Greefrath, 2011), we formulated our essential components for our modeling activities. Unlike some other approaches (e.g., Ferri, 2018), our modeling activities already included models that represent the given situations, which enabled students to work mathematically to transform the real model into a mathematical one, then interpret the results in the real world based on the mathematical results they obtained.

The main components of our modeling activities were: (a) Simulation: each task of the designed modeling activities includes a simulation and digital tools that allow interaction with the various components of the model, offloading the student's mathematical work to these tools; (b) Example eliciting: the designed modeling activities consist of example-eliciting tasks, asking students to submit more than one correct solution for various input data. Example eliciting is a vital element in the modeling process, especially given that examples generated by students reflect their understanding of particular mathematical concepts, their difficulties, and possible inadequacies in their perceptions; (c) Modularity: the modeling activities were designed in a modular way, so that the first tasks serve to create familiarity with the context of the activity, whereas the advanced tasks require a deeper level of thinking and aim to stimulate students to generalize and consider the wider aspects of their solutions.

According to the design principles we articulated in the first phase, we designed a new modeling activity: “Head-to-head dice competition” activity.

Second phase: Clarifying and consolidating the design principles using professional advice

In the second phase, we further examined and clarified the design principles with a group of professionals. Their experience with the activity resulted in four main suggestions, described below in the context in which they emerged.

1. Introductory task. During the professional development meetings, teachers expressed a need for an introductory task that helps students familiarize themselves with the context and the various tools of

the simulation. Specifically, for the Head-to-head competition activity, teachers suggested adding a task after the first task to facilitate the transition between the given models (the dice and the table):

> I feel that there is a missing task that asks for a 50-50 probability using the table, which will help students understand the transition from task 1 to task 2. The task will help students using the example they suggested of a 50-50 probability, to change some of the numbers so they get a greater probability for the orange die to win (Orna, a teacher, 4th meeting at the professional development program, summer 2020)

2. 5-10-minute videos. Two types of videos were suggested; a technical one that guides students in using the model and the simulation in each activity, as suggested by one of the teachers: “You should add a short video that explains how to use the tools and the simulation, and the teacher should be present in case there are any questions” (Tami, a teacher educator, 2nd meeting, 2020). In addition, another video was suggested that summarizes classroom performance of the activity and the class discussion: “I would be happy to hear from other teachers who performed the activities in class, what are the main points of the discussion they conducted and what are their recommendations to other teachers” (Marta, a teacher, 5th meeting at the professional development program, summer 2021)

3. Teacher’s guide. Many teachers agreed with the teacher that suggested to have a written guide for each activity intended for teachers: “As a teacher, to make it easier and more convenient for me, I would like to have a written guide for each task for whom it is suitable, for which classes, and what its mathematical topic is” (Toni, a teacher educator, summer 2021)

4. Flexibility of design. Enabling teachers to edit the activity (add or to remove tasks or change other attributes) to adjust it to their classroom. As one teacher pointed out, teachers can use this feature for various aims, e.g., to adapt activities to a particular lesson or to change the formulation of the tasks: “Due to system constraints, I do not have enough time to complete all tasks. I prefer to have the ability to select some of the tasks from the activity” (Sara, a teacher, 5th meeting at the professional development program, summer 2021)

Third phase: Enactment of the activity

In the third phase, we implemented the activity in mathematics lessons and examined the students’ interaction with the modeling activity and with the teacher in the class discussion. We report the results of the students’ work in four parts, according to the various components of the modeling process that appear in each activity: 1. Simplifying and understanding the situation of the problem. Because of the difficulty in understanding the given problem, as observed in the class and reported by the students, we found that it was necessary for the teacher to solve and discuss the first introductory task together with the students, and to use short videos that explain how to use the technological model. One student reported: “I could not always understand the situation on my own. I needed the explanation of the teacher, to introduce the activity and then I could work on the other tasks on my own” (Hana, a 9th grade student); 2. Transforming the real model into a mathematical model by working mathematically. The students’ submissions and self-reports indicated that they managed the transformation from visual representation (two-dimensional matrix) to the mathematical model in the dice activity. However, there is a need to conduct a discussion after each task during which students raise mathematical ideas and compare the various solutions; 3. Obtaining mathematical results that are interpreted in the real world as real results. During the class observation, students succeeded in interpreting the mathematical results as real results. Most students submitted correct answers for the fourth task (Figure 2c), in which they were asked to assign numbers to the sides of the dice in such a way that the orange die has precisely a 1/4 chance of winning. Figure 2c shows an answer that includes 9 orange squares (¼×36=9), as required in the task; 4. Validating the results. 83% of students reported that they used the simulation to evaluate their simulation results, and that it saved them many long calculations. The class discussion following the activity validated their answers.

Fourth phase: Evaluation and redesign

Based on the results of the consultation phase and the enactment of the activity, we redesigned it according to the following principles: (1) Principles related to the activity structure: (a) In addition to the modularity of the tasks, each activity will include an introductory task aimed at assisting students in becoming familiar with the technological environment and the various tools of the simulation. The task is intended to be mediated by a teacher. (b) The teachers will be able to edit the activity (to add, to remove, and to edit tasks) according to their needs. (2) Principles related to the given tools for students and for teachers: (a) Short videos will be prepared for teachers and students on each activity. (b) A written guide for teachers that will include teachers' comments and reviews of the activity. (3) Principle related to the teacher role: The transition between the tasks will include a discussion with the students to illustrate the aim of each task. This will be noted in the written guide for teachers.

Note that all principles mentioned above will be applied also to the new activities that will be developed as part of the larger research project.

Discussion

In this paper, we described research leading to design principles of mathematical modeling activities, giving examples based on "Head-to-head dice competition" activity. As researchers stress, the modeling process starts with simplifying and understanding the situation of a given problem (Ferri, 2018; Greefrath, 2011). In the present study, the results indicate that many students had difficulty in understanding the dice problem, which means they needed help in starting the modeling process. This points out to the important role of the teacher in introducing the activity, mediating the first task and discussing students' answers after each task. Furthermore, we found that technology played an important role as students were solving the tasks: the simulation assisted in checking the results of the students' assumptions and in simplifying difficult procedures. The technology illustrated the relationships between the different components of the given model, enabling students to investigate different contexts and to submit more than one correct solution for various input data (Wilensky & Rand, 2015). Our findings confirm the claim of some researchers that technology can play a pivotal role in supporting and promoting mathematical modeling (Greefrath, 2011).

The process of consolidating design principles of modeling activities attests to the value and the need for communication tools (e.g., short videos and a written guide), both during the development process (Bakker, 2018), to connect between developers and teachers, and during the use of the activities by the teachers. This conclusion will be taken into account in the consolidating process of the design principles in the continued research.

Acknowledgments

We wish to thank the late Prof. Judah L. Schwartz for his ideas, insight, and support of the Thinking Models Project, and gratefully acknowledge funding by the Trump Family Foundation, grant 355.

Developing mathematical modelling skills for mathematics teachers through 3D modelling and 3D printing (3DMP)

Description of Research Topic

Mathematical modelling (MM) skills are considered highly valuable for Science, Technology, Arts, Engineering, and Mathematics (STEAM)-based education. MM is also part of geometry as is used for example in 3D modelling and 3D printing (3DMP). This overlapping can contain new forms of training teachers in an emerging technology, their MM skills, and providing them with tools to teach MM based exercises. MM aims at connecting real world problems with mathematics as means to solve these problems with a feedback improvement loop (Blum & Leiss, 2005). A mathematisation and de-mathematisation process has to be performed as a link from the mathematical model to the real-world solution and after the modelling step, a validation step is performed to investigate whether adaptation is necessary (Jankvist & Niss, 2020). This process has similarities to 3DMP where real world problems are also tackled by mathematising the problem, modelling it, de-matematising it by the following 3D print, and validating the result by iteratively checking whether improving the model is necessary. For example, to receive 8 cookies from a given dough size, a 3DMP cookie cutter could be created where the solution can be tested after printing. This suggests that at least for some areas such as geometry, 3DMP can be used as an instance of a MM process. Approaches to use 3D printing can improve MM skills as research indicates in the training of 50 mathematics teachers in 3D printing that reported perceived improvement of their MM skills as was also visible from their 3D prints (Asempapa & Love, 2021). This trains modelling skills, by transforming real-world information into mathematical concepts and skills, referring to the model of Blum and Leiss (2005), are highly needed for teachers to instruct their students in mathematics education. As both MM and adopting new technologies can be challenging for teachers, ways to improve technological problem-solving skills and exercises teachers can use should gain more attention (Drijvers et al. 2013). In this poster, formatted by A0 size and containing links to GeoGebra resources, we will present data driven elements for a pedagogical framework of a 3DMP course that aims at supporting Austrian pre-service-mathematics-teachers (PSMT). Our question is: what are attributes of a course framework that trains 3DMP and MM skills? We want to find hints for insight into needed ingredients that help them master this technology and provide MM exercises the PSMT's can use in their later lessons.

Steps Towards a Course Framework and Preliminary Results of the first attempt

The basis of our first course attempt was experiences of 3DMP workshops in 10 schools in Montenegro which were conducted in a design-based research manner introducing the technology and possible exercises. A task for the teachers was to create a cookie cutter with specific constraints such as size- and thickness limitations of the 3D printed version. A theoretical part contained examples of applications of the technology in mathematics lessons and personalized aids for students, theory about 3D models and modelling as well as the theory about the 3D printing process. A practical part aimed at getting familiar modelling first models, printing and revising them after adaptations to the model iteratively. After a year, we interviewed 37 of them to learn about their view and usage of the technology. During the analysis of the transcripts we found that these teachers reported that the course and working with 3D modelling in particular improved, amongst others, their MM skills. So, the concept of first course modules was based on the structure and experiences of these workshops.

We created three 3DMP modules focusing on 3D modelling for 60 Austrian PSMTs with a content structure similar to the workshops in Montenegro that accompanied a geometry course for second level education. The PSMTs had to create their own projects documented in GeoGebra books. The projects should explain a problem and the models to solve it had to fulfil the constraints of a certain printing time. They had to report their ideas, give feedback to each other's projects and the models had to be revised accordingly. This led to new and improved 3D models similar to the process described by Blum and Leiss (2005). We read through the documentation and found hints that the 3D modelling part was especially useful to train the mathematization step. We took these learnings to design a course structure concept to support 3DMP and MM skill improvement.

Discussion and Presentation: A Course Framework Concept for Teachers

The poster contains a description of the setup of the course, a description of the evaluation of the first course and a framework for upcoming courses. Based on this first course, we will develop a course dedicated only to 3DMP and check the PSMTs MM skills during the course. In the course, 3DMP and MM will be introduced. We give the participants a geometrical modelling task by letting them create mathematical 3D mazes in GeoGebra, then will conduct the course and give them a task requiring similar skills that can also be solved in GeoGebra. This task has to be solved in individual projects. A questionnaire and looking at the documentation in the GeoGebra books about their experiences and possible changes will provides more insight if and which aspects of the course changed their skills in mathematical modelling in geometry. This will help to identify aspects of how a 3DMP course should be shaped that also helps improve MM skills. We hope to create a new possibility of raising the sensitivity of future mathematics teachers for MM by connecting it to 3DMP.

The role of models and modelling in the pandemics' evolution: transposing an 'study and research path' to secondary school

Susana Vasquez[1], Berta Barquero[1] and Marianna Bosch[1]

This paper discusses the design of a teacher education proposal aiming to provide tools to secondary school teachers to deal with the teaching of modelling in interdisciplinarity contexts. We start by briefly presenting the case of a study and research path for teacher education (SRP-TE) about disseminating the fundamental role of models and modelling when interacting in the modelling process of the pandemics. We then focus more specifically on the last modules of the SRP-TE, when some of the interdisciplinary research projects are adapted and transposed to secondary school. We present an experience during the academic years 2020/21 with an open teaching project to inquire into the impact of the COVID-19 led by a team of teachers from different disciplines intervene. We analyze the conditions that facilitate the development of this project and the limitations that hinder its progress as a richer modelling activity.

Keywords: Modelling, interdisciplinarity, study and research paths, secondary school, pandemics.

Introduction

Research in mathematics education has recognised the importance of including applications and mathematical modelling in mathematics teaching and learning (Blum, 2015). Pollak (1969, p. 401) introduces the importance of problem posing stating that "the student has as much right to participate in the derivation for the mathematical model and in checking the degree of its validity as he has to repeat any experiment to satisfy himself of its validity". In this sense, including mathematical modelling applications involve finding genuine problems for students to pose good questions to study.

Besides all the progress made in research and the support of educational policies and curriculum reforms, implementing a well-established activity on modelling must confront big constraints for its long-term and large-scale dissemination. In this respect, we have several examples of major issues in our society that require a collective scientific effort working across the boundaries of the scientific disciplines, where mathematics and mathematical modelling can be seen and act as service subjects.

The COVID-19 pandemic has shown more than ever that students and, more in general, citizens need to understand how mathematical and scientific advances contribute to understanding societal phenomena. In addition, "the pandemic illustrates how the operation of science changes when questions of urgency, stakes, values and uncertainty collide (Saltelli et al., 2020). People feel the need to understand what mathematical models can provide, how we may interpret the predictions and, more generally, how they help understand complex systems such as the pandemics' evolution.

There is no doubt about the critical constraints that hinder the long-term "survival" of modelling activities in interdisciplinarity contexts in schools. They can be interpreted as a consequence of important didactic phenomena that exist in school institutions, such as the isolation of disciplines and the prevalence of monodisciplinary curricula (Michelsen, 2006, p. 269), the dominant way to organise the teaching and learning of school disciplines (based on the logic of concepts rather than the logic of problems), and the inexistence of epistemological and didactic tools to approach modelling in the interaction among disciplines.

When discussing interdisciplinary education, it is clearly related to the importance of STEM education (Maass et al., 2019) in three different approaches: twenty-first-century skills, mathematical modelling, and education for responsible citizenship. English (2016, p. 362) makes the role of modelling in STEM education clear “modelling is a powerful vehicle for bringing features of 21st century problems into the mathematics classroom”.

Within the framework of the anthropological theory of the didactic (ATD), a change of school paradigm (Chevallard, 2015) is proposed to overcome some of the main didactic phenomena linked to the “monumentalisation” of the taught knowledge. This change has been described in terms of a paradigm shift, from the paradigm of visiting works to the paradigm of questioning the world. Chevallard characterises the transformation in mathematics education not only at the pedagogical level (“how to teach?”) but also includes the changes the paradigm shift may have on the didactic level, dealing with the question about “what and how to teach?” In the paradigm of questioning the world, the knowledge to be taught is associated with the inquiry of relevant questions. Approaching these questions includes moments of study (searching for available answers in the media) and moments of inquiry (deconstruction and reconstruction of knowledge to generate one’s answer). Implementing question-led study processes helps the knowledge to be taught to become dynamic, provisional, and collective (compared to the traditional notion of knowledge in school institutions). In the ATD, the so-called *study and research paths* have been introduced to facilitate the inclusion of mathematical modelling in educational systems and, more importantly, to explicitly situate mathematical modelling problems at the centre of teaching and learning practices (see Bosch, 2018). More recently, our research team have been working with the proposal of *study and research paths for teacher education* (SRP-TE) (Barquero et al., 2018), an inquiry-based process combining practical and theoretical questioning of outside and inside school scientific activities.

Given the fundamental role of models and modelling in the understanding and social dissemination of the pandemics, we present our experience with the design of an SRP-TE about decoding the evolution of the pandemics. Its design and implementation, developed in the framework of the European project IDENTITIES, wanted to work with teachers to question the necessary tools for the analysis and design of interdisciplinary projects in secondary school. We then focus on the last modules of the SRP-TE when some of the interdisciplinary research projects are adapted and transposed into secondary school. We focus on the experience during the academic years 2020/21 with an open teaching project inquiring into the impact of the evolution of the COVID-19 where a team of teachers from different disciplines intervened. In this paper, we continue the study to answer the research questions: *What are the conditions facilitating the development of this project and the limitations hindering its progress towards a more prosperous interdisciplinary modelling activity?*

First contact with the experience with an SRP-TE about the COVID-19 evolution

In the context of the IDENTITIES project (https://identitiesproject.eu), it has been proposed the design of an instructional proposal for preservice secondary school teachers based on an adaptation of the structure of the SRP-TE (Barquero et al., 2018). One of the four proposals has focused on the role of models and modelling to understand the COVID-19 evolution. It was developed in a local implementation in the University of Barcelona and in an international Summer School, where the first two authors were involved, as a participant and as an educator, respectively. The adaptation of the general structure of the SRP-TE consisted of four modules. Participants had to assume different roles to facilitate questioning together (teachers and educators) the way to describe, analyse and design possible modelling activities that could be transposed to secondary schools to address live societal questions that emerged during the scientific approach of the pandemics.

In *module 1*, participants might act as "explorers" to analyse a set of news and research dissemination papers that the researchers-designers had selected to see the evolution of the problems addressed by the scientific community and analyse the role assigned to the disciplines, in particular, to mathematics. From this first analysis, participants with educators delimited some possible lines of inquiry that involved models and modelling and the interaction among different disciplines. The topic addressed in each line were: (1) The complexity of delimiting the system to model: analysing data, (2) The role of the equation-based models: what can we consider a 'good' model? what are models for?; and (3) Agent-based models and simulations: Simulating scenarios to help make decisions about societal restrictions. *Module 2* asked participants to experience an SRP, previously designed by the researcher-educators, about the lines mentioned above of inquiry. Participants had to assume the role of "student". The main goal of this module is to make participants carry out an unfamiliar activity that could, to a certain extent, exist in an ordinary secondary school classroom. *Module 3* refers to the collective analysis of the SRP that they come to be experienced as students, but now adopting a role of "analyst". Some specific tools were here introduced to help teachers carry out the analysis of the activity carried out. For instance, one of the provided tools takes the form of a questions-answers map (Winsløw et al., 2013) which help to make explicit the kind of disciplinary and interdisciplinary questions and answers that emerged in their experience with the SRP. In *module 4,* teachers in training worked in the design of an adaptation of the experienced SRP. And, in case they had the chance, they implemented them in real secondary school classrooms. The work developed with one of the participants (researcher in didactics and the paper's first author) is the case study we focus on in the following sections.

Design of an SRP about modelling the COVID-19 evolution for secondary school

Institutional context and conditions for the implementation

The SRP about modelling the COVID-19 evolution has been implemented twice, in April-June 2020, with the beginning of the pandemic, and in February-March 2021. Due to the exceptional conditions of the first implementation, this paper focuses on the second implementation as its design was improved and the conditions for implementation were more stable (at least, than during the confinement). The implementation was carried out at Col·legi Natzaret, in Esplugues de Llobregat, a town near Barcelona (Spain), with 60 students of grade 10 (15-17 years old) distributed in two parallel groups. It was developed as an interdisciplinary project involving the subjects of mathematics, biology, and oral and written expression. Students were organised in working teams of six members, with heterogeneity in relation to their academic performance. The SRP run over 17 sessions of 1 hour during the official hours of mathematics, biology and plurilingual expression. It ran under relatively regular conditions, although the limitations due to the pandemics: the parallel groups could not interact, and each teacher was assigned to only one of the groups. Four teachers participated in the implementation: two mathematics teachers (one being the paper's first author), a biology teacher, and an English teacher (both teachers of optional subjects, who each had half of the students). In collaboration with her research team, the first author developed the *a priori* design of the SRP. The rest of the teachers had no direct involvement in the design. Still, they got actively engaged in deciding how to present the project to students and in the *in vivo* analysis during its implementation. Some special sessions were organised with all the teachers to agree on how to introduce the project, the timing, the way to distribute the students and the strategy to manage the SRP. Then, during the implementation, the teachers shared a journal where they daily reported their work with the class and the teaching materials (their presentations, students' reports, evaluation criteria, among other aspects).

Students worked collaboratively with online and digital tools. The teachers used a shared google presentation to report the progress of each working team. In addition, after each session, the working teams worked with the same template to document the advances of their inquiry. They had to report on the questions they had addressed, the temporary answers found, the tasks developed individually and in groups, and the new questions to follow with. Besides these shared documents, students had access to a presentation with some common instructions, indicating what was expected from their work and the steps to follow. From the start, the students were informed that they were responsible for defining the questions to address and the hypothesis they had about the pandemic evolution. They had to update their question-answer map regularly and, in the end, prepare an informative video presenting the results from their research to be distributed to the school community. The SRP teachers evaluated the students' presentations, with some invited teachers from other subjects.

The openness of the generating question of the SRP and its devolution

One crucial difference with other previous implemented SRP is that this one did not start from the same common generating question. On the contrary, students were asked to confront a more general extra-mathematical problem of particular social relevance with an excess of news related to the pandemic. As the older students in the compulsory secondary school level, they were asked to run an awareness campaign for the school about the pandemic and its impact on society. They were responsible for providing contrasted and scientifically founded information and defining what they wanted to address.

In the beginning, the working teams were told to approach their research from three complementary points of view: from the available data (accessible through the Spanish government website) and the mathematical models they could use (*Which data may be selected to understand the evolution of the pandemic? How can mathematics and mathematical models help us to understand the pandemics evolution?*); from the biological knowledge of the disease (*How is the virus behaving?*); and from the societal impact of the pandemic (*What impact and effects are the pandemics having on our society?*). The working teams were asked to delimit their focus by always keeping in mind these three complementary general questions. Students started by gathering the concerns of the educational community, starting with their own and surveying their classmates and families. This helped them define the questions they wanted to address and plan the first steps of their particular SRP. At the end of these first steps, each team had to present the general topic and identify three interrelated "researchable" questions concerning the mathematical, biological and societal aspects. Some examples of the researchable questions they posed are: *How long does the COVID-19 survive on a surface? What are the characteristics of the virus that make it so deadly? What age groups are the ones more affected? What are the physical sequelae of the disease?* About the societal questions, examples of the ones proposed by the students were: *How has the pandemic affected tourism in Barcelona? How has confinement affected people's daily lives? What restrictions were implemented in Madrid during the three waves in comparison to Barcelona?* Concerning the mathematics questions, those with a descriptive nature were more frequent: *Which autonomic communities in Spain have been more affected? How can we measure if the first wave was worse than the rest? Are there important differences between the evolution of the case numbers (infected, death, recovered) among the two consecutive years?* Moreover, there were also some groups that included questions about the evolution of the data: *How has COVID evolved in Catalonia? How has it evolved in the different counties?* As it can be read in the project presentation (available at https://bit.ly/3tRQpPz), the whole implementation followed three main phases. The first phase with the (a) generation of researchable questions, (b) exploration of databases, and (c) presentation of specific questions and hypotheses to address. A second one is where they focus more on (a) looking for and organising the most relevant data for their inquiry, and (b) analysing data and proposing models to fit data and/or predict the evolution of the pandemics. A third and last step, where students had to work on the informative video. In the following section, we focus on the students' work in the first two phases, paying special attention to the researchable questions with a mathematics intervention.

Results of the experienced SRP about the COVID-19 evolution

During the sessions guided by the mathematics teachers, the different working groups addressed their researchable questions. To facilitate their work, the mathematics teachers were asked to follow a structured report. On the one hand, each working team had to make explicit the main questions they wanted to address, their hypothesis or preliminary answers, and the data they worked with. On the other hand, they had to fill out their *map of questions and answers* to describe the particular study and research trajectory they were following. This device, which was used during the whole implementation, took a crucial role for several reasons. First, it allowed students to have a common instrument for all the sessions and make explicit the evolution of the inquiry. Second, it facilitated that the teachers from the different disciplines could follow the work of the working teams. Moreover, students used this organisation to address the questions of each discipline with the corresponding teachers. Additionally, at the end of the implementation, the assessment of these maps considers the completeness and classification of all the elements, the relevance of the questions, their creativity and accuracy.

Five sessions were devoted to the first phase of the project. During these sessions, students were provided with a database from the Spanish ministry that regularly updated the data about the evolution of the pandemic since its beginning. Students found different spreadsheets with accumulated data on cases, deaths, ICU admissions. These worksheets also included information by sex, age groups, provinces, and communities. This large amount of data created important limitations. On the one hand, they had to be very careful in defining what they were interested in looking at, that is, to delimit and construct the *system*, as well as the particular questions they wanted to address. That is why the teachers were especially attentive to help them on delimiting the system by selecting the variables to consider, formulating the initial hypothesis to contrast, etc. On the other hand, they needed to learn some techniques to work with Excel to manipulate big spreadsheets easily. They had some experience with Excel but as beginners' users. Then, the mathematics teachers had to dedicate some common sessions to respond to these necessities. For instance, students were asked how to sort a list of data by value, how to filter by defining some criteria (e.g., provinces or age groups), among other utilities.

In the particular case of *Team A*, they were first interested in this initial question: "$Q_{\text{0-Team A:}}$ *Which has been the "worst" wave of the pandemics in Spain? Has the second wave been worse than the first one* (as said in the media)*?*". In these first steps, they started to define what they wanted to address (length, number of infections, hospitalise and death, in global and by different groupings):

$Q_{\text{1\_dates}}$: How long did each wave take?

$Q_{1.1}$: When do we start counting the beginning of a wave and its ending?

$Q_{\text{2\_infections}}$: How many infections have there been in each wave?

$Q_{2.1}$: How many deaths by sex were there? In total? By sex? By age group?

$Q_{2.2}$: Which was the age group more infected?

$Q_{2.2.1}$: How many are infected between 0-9 years old? Between 10-19? Between 20-29?...

$Q_{\text{3\_hospitalizations}}$: How many people were hospitalised during the first wave?

$Q_{3.1}$: How many deaths by sex were there? In total? By sex? By age group?

$Q_{\text{4\_deathss:}}$ What is the number of deaths in each wave?

$Q_{4.1:}$ How many deaths by sex were there? In total? By sex? By age group?

$Q_{4.1.1:}$ What can explain that men seem more likely to die?

$Q_{4.1.2:}$ Do we have the same tendency of deaths growth by each group age?

These questions mainly correspond to delimiting the system and representing the data numerically and graphically. The same happened with the rest of the groups, who mostly worked on the graphical representation of the data (once selected and manipulated). For groups who pose some questions about the pandemic evolution, the most common was the graphical representation of data concerning time. For instance, we present the questions made by *Team B*:

$Q_{\text{0-Team B}}$: Which wave has affected Madrid the most?

Q_1: Which wave shows the highest speed in the increase in the number of cases? And less?

$Q_{1.1}$: What is the date with the most cases registered? $Q_{1.2}$: How long has each wave lasted? $Q_{1.3}$: Why are there fewer registered cases on the weekends? $Q_{1.4}$: How do restrictions affect the registration of cases?

$Q_{2:}$ Which wave has the highest number of cases, regardless of its duration?

$Q_{3:}$ Which wave presents the highest number of cases, considering its duration?

This team wanted to analyse the variation in the number of cases. They defined and calculated the *speed* of the number of cases using variation taxes. However, none of them started to propose equation-based models to fit the data and forecast what can happen in the future. All the groups posed questions to describe the data or compare them by age or place, but none of them tried to go further.

In the last session, the teams made presentations to their peers. They discussed questions and suggestions. Interesting ideas emerged: which is the correct way of comparing the data from two or more provinces? From this discussion, they concluded that it was necessary to introduce *relative variables*, dividing the cases by the population, to compare them with accuracy.

Conclusions and discussion for future implementations

In this paper. we want to focus on the ecology of the SRP. More concretely, about what conditions and limitations the SRP reveals. About the conditions that facilitate the implementation of the SRP, we can detect three different aspects: (1) the *a priori* design of the SRP, (2) the SRP's management tools, and (3) the questions and answers maps.

When preparing the design of the SRP, the choice of the initial question is essential, but so can be the development of the path that will lead to the potential mathematical activity. For this, teachers must develop the pathway in advance: mastering, at a professional level, the activity of mathematical modelling, so that they can identify the student's processes and know-how to redirect them without forcing them or giving them the feeling that they are being deprived of the ability to decide the process of the research. But also, to identify when students open different lines of inquiry and distinguish whether these will lead to a rich mathematical activity. About the SRP management tools, we note the shared teacher diary as a tool that helped teachers keep an overview of the process, even when they did not share it with all the students. On the other hand, the scoring system for student contributions, where teachers had a daily record of which students had made a positive contribution, helped generate class discussions where students shared their progress and commented on their opinions of other students' work. Finally, the *questions and answer map* was found by the students as a rich tool. These students were used to working with this kind of tool, so they had no problems or difficulties understanding what was being asked of them. Also, as it was recommended to build since the beginning of their research, they used this tool to keep track of their daily progress and to present the final product.

Related to the constraints that hindered the progress of the SRP, we can identify (1) the lack of coordination time available, (2) the awareness of the interdisciplinary concept, and (3) the time slots available to do the project. We can highlight the lack of coordination time available to teachers, who rarely have time to share and reflect on what happened in class and have to use moments between corridors or before entering the classroom. Interdisciplinary work needs quality time for the teachers to share opinions and make decisions. The responsibility of this aspect belongs to the school, which has to provide teachers with resources to facilitate the success of the teaching activity. Besides, teachers also have some responsibility for the success of the SRP. They need to be aware of the difference between carrying out a multidisciplinary project or an interdisciplinary one. In this study case, teachers had not been explicitly given this difference. In the next experimentations, we will try to introduce this difference to see if teachers become more involved in disciplines other than their own. Finally, the last constraint to be considered was the time organisation of the project. All the students were taking mathematics, but others were not taking biology or multilingual expression.

They were taking technology, which was not involved in the project. Therefore, some students dedicated more hours than others to the development of the project. In the same way, the mathematics teachers spent 4 hours per week and the teachers of the optional subjects only 3 hours per week. This was an important constraint for both teachers and students, who were unequally involved. This causes hierarchies in the project production and sometimes results in students not being able to participate as they feel disconnected from their team's progress.

The modelling cycle as analytic research tool and how it can be enriched beyond the cognitive dimension

Pauline Vos[1] and Peter Frejd[2]

[1]University of Agder, Norway; pauline.vos@uia.no

[2]University of Linköping, Sweden; peter.frejd@liu.se

The modelling cycle is a theoretical construct frequently applied in research studies on mathematical modelling. On the one hand, the modelling cycle highlights essential aspects of modelling, which makes it a tool for conceptualizing. On the other hand, the modeling cycle can be used as a research tool for analysis of students' work. In the latter case, it has the limitation of primarily yielding results of a cognitive nature. We sought ways to include other aspects to analyze, such as metacognitive strategies, tool use, and social norms. These aspects support and change the cognitive activities involved in mathematical modelling practice. Rather than the standard modelling cycle, we propose an enriched modelling cycle with overarching layers for analysis of results. The enriched modelling cycle is a wider theoretical framework with interacting dimensions that affect the phases in the modelling cycle. We discuss potentials and challenges of this framework for new research studies.

Keywords: cognition, mathematical modelling, modelling cycle, social norms, theoretical frame.

Introduction

In this theoretical paper, we focus on theoretical constructs applied in many research studies on the teaching, learning, and assessing of mathematical modelling. Review studies on research on mathematical modelling education have been published by Cevikbas et al. (2021), Geiger and Frejd (2015), Kaiser and Brand (2015), Schukajlow et al. (2018) and Stillman (2019). These reviews show that a considerable number of studies apply a modelling cycle (MC) as theoretical framework for analysis of data in their research. With this paper, we aim at opening a discussion on benefits and limitations of MCs as a tool for analysis. This leads us to present possibilities to enrich the MC as theoretical framework, so it can assist researchers in further analyzing and theorizing mathematical modelling education[1].

This paper arose from a discussion on the importance of collaboration in mathematical modelling, as also noted by Blum (2002): how can aspects of groupwork, such as *agency* and *accountability* be analyzed in research applying an MC? Also, we discussed that research using a MC-based framework observed students having *blockages* in the modelling process, and that these were of a *cognitive* nature, that is, in students' minds (e.g., Galbraith & Stillman, 2006). However, students' problems could also be *blockages* caused by the norms of the didactical contract (Brousseau, 2002), where students are taught, for example, to avoid using extra-mathematical knowledge in mathematics task. When analyzed as blockages caused by the environment, the research results shed light on underlying mechanisms that hinder change; blockages in the educational environments may be more persistent

[1] This paper extends a short paragraph in Frejd and Vos (2021), where we presented the enriched modelling cycle. In the present paper we have more room for backgrounds and elaborations.

and harder to remove than cognitive blockages in students. So, why does research applying a MC-based framework yield cognitive blockages and not *socio-cultural* blockages?

Our discussion led to studying the essence of MC-based frameworks, regarding their benefits and limitations in analyzing aspects in modelling activities. This inspired us to develop an enrichment perspective on MC-based frameworks, so these can zoom out and yield analytic results that could be, for example, *social* in nature. This enrichment perspective should assist researchers of modelling education to create new angles in their data analysis, and thus reach new research results.

The modelling cycle as tool for conceptualizing and analyzing

Much research on mathematical modelling describes mathematical modelling through a *modelling cycle* (Niss & Blum, 2020; Geiger & Frejd, 2015). A MC is a schematic diagram showing mathematical modelling as a cyclic process, which consists of subsequent phases. See Figure 1 for an often-used example from Blum (2015), which shows seven phases in the modelling process; other MCs may have fewer or more phases and other wordings (Perrenet & Zwaneveld, 2012).

The MC in Figure 1 builds on an earlier version by Blum and Leiβ (2007), in which the 1st phase was named *understanding*, to indicate that the modeling process starts from a problem situation that needs to be understood. In the new version of this MC (Blum, 2015), it is written *constructing* to indicate that a modeller needs to create a mental model of the problem and the task ahead. After this start, the modeller goes through different phases by structuring and simplifying the problem context (e.g., making a rough drawing of the problem situation), which is mathematizable (e.g., by creating algebraic formulas), and which can be worked on mathematically (e.g., by manipulating the algebraic formulas). The mathematical results thereof can be interpreted and validated considering the original problem. In case the results are considered inadequate for the real situation, the entire modelling process is repeated. If the modeller is ‘ready’, the results can be *exposed*, that is: presented to others.

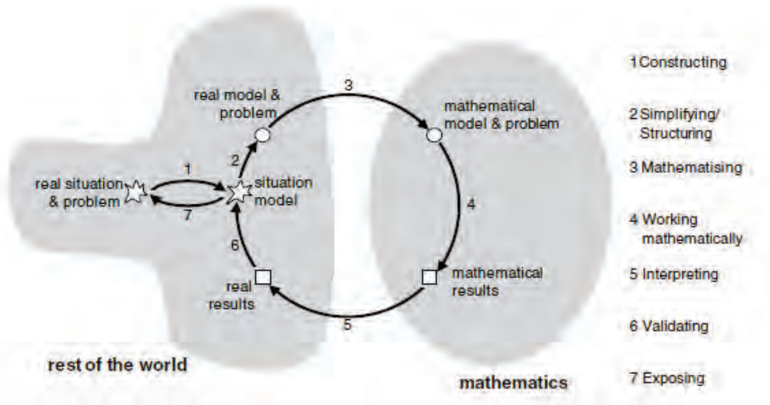

Figure 1: Modelling cycle from Blum (2015)

When students are given a modelling task, students follow other routes than what is described in a MC, ‘jumping’ back-and-forth between phases (Borromeo Ferri, 2006; Ärlebäck, 2009). However, most phases are somewhere observed in students’ activities. Thus, a MC does neither show what a modeller does step-by-step, nor is it a recipe to be strictly followed. Niss and Blum (2020) explain that a MC “should be understood as an *analytic* (ideal-type) *reconstruction* of the steps of modelling necessarily present, explicitly or implicitly, as an instrument for capturing and understanding the principal processes in mathematical modelling" (p. 14, italics by the authors). Thus, a MC is a *tool* for researchers and teachers to apprehend, comprehend, recognize, explain, and analyze important aspects in modelling, independent of whether it is done by an expert or a novice. Thus, a MC does not offer a definition, that is, it does not offer an explicit statement clarifying what mathematical modelling is. Also, a MC does not characterize mathematical modelling; that is, it does not offer qualities of modelling. Rather, a MC *conceptualizes* mathematical modelling; that is, it offers an abstract and structured idea of essential aspects, which is simplified so it is practical for use in teacher education, in educational-political discussions, and in research. In other words, a MC is a *model*.

The advantages of conceptualizing mathematical modelling through a MC are manifold. For instance, MCs show that modelling is complex, and that each phase affects others dynamically. Also, MCs show that modelling starts from real life and returns to it, and that mathematics is a useful toolbox in the solution process. Also, MCs show that modelling is not a purely mathematical activity, yet that mathematical activities play a central role. Also, MCs show that modelling differs from 'applying mathematics', which starts from a mathematical object, concept or algorithm that subsequently is used in a non-mathematical context, regardless of whether then a problem will be solved.

Apart from using MCs as conceptualization tool, researchers use MCs as an *analytic tool* to analyze their data in light of the different phases that a MC distinguishes. For example, we see that MCs are used to analyze students' activities regarding when they are in which phase (e.g., Ärlebäck, 2009), to analyze students' modelling competences regarding whether students are able to 'pass' a certain phase (e.g., Haines, Crouch, & Davis, 2000), to analyze mathematics tasks for certain emphases of modelling (Frejd, 2011), or to analyze classroom culture for an emphasis on certain modelling phases (Brady & Jung, 2021). The use of MCs as analytic tool yields a rich body of knowledge.

The modelling cycle with other dimensions than the cognitive dimension

When MCs are used as analytic tool in research of mathematical modelling, the results will be framed by it. The standard MC describes *cognitive* activities, which are activities that a researcher can observe in, or deduct from, a modeller's speech, gestures, writings, reactions and other explicit or implicit expressions. More generally, cognitive activities involve mental efforts to use and make sense of information. Activities such as speaking, listening, reading, remembering, non-routine problem solving, decision making, and sense making are mentioned as examples of cognitive activities. Cognitive activities can be learnt through experience or by being taught.

When an analytic framework has a cognitive focus, the research results will accordingly be primarily of a cognitive nature. This means that these have an individual's or a group's mental activities as unit of analysis. With an emphasis on cognitive aspects, the research may not capture other aspects that also play a role in mathematical modelling. Below, we give a few aspects that are not immediately captured by a theoretical framework based on the cognitive activities in a MC.

A dimension for metacognitive strategies

Successful mathematical modelling involves *metacognitive strategies* (e.g., Maaβ, 2006; Stillman, 1998, Vorhölter, 2018). These are needed for regulating and coordinating the many processes in modelling, both individual and group processes. During the modelling work, aims and outcomes need to be coordinated and regulated considering (1) goals in the task, (2) resources present, (3) the didactical contract from the teacher, and so forth. Different metacognitive strategies can be linked to each of the different phases in a MC, see Table 1. For instance, when starting, students need to ‘read’ the intentions into a task description and anticipate what they can do to reach a satisfying answer. In each of the phases in the MC, they can expect unexpected situations and may reflectively change the initial plans. They need to anticipate, reflect, plan, monitor, etc. From a research point of view, to analyze metacognitive strategies, one needs a different theoretical framework than for cognitive activities. Yet, metacognitive strategies and cognitive activities are intertwined. So, one can perceive the metacognitive strategies as an overarching layer over the standard MC, whereby the metacognitive strategies and the cognitive activities are two dimensions in one theoretical framework.

A dimension for tool use

Another aspect in mathematical modelling not captured in the standard MC is the use of *tools*. Therefore, Greefrath (2011) drew an alternative MC describing functions of digital tools in each phase of the MC. We want to extend this idea, building on Vygotskian theory (Williams & Goos, 2013), which explains that any cognitive activity is always *mediated* by tools, such as pens, blackboards, or digital tools. Mediation entails that the tool changes both the results of the activity (e.g., a mathematical answer becomes more precise), but also changes the cognitive activities (e.g., writing down intermediate steps off-loads memory demands). When starting on a modelling task, a modeller can try to understand the problem by using *Wikipedia* as inquiry tool. Another tool at the start of a modelling process is the *task sheet*, which offers students the information to be used and the guidelines to follow. Important tools in modelling are paper and pencil for making notes and sketches. At the very end of the modelling process, a modeller will present the results of the activity, possibly in written form or in an oral presentation to an audience. Thus, tool-use can be another analytic dimension that can be an overarching layer over the standard MC, see Table 1 and Figure 2.

A dimension for social norms

Another analytic dimension for research on mathematical modelling can be *social norms*. These are socially shared, implicit or explicit standards of acceptable behavior. As Blum’s (2015) MC shows, modelling takes place in two worlds: the ‘mathematical world’ and the ‘rest of the world’, in which there are different social norms. For instance, in the ‘rest of the world’, number answers can be estimations and, hence, not so mathematically precise. Yet, when presenting the final answer of the problem to the *client*, a modeller will abide to presentation norms (e.g., correct spelling, attractive lay-out). Regarding norms in the mathematical world, Yackel and Cobb (1996) described *socio-mathematical norms*, such as the use of preferred symbols (e.g., x and y) rather than creative inventions (e.g., ȝ and ͼ), and the specific way to justify claims (by giving a proof rather than a few examples). Also, there are classroom norms, also known as the didactical contract (Brousseau, 2002). Also, in groupwork, there may be competing norms, with some students making the effort because they consider the activity relevant, whereas others do it to pass the exam (Hernandez-Martinez & Vos, 2018). Thus, social norms will impact any modelling activity in many ways, and these may differ between the phases. We put some norms indicatively in Table 1 without claim of completeness, since research on this theme is still scarce and recent (e.g., Bonotto, 2020; Dede, 2019). Table 1 shows the phases in the MC with analytic dimensions for metacognition, tool use, and social norms that all differently interact and modify the cognitive modelling activities.

Table 1: Phases in the modelling process with indicative dimensions for cognitive activities, metacognitive strategies, tool use and social norms

	Cognitive activities	Metacognitive strategies	Tool use	Social norms
1	Con-structing	strategies to understand and reformulate the problem, to use additional information	Interpret task sheet, investigate resources (e.g. Wikipedia)	Norms within the team, in the classroom, norms of the *owner/client* of the problem
2	Simpli-fying/ structuring	strategies to select and organize information, develop plans, anticipate later actions, to monitor progress	Experiment with pen-and-paper (p&p), sketch & drawing tools, spreadsheets, etc.	Norms within the team, in the classroom, norms about what aspects to choose and the extent to which creativity is permitted
3	Mathema-tizing	strategies to organize infor-mation, develop & implement plans, to monitor progress	Visualize and organize with p&p, spreadsheet, plotter	Norms within the team, in the classroom, norms on using standard methods and being creative
4	Working mathema-tically	strategies to implement plans, to monitor progress	Calculate & simulate with pen-and-paper, Geogebra, CAS, etc,	Norms within the team, socio-mathematical norms on rigor, accuracy, use of common sense
5	Inter-preting	strategies to interpret results, to face unplanned outcomes	Visualize with p&p, presentation tools	Norms within the team, in the classroom and with the client in the process of interpreting
6	Validating	strategies to verify results, to invite critique, to evaluate the process and products	Control using p&p, information resources	Norms within the team, in the classroom and with the client on what can be regarded as 'validating'
7	Exposing	strategies to present results, to communicate and convince	Present using p&p or digital tools	Norms in the team, classroom, with the *client*, focusing on convincing

Conclusion

In this paper, we have looked at MC-based frameworks for analyzing aspects of modelling education and observed that such research has yielded a rich body of results, but that these are primarily of a cognitive nature and may obscure other aspects that play a role in modelling. Therefore, we suggest enriching the MC with overarching dimensions, such as metacognition, tool use or social norms, see Figure 2. The overarching dimensions can be supplemented or replaced by other dimensions that also affect the MC phases in different ways. Examples of alternative dimensions are *creativity* (Lu &

Kaiser, 2021), *flexibility* (Andresen, 2007) or *language* (Vorhölter et al., 2013). We suggest that also students’ *attitudes* may differ between the phases; so far, research connecting modelling to attitudes has focused on how modelling activities relate to students’ attitudes in mathematics in general (Chamberlin & Sriraman, 2019), and not on affect in different phases of modelling

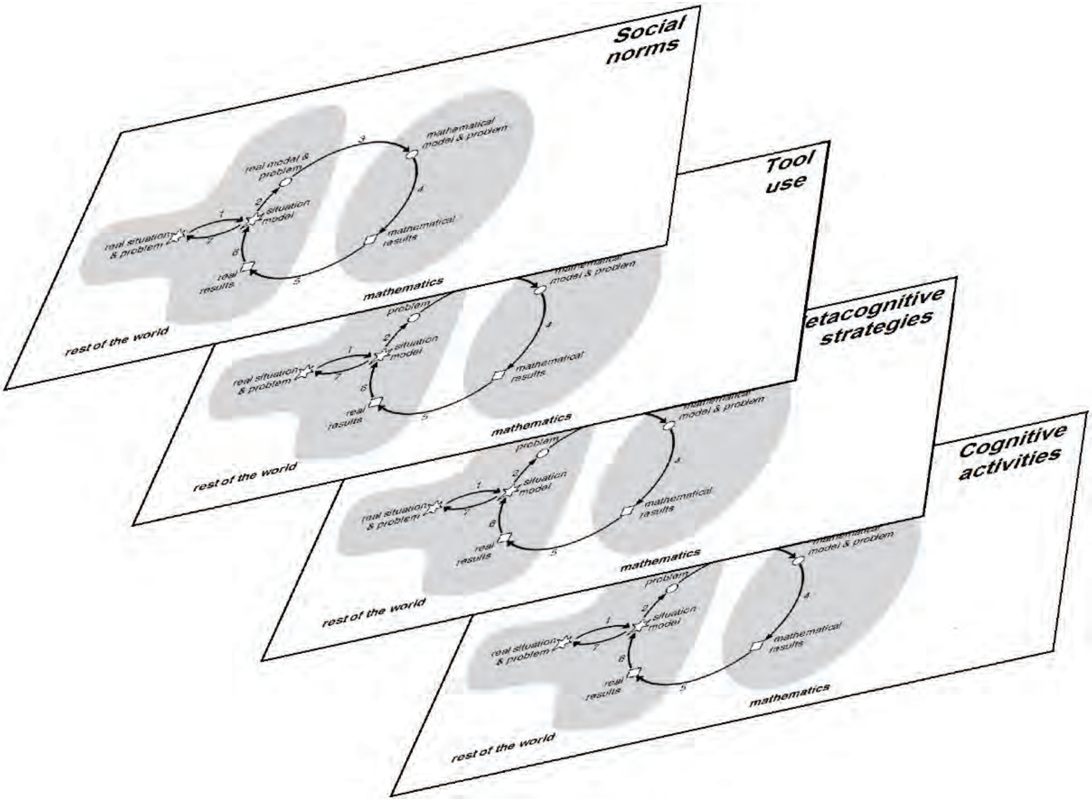

Figure 2: The enriched modelling cycle with four dimensions for analyzing modelling activities

Mathematical modelling is a complex and dynamic activity, and because of that it deserves to be studied from different perspectives. An enriched MC with a variety of overarching dimensions over the standard MC may enable modelling researchers to extend and deepen their research. This should give theoretical insights into how different dimensions interact and may reveal how students’ cognitive modelling competencies are affected by various aspects that haven been obscured so far.

Of course, any theoretical frame has its limitations. The enriched MC is an analytic tool for students’ modelling activities, and not a tool to design modelling tasks or a modelling curriculum. Also, it may be overwhelming to novices, and therefore, in teacher education or in educational-political discussions, the standard MC is more practical to keep a focus on aspects of mathematical modelling. However, the enriched MC should enable researchers to zoom out beyond the cognitive dimension and to further theorize the learning, teaching and assessing of mathematical modelling.

When mathematics in three acts meets mathematical modelling

Shengtian Zhou[1] and Ragnhild Hansen[2]

[1]Western Norway University of Applied Sciences, Norway; shzh@hvl.no

[2]Western Norway University of Applied Sciences, Norway; rhan@hvl.no

In this article, we investigate how the introduction of the pedagogical method, "mathematics in three acts" to preservice teachers influenced their mathematical modelling, while on practicum. We analyzed documentation, of groups of preservice teachers, on their experience of teaching modelling lessons. One finding was that the groups were able to use "mathematics in three acts" to produce modelling problems that fulfilled certain criteria in our selected framework, but they had difficulty finding modelling problems for the lower grades (grades 1-3). We also found that the preservice teachers appeared to emphasize the subprocess of working mathematically and devalue the subprocesses simplifying/structuring, mathematising, and validating, when guiding the pupils through a modelling process in a "mathematics in three acts" lesson.

Keywords: Mathematical modelling, "mathematics in three acts", modelling problem, modelling process.

Introduction and literature review

Internationally, mathematical modelling was traditionally reserved for secondary schools. Only in the last two decades did researchers begin to see value in modelling for primary education (e.g., English & Watters, 2005). In Norway, modelling was introduced to primary school (grades 1-7) in 2020, when a new and revised version of the national curriculum included modelling and applications as one of several core elements. At our university, mathematical modelling was not part of the teacher education for preservice teachers for grades 1-7 until 2018. In 2018, a research project, LATACME[1], began, which focused on mathematics teacher education for grades 1-7, including a focus on modelling. LATACME uses an educational design research approach, that uses an analysis of experiences in design cycles, to refine or change teacher education practices in forthcoming cycles with the overall aim of improving educational practices and developing theory about those practices. According to Borromeo Ferri (2018), educational modelling courses should keep a balance between theory and practice. Consequently, at the beginning of the project, the LATACME research-practitioner team recommended teacher educators to introduce theories about mathematical modelling in their work with preservice teachers (PSTs), and to ask the PSTs to prepare and implement a modelling lesson when on practicum.

Research by Paolucci and Wessels (2017) had shown that while PSTs were relatively proficient in identifying and presenting relevant real-world problem contexts to young children, they had difficulty with formulating problems satisfying certain design principles which characterized "good" modelling problems. Reflecting on data from the first-year design cycle (2018-19) researchers in LATACME

[1] Learning about teaching argumentation and critical mathematics education in multilingual classrooms (LATACME, https://prosjekt.hvl.np/latacme/) funded by the Research Council of Norway. The project period is 2018–2022.

observed that the modelling problems suggested by their PSTs had been based on real-world situations that were familiar to the pupils, but the modelling processes were seldom fully developed. More detailed investigations showed that the PSTs had difficulties with balancing pupils' independence when guiding the different work subprocesses (Hansen, 2021). In the next design cycle (2019-20), the research-practitioner team recommended the teacher educators introduced the PSTs to the didactical method "mathematics in three acts" (MITA) to investigate whether this method could assist PSTs in introducing modelling problems which could support pupils with an appropriate amount of guidance to work through a complete modelling process. MITA was designed by Meyer (2011) to encourage learners to pose and work on mathematical problems and it was further developed in Lomax et al (2017). The basic features of the method are illustrated in Figure 1.

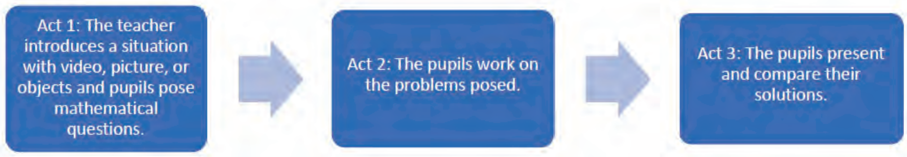

Figure 1: Mathematics in Three Acts (inspired by Meyer, 2011; Lomax et al., 2007)

However, it was by no means certain that MITA would achieve the desired effect. Dogan (2020) had found that a group of PSTs were successful in creating problems that were based on real-world contexts, but only a part of the problems could be classified as being model eliciting. To study how effective MITA was in assisting the PSTs in introducing problems that could be classified as "good" modelling problems in Act 1, we decided to evaluate the problems the PSTs adopted in their modelling lessons via MITA in terms of criteria to Dogan (2020), who proposed four criteria: reality, openness, complexity, and model eliciting. This would form the second cycle of the education design research approach for this aspect of LATACME.

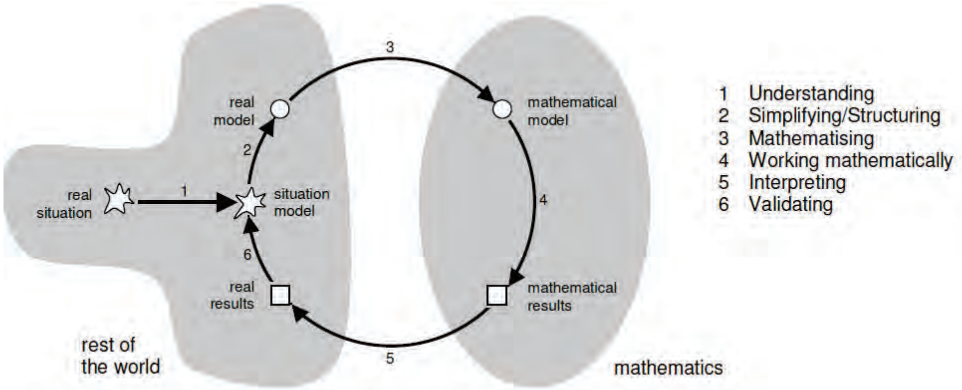

Figure 2: Modelling Cycle (Blum & Leiß, 2006)

After a modelling problem is chosen, solving it involves several subprocesses, which are not usually carried out linearly. The modelling process has been illustrated in various ways. As shown in Figure 2, Blum and Leiß (2006) emphasizes the cyclical nature of a mathematical modelling process and describes the common subprocesses, that in return require different competencies involved in solving a modelling problem (Maaβ, 2007).

While MITA suggests a linear working process (see Figure 1), the modelling cycle (see Figure 2) indicates the constant movement between the sub-processes. This suggests that some of the subprocesses, such as validating, in typical modelling cyclical processes, may easier to be overlooked when engaged in MITA. The second aim of our study was therefore to investigate to what extent subprocesses of the modelling cycle (Blum & Leiß, 2006) were present in lessons based on MITA.

Conceptual framework and research questions

Borromeo Ferri stated that in modelling lessons, "the selection and the quality of tasks for lessons are essential for mathematical understanding, for promoting students' mathematical practices and competencies" (2018, p.41). Synthesizing earlier research, Dogan (2020) proposed four criteria to evaluate modelling problems posed by PSTs: reality, openness, complexity, and model eliciting. The reality criterion requires that the modelling problem comes from a real-world situation and aligns with the reality of the pupils (Lesh & Doerr, 2003; Maaβ, 2007; Dogan, 2020). A modelling problem satisfies the reality criterion if it allows pupils to interpret the problem based on their experience and their mathematical knowledge. The openness criterion requires a modelling problem to be interpretable in multiple ways, open-ended and to allow for different solution paths (Maaβ, 207; Dogan, 2020). A complex modelling problem requires the pupils to understand the context and search for relevant data, and to be cognitively demanding to solve (Dogan, 2020; Borromeo Ferri, 2018). The model eliciting property ensures that a modelling problem should promote the modelling process, and requires the students to use mathematics to construct, describe or explain situations (Dogan, 2020; Lesh & Doerr, 2003).

Based on our twin aims for this paper, our research questions are about the MITA lessons described by groups of PSTs when reflecting on their practicum:

RQ1: Which of the four criteria (reality, openness, complexity and model eliciting), were most commonly found to be fulfilled by the modelling problems in the lessons?

RQ2: Which of the subprocesses of the modelling cycle were present in the PSTs' descriptions of the pupils' work processes?

Research Method

The investigation was conducted by using document analysis (Bowen, 2009). The units of analysis were 16 written assignments from groups of PSTs for 1-7 grades. The assignments were classified according to the four criteria in Dogan (2020) and the subprocesses of the modelling cycle by Blum and Leiß (2006) depicted in Figure 2.

Research Context and Participants

These PSTs were in the first semester of their second year of their teacher education. General theories on mathematical modelling and MITA were introduced to them through 3 three-hour lectures combined with literature reading. The PST-groups were then asked to plan and carry out a modelling lesson while on practicum. After practicum, the PST-groups were asked to describe and reflect on their modelling lessons. A total of 16 PST-groups with 3-5 PSTs in each group, gave permission for us to analyze their assignments. Of these groups, 15 had used the MITA structure for their modelling lessons. One of these groups reported to have performed two different modelling lessons. Therefore, we analyzed 15 assignments which contained 16 modelling lessons.

Data analysis

To evaluate modelling problems used by the PST-groups in their modelling lessons via MITA (RQ1), we used the four criteria reality, openness, complexity, and model eliciting (Dogan, 2020; Lesh & Doerr, 2003). After having identified the modelling problems the PST-groups described in their assignments, we categorized them according to the four criteria according to the questions in Table 1 which was based on the work of Dogan (2020). In the next section, we provide an example from one of the PSTs' assignments and a detailed description of how the analysis was carried out.

Table 1: Criteria for evaluating modelling problems via MITA

Criteria	Guiding questions for each criterion
Reality	1.Whether the problem sprang from real life of the pupils. 2. Whether the problem was suitable for the pupils' academic level.
Openness	Whether the problem was open for different interpretations or solving methods.
Complexity	1. Whether the problem was cognitively demanding for the pupils to interpret the problem. 2. Whether the problem could make the pupils to see the need of mathematics.
Model eliciting	Whether the problem required the pupils to generate a model.

To identify the modelling subprocesses the PSTs described the pupils going through, we analyzed the documents using the characteristics of the subprocesses described by Blum and Leiß (2006) (see Figure 2).

Results

The assignments contained MITA lessons. Some included dialogues from Act 1, while others described the dialogues implicitly. We chose here to present an extract from an assignment of one of the PST-groups, where the dialogues from Act 1 were described explicitly. This was typical of the assignment data and we use it to explain how our data analysis in more detail.

Extract from an assignment

This PST group described that they had implemented a modelling session over three lessons of 45 minutes each, in a grade 4 class with 22 pupils, using the MITA structure.

The PSTs described that in Act 1 they had presented a video about global warming. The PSTs and the pupils talked about this video and tried to understand some graphs about climate change. The PSTs described that the pupil had raised many concerns, among which the PSTs had identified two interesting questions, "*Is it possible to find out* how *much warmer it will be when I grow up*?" and "*How many years will it take before the sea rises over the dock (Bryggen) in Bergen*?" The PSTs reported that the last question had been chosen for this modelling session.

The document then reported that in Act 2 the PST-group had started the lesson with a discussion about what would happen if the sea level continued to rise. They had afterwards asked the pupils to think about what they needed to know to answer this question. The PSTs together with the pupils had concluded that one must know the present height and how much the sea level rises per year. The PSTs then wrote *"we found that the dock height above the sea level is 720 mm"*, and *"… that the sea level rises 3.4 mm per year. Since the pupils have not learned decimal numbers, we decided to round down to 3 mm per year"*. Afterwards, they had provided the pupils with a table with two columns, where one column was a list of the years from 2016 to 2022 plus the year 2032, and the other column were the sea levels with the first three years' sea levels 43 mm, 46 mm and 49 mm. In groups, the pupils had been supposed to fill in the table, with the PSTs being available for the pupils' questions. The PSTs also mentioned that some pupils were critical about the table, by for example saying that "*It is not certain the water rises all the time*".

In Act 3, the PST group had divided the pupils into groups of four. Having their table and calculations at hand, the pupils had been asked to answer the question "how many years will it take before the sea rises over the dock (Bryggen) in Bergen?". After about 30 minutes of group work, the PSTs had a summary, with one of the PSTs showing a solution method with centicubes.

Analysis of the example

The problem "How many years will it take before the sea rises over the dock (Bryggen) in Bergen?" was chosen after Act 1. It is likely that Bryggen would be familiar to most pupils in the class and as such most pupils would want to find out what could happen in the future, using this as a benchmark to understand the implications of climate change. From the PSTs' description, the mathematics involved seemed to be suitable for grade 4 pupils. The problem, therefore, fulfilled the realistic criterion. The problem also fulfilled the openness criterion as it allowed several different interpretations (e.g., what does "over the dock" mean?) and different solving strategies. It also required solvers to orient themselves, simplify, find needed information, and to use mathematics to find the solution(s). Consequently, we interpreted it as being complex. As the problem also seemed to invite pupils to generate a model, the problem was also classified as model eliciting. Thus, we considered the problem to be realistic, open, complex and model eliciting.

In regard to the second research question, we identified the modelling sub-processes that were evident in what the PSTs described the pupils as doing in Act 2 and Act 3 of the modelling sequence. For the first subprocess, "understanding", the PSTs indicated that the pupils had the opportunity to interpret the modelling problem in classroom discussions about the consequences of sea-level rise. They also had to identify and understand the information they needed to answer the problem. However, from what they described, it seemed that the PSTs took over the next subprocess "simplifying/structuring" themselves, since they provided the height of the dock and rounded down the height that the average sea level rises per year. In addition, they presented a table to represent the situation, an activity that we interpreted as part of the "mathematising" sub-process, so that the pupils just had to complete the table. By completing the table, the pupils concentrated on the subprocess "working mathematically" and implicitly the subprocess "interpreting" in the context of the real model. The subprocess of validating was not promoted by the PSTs.

General results

There were 11 problems in total (see Table 2) that satisfied all the quality criteria. Of those which did not fulfill all the criteria, most of the problems were for pupils in the first few grades of school. One modelling problem for grade 1 failed the reality criterion, and 3 modelling problems for grade 2 and 1 modelling problem for grade 3 failed the openness, complexity or/and modelling eliciting criteria.

Table 2: Number of modelling problems that fulfil each criterion

	Reality	Openness	Complexity	Model-eliciting
Number of modelling problems out of 16	15	13	12	12

Table 3: Analysis of the modelling subprocesses that were present

	Understanding	Simplifying	Mathematising	Working mathematically	Interpreting	Validating
No.	11	1	6	11	11	5

We found that where the PSTs' modelling problems did not fulfil all four criteria in our framework, there were also lack of the modelling subprocesses in the descriptions. For four of the modelling problems this was because that the complexity of the problems was too low for the grades (complexity criterion was not fulfilled). Therefore, we restricted identification of modelling subprocesses to the 11 modelling lessons in which the modelling problems satisfied all four criteria for good problems. Table 3 presents the analysis of the modelling process for these 11 modelling lessons. It shows that the sub-processes simplifying, mathematising, and validating were often absent in these lessons. In particular, the subprocess simplifying only appeared in one of the modelling lessons. In the one modelling lesson that involved all subprocesses failed to repeat subprocesses for one or more cycles, suggesting a linear rather than a cyclical approach to modelling.

Discussion

When it comes to the first research question, our result showed that 11 out of 16 lessons adopted modelling problems that satisfied all four criteria, and 15 of the problems satisfied the reality criterion (Table 2). We can compare this with the results by Dogan (2020), who found that PSTs had difficulties constructing modelling questions that fulfilled all four criteria (5 out 17 in his case fulfilled all criteria, and 12 of 17 fulfilled the reality criterion). In our analysis, we interpreted that through MITA the PSTs were able to encourage the pupils to come up with accessible modelling problems from familiar contexts. In some of the lessons, the pupils asked a wide range of questions through Act 1, which gave the PSTs some freedom to choose open, model eliciting problems with adequate complexity. This can be illustrated by an example from a PST group reported having presented the pupils with a short video of Usain Bolt running a competition. Some questions that the pupils asked were: how fast did Usain Bolt run in that competition? How many centimeters did he run? How much does he earn as a runner? How old will Usain Bolt become?

The fact that the 5 cases that failed one or more criteria in Table 1 were for lower grades (1-3 grades) is interesting. Paolucci and Wessels (2017) raised also the concern about the PSTs' capacity to create modelling problems for lower grades, especially for grade 1. One of the PST groups stated, "since there is not much theory [mathematical knowledge] available for 2nd graders, we choose to look at the mathematical curricular goals". This indicates that the PSTs thought the difficulty lay in the fact that pupils in lower grades did not have sufficient knowledge in mathematics, so that there are a limited number of mathematical topics to work with. This suggests that PSTs need more guidance from teacher educators in designing modelling problems for lower grades.

In response to the second research question, we found that the main modelling activities took place in Act 2 and Act 3. In these acts, the PSTs guided the pupils through the modelling process to solve the problems posed in Act 1. Our analysis showed that the subprocess simplifying/constructing was missing for 10 of the 11 modelling processes. In most cases the PSTs took over the modelling problems and simplified and structured them for the pupils. Only in 6 of the 11 modelling processes did the pupils need to transfer the real model to a mathematical model. Ng (2018) and Hansen (2021) pointed out similar tendencies among experienced teachers and PSTs respectively that were new beginners in teaching modelling, that is, that the teachers and PSTs tended to provide scaffolding because they perceived mathematical modelling to be challenging for their pupils.

The PSTs also did not often include the validating subprocess in the modelling cycle. Only 5 out of 11 PST groups used this sub-process. Our result showed that in the descriptions in the assignments the cyclic nature of the modelling process seemed to be absent in the lessons, whereas the subprocess "working mathematically" was always part of the process. We suspect MITA could have affected both the cyclicity of the modelling process and the focus on working mathematically. Act 3 in MITA was designed to let the pupils to compare and reflect over solution methods, and it did not suggest that pupils should go back to re-solve the problem or refine the solution to the problem. Therefore, the cyclicity was not part of the process suggested by MITA.

Conclusion

There are two main conclusions from this study. The first is that we found through MITA the PSTs were able to arrive at modelling problems that included the pupils' perspective, but that they had difficulty to find modelling problems for the lower grades (grades 1-3). The second conclusion is that even if the PSTs arrived at appropriate modelling problems together with the pupils, the corresponding modelling process through MITA did not necessarily contain all the subprocesses of the modelling cycle. In particular, the subprocesses simplifying/structuring, mathematising, and validating were often missing. This is interesting, and it asks for more attention towards how to instruct PSTs to include these subprocesses in their modelling practice in teacher education.

Acknowledgments

This research was part of the research project LATACME. We thank Tamsin Meaney and Angelika Bikner-Ahsbahs for their comments and encouragement.

TWG07: Adult Mathematics Education

Introduction to TWG07 Adult Mathematics Education

Beth Kelly[1], Javier Díez-Palomar[2], Fiona Faulkner [3], Kees Hoogland[4]

This paper is a summary paper of the Thematic Working Group (TWG) on Adult Mathematics Education (AME). As the only thematic working group that focuses on adults' lived experiences of mathematics, the research makes an important contribution to the field of Mathematics Education. The main themes in this group identify that adult numerical behaviour goes beyond the mathematics skills, knowledge, and procedures taught in formal education It is multifaceted, requiring the use of higher order skills of analysis and judgement, applied within a broad array of life's contexts, experienced through a range of emotions. The research in this group points to the need to raise the profile of research that shows the benefits to adults of learning mathematics but also the long term economic disbenefits in the neglect of teaching and teacher training for this group.

Keywords: Adult Mathematics Education, Numeracy, PIAAC,

Introduction

One thing the pandemic has taught us is that understanding mathematics and its role and influence on peoples' lives really matters. Every day we were shown graphs and charts indicating trends that were used to make predictions about the world's health and economic situations with significant implications on our individual behaviour. We were shown countless exponential graphs, numbers in the billions and given numerical risk analyses of actions, which increased the demands on our mathematical interpreting, understanding, and reasoning to make sensible decisions on our behaviour with huge impact on our lives. Yet the mathematics being learned in schools seemed to be reduced in content and unequal in access (Hodgen, Taylor, Jacques, Tereshchenko, Kwok, & Cockerill, 2020), distant from what was needed to help understand the situation.

Hoogland and Díez- Palomar (2022, this publication) argue that society is becoming increasingly mathematised, and the demands on adults to make numerate decisions that impact on their lives is considerable, yet interest in research into the world of adults learning mathematics and life-long learning lacks attention. This is already a long-lasting problem. Coben (1994) argued interest in research into adult numeracy only started to be recognised for its importance when she highlighted the differences in cultures between academic research and those involved in adult numeracy and mathematics education. Reinforcing the idea that adults learning mathematics was different from school based mathematics, Withnall (1994) further argued rather than it being a set of mechanistic, isolated mathematical skills which can be acquired free of context and then applied to real life, numeracy is better understood in relation to the demands on adults' lives in their broader contexts, where communication skills are key to interpreting the variety of 'mathematical codes' encountered and on which we are asked to exercise judgement to ensure a useful outcome.

Since then, with nearly 30 years of research plus the establishment of a global forum Adults Learning Mathematics (ALM), practitioners and researchers have been exploring their understanding of adults' ability to learn and utilise mathematical information. In response to economic, social, and technological changes, our understanding of the field of adults learning mathematics has developed, yet still many citizens lack the numeracy competencies to enable them to fully participate (Gal, Grotlüschen, Tout & Kaiser, 2020; Hoogland & Díez-Palomar, 2022, this publication; Yasukawa, Rogers, Jackson, & Street, 2018) and few trust numbers enough to deal with, let alone challenge, a world in which fake-news can flourish. These factors have profound implications for the way in which numerical skills are taught and learnt in adult education programmes.

Emerging themes in Adult Mathematics Education

The content of this working group requires us to consider the notion of numerate behaviour in its widest sense, exploring a range of ideas, contexts and applications, probing further the relationship between numeracy and mathematics.

Contributions focus on:

- Reflecting on the field of adult numeracy and its relationship with mathematics.
- Numeracy as a lived experience of mathematical calculations and procedures in social economic and political contexts.
- Developing numeracy and mathematical skills with adults, including vocational education.

These themes reinforce the need to recognise that adults' experiences with mathematics inform judgements affecting their lives far beyond the classroom. The breadth of papers in this working group reflects the wide scope of the field of Adult Numeracy. The single working group focused on adults' mathematical experiences in this CERME 12 conference points to an important contribution that the understanding of adults' lived experiences of mathematics, both inside and outside formal state sponsored education systems, adds to our understanding of Mathematics Education. Adults and their numeracy skills are intertwined with the political, social and economic systems, are shaped by, but also shape those lived experiences (Lerman, 2000). In the next paragraphs we introduce the papers outlining the contributions to the three areas of focus.

Reflecting on the field of adult numeracy and its relationship with mathematics

Kaye, past chair of ALM, discusses the historical development of the concept of numeracy. Taking a philosophical view, using Thomas Kuhn's notion of lexicon and incommensurability, Kaye likens the development of the field of adult numeracy to a paradigm shift. Emerging from the field of mathematics education research, almost in a Darwinian sense (Kuhn, Conant, & Haugeland, 2000, p 98-101), responding to historical, environmental, and social changes. Kaye seeks to research the notion of adult numeracy using Kuhn's paradigm shift. He argues for the need to find agreement in the concepts of what numeracy is, so that it can be utilised to critique mathematics research. Although he concedes that many languages do not have a word for 'numeracy', he maintains many countries and contexts have similar adult learners in similar situations with similar numerate behaviours.

Diez- Palomar and Hoogland (2022, this publication) undertook a literature review into the field of adult numeracy over the last 20 years, to identify the topics investigated and where gaps have appeared that could point to new lines of enquiry. The main findings suggest research most often cited focused on the contexts of health and social care, followed by articles on numeracy in everyday life. Most higher order skills cited were processing information, problem-solving and critical thinking. Most of the cited articles were based on quantities and numbers, perhaps not surprisingly given the time span, few studies focused on apps or digital skills. When considering dispositions most focused on self-confidence.

It is apparent that while many within the field of adult numeracy research are aware of important contributions, the work is less well known outside this field and so work needs to be done to raise the visibility of our research in other domains and with policy makers. Increased visibility is important to inform policies on adult mathematics education, with as main focal point the idea that numeracy is a multi-faceted concept.

Adult numeracy is more than mathematical skills, knowledge, and procedures taught in schools. It is complex encompassing higher order skills, applied to a broad range of contexts, experienced through a range of emotions. The Common European Numeracy Framework (CENF) by Hoogland and Diaz-Palomar (2022, this publication) brings up to date our understanding of what society requires from adults. They identify four aspects to numerate behaviour. Suggesting adults need to be able to recognise and apply appropriate mathematical concepts but within many different everyday contexts; to use higher order skills to process, reason and analyse the numerical information that influences decisions affecting their daily lives. All of this while recognising adults have many beliefs and feelings related to mathematics itself, developed through lived experiences, which will affect their judgement when dealing with numbers. Spiegelhalter (2017) also writes about this in relation to the notion of 'trust' in numbers when surrounded by fake-news. The CENF illustrates a way to research aspects of the field of adult numeracy encompassing the lived experience of mathematics education. Hoogland and Diez- Palomar further point to the increased 'mathematisation of society' through technological developments, where people must make numeracy-based decisions all day long. While arguing that equipping people with the necessary skills will be a big challenge, they posit this will require us moving away from 'mastering the execution of calculations with pen and paper to recognising numeracy as a multifaceted concept needed for the 21st century'. Work related to the CENF framework will, in the future be linked with PIAAC as well as the development of teaching resources and professional development modules, to help disseminate the ideas futher.

Numeracy as a lived experience of mathematical calculations and procedures, in political, economic, and social contexts

Kelly, (2022, this publication) chair of ALM, explores the financial literacy skills and knowledge needed to survive in complex financial systems. She uses the notion of financial vulnerability (Gal et al, 2020) to research the extent of global economic need, the impact of western economic systems, community influences and individual risk factors. She identifies financial vulnerability as a global issue, affecting women more than men, arguing that this has a lot to do with societies' gendered expectations of female and male roles. Other vulnerable groups include those who are disabled, single parents and people living in marginalised communities, and the COVID pandemic has made life more difficult for those already financially squeezed. Mathematical calculations, such as interest, are key to understanding many financial concepts. But making sound financial judgements in real life also requires the ability to analyse, and reason what those interest rates mean, for example, when taking out loans. She found most current national child-focused financial education resources in the UK focus on dispositions towards money considering psychological and emotional relationships with money and mathematics. While adult numeracy skills and knowledge are essential to making sound judgements in financial decision-making, so are literacy and digital capability skills as well as understanding emotional attachments. Kelly argues that financial literacy education can be seen as one way to combat financial vulnerability but to be effective needs to focus on learners' priorities.

Byrne and Harrison (2022, this publication) give an insight into numeracy education in prisons, a particular but very important context within society. Mathematics education in prison is a basic life skill (Council of Europe, 1990) yet Byrne and Harrison found it varies considerably across countries and within national systems. Despite this variation the Mathematics in Prisons (MiP) group was established by two practitioners, one in Ireland and one in the USA, whose research focus is centred upon those learning mathematics within the 'secure estate'. Prisons over the centuries have been seen as agents of the state to reform, to penalize, to encourage desistance from crime, and more recently to encourage lifelong learning and personal transformation. The MiP group shares the later goals and explores similar experiences in the maths classrooms. All tutors work with students who may not have chosen to study mathematics were they not in prison. Yet Byrne and Harrison found this experience can encourage reflection and become a turning point in an individual's life, as mathematics is a gateway to further and higher education. The MiP group plans to support those working across international boundaries, overcoming the challenges of variation in language and culture, exploring the value of learning mathematics for different groups and aim to use this CERME platform to further raise awareness of the group and to recruit members.

Dulam and Hoogland (2022, this puplication) utilise the large database provided through PIAAC to explore numbers in an economic context examining the consequences of a mismatch between workforce skills and employment on the economy. At individual (micro) level, where skills-mismatch can lead to lower job satisfaction and wages. At company (meso) level where mismatch leads to a higher staff turnover and inefficiencies and at a country (macro) level, leading to unemployment, lower productivity, and lower economic growth mainly due to wasting human capital (OECD, 2013).

They find skill levels vary over time in adults' lives and with employment opportunities. But they also question how reliable the actual measurements of over and under skill levels are. In their research they found being over-skilled for a job is more likely for men, younger age-groups, those with higher education, and for people who use their numeracy skills often at work. Also, the likelihood of being over-skilled increases as the frequency of using numeracy skills at work increases. Further consideration needs to be made to fully appreciate the implications of some of the findings. For example, employing over skilled men might be due to an inbuilt gender bias within certain job roles and industries where males are more likely to be employed over females, which would affect a skills mismatch. Also, some countries' employment policies are attached to certain financial penalties which are imposed if people do not accept employment offered, consequently this can 'push' over-skilled people into lower skilled jobs.

Exploring context as a broader notion of democracy Lindenskov (2022, this publication), considers the skills and knowledge essential to understanding how mathematical thinking underpins the very essence of our political and social systems. She argues that mathematics underpins our lives both inside and outside education, in both formal and informal ways. For example, using the same numbers but comparing election outcomes in countries that use ‘first past the post’ algorithms with those using a proportional representation system. Lindenskov argues that such exercises give a better understanding of how mathematics shapes our parliaments, our laws and our lives. She further posits democracy can influence the classroom through the teaching approaches used, as well as the topics covered. This links back to the role that numerate behaviour has in adults’ lives going beyond the classroom, and how research into the field of numeracy helps us better understand how mathematics can inform, influence, and empower adults’ daily lives.

Developing numeracy and mathematical skills with adults, including vocational education.

Investigating mathematics education with adults and different aspects of the mathematical skills and knowledge of teachers and their students is a rich source of research into adults learning mathematics. This section points to several gaps in teacher training and continuing professional development courses for those involved with mathematics education for adults, especially those asked to teach numeracy to adults but without the specialist knowledge to support their endeavours. Is it any wonder that results from PIAAC and OECD surveys show that in all but one participating country, at least 10% of the adults are proficient below level 1 of the 6-point scale in literacy or numeracy (Hoogland, Kelly & Díez-Palomar, 2019, p.1294)?

Bradtke and Ferri (2022, this publication) explore the mathematical competence of vocational teachers whose main subject is economics, comparing prospective teachers who have mathematics as a subject in their curriculum with those who have not. In their research they found that most vocational teachers did not receive any mathematical training in their studies, although they use, among other things, the percentage calculation in business lessons. In a pilot study, an instrument was validated to record whether the mathematical model of compound interest is recognised and successfully applied in different situations, by the two groups of teachers. The results showed that even student teachers with mathematics as a subject have difficulties with its application to the economic problems. This is interesting when reflecting on the importance of understanding and applying percentage calculations at a global level to economic growth figures, but also to more individual financial decision-making when applied to making interest payments on savings and credit. It points to an important deficiency in education systems that can have serious widespread repercussions, where teachers’ lack of mathematical understanding is passed on to the students, known in economic terms as the multiplier effect.

Responding to a national push for problem-solving to be introduced into the mathematics taught in schools and colleges in order that it can be utilised more effectively in people’s jobs and lives, Faulkner, Breen, Prendergast and Carr (2022, this publication) compare the problem-solving and procedural skills of adults in mathematics education in Ireland. They find that adults in mathematics education in Ireland have significantly weaker problem-solving skills in mathematics when compared with procedural skills. This lack of problem-solving skills aligns with findings amongst third level students in schools, however the same investment/interest in improving the provision of mathematics education for adult learners is not present. They further argue that these findings are misaligned with one of the key recommendations of the ‘Adult numeracy: Assessment and development’ policy to “invest in the development of national capacities to measure and improve adult numeracy” (Gal & UNESCO, 2020, p.3).

This lack of investment in appropriate teacher training for adult numeracy educators is exacerbated for those who are asked to take on the responsibility of teaching adults’ numeracy without the requisite skills and knowledge, as research shows by Prendergast, O’Meara, O’Sullivan, and Faulkner (2022, this publication). Their research highlights an unmet demand for professional development in adult numeracy education, with many numeracy practitioners looking for opportunities to develop their practice. In response to this need this research group aims to establish a series of online ‘Numeracy-Meets’ for adult numeracy practitioners. They outline a new model of support that focuses on topics such as Family Numeracy and Financial Literacy rather than teaching traditional topics such as fractions in isolation. Through the establishment of an informal community of practice they aim to meet the professional development needs of practitioners. It is early days for this project which, if successful, hopes to expand its reach both nationally and internationally.

Forster, Faulkner and Prendergast (2022, this publication) have also undertaken further study into the relationship between psychosocial factors, demographics, the level of mathematics studied and progression for Access students. Their findings show that students studying foundation mathematics had significantly higher scores for amotivation and neuroticism. While those who chose to study advanced mathematics, students had ranked more highly for general self-efficacy (GSE), belief about mathematics ability (BMA) and intrinsic motivation to know. Additionally, female students were significantly less likely to study advanced mathematics than males. Non-Irish nationals studying advanced mathematics were significantly less likely to progress to higher education than their peers. All these findings need to be further explored in relation to motivation and reasons for study in relation to the notion of success. The research recommends teachers engaging students in enactive self-mastery but also the importance of role-modelling and verbal persuasion in encouraging progression to higher education and higher-level mathematics studies.

Stacey (2022, this publication) in her doctoral research seeks to explore possible changing perceptions in relation to adults’ motivations, mathematics anxieties around mathematics and confidence while learning mathematics. Working with adult numeracy learners (19+) returning to the further education sector in the UK to study GCSE Mathematics. Although still in the pilot phase, her paper also raises several key issues in relation to continuing professional development for numeracy teachers. She highlights the very under-researched group of adult learners (+19), as most research on learners’ perceptions of mathematics has been conducted with school aged, 16–18-year-olds in further and higher education students. She also raises the issue of variation in professional development for teachers on offer, highlighting a lack of understanding of how different countries and universities organise both full and part time doctoral education as part of their professional development programmes.

Forwarding the field

The papers in this workshop show research into the field of adult numeracy has a huge amount to offer the teaching of mathematics in schools, as it reflects the lived experience of numbers recognising its complexities. Yet as Diez-Palomar and Hoogland (2022, this publication) found, numeracy has very little visibility in the research world which means it is out of the reach of policy makers. This is undoubtedly a result of Coben's (1994) ideas of differences in cultures in the research world on school mathematics education and the practitioners' experience of teaching adults. But it can also be seen as developing from a historical deficit of political interest and funding in adult education outside university level. For example, in the UK until PIAAC identified national skills discrepancies there was little interest or investment in developing the numeracy and literacy skills of adults. Researchers in the field of adult numeracy need to explore ways to promote the wealth of research that exsits in this area, but also the significant gaps. The pandemic and the greater use of technology also offer more opportunities for practitioners and researchers to join, network, and promote the benefits of adult numeracy.

The papers outline a strong case for interest and investment in adults' numeracy education, when considering the impact on people's lives and the potential empowering and transforming nature of mathematics. However, the research into the resultant effects of an over skilled or under skilled workforce on global economic inefficiencies, job dissatisfaction, high turnover costs and loss of productivity are clearly made. Yet papers in this working group provide clear evidence of underinvestment in adult education with the serious consequences it has for learners at all levels.

Conclusion

Employers, politicians, and educators want people to have a higher quality of numerate and mathematical behaviour to handle numeracy situations effectively in their daily lives, but typically use standardized school mathematics tests to assess these qualities. Unfortunately, most of these tests are not designed to capture the multifaceted nature of numerate behaviour and therefore provide an image that is too narrow to reflect such behaviour. The research field of adult numeracy and mathematics education recognises the complexity of numerate and mathematical behaviour and offers insights into possible approaches that can be used within mathematics education, casting a broader light on the intricacies of mathematical and numerate behaviour in the context of everyday life.

The notion that technology is leading to a society becoming increasingly 'mathematised' should be considered more seriously in research on mathematics education, for instance by using global research databases, such as PIAAC (OECD, 2019), that enables us to compare and analyse how different societies and countries deal with this issue in their educational policies and practices.

Research in this working group shows the importance of adult numeracy research in relation to life opportunities and inclusive societies, yet point to a lack of visibility in academic research with the consequent lack of effect in learning from work undertaken into adult numeracy research and practice. Understandably policy makers are currently focused on the long-term effects of the Covid -19 pandemic on school children and their learning. Yet these few texts indicate a real need for resources to be invested beyond schools to respond to the demands on adults' numeracy requirements to engage fully in life chances relating to health, finances, employability and through civic society.

The mathematical competence of vocational teachers with a focus on economics - an empirical comparison between prospective teachers with and without mathematics as a subject

Niclas Bradtke[1] and Rita Borromeo Ferri[2]

[1]University of Kassel, Department of Mathematics, Germany, nbradtke@mathematik.uni-kassel.de

[2]University of Kassel, Department of Mathematics, Germany, borromeo@mathematik.uni-kassel.de

Keywords: Grundvorstellungen, teacher education, professional mathematical knowledge, percentage calculation.

Theoretical background

Percentage calculation is one of the most important mathematical topics for everyday life and work (Parker & Leinhardt 1995). Vocational teachers focusing on economics use it in their teaching, but little is known about their own knowledge of it. It is likely that they may draw on their mathematical knowledge from school and their training does not usually include any mathematics education content on percentage calculation. Initial studies indicate that their understanding is incomplete (Bradtke 2018). Therefore, we are investigating the research question: Do vocational teachers focusing on economics, who do not specialise in mathematics, have a professional mathematical knowledge of the content percentage calculation?

In German research on mathematics education, the existence of an adequate understanding of the concept is examined by checking whether the normative Grundvorstellungen (desired ideas about a mathematical content) are present and can also be applied situationally. To test this, vocational teachers focusing on economics were asked to solve tasks involving percentage calculation. It is argued that if they can solve the tasks, it is likely that they have the appropriate Grundvorstellungen, otherwise, deficits are to be expected. Furthermore, the Grundvorstellungen of a mathematical concept are considered sustainable if they can be activated in different situations (Padberg & Wartha 2017). Compound interest also plays a special role in commercial calculations but only with solid/broad Grundvorstellungen is one competent in dealing with the mathematical content. Difficulties with this operation are also increasingly reported in Anglo-American countries (Parker & Leinhardt 1995).

If we look at the essential mathematical activities of vocational teachers focusing on economics in commercial education, then the teacher should be able to solve the tasks him/herself as well as recognise errors in the processing of tasks and describe the error. Along these three contexts, we have set twelve tasks involving compound interest in order to determine how viable the conceptions of this term are.

Methodology

In a pilot study, 77 secondary school student teachers' mathematics was surveyed (semester: mean 3.44; standard deviation 1.93). The pilot study took place in the winter semester 2021/2022 at the University of Kassel. No vocational teachers with a focus on economics were surveyed, as they were held back for the main study due to their low numbers. Participants in the pilot study were secondary school student teachers with mathematics as a subject. It is argued if they have difficulties with the concept of compound interest, then it is very likely that vocational student teachers without mathematics as a subject do as well. The study was designed as an online achievement test. The invitation link was sent to prospective students on our course on mathematics education in the first secondary school via Moodle. Participation in the study was linked to compensation opportunities for academic performance.

Results

Compound interest was tested through nine tasks with varying demand situations. On average, 7.4 tasks could be solved with a standard deviation of 2.54. The scale formed an alpha coefficient of α = .755. For three items, the item discriminatory power is slightly below .3. These are to be revised in the next pilot study. The distribution of scores is as shown in the histogram (see Figure 1).

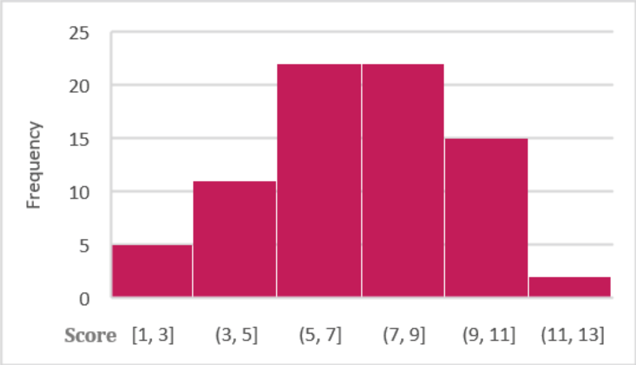

Figure 1: Results on the viability of the Grundvorstellungen for multiple changes of the original size

Discussion

The secondary school student teachers with mathematics as a subject do not seem to be able to solve compound interest problems in all contexts. This suggests that they do not recognise the problem type of compound interest in some contexts and therefore cannot apply the Grundvorstellungen associated with this problem type. If student teachers with mathematics already have this difficulty, then it can be assumed that this is even more serious for vocational student teachers without mathematics as a subject. Whether vocational teacher have difficulties in this regard will be investigated in a further study.

ALM Mathematics in Prison (MiP)

Catherine Byrne [1] and Tatiana Harrison [2]

[1] Adults Learning Maths (ALM), Ireland; tg-mathsinprisons@alm-online.net

[2]Adults Learning Maths (ALM), USA; tg-mathsinprisons@alm-online.net

Mathematics in Prison (MiP) topic group is a new initiative developed by Adults Learning Mathematics - International Research Forum (ALM). Our mission is to link practitioners and researchers interested in the field of Mathematics education in prisons and correctional education contexts. The topic group was developed in response to the ALM virtual seminar series, which featured a variety of speakers on various topics related to adults and Mathematics during 2021 and 2022. Discussions among participants at some events expressed interest in the field, and ALM responded by facilitating the development of a dedicated Mathematics in Prison group. Members joined from different parts of the world, all with an interest in Mathematics education in the secure estate. The group focuses on the challenges and opportunities of learning mathematics in this unique and under researched context.

Keywords: Adults mathematics education, teaching resources, correctional education, desistance.

Introduction

The MiP topic group first presented on the work of their work in a workshop at ALM 28, a virtual conference from the University of Hamburg. Members of the group presented an informal session where each taught a class on ratio, as this is a topic many of the group find is a challenge for their adult students. Participants were encouraged to share their perspectives and experiences in this field.

The two authors of this paper are practitioners in the field who are also researching for a PhD and wish to share their teaching experiences. Their research and to connect with practitioners. These goals were extended were shared within the topic group, to offers a forum to share good practice, discuss methodologies and explore the challenges practitioners and researchers face working in the secure estate. The group encourages informal conversations between practitioners and researchers to identify common themes and investigate ways that the MiP topic group might support mathematics education in this context in the future. Practitioners study experiences, literature, and best practices (Ginsburg 2019), and investigate topics such as teaching fractions, assessment and technology enhanced learning.

The focus of the paper is to open this topic for discussion and invite others from the field to connect with us, from any background, and together we can develop the vision activities of the group. We hope in future that we can identify some common themes emerging in the field of mathematics education in prisons. As the group has been in existence for a very short time, this paper reflects how we opened this discussion rather than describing findings. We would like in future to gather relevant literature and give practitioners the opportunity to reflect on the literature as it relates to their practice, possibly in the form of a professional book club.

The Prison Education Context

In our meetings we found that Mathematics education in different countries varies in language, culture, curriculum, philosophy, delivery, and statutory basis. For example, there are different terms within the group's members for students, for staff, for the education service, and even for the subject of Mathematics itself. Our first task was to discuss the language of our work with the others in the group so we could communicate in a nonjudgmental way with each other.

There are many differences in the education services in prisons across the world, and this is reflected in the language used. Prisons over the centuries been seen as agents of the state to reform, to penalize, to encourage desistance from crime, and to encourage lifelong learning and personal transformation. In spite of this, in the MIP group, we felt that we share many similar experiences in our Maths classrooms.

We all work with students who may not have chosen to study Mathematics except that they found themselves in prison. This experience can encourage reflection and become a turning point in an individual's' life, as mathematics is a gateway to further and higher education. Many have spent years away from formal education and may never have considered returning to education if they were not in this context. The process of capturing the stories and experiences of students learning Mathematics in informal contexts such as prisons, and workplace education settings (Kelly 2016), may help develop insights and understanding for future researchers, teachers, and teacher trainers.

Overview of the Mathematics in Prison Topic Group

As stated, the MiP group grew out of the discussion prompted by the fourth virtual ALM seminar "Adults Mathematics in Prison Education". This was led by Linda Ahl who presented her research on the teaching of Adults mathematics in prison education". After the discussion, ALM trustees decided to advertise the first topic group meeting through the ALM mailing list. The first gathering included participants from Sweden, UK, Canada, USA, Ireland, Northern Ireland. While some could not attend, there was wide interest who wish to keep in touch with developments of the group. We have also had queries from Asia.

The MiP group has permeable boundaries with few barriers to relations with outsiders. We have been contacted by approximately twenty people who expressed interest in the group. Not all have attended all meetings but remain in touch with the group. Some of the members of the MiP group are currently teachers of mathematics in prisons, while others work in universities, and others are researchers. People who contacted the group are mostly mathematics teachers and many are teaching at different levels from basic to advanced. Generally, education in prison follows the national curriculum of the country at many different levels, but this is an area we have not investigated in detail as this group is still at an exploratory stage.

Communication was going to be a challenge for the group, due to the different time zones and the digital divide (Hopkins et al. 2015) between those working in prisons and those in the community. The impact of this was that the groups was not all able to access video calls in work hours, so the decision was made to rotate the times of the meetings, communicate outside our work settings, to communicate online and send content to each other using technology platforms in advance of the meetings.

We reflected on the best way to communicate with those in the group before and during the meeting, and we decided to use Google Jamboard. This interactive smartboard enables teachers and students to collaborate on a virtual whiteboard, to allow to brainstorm ideas and create sketches (Virto et al 2020). We set up a link to Google Jamboard with questions composed by the group leaders ahead of the meeting. At the meeting, we invited participants to answer the questions and contribute to discussions suggested on the Jamboard.

Table 1: Questions on MiP questionnaire

Question	**Purpose**
What is your name?	To connect
What is your workplace?	To find out type of institutions, for example, secure or open.
Where s it located?	To find geographical context and possibly form local clusters.
What is your specific interest in Mathematics teaching?	To develop topic clusters.
What is your students' profile?	To see age and nationality profile
What are your students' goals?	To understand motivations.
What are your goals for the future of MiP?	To help plan.
What are your optimal times to meet?	To plan a calendar and rotate times for different time zones.
What dilemmas and challenges do you meet in your work?	To understand ethical and moral issues relevant to the work.
What words would you include in our community glossary?	Suggestion: include terms for students, staff, Mathematics.

We invited the group participants to answer on Jamboard on topics including their name, their workplace, their location, their student profile (general comments on age and nationalities), the goals of our students and their Mathematics learning objectives, the best times to meet, dilemmas and challenges we experience at work, our specific interests in mathematics teaching, our goals for the future of the MiP group, setting up a community glossary relating to our work. We are keen that the group remains open to future questions and observations from the existing members and future ones, so we plan to be flexible in organizing meetings. We are considering future formats and may look at other platforms, such as padlet.

The disadvantage of Jamboard is that anyone can remove and add material. As participants are working in prisons, there is awareness of the need for privacy and security. The decision was made to safeguard the group's discussion by sharing the link during the meeting so people could add ideas and then we closed the link so no one else could change or share it. Finally, we shared a PDF of the meeting and brainstorming with the participants. A summary of the discussion was shared with the ALM trustees.

The content gathered indicated that educators were working with a wide range of age groups, in different departmental systems and with varied resources. The use of IT within the secure systems was diverse and this is one area that could be an important source sharing ideas and approaches to developing mathematics.

One of the challenges in teaching mathematics is this sector is how to be authentic and remain true to the needs of our students. Ahl (2020) comments that discussions on prisons can create curiosity in those who are not familiar with the field. As Szifris (2018) comments, this curiosity may be fed by the lack of educational research. Other professions have researched education in prison, from their own professional lenses, whether through the perspective of criminology and the impact ion desistance, or from a psychological point of view. The MiP group are clear in our mission, which is to support and investigate Mathematics education in prisons, while respecting the dignity and privacy of staff and students.

Rationale and Statutory basis for teaching and researching mathematics in prisons

Education has been a part of everyday life in prisons for centuries, yet it is still generally under theorized (Szifris 2018). While adult Mathematics is a more limited field of research than mathematics education in mainstream areas (Safford-Ramus et al 2016) yet have skills and knowledge and adult Mathematics education in prison is even more limited. Ahl (2020) has recently added to the field in a study based on mathematics education in Swedish prisons, and who argues for more research into this specialist field. Anecdotal evidence from practitioners in the MiP meetings and from research (Creese 2016) suggests that prisoners and people in detention have unmet needs in mathematics and numeracy.

Mathematics education in prison is a basic life skill (Council of Europe 1990). Yet it varies considerably across countries and within national systems. Levels of mathematics education have been investigated in prisons in the UK (Creese 2016) and the USA (Rampey et al 2016). In Ireland priority is given to those in prison with basic educational needs, including numeracy and literacy (Irish Prison Service 2019). In the UK, Coates (2016) advocates for development of basic skills in mathematics, as well as English, and Information and Communications Technology (ICT).

Future ideas for activities in the MiP Topic Group

We look forward to presenting at CERME12 as it will help us to plan for our activities in the future, regarding the approach the group will take. We plan to gather more reflections on experiences from within mathematics classrooms in this context. This may include instructional strategies, teachers' professional development needs and experiences. We plan to collaborate on the instructional strategies and materials and their impact in classrooms that teachers share with us. Assessment in adult education is a core issue and mathematics assessment in prisons is an important concern as mathematics is a gateway subject to further education. We plan to connect with other groups related to Mathematics and education in the secure estate and correctional settings.

We plan to keep the gatherings in our groups as open as possible, some sources for discussion in this group include an educator developing a curriculum or resources for a specific group of adult learners. Another option may be to pose a problem for the group on a specific problem or project the group could reflect on why the students struggle with this topic and offer strategies on how to deal with it. Another idea could be to reflect on the impact and relevance for the practitioner of an article or book, like a professional book club. This could lead to activities and experiments in-class in the future which may confirm or challenge our original findings.

Recently two members of the MiP group presented a workshop at the Australian Correctional Education Association conference, held online. This opened the topic to a new set of researchers, practitioners and policy makers. The topic provoked discussions and interest and we expect to have new members in the group in the future, and develop links with related Australasian groups.

Conclusion

We anticipate that this topic group will provide a forum, within ALM, where Maths in prison practitioners and researchers can connect, share resources, and support each other in their work. The group is at an early stage, and we look forward to the developments in the future.

We hope that this paper and conference will help to publicize the topic group and add to the limited research in this field. The meetings have provoked lively discussion and have illustrated that the field of mathematics education in prisons has more features in common than it has differences.

We look forward to developing a dialogue on continuing professional development within this sector across national boundaries. This could take the form of pieces about practice, or it may include action research from individual practitioners' or teaching experiments. It may involve learners, their communities, and teachers, in line with all appropriate ethical guidelines. We do not yet have an overview of the different policies regarding curriculum and accreditation of Maths education in the prison context, so we hope to learn more about the role of governments in education policy on different countries.

Acknowledgment

We acknowledge the inspiration and support from the Adults Learning Maths trustees in the development of this topic group.

Research contributions to adults learning mathematics in the field of numeracy in the last twenty years

Javier Díez-Palomar[1] and Kees Hoogland[2]

[1]University of Barcelona, Faculty of Education, Barcelona, Spain; jdiezpalomar@ub.edu

[2]HU University of Applied Sciences Utrecht, Utrecht, The Netherlands; kees.hoogland@hu.nl

This paper explores the contributions of research to the field of adults learning mathematics (ALM) in the last twenty years. The results of the review of the literature on ALM show that the most cited studies that have been published in the last twenty years tend to focus on the field of numeracy to understand health data (such as understanding how to dose a medicine in a medical treatment). However, we know little about key aspects of how adults learn mathematics, what obstacles they encounter, and how they overcome them. This paper identifies the main gaps that ALM research faces in the coming years.

Keywords: Numeracy, Adult Education.

The concept of numeracy

In its origins, the word numeracy was closely related to the concept of quantitative literacy (Tout, 2020). Thinking quantitatively has been the focus in educational research focused on mathematics since the last century. As Sowder (1989) says, most of the research on how we learn mathematics over several decades focused on mathematical intuition, higher-order thinking, mental schemes for understanding mathematics, and the development of quantitative thinking. In the last forty years, it should be added that research in the field of mathematics didactics has diversified into other areas beyond the strictly cognitive.

However, almost all the research that has increased our understanding of how we learn mathematics and how we can develop those innate mathematical skills that we all have, for the mere fact of being human beings, focuses on early childhood, adolescence and up to the age of university studies (Carpenter, Dossey, & Koehler, 2004). Instead, in "adulthood", there are few investigations, and of those that do exist almost all related to literacy, functional literacy, dispositions towards mathematics, and mathematics embedded in different contexts (workplace, etc.). There are studies on what mathematics we use in adult life, measuring the ‘mathematics’ we know, the challenges that adults should know to be ‘mathematically competent’ in today's world and explorations into the vulnerability of certain people and certain people social groups who lack certain knowledge and skills. Nevertheless, there is a big gap (comparatively speaking) in research into how adults learn mathematics, what research has contributed to this regard, and the gaps that need to be filled in the coming years or decades.

The objective of this paper is to review what research is being carried out in the last twenty years in the field of ALM, to identify what are the topics that are being investigated, and where there are gaps that would open new lines of research in the future on how adults learn mathematics.

Background

The first piece of evidence we have about ALM is that adults already know maths. Mathematical knowledge (the ability to think and reason in mathematical terms) is an innate skill. In the same way, that speech is a human skill that manifests itself early when children begin to speak. Mathematical thinking is also part of our ability to represent the world and solve problems. Therefore, when we talk about learning mathematics as adults we talk about academic, formal and ‘pencil and paper’ mathematics, similar to what we refer to when we talk about literacy, for example where we speak about reading and writing in the printed letter.

Unlike literacy, where researchers claim that it refers to the knowledge and proficiency in the use of texts, in the case of numeracy, the definitions we usually use go beyond defining numeracy as the understanding and use of the ‘printed number’. As Tout (2020) says numeracy not only refers to mathematical content but is a ‘way of thinking, of reasoning, of acting’. It has more to do with a set of skills related to ‘numerated’ behavior that goes beyond the simple use of mathematical objects and their representations. That is why it is difficult to establish the boundaries of the concept and, therefore, establish the bases of didactic research on how to ‘learn’ numeracy. Numeracy seems to be an innate human trait. However, it is also learned and, from the point of view of contents, procedures and ways of thinking and reasoning mathematically, it is a complex set of knowledge.

Another problem is the invisibility that some authors, such as Wedege (2010), have pointed out around mathematics and numeracy. That is, there are forms of thought and reasoning that are typical of mathematics. However, as they are part of our way of representing and understanding the world around us, they are not recognized as ‘mathematics’ (nor as numeracy). Examples that help to understand this paradox (well-studied in the field of ALM) are, for example, making estimates, identifying quantities, and comparing them with each other, considering risks associated with the subjective perception of probability, etc. Many people play the lottery because they are hoping to win the prize. They also decide to go out for the weekend after watching the weather forecast on TV. However, it is more difficult to find people who, before buying the lottery number, use Laplace's rule to calculate the probability they have of winning the prize, we do not make a count using the laws of combinatorics of how many different chances there are of obtaining the six winning numbers of the weekly lottery (among the 36 possible), nor do we use the density distribution of the event ‘being sunny’ or ‘raining’ when we prepare to spend the weekend away from home.

This apparent ‘over-definition’ of the concept of numeracy poses difficulties, as evidenced by the fact that it has been a concept that has been evolving since it first began to be used in the mid-twentieth century (Hoogland et al., 2019). During all these years, the concept of numeracy has gone from being defined as the knowledge of basic arithmetic objects and procedures (knowing how to add, subtract, multiply and divide, and some of the rules and properties of basic operations) to being defined as a social practice that involves the use of numbers (and mathematics by extension) to solve problems of everyday life, make decisions, value information and act on the world around us (multifaceted concept).

Teaching numeracy to adults

Different studies show that when children enter kindergarten at 3 or 4 years old, they already have developed what we would call ‘number sense’ (Westwood, 2021). Children know how to make comparisons between numbers, they know how to discriminate between quantities, and they know how to count accurately. So, when they get to school, what do they learn? According to research in our field, it seems clear that what they learn is the ‘academic’ language of mathematics, including the written representation of numbers and their characteristics and properties. They learn to reason with numbers. They are presented with ‘problems’ and asked to solve them, training them to develop that innate capacity that we all have, which is to solve problems.

Furthermore, that is called ‘teaching math’. According to the type of mathematical object being taught, we will discuss arithmetic, algebra, geometry, etc. Mathematical objects, as we know, are part of conceptual structures, the components of which are very precisely related. For some, mathematics is the ‘language of precision’, such as Ernest (2003) reflects upon when he analyzes the different philosophies of mathematics.

We have some indications of explanatory models of how learning works: for example, Dreyfus and Dreyfus (2005) argue that teaching first goes through verbal descriptions and rules, then the second phase of association, and a third of automation; they affirm that learning is a more global process (holistic), in which holistic patterns are recognized because of interaction with the environment in multiple different situations. Hatano (1988) confirms this, claiming that learning goes beyond rule-based knowledge.

Nevertheless, what happens when we talk about teaching and learning mathematics in adults? There is no accumulated knowledge base on how adults learn mathematics comparable to the work that has been done with children and young people.

Therefore, in this paper, we have conducted a systematic review of the literature, looking for everything that has been written about adults and numeracy in the last twenty years to see to what extent the previous statement is true (or not).

Methods

To answer the research question posed here, we have conducted a systematic review of studies into numeracy and adults published in journals included in the Web of Science database from January 1, 2000, to June 1, 2021. To perform the query, the words *numeracy* AND *adults* were used.

The search generated a first database of a total of 843 articles published in that period. To select a sample of them, the following procedure was followed:

(1) We sorted all articles by the total number of citations, from the one with the most citations (1,836 citations) to those with no citations.

(2) The articles were grouped by quartiles, generating four groups ordered according to citations: A, B, C and D, as shown in the attached Table.

Table 1: Grouping of articles according to quartile by the level of citations

	Range of citations		Range of citations
A (25%)	19- 1,836	C (75%)	2-6
B (50%)	7-18	D (100%)	0-1

(3) From each quartile, (the first) ten articles that met the following criteria were chosen:

- Articles with a defined research question, a clearly explained methodology (that meets the criteria of replicability, reliability, and validity), a section of results, and conclusions (answer to the research question). We excluded all articles of a conceptual, reflective nature and those which are not based on empirical research.
- Articles that deal with the learning of mathematics of adults.
- Articles that comply with the dimensions and components of empirical studies from an adaptation by Taylor et al. (2021), as shown in Table 2.

Table 2. Criteria characterizing the components used to select the empirical studies on numeracy by dimension (adapted from Taylor et al. 2021)

Criteria	Dimension	Component
Clear identified research question(s)	Research Design	Rigor
Appropriate unit of study (school, classroom, adult learner,...)	Research Design	Rigor
Clear description of the research design	Research Design	Rigor
Target population defined	Research Design	Rigor
Appropriate statistical analysis	Research Design	Rigor
Appropriate qualitative analysis	Research Design	Rigor
Clear defined unit of analysis	Research Design	Rigor
Consent forms	Research Design	Rigor
Valid and reliable measurement	Research Design	Measurement validity
Size and significance effects are reported	Research Design	Reliability
Limitations are reported	Research Design	Reliability
Use of randomness as criteria for selecting the sample	Research Design	Reliability
Triangulation	Research Design	Reliability

Evidence of transferability to other contexts	Research Design	Generability
Adequate description of the sample /intended population	Research Design	Generability
Description of the research activities conducted	Research Design	Replicability
Clear information about the financial sources (grants, etc.)	Research Design	Independence of the researcher
Consistent, statistically significant positive effect on an outcome	Effectiveness	Overall effectiveness
Findings are reported across different contexts	Effectiveness	Consistency of effects
Contributions persist over time	Effectiveness	Sustainability
Clear criteria to identify the target population	Impact	Inclusion criteria
Detailed documentation of all components of the study (how, to whom, and by whom is intended to be conducted)	Impact	Implementation feasibility
A clear description of the intended effects in the consent forms	Impact	Implementation feasibility

The total sample of selected articles has been 40 articles, ten from each of the quartiles.

Results

Below are the results obtained from the analysis of the sample of forty selected articles.

First quartile

Almost all the articles in the group that generate the most citations are articles in the field of health, published in journals of medicine, nursing, or health psychology. The most recurrent theme that appears in these articles is the study of the extent to which adults who participate in them can read and interpret the instructions of the medicines to apply the doses correctly. Many studies investigate the skills of nurses to apply the doses of medicines to patients correctly. There are also some studies on the understanding of risk and probability in decision-making. From the point of view of higher-order skills, most of the selected articles focus on the processing information skill or the problem-solving skill. In half of them, we have identified the skill of critical thinking' none refer to managing situations. Regarding the contents that appear in the selected articles, most focus on quantity and number'. The two other contents that appear are 'pattern, relationships and change' and data and chance. There is no article that talks about the use of the calculator, the use of apps or spreadsheets, or digital skills.

Second quartile

In the second quartile, we find the same trend as in the first quartile: most of the articles that appear are published in health journals (medical research, neurological sciences, neuropsychiatry), although we also find a journal of gerontology and another on literacy and numeracy studies. Finally, there are two articles published in a generic journal as Plos One. Regarding the research topics, the topics are more diverse than in the case of the investigations of the first quartile. In the previous group, we also found some studies on misunderstandings in adults with cognitive impairment when reading medication instructions. However, in addition to that topic, we find other research topics: the understanding of risk estimates using an online risk calculator when outcomes are expressed using integers, the impact of age on non-optimal decision-making, the management of domestic aspects using the Internet (shopping and banking skills), the financial literacy of adults, among others. On higher-order skills, unlike the studies reported in the first group, here we find that most refer to critical thinking or processing information. We also find somewhere that the problem-solving skills of adults are studied. From a content standpoint, most focus on quantity and number. We also find other topics more punctually, such as data and chance or the patterns, relationships, and change. It highlights that several of them include the use of digital applications.

Third quartile

In this third group of articles, some study of the field of medicine continues to appear. Nevertheless, unlike previous groups, these types of studies are the minority. The studies in this group are published in journals from various disciplines, such as education and development, policies, and assessment. As you can see, most are journals in the field of education. The topics studied are numeracy skills and labour market outcomes among indigenous populations, comparison between groups of adults from different socio-economic classes based on PIAAC results, assessment of objective and subjective health about numerical skills, perception of the incidence of specific disease and the survival rate, interactions between adults and children in contexts of learning informal mathematics (grocery store), etc. From the point of view of higher-order skills, in this group, the studies focus on skills such as processing information, problem-solving or critical thinking in the vast majority. We found no case of mathematizing or managing situations. Regarding the analyzed mathematical contents, those related to the dimension of quantity and number appear above all. In some cases, also what refers to data (using and reading statistics) and chance (making predictions, assessing the opportunity/risk of making a particular decision).

Fourth quartile

In this fourth group, the articles that are most cited are published in education or lifelong learning journals, specifically aimed at adult education. There are also some articles in specialized journals of mathematics education. In a minority way, journals from the field of health appear. From the point of view of the topics studied in the articles of this group, there are studies on how adults solve problems in the context of everyday life (evidence problems), the result of tests to measure the level of numeracy measured with tests (both standardized, such as PIAAC, and tests created *ad hoc*). There are also several studies related to motivation (emotional dimension), anxiety about mathematics, etc. Finally, we also find studies on the type of mathematics and mathematical skills needed to develop certain occupations in the labour market, mainly of an ethnographic (observational) nature. From the point of view of higher-order skills, in these studies, it is customary to study the skills of analyzing situations, processing information, and to a lesser extent, problem-solving and critical thinking. As far as mathematical content is concerned, they usually focus on aspects of quantity and number, or data and chance.

Discussion and conclusions

The first result we have is that the vast majority of empirical studies are in the field of health and refer to aspects such as literacy and numeracy to understand the instructions regarding the dosage of medicines, or the understanding and application of medical treatments, or related to considering the pros and cons to make a particular health decision. In all these cases, the most outstanding aspect that appears in the studies is how adults can understand quantitative data, read the representations of that data (graphs, tables; but also, data of absolute frequencies, or percentages), and compare one set of data with another, to make decisions based on that understanding. In addition, study aspects include the understanding and management of risks and the making of decisions in environments of uncertainty with limited information.

A second result that we have found is that there is an excess of articles which consists of reflections, narratives, conceptualizations, etc., with as main content considerations, theoretical points of view, which are illustrated with concrete examples, discussions on research already published (meta-research), and specific cases of the knowledge of the author(s).

Third, the empirical studies on ALM suggest that adults learn from making connections: new mathematical objects are incorporated into our previous cognitive schemes. Several studies suggest that adult math learning is contextual: we use our experience knowledge (in the workplace, at home, in the supermarket, etc.) to incorporate new mathematical objects into our mathematical knowledge. To do this, we usually use skills such as processing information, problem-solving, and critical thinking.

Fourth, this literature review shows that one of the lines of research in ALM is on emotions. There are several studies related to the emotional response that adults give to mathematics and its learning.

Finally, fifth, the most remarkable result we have found is that the actual process of learning mathematics by adults is hardly investigated. This is reflected in the topics that appear in scientific databases such as WoS (Web of Science) which focuses mainly on what topics adults should learn, such as functions, logarithms, derivatives, geometric theorems, spatial thinking, probabilistic reasoning and Markov chains. We didn’t find much research on what actually happens when an adult is learning a mathematical concept and how s/he solves mathematical problems (Contextually? Drawing on everyday experience? Through interactions?). We didn’t find evidence if what we know from studies from different perspectives, such as the semantic fields, the cognitivist approach, socio-cultural studies, also applies to the case of adults.

Our main conclusion is that much more research is needed in the field of ALM, at least to contrast with what we know about research on learning mathematics with children and young people. Does it apply in the same way to adults? Or does adult learning works differently and, therefore, do we have to teach/support it in other ways (impact on the curriculum), and evaluate it also in other ways (impact on assessment, such as PIAAC, for example)?

Limitations

The scientific literature review study presented here is not exhaustive. A systematic literature review process has been followed, using WoS (Web of Science) to identify scientific articles on numeracy in the field of adults learning mathematics. However, we are aware that despite this effort to systematize, it is impossible to have reached the total number of studies carried out in this area and on this subject throughout the world.

The sample has a noticeable bias towards certain topics, because the different fields of research have different traditions from the point of view of citations. Thus, for example, in medicine, there is a greater tradition of citation than in other areas, which explains the over-representation in our sample of articles published in this type of journal. For further studies, it is planned to correct for this effect. But on the other hand, we must also consider that the level of citation is also an indicator of the visibility of the work.

Measuring numeracy skills mismatch with PIAAC data

Tina Dulam[1] and Kees Hoogland[2]

[1] HU University of Applied Sciences & Utrecht University, Utrecht, The Netherlands; tina.dulam@hu.nl

[2]HU University of Applied Sciences Utrecht, Utrecht, The Netherlands; kees.hoogland@hu.nl

We assess the incidence of numeracy skills mismatch in five countries: Belgium, Chile, Italy, Netherlands, and the United States of America. To do this, we make use of a new approach (Brun-Schamme & Rey, 2021), namely by identifying someone as being mismatched if the score for numeracy skills is outside the interval [median – SD , median + SD]. *We make use of the PIAAC dataset, collected by the OECD, a survey that measures adults' proficiency in numeracy among other type of skills. We find that 14% of the workers are over-skilled, whereas 16% are under-skilled. Being over-skilled is more likely for men, younger age-groups, having a high level of education, using numeracy skills often at work, and having studied science, mathematics, and engineering.*

Keywords: Numeracy, skills mismatch, over-skilled, under-skilled, occupations.

Introduction

The world has seen major developments in technological progress, human capital formation, and labour demand. Numeracy has increasingly become one of the crucial basic skills for adults to cope with the digitalised and technologized 21st-century society. Having an adequate numeracy level determines the success of individuals' participation in their roles as citizens and professionals. Hence there is a need to measure the numeracy proficiency and whether there is a good match between the possessed skills and required skills in numeracy.

Skills mismatch, defined as possessing qualifications or skills that does not adequately meet the qualifications or skills necessary for the doing one's job, has negative effects at all levels of the economy: at individual (micro) level, skills mismatch is leads to lower job satisfaction and wages. At company (meso) level mismatch leads to a higher staff turnover, and inefficiencies. At country (macro) level, to unemployment, lower productivity[1] and lower economic growth mainly due to wasting human capital (OECD, 2013). The aim of this study is to inform national policymakers on lifelong learning especially regarding numeracy and the mismatch of skills.

The Programme for International Assessment of Adult Competencies (PIAAC), a major survey conducted by the OECD in over 40 countries, provides the opportunity to measure skills proficiency (in literacy, numeracy, and problem solving in a technological rich environment) and the degree to which people are well-matched in a harmonized way. This paper focusses on numeracy skills, because 1) these skills are the most comparable throughout different countries (Perry et al., 2016) and 2) these skills have a mathematical foundation.

[1] Being under-skilled can lead to lower productivity because the worker is performing below the required skills.

The OECD (2013) defines numeracy skills as “the ability to access, use, interpret and communicate mathematical information and ideas in order to engage in and manage the mathematical demands of a range of situations in adult life.” To this end, numeracy involves “managing a situation or solving a problem in a real context, by responding to mathematical content/information/ideas represented in multiple ways.”

Theoretical background

Human capital is formed by the skills and education an individual gains over time (Wiederhold & Ackermann-Piek, 2014). Human capital positively affects an individual’s success, and productivity. To put skills to effective use, it is important that they are aligned with the required skills at work. Wiederhold and Ackermann-Piek (2014) discuss the reasons why workers may be over-skilled or under-skilled. Factors that may play a role are shifts or changes in the economy, the occupation type, the timing in the professional career (experience), discrimination in the labour market, and family responsibilities.

Pellizari and Fichen (2013) developed a theoretical framework to define and measure skills mismatch with PIAAC data. In this framework jobs are defined as production functions and skill use, which is treated as an endogenous choice of the worker, is considered as the only input. The model furthermore assumes that there are fixed costs to carry out the job and that the marginal product of used skills is locally constant and that it declines above a certain threshold (it is equal to zero). These assumptions lead two critical values in the definition of skills mismatch, namely that workers with a skill proficiency below the lower critical value are under-skilled and workers above the upper critical value are over-skilled. Furthermore, the model assumes that production technologies of firms do not change and that the skills mismatch is measured in the short run.

Several studies (OECD, 2013; Perry et al., 2016, McGuinness et al., 2018, Flisi et al., 2017, Allen et al., 2011) have used PIAAC data to measure skills-mismatch in various ways. This paper applies the latest approach as developed by Brun-Schammé and Rey (2021) to measure numeracy mismatch. Flisi et al. (2017) provide 20 indicators for occupational mismatch for 17 European countries, whereas Perry et al. (2016) evaluates six measures for mismatch. The preferred method by the OECD, developed by Pellizari and Fichen (2013), is the method where self-reported[2] mismatch is identified as an objective measure (whether the score for numeracy skills exceeds 95th percentile of the distribution within the same occupation or whether it is lower than the 5th percentile of the distribution). The main argument against this method is firstly, the bias raised due to overconfidence or misinterpretation, and secondly, that the mismatch is measured within one-digit occupational code leaving little room for the heterogeneity within the 1-digit occupation. Brun-Schammé and Rey’s approach therefore make use of the two-digit occupation code to take some more heterogeneity into account (ending up with 40 occupational categories instead of 10). It assesses the skills mismatch for France and categorizes someone as being mismatch if the score for numeracy skills is outside the mean and one standard deviation. Using this approach, we assess the prevalence of skills mismatch

[2] By asking workers whether they can do a more demanding job or whether they need extra training to their job.

in five countries, and look for associations between mismatch and socio-demographic and job-related characteristics such as job satisfaction, wages, and skills use.

Data and methods

The PIAAC dataset is based on an international comparable survey conducted by the OECD in over 40 countries in three rounds: the first one in 2011-12, the second in 2014-15, and third in 2017. The data we use are for Belgium, Netherlands, and Italy from the first round, Chile the second, and the USA from the third round. Around 5000 non-institutionalized people per country were surveyed. To obtain representative results, the sample was chosen through a multistage clustered design. The proficiency scores in the original dataset were based on the Item Response Theory scaling methodology resulting in 10 plausible values for each type of skill proficiency in the dataset (Yamamoto et al., 2013).

We perform a quantitative analysis, by measuring the incidence of numeracy skills mismatch conforming to Brun-Schammé and Rey (2021) as follows. Firstly, we calculate the median and standard deviation of the numeracy skills score[3] for each two-digit ISCO occupation. Secondly, we qualify a worker as being over-skilled if the score for numeracy proficiency score is above the median plus one standard deviation and as being under-skilled if the numeracy proficiency score is below the median minus one standard deviation.

We furthermore perform binary logistic regression to study the association between mismatch and socio-demographic and job-related variables. Our sample size is 12,166 in total.

Table 1 below provides the statistics. We see that on average 14% of the workers are over-skilled and 16% under-skilled. A critique from Pellizari and Fichen (2013) is that having a mismatch percentage of 30% can be attributed to the normal distribution of numeracy proficiency skills score. In a normal distribution, for instance, 32% will score below or above one standard deviation from the median. Nevertheless, it can be interesting to find out which variables are associated with being over-skilled and under-skilled respectively.

Table 1: Descriptive statistics

Variable (in percent)	Total	Belgium	Chile	Italy	Netherlands	USA
Over-skilled	14.13	13.56	15.49	14.29	13.18	14.6
Under-skilled	16.37	17.35	16.43	16.66	16.24	14.76
Gender (% of women)	50.64	49.76	50.84	48.69	50.6	53.87
Education level

Results

Figures 1-4 below are based on performing a binary logistic regression of being over-skilled on gender, age-group, education level (alternated by area of study), migrant status, occupation, working part-time or not, firm size, and numeracy use at work. The country was entered as a control variable. In the figures we see the probability of being over-skilled by each of these variables.

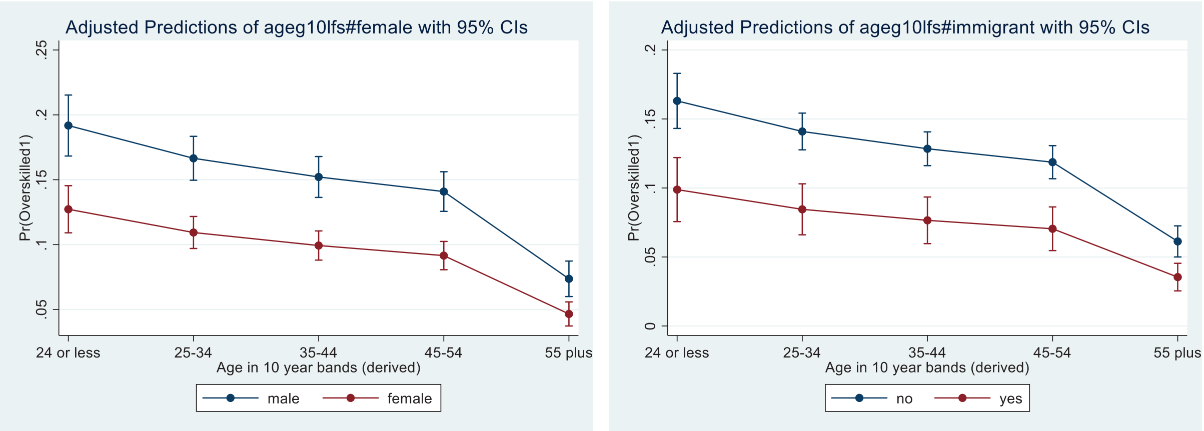

Figure 1: The probability of being over-skilled by gender, age-group, and migrant status

Men are significantly more likely to be over-skilled than women, controlling for other factors. The probability is 18 percent for men, compared to 14% for women. The probability of being over-skilled declines over years.

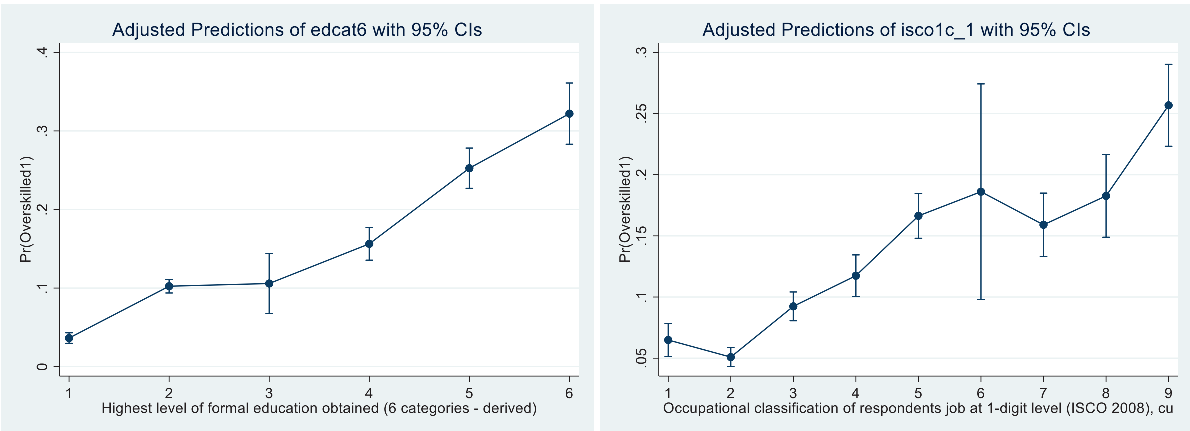

Figure 2: The probability of being over-skilled by education level[4] and occupation[5]

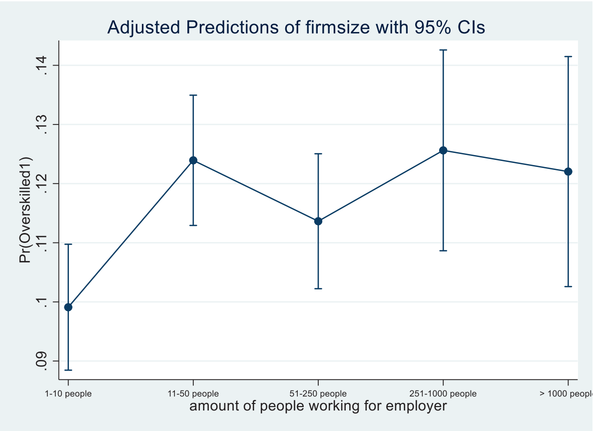
Being higher educated has a significant positive association with being over-skilled, controlling for other factors. People in elementary occupations are more likely to be over-skilled than people in other occupations.

[4] Legenda: 1 = Lower secondary or less (ISCED 1,2, 3C short or less), 2= Upper secondary (ISCED 3A-B, C long), 3 = Post-secondary, non-tertiary (ISCED 4A-B-C), 4 = Tertiary – professional degree (ISCED 5B), 5 = Tertiary – bachelor degree (ISCED 5A), 6= Tertiary – master/research degree (ISCED 5A/6)

[5] Legenda: 0 = Armed forces, 1 = Legislators, senior officials and managers, 2 = Professionals, 3 = Technicians and associate professionals, 4 = Clerks, 5 = Service workers and shop and market sales workers, 6 = Skilled agricultural and fishery workers, 7 = Craft and related trades workers, 8 = Plant and machine operators and assemblers, 9 = Elementary occupations



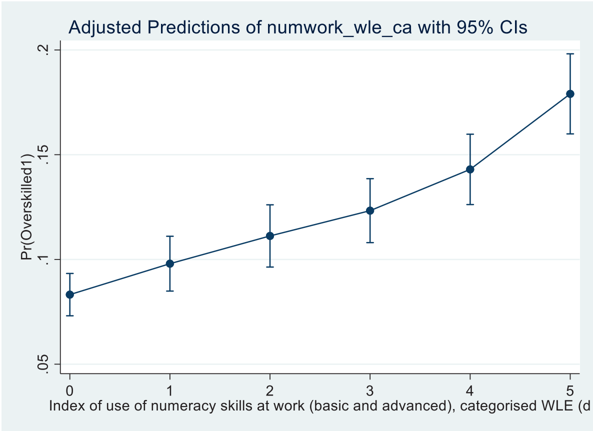


Figure 3: The probability of being over-skilled by firm-size and use of numeracy skills[6]

There is no significant difference in the probability of being over-skilled across firm of various sizes. Furthermore, we see that the likelihood of being over-skilled increases as the frequency of using numeracy skills at work increases.

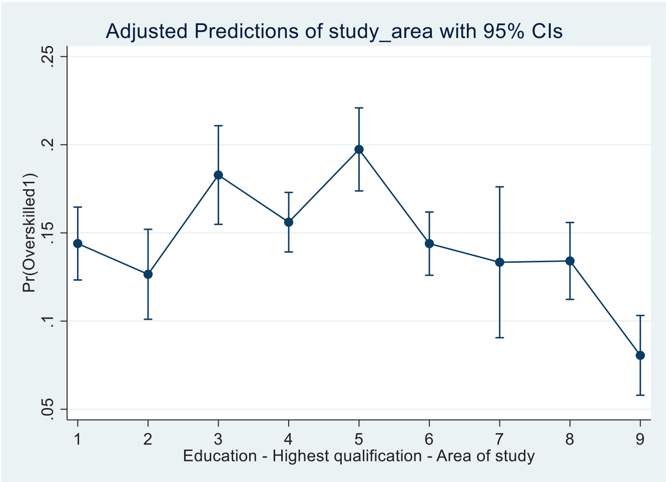

Figure 4: The probability of being over-skilled by area of study7

Being over-skilled is significantly more likely for people who studied science, mathematics and computing and significantly less likely for people who studied services.

Conclusion

Being over-skilled is more likely for men, younger age-groups, higher education, and for people who use their numeracy skills often at work. Also, people who studied science, mathematics and computing are significantly more likely to be over-skilled. Our results are largely in line with what earlier studies showed, although we used a different measure and other sample set. Further studies

---

[6] Legenda: 0 = All zero response, 1= Lowest to 20%., 2 = More than 20% to 40%, 3 = More than 40% to 60%, 4 = More than 60% to 80%, and 5 =More than 80%

[7] 1 = General programmes, 2 = Teacher training and education science, 3 = Humanities, languages and arts, 4 = Social sciences, business and law, 5 = Science, mathematics and computing, 6 = Engineering, manufacturing and construction, 7 = Agriculture and veterinary, 8 = Health and welfare, 9 = Services

should focus on the reasons why certain study areas are significantly associated with the probability of being over-skilled and on improving the measure for mismatch.

A desire to have students and citizens who are numerate and effective problem solvers is a common goal internationally (Gal & UNESCO, 2020). This desire is no different in an Irish context across all areas of education including adult mathematics education (SOLAS, 2020). This research used diagnostic testing to determine and compare the mathematical problem solving and procedural skills of a cohort of adult students in an Irish University. The diagnostic test, which was developed by the authors using the second level mathematics curriculum in Ireland as a guide, revealed that all adult students had statistically significantly lower mathematical problem solving skills when compared to procedural skills. These findings raise concern about the problem solving skills of adult learners. Discussion around the implications of such findings for best practice in adult mathematics education are outlined.

Keywords: Adult mathematics education, undergraduate mathematics education, diagnostic testing, procedural skills, problem solving skills.

Introduction

The desire of having numerate citizens and students who can problem solve effectively is often driven by a nations need to stay economically competitive (Perkins & Clerkin, 2020). Adult mathematical numeracy is essential to ensuring job markets, economies and societies prosper in addition to the having a key role in improving the lives of citizens (Gal & UNESCO, 2020). Much literature exists on the importance of the development of problem solving skills in mathematics (IBEC, 2015) and a subsequent need to use effective pedagogical practices to support this (Foshay & Kirkley, 2003). Despite these uncontested and commonly reported findings adult mathematics education is often overlooked when it comes to providing appropriate provision in terms of its development and improvement (Gal & UNESCO, 2020). The aforementioned body of research has resulted in an overhaul of the second level mathematics curriculum in Ireland in addition to heavily funded government programmes to upskill second level teachers. The same opportunities or investment have not been afforded in adult mathematics education. In an era where equality, diversity and inclusion are at the fore front of all higher education policies it seems remiss that those less advantaged, i.e., adult students on an [1]Access Foundation Programme, are not offered at least the same supports and opportunities as the more advantaged in society. Some details of the overhaul to the second level mathematics curriculum in Ireland in 2010 as well as some literature surrounding problem solving in general and in the context of the new mathematics curriculum in second level education is also discussed in order to provide context for the development of the diagnostic test used within this research.

Literature Review

The second level mathematics curriculum in Ireland

In 2010 a new mathematics curriculum was introduced in second level education in Ireland entitled ‘Project Maths’ (PM) (Prendergast et al., 2017). The rationale for the introduction of a new curriculum was to change from the traditional ‘chalk and talk’ teaching methodologies predominately being employed so that students would have improved understanding of mathematical concepts and improved engagement with the subject (Hourigan & O’Donoghue, 2007). The change from more traditional approaches to teaching mathematics to more student-centred approaches which focus on teaching for understanding was partially due to Irish students' comparative poor performance on an international platform (Humphreys, 2015). Another motivator for the change was the emerging literature relating to the constant and steady decline in students’ basic mathematics skills on entry to third level education over the past two decades (Faulkner et al., 2010).

Like previous studies in the area Treacy and Faulkner (2015) found that students’ basic mathematical skills on entry to third level education, between 2003 and 2013, had declined. This study examined a time period which included students pre and post PM. What seemed positive about this study's findings however was the suggestion that students' problem solving skills may have improved over this time period. An examination of lecturers' perceptions of the change in mathematical performances, if any, after the introduction of PM found that lecturers felt that students’ procedural skills were still on the decline but that possibly their openness to working with mathematics problems and problems that were not familiar to them when compared to previous cohorts of students had improved (Prendergast et al., 2017)

Problem Solving in Mathematics

The need to document and improve students' problem solving skills through new and innovative pedagogical practices is omnipresent in education literature however it is not a straightforward practice to implement or even a concept that is very well understood (Kilpatrick, 1969). Despite the challenge of defining problem solving in mathematics and understanding the best approaches to teaching it effectively it remains to be a skill that is very much desired by both employers and those in higher education institutions (Vordermann et al., 2011). The desire for this problem solving skill set often stems from it reportedly not being at the disposal of many school leavers (Jones et al., 2014).

---

[1]The Access Foundation Programme is a one year preparatory programme for students wishing to peruse an undergraduate programme at certificate or degree level in Ireland. The programme provides a root to education for students from communities which lack a strong tradition of participation in third level education.

Additionally, research in this area emphasises the long length of time that students spend in formal education learning mathematical skills which they then find very challenging to transfer to further education and/or a working environment (Treilibs, 1979). Such realisations have resulted in many countries, including Ireland, trying to change their school curricula in response to the issues students are displaying with applying problem solving skills in mathematics upon leaving school (Soh, 2008). This "hiatus" between formal mathematics education and the workplace has also been acknowledged in research by FitzSimons and Boistrup (2017) who offer some suggestions as to how to overcome such issues by recontextualising the mathematics in different types of work and how the recontextualization could be incorporated into formal education settings so that the mathematics can be identified, and a context can be offered. The approach to improving problem solving employed in second level education in Ireland is considered next.

Problem Solving and Mathematics Education in Irish Second Level Schools

Project Maths and Problem Solving

The second level Project Maths curriculum in Ireland defines problem solving as the following:

"Problem Solving means engaging in a task for which the solution is not immediately obvious. Problem solving is integral to mathematical learning. In day-to-day life and in the workplace the ability to problem solve is a highly advantageous skill. In the mathematics classroom problem solving should not be met in isolation but should permeate all aspects of the teaching and learning experience. Problems may concern purely mathematical matters or some applied context."

The description of problem solving outlined in the PM curriculum can be seen to be in line with Polya's (1945) interpretation of problem solving which involves engaging with real problems by guessing, discovering and trying to make sense of mathematics. It has also been likened to the Programme for International Student Assessment (PISA) which consists of theoretical underpinnings focus on everyday problems that often occur when interacting for example with a device that is unfamiliar for the first time (OECD, 2014). This could be seen to be in contrast with the previous focus of the Irish second level mathematics curriculum in which problem solving was more commonly described as 'an ideal of problem solving' (McClure, 2013) where the focus is on solving a set of 'problems' using prescribed and practiced techniques (Faulkner et al., 2021). Details of the diagnostic test that was developed, and informed by PM, are outlined in the methodology section which follows.

Methodology

Measuring Problem Solving: The Diagnostic Test

A diagnostic test was developed to determine students' problem solving and procedural skills in mathematics on entry to adult and undergraduate education.

Diagnostic Test Design

Four mathematics educators from two higher education institutions in Ireland developed the paper based diagnostic test. The diagnostic test was designed with a focus on examining the basic mathematical skills of students beginning their studies who hoped to pursue degree programmes with an engineering/technology focus. Several controls were put in place to ensure that the test measured what it had set out to. Such controls included using the second level mathematics curriculum and its interpretation of what constitutes problem solving skills as a guide. The initial draft of the test was examined critically by five mathematics education specialists from different institutions around Ireland and the feedback was incorporated to improve the test prior to distribution.

Contents of the Diagnostic Test

The diagnostic test is broken down into two sections: Procedural questions (Section A) and problem solving questions (Section B). Both sections consist of 11 questions in total. Each question in section A of the test is paired with a question in section B i.e., the paired questions require the same procedural skill(s) to successfully complete them with the section B questions also involving some real-world context. All of the section B questions were sourced from state examination papers that second level students take when completing their second level schooling in Ireland. It was thought that taking questions from the state examination papers allowed for the diagnostic test to directly mirror the second level curriculum's interpretation of what constitutes problem solving (Faulkner et al., 2021).

Data Analysis

The Statistical Package for Social Sciences (Version 22.0) was used to analyse and interpret the diagnostic test data. Independent samples t-tests were used to test for statistically significant differences between the mean performances of participants with different demographic backgrounds. Chi-squared tests were used to test for statistically significant associations between the qualitative variables. A 5% level of significance was used for all tests and no adjustment were made for multiple testing. It should be noted that the aim of the research was purely quantitative in nature, i.e. to determine and compare students procedural and problem solving skills in mathematics, rather than a more in depth investigation into students approaches to completing the diagnostic test questions.

Sample

Within this study 87 students undertook the test. Of these students 34.5% (30) were adult students from the Access Foundation Programme. These adult students were enrolled on an advanced mathematics module with the intention of pursuing a degree programme which has a technology/engineering focus. The advanced mathematics module contains content that mirrors that completed by second level students. 65.5% (57) were first year undergraduate students enrolled in an engineering programme. These two groups of students were chosen for comparison in this research as both were currently/intending to pursue a similar undergraduate discipline (engineering/technical focus) and it was of interest to the authors to determine and compare their mathematical skills and preparedness. It was also of interest to see if the traditional students coming from second level mathematics education were demonstrating equally as good problem solving skills as procedural skills in mathematics or did the adult students perform better than the traditional students and could this possibly be linked to skills previously learned in the workplace. It should be noted that all the Access Foundation Students with the except of 1 were male.

Results

Adult and engineering students were examined as one group initially and the results showed that students performed statistically significantly better in the section A ($\bar{x}$= 57.2) than they did in section B of the test ($\bar{x}$= 32.3) (p=0.00).

The data was then examined by analysing how the adult students' performance compared to the engineering students' performance. This analysis found that the adult students' performed to a statistically significantly lower standard when compared to the engineering students in both section A and section B of the diagnostic test (p=0.00).

Further analysis of the adult students found that they performed statistically significantly worse in section B (=18.7) of the diagnostic test when compared to section A (=43.1) ($p<0.001$). The same analysis was carried out for engineering students and found that they performed statistically significantly worse in section B ($\bar{x}$=39.5) of the test when compared to section A ($\bar{x}$= 64.6) ($p <0.001$).

Discussion

All students (adult and engineering) performed statistically significantly better in the procedural section of the diagnostic test (i.e., Section A) when compared to the problem solving section of the test (i.e., Section B). Therefore, the strengths and weaknesses of each group of students was found to be the same despite the adult students performing to a lower standard overall. The demographic of students that was most likely to perform better in all aspects of the diagnostic test were those who were enrolled on the engineering programme and were male and Irish. Despite this however this characterisation of student still performed statistically significantly worse in section B of the diagnostic test compared to section A. These findings highlight the apparent challenge that all student cohorts within this research have with applying what could be considered basic mathematical concepts to applied scenarios. The concepts required to answer the paired questions are the same. For example, Q5 in section A asks students to calculate the difference in area between a rectangle and a circle and the paired question in section B asks students to determine how much of a pool area (rectangular in shape) is taken up by a jacuzzi (circular in shape)

It is however acknowledged that there is a possibility of some intrinsic difference in difficulty level between the questions in each section of the test due to the problem solving questions requiring more processing to successfully complete the questions. This is certainly likely to be the case when the adult mathematics students are considered as they have not been exposed to a second level school system for a long period of time and if/when they did the teaching approach would have been very much focussed on chalk and talk teaching methodologies with little focus on context or problem solving. The finding is therefore of more note when the engineering students are considered as the teaching approaches that they have been exposed to in second level education in recent years (i.e., problem solving focussed) might be expected to negate or at least reduce the additional challenge that the problem solving questions may present (Faulkner et al., 2021).

When we consider the example of Q5 previously given in the context of the engineering students it raises questions about how traditional students are adapting to learning mathematics in second level education which is not solely based on procedural skills and involves some level of real world thinking and contextualisation. Research has indicated that engineers are graduating with good knowledge of fundamental engineering science and computer literacy but little ability to apply this in practice (Mills and Treagust, 2003). The suggested challenges faced by traditional students in undergraduate mathematics who have been exposed to problem solving teaching methodologies in second level education should be recognised by those in adult mathematics education wishing to employ such teaching methodologies.

As previously alluded to perhaps it is not as surprising that the adult learners do not perform as well as the traditional students predominately entering higher education directly from second level education. It is possible that literacy issues also play a key role in the challenge that the adult learners face. This has been found to be the case in related research into adult mathematics education (Prendergast et al., 2017). Although the anticipated challenge of literacy was considered and acknowledged in the development stages of Project Maths it was deemed a necessary challenge for those wishing to be successful in problem solving across all disciplines (Foshay & Kirkley, 2003; Faulkner et al., 2021).

So, what can we learn in terms of adult mathematics education? We know that those in adult mathematics education display similar patterns of challenges in terms of their procedural and problem solving skills as compared with traditional students however to a larger degree. We also know that adult learners despite this common initial underperformance and categorisation of being 'at risk' of failing mathematics often improve to a large degree due largely to engagement with mathematical support services (Faulkner et al., 2021). The focus however for those in adult mathematics education is so often on remediation rather than on proactive measures to ensure best practice is in place for them for example via engaging in mathematics education with appropriately trained mathematics educationalists. A focus in adult mathematics education on problem solving skills in mathematics is needed for the same reasons that it is advocated and provided for in second level education. Adult mathematics education deserves at least the same level of teaching qualifications that those in primary and secondary education in Ireland have. There is a new phenomenon in educational research currently being examined relating to what have become known as out-of-field teachers of mathematics. These are teachers in second level education who are teaching mathematics but not suitably qualified to do so. Continuous professional development programmes are now being put in place to upskill such teachers (Hobbs & Törner, 2019). The norm is adult mathematics education is to have out-of-field teachers and no such measures have been put in place; this needs to become part of the national and international agenda.

Conclusion and Recommendations

Although initial studies into PM have indicated that students' problem solving skills may have improved in recent years (Treacy & Faulkner, 2015) and that lecturers perceive students as being more open to engaging with unseen mathematics problems (Prendergast et al., 2017), this research highlights the comparatively weaker skills that those in adult mathematics education demonstrate in problem solving in mathematics compared to procedural skills in mathematics. This pattern of performance is mirrored amongst those in beginning undergraduate engineering programmes despite them coming directly from a second level mathematics education which has come to focus more on problem solving and teaching for understanding. Acknowledgement should be given to future work in this area taking into account the greater conceptual challenge faced by students when completing the problem solving questions and a more detailed marking scheme than right/wrong should be therefore be considered when analysing students' performance in this area.

The rationale behind the changes made to second level mathematics education is research based and changes/improvements in students' performances on entry to higher education may take time to become embedded. Attention must be given however to the relatively similar challenges evidently faced by adult mathematics students in problem solving and the lack of provision and investment in their mathematics curriculum and teacher training. Such disparity has been raised in this research paper and should be investigated further to provide a platform for improved future provision of adult mathematics education. The 'Adult numeracy: Assessment and development' policy outlines the significant numeracy challenges faced internationally and makes 3 recommendations one of which involves "investing in the development of national capacities to measure and improve adult numeracy" (Gal & UNESCO, 2020, p.3). This international and recent recommendation very clearly aligns with the research being outlined.

Psychosocial factors, level of mathematics and progression in an access programme

Annette Forster[1], Fiona Faulkner[2] and Mark Prendergast[3]

[1]Technological University Dublin, Ireland; D16127663@mytudublin.ie

[2]Technological University Dublin, Ireland; fiona.faulkner@tudublin.ie

This study examined the relationship between Access students' psychosocial characteristics, the level of mathematics module (advanced, intermediate or fundamental) they chose and their progression to higher education. A quantitative approach was adopted for this portion of the study, which took place over three academic years, 2017 - 2020. Questionnaires were completed by 184 students in the Access programme at Technological University Dublin. Results revealed that students with higher belief in their mathematics ability were more likely to study advanced mathematics and more likely to progress to higher education. Male students were more likely to study advanced mathematics than females and non-Irish nationals who studied advanced mathematics had higher belief in their mathematics abilities than Irish nationals but were less likely to progress than their peers.

Keywords: Access programme, psychosocial, mathematics level, self-belief, progression.

Introduction

Higher education has many societal and personal benefits but there are low participation rates for students from some sections of society, including students who are socioeconomically disadvantaged (Archer et al., 2005) and adults aged 25 – 64 years old (Eurostat, 2019). Access programmes have been established to address these inequalities by tackling the social, educational, and financial barriers that some students experience in accessing higher education (O'Reilly, 2008). To date, there has been little research on Access student progression, particularly in relation to mathematics. The goal of this study is to examine whether the psychosocial factors of motivation, personality traits, general self-efficacy (GSE) and belief about mathematics abilities (BMA) affect the level of mathematics module Access students choose and their progression to higher education.

Psychosocial Factors Affecting Progression in Higher Education

Personality traits, including extraversion, agreeableness, conscientiousness, neuroticism, and openness to experience (McCrae & John, 1992), play a role in determining a student's educational attainment (Lenton, 2014). The personality factors of conscientiousness and openness have been found to affect students' mathematics grades (Furnham et al., 2009). Lipnevich et al. (2016) contend that conscientiousness may be beneficial for mathematics performance because it results in persistent and thorough learning, while openness has been linked to deep learning. Personality traits affect a student's likelihood to progress in higher education (Altman, 2017).

Self-efficacy affects individuals' perceptions about their abilities related to a given task (Hutchison et al., 2006) and their ability to learn (Schulze & Schulze, 2003). Schöber et al. (2018) found that self-efficacy affected mathematics achievement. According to Hall and Ponton (2005), positive experiences with mathematics increase students' self-efficacy. Overall, research indicates that students with higher self-efficacy are more likely to progress (Erb & Drysfales, 2017).

Intrinsic and extrinsic motivation have been widely studied. Intrinsically motivated individuals do something for the inherent satisfaction they get from a behaviour, extrinsically motivated individuals engage in a behaviour for the reward they gain through external control or self-regulation (Ryan & Deci, 2000). According to Ryan and Deci, amotivated individuals are not motivated to engage in a behaviour and feel they have no control over that behaviour. Some researchers contend that lower intrinsic motivation negatively affects student performance (Augustyniak et al., 2016) and their progression in education (Vallerand et al., 1997). There is a positive relationship between mathematics self-efficacy and students' intrinsic motivation and progression (Skaalvik et al., 2015). This study examined the relationship between psychosocial factors, Access students' mathematical experiences and their progression to undergraduate studies.

Method

Technological University Dublin (TU Dublin) offers a one-year Access programme, which provides an alternative route to higher education for mature students (students aged 23 years and older) and for young adults (students aged 22 years and under) who are socio-economically disadvantaged (Technological University Dublin, 2020). Participating students choose one mathematics module each semester at fundamental, intermediate or advanced level.

The main study, which took place over three academic years, 2017 - 2020, adopted an explanatory, sequential mixed methods approach. The ethics committee at TU Dublin provided ethical approval for the study. During the quantitative phase of the research, Access students completed a 29-item questionnaire at the start of the academic year. The questionnaire included the 28-item Academic Motivation Scale (Vallerand et al., 1992). It also included John and Srivastava's (1999) 44-item Big Five Inventory, which organizes personality traits in terms of the five dimensions of extraversion, agreeableness, conscientiousness, neuroticism, and openness to experiences. Schwarzer & Jerusalem's (1995)10-item General Self-Efficacy Scale was included to assess students' ability to deal with unusual or difficult situations. Additionally, students rated their BMA using a five-point Likert scale, where 1 represented 'excellent' and 5 represented 'poor'.

Progression was measured based on whether students were offered a place at a higher education institution or not. The data was analysed using SPSS. Mann-Whitney U tests (U) were conducted to compare the mean ranks of data where one variable was dichotomous, and the other variable was ordinal. Chi-square tests ($\chi 2$) were employed when both variables were dichotomous. Independence of observations was observed for all Mann-Whitney and chi-square tests.

Results

One hundred and eighty-four Access students completed questionnaires over the three years of the study. Forty-nine percent were female, 51 percent were male, 43 percent were young adults and 57 percent were mature students. Overall, 25 percent of Access students were enrolled in fundamental mathematics, 64 percent in intermediate mathematics and 11 percent in advanced mathematics. A Mann-Whitney test revealed that students who studied advanced mathematics had significantly higher mean ranks for intrinsic motivation to know than their peers (U = 945.5, p = .071).

Additionally, students who studied intermediate mathematics had higher mean ranks for extrinsic motivation external than their peers (U = 2639.5, p = .033). Students who studied fundamental mathematics had significantly higher mean ranks for amotivation than students who studied advanced or intermediate mathematics (U = 1732.5, p = .002). Young adult students had a significantly higher mean rank for extrinsic motivation than mature students (U = 2197, p = .038).

There was no significant difference in mean ranks for most personality traits based on the level of mathematics students studied. However, students who studied fundamental mathematics had a higher mean rank for neuroticism than their peers (U = 1613, p = .020). Additionally, young adults had a significantly higher mean rank for extroversion than mature students (U = 1910, p = .001).

Fundamental mathematics students had a significantly lower mean rank for general self-efficacy (GSE) than students who studied intermediate or advanced mathematics (U = 3090, p = .038). Moreover, students who studied intermediate mathematics had a significantly higher mean rank for self-efficacy than their peers (U = 2732, p = .017). Although male and female students did not differ in their mean ranks for GSE (U = 3409.5, p = .826), males were significantly more likely to study advanced mathematics than females ($\chi2$ = 4.93, df = 1, p = .026). Additionally, non-Irish nationals had significantly higher mean ranks for GSE than Irish nationals (U = 3999, p = .007) and were more likely to study advanced mathematics or intermediate mathematics than Irish nationals ($\chi2$ = 3.58, df = 1, p = .059).

Students who studied fundamental mathematics had a significantly lower mean rank for belief about mathematics their abilities (BMA) than those studying intermediate or advanced mathematics (U = 3562, p = .014), and students studying advanced mathematics had a higher mean rank for BMA than their peers (U = 97.6, p < .001). Additionally, non-Irish nationals had a significantly higher mean rank for BMA than their Irish peers (U = 4916.5, p < .001). The findings related to psychosocial factors are outlined in Table 1.

Table 1: A Comparison of Mann Whitney Mean Ranks for Psychosocial Factors by Mathematics Level, Age and Nationality

	Mann Whitney Mean Ranks				
	Mathematics Level			Age	Nationality
	Fundamental	Intermediate	Advanced	Young Adult	Non-Irish National
Motivation					
Intrinsic motivation to Know			Higher		
Extrinsic Motivation External		Higher			
Extrinsic Motivation Total				Higher	
Amotivation	Higher				

Personality					
Neuroticism	Higher				
Extroversion				Higher	
Self-Efficacy	Lower	Higher			Higher
BMA	Lower				Higher

Mathematics and Progression

Overall, 85% of students who studied fundamental mathematics, 84% of those who studied intermediate mathematics and 89% of students who studied advanced mathematics progressed to higher education. Statistically, students studying intermediate mathematics were more likely to progress (χ^2 = 7.57, df = 1, *p* = .006) than those studying fundamental or advanced mathematics.

Moreover, mature students studying intermediate mathematics were more likely to progress than their young adult peers ($\chi2$ = 8.39, df = 1, *p* = .004), but non-Irish nationals who studied advanced mathematics had lower progression rates than Irish nationals ($\chi2$ = 2.92, df = 1, *p* = .087).

There was no statistically significant difference in progression based on students' mean ranks for intrinsic motivation total (*U* = 2647.5, *p* = .552) or extrinsic motivation total (*U* = 2363, *p* = .969). Moreover, students' mean ranks for amotivation were not significantly different depending on whether they progressed or not (*U* = 3076.5, *p* = .329).

Overall, there was no significant difference in mean ranks for personality traits based on whether Access students progressed or not – extraversion (*U* = 2521, *p* = .909), agreeableness (*U* = 2245, *p* = .872), conscientiousness (*U* = 1978, *p* = .140), neuroticism (*U* = 2681, *p* = .856) or openness (*U* = 2149, *p* = .114).

Additionally, there was no statistically significant difference in progression based on Access students' mean rank for GSE (*U* = 2815.5, *p* = .425). However, students who progressed had significantly higher mean ranks for BMA than those who did not progress (*U* = 2807.5, *p* = .022).

Discussion

This study aimed to determine whether there was a relationship between the psychosocial factors of motivation, personality traits, GSE and BMA and the level of mathematics Access students study as well as their progression to higher education. The findings revealed a relationship between all four psychosocial factors and the level of mathematics module Access students studied.

Access students who studied fundamental mathematics had significantly higher mean ranks for amotivation and neuroticism and significantly lower mean ranks for GSE and BMA than their peers. Prior performance has been found to be a predictor of students' self-efficacy in mathematics (Lopez and Lent, 1992), while students with higher self-belief in their ability to succeed in higher education mathematics classes have better mathematical skills (Hall and Panton, 2005). Access students with lower GSE and BMA may have weaker mathematics skills or their past performance in mathematics may have affected their BMA as indicated by Lopez and Lent (1992). Additionally, research indicates that neuroticism creates negative emotions, results in failure to progress and results in a negative reaction to the fear of failure (Barthelemy & Lounsbury, 2009). Fundamental mathematics students' lower mean ranks for GSE and BMA, in conjunction with their higher neuroticism scores, may have resulted in amotivation, as individuals who are not motivated to engage in a behaviour, may feel they have no control over that behaviour (Ryan & Deci, 2000).

Alternatively, advanced mathematics students had higher mean ranks for GSE, BMA and intrinsic motivation to know, which is regulated by the pleasure of learning something. Mueller et al. (2011) contended that intrinsic motivation increases self-efficacy and results in the development of more favourable tendencies towards learning mathematics, which may have influenced students' decision to choose the advanced mathematics module in the Access programme.

Although male and female student had similar mean ranks for GSE and BMA, females were less likely to study advanced mathematics. This may be because mathematics is seen as masculine (Mendick, 2005) and because males are more likely to choose mathematics intensive careers (Law, 2018). Access students choose the level of their mathematics module based on the higher education course they wish to pursue, and male Access students were more likely to aspire to study mathematics intensive fields such as engineering, physics and computer science than female Access students.

Access students with higher BMA scores had higher progression rates than their peers. Students generally have a good awareness of their academic abilities (Mattern & Shaw, 2010; Reason, 2003). Mattern and Shaw (2010) also found that students with higher BMA had higher GPAs and were more likely to progress from first to second year of higher education.

Although there were no significant differences in progression in relation to personality traits, motivation or GSE, mature students studying intermediate mathematics had higher progression rates than young adults. Young adult students had higher mean rank scores for extrinsic motivation than mature students. Research indicates that students thrive in an educational setting where they are more intrinsically motivated (Ryan & Deci, 2000), which may explain the lower progression rates for young adults studying intermediate mathematics. Moreover, young adult Access students had significantly higher extroversion scores than mature students, and extroversion is negatively related to educational attainment (van Eijck & DeGraaf, 2004).

Non-Irish nationals studying advanced mathematics were significantly less likely to progress than their peers although they had higher mean ranks for BMA and GSE. Non-Irish nationals, who were non-native English speakers, may have failed to progress because they experienced difficulties in modules that required advanced English language skills. Higher education students' academic achievement can be affected by English competency (Harris & Ní Chonaill, 2016).

Limitations and Recommendations

The sample size was relatively small, although it represented 67 percent of participants in the Access programme over the three years of the study. Additionally, the General Self-efficacy Scale was employed in the questionnaire, but a college self-efficacy scale may have been more pertinent. Asking participants to complete the AMS and the GSE at the end of the Access programme as well as at the start would have indicated whether Access students' self-efficacy, BMA or intrinsic motivation increased during their studies.

Future research should examine more closely why Access students choose the level of mathematics modules that they do, their previous mathematics performance and the reasons why non-Irish nationals studying advanced mathematics are less likely to progress than their Irish peers. This data would help to determine whether the relationships identified in the current study are causal relationships or whether they are affected by other confounding factors.

Conclusion

Although there is no difference in progression, overall, depending on the psychosocial factors of motivation, personality and GSE, these factors may affect the level of mathematics modules that students choose to study. This in turn may affect the higher education courses students aspire to, as mathematics intensive courses may require advanced mathematics. Therefore, it is important that students are made aware of the opportunities that advanced mathematics can afford them.

Given that students with higher BMA had higher progression rates, overall, Access students should be encouraged to improve their BMA and their GSE by following Heslin and Kelhe's (2006) recommendations of engaging students in enactive self-mastery, role-modelling and verbal persuasion.

The Mathematisation of society: rethinking basic skills for adults

Kees Hoogland[1] and Javier Díez-Palomar[2]

[1]HU University of Applied Sciences Utrecht, Utrecht, The Netherlands; kees.hoogland@hu.nl

[2]University of Barcelona, Faculty of Education, Barcelona, Spain; jdiezpalomar@ub.edu

Technology, data use, and digitisation are based on mathematical structures, and this permeates many aspects of our daily lives: apps, online activities, and all kinds of communication. Equipping people to deal with this mathematisation of society is a big challenge. Which competences are needed, which skills must be mastered? Which dispositions are helpful? These are the questions that matter in the development of adult education. The concept of numeracy is mentioned already for many years as a possible useful approach to equip adults with the necessary skills. In this paper we will argue that is only true when numeracy is defined as a multifaceted concept which combines knowledges, skills, higher order skills, context and dispositions.

Keywords: Numeracy, basic skills, adult education.

Introduction

World-wide, too many citizens lack the necessary numeracy competencies to participate autonomously and effectively in our technologized and number-drenched societies and consequently many citizens are overlooked for certain jobs and have problems in their daily life, dealing with the fast-growing abundance of number-related situations. In literature, these numeracy competencies are mentioned specifically in studies on 21st century skills, global competences, and skills for the 4th industrial revolution (OECD, 2016; Schwab, 2016; Voogt & Roblin, 2012).

Considering numeracy as a social practice seems to be the most promising way forward to battle low numeracy and empower adults with a broad and effective repertoire of numerate behaviour to cope with situations in work and daily life. We cite (Oughton, 2013): “A social practice view of numeracy not only takes into account the different contexts in which numeracy is practised, such as school, college, work and home, but also how people’s life and histories, goals, values and attitudes will influence the way they carry out numeracy (p16). An even richer collection of ideas on this approach can be found in Numeracy as a Social Practice (Yasukawa et al., 2018).

Background

For the past three years, we have been working in an Erasmus+ project on a Common European Numeracy Framework, which uses a multifaceted definition of numerate behaviour, incorporating knowledge and skills, use of tools, higher order skills, and dispositions. The combination of these aspects is seen as increasingly crucial in the quality of numerate behaviour to act autonomously, reflect critically, and make sound decisions in our number-drenched society. In a sense, numeracy is the new literacy in today’s society. This gives rise to reconsider fundamentally the idea of “basic skills” in mathematics and numeracy for primary and secondary education. Numeracy is about how people deal with the quantitative and multidimensional phenomena in the world around us, both in daily-life situations and professional contexts. In the latest and most state-of-the art definitions of numeracy, it is described as a broad and multifaceted concept and as a social practice. It manifests itself in a plethora of observed numerate practices of people, showing that numerate behaviour is affected by cultural, social, personal, emotional traits, and societal power relations. In short, numeracy takes the person and his/her relationship with the world as a starting point.

A historical timeline

The picture in Figure 1 is by some researchers considered to be one of the he first examples of human numerate practices in "writing".

Figure 1: Schoyen collection: ms-1717-beer-inanna-uruk

It is a Sumerian pictographic script from the 31st century BC on a tablet, which is part of the Schøyen collection in Oslo, Norway (The Schoeyen Collection, 2021). The tablet is presumed to be giving information on the production of beer 5000 years ago. Reading from right to left, we see the barley delivered, then the brick building - presumably the brewery -, and the barley in the jar resulting in the beer. It is the earliest representation in history of an industrial process. Looking at this tablet from a mathematical perspective, we see that the use of quantitative notations is meaningful and purposeful. For the documentation of the brewing process an external tool is used in this tablet. And a mix of cognitive tools is used: pictorials, quantities and order of process. So, using schematic, symbolic, quantitative and visual notations to describe the real world and to communicate with others, which is mathematics, is as old as the written language of the first civilized societies. It is good to remember that we as mankind have used symbols and other visual representations to describe ánd control the world for millennia, basically as long as we have had civilized societies.

Before the art of printing, the use of writing material and the use of a mathematical repertoire was only for expert and privileged citizen. So was the use of mathematical knowledge and skills.

Nevertheless, like people have always used language to express themselves, they also have always used logic reasoning, problem solving, estimating, planning and many more cognitive processes which we now categorize under mathematical cognitive processes or meta-cognitive processes.

The wide-spread use of pen-and-paper has given people the opportunity to use this "new technology" to do actual calculations, which was one of the driving forces of the industrial revolution.

The pen-and-paper techniques were introduced in the mass education which roughly started at the beginning of the 20th century and has since then been dominant in steering the goals of primary mathematics education, likewise the pen-and-paper algebraic manipulation which brought acting mathematically to a much broader mass was steering the content of secondary maths education.

If we look a bit closer to the last 75 years, we see that the pen and paper calculations with numbers or variables permeated so deep into the educational system, that it has become a goal in itself, instead of a means to provide answers to typical kind of problems. It permeated so deep that it now even has survived its relevancy and is more a driving force for wide-spread math anxiety than that it delivers students a useful repertoire.

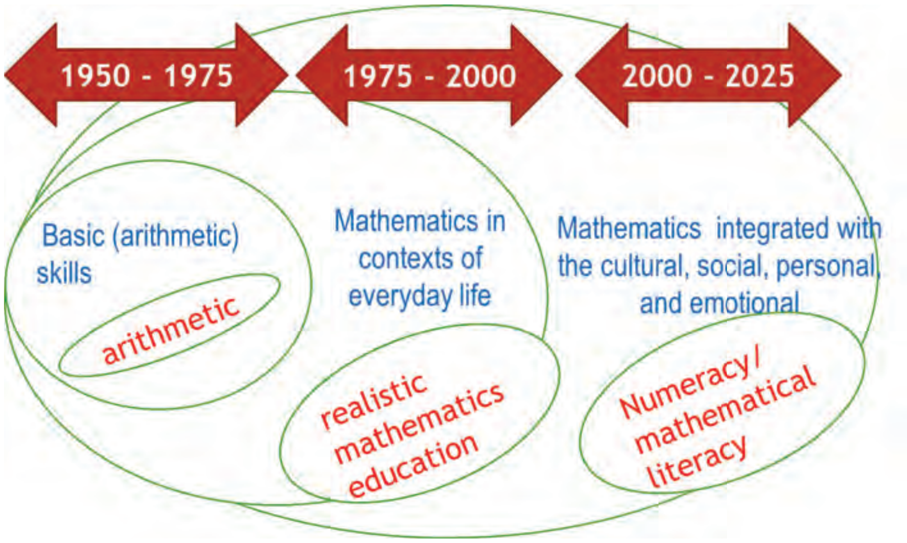

Figure 2: Relevant mathematics for use in daily life

After WWII, in the third quarter of last century (1950-1975), there was a broad consensus that the best way to prepare students to the needs of society should consist of practicing operations on bare numbers according to fixed procedures by hand and on paper: adding, subtracting, multiplying and dividing. Long division is the iconic image of this perspective.

Was that a relevant activity? Yes, very relevant. Before 1975 there were simply no electronic calculators available to the common user and almost everything had to be calculated by hand and with pen and paper. Every factory built in the reconstruction of society after WWII, every rocket shot to the moon, every conveyor belt production process was created by engineers who carried out complex calculations with pen and paper. But also, almost all retail transactions were based on manual calculations. However, the quantitative side of the world today looks very different and performing large calculations with only pen and paper has almost completely lost its relevance.

In the fourth quarter of last century (1975 – 2000) all kinds of mechanical and electronical tools made an appearance which made manual work for a large part superfluous: calculators, electronic cash registers, spreadsheets, et cetera became part and parcel of daily life activities. In education, the desire arose not only to learn the pen-and-paper skills, but also to teach where and how these skills could be used to solve problems from daily life. Situations from reality became part of education in many forms: applications, simulations, contexts, projects, et cetera. The emergence of Realistic Mathematics Education (Gravemeijer, 1994; van den Heuvel-Panhuizen, 2001) is an example of this perspective.

In the first quarter of this century (2000-2025), a third perspective on numeracy is rapidly gaining popularity worldwide. From this perspective students have to be "numerate" in order to deal with the quantitative side of the world. Numeracy takes the person and his/her relationship with the world as a starting point. The quantitative side of the world is so rich, so varied and sometimes so complex, that people need a very extensive repertoire to cope with it. From this perspective, numeracy is an inseparable part of personal development. Immediately after birth, the first interactions of the young born with numbers, patterns and structures in time and space, are discernible. Our brains are said to be hardwired to deal with numbers, structures and patterns (Butterworth, 1999; Dehaene, 2011; Devlin, 1996) The body supports numeracy development by moving and relating to the three-dimensional physical environment. And manifestation of mathematical structures are visible in all cultures (Bishop, 1991).

Interest in the psychological side of mathematics learning is also increasingly the subject of study. Many difficulties student have with mathematics and numeracy can be associated with psychological problems caused by educational settings of exclusion and selection and strict right/wrong regimes (see for example the literature on math anxiety (Dowker et al., 2016; Maloney et al., 2013)). It is good to realise that math anxiety is not a student characteristic, but rather an educational characteristic.

Part of numeracy is also how to deal with the avalanche of quantitative data that today's society produces and uses for economic traffic, the political process and daily life. It is mainly about drawing conclusions from numerical information. Interpreting, analysing, organizing, estimating, structuring, selecting and critically considering quantitative information are skills associated with numeracy. Appropriate education in this area is developing worldwide.

However, the development of a functional and modern conceptualization of numeracy is slow. In politics and the (social) media, the perspective from 1950-1975 is often still dominant.

What are then the aspects of the numerate world in the 21st century? In our search for the aspects of numerate behaviour in today's world, we came quick-and-dirty to the list of cognitions and manifestations in figure 3.

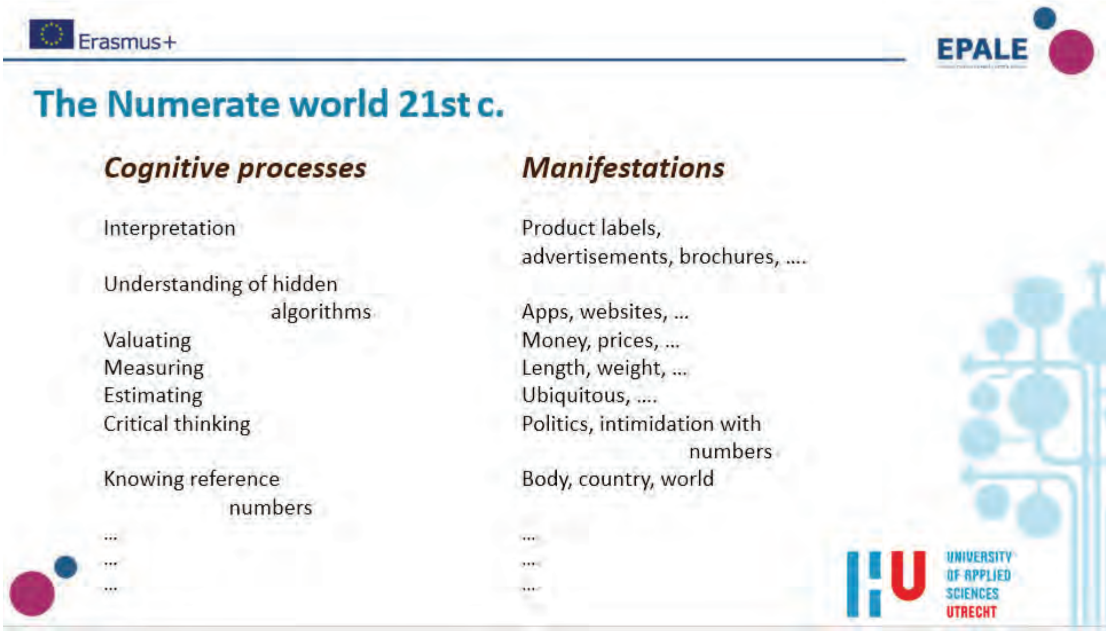

Figure 3: Cognitions and manifestations

A multifaceted framework

What are then these new basic skills needed to cope with living in contemporary society? Among researchers and practitioners there is a growing consensus that a numeracy framework which describes numerate behaviour and numeracy practices should contain much more than only content descriptions. As important are dispositions, attitudes, higher order skills, and aspects of agency, and self-efficacy.

In 2019, funded by the European Union, an Erasmus+ project started under the name Common European Numeracy Framework (CENF) to create an overview of the relevant aspects which matter in the quality of numerate behaviour of a citizen. This was based on a literature review on emergent themes in numeracy, a wide-scale European Numeracy Survey, and expert consultations. The main categories of aspects which were discerned, are: Content knowledge and skills, Context, Cognitive processes (especially higher order skills), and Dispositions. See figure 4.

In the CENF, for each category and subcategory (e.g., Quantity and Number, Self-efficacy, Mathematising) descriptions of observable numerate behaviour were developed.

The aspects which are categorised under cognitive processes and dispositions are used also quite often in educational research and literature in a generic way. They also appear in other kind of frameworks. There is, for instance, a substantial overlap of the category ‘Higher order skills’ with frameworks for 21st century skills (Csapó & Funke, 2017; Geiger et al., 2015; Hoogland et al., 2018; Voogt & Roblin, 2012)The aspects under disposition can also be found in literature on motivation in education and even more general literature on personal traits (Eccles, 1996). In this numeracy framework we have described these aspects in terms of numerate behaviour, or otherwise stated, in terms of how these aspects play out in numeracy situations.

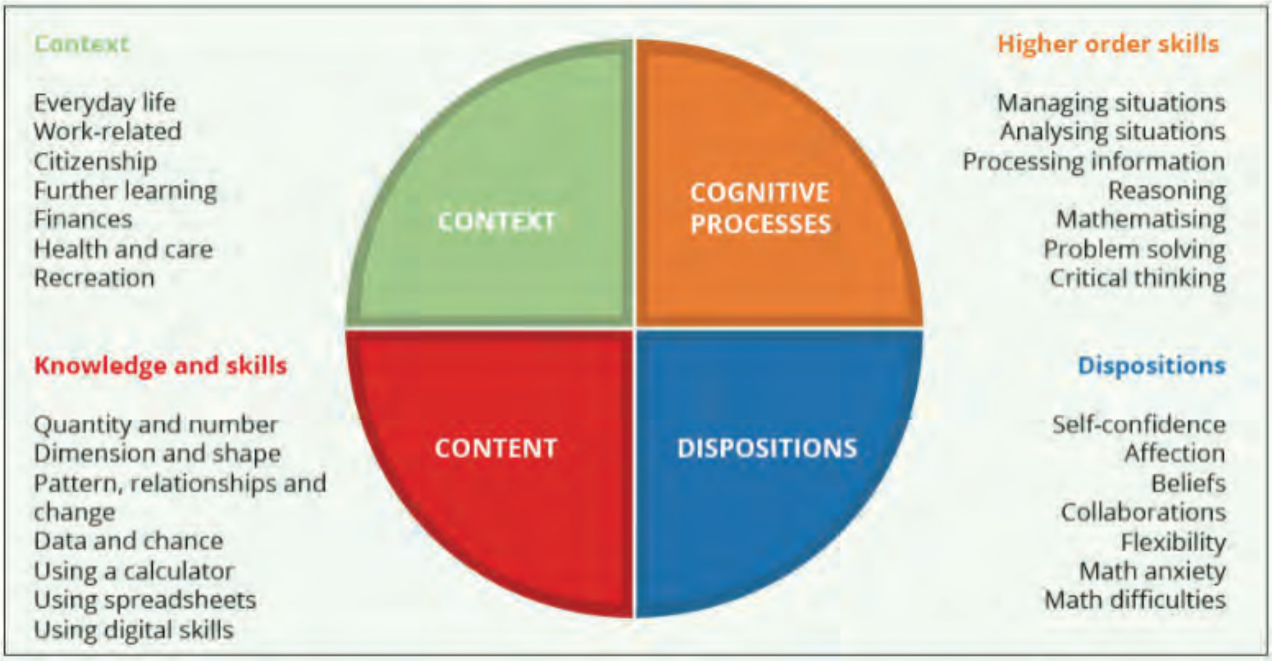

Figure 4: What matters in the quality of numerate behaviour?

Furthermore, the descriptors are formulated as a rubric with six levels, so that they may give indications for possible learning trajectories. By this, teachers and learners in adult education can establish together which (combinations of) aspects of numerate behaviour can be addressed to improve the quality of the learner's numerate behaviour.

The six levels are labelled X1, X2, Y1, Y2, Z1, and Z2. Roughly, the levels X refer to use of numeracy in daily-life house-hold situations, the levels Y refer to the numeracy activities of a citizen actively participating in nowadays societies, including being critical to numerate communication in news and social media, and the levels Z refer to the use of numeracy in professional settings, by users and producers of numerate communication. Clearly, there is an overlap in all these levels and activities, but the distinction is made to make it easier to have a focuses discussion on numeracy, necessary numeracy, developing numeracy skills, and improving the quality of numerate behaviour.

A few aspects highlighted

In the quadrant of content knowledge and skills, we see a reference to the well-known content categories as we can find in subsequent assessment frameworks of PISA and PIAAC (OECD, 2012, 2013, 2021a, 2021b; PIAAC Numeracy Expert Group, 2009). But added to that is the use of computational tools. The relevant and adequate use of computational tools is becoming more and more a basic skill, than the calculation the tool performs. There is a wide-spread narrative that pen-and-paper skills must proceed the development of tool use, but there is now evidence for the causality of that. Working together on using tools, understanding numbers and calculations, and establishing which basis facts should be part of the mental repertoire seems to be more an obvious choice for designing educational trajectories.

In the quadrant on dispositions, we want to highlight the aspect of math anxiety. We like to stress the fact that math anxiety is a typical school product, produced by endless feedback on right and wrong answers with corresponding feelings of stress and fear causing in many individuals a long-lasting urge to deflect any mathematical connotations, and sometimes any connotations to numbers. In adult mathematics education coping with math anxiety is one of the biggest challenges. Without school experiences there exists no math anxiety. Young children don't have anxieties in using numbers, quantities, measurements et cetera. It comes naturally to them. The brain and the body are hardwired for it. Maths is arguably originating from abstracted actions and gestures in concrete situations (Butterworth, 1999).

The rubrics are all first versions developed in recent years. The aim is to discuss them with experts, policy makers and practitioners to see whether the descriptions can be clarified, refined, and linked to educational numerate practice.

Discussion and conclusions

For adults to deal with the quantitative aspects of real life, a new set of basic skills is necessary. Limiting basic skills to only calculations and manipulation with variables and algebraic forms are clearly not sufficient anymore to deal with the abundance of mathematical and mathematical based manifestations. As long as education keeps focusing on a 19^{th} and 20^{th} century perspective of mastering the execution of calculations with pen and paper, adults will not gain the necessary competences for full participation in contemporary society.

The Common European Numeracy Framework as it is developed in an Erasmus+ project during the years 2018-2021 in close collaboration between European countries can contribute to a highly necessary shift in the definition of necessary basic skills for adults to cope with the problems in daily life and professions. The framework advocates a more holistic approach which intertwines knowledge and skills, context, higher order skills and dispositions.

Adult numeracy – a paradigm shift?

David Kaye

Independent researcher, London, United Kingdom; david.m.kaye@btopenworld.com

I present the ground-breaking theories about scientific revolutions by Thomas Kuhn and his development of those theories, particularly the concepts of incommensurability and lexical change. I review the long-standing theoretical discussion about adult numeracy and the extensive attempts to reach some agreement upon which to build a research domain alongside mathematics education research. I propose that Kuhn's conceptual analysis can be applied to the emergence of adult numeracy out of the field of mathematics education research to form a new paradigm of education research.

Keywords: Numeracy, paradigm, incommensurability.

Introduction

I will summarise the development of Thomas Kuhn's theory in the 30 years after the publication of *The Structure of Scientific Revolutions*, (1962) particularly in the works published as *The road since structure* (Kuhn, et al., 2002) with reference to fluid lexicons and incommensurability. I will use these philosophical concepts to critique the repeated attempts to explain and define adult numeracy, and the many contexts in which mathematics is found wanting in describing an adults' numerate accomplishments.

My main proposal is to apply Kuhn's analysis of a scientific revolution to the emergence of adult numeracy in the field of mathematics education research. Subsequently can I use the resultant research process to establish adult numeracy as a discipline in its own right and initiate further research along similar lines? The hope is that such research can produce a body of knowledge that will transform how the majority of the adult population views numeracy education and practice.

Kuhn, scientific revolution, paradigm change

The concept of the paradigm and paradigm change is central to Kuhn's argument. Unfortunately, the term 'paradigm' has been much over-used (see for example Rogers, 2002, p. 487) and so it is worth looking at what Kuhn said.

> The transition from a paradigm in crisis to a new one from which a new tradition of normal science can emerge is far from a cumulative process, one achieved by an articulation or extension of the old paradigm. Rather it is a reconstruction of the field from new fundamentals, a reconstruction that changes some of the field's most elementary theoretical generalizations as well as many of its paradigm methods and applications. (Kuhn, 1962, p. 84)

This makes us realize that that nature of the change involved is deep, significant and conceptually challenging. In proposing the theory Kuhn sees a very significant role for the growing dominance of a new paradigm making changes to the direction of future research. He says "But paradigm debates are not really about relative problem-solving ability . . . Instead, the issue is which paradigm should in the future guide research on problems" (Kuhn et al., 2002, p. 156).

Revisit Structure –lexicon – incommensurability

In his later work, revisiting the theory of scientific revolutions and responding to the very many criticisms that were made of ‘Structure’ Kuhn puts greater emphasis on the use of language and the significance of a research community sharing ‘a core’. The introduction of two additional concepts, lexical change and incommensurability, make the theory even more applicable to the emergence of adult numeracy as a new research field, as I will show.

> People who share a core, like those who share a lexical structure, can understand each other, communicate about their differences, and so on. If on the other hand, core or lexical structures differ, then what appears to be disagreement about fact (which kind does a particular term belong to?) proves to be incomprehension (the two are using the same name for different kinds). The would-be communicants have encountered incommensurability, and communication breaks down in an especially frustrating way. . .. What the participants in communication fail to share is not so much belief as a common culture. (Kuhn et al., 2002, p. 239-240)

Kuhn later clarifies what he means by a lexicon.

> A lexicon or lexical structure is the long-term product of tribal experience in the natural and social worlds, but its logical status, like that of word meanings in general, is that of convention. Each lexicon makes possible a corresponding form of life within which the truth or falsity of propositions may be both claimed and rationally justified, but the justification of lexicons or of lexical change can only be pragmatic. (Kuhn et al., 2002, p. 244)

This theoretical approach begins to give us a vocabulary and philosophical approach to explore and explain the gulf that has opened up between adult numeracy education researchers and practitioners and others in the mathematics education world.

Revisiting numeracy – again

I have been involved in examining how numeracy has been used and defined in the particular context of Adults Learning Mathematics for twenty-five years and give for reference two conference proceedings. (Kaye, 2003 and Kaye, 2015)

This is continuing a discussion that takes place in every conference about teaching adults' numeracy (and mathematics). Making a strong connection with the tradition we are making in CERME here is a view of the situation by Kees Hoogland in his introduction to the papers presented at CERME 11. This both gives an overview and identifies some of the problems.

> Although there is a broad acknowledgment that an array of psychological and sociological factors are important in (the results of) adult education, there is not yet a well-researched set of examples how in practice this can be taken into account in a more systematic and effective way. The practice of adult numeracy education is still a plethora of different content descriptions and goals that vary from very back-to-the-basics to very sophisticated higher-order skills. . .. The twin goals of trying to establish a firm definition of numeracy which acknowledges the multifaceted nature of adult’s mathematical practices while identifying consistent teaching approaches should be of concern to the global AME community. (Hoogland et al., 2019, pp. 1298/9)

Two recent summaries published in 2015 and 2020 in the ZDM mathematical journal review recent research into numeracy. In the introductory paper by Geiger et al (2015) various statements about what numeracy is (or is not) are presented.

> Although what is meant by numeracy varies between countries, it is now broadly accepted that being numerate extends beyond the mastery of basic arithmetic skills to how to connect the mathematics learnt in formal situations, such as school classrooms, to real world problems. (p. 531)

> While there is an increasing focus on numeracy internationally, there is not yet a widely accepted definition for this construct or of the fundamental characteristics that describe this idea. Thus, the meaning of numeracy still varies widely across international borders . . . (p. 532)

This is followed by a section headed ‘Facets of numeracy’

> The intrinsic usefulness of mathematics means that it provides a way of reasoning about, and functioning within, different societies with diverse social norms, values, cultures, and traditions. Unsurprisingly, this gives rise to related but distinct ways of conceptualising and identifying numeracy practices. (p. 535)

We see that numeracy is described as both an ‘idea’ and a ‘construct’; we see repeatedly stated that there is no agreement on what ‘numeracy’ means; and we find that ‘mathematics’ creeps into the descriptions, without being defined.

Another useful summary is the survey paper by Gal, Grotlüschen, Tout and Kaiser (2020). The title makes clear it has a focus on adults ‘Numeracy, adult education, and vulnerable adults: a critical view of a neglected field’ and provides its own definition of numeracy.

> Adult numeracy is a construct related to the ways people cope with the many mathematical, quantitative, and statistical demands of adult life. Some definitions of *numeracy* emphasize basic computational skills or focus on emergent numeracy at a young age. In this paper, however, numeracy is used broadly to encompass a set of diverse skills, knowledge-bases, dispositions and affect, communication abilities, and practices and behaviors, that range from simple to very advanced, relate to mathematics and statistics, and that individuals need or use in order to engage and manage diverse life situations and tasks in the adult world. (Gal et al., 2020, p. 378)

Many similar definitions have been given over the years. Other researchers have looked at mathematics in other contexts and chosen alternatives to ‘adult numeracy’ such as ethnomathematics and indigenous mathematics These fields have seen the debates around ‘numeracy’ as irrelevant (or a distraction) and have sought in other ways, and for other purposes, to redefine ‘mathematics’ and ‘mathematics education’. The use of these terms is part of the lexical change I am drawing attention to.

Ethnomathematics is summarized in this introduction to the topic group on ethnomathematics at ICME 13 (2016)

> The application of ethnomathematical approaches allows us the opportunity to examine local knowledge systems and give insight into forms of mathematics used in diverse contexts and cultural groups. The pedagogical approach that connects this diversity of mathematics is best

represented by a process of translation and elaboration of the problems and questions taken from daily phenomena.

In addition, I also wish to reference the works of Gelsa Knjnick (2021) with the Landless Movement in Brazil and that of Marta Civil (2021) with parents from mainly Mexican origin in the USA.

These studies and investigations are often left out of the discussion around adult numeracy. They focus on presenting and defending the mathematics within particular cultures, which along with all other social, political, and cultural traditions and values have been suppressed. These need to be included as they too are trying to redefine mathematics education.

The mathematics of indigenous people needs to be noted too. One particularly powerful article is 'Mathematix: 'Towards a way of being' by Rochelle Gutierrez (2019) which presents the case of the mathematics (mathematx) of the indigenous peoples of North America.

> In this paper, I seek to analyze some of the specific ways that Western mathematics in US schools operates as a form of dispossession and how mathematx addresses the need for Indigenous people to continue to remake themselves while interacting with non-Indigenous people. (p. 67)

Gutierrez later gives an example in which the relationship to, and naming of, geometric shapes is very different to the Western tradition.

> For example, the word for square literally means "it squares itself" which is an action performed rather than an enduring property of the object. Ardoch Algonquin First Nation member and Anishinaabemowin teacher Marjolaine LaPointe recounts, I was thinking of this word, kakadeyaa, which means a square, but it's not a noun. It's a verb which means it's squaring itself. And kakadeyaa has this k sound, which is a cutting, a grouping, a separating, and when we break the language down into those sound-based parts, we start thinking in three dimensions as opposed to binaries of "this is this and this is that" and we see relationships between many things. (pp. 73-74)

There are numerous other examples drawing on indigenous numeracy (or 'mathematics') making a case to have a much wider understanding of what 'mathematics' might be. For example, the work of Linda Furuto (2018) on the traditions of Hawai'I and the Pacific Also the work of Marcia Ascher (2005), which deals with similar indigenous concepts outside of the education sector. And not forgetting the trail-blazing publication by Claudia Zaslavsky's 'Africa Counts' (1979) originally published in 1973.

What about mathematics?

As I have shown in this paper the concept, principle, practice and justification for 'numeracy' has been repeated many, many times. However, whilst 'numeracy' is explained in some way as doing something with mathematical concepts (or skills) 'mathematics' is very rarely defined. As Coben (2006, p. 21) has said "The nature of the relationship between numeracy and mathematics is elusive". Coben (2006, p. 21) noted that "'Mathematics' is taken to mean mathematics learned and taught at any level, including the most basic". Anecdotally, I re-call having a discussion about this with a group of trainee adult numeracy teachers and one contribution was (as I remember it) "Everyone knows what mathematics is – there is a degree in it". I have been thinking about this ever since and have previously given examples of statements about mathematics, alongside those of numeracy, in a guide to teachers of adult numeracy (Kaye, 2013).

Numeracy, incommensurability and lexical change

I now return to the ideas of incommensurability and lexical change to argue that these need to be applied to using numeracy in the context of both adult education and people's lives. As has been shown there is a very strong research tradition that is comfortable with recognizing the importance of numeracy in adult education and many of those studies have arisen because of concerns about 'poor numeracy' in the adult population (O'Donoghue, 2000, p. 103). In fact, these concerns go back for about 60 years. All reviews of using numeracy speak of the Cockroft report published in 1982, which in turn refers back to the Crowther Report published in 1959. Within paragraphs 35 to 39 of the Cockcroft report there is a discussion about the scope and range of 'numeracy'. As is the case in many official and research documents (on mathematics education) the target group is school children. However, as I have argued elsewhere (Kaye, 2018, pp. 11-37) once societal, cultural and political aspects of life are under consideration this is far more relevant to adult or lifelong learning, than school mathematics. What is important is that the argument is still the same between a 'small numeracy' or a 'big numeracy'. In the words of the Cockroft report (1982) (emphasis in the original report):

> *We would wish the word 'numerate' to imply the possession of two attributes*. The first of these is an 'at-homeness with numbers and an ability to make use of mathematical skills . . . The second is an ability to have some appreciation and understanding of information which is presented in mathematical terms, for instance in graphs, charts or tables or by reference to percentage increase or decrease. . . . *Our concern is that those who set out to make their pupils 'numerate' should pay attention to the wider aspects of numeracy and not be content merely to develop the skill of computation. (*Cockcroft, 1982, para. 39 p. 11)

The same discussion has been taking place ever since.

If the (adult) numeracy research community has been trying to fit numeracy practices into mathematics education and cannot find a 'good fit' then I think we have a conceptual problem of incommensurability. With a broad view of adult numeracy encompassing people's lives, including their work and cultural experiences, coming from every educational, class and ethnic background there is no common lexicon with a mathematics education built on the foundations of pure mathematics finding truth through logic and proof.

A new paradigm

There are indications that some researchers over the last twenty years have become aware of the need to question the current research domains and look for developments that establish what I consider is a new research paradigm.

In Jablonka's (2003, p. 87) section on 'Mathematical literacy for environmental awareness', a discussion about the fundamental nature of mathematical knowledge is introduced. It concludes "Consequently it is argued that mathematical literacy involves an attempt at changing the perception of mathematics towards a more human view in the hope that this may eventually even lead to the development of new forms of mathematics".

Coben (2006) published the article ‘What is specific about research in adult numeracy and mathematics education? She introduced a ‘professional knowledge domain’ and expressed her view of the current state of research.

> Research in adult numeracy and mathematics teaching and learning is still in the exploratory phase of development. There is much conceptual uncertainty, manifested in shifting relationships between numeracy and mathematics and between numeracy and literacy, and reflecting similarly shifting relationships between these areas in educational practice. (Coben, 2006, p. 29)

In a later work on numeracy (and mathematical literacy) curricula Jablonka (2015) expressed a great deal of concern about the nature of assessment items used to measure adults’ levels of numeracy. Jablonka critiques how mathematics is contextualisesd in the numeracy/mathematical literacy assessments.

> The incorporation of N/ML activities into mathematics curricula that specify mathematical knowledge in terms of generalisation and specialisation of *mathematical* meanings entails a recontextualisation that brings about a shift of criteria for what counts as an accomplishment of a task. This needs to be recognised in any attempt of inserting N/ ML activities into a *mathematics* curriculum (Jablonka, 2015, p. 606/7)

The reference to N/ML is to Numeracy/Mathematical Literacy and the italics is in the original. This again shows that trying to talk about adult numeracy in terms of ‘mathematical meaning’ brings about considerable confusion, most of which arises from ‘context’ in its broadest sense. In some ways it is not surprising as everything we have looked at so far emphasises that adult numeracy and numeracy activities and practices contain or are defined by ‘context’. Mathematics and traditional ‘mathematics education’ is considered context free. They are inconmenesurable as previously discussed.

Conclusion

This report presents a theoretical approach to research into adult numeracy education and practice. It uses the philosophical approach of Thomas Kuhn of the paradigm change, first described in the Structure of the Scientific Revolution (published in 1962) and subsequently developed over the next 30 years. The introduction of concepts like incommensurability and lexicon fluidity allowed this powerful analytical tool to be applied to the ongoing debate about adult numeracy. Combining this theoretical approach with a well-informed account of defining adult numeracy I have made the claim that adult numeracy research represents a paradigm change in the context of mathematical education research. There have been repeated attempts to explain and explore adult numeracy with the incommensurable lexicon of pure mathematics and its related educational processes, which have failed.

As Kuhn (2002, pp. 97-99) himself says this can only become really apparent if future research recognises the lexical divergence and with more and more researchers (and practitioners) using the new taxonomy, a new branch of education research evolves as does a new species through Darwinian evolution. A new habitat is defined where adult numeracy can grow freely.

Financial literacy and numeracy: exploring the skills and knowledge needed to survive in complex financial systems

Beth Kelly

UCL Institute of Education, London, United Kingdom; beth.kelly@ucl.ac.uk

Research shows that even before the pandemic many people were financially vulnerable, in the sense that they were struggling to 'make ends meet' relying on loans to cover even day-to-day costs. This paper outlines literature research undertaken to support a European funded project, called Money Matters, that aims to develop resources to help improve the financial literacy skills and knowledge of families defined as disadvantaged or financially vulnerable. Developing financial literacy skills, knowledge and behaviours is identified as one way to support families who feel insecure about their financial situations. The paper examines what is meant by financial literacy, the knowledge, skills, and pedagogies, and identifies a considerable range of factors related to financial vulnerability and points to the challenges of developing the wide range of necessary skills and knowledge, including numeracy, that families need to survive in an economy with complex financial tools on limited resources.

Key words: Financial literacy, financial vulnerability, family learning, money, financial numeracy.

Introduction

This research supports a project funded through Erasmus + called Money Matters, that seeks to help disadvantaged families develop their financial literacy skills and knowledge. Building on a variety of skills from 6 partner organisations across Europe it aims to develop the financial literacy skills of a network of educators trained to use a pedagogic approach that includes the whole family utilising both online games and apps as well as comic book resources to help achieve greater financial wellbeing.

Developing financial literacy skills, knowledge and behaviours are promoted by many international organisations to support people in overcoming financial disadvantage. Producing resources to support families identified as vulnerable in the development of their financial literacy skills requires the combination of many different sets of knowledge, skills and related pedagogies including financial literacy, numeracy and literacy skills, family learning approaches and digital technologies developments. This paper limits its focus to exploring the notion of financial literacy, financial vulnerability as well as approaches taken in current financial education in the UK aimed at families. The research explores the role of numeracy and how it contributes to the development of financial literacy skills and knowledge. It moves on to consider the challenge of developing the wide range of necessary skills and knowledge, including numeracy, needed by those experiencing financial vulnerability and challenges in their everyday lives.

Financial skills, knowledge, and behaviours

Many countries and international organisations promote the development of people's financial skills and knowledge as important for inclusion in society and as a way of countering financial vulnerability, thus encapsulating the twin aims of empowering citizens but also contributing to the overall stability of current financial systems (OECD/INEF, 2020). When identifying essential financial skills, the Organisation for Economic Development International Network for Financial Education (OECD/INEF) and the European Union (EU), tend to use the term financial literacy, while the United Kingdom (UK) and the World Bank (2013) use the term financial capability, although often these terms seem to be used interchangeably.

Essentially both financial capability and financial literacy are similar in their range of characteristics and look at the skills and knowledge needed by individuals to function within Western economies. By 2018 both the OECD/INEF, the EU and the UK include wellbeing as a key aspect of financial literacy and consider how to develop the resilience to achieve this. Arguing improving financial literacy is pertinent during times of economic volatility, suggesting financial resilience consists of developing

> '…a financial cushion, coping with a financial shortfall and stress, and behavioural traits promoting long-term planning and saving, keeping control over money, taking care with expenditure, and avoiding financial fraud' (OECD/INEF, 2020, p. 7)

However, Storchi and Johnson (2016) argue that developing financial wellbeing is not simply about improving how people access financial services and support or identifying 'optimal behaviours'. Rather they posit people in different social, cultural, and economic environments may have different financial and wellbeing goals. Hence people may access the same resources but use them in different ways, reflecting their own notions of wellbeing. Given that nearly half of the population in the UK are benefit dependent or on low incomes (Money Advice Service, 2016) their notions of wellbeing may be very different to someone who has the resources to consider long term investments.

Storchi and Johnson (2016) also argue that a simple lack of money may affect people's decisions more than lack of financial knowledge.

What is financial vulnerability?

Research shows that significant numbers of people were already struggling financially before the COVID-19 pandemic and now, given the impact on the world economy, are under even more financial pressure (Lusardi, Hasler, & Yakoboski, 2020; OECD/INEF, 2020; Social Metrics Commission, 2020). There are many ways to describe people in difficult financial situations who are 'struggling to make ends meet' and experiencing feelings of insecurity relating to debt and savings. In this article we use the term financial vulnerability termed by Gal, Grotlüschen, Tout and Kaiser (2020) to describe people who might be identified as financially fragile, financially stressed, squeezed, or struggling.

When families who are already financially vulnerable are caught up in unexpected single negative events, such as the loss of employment or being furloughed, they can be left in difficult positions with a limited number of options available to them to help overcome their problems. Certainly, the COVID-19 pandemic could be identified as one such significant negative event with long term implications for many families who have little or no savings or 'back up money' (Kelly, Smith & Kaye, 2022) to support them during this time. While debt consolidation and restructuring may be one option, more often other more precarious choices are used including short-term ‘pay day’ loans with excessive interest rates or the overuse of credit cards with minimum repayments (Gathergood, 2012).

Some countries do have financial organisations that are committed to working with families in debt, to help plan a way out of distressful situations (Lusardi, Hasler & Yakoboski, 2020; Financial Capability Lab, 2018). However, research also points out that financially vulnerable families have little awareness, or confidence, in accessing financial organisations and support that is available to them. Hence families with low levels of financial literacy, who are experiencing debt, struggle to get out of the cycle of debt (Financial Capability Lab, May 2018), reinforcing the notion of a financial environment that appears to provide limited effective support that might help overcome vulnerability.

Factors influencing financial vulnerability

Psychological research tends to focus financial literacy more on individual personality types, linking those with problems of self-control to the use of quick access but high-cost solutions such as ‘pay day’ loans (Gathergood, 2012). Exploring the wider notion of vulnerability Gal, Grotlüschen, Tout and Kaiser (2020) identify that financial vulnerability is linked to debt and identify numeracy skills as key to understanding complex financial decision making.

The OECD (2013) found that in many countries, women displayed lower financial knowledge than men and identified as being less confident in their financial knowledge. The report argues that barriers to women developing financial literacy are often linked to their socio-economic position in society and the different social norms around finance expected between men and women. However, women tend to live longer than men but on average earn less which suggests deeper structural barriers within societies that women experience. Hence Gal, Grotlüschen, Tout and Kaiser (2020) point to gender as important issue when researching financial literacy and vulnerability. Further research identifies other factors linking lower levels of financial literacy to financial vulnerability, including being ‘young, a single parent, in poor health, unemployed and with low income’ (West & Worthington, 2018, p 331), having a disability (Lusardi, Hasler &Yakoboski, 2020), as well as age and limited digital capabilities (OECD/INEF, 2020). The number of factors identified in relation to financial vulnerability points to the need for a variety of approaches to develop relevant and useful financial skills and knowledge.

Financial vulnerability is a global issue. Research by the OECD/INEF (2020) found that 42% of individuals responding to their survey, across 26 countries from Asia, Europe, and Latin America, felt ‘financially stressed’, in that they worry about meeting their everyday living expenses. Lusardi, Hasler and Yakoboski (2020) point to 27% of the US population being ‘financially fragile’, in that they would have difficulty ‘coming up with $2000 in an emergency, and this was in January 2020 before the pandemic hit. The Money Advice Service (2016) report indicates that well before the 2020 COVID crisis, nearly half of the population of the UK were either on very low incomes, benefit dependant or heavily reliant on credit. This ‘squeezed’ group are often working nonetheless have ‘significant financial commitments but little provision for coping with sudden changes such as unexpected bills, being made redundant, unexpected medical costs.

Baron’s (2015) research with marginalised communities in Canada reinforces the notion of increased financial vulnerability amongst the most disadvantaged in society. She argues living in communities where there is a low median income, where unemployment is common, income is low and there is little surplus available for long-term savings or investments as contributing to financial vulnerability. A financial environment where temporary contracts and low levels of pay are common, such as in the UK, also contributes to in-work poverty, meaning many families struggle to make ends meet relying on benefits and food banks to get by (Beatty, Bennet & Hawkins, 2021). When considering financial education for disadvantaged groups the notion of putting aside money for savings and long-term investments may be relevant but less of a day-to-day priority.

Financial education-developing financial skills and knowledge

Still the OECD/INEF argues that the main factor hindering possible resolutions of family debt is the lack of key financial literacy skills. Focusing on individuals' behaviours Lusardi (2019) argues financial education is needed to help people counteract ineffective spending and expensive borrowing by learning about financial planning and debt management. Lusardi, Hasler and Yakoboski (2020) recognise that people who are financially vulnerable are hardest hit during economic crises yet they still argue that financial education is important for the well–being of individuals as well as the whole of society. Hence it should be provided in schools, workplaces and in the community, targeting different age groups related to different financial imperatives. However, Willis (2008) posits the issue of financial vulnerability is more systemic and not easily solved through financial education courses. He identifies the current economic environment as made up of complex financial products and services that are constantly changing, making financial vulnerability a consequence of such financial systems rather than an individual problem of skills deficit and behaviour.

While Willis (2008) continues to see little value in financial education in schools, others argue the notion of financial literacy development in later life is less effective pointing to research that shows most people's financial behaviours and habits are developed while very young and become fixed (Whitebread and Bingham, 2013). However, Mundy (2011) posits that 'financial teachable moments' happen at particular times throughout life when big changes happen, such as when a baby is expected, going to college, getting married or divorced. Kelly, Moulton, and Stone (2014) identified one such 'teachable moment' when a significant change occurred in the UK benefit system during the introduction of Universal Credit. Adults experienced a dramatic change in their benefit payments from weekly cash payments to monthly online payments, requiring claimants to develop digital as well as financial skills to access and manage their money.

Financial literacy, numeracy skills and family learning

Researchers (Baron, 2015; Skagerlund, Lind, Strömbäck, Tinghög and Västfjäll, 2018) argue that mathematics is the driving force behind becoming financially literate and has a dual effect on the population's skill, raising both mathematical skills and knowledge and financial literacy levels.

Research also suggests the focus and reasons for developing financial and numeracy skills change over time. In families with younger children, Skwarchuk, Sowinski, and LeFevre (2014) identify both formal and non-formal activities in the home as important because they develop different aspects of literacy and numeracy skills. In numeracy, formal activities tended to develop symbolic skills such as number skills, whereas informal activities such as games and cooking tended to influence attitudes towards mathematics activities. When developing mathematical skills and attitudes in younger children Ramani and Siegler (2015) highlight the importance of the social context of home learning and the contribution informal activities, such as cooking and shopping, make to acquiring new skills, such as helping to develop a sense of size, weight, volume and even ratio. Whitebread and Bingham (2013) also posit that young children respond to social and emotional interactions with parents, grandparents and carers and enjoy joining in with adult financial practices such as shopping, where they can be given responsibilities for spending and budgeting. They see learning within the family as key in the development of younger children's financial 'habits of mind' arguing they develop 'executive functions' of mind that influence more specific financial understandings which come later. They posit that 2- to 3-year-olds can be encouraged to start counting, comparing sizes and quantities helping them develop language. By 7 years old they start to have a sense of 'value' and equivalences so, for example, they can understand that a small 5 pence piece is equivalent to 5 big pennies, so value is not indicated by the size of the coin. With older children it might be useful to link discussions around income, expenditure, and affordability to the impact of purchases on wider society and the environment. Where price can relate to where the item is made, working conditions of those producing the items and the cost to the environment in the making and transportation of the item. Gal, Grotlüschen, Tout and Kaiser (2020) point to the need for good numeracy skills to support financial skills later in life in order to understand credit, compare utility bill offers and undertake more complex longer term financial planning needed for retirement or taxation. Indeed, they argue that the term financial numeracy should be used rather than financial literacy to emphasise the importance of those underpinning skills.

But the Money Advice Service (2016) points to a wider range of skills that enable or inhibit financial well-being, these include financial confidence, digital engagement, and the ability to seek advice and guidance. Two current large scale financial education programmes aimed at supporting families in the UK focus on the psychological and emotional aspects of finances highlighting the importance of talking about money. They also reason those early financial habits learned from parents influence children in their attitudes to money later in life. (Campaign for Learning, 2021; Made of Money, 2021).

Marta Civil (2016) points to the importance of ensuring learning is centred on families' lives and their lived experiences. In her work with excluded people in US society, she argues it is important to view the parents not just as adult learners but also as 'funds of knowledge'. Using this approach Civil posits teaching and learning should focus 'our attention on the culturally situated everyday practices of the learners. It should be grounded in a dynamic view of culture as lived experiences' (2016, p 46) hence financial education needs to start from what the learners view as important in their daily lives, which may differ from that of the educator or trainer. This awareness is important when developing resources with diverse families who may be identified as financially disadvantaged or vulnerable.

Conclusions
