- Explain and discuss with students how to help and how to request for help during an activity.
- Encourage effective ways of cooperation and collaboration, for which explicit work with the class is necessary.

The design principles listed and the OATLP cycle are the result of the first phase of the project OPEN-MATH and are the starting point of an interdisciplinary dialogue among the two involved theories: the reciprocal relation of the design principles and the link between each one of them with inclusion in mathematics, and with the specific constructs defining it operationally, will be object of further studies.

The role of examples in early algebra for students with Mathematical Learning Difficulties

Francesca Gregorio

University of Paris, Univ Paris Est Creteil, CY Cergy Paris Université, Univ. Lille, UNIROUEN, LDAR, F-75013 Paris, France and HEP Vaud, Switzerland; francesca.gregorio@hepl.ch

Recent years have been marked by a growing research interest in students with Mathematical Learning Difficulties (MLD, acronym which denotes specific and/or severe difficulties in mathematics). Most research on MLD has focused almost exclusively on the arithmetic domain, but in recent years, research has begun to taking into consideration other mathematical domains, for example algebra. The present research aims at answering the following research question: What is the role of examples in algebraic thinking for students with MLD? Using Balacheff's typology of proofs, different types of examples are identified: naïve empiricism, crucial experiment, example to spot the regularity and generic example. These examples can be used as tools for observing algebraic thinking in students with MLD and they support the occurrence of algebraic thinking in this population.

Keywords: MLD, mathematical learning difficulties, mathematical learning disabilities, early algebra, role of examples.

Introduction and literature review

Recent years have been marked by a growing research interest in *Mathematical Learning Difficulties* (MLD). This interest, which until a few years ago belonged mainly to the psychological domain, now also concerns mathematics education. An example of this growing interest is the recent creation of *TGW25 Inclusive Mathematics Education – Challenges for Students with Special Needs* for CERME11 in 2019.

The relative youth of this field is reflected in a lack of unanimity on the meaning of the acronym MLD. Some researchers speak of *Mathematical Learning Difficulties*, others of *Disabilities* and others of *Disorders* (Baccaglini et al., 2020). The acronym is therefore used in mathematics education in a polysemic way and to identify different populations (Deruaz et al., 2020; Lewis & Fisher, 2016; Scherer et al., 2016). According to Deruaz et al. (2020), it can refer to students who have been diagnosed with a learning disorder specific to mathematics through a standardised test, usually psychological, and through defined criteria (such as cutoff, etc.). The same acronym can be found to refer to students who have been diagnosed with another learning disorder, not specific to mathematics, but which may have an impact on their learning (e.g., dyslexia or dyspraxia). The term MLD is also used to refer to students who have severe difficulties in mathematics without ever having been diagnosed. The latter category is designated through non-standardised tests, or through teacher assessment.

Despite the wide variety of definitions, they have in common the focus on students with specific and/or severe difficulties in mathematics (Deruaz et al. 2020). This "inclusive" vision of MLD which is not necessarily linked to a medical certificate attesting the difficulties of the students seems to be the most appropriate for mathematics education. Indeed, this research field aims to take charge of all students and their difficulties, regardless of whether or not a diagnosis has been obtained.

Most research on MLD has focused almost exclusively on the arithmetic domain, on number sense and basic arithmetic calculations (Deruaz. et al., 2020; Lewis & Fisher, 2016). In recent years, research has begun to broaden its scope, taking into consideration other mathematical domains, for example equations are included by Karagiannakis et al. (2016) in a battery of tasks designed to detect the causes of difficulties for students with MLD. Furthermore, recent studies in cognitive science have shown that learning difficulties in mathematics are heterogeneous (Fias et al., 2013) and affect several aspects of mathematical skills (Kaufmann et al., 2013). Although there are early signs of interest in other areas of mathematics, these are very rare. This finding shows the need for further research concerning students with MLD, that considers other areas of mathematics. And, as Lewis and Fisher (2016, p.365) say, "in particular, it is critically important that researchers begin to explore MLD in algebra, given its role as an educational gatekeeper".

The last decades of research in mathematics education on algebra have been marked by an interest in *early algebra*, a specific area of teaching identified as a bridge between arithmetic and algebra (Malara and Navarra, 2018). It is a meta-discipline that links arithmetic and algebra and can use mathematical tasks and problems traditionally presented in the arithmetic domain to highlight algebraic processes and algebraic reasoning necessary for a good understanding of algebra (in the traditional sense, Malara and Navarra, 2018). This approach favours the development of a certain way of thinking, *algebraic thinking*, which does not necessarily need the standard algebraic symbolism to be addressed and which is necessary for a proper learning of traditional algebra (Kieran et al., 2016). Malara and Navarra (2018) identify some main language constructs that are fundamental in order to generate new ways to see arithmetic and thus algebraic thinking. One of them is argumentation. Argumentation and its verbalisation are crucial in the approach to generalisation and early algebra. In fact, it fosters students to explicit ideas and procedures of which they were not fully aware before trying to express them. Argumentation and justification make it possible to make explicit an algebraic reasoning that would otherwise remain implicit.

Early algebra therefore seems to be a mathematical domain that is particularly well suited to research about students with MLD because it allows the research to be taken up where it has been left off, at arithmetic, and to bridge the gap with the new mathematical discipline, algebra. Furthermore, it is ideal with students with MLD because it allows algebraic concepts to be tackled without standard algebraic symbolism (which not all students with MLD encounter in their schooling). Although this topic is of great scientific interest, we are currently unaware of any research publications concerning students with MLD in early algebra.

Theoretical framework and research question

The literature review described above led us to become interested in the behaviour of students with MLD in early algebra, wanting to tackle the problem of how we can describe the algebraic thinking of students with MLD. In particular, as we see in the previous section, argumentation and justification are fundamental for algebraic thinking. This consideration leads us to the research question: *What is the role of examples in algebraic thinking for students with MLD?* Our hypothesis is that examples are an opportunity for producing argumentation and justifications and thus showing algebraic thinking of students with MLD. Focusing on examples, we can observe students with MLD using algebraic thinking. On the one hand, therefore, examples serve to study the algebraic reasoning of students with MLD. On the other hand, students with MLD are a good population to study the role of examples in mathematical reasoning since they use examples often. It is important to note that the present research focuses on studying the reasoning of students with MLD, without having the ambition to propose a teaching intervention. This could be an idea for future research that would build on the results of current research to construct the intervention.

To answer the research question, we relied on the theoretical framework of Balacheff's (1987), who created a typology for proofs. The typology offers a classification on the basis of the knowledge involved and the nature of the underlying rationality. From this perspective, the proof is understood as an explanation accepted at a certain point in time by a certain community. There are two main types of proof: pragmatic proofs and intellectual proofs. Pragmatic proofs are action-related and carried out by the students themselves to establish the truth of a certain proposition. If access to this realisation is not possible and the action must be abandoned, we speak of intellectual proofs.

1. *Naïve empiricism* is the first stage of pragmatic proofs. It occurs when the validity of a statement is proved from one or a small number of cases.
2. The *crucial experiment* proves a statement by presenting an example that the student recognises as being as non-specific as possible. If the proposition is true in this case, then it must necessarily be always true. Crucial experiment, which remains a pragmatic proof, differs from naïve empiricism in that the generality of the proposition is taken into account and made explicit.
3. A *generic example* lies on the borderline between pragmatic and intellectual proofs. A proposition can be proved by means of the generic example when a specific case is not treated in its particularity but as representative of a certain family of objects with an argument that can be extended to a whole class of objects. This type of proof consists of proving the validity of an assertion by performing operations or transformations on a particular case, but at the same time use is made of the properties and structure that characterise the class that this particular case represents.
4. *The thought experiment* allows proving by internalising the action and detaching it from its concretisation on a particular representative. By remaining linked to anecdotal temporality, it abandons the treatment of a particular case, as was the case for the generic example.

This typology should not be understood as a tool to assign each student a possible level of knowledge or to identify the cognitive level they are at. It is not a set of successive stages that students must reach in a given order, it is simply a tool for describing students' actions in a certain context in a given mathematical task.

Method

Context and participants

The data presented in this paper has been selected from more extensive research in which more students (19 in total) and more mathematical problems (8 in total) were taken into account.

Data were collected in the canton of Vaud, in the French-speaking part of Switzerland. In this region, interest in school inclusion has grown in recent years. This is evident for example from the creation of the *Concept 360°* (DFJC, 2019), a project which aims to establish the principles of a school that responds to the specific needs of all students. In spite of this growing interest, school organisation is divided into different types of schools (ordinary schools and specialised schools) or school levels depending on pupils' abilities and grades.

The participants were selected based on their severe and/or persistent difficulties in mathematics, as defined by Deruaz. et al. (2020) and described in the previous paragraphs.

In particular, for the research presented in these pages, the students belonged to different classes of lower secondary school (7^{th}-9^{th} grade in Switzerland, 12-14 years old) and have different profiles.

1. Student A (9^{th} grade) is enrolled in an ordinary school, in the level for students with the best grades. Student A has good results in all subjects except mathematics, in which she is considered to be in severe difficulty by her teacher.
2. Student B (8^{th} grade) is schooled in a special teaching class. Student B has a diagnosis of dysphasia and dyslexia and has severe difficulties in all subjects, including mathematics.
3. Student C (8^{th} grade) is enrolled in an ordinary school, in the level for students with low grades. Student C has a diagnosis of dyscalculia and dyspraxia.

Procedure

Data were collected through clinical interviews. This is a semi-directive, open-ended interview between a researcher and a student, whose aim is to encourage the manifestation and observation of mathematical thinking (Ginsburg, 1981). The student interviewed had the task of solving the assigned problem by explaining their procedure. The researcher intervened to ask questions requesting clarification of the procedure used or to unblock the situation in case of difficulty. The aim of the interview was to get the students to show a large number of examples and to progress in their mathematical reasoning. The researcher therefore tried to create the ideal contextual conditions for this objective, by relaying the students' statements to allow them to show their full potential, but without replacing them in finding the answer.

The interviews are filmed and the audio transcribed. The unit of analysis consisted of students' oral and written contributions. These have been analysed on the basis of the typology of proofs (Balacheff, 1987) with a particular focus on the use of examples in algebraic thinking: each sentence said by the students and each written production produced were read and, when relevant, categorised according to a category of the typology.

Mathematical problem

The interview was about solving the following mathematical problem: *If I add two odd numbers, do I always get an even number?*[1]

The chosen problem develops algebraic thinking as it allows us to work on a property of numbers (being odd or even) and on the structure of ℤ (there is a regular alternation of odd and even numbers) by providing evidence for the reasoning carried out. The chosen problem is particularly well suited to answering the research question because the understanding of the statement and the result are facilitated by the mediation of the examples, and examples are not provided directly from the statement but must be created independently by the student, according to his needs.

Results

The analysis through Balacheff's (1987) framework of the clinical interviews allowed us to identify different types of examples created by the students and used to solve the problem.

The first type of example, the *naïve empiricism*, is what the student produces right after starting to work on the problem, it is the first example which lets her begin tacking the problem. For instance, student B starts the problem in the following way:

Researcher: Yes, it requires taking...
Student B: Multiples of two.
Researcher: Two odd numbers. If I take two odd numbers and add them together, do we get an even or an odd number?
Student B: Yes… even… we can… if you do 3+3, it gives 6.

The examples enable the students to start reasoning and to approach the problem that otherwise would remain unreachable.

After the first example, students give other examples, and then other examples, until generality is taken into account and explicitly evoked. For example, student B continues his reasoning:

Researcher: What do you think, if I add an even number plus another even number, how will the result be?
Student B: Even.
Researcher: How do you know?
Student B: Well, if you add 12 plus 12 that's 24 and if you add 14 plus 14 that's 28 and it's always even, otherwise 4 plus 4 is 8, 6 plus 6 is 12, 8 plus 8 is 16, it's always even.

This list of examples ensures the generality of the statement. There are so many examples that, for the student, this is enough to support the generality of the statement. We call this the *crucial experiment*. The crucial experiment may also be given by a single example which in the view of the students is so unspecific that if the statement is true in that case, then it is always true. What is important for the crucial experiment is that the generality of the situation is evoked, in this aspect the crucial experiment is different form the naïve empiricism.

[1] The mathematical problem and transcriptions were translated into English by the author of the text from the original French version.

This iteration of examples leads the student to spot the regularity of the situation and to understand that this regularity has a motivation. The student evokes the fact that the regularity can be identified, understood and generalised. Student A says:

Researcher: We want to understand whether if we add two odd numbers, we always get an even number. Do you remember what an even number is, and an odd number?

Student A: Yes, of course I do. Well... by giving examples. For example, 3 plus 3 is 6. 3 plus 7 is 10. 3 plus 11 is 14. So yes, I think it will always be like that, because there is something logical behind it. In any case, I don't have an example that comes to mind where it wouldn't be possible.

Here the students take into consideration the generality of the situation and she does something more: the example let her see that the regularity has motivations and can be understood and explained. It is “logical”, as the student says. The example generates in the student the need for regularity. With respect to Balacheff’s (1987) typology, his example, *example to spot the regularity*, is not a new category but it is between the crucial experiment and the generic example. It has some characteristics of the pragmatic proofs (it is linked to the action on a limited number of particular cases) and some other characteristics of the intellectual proofs (not only is regularity evoked as in the crucial experiment, but the existence of a logical structure behind this regularity is also evoked).

Examples can also be used to generalise the regularity through a *generic example*. In this case, the example is not treated in its particularity, but as representative of a certain family of objects. The generic example uses the characteristic properties and structures of a certain class of objects by relying on one of its representatives for the implementation of the reasoning. For instance, student C writes $7 + 7 = 14 : 2 = 7$ (Figure 1) and says:

Researcher: Okay, so the question here is... When you add two numbers that are odd, is the result even or odd?

Student C: Yes, okay.

Researcher: Do you have any ideas?

Student C: Well, I could take, for example, 3 which is odd plus 3. That's 6, which is even because if you do 6 divided by 2, it's 3. Then if I take 5 plus 5 which is odd, it's 10. Which is also divided by 2. 7 plus 7, 14, which is also divided by 2. Well, yes, because each time you make an odd number plus another odd number, the same one (indicating 7 on his example), it gives this number (indicating 14) and this number is even because each time, you can divide it by 2 to give 7... well, to give the (indicating 7)…

Here the student is proving that every time that we add two times the same odd number, the result can be divided by 2, so it is even. He solves a particular case of the given problem. He uses the example “7 plus 7”, to support a general reasoning and this particular example is necessary to produce a reasoning that otherwise he couldn’t have had.

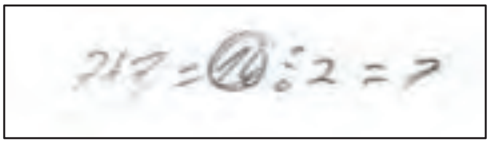

Figure 1: Generic example given by student C

It is interesting to note that this example falls into the generic example category because in the words used by student C we can find references to the particular case (“it gives *this* number”). And also, the gestures (e.g. "*indicating* 14") show that the reasoning is based on the particular case reported in Figure 1. A less thorough analysis could have suggested a thought experiment.

Discussion

The results provide some first answers to the research question: *What is the role of examples in algebraic thinking for students with MLD?*

First of all, the results show that different examples can be used for different purposes (Table 1). They can be used for the student herself, with an *internal purpose*. Examples are essential for the exploration phase: understanding the statement and getting an idea of the results, taking ownership of the problem, entering in reasoning (naïve empiricism), conjecturing (crucial experiment), to spot the regularity of the situation. Examples are also used for solving and proving the conjecture (generic example).

Table 1: The typology of examples in algebraic proofs

Naïve empiricism	Crucial experiment	Example to spot the regularity	Generic example
The first example which lets the students in the problem and in reasoning	The generality of the situation is evoked	The situation is recognised as regular	The example is used as representative of a family of objects

In addition to the internal purposes, examples can also be used in *interaction with others*, to communicate the results obtained.

Table 1 shows how the examples generated by the argumentation promote the generalisation of the mathematical problem by inducing a tendency for students to think algebraically.

Examples can have different status and different roles in algebraic thinking and proving; they can be used as tools for reasoning and for producing algebraic thinking. Examples are particularly important for students with severe difficulties as students with MLD because in this case they support students' thinking, algebraic thinking, which would not be possible without them.

The results show that students with MLD showed traces of algebraic thinking, despite their severe difficulties in mathematics. This is particularly interesting taking in consideration that our sample is also composed by a student who attends a special class, where students rarely encounter certain advanced mathematical topics as algebra.

With students with severe difficulties, pushing towards simplification and meaninglessness in favour of technique is not indispensable, nor is it always fruitful. The results of this research show that proposing problems that make use of *algebraic thinking* is possible.

The study presented here is part of an ongoing research project which macro-objective is to understand if and how students with MLD manifest algebraic thinking. We will carry out further analyses in order to describe the algebraic thinking of these students in more detail.

Inclusive math practices in primary school

Uta Häsel-Weide[1], Marcus Nührenbörger[2]

[1]University of Paderborn, Institute of Mathematics, Germany; uta.haesel.weide@math.uni-paderborn.de

[2]TU Dortmund University, Faculty of Mathematics, Germany; marcus.nuehrenboerger@tu-dortmund.de

In the last 10 years inclusive settings in mathematics have increased in German primary schools. In essence, inclusive mathematics education means giving all students equal opportunities for mathematical education, regardless of their subjective learning requirements and learning potential. In our research project we reflect on the one hand central design principles for developing substantial teaching units for inclusive classes. On the other hand, we analyze the emergence and development of practices focusing on the teaching processes of thematizing and negotiating mathematical contents. For this purpose, 22 class discussions from lessons were examined with regard to the reconstructable practices.

Keywords: Inclusion, practices, natural differentiation, multiplication, discourse.

Introduction

"Inclusive schools aim to involve all learners in quality learning experiences which empower them to become active participants in a more equitable system" (Scherer, et al., 2016, 640). Inclusive education in math classes aims at breaking down barriers and creating universal approaches to math learning. Regarding mathematics education, the main aim is to enable all children developing basic mathematical competences in interaction with others.

Even though the primary school in Germany traditionally sees itself as a school for all, the teachers (children, parents, …) are shaped by a system that is traditionally and currently geared towards segregation and is changing very slowly to an inclusive school. In subject didactics, an understanding of inclusion seems to be established in everyday teaching that is based on a one-sided deficit conceptualisation of the concept of inclusion and reduces inclusion to "compensatory support measures" for precisely those children who seem to have deficits. But inclusive education does not mean that only few children need special support. Rather, inclusion means paying attention to each individual person with his or her individual prerequisites and potentials. Different children cannot and do not have to achieve the same goals. Inclusive education demands from all children exactly what they can achieve. Inclusive teaching engages children to bring in their own needs and interests. They are also allowed to set their own priorities within a certain framework and develop a personal educational profile through their chosen topics and subjects. The diversity of children is also reflected in the fact that they learn differently — at different speeds, in different ways and with different prerequisites. Therefore, inclusive mathematics teaching aims to offer learning opportunities that are individually adaptable and enable mathematics learning in community with others, regardless of competences, learning requirements, interests, and development potentials (Scherer et al., 2019).

In our paper we focus on the ongoing practices in inclusive math education with respect to the research question addressed: “Which practices characterise the plenary in introduction and reflection and how far do they correspond to the normative aims?”

Theoretical framework

In many cases of everyday math teaching in inclusive classes, however, teachers cope with the heterogeneity of the children mainly by using individualised working materials organized in station work or plan work. This organisation at first glance promises differentiated learning progress for each child, as well as optimal development of potential: each child works on a prescribed (sometimes also designed by the child) learning plan at different places and with different levels of support. The children's learning activities only take place side by side. This poses the risk that the learning quality of the lessons is reduced and that the children cannot optimally develop their potential. But mathematical learning processes are particularly dependent on content-related social negotiation processes. Therefore, children need to share mathematical discoveries and to present one´s own reflections as well as to communicate and explain them to others (Steinbring, 1997). This is not possible, if children have to learn more or less on their own.

Consequently, there is a need for the design of substantial teaching materials and for the research of practices of math teaching and collaborative math learning processes in inclusive settings.

Principles and learning situations of inclusive math education

The intertwine dimensions of personhood, sociality, and complexity link subject-specific and social participation. In recent years, different guiding principles have emerged for the design of inclusive mathematics teaching (Häsel-Weide & Nührenbörger, 2021). We refer to four design principles that aim to consider the different potentials of the learners and to connect to them in a targeted way:

(1) accessibility to the common subject matter for all children,

(2) subject learning at different levels,

(3) active exploration of content connections and finally

(4) initiation of common learning phases for all children with social negotiation processes of communicating, representing, and arguing.

Reflecting these four principles substantial learning environments and the task formats on which they are based (Wittmann, 1995) are a basis for the design of mathematical learning situations in primary schools. The environments consider the idea of differential sensitivity, i. e. reflective perception of the heterogeneous competencies of children in a concrete learning situation. The influence of academic and content language for the understanding of mathematical concepts is highlighted as well as the use of appropriate material.

But fundamental for successfully initiated joint learning processes are not only substantial task formats, which focus on the basis staff. The support of teachers seems to play a special role for the learning processes. Especially children with difficulties in learning mathematics seem to be dependent on impulses that support the solution process (Korten, 2020). These challenge them to think about mathematical patterns and structures as well as their own and others' thought and solution processes. But not all impulses do this in the same way. Pfister et al. (2015) investigate the scaffolding processes of teacher in inclusive classes. They see differences in the way teachers stimulate the interaction and active the children regarding to the mathematical subject. The video study of Krähenmann et al. (2019) shows, that teachers have difficulties in creating common and at the same time differentiating learning situations. Teachers either provide common but not differentiating learning opportunities for a very heterogeneous learning group or differentiating learning opportunities where joint learning did not take place.

Social and subject-matter practices

Practices are established as a "theoretical construct that allows us to talk explicitly about collective mathematical development" (Cobb, 1998, p. 34). Characterising inclusive practices, a distinction can be made between normative pedagogical practices and the practices that can actually be reconstructed in the observation of teaching. Normativ inclusive practices are e.g. formulated in the Index for Inclusion and describe how practices should be. The dimension of "developing inclusive practices" contains the following three aspects: (1) "Lessons are planned with the diversity of students in mind", (2) "Lessons strengthen the participation of all students" or even (3) "Students learn together" (Booth & Ainscow, 2002). "Mathematical practices include problem solving, sense making, reasoning, modeling, abstracting, generalizing, and looking for patterns, structure, or regularity" (Moschkovich, 2015, p. 1068).

These practices can be distinguished from concrete teaching practices, which Hirschauer (2016) describes as "ways of doing". He defines 'practice' as a physical consummation of social phenomena such as "types of activities, ways of acting, patterns of behavior, forms of interaction" (Hirschauer, 2016, S. 46; transl. by the authors). Practices are analytical units and describe structures, customs, or things themselves which influence teaching and shape learning.

Design of the Study

In our project IGEL M (Inclusive practices in shared learning opportunities in mathematics) we develop existing learning environments further by conducting didactic teaching-learning experiments for inclusive learning settings and by analyzing mathematical learning processes from a qualitative perspective (Häsel-Weide & Nührenbörger, 2021). We focus on the mathematical practices in inclusive lessons. The analysis follows an interactionist perspective, focusing on the classroom microculture and mathematical practices.

We accompany classes during their time in primary school and visit them 4-5 times a school year. In cooperation between the teacher of the class and the authors of the paper we plan learning environments, select material and develop further. The lessons, carried out by the teacher, are videographed and used to a) answer the research questions as well as b) to reflect jointly the quality of the learning. Actually 22 lessons are videographed, each subject was realized in two consecutive lessons. In detail, we tackle three research questions in the project, but in the following, we focus on the first question:

RQ1) Which practices characterise the plenary in introduction and reflection?

RQ2) Which practices characterise the collaborative work of children?

RQ2) Which mathematical understanding can be reconstructed? How far differences the understanding?

The reconstruction of the practices bases on the videographed teaching and learning situations. Corresponding transcripts were interpreted by a group of researchers finding different typifications. The interpretation of the negotiation processes follows four analytical steps: (1) Video scenes are transcribed. (2) In discursive analyses of the researchers involved, these are paraphrased and interpreted by means of turn-by-turn analysis. (3) In discourse, plausible typifications of practices are elaborated by categorising patterns of interaction or activities. (4) The practices are compared comparatively with other analyses of other scenes and examined in a generalised way (Voigt, 1994).

Analysis of an episode

Learning environment

This paper is about a common task to explore the distributive relationships between so-called easy and more difficult tasks. In essence, the students first must recognise the doubling tasks (multiplier 2) and solve the neighboring task (the multiplier 2 is increased by 1) with the help of this (see Figure Fig. 1).

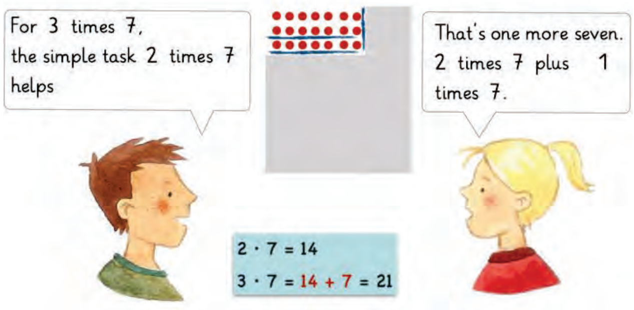

Fig 1: Neighboring tasks. Deriving a solution for a simple task for calculating a difficult task (Nührenbörger et. al., 2017; Illustration by K. Mosen, PIKAS)

The basic material for all students is therefore not limited to recognising simple multiplication tables, but to exploring the structural relationships. Children with mathematical learning difficulties have great issues in seeing the structure, understanding the operation, and deriving results. According to the idea of sensitivity of different competences, this must be considered in inclusive classes. For this purpose, both representation-sensitive and language-sensitive supports are offered to enable access to the common learning object. For example, students can show the simple painting angle task on the 100 field and then move the angle down one line. Moving the painting angle down represents increasing the multiplier by 1, so that the product increases by the multiplicand once.

This multiplication relationship can be supported linguistically by picking up on speaking in groups (see example of students) and by verbalising the move of the angle. If not all students in an inclusive class are already working in the number range up to 100 or if, for example, the whole multiplication table still seems too complex, the distributive relationships can also be explored in qualitatively differentiated tasks with a structurally reduced field (the 25 field, consisting of 5 times 5 points, see Figure 2).

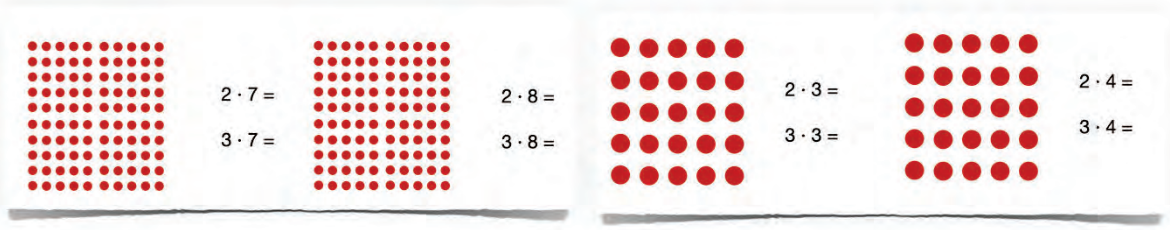

Fig 2: Neighboring tasks at the 100 field and 25 field

In an inclusive class, these tasks can be worked on individually. On the other hand, the students can also work cooperatively in pairs on such a task: For example, one child looks for and shows the easy task, the other notes it down. Then the more difficult task is derived from it by shifting the painting angle and noting and calculating the task in relation to the previous one.

Plenary practices

At the beginning of the lesson, the teacher highlights the aim of the lesson and links it to previous related topics (see transcript). She reminds the students that simple tasks have already been used in addition. The teacher also points out that the result should be found with the help of simple tasks, not by counting.

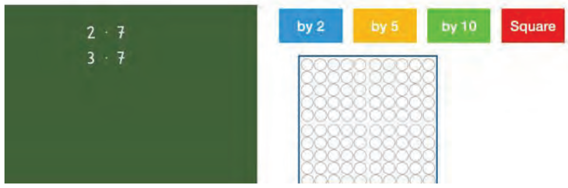

Fig 3: Blackboard picture for the neighboring task

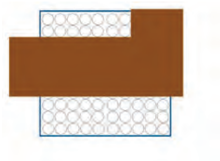
Teacher: Today we calculate difficult multiplication tasks. You may remember from the plus tasks, we did that too. If you can do a simple multiplication task and you know it well, it will help you to solve a difficult task. Then you don't have to start counting or calculating all over again. Yes? And today, I want to show you how this simple task can be a help. Ok? (*goes to the blackboard and points to the tasks 2 - 7 and 3 - 7*). If you have two tasks, think for yourself which of the two tasks is a simple task. Josie.

Josie: Two times seven

Teacher: Why? (*she marks the task 2 · 7 with an x*)

Josie: Because it is a task by two

Teacher: Ok. Good.



Josie: Shall I tell the result?

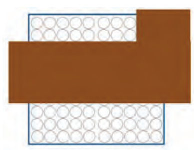
Teacher: I will mark first and then you can tell me the result, ok? (*she takes the multiplication-angle and a pen*). How many are in a row? Frederic

Frederic: Seven

Teacher: (*puts the multiplication-angle on the dot field)* Josie, now.

Josie: Fourteen.

Teacher: So, now we have to think. The next task is called what? The difficult multiplication task. Lea.



Lea: Three times seven

Teacher: What do I have to do to get three times seven?

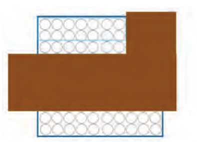
Lea: One to the right

Teacher: (*moves the angle; a couple of children raise both arms*)

Lea: (names a child)

Child: Now the tasks are called two times eight. You have to move one to the left and one down.

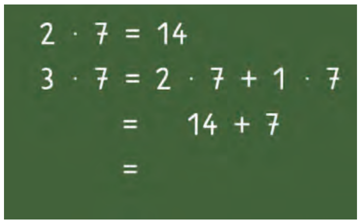
Teacher: So you mean I should go back first and then down. I'll use a different colour, I think you can see it a bit better then. What has been added? (*points on the third row of the field*). Doreen.



Doreen: Seven once again

The teacher always switches between different the symbolic and verbal form of task presentation and the iconic dot field. Josie must wait before she is allowed to give the answer, because the task should first be presented in dot field. Even after the difficult tasks has been solved, she asks the children to look again to the added quantity on the dot field. In doing so, the teacher highlights the connection between the representation. This explicit connection important especially for children with difficulties. The teacher asks the children how the angle must be shifted, too. Leading the conversation, the teacher picks the children. Most of them put up their hands. With this practice she decides which children in participate in the classroom conversation. But the practice “veto” differs from this routine. If the children do not agree with an answer, they rise both hands. Then the student (Lea), who gave the disputed answer chooses someone, to put forward their argument. Similarly, the practice “help” works, which can be reconstructed if children could not solve the tasks or answer questions. Asking for help they pick up a classmate who answers for them (Jonas):

After both tasks are solved and both results are called, the teacher initiates a discussion how to calculate 14 + 7 without counting. Jonas probably remembers the solution already given but had difficulty formulating his way of calculating.



Teacher:	Ok. How do you calculate? You want to tell me the solution right away, don´t you? How much is that? Do you know, Jonas?
Jonas:	Twenty-one
Teacher:	Can you tell me how you can calculate this cleverly without counting. (..)? How far do you calculate first? (..). How did you calculate it? (...) Do you know? Would you like to get some help?
Jonas:	Ahmad.
Ahmad:	First I calculated fourteen and then I added seven.

The teacher seems to be aware that there may be a difficulty in adding the multiplicand to the product of the simple task. So, she asks for a clever, non-counting strategy to solve the addition. She picks up Jonas, who mentioned the result, but did not explain the process. Probably he remembers the solution, which has already been mentioned in the interaction. Jonas asks Ahmad for help, who himself mentions the task without explaining a clever strategy for calculating. Bruno explains later: “You take fourteen plus six, then it's twenty. Then you have to add one more because there was one left and then it's twenty-one”.

In summary, the plenary is characterised by the teacher's effort to connect easy and difficult tasks in an understanding-oriented way. The teacher also addresses skillful calculation strategies in addition. The new subject is connected with past subject. These practices address children with difficulties and allow them to participate without making the address explicit. But, the teacher uses (only) an example for the class discourse with fits to the regular stuff and probably overtaxes children, who work in the reduced field. However, the simple task chosen is one with 2, which should already be familiar to all children as a doubling task.

Results

The practices that are evident in this selected scene are typical of inclusive math practices that could be reconstructed in plenaries at the beginning of inclusive class (Häsel-Weide & Nührenbörger, 2021). Those discourses are characterized by the following practices:

Presentation of the subject

- *Explication of the subject*: The subject and the aims of the lesson are explicated and, in many times, classified as simple, basic or elaborated. This may give orientation for all children in an inclusive class, but could also categorise different children regarding to the used material.
- *Presentation of the subject in different forms*: The didactic-normative inclusive practice of presenting a mathematical object on different levels of representation is established as a basic practice for all pupils and all subjects.

Initiation and moderation of subject-related discourses

- *Initiation and decision of participation by the teacher:* The participation of different children is initiated and controlled by the teacher, picking up students in connection with explicitly formulated questions and impulses.
- *Self-responsible participation practices*: The practices of “veto” and “help” were agreed upon in the class between teacher and children as conversation practices and now moderated by the children themselves. So, they take responsibility for the joint learning process. These practices include the opportunity to make alternative interpretations or to pick up and explain mistakes. Children with good mathematical understanding thus remain involved in the conversation and children with difficulties have the opportunity to decide for themselves when to ask for help. All learners in the inclusive class are involved, empowered and supported.
- *Creating subject-related discourses*: The conversation is condensed and directed towards mathematical aspects that the teacher considers important for all learners. Nevertheless, the children are asked to argue and to verbalise freely.

The reconstructed inclusive mathematical practices move in the field of tension between multi-layered-structural explorations and discursive discussions on the one hand, and condensed, focussed treatments on other. In the analysed scene, no obvious assignments of level are made, nevertheless, a closer analysis shows corresponding to other studies (e.g. Straeler-Pohl, et. al. 2014) that higher-performing children are asked for explanations and help by the teacher, but also by their classmates. Lower-performing children are just only asked to help with routine tasks or tasks to secure the basic material. In this sense, the aim that “all students are empowered to engage meaningfully in mathematical practices, for such engagement is the source of agency and identity” (Schoenfeld, 2020, p. 1173), has not yet been fully achieved.

Low-achieving secondary students learn mathematical problem solving – A longitudinal, qualitative video study

Raja Herold-Blasius[1] and Benjamin Rott[2]

[1]TU Dortmund University, Dortmund, Germany; raja.herold-blasius@tu-dortmund.de

[2]University of Cologne, Germany; benjamin.rott@uni-koeln.de

Mathematical problem solving is hard to learn and difficult to teach – esp. for classrooms including low-achieving (LA) students. We investigate what difficulties LA students encounter when solving problems and how their problem-solving behavior develops within a period of nine months. Within a broader project, three pairs of LA students have been videotaped four times over a period of nine months. For this contribution, the video data of the first and fourth collection were analyzed. To do so, each problem-solving process was coded using four different codings: episodes, heuristics, self-regulatory activities, and success. We identified three main difficulties that students encounter: basic knowledge, stagnated development of heuristics, and a lack of self-regulation.

Keywords: heuristics, problem solving, resources, strategy keys, strategy prompts.

Introduction and theoretical background

In many countries around the world (as in Germany), becoming competent in solving problems is an integral goal of mathematics curricula (Liljedahl & Cai, 2021). Students are supposed to acquire strategies, apply those flexibly and, thus, master solving problems (NCTM, 2000). Yet, problem solving itself is a very complex process which is hard to learn (Schoenfeld, 1985). This applies especially for low-achieving (LA) students and students with learning difficulties (LD) (Montague et al., 2011). The situation in schools becomes even more delicate as teachers report that "teaching large heterogeneous groups of students with varied academic level" is stressful (Shernoff et al., 2011, p. 65). Again, if students show difficulties within "regular" mathematics lessons, they can be expected to show even more differences when working on non-routine problems.

Our review of the literature reveals a lack of studies regarding problem solving of LA students and students with LD with the exception of word problems for which it is known that "[s]tudents with LD are characteristically poor problem solvers. They typically lack knowledge of problem-solving processes, particularly those necessary for representing problems and, therefore, need to be taught those processes explicitly" (Montague et al., 2011, p. 263). At the same time, these students lack proper strategy use; instead, they "infrequently abandon and replace ineffective strategies, rarely adapt previously learned strategies, and typically do not generalize strategy use across domains" (Montague et al., 2011, p. 263). Yet, word problems often do not initiate non-routine problem-solving processes (Liljedahl, 2021, p. 25).

Thus, if it is that difficult for LA students and students with LD to master word problems, it will be even more difficult for them to work on non-routine problems. At the same time, these students should learn to solve problems as this is an essential skill for learning in the 21st century.

Research interest and questions

Here, we refer to problem solving as working on *non-routine* problems. We report about a longitudinal, qualitative study that addresses the learning of mathematical problem solving within regular math lessons including LA students, that is students who “experience mild but persistent learning difficulties” (Geary et al., 2012, p. 206). We investigate the following questions: (1) What difficulties do LA students encounter when solving mathematical problems? and (2) How does their problem-solving behavior develop over a period of nine months?

Design of the study

We conducted an intervention study involving 162 students (aged 11 to 14 years, grades 5 to 7) in Germany. All students are from a regular comprehensive school with all ability levels; hence, there is a representative selection of the early secondary students – also inclusive and integrative students. We gathered the students’ math and German grades and used these to group the students into high, middle, and low achievers. We asked their teachers to verify this grouping based on their experience. A standardized maths test was not carried out within this study.

The design of our study is based on three current and well-established approaches for supporting teachers and students within very heterogeneous classrooms: (1) “allow students to work on mathematical problem solving tasks in pairs or in small groups”, (2) “provid[e] all students with high-quality mathematics instruction [by] present[ing] the whole class with the same low-floor, high-ceiling, open-ended, problem-solving task”, and (3) “teach mathematics through challenging task, and use enabling and extending prompts to differentiate instruction” (Russo et al., 2020, p. 49).

Over a period of nine months, the students encountered mathematical problems on a regular basis in their math lessons (approach 2). This is not only part of the national curriculum but also part of the intervention. To support the students, they were introduced to so-called *strategy keys* – these are cards in the shape of keys with one general heuristic written on each key, used to trigger the use of heuristics (approach 3: strategy prompts). We refer to heuristics as problem-solving strategies that students can implement when working on a problem, including “mental operations typically useful for the solution of problems” (Pólya 1945, p. 2). That strategy keys are effective in activating the use of heuristics and fostering self-regulatory activities has been shown empirically by Herold-Blasius (2021) in a project with mathematically interested 3rd and 4th graders. In the study at hand, the keys were introduced to the students within one introductory lesson; thereafter, they were allowed to use the keys whenever they “got stuck” within their problem-solving processes.

Within this project, qualitative data was collected at four different points of time. Thus, 30 pairs of students (approach 1) were videotaped and asked to think aloud while working on non-routine mathematical problems. After finishing the problem-solving processes, they were interviewed and their solution sheets were gathered. The chosen problems were structurally similar throughout the entire study, mainly arithmetic and sometimes geometric. This way, we aimed at comparing the processes more objectively than by using different problems each time.

Due to different reasons only eight of those 30 pairs were constant in their composition at all points of data collection. For the contribution at hand, we filtered the three low-achieving pairs of students.

Their problem-solving processes of the first and last video collection as well as the matching worksheets are focused on in this paper. Using this data, we illustrate how the encountered difficulties and if problem-solving skills develop in 9 months.

Two mathematical problems of the study are used as basis for the paper at hand:

- *Seven Gates*: A man picks apples. On his way to town, he has to pass seven gates. At each gate stands a guardian claiming half of the apples and one apple extra. At the end, the man has only one apple left. How many apples did he have at the beginning? (Bruder et al., 2005)
- *Traffic Jam in Space*: In order to reduce the amount of traffic between galaxies in space, the Intergalactic Council has decided to impose customs duties on commercial travelers. Each time a trader changes galaxies, he must now give up a quarter of his goods, plus one more piece. Plutix distributes toxic-green paint. Arriving at his destination, he still has 23 buckets after having to stop at the intergalactic customs three times and hand in goods. How many buckets did he have loaded at the beginning of his journey? (Collet, 2009)

Both problems are similar in their construction: Someone has to pass a certain number of steps (gates or duties) at which part of an initial amount of something has to be paid – either half or a quarter and one extra. In both problems, the amount at the end is given, so working backwards is the most appropriate strategy. However, other heuristics can either support the working backwards (e.g., aid to systemize or a figure) or open other approaches (e.g., working forward).

Methods – Coding of the data

Each problem-solving process is coded in four different ways in order to describe the problem-solving process as detailed as possible: 1) episodes within the process, 2) heuristics used in the process, 3) self-regulatory activities within the process, and 4) success of the process. Codings 1), 2), and 3) are process-oriented (i.e., using video data), whereas coding 4) is product-oriented (i.e., using the students' written worksheets). Each coding will be explained in the subsequent sections.

Process coding – Episodes: Schoenfeld (1985) defined an episode as period of time during which an individual does the same. He identified six types of episodes (see Table 1 for types relevant here).

Process coding – Heuristics: Appearances of heuristic techniques, such as drawing a figure, generating examples, or trying systematically, were coded using a manual based on ideas by Koichu, Berman, and Moore (2007) (cf. Rott, 2013). Codes relevant for this paper are specified in Table 2.

Process coding – Self-regulation: To code self-regulatory activities within problem-solving processes, we used Schoenfeld's (1985) differentiation between local and meta assessment. "*Local assessment* is an evaluation of the current state of the solution at a microscopic level". (Schoenfeld, 1985, p. 299) So, whenever students check their results, local assessment occurs within a problem-solving process, (see Table 3). *Meta assessment* did not occur within the given data and will not be addressed any further here. Additionally, we identified self-regulatory activities is the *interaction with the strategy keys* (cf. Herold-Blasius 2021, showing that using keys can be interpreted as an act of self-regulation). This is because students realize that they need help when they get stuck and they know where to get this help from – the strategy keys. Also, several pre-, while- and post-actional activities of self-regulation could be identified when interacting with the keys (Zimmerman, 2000).

Code	Description
Reading or rereading	The problem is read or re-read. It also contains the silent period after reading.
Analyzing the problem	The problem solver tries to understand the problem, e. g. by thinking about what is sought and what is given.
Exploring	The problem solver investigates the problem which might be more or less chaotic.

Table 1: Codes to identify episodes

Code (Abbreviation)	Description
Sought and given (S & G)	Checking for information given in the problem and what is searched for
Aid for systematization (AfS)	Introducing structuring elements that help to carry out activities
Working backwards (WoBa)	Focusing the aim of the problem/the sought and working from there to the starting point; sometimes mathematical operations must be reversed

Table 2: Codes to identify heuristics

Code (Appreviation)	Description
Local assessment	Evaluation of the current state of the solution, e. g. check results
Interaction with strategy keys	Students read, touch, discuss about the keys or choose a specific key

Table 3: Codes to identify self-regulatory activities

Product coding: Solution

The students' solution sheets, thus, products, were graded in four categories of success:

1. *No access*, when they showed no signs of understanding the task properly or did not work on it meaningfully.
2. *Basic access*, when the pupils mainly understood the problem and showed a basic approach.
3. *Advanced access*, when they understood the problem properly and solved it for the most part.
4. *Full access*, when the pupils solved the task properly and presented appropriate reasons, if necessary. (Rott, 2013, pp. 115–116)

Results

Here, we present the problem-solving processes of three pairs of LA students that worked on the problems Seven Gates and Traffic Jam in Space (1st and 4th video recording, resp.).

K & M: Seven Gates (1st video collection)

During K & M's work on the problem Seven Gates, they spent most of their time in exploration phases. This indicates that both girls did not follow a specific plan.

Concerning heuristics, M & K *reread* the Seven Gate problem and applied solution methods as if the problem were a *routine task*. This means they used all given numbers and put them in some (possibly random) mathematical relation:

M: Can we not just do seven times seven because it's seven gates and then plus seven because another apple for each? [writing: $7 \cdot 7 = 49; 49 + 7 = 56; 56 + = 57;$ *"The man picked up 57 apples."*]

Self-regulatory activities could not be identified and their solution was coded as basic access.

Combining, it seems as if K & M did not understand the problem properly. They understood that there are seven gates and seven guardians and that there is one apple left. However, they could not bring this information together and, thus, treated the problem as if it were a routine task.

K & M: Traffic Jam in Space (4th video collection)

During the problem Traffic Jam in space, both worked within an exploration phase. Concerning their heuristics, they *reread* the problem – as they did in the Seven Gates problem. Yet, they also used an *aid to systemize* as they first drew and later numbered the gates (1, 2, 3). Also, they talked about how they want to proceed and decided that *working backwards* to be an expedient approach. Again, self-regulatory activities could not be identified and their solution was coded as basic access.

Concluding, K& M understand the problem much better, talk about possible heuristics to use and find helpful mathematical operations to work on the problem. Still, to solve the problem correctly they need knowledge about fractions – which they should have but did not show or seem to have. So, when solving mathematical problems, it is not sufficient to understand the problem and to select an appropriate heuristic. It is also necessary to bring along adequate mathematical knowledge.

M & F: Seven Gates (1st video collection)

M & F read the problem and analyze it. M has an idea to calculate straight away (implementation):

M: There is one [apple] left. If they. Double of one is two. Then an extra apple is three.
F: That's the second gate.
M: If we had six and one it would be seven. So, we had two gates.

M has an idea; F follows it and both carry out their plan. Concerning their heuristics, they *work backwards* and use an *aid to systemize* the number of gates by numbering them. At half of the process, F checked the results and figured that doubling the number of apples and then adding one does not work when working forward. However, this self-regulatory activity does not lead to a change of calculation. Still, with 255 apples as their final result, they have a solution coded as advanced access.

Summing up, M & F talk with and understand each other. It seems to be sufficient if one of them has an idea because the other one follows. They are able to select appropriate heuristics and even show a self-regulatory activity. Yet, only recognizing that something might be wrong does not make them change their solution path. Hence, they might be skilled with a seed of self-regulation, that might not have been developed fully yet (Herold-Blasius, 2021).

M & F: Traffic Jam in Space (4th video collection)

After reading this problem, both recognize that they have worked on a similar problem before. This might be one reason why M decides to *work backwards* and to draw the customs stations (*aid for systematization*) right at the beginning. Their first idea is to add one to 23 and then to add one quarter of 24 to 24 which is 30. However, they check their results (self-regulatory activity) and recognize that their calculation does not work – having 30 and taking away one quarter and one extra. At some point (after 11 min) M decides to just do the calculations – without thinking about it anymore. At the end (after 17 min), they explain their strategy use explicitly:

M:	I have calculated 62.5 divided by 4.
Interviewer:	62.5 divided by 4. And why?
M:	Because when you work backwards you can also do it forwards. This way you can check it.

To conclude, both are able to select heuristics and to check their result (self-regulatory activity) – in both processes. Yet, they cannot use this to change their procedure and do not find the correct result. Within the nine months, they did not learn how to change their working backwards in a productive way. Possibly, explicit teaching could have helped here to develop this self-regulatory seed.

F & N: Seven Gates (1st video collection)

F & N start their work by analyzing the problem and roughly estimating a possible result.

N:	There must be an awful lot of them.

They then try to solve the problem within an exploration phase. In terms of heuristics, they looked for the *sought and given* first and *reread* the problem after about five minutes. Shortly after, they interacted with the strategy keys (self-regulatory activity) which led them to a new strategy – *working backwards*. Later they combined this heuristic with an *aid to systematize* to keep track of the number of gates. Their entire process took 14 minutes and F & N's solution was coded as advanced access.

In F & N's process it was noticeable that they extensively discussed the order of operations – first addition and then multiplication or vice versa. At the end, the writer determined the order. Also, after interacting with the strategy keys, they employed the heuristic *work backwards*.

F & N: Traffic Jam in Space (4th video collection)

After reading the problem they analyze it and then work on it. Concerning heuristics, they *reread* the problem, looked for the *sought and given* and used an *auxiliary element* by marking relevant information in the given text. After 7 minutes, they started *working backwards* and later drew some *figures* visualizing the quarter. After 34 minutes, they again used an *aid to systematize* to keep track of the number of gates. Their process lasted ca. 42 minutes and their solution was coded as advanced access.

Both students interact with the strategy keys at three points within the process (self-regulatory activity). However, they did not find a productive way of integrating them.

F & N's problem-solving process is characterized by showing seeds of purposeful problem-solving behavior: First, they mark relevant information but then do not really use it within their solution process. Second, they talk about the order of operations; yet, F – the writer – determines it without N arguing against it. Third, they use circles as visualization of the quarters. Still, this is not used for their calculations or any progress within the problem-solving process. It is remarkable that both calculate with approximated numbers. So, it seems as if their conception of numbers and fractions is suitable for everyday use. Hence, their mathematical knowledge seems to be at a sufficient level.

In conclusion, F & N show similar behavior e.g. by working backwards (key: work backwards). At the same time, they use new behavior such as marking information (key: use different colours) or drawing figures (key: draw a picture). Possibly, both students have internalized the strategy keys and can now employ heuristics without even looking at the keys. They have expanded their heuristics repertoire and internalized heuristics, although this does not lead them to correct solutions yet.

Discussion

For this contribution, we observed the problem-solving behavior of three pairs of LA students over a period of nine months. We showed what kind of difficulties LA students encounter when solving mathematical problems and how their problem-solving behavior develops over the given period.

Three obstacles have been identified: lack of knowledge, stagnated development of heuristics, and lack of self-regulation. First, students (see K & M) need a certain level of mathematical knowledge to properly engage in problem solving. This result is not surprising as Schoenfeld (1995) had already stated this. Yet, there is no concept on how a lack of mathematical knowledge could be compensated using aids without revealing too much – and this is crucial especially for LA students. Students need sufficient knowledge or to develop "the ability to retrieve basic facts from long-term memory" (Geary et al., 2012, p. 206) in order to experience a non-routine problem-solving process.

Second, the strategy keys aimed at activating known heuristics. F & N know heuristics and are able to select appropriate ones. Still, this is not sufficient to successfully work on mathematical problems, as they do not find the correct result. Their heuristic development has stagnated within our study.

Third, F & N interacted with the strategy keys and M & F checked their results within the problem-solving process. Thus, both pairs showed self-regulatory activities. Yet, this did not result in a correct solution. We claim that regarding self-regulation, these students dispose of only seeds rather than a full self-regulatory competence (Stein, 1995) – so they know a self-regulatory activity and they know how to use it, but they cannot integrate it in their processes in a goal-oriented manner.

In the future, it should be investigated how LA students can be enabled to successfully solve mathematical problems. Possibly the introduction phase of a problem solving lesson could be a fruitful resource to support especially LA students (see Häsel-Weide & Nührenbörger, 2022).

Acknowledgment

We want to thank S. Kneip, B. Koenen, J. Fastermann, the students as well as the head of Anne-Frank-Gesamtschule in Havixbeck for the chance to carry out this study and for their commitment.

Participation of students with learning disabilities in the context of probability

Tarik Jaschke

University of Bremen, Germany; boujada@uni-bremen.de

Keywords: Participation, inclusion, probability.

Motivation

The inclusion of students with learning disabilities into the general educational system has substantially grown in the last decades (Häsel-Weide & Nührenbörger, 2021). One central challenge for this inclusion is to realize participation in classroom interactions (Jung & Schütte, 2017). With respect to mathematics education, participation comprises social and content-related aspects. Precisely because both, social and content-related participation, are necessary for learning mathematics. Understanding successful conditions for allowing students with learning disabilities to participate in heterogeneous classes is necessary for the factual inclusion of these students. Participation can also be understood as the option for everyone to engage in society (Jung & Schütte, 2017, p. 1500). Participation in society includes to practice basic rights, which also requires a sustainable understanding of mathematics, particularly chance and probability. Therefore, inclusive mathematics education and instruction should also focus on these fields.

The aim of my PhD project is to investigate social and content-related participation of students with learning disabilities in courses on chance and probability. My focus is on negotiations among students who use and develop different conceptions of probability. Guiding questions are (1) how every student can participate in emerging negotiations in inclusive classes and (2) how they can develop their individual ideas while interacting with other students.

This study provides both empirical and theoretical evidence that a content-related participation of students with learning disabilities is possible in negotiations of the concept of probability in inclusive classes towards the end of lower secondary school.

Theoretical framework

Jung and Schütte (2017) distinguish three types of participation in inclusive classes: (1) spatial, (2) social, and (3) content-related participation. Content-related participation refers to students' engagement in content-related negotiations, their interaction with supplied material and delivered content by the teacher (Jung & Schütte, 2017, p. 1502), for example, contributing the Laplacian probability to roll a five with a regular dice is equal to one sixth into the collective negotiation. From an interactionist perspective of learning, both spatial and social participation are necessary for content-related participation.

Using social negotiations to support individual learning processes is a key approach in inclusive mathematics education (Häsel-Weide & Nührenbörger, 2021, p. 50). Content-related participation in those negotiations requires that all students can contribute relevant content and extend their individual conceptions. In heterogenous groups, this might require an extra effort in collective argumentations when sharing different ideas and perceptions for students with learning disabilities.

Research project and methodology

In my research project a learning environment on probability was designed for grade nine classes with the above goals in mind. The students were meant to work in groups of three to four students so that exchange and negotiations of meaning could emerge. Each group had students of different levels in their mathematical competences. While every group was recorded both auditory and visual, groups with students with learning disabilities are the main focus. From those transcripts, the content-related participation, the use of visualizations and development of conceptions of probability are reconstructed. The following research questions guide this study:

- What fosters negotiations in class that allow all students to participate in negotiations?
- What are typical characteristics of negotiations in inclusive settings? How do contributions on different levels support a development of shared meanings of probability?

The tasks and the learning environment

Each task was designed with the intent to allow every student to grasp a concept of probability. Further, the learning environment was designed to engage students at different levels to interact with each other. Every student was supposed to participate both in group and class discourses. To support this, (1) different representations, (2) empirical and theoretical approaches and (3) subjective and objective perspectives for the concept of probability are provided. The design allows different approaches so that negotiation processes would be initiated and individuals could add their point of view. For example, one task engages dyadic groups to examine the repeated drawing of three distinguishable balls. After the groups collected empirical data, interpreted the data qualitatively and constructed different diagrams, every student has to deduce probabilities and reason those independently. Afterwards, the students negotiate both a probability and an associated reasoning collectively, providing every student the opportunity for content-related participation.

So far, my data show that students with learning disabilities can participate in negotiations about chance and probability, even if different perspectives emerge. Students with learning disabilities are generally able to either contribute their own ideas or adopt other students' meanings and reason from these points of view. Addressing on group differences, there are significant deviations. Some groups are able to construct fertile circumstances while others are not. The poster demonstrates the connection between the task, anticipated negotiation processes and the preliminary results.

Cooperation of mathematics teaching and special education – seminar concept and experiences

Tabea Knobbe, Christof Schreiber and Michaela Timberlake

Justus-Liebig-University, Giessen, Germany; tabea.knobbe@math.uni-giessen.de; christof.schreiber@math.uni-giessen.de; michaela.timberlake@erziehung.uni-giessen.de

In cooperation with the Institute for Special Education and Inclusive Learning and the Institute for Mathematical Education, different seminars were conceptualized in which students studying elementary and special needs education examined the use of digital media in an inclusive classroom setting. We will now introduce the starting situation for such seminars and describe one of the seminar concepts in more detail. To conclude, we will consider impressions from students.

Keywords: Inclusive settings, multi-professional teams, teacher education, digital media.

Starting Situation

Nationally and internationally, political actors place demands on teacher training in the areas of inclusion and digital media:

- In the UN Convention on the Rights of Persons with Disabilities (2006), in addition to the right to education for all people (ibid., Article 24), access to information, etc. (ibid., Article 4) is required in order to enable full and effective participation in society.

- The "Equity Principle" of NCTM Standards (2003) demands that teachers must be professionalized in order to be able to deal with the heterogeneous starting positions of the students (ibid., p. 13f.). Learning mathematics with electronic technology is presented there as essential. It also offers many opportunities to support learning, especially for students with physical challenges (ibid., p. 25) and other handicaps.

- The conclusions on inclusion in diversity with the aim of high-quality education for all call for the basic and advanced training of teachers, "and foster their motivation and competences [...] to deal with diversity" (European Union, 2017, C 62/5). This also includes "systematic incentives and training to allow teachers to experiment with digital pedagogies" (ibid.).

- The Conference of Ministers of Education and Cultural Affairs (KMK) for Germany calls on the universities in particular to anchor media education in teacher training. The aim is to address the media experiences of the learners in the classroom. In addition, they should be able to analyze available media and use them as required for teaching and fostering (KMK, 2012). Work in multi-professional teams in teacher training should also be intensified in order to enable a multi-perspective view of the child and the interaction between teacher and child (KMK, 2015).

At the Justus Liebig University in Giessen there are no joint events for students studying elementary and special education due to the study regulations. A collegial cooperation with the aim of joint planning of lessons, however, requires knowledge to be acquired about the other profession, and this as early as possible (Hattermann et al., 2014).

Building on existing experience with interdisciplinary activities (Rudinger et al., 2018), new seminars were designed that address the use of digital media in inclusive settings and enable students studying primary and special education to learn together. These students are usually in their penultimate semester. The elementary teacher students study mathematics as a subject, while the special education students usually do not, moreover, their prior knowledge of mathematics didactics usually relates to only one compulsory module.

Digital media is seen as a special aid for differentiation and support in cooperative, inclusive teaching (Bonow et al., 2019). Digital media seems to have particular potential here, since, for example, direct control via input gestures on the screen of tablets eliminates the need for the computer to coordinate hand, eye and mouse (Walter, 2017). However, digital media also offers new possibilities for representing mathematics, e.g., by focusing on written and graphic communication in projects for chatting about mathematics (Schreiber, 2013) or on the oral presentation of mathematics when creating audio podcasts (Schreiber & Klose, 2017). In mathematics didactics, the possibility of creating or using videos is currently seen as a way of learning mathematics (e.g., Leinigen, 2020). In particular, the potential of synchronously linked representations (Schulz & Walter, 2019) can be used in the creation and use of videos in terms of mathematics didactics. Since the individual requirements of the learner can be addressed, there is potential here for use in an inclusive setting (Fehrmann, 2019).

Seminar Concept

The seminar “Explain! Videos in inclusive math lessons” is attended in equal parts by students studying to become teachers in primary and special education. The course has been offered since the winter semester 2020/21, and 42 students participated in the first two course offerings. The seminar program is divided into three different phases. First, basic theory is worked out, then work is done on a specific (Hirt & Wälti, 2012) substantial learning environment (SLE) (Scherer, 2019). Third, video sequences are created for this SLE. Working together in mixed teaching groups plays a central role in order to give the students their first experience of multi-professional cooperation.

In the first phase, important theoretical basics for the use of videos in mathematics lessons are developed. Particularly addressed is the point that explanation should not be given exclusively in the sense of transferring knowledge (Kiel, 1999) through the video, but rather the students should be encouraged by the video to negotiate or develop knowledge (ibid.) by explaining something themselves. The concepts of an SLE and natural differentiation (e.g., Scherer, 2019) are used as the theoretical groundwork for inclusive math lessons, and form an important basis for further work in the seminar.

Natural differentiation is characterized by having the same learning opportunity for all students. This learning offer is mathematically rich and complex, so that the processing can take place at different, naturally resulting complexity levels. Different learning requirements can also be catered for by giving the pupils the greatest possible freedom in the way they work on and solve problems or in the way they present them, and in the notation they use. This also enables social learning from and with each other in a natural way (Scherer, 2019).

A substantial learning environment (SLE) uses the principles of natural differentiation to teach slow and fast learners together. SLE is guided by core content, goals, and principles of mathematics instruction that have mathematical substance. Tasks should have a high cognitive activation potential that allows accessibility and independent activity by all learners (Hirt & Wälti, 2012).

In the next phase, the students work on an SLE for primary school students as described in Hirt and Wälti (2012). The SLEs address different mathematical topics: arithmetic, measurement and modelling, and geometry. The students should first analyze the SLE in terms of content and mathematics by working on the tasks themselves and making a well-founded decision as to which video formats can be used to support the subtasks.

A method developed by Schreiber and Schulz (2017) is used to create the film (see Figure 1). This is a method that, in addition to being used in teacher training, can also be used in schools to create films on mathematical content together with students (Schreiber & Schulz, 2017; Leinigen, 2020; Fehrmann, 2019). In addition to the products created, the seminar should also provide students with suggestions for using the method in school.

Figure 1: Process of film creation (Schreiber & Schulz 2017)

The video creation phase takes up most of the semester. Individual steps of the method can already be worked on in the theoretical phase of the seminar. **(1) Determine the Content**: The students decide on one of the proposed learning environments when they are divided into groups. **(2) Factual Analysis**: The students first work on the learning environment themselves in order to grasp the depth of the mathematical subject. The mathematical richness of a learning environment allows the students to make interesting discoveries beyond the content and learning objectives of the primary level. Dealing with the learning environment should also lead to considerations as to which subtasks could be supported by individual video sequences and what a meaningful, cognitively stimulating video application could look like. **(3) Script I:** Video sequences are planned in the form of scripts. **(4) Peer Review:** These scripts are discussed in groups in the seminar and students edit their scripts based on feedback from fellow students and instructors. **(5) Script II:** Only completely revised scripts are approved for video production. **(6) Film Creation:** The type of technical implementation of the video sequences is up to the students. For example, videos may be created using the laying technique, stop-motion technique, screencasts, etc.

The learning environment should be supported by at least two video sequences between 30 seconds and 2 minutes in length. Additional materials, such as worksheets, haptic material, etc., are also necessary for the implementation of the learning environment. Due to the corona virus pandemic, the students were not able to try out all the videos themselves in classes. However, the video sequences were occasionally used by teachers in alternating or online lessons, so the students received useful feedback from the teachers on their products. For a time after the pandemic it is planned that the students can also try out the videos themselves.

Seminar Focus and Goals

The goal of the seminar is for participants to get ideas for designing videos for inclusive mathematics classes. The guiding principle for this is the assumption that inclusive teaching can only succeed together – in multi-professional collaboration.

One focus of the seminar is to **work in multi-professional teams**. This is promoted by the mixed teaching groups in which the students work together during the entire seminar. There is a social exchange about experiences and competencies, which leads to different perspectives and roles in the classroom becoming clear. Particularly when creating the videos, different expertise and competencies become clear. The primary education students bring expertise in mathematics didactics, the special education students can accompany the planning from the perspective of special education. In this way, differentiation levels are built in, or special education needs are explicitly considered in order to make the videos accessible to the target group. Thus, the primary education students can achieve more understanding of individual support needs. In the peer review of the video scripts, the students benefit again from the different perspectives and previous experiences of fellow students, so that a wide range of feedback can be given. This intensive exchange about the scripts serves to build up knowledge about the qualifications and areas of responsibility of future colleagues and is intended to facilitate later cooperation (e.g., Rudinger et al., 2018; Bonow et al., 2019).

The second focus of the seminar is to **work with digital media**. The media skills of the students are first strengthened (KMK, 2012) by creating videos themselves using different techniques. Promoting media literacy also includes providing a meaningful rationale for the video sequences in terms of subject didactics (ibid.). Possible uses of videos in (inclusive) education are also reflected upon. For school practice, there is also a focus on the media competence of the students. The video creation method carried out in the seminar is also suitable for school practice (Schreiber & Schulz, 2017; Leinigen, 2020). Through the guided assignment, students can acquire media skills.

Results of the Seminar

To use videos within a naturally differentiated learning environment, care is taken that the videos are not only intended for passive consumption, but also cognitively stimulate the students. In the end, there should be an opening through a follow-up task or something similar. This can be implemented using different video formats. There are also many possible uses within a learning environment. The video can give a general introduction, it can provide additional, differentiated help, explain a task or a task format, or provide an impulse to discover a mathematical structure (e.g., Kristinsdóttir et al., 2018).

In the following, videos on the learning environment “rolling the die” for grade 4 are discussed as an example. This learning environment (Hirt & Wälti, 2012, p. 240ff.) is about recognizing and using symmetries and patterns by rolling a die with a colored side on a playing surface with square divisions (like a chessboard), until the marked surface is facing up again. In the middle of the game board is the starting square. The number of rolling movements is noted on the target square. If care is taken to reach the squares with as few rolling movements as possible, a symmetrical pattern results. The learning environment is enacted with the help of the videos. Since it naturally contains differentiating tasks, it should also be applicable in inclusive settings. All pupils in a class should be able to use the videos, as these videos should enable discoveries at different levels. Potentials for special education needs are also considered in the videos. The students use a mixture of discussed and animated PowerPoint slides with symbolic representations of the playing field and self-made video sequences in which they can be seen rolling a large cube on a playing field. The students start with a video sequence in which the “rules of the game” are explained.

This video has great potential in many ways. For example, the video is suitable for beginners. The basic rules of the game and the task format are explained here. Students can watch the video several times to internalize all the rules. This is a cognitive relief, as the children do not have to read the rules for themselves. In addition, the combination of image and sound enables several levels of representation to be combined (Schulz & Walter 2019). In this example, understanding can be ensured by explicitly pointing to the edge. The fact that the die rolling is demonstrated directly on the real model reduces the cognitive burden, as there is no change to the symbolic level here.

The following video explains that the number of rolling movements of the die is considered. Two examples are used to determine squares that can be reached in 4 moves. The two protagonists take turns rolling the die. The main rule is to always begin on the starting square, with one student improving upon the other. The two squares reached are marked with the number 4 and colored in blue. The number 7 is given to the square directly below the start square. The other student protests that 3 is the correct answer. The video ends with the task: “Which girl is right? Check it. Try to find out the number of rolling movements for as many fields as possible.”

The video, created by students for the fourth grade, shows that mathematical learning videos can also be an explicit stimulus for learning through discovery: here a problem is posed, which the students should solve independently and in an action-oriented manner. Occasions for mathematical discussions may also arise and communication about mathematical phenomena becomes possible. Explanations need not necessarily be given exclusively through the video, but can also be developed and negotiated by the students amongst themselves based on the impulses of the video.

Coming back to the above posed question: Both persons are right. The square can be reached with 3 and 7 movements. An unambiguous answer is only possibly if the condition of using as few movements as possible is included. Furthermore, there are different possibilities to reach the square with 3 or 7 movements. This can also be discovered and become an occasion for discussion for the students. The further expansion of the task of finding out the number of rolling movements for as many squares as possible also allows processing on different mathematical levels. In this way, "simple" squares can be reached first, or the criterion of minimal movements can be ignored. The task is also solved if the playing field is not completely labeled. It is also possible for high-performing children to find different paths for other squares. The videos address the idea of natural differentiation and thus enable learning on the same subject. Both videos are designed in the sense of natural differentiation and are therefore intended for all children. Further differentiation is not necessary here, but the videos are only one part of the learning environment. In the implementation of the learning environment in class, there are further tasks or social learning opportunities, which must also be adapted to the inclusive setting.

Voices from the Seminar

The evaluation of the seminar refers to results of a pre-post questionnaire and to informal, oral statements by the students on seminar reflection. Using questionnaires, the students were asked about attitudes, experiences, and self-efficacy regarding inclusive teaching with digital media. The results from two course offerings are available from the beginning and the end of the semester. They show that the students mostly trust themselves to work in a team with teachers from other professions. This positive self-assessment of the students increased again at the end of the semester. While 3 people stated at the beginning of the semester that they did not trust themselves to work with teachers from other professions, after one semester all 42 students questioned agreed or completely agreed that they could. The students commented on this, for example, that working together in mixed teaching groups was “an enrichment because you could think outside the box”. It was noted that the group often did not know each other, but it was precisely this what enabled other perspectives to be taken throughout the intensive exchange.

The detailed feedback regarding the scripts, which was given during the peer review, was also rated positively. It could be observed that the different fields of expertise ensured that the scripts were dealt with in great detail and intensively, and that there were helpful tips on how to design the video sequences.

Regarding the use of digital media, the students report learning successes in terms of video creation and the beneficial use of videos in the classroom. For example, one student said, “I believe that using videos can lead to more motivation because it is rather unusual. In any case, this shows that math does not have to be taught in such a dry way!” It was also noted that the videos are “very suitable for natural differentiation” and thus offer opportunities for inclusive teaching.

In addition to successes, the students also report challenges on the technical level: the process of video creation was more complex than initially thought, and lighting conditions, camera position, speed, etc. must be considered when the video is produced. Moreover, time required to create the videos was also critically reflected upon. Therefore, this task was reduced for the second run. This feedback underpins the claim that the teachers themselves should acquire certain media-technical skills (cf. KMK, 2012).

Overall, the seminar not only enabled students to feel more confident when using and creating videos, but the results of the evaluation also show that the self-efficacy assessed by the students themselves in relation to the general use of different digital media in the classroom during the semester increased. The proportion of students who feel (rather) unsafe about using digital media was reduced from 10 to 4 people over the course of the semester, while the proportion of students who (rather) trust themselves to use digital media increased from 33 to 38 people. These positive results indicate that students benefit from their experiences using and producing digital media.

Acknowledgement

Working with objects of representation in practical contexts on length in inclusive classrooms

Yola Koch

TU Dortmund University, Germany; yola.koch@math.tu-dortmund.de

Due to the growing number of children with special educational needs in German primary schools, research on inclusive settings in mathematics has increased in recent years. This research primarily focuses on arithmetic settings. Little attention has been paid to measurement processes, especially for children with learning or mental difficulties. The following paper gives an example for inclusive education on lengths to gain social and content-related participation. The developed learning environment is based on the learner's interaction and takes into account the use of objects for representation and learning in practical contexts.

Keywords: Inclusion, participation, objects of representation, practical contexts.

Introduction

Since the UN Convention on the Rights of Persons with Disabilities, the German government seeks to implement an inclusive school system. This makes it necessary to think about how all children can participate by considering empirical research on teaching mathematics. The focus in this work is on the learning processes of children who need special support in learning and/or their cognitive functions because in inclusive teaching children with cognitive disabilities often work only on different subjects and are less involved in common learning situations (Korff, 2015). According to the guidelines of the Ministry for Schools and Education of North Rhine-Westphalia (an area in Germany) *learning difficulties* are severe, persist over longtime and effect several aspects of the children's development (§4 AO-SF NRW). There is a need for support in the *mental development* if cognitive learning and the development of the personality are permanently and severely impaired (§5 AO-SF NRW). Nevertheless, even if the focus is on children with special educational needs (SEN), all other diversity aspects are also respected in the underlying understanding of inclusion in this work. It can be assumed that the resulting indications for teaching will be important for *all* children.

A change of perspective has taken place in mathematics education in recent years: children should not only solve tasks by using fixed procedures, but they should instead understand mathematical structures and learn to use them flexibly. Although studies suggest that all children, also those with SEN, can benefit from learning actively and by exploring mathematical structures (Scherer, 2009), this is often still not taken into account in inclusive classrooms. Learning mathematical structures can be supported by working with objects and tasks in practical situations. Therefore, this study integrates those aspects.

Firstly, the concepts of participation, learning with objects of representation and in practical contexts are discussed. In a second step, the design of the study is described and first results will be presented.

Theoretical background

Several theoretical concepts are relevant for the study and are, thus, briefly described below.

Participation in inclusive classrooms

The term "participation" is closely related to inclusion. Whilst there are different understandings of inclusion, one central goal is to achieve participation (Booth & Ainscow, 2002). According to the *Index of inclusion*, a guideline for the development of inclusive educational institutions,

> Participation means learning alongside others and collaborating with them in shared learning experiences. It requires active engagement with learning and having a say in how education is experienced. More deeply, it is about being recognised, accepted and valued for oneself. (Booth & Ainscow, 2002, p. 3)

This definition includes especially various social aspects. In addition, Roos (2014) emphasizes that content-related aspects are also important for participation and she generally distinguishes spatial, social and didactical (content-related) inclusion. In the following, both *social* and *content-related participation* will be discussed in more detail.

Social participation

Koster et al. (2009) distinguish four aspects of social participation: friendship/relationships, positive contacts/interactions, acceptance by classmates and students' social self-perception. These aspects seem to be related to positive interactions. There are different ways of interacting, depending on the children's abilities. It "cannot be for all children to participate actively in class in the same way" (Jung & Schütte, 2017, p. 1503). According to Krummheuer and Brandt's (2001) participation schema one can be included by being a productive participant (e.g. by initiating a conversation, repeating what someone has said - verbally/nonverbally), or by being a receptive participant (e.g. by listening to what others say) (Krummheuer, 2007). Hence, different manifestations of social participation seem to exist. In this study, different forms of *involvement* will be mentioned. Involvement means interacting with others and can be described by different interactional reactions.

Content-related participation

Content-related participation means "being included in mathematical practice of the classroom" (Roos, 2014, p. 39). Interacting with others is important for social as well as for content-related participation: by interacting, social participation can be realized and content-related participation is influenced by the interaction with others. This understanding is based on a social-constructivist perspective on learning. According to this perspective, the experiences of a person influence the individual construction of knowledge (e.g., Miller, 2002). In this context it is important to define learning processes more precisely. Based on the epistemological perspective, learning is defined as an increasingly differentiating process of interpretation. New knowledge is the extension of prior knowledge by exploring mathematical structures and generalizations. This is a highly individual construction process which is influenced by the interpreter's subjective characteristics and the way mathematical knowledge is presented in these various situations (e.g., Nührenbörger & Schwarzkopf, 2016; Steinbring, 2005; Voigt, 1994). Among others, Steinbring (1997) emphasizes the role of signs for mathematical knowledge. Signs are used for describing and coding mathematical knowledge.

> In elementary teaching, these [signs or symbols] are mainly arithmetical number signs. These signs, on their own, do not have a meaning. The meaning of a mathematical sign has to be constructed by the student. (Steinbring, 2005, p. 21)

Referring to the semiotic triangle of de Saussure and Luhmann's concept of communication, Steinbring (1997) worked out a triangular scheme, the "epistemological triangle", for describing and analyzing children's comprehension. The sign/symbol contains the new, still unknown mathematical knowledge. It has to be interpreted by the individual person by referring to probably familiar reference contexts. In the interplay between sign and reference context, the new concept is established. In this process of negotiation, the three aspects are balanced and support each other (Steinbring, 2005).

Learning with objects of representation and in practical contexts

In inclusive settings it is important to enable students to find different approaches to a task and to explore mathematical structures (Häsel-Weide & Nührenbörger, 2015). This can be supported by working with objects and tasks in practical situations.

For teaching numbers, Schipper (2009) distinguishes different functions of *manipulatives*, which can be transferred to other mathematical contents as well: manipulatives for solving a task, for understanding abstract mathematical concepts and as assistance for communication, argumentation or reflection. In inclusive classrooms manipulatives are often used only as a tool for solving a task (Korff, 2015), but not for communicating or demonstrating the learners' ways of thinking. But this exactly could be important when, for example, working with children who have difficulties in verbally expressing thoughts. Therefore, it is helpful that the researcher may be able to also analyze the children's understanding by observing how they use the objects. Regarding Schipper's (2009) second aspect – manipulatives for understanding abstract mathematical concepts – there is consensus that "the purpose of using manipulatives in mathematics is to help the learner understand abstract concepts" Kosko et al., 2010, p. 80). In this context, understanding the interrelationship of representations is of great importance and needs to be practiced. However, using concrete objects in teaching does not guarantee a meaningful learning process. Referring to the epistemological perspective described above, Söbbeke (2005) showed that the interpretation of manipulatives is not obvious and cannot be predefined by teachers. How objects and the structures they represent are interpreted by the learner depends on the context and the individual experiences. This active process can result in different interpretations. In the process of negotiation, the concrete objects can represent a new sign/symbol that has to be negotiated or it can be used as familiar reference context for negotiating other mathematical concepts (Söbbeke, 2005).

The word "*context*" can be defined differently. Van den Heuvel-Panhuizen (2005) distinguishes between contexts referring to the learning environment and contexts such as "a characteristic of a task presented to the students" (van den Heuvel-Panhuizen, 2005, p. 2). In the following, context is understood to be the task context, in particular a situation relating to everyday life. It is not possible to draw the conclusion that using context tasks will automatically improve learning. However, some positive effects of using contexts are reported in different studies. The context can increase the students' motivation, so that they are possibly more willing to solve the task (Scherer, 2009). Moreover, "while working on context problems, the students can develop mathematical tools and understanding" (van den Heuvel-Panhuizen, 2005, p.2). For example, Selter (1998) shows that in context tasks, students can solve tasks with requirements that had not yet been discussed in class up to that point. On the other hand, contexts can distract and complicate the learning process (Scherer, 2009), especially when it is an unknown context for students. In this study, a familiar context is included in order to use the context as a learning opportunity. However, it is important that not only the context is relevant here, but that the students can explore mathematical structures while working on the tasks (Korff, 2015).

Design of the study

The study is based on Design Science. This implies designing, implementing and analyzing a learning environment to get information about the involved mathematical structures and the students' ways of thinking (Nührenbörger et al., 2016). In this study an interactive learning environment on length (this will be further clarified below) and money was conducted, three lessons each on length and money, respectively. The three sessions on length/money were structured similarly: first, the children's prior knowledge of length/money and of the context situation was assessed and the objects of representation were introduced. This introduction was particularly important so that the children could use the objects in subsequent sessions, when working on two to three context tasks.

The design of the learning environment builds on the basic principles of individual goal-differentiated learning on a common subject (based on Feuser, 1995), learning with objects of representation, learning in practical contexts, and in interaction. These principles are closely interrelated (Figure 1).

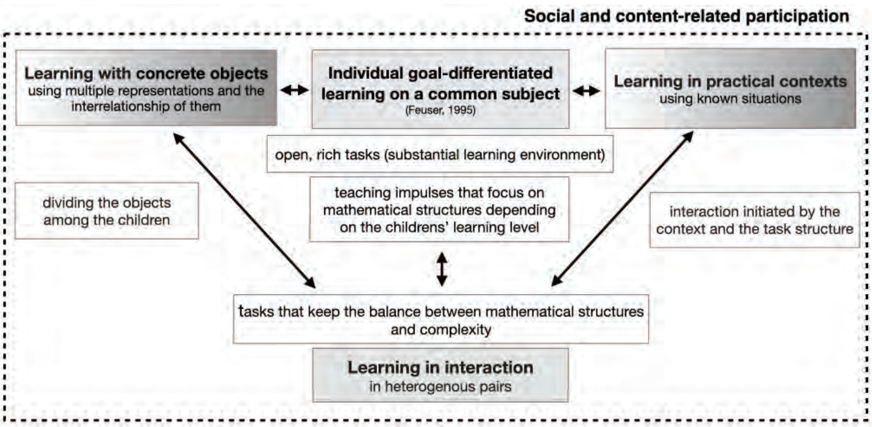

Figure 1: Design principles of the study

The learning environment was tested with different pairs of children (one child with SEN; the other child without SEN) in grades three and four at German inclusive primary schools. The pairs were formed in such a way to take into account the high (expected) range of heterogeneity in inclusive classrooms and to be able to focus on the participation of all children. The children were videotaped and observed while working on the tasks. Additionally, follow-up-questions were asked to find out more about the children's understanding or to intensify their interaction. Aims of the study are to look at the handling of the concrete objects and the influence of the task's context on the development of competences regarding length/(money). Aspects of social involvement are to be worked out and linked with content-related aspects.

Design of the first task on length

The long jump was the subject of the length tasks. Therefore, a long jump field was simulated in the classroom. As objects of representation wooden sticks of different lengths were used, which serve as representatives of standard units (1m, 10cm, 1cm) and of other length (50cm, 20cm, 5cm, 2cm) that can be set in relation to standard units (e.g., 50cm as half as long as 1m). With the sticks, the children compare, estimate and measure length in a practical context, whereby various skills for measurement can be trained. The relation between units and sub-units (especially m and cm) can, for example, be vividly addressed, which is important for the measurement process (Nührenbörger, 2004).

As a first approach to the task a pair of sneakers was put in the jumping area. Every child had sticks of different length (the sticks of each length are multiple available) at their disposal. The children were asked to find out the given jumping distance indicated by the position of the sneakers by using their sticks and to present and discuss their ideas. Then, the children took turns to do the long jump and measure each other's jumping distance.

First Results

The study at hand uses a qualitative methodology. To get a first impression of the nature of the participation in the learning environment, a short scene is analyzed below. A descriptive approach was chosen to describe social participation. The interrelated reactions of the children were examined with regard to possible triggers and reactions. For content-related participation, an attempt was made to analyze the children's understanding with the epistemological triangle.

In the scene two boys around nine years old, Nic (without SEN) and Jan (with mental difficulties of no specific reason, SON IQ range: 47-64), are working together. A pair of sneakers stands at around 2m 3cm in the jumping field. Nic already worked out the jumping distance with his sticks. Meanwhile, Jan has been looking at his sticks but has not yet started measuring the jumping distance. Then, the children start working out the distance with Jan's objects. They have already put two one-meter sticks in the jumping area, starting at the take-off bar. Nic tries to explain to Jan that they cannot use another one-meter stick anymore and that they need "small things". Jan then fetches a two-centimeter stick.

1	Nic:	Then let's take a few (*takes the 2cm stick from Jan*). Look. Then we put it there now (*puts the 2cm long stick against the already lying 1m sticks*). And now it's still like that, so now we have to look (*points to the gap between the lying sticks and the heel of the shoe*) how far does it go? And I don't think a two will fit there anymore, so we need a very small one (*indicates a small distance between thumb and forefinger*).
2	Jan:	(*turns to his supply of sticks*) Very small.
3	Nic:	Very, very small.
4	Jan:	(*takes a 1cm long stick and holds out the stick to Nic*)
5	Nic:	Let's take one of these, put it here (*puts the 1cm stick in the gap*) and then it fits. So now we have two meters and then we have two and one (*holds up two fingers, looks at Jan*). What is this? I have two plus one (*holds up a third finger*). How much is that?
6	Jan:	(*looks at Nic's fingers*) One, two, three.
7	Nic:	So, it's two meters and three centimeters.

Nic explains his approach while acting. He extends the two meters (consisting of two one-meter sticks) with another two-centimeter stick and points out the remaining gap between the end of the track and the shoe. He seems to refer to a strategy for measuring with the help of the sticks because he suggests that another two-centimeter stick will not fit anymore. Nic concludes that an even shorter stick is now needed (line 1). Jan takes up Nic's description "a very small" and repeats part of the statement (line 2). The comments of the two boys refer to each other linguistically. Nic specifies his statement by adding another "very" (line 3). With this description, he classifies the difference between two centimeters (which was previously called "small") and one centimeter ("very, very small"). Jan identifies a one-centimeter stick and holds it out to Nic. After Nic has put the stick down next to the other sticks (as their extension) he points out: "And then it fits" (line 5). He turns to the next step in the process: naming the result of the measurement, and distinguishes between meters and centimeters. Nic names the two meters with the corresponding measurement attribute without explicitly naming the calculation one plus one. In the case of centimeters, a calculation seems appropriate to him. He asks Jan: "Two plus one. How much is that?" (line 5) and holds up the result with his fingers. Jan counts "one, two, three" by looking at Nic's fingers. Nic integrates Jan's answer in his solution: "So, it's two meters and three centimeters" (line 7).

In the scene Jan participates socially, in particular. Nic takes over the role of a teacher who dictates Jan what to think and do. By asking questions he guides him through the solution process and thus integrates him socially. In the process, Nic implements his own thoughts and solution process, but seems to try to adapt his explanations to Jan's abilities. Jan seems to be able to go along with that and to participate by answering questions or taking action (e.g., identifying, handing sticks to Nic).

In terms of content-related participation, one concept that Jan might express in this scene is analyzed in figure 2 (other concepts are not presented due to the limited number of pages in this article).

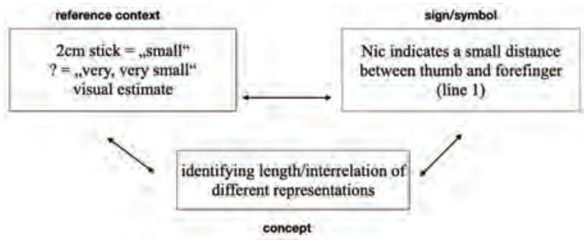

Figure 2: Jan's interpretation

The sign Jan has to interpret is Nic's indication of a small distance with his fingers. As reference context Jan probably refers to the description used previously for the two-centimeter stick as "small" and identifies a smaller one with the strategy of visual estimate. Thus, identifying length and the interrelationship of representations ("very, very small" – indication of the distance with the fingers – wooden stick) seem to be the concept that Jan expresses indirectly.

Conclusion

The scene shows that there are different aspects of social involvement. The interrelated reactions establish a joint working process in which both children are actively involved. In terms of content-related participation, it can be stated that the environment accommodates the children's individual learning process. While Nic probably has the procedure of measurement in mind and oversees the entire situation, Jan deals with different aspects concerning the measurement process: identifying length, the interrelationship of representations and counting (line 7). Thus, for Jan, single aspects are picked out from the complexity of the context and the requirements. It must be noted that even Jan's "small" actions (analyzed in figure 2) include an interpretation, even if Nic gives many instructions. Jan has to interpret the interrelationship of the representations on his own. He therefore participates in terms of content, although he is hardly involved in a common solution process. In the scene, using concrete objects serves different functions (Schipper, 2009): the sticks are especially used, as part of the given task, for solving the task but at the same time they represent abstract mathematical concepts, which the children have to interpret. Moreover, using concrete objects seems to support the communication and participation.

This scene only gives a short impression of participation. More scenes will be transcribed and further analyzed to draw conclusions with respect to social and content-related participation, especially in terms of learning with objects and in practical contexts.

MathCityMap and supporting learners with exceptional difficulties in learning mathematics

Philipp Larmann and Matthias Ludwig

Goethe University Frankfurt a.M., IDMI MATIS I, Germany; larmann@math.uni-frankfurt.de; ludwig@math.uni-frankfurt.de

Keywords: Mathematical competences, digital tools, learning difficulties.

Exceptional difficulties in learning mathematics

The term “exceptional difficulties in learning mathematics” is used to describe serious and persistent difficulties in learning mathematics (Gaidoschik et al., 2021). It therefore follows the more widely known terminology of “mathematical learning difficulties” (Mazzocco, 2008). This circumscription, which captures both diagnosed (e.g., dyscalculia) and undiagnosed problems on the learners' side, is used for two central reasons. First, to avoid a one-sided view that attributes the causes of difficulties only to individual factors. Second, the plural “difficulties” is intended to indicate that a wide range of problems can manifest themselves in a variety of forms in an individual learner (Gaidoschik et al., 2021). Typically, exceptional difficulties are found in the three central mathematical basic skills: understanding natural numbers, understanding the decimal place-value system, and understanding arithmetic operations. If those deficits are too serious, subsequent topics (e.g., decimals, algebra, etc.) can hardly be understood and, in the best case, can only be learnt by rote (Prediger et al., 2019).

MathCityMap – theoretical background and concept

The idea of mathematical learning trails already emerged in the 1980s. A math trail is a walk on which mathematical tasks are implemented at various interesting objects along the way in order to make mathematics directly experienceable in the real world (Shoaf et al., 2004). The EIS principle according to Bruner, which has already proven itself in special and regular schools alike (Ozdem-Yilmaz & Bilican, 2020), can be mentioned as the basic theoretical idea of this concept. On the trails, learners gain important mathematical experiences at different levels of representation of mathematics. They work enactively on real objects (e.g., measuring objects with tools), iconically (e.g., drawing, modelling the objects), and symbolically (e.g., calculations). Especially lower-performing learners benefit from this type of outdoor learning and can better understand content and procedures based on the concretely experienced examples (Buchholtz & Armbrust, 2018). The MathCityMap project has succeeded in developing this original concept further and bringing it into the digital age as well as embedding it in school contexts. Tasks are now found via GPS data in an app, which already provides specific and graded help. On the tasks themselves, the learners work in small groups, whereby they can stay in contact with the teacher via a chat function. The solutions found can already be checked on site in the app, where a detailed sample solution can be retrieved (Gurjanow et al., 2017).

Research question

From the theoretical background on which the concept of MathCityMap is based and its potential for exceptional difficulties, the following research question arises: How can MathCityMap be used to support students with exceptional difficulties in learning mathematics? This question is supported by criteria of successful support, which MathCityMap seems to fulfil. For example, learning on MathCityMap tasks always happens in discourse with other learners, and on learning objects that make natural differentiation possible (Gaidoschik et al., 2021, p. 12). An examination of the suitability is to be carried out with this investigation for the first time.

Outlook

In order to answer this question, a qualitative study will be conducted within the framework of the support project Mathe.Kind, which will be implemented at Goethe University Frankfurt in 2022 and is founded by the researchers that are also working on MathCityMap. Here, students with exceptional difficulties in learning mathematics will be individually supported in reducing their deficits and building up their competencies. MathCityMap will be used as a learning environment in different support sessions. Afterwards, it will be checked if certain difficulties could be reduced. For this purpose, task-supported interviews will be conducted with the students before and after the support sessions. To increase the accessibility of MathCityMap, the app will be equipped with a read-aloud function and an “easy language” setting option before the study is conducted.

Introduction

Digitization and inclusive education are two of the most complex challenges that contemporary teaching practice must deal with. In our view, inclusive education is more than just disabled and non-disabled pupils learning together, but mirrors the complexity of inclusion in society as a whole. (Ainscow 2007, p. 3). The two challenges are often dealt with separately or they are put into a charged relationship. The complexity and diffuseness of both discourses can be seen as the reasons for this (Lücke, 2021). In academic research only a few theoretical and empirical efforts can be found that try to think these two domains together (Viermann & Meyer, 2022). Our research efforts try to combine digitization and diversity in the mathematics classroom into one interwoven concept to design subject teaching with both challenges in mind. Furthermore, we try to specify opportunities and challenges of digitized subject teaching in mathematics to realize dealing with diversity.

Learning in a digitized environment

When dealing with digitization in the context of schools and especially in primary schools, people often act cautiously because the common idea of a digitized learning environment is, that children sit alone in front of a computer. Digitized learning settings are much more than solving problems with the help of a computer. Brandhofer et al. (2018) describe four different perspectives on learning in a digitized environment: 1. Education with digital media, which describes using digital media to shape learning. 2. Education about digital media, which describe learning about e.g., the functionality of different media. 3. Education in spite of digital media, which thinks of the possible distractions digital media offer. 4. Education through digital media, which describes digital media as the enabler of education. To overcome the dualism of inclusive education and digitization, digitization has to be seen as a chance to realize inclusive education and an inclusive education-oriented perspective has to be understood as a standpoint for discourse on digitization. The questions that arise from these thoughts are *How can digitization help to extend and improve inclusive mathematical education?* and *How can education* ***about*** *digital media connected to mathematics be designed?* Firstly, we want to expand the model introduced above with the dimension of diversity. Therefore, we try to see mathematics learning in an inclusive education environment as 1. Inclusive education with digital media. 2. Inclusive education about digital media. 3. Inclusive education despite digital media. 4. Inclusive education through digital media.

Challenges

One of the challenges in the conception and design of inclusive digitized mathematics education is the development of appropriate learning methods. Learning environments with mathematics tasks that a multitude of students with different abilities and needs can work on have to be designed with this diverse audience in mind. The concept of natural differentiation (Krauthausen & Scherer, 2014) is a fundamental tool to address different abilities with one task. Natural differentiation follows five characteristics: same task for all students, free choice of aids and means of presentation, social learning, educational framing, and certain amount of complexity. Especially the last characteristic is important as the task has to offer students the opportunity to develop different types of answers with their different approaches on the task itself. For digitized inclusive mathematics teaching, we try to adapt these five characteristics of natural differentiation regarding the conditions of digitality.

Examples

The example presented in this poster is a further development of the learning environment *Muster im Kreis (Patterns in a circle)* from Hirt & Wälti (2010). We use the app GeoGebra to realize the digital enhancement of the task. The students have different representations of a circle (geoboard, on paper, digital). They will have access to an interactive digital worksheet that can be manipulated on different levels. Task 1 and 2 are mainly a digital version of the original tasks. Task 3 introduces a possible addition that cannot be realized with a geoboard or the paper worksheet used in the original task. The seamless scaling of the circle provides the opportunity to change complexity to the student's abilities. The main idea is not to replace the haptic materials from the original task but to introduce the digital version as a possible enhancement and one further way to make the task accessible.

Since 2013, we have studied a support scheme for students who have difficulties solving mathematical problems. We call this a "preventive support scheme" and are interested in modelling its functions. These interventions take place before and after a specific classroom session, in order to facilitate the students' introduction to the planned learning situation, their involvement in the work required and their appropriation of the target knowledge. The work proposed in this scheme can take various forms and the aim of this communication is to illustrate this point by presenting, for a given situation, different tasks which can be proposed either before or after the classroom session. This study will allow us to highlight the precautions to be taken to design such devices.

Keywords: Didactic system, preventive support scheme, students in difficulty, fractions.

Introduction

Our research focuses on students who have difficulties solving mathematical problems (they fail to engage the situation, hesitate, do not know how to start, wait for their peers to find the solution…). Since 2013, we have studied the effects of a support scheme for them which we call "preventive support schemes" (Millon-Fauré et al., 2021). Unlike other support initiatives implemented after classroom sessions as part of remedial strategies, the proposed preventive strategy is implemented both before and after mathematical problem-solving sessions involving all students: a supervisor (teacher, remedial education specialist, *etc*.) works, before and after the classroom session, with a small group of students deemed (by the teacher) to have difficulties in problem solving. The "preventive" aspect of this scheme is linked, not to the learning difficulties that these students may encounter in a problem-solving context, but rather to the difficulties they demonstrate in taking their place as learners in such a context (Assude & Millon-Fauré, 2021; Tambone, 2014).

The choice of tasks which can be proposed within the framework of this scheme is sometimes not a clear one since it is necessary to facilitate the students' participation in class while not overly advancing in the actual problem-solving. It is for this reason that we want to present in this paper, for a specific classroom session on fractions, different options which could be proposed in the preventive support scheme, either before or after the classroom session. To do this, we will first quickly describe the different functions of the preventive support scheme.

Theoretical framework: the preventive support scheme

To model this preventive support scheme, we draw on the notion of the didactic system and the (structure; functions) coupling. The didactic system comprises three elements (knowledge, student and teacher/supervisor) and all interrelationships between these. Chevallard (1999) distinguishes between two types of didactical systems: the principal didactical system (PDS), essentially the classroom, and the auxiliary didactical systems (ADS), which include some, but not all students of the PDS and are peripheral to the class. The ADS follows the same objectives as the class but does not have its own program. Thus, the class, which guides the study of the target knowledge, consists of the PDS, for which two ADS are provided: one before (pre-ADS) and one after (post-ADS) the classroom session. Supervising a small group of students, the pre-ADS aims to create favorable conditions so that students who are deemed to be "in difficulty" can better integrate the study during the PDS (therefore this device is part of an inclusive perspective). The post-ADS, held after the classroom session, is a further work session with the same group of students, with the purpose of revisiting the knowledge presented in the PDS. The aim of this scheme is to enable students in difficulty to catch up with their classmates and it is therefore not relevant for all the students in the class. These two ADSs depend on the PDS, which determines what the student is supposed to know and do. In summary, we have the following structure:

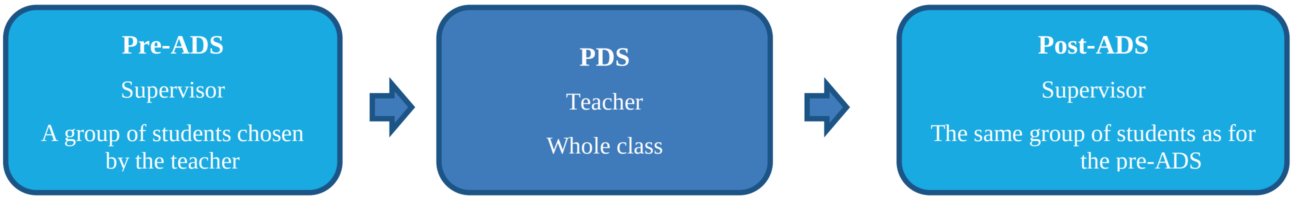

Figure 1: Structure of the preventive support scheme

The pre-ADS

Through our analyses of different potential iterations of preventive support schemes we were able to identify several functions associated with the pre-ADS (Assude, Koudogbo et al., 2016; Assude & Millon-Fauré, 2021; Theis et al., 2014).

The *mesogenetic function* relates to the introduction, during the pre-ADS, of different objects which will make up the PDS milieu. These objects may vary, as they depend on the nature of the situation studied in the PDS. Certain pre-ADSs present the instructions for the problem which will be worked on later in the PDS. In others, objects of formerly acquired knowledge, useful for the work to be done in the PDS, are introduced. Generally speaking, this mesogenetic function enables struggling students participating in the ADS to become familiar with certain objects of the PDS milieu before the other students in the class.

The *chronogenetic function* plays out on two levels: not only do the students involved in the pre-ADS have more time to become familiar with certain objects of the milieu but above all this additional work is set up before the session so that they have a little bit of advance on their classmates. It is nevertheless important to note that, the didactic time (Chevallard & Mercier, 1987) does not progress. In practice, the aim of the pre-ADS is to prepare students to fully engage in solving the problem set out in the PDS, but not to solve it before the other students.

The *topogenetic function* has been demonstrated through numerous observations made during the various experiments conducted within the preventive support scheme, since the students in difficulty have been shown to be capable of fully assuming their role as students in the PDS. We were able to observe that they are very often able to engage as fully as the other students in the PDS situation, and even to contribute to the progress of didactic time, despite having been deemed to have difficulties. Moreover, the teachers were able to confirm that this level of involvement of these students in difficulty was unusual.

The post-ADS

This auxiliary didactic system presents three functions (Assude & Millon-Fauré, 2021; Morin et al., 2019; Theis et al., 2016).

First of all, it presents a *memory function*, since the aim is to have the students recall the session and revisit the essential steps of the lesson. This work seems particularly formative insofar as the description of the various events and their chronology make it possible for students to better understand the articulations between the various concepts approached and the path which led to the construction of the new knowledge. Assude and Paquelier (2005) similarly emphasize the benefits of this recollection and highlight three of its effects: the expression of a personal time in the classroom, the reconfiguration of the student's lived experience and a time recalled as a shared time. The researchers nevertheless specify that this exercise can prove delicate for most of the students to perform and requires specific guidance by the supervisor, which underlines the value of this memory function in the post-ADS.

This ADS also presents a *renewal of the institutionalization*, wherein the supervisor asks the students what should be remembered following the PDS session. This question will lead students to explain the knowledge involved in different ways. These successive reformulations are intended to help students in difficulties to better understand the processes of decontextualization and depersonalization involved in the taught knowledge, which can enable them to make up for the delay they often experience at this point. Indeed, we observed that some students needed more time than their peers to access the targeted knowledge: implementing these post-ADSs sometimes enables certain students to complete a process of learning that had only begun in the classroom (Assude & Millon-Fauré, 2021). This time of recalling the lesson can also lead the students present to ask questions about certain aspects they had not dared to raise in class. These reformulations can furthermore facilitate knowledge.

We also observe a *reinvestment function*, as the post-ADS helps the students to transfer the knowledge discovered in a given situation, to use it in another context. Indeed, it is not only a matter of the student having understood and memorized the problem taught during the PDS: they must also be able to contextualize this knowledge and use it in a new situation, which may sometimes require the support of the supervisor. In order to facilitate the implementation of this articulation between taught knowledge and operational knowledge in different contexts, the supervisor will propose, during the post-ADS, to solve similar tasks or a reflection on the types of tasks in which the targeted techniques could prove useful. However, care should be taken to ensure that the tasks proposed are not too different from those worked on during the PDS, otherwise the student may not be able to build on the knowledge acquired in the PDS.

With these theoretical underpinnings, the purpose of this paper is to consider different pre- and post-ADS actions which can be implemented for a given class session.

Methodological aspects

Our work contributes to the recent current of collaborative research (Bednarz, 2013). The data collected during this project consisted of all ADSs and PDS plans, video recordings of pre- and post-ADS sessions, PDS sessions, student productions, and recordings of interviews with teachers and supervisors before and after each preventive support scheme session. We conducted an *a priori* analysis of the sessions and then viewed the sessions, annotating the verbatim with respect to the potential functions of pre- and post-ADS of the scheme and their effects. We were particularly interested in the students who had participated in the two ADS sessions: we observed the manifestations of the functions, the way that these students engage the situation, and analyzed the proposed techniques and their possible difficulties in order to study their evolution during the sessions. Examples of analyses are presented in our previous articles (Assude, Koudogbo et al., 2016; Assude & Millon-Fauré, 2021; Theis et al., 2014).

To present the potential actions to be implemented before (pre-ADS) and after (post-ADS) the classroom session, which emerged during the implementation of this scheme and the reflections of the team, the focus of this communication is on a specific class session targeting the concept of fractions. The main task of the PDS was to find the whole from one or several parts (Van de Walle & Lovin, 2005).

A priori analysis

The first targeted task is to reconstitute the whole from its quarter, represented by a small cardboard square. The main technique here is to draw the outline of the square four times on the paper to form a whole. The main potential erroneous techniques are the following: performing the reverse of the task or drawing the original square and reproduce it four more times to have a total of five parts instead of four. In the second task, students can reconstitute the whole from its third, represented by a small Cuisenaire© rod. The techniques required for this task are similar to the first, but here are aided by the use of rods. The final targeted task is to reconstruct the whole from its three-fifths, represented by a cardboard rectangle. Examples of incorrect techniques associated with understanding the role of the denominator or numerator of the fraction would be to reproduce the cardboard five times since it is one-fifth, or to reproduce it three times since there are three.

To illustrate the nature of the work proposed in the preventive support scheme, we will now describe different pre- and post-ADS which could be implemented for this particular session. These proposals are based on analyses of the experiments we have conducted, several of which have been effectively implemented.

Propositions for potential pre- and post-ADS

From these three tasks proposed in the PDS, several pre- and post- ADS can be outlined. These are presented hereafter by analyzing them in terms of their potential functions, always with the aim of making problem solving accessible to these students and enhancing their participation in class.

Potential pre-ADS

A first action could be to **reactivate certain objects of formerly acquired knowledge** which are required during the PDS session to ensure that the students will be able to use them *(mesogenetic function).* In the particular case of the classroom session observed here, the supervisor could for instance decide to ask the students questions about the concept of fractions: what do they remember about fractions? Could they give examples of fractions? How can a given fraction be represented? It is also possible here to return to the lexicon linked to this mathematical concept, such as the terms 'numerator' or 'denominator'. It should be noted that this vocabulary is not really essential for understanding the PDS instructions or for solving the proposed problem, but it can facilitate the description of the techniques that will be used in the class.

A second possibility consists of **presenting to the students the instructions of the problem subsequently worked on** and to **focus the questioning on the understanding of the task**, while taking care not to make the students actually perform the task (*mesogenetic* and *chronogenetic* functions). The instructions of the problem chosen being quite limited, this choice can prove difficult or even irrelevant for the supervisor to implement.

Along the same lines, it could also be useful to **have the students work on a similar type of task** to that of the PDS but with different numbers, for example, more simple fractions such as a half or third (*mesogenetic* and *chronogenetic* functions). However, the supervisor must be mindful not to advance on the didactic time by working on techniques which are too similar to those required in the PDS.

Another option is to **work on techniques which are relevant to the PDS tasks** by asking students to identify a part of a whole using a material support (*mesogenetic* function): for example, find the quarter from a whole represented by a rectangular piece of paper. The corresponding technique consists of sharing the whole into four equal parts (by folding, cutting or marking), then identifying the unit fraction one quarter of the whole (by hatching, coloring or superimposing). By isolating the quarter of the whole, it is possible to observe that the parts are all the same size and that what remains (three quarters) is the complement to constitute the whole (four quarters). This technique helps to convey the "part of a whole" meaning of a fraction as well as the relationships between the parts and the whole. This will be useful in solving the PDS tasks (reconstructing the whole from a part of the whole).

Regarding techniques involving the Cuisenaire© rods, it could also be useful to take a moment to **discuss the material** with regards to fractions (*mesogenetic* function). Indeed, it is very likely that the students had already used this material in the context of counting and the first operations on integers. They therefore know that each colored rod has, in the context of natural numbers, a specific length and represents that number (for example, the red rod has a length of 2 cm and represents the number 2). However, when used in the context of fractions, the measurement of the rods differs depending on the unit chosen. Thus, it is necessary for students to choose the rod that represents the whole (or the unit) and this rod can be different to the situations illustrated. These differences can then be pointed out during the pre-ADS, either in the context of a more open discussion based on a simple task of representing a fraction from a whole, or in a more direct way by the supervisor.

Potential post-ADS

The supervisor can first of all ask the class to **recount what happened in the PDS session** *(memory* function). The supervisor's questions will encourage the students to enrich certain passages of their narration by expanding on points that were perhaps covered too quickly. It is also possible to use elements from the PDS to facilitate this recollection: for example, the supervisor can present photos of the board taken during the classroom session or certain student productions. It is also possible to make a video recording of the session and then to extract some key segments which the students must then comment on. It should be noted that, for this type of preventive support scheme, the fact that the post-ADS supervisor is not the class teacher can be an advantage. Indeed, in the students' eyes, questions about the session will seem much more justified than if they are asked by someone who attended the session.

A second type of post-ADS consists of **questioning the students on what they should retain from the session**. It is then a question of activating the didactic memory of the class in order to make the pupils reiterate the knowledge stated in class, possibly after certain reformulations guided by the teacher (*memory* and *recollection of the lesson* functions).

The supervisor can **propose a similar type of task** to that proposed in the PDS and which can be solved in the same way, while being mindful not to propose a more complex task (at the risk of losing the benefit of the confidence acquired by the students during the pre-ADS/PDS). This enables the student to apply the technique acquired during the PDS (*reinvestment* function). One variant consists of **asking students to propose a similar type of task** to that given during the PDS, being nevertheless mindful that the task should not be too different to the original task (the supervisor no longer controls the didactic variables in this case).

A fourth type of post-ADS could take the form of **revisiting a difficulty observed during the PDS** (*memory* and *recollection of the lesson* functions)**.** For example, the final task related to reconstituting the whole from its three fifths represents an obstacle for students who struggle. It might therefore be interesting to return specifically to this task and ask students to comment on the strategies, correct or otherwise, which may have been employed by their peers.

Conclusion

The purpose of this communication is to consider what preventive measures can be put in place to support students identified as having learning difficulties before and after a class session on mathematical problem solving. It is true that the students are taken apart before and after the class session, but this measure allows them to become more involved in the mathematical task and to contribute to it like all the other students. This is a device that gives them back their power to learn in synchrony with the other students in the class.

Thus, after having specified the functions of the scheme, we have, from an experimentation based on the concept of fractions, presented the tasks proposed in the PDS and suggested other possible interventions. Below is a schematic summary of the pre- and post-ADS associated with the chosen classroom session (PDS) (Table 1). Such analyses can be made for other mathematical topics as measure of length (Theis et al., 2014), notion of area (Assude, Millon-Fauré et al., 2016), volume (Marchand et al., 2021) or construction programs (Millon-Fauré et al., 2021).

Possible actions – pre-ADS	PDS	Possible actions – post-ADS
- Reactivate certain objects of formerly acquired knowledge required to solve the PDS tasks - Question the students on their understanding of the PDS instructions - Work on formerly acquired techniques relevant to the PDS - Discuss the material of the PDS	T_1: Reconstitute the whole from its quarter (cardboard) T_2: Reconstitute the whole from its third (rod) T_3: Reconstitute the whole from its three-fifths (cardboard)	- Recount what happened in the classroom sessions - Question the students about what they should retain from the session - Propose a similar task to the students - Revisit a difficulty observed in the PDS

Table 1: Overview of potential actions for the pre- and post-ADS

The result is a range of possible tasks available to supervisors involved in the system. The choice of one of these tasks depends on the students, their difficulties, the PDS teacher, the ADS supervisor and the situation itself.
This study thus illustrates the richness of the preventive support scheme, which can be adapted by the teachers/supervisors in various ways. However, these choices directly influence the effects of the pre-ADS on the PDS and in turn the PDS on the post-ADS and can sometimes call into question the possible gains in terms of student engagement. This is particularly true when tasks that are too similar to those of the PDS are dealt with in the pre-ADS, or when tasks that are too complex are introduced in the post-ADS, which shifts away from the aims of the classroom session and generates certain effects related to the topogenetic function. For this reason, we believe it is essential to inform teachers/supervisors of the different options available, so that they can then choose the one which will prove most beneficial for their students.

Inclusive landscapes of investigation in mathematics classrooms with deaf and hearing students

Amanda Queiroz Moura

University of Klagenfurt, Austria; amanda.queiroz@aau.at

This paper aims to discuss possibilities for educational mathematics practices addressing the inclusion of deaf students in regular schools. In order that I present reflections on the meetings amongst deaf and hearing students in mathematic classes in a Brazilian context. My reference for such discussions is the results of my doctoral research whose focus was interaction in a mathematics classroom in which students speak different languages – Portuguese and Brazilian Language of Signs. First, I present the context of deaf education in Brazil. Following, I present the design of the study and my reflections concerning the dialogical interaction pattern and aspects of Inclusive Landscapes of Investigation with reference to mathematics classes where deaf and hearing students are together. I conclude that educational practices based on Inclusive Landscapes of Investigation can support mathematics classes in the context of inclusion of deaf students in regular school.

Keywords: Inclusive mathematics education, meetings amongst differences, dialogue.

Introduction

Inclusive Education has been based on concepts related to human rights and progresses towards an ideal of equity, which recognizes the different means and conditions for different groups or people to have access to the same rights (Moura, 2021; Skovsmose, 2019). According to Kollosche et al. (2019), most investigations involving this theme in the context of Mathematics Education have been presented through concerns related to students with disabilities or special needs. For the authors, the main motivation for that has been established through legislation, international agreements, and educational practices in schools.

However, the notion of inclusive education, especially in the field of mathematics education, has been discussed as something that challenges the diversity we find in classrooms in general (Bishop et al., 2015; Skovsmose, 2019). In this sense, researchers have been discussing the different obstacles to inclusive education, as well as the possibilities for dealing with them through an agenda of equity and inclusion in mathematics education (Skovsmose, 2019; Moura, 2021; Roos & Bagger, 2021).

The discussions presented in this paper aims to contribute to this agenda through an experience in Brazil's educational context, where most of the concerns of inclusive education are related to schooling for people with disabilities. Since 2008, the introduction of new educational policies determines that these students become enrolled in regular schools[1]. Thus, the proposed discussion

[1] Regular schools are public or private schools which do not include specially assigned special education or student behavioral intervention programs within or outside the enrolled schools

here is directed to the inclusion and permanence of deaf students, as well as the need to provide effective inclusive practices for these students.

The present paper aims to discuss possibilities for mathematics practices addressing the inclusion of deaf students in mathematics classrooms in regular schools. Such discussions are based on the results of a doctoral research that sought to understand how interactions happen in mathematics classes where deaf and hearing students are together, and the tasks are organized according to the perspective of Landscapes of Investigation (Moura, 2020).

The doctoral research data were generated in mathematics classes of a fifth-grade class of elementary school (10 years old) of a municipal public school in the state of São Paulo, Brazil. This school is recognized in the city for the work it has been doing for the inclusion of deaf students by adopting a pedagogical proposal based on a bilingual perspective of education, in which the first language of communication and schooling for deaf students is the Brazilian Sign Language (Libras) and the Portuguese language is used in its written form, which is teaching and learned based on the experiences obtained through sign language.

With a total of 22 participants, including three interpreters, two teachers, and 17 students, of whom five were deaf and 12 were hearing, data production involved the planning and development of the tasks were based on the proposal of Landscapes of Investigation, according to the perspective of Skovsmose (2000). In which follows I present the theoretical framework relate to the context of the research.

Theoretical Background

Although the presence of sign language interpreters doesn't guarantee the inclusion of deaf students in the teaching and learning practices, having this professional in the classes where deaf and hearing students are together is the first step to the promote equity. The role of sign language interpreters has been redefining over the last few years, in view of the demand for the classroom and the implementation of different practices. With this, the relationship between professors, interpreters, and students, as well as the ways of communication have been shown to be distinct (Moura, 2020).

Regarding the mathematics classes, research have been indicating that there is no direct interaction between deaf and hearing students and neither between teachers nor deaf students (Borges & Nogueira, 2019). Thus, usually teachers communicate with hearing students and interpreters. Interpreters mediate the interaction between deaf students and the teacher and with other students when there is an opportunity (or need). Deaf students communicate directly only with each other and/or with the interpreter, and the answers to the deaf student's questions are almost always given by the interpreter and not the teacher, causing the isolation of these students in the classroom.

Based on this fact, Moura (2020) suggests thinking of an interaction pattern like the one described in Figure 1.

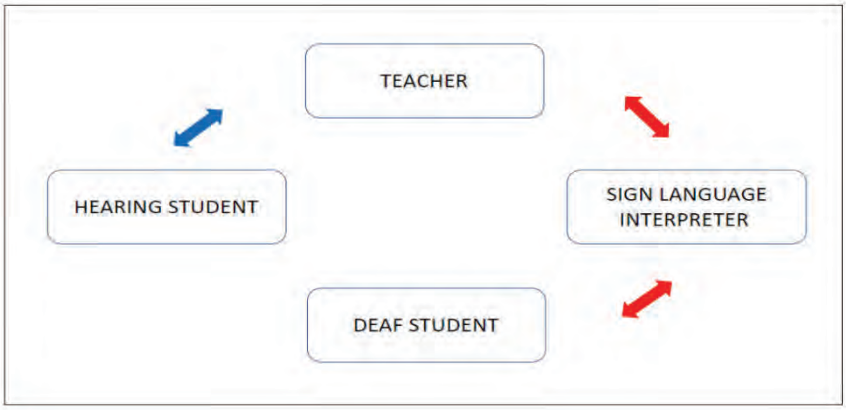

Figure 1: Interaction pattern in classes with deaf students and sign language interpreter

In the classes in which this communication pattern is common, is also possible to realize the little interaction between teachers and interpreters. In this sense, it is believed that this interaction pattern contributes for the interpreter to assume the responsibility for teaching the contents to students. According to Silva and Oliveira (2016), situations like this are common in classrooms where are together deaf and hearing students, and in addition to giving the interpreter a role that does not concern him/her, they end up further distancing deaf students and teachers, since the reference of these students becomes the interpreter and not the teacher. In other words, they only share the same space with the hearing students, there is not an effective inclusion.

In mathematics classes, the concerns about these conditions are bigger, since the sign language interpreters don't have enough mathematics knowledge to teach the contents to deaf students (Pinto & Segadas, 2019). Usually, they teach what they understand from the explanations of the teachers, but certainly, this understanding can be incomplete or insufficient, causing inequality of opportunities of mathematics learning to deaf students.

In addition, this pattern of interaction also reinforces the practice of teaching methodologies designed and directed to listeners, based on the belief that the performance of the interpreter is enough to make the deaf understand the content (Borges & Nogueira, 2019). Although deaf students are educated through Libras, authors (Borges & Nogueira, 2019; Moura, 2020) emphasizes the importance of thinking about methodological strategies that consider the presence of deaf people in the classroom where the majority are hearing students.

Hence, the use of methodological strategies for each student could follow his/her own path towards knowledge, has been expanding. This new way of thinking methodological strategies that favor the learning of students with disabilities, Fernandes (2017) calls construction. According to this author, this proposal involves the construction of a context that allows for the sharing of perspectives and the negotiation of meanings, also enabling the development of autonomy and understanding of mathematical learning processes.

Thus, the ways of teaching and learning mathematics can be explored in a shared space, making the knowledge of this subject be understood in different ways. For this, it is essential to create learning environments that accommodate the differences of students and allow learning across them.

Design of the Study

This investigation used a qualitative approach and, as a methodological procedure, participant observation, which allowed me to investigate the object of study in its context from my insertion in the group of students (Queiroz et al., 2007). This method favored an understanding of how interactions happen in mathematics classes where deaf and hearing people are together, and also the tensions that exist in the process of inclusion of deaf students in regular schools.

These classes were recorded in audio and video and notes were made by the researcher. From these records, episodes were constructed in which the interactions between participants are described. To help structure the episodes, we sought to analyze the videos along with the audios, inspired by the analysis phases presented by Powell et al. (2004).

After, these episodes were analyzed in view of the aims of the research, where some aspects concerning the proposal of Landscapes of Investigation in a context with deaf and hearing students could be identified. In the following, we present results and discussion where we reflect on aspects that support inclusive mathematics practices addressing deaf students in classrooms in regular schools.

Results and Discussions

Seeking to create mathematics learning environments that accommodate the differences of students, in my doctoral research I presume that the Landscapes of Investigation proposal could provide an inclusive learning environment. Usually, in mathematics classes, the teaching is organized based on some theoretical explanations followed by exercises involving techniques and procedures presented previous by teachers. Landscapes of investigation break with this exercise paradigm through dialogical communication, allowing the students to be responsible for their own learning process and encouraging experimentations. The students are invited to engage in investigative tasks, which makes room for the discovery of mathematical facts, refutations, production of new meanings, critiques, reflections, hypothesis testing, and cooperation (Skovsmose, 2000).

Landscapes of Investigation played a central role in the research. The main pattern of communication is dialogue, in which the teacher leaves the centrality of the class and the perspectives of everyone else start to gain importance. Thus, through investigation, deaf and hearing students have the opportunity to interact. Whether directly or with the mediation of the interpreter, students get to know the perspectives of each other in a cooperative manner on an equity condition. The valorization of sign language encourages hearing students and teachers to learn the language to communicate with deaf colleagues, expanding the possibilities of interaction between students and conducting the investigation in different ways. It is possible to experience other ways of learning.

In the episodes of the classroom that made part of my doctoral research, I identified an interaction pattern in math classes with deaf and hearing students that I named Dialogical Interaction Pattern as illustrated in Figure 2.

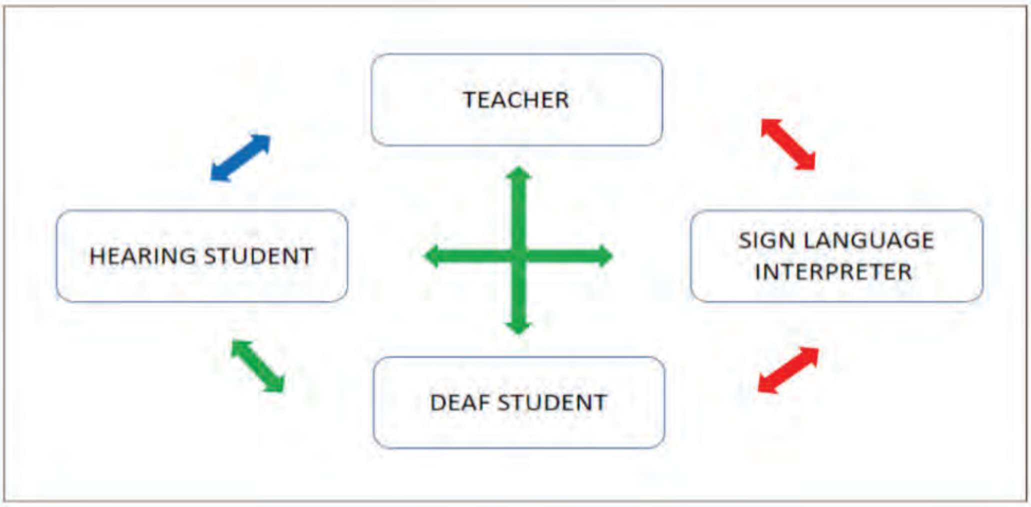

Figure 2: Dialogical Interaction Pattern

In this new pattern, the teacher leaves the centrality of actions enabling new interactions to emerge, namely, interactions between teachers and deaf students, interactions between deaf students and hearing students, and interactions between interpreters and hearing students.

When seeking to understand the perspectives of students and interpreters, the teacher leaves of being the only one to have something to teach. Active listening, as well as teacher displacement to understand the student's perspectives, contributes to overcoming the vertical relationship between professor and students. The teacher is still responsible for planning, mediation, decisions on methodologies appropriate to the various mathematical contents and by assessment strategies. However, the teacher is no longer the one who only teaches, and the student is no longer the one who only learns.

In this learning environment, teachers have the opportunity to learn too with deaf students and sign language interpreters. This movement towards overcoming the vertical relationship during classes allows deaf students to share their perspectives, their way to understand the world, and their language. For this, they rely on the help of a sign language interpreter who, after the deaf, is the main disseminator of deaf culture and identity. The partnership between teachers and interpreters is strengthened in order to contribute to the cooperation among deaf and hearing students. By moving to understand the perspectives of students, the teacher is open to the redefinition of ideas and positions, respecting the different ways of learning and paths to be followed. Thus, the planning and methodological assessment strategies start to also consider the perspectives of deaf students and how they experience the world, which is essential for the construction of equity.

To emphasize the potential of learning environments based on Landscape of Investigation for the inclusion of people with different skills or backgrounds, Skovsmose (2019) defines Inclusive Landscapes of Investigation. A proposal based on a universal design for learning perspective, which seeks to eliminate the need for adaptations through the construction of pedagogical strategies accessible to all students, highlighting the particularities of students as possibilities and not as obstacles to carrying out the tasks.

In Inclusive Landscapes of Investigation, dialogue is assumed as a pattern for interaction favoring cooperation and the construction of equity, in other words, is an environment of learning in which the Dialogical Interaction Pattern is established. From this idea, Skovsmose (2019) highlights three aspects concerning Inclusive Landscapes of Investigation: facilitate investigations; enable an environment of learning accessible to students; favoring for collaboration among students.

During the analyses of the classroom episodes, beyond these three aspects highlighted by Skovsmose (2019), was possible to identify more five as aspects essential which emerged from the Dialogical Interaction Pattern in this Inclusive Landscapes of Investigation: contribution to the construction of equity through the appreciation of sign language; recognition of the sign language interpreter as someone who can contribute to the learning of all; the opening of spaces for the negotiation of signs of mathematical terms that still do not have a defined sign in Brazilian Sign Language; possibility of other learning (and investigations) that support students' mathematical learning; opportunity for students to experience new ways of learning, contributing to the critical and reflective knowledge. Thus, we can say that there are eight important aspects when considering the proposal of Inclusive Landscapes of Investigation mathematics classes with deaf and hearing students.

The facilitation of investigation is an aspect that must be considered from the planning of tasks. Doing investigation is an open task that does not include solving an exercise list. Thus, it is important to seek to develop tasks with different possibilities for answers and to invite students to an investigation.

Enabling an environment of learning accessible to all students is an aspect that must be considered from the planning of tasks. Doing investigation is an open task that does not include solving an exercise list. Thus, it is important to seek to develop tasks with different possibilities for answers and to invite students to an investigation.

The favoring for collaboration among students is mainly due to the dialogic interaction between them. Include sign language in the curriculum of subjects, is a way to appreciate both the deaf culture and the sign language, supporting hearing students to learn sign language in order to interact with the deaf colleagues.

The recognition of the sign language interpreter as someone who can contribute to the learning of all is related to the relationship between teachers, students, and interpreters. The sign language interpreter beyond teaching sign language for all students, can encourage students to use this language for the interactions, as well as can engage in the investigation with the students, sharing the mediation tasks with the teacher.

Opening of spaces for the negotiation of signs of mathematical terms that still do not have a defined sign in sign language is extremely important in classes with the presence of deaf students, as it contributes to the understanding of mathematical concepts. Generally, these negotiations are not foreseen in the planning of tasks but having a learning environment that allows them to be carried out, as in the proposed Inclusive Landscapes of Investigation, is an essential support for the learning process of mathematics for deaf students.

The possibility of other learning (and investigations) that support student´s mathematical learning concerns learning concepts or ideas that are not directly related to the subject investigated, but such understanding is necessary for mathematical concepts or problem situations understood or resolved.

The opportunity for students to experience new ways of learning, contributing to critical and reflective knowledge. This type of knowledge is related to the knowledge that allows students to develop their own mathematical strategies and conjectures.

Finally, I emphasize that Inclusive Landscapes of Investigate are constructions. Thus, the development of tasks based on this proposal can take on different characteristics and formats. There is no instruction guide for such constructions, however, the eight aspects presented are fundamental when considering a pattern of dialogic interaction and can be seen as aspects that contribute to the composition of these landscapes. In other words, these aspects are only possible through a change from the interaction pattern that usually happens in the mathematics classroom (Figure 1) for the new interaction pattern (Figure 2), which has dialogue communication as the protagonist. The inclusion of task proposals based on this format can create new possibilities for deaf and hearing students to learn mathematics together.

Concluding Remarks

Seeking to contribute to the construction of a culture of mathematics education that values differences and diversity, Skovsmose (2019) proposes that Inclusive Education be thought of as a new way of providing meetings amongst differences. Therefore, I understand these encounters as a human ability to be with the other (or others) experiencing a mutual relationship, which suggests a movement, an action of discovering, an act of being aware of new things.

Thinking inclusive education in terms of meetings amongst different people is to think of an education that recognizes and values the difference of each one and that envisions the possibility of learning from what is different. In other words, is an education that brings concerns about all students, whether this student with disability or not, with special needs or not. In this perspective, each student is unique and has their own way to handle mathematics. Knowing different ways of relating to mathematics also contributed to the development of a critical view that allows us to look beyond stereotypes and/or pre-established conceptions about the other.

In this regard, I see the meeting between deaf and hearing people at school as a meeting between students who speak different languages, who recognize and value this linguistic difference, as well as the learning possibilities that can emerge through cooperation and equity.

In this paper, I bring Inclusive Landscapes of Investigation as a possibility for mathematics practices addressing the inclusion of deaf students in mathematics classrooms in regular schools, in view of the meetings amongst deaf and hearing students in mathematics classes. Through dialogical interaction pattern, new meetings are facilitated in the classroom. Teachers meet deaf students and sign language interpreters, sign language interpreters meet hearing students, hearing students meet deaf students. These meetings do not only refer to sharing the same classroom, but to a movement of seeing the other, of wanting to be together, favoring cooperation and the construction of equity, crucial elements for the inclusion of deaf students in mathematics classes.

Finally, I understand that the reflections and conclusions presented in this paper may support mathematics education practices that focus on diversity. The feasibility of dialogic interaction between two culturally different groups – deaf and hearing people – shows us new possibilities for the participation of all students in conditions of equity and cooperation during the mathematics learning process.

CLIL in teaching pupils with special needs

Jarmila Novotná[1] and Hana Moraová[2]

[1]Charles University, Faculty of Education, Prague, Czech Republic; CeDS, Université Bordeaux, France; jarmila.novotna@pedf.cuni.cz

[2]Charles University, Faculty of Education, Prague, Czech Republic; moraova@seznam.cz

Keywords: Inclusive education, pupils with special needs, CLIL (Content and Language Integrated Learning), materials for teaching.

Introduction

Education of pupils with special needs (PSN) has been studied for several decades (see e.g. Farrell, 2001). In many countries, it is an exception to find a homogeneous classroom where PSN are not present, which increases the demands on the teacher. At present, the traditional understanding of PSN is challenged by the presence of pupils with different mother tongues and low level of understanding the language of instruction, which is in most cases the mother tongue of the majority of pupils in the classroom. These children are in some countries considered as PSN while other countries do not classify them as such, despite the fact that they require similar support.

The poster presents results of a study of implementing CLIL[1] in classrooms with PSN. Attention is paid to the rules for creating suitable CLIL materials for this environment. Three pillars originally developed for materials in linguistically and socio-culturally heterogeneous classes are considered as the basis; the reported study suggests that they are appropriate if principles for teaching pupils with special needs are added.

Theoretical background

In the Czech Republic, there is an increasing demand for using non-traditional teaching strategies that develop pupils' language skills and thus their preparedness for future career, like e.g. CLIL. There are studies about the pros and cons of using CLIL, the majority of which present CLIL as a useful teaching strategy. However, taking into account the introduction, there are very few studies about using CLIL with PSN. We found only one work focusing on this issue (Karlíková, 2020). Karlíková studies CLIL teaching at primary school with a focus on PSN, specifically on pupils with learning disabilities and pupils from socially disadvantaged backgrounds. Her research shows that CLIL has no negative impact on the sample of pupils from socially disadvantaged backgrounds. At the same time her research neither confirms nor refutes the potential of teaching CLIL to pupils with learning disabilities. There are many questions that still need to be paid attention to and validated.

In Novotná, Moraová and Ulovec (2021) and Novotná, Ulovec and Moraová (2020), three pillars for a successful creation of materials for teaching in culturally and socio-culturally heterogeneous primary and secondary classrooms are presented and discussed: *Topics of interest for all pupils, Using*

[1] CLIL – Content and Language Integrated Learning refers to the teaching of a non-linguistic subject through a foreign language. CLIL works with an equilibrium between content and language learning.

cultural differences as funds of knowledge, and *How (seemingly) simple things can be very different (and difficult) in other places and cultures.*

Research question

The pillars were developed for the work in linguistically and socio-culturally heterogeneous classrooms, not for teaching PSN in inclusive classrooms. Although we see a lot of similarities when working with PSN in an inclusive classroom, it is not clear if the three pillars are sufficient for preparing materials for CLIL lessons in classrooms where PSN are integrated. Our study presented on the poster focuses exactly on this question.

Results and discussion

In cooperation with practising teachers we observed CLIL lessons in inclusive classrooms and analysed materials prepared by teachers for PSN in their classes. In accordance with Karlíková's results (2020) we found that using CLIL with them based on appropriately designed materials is not an obstacle for majority of PSN that participated in our study. However, the three above mentioned pillars are not sufficient for creating a good CLIL material for PSN. It is not surprising that the fourth pillar, *Respecting PSN's individual differences*, must be added. For example for pupils with dyslexia it is good to shorten all texts, add colours and illustrative pictures. Considering the presence of different types of learners, a matching exercise may be text – text as well as text – picture. The materials should give enough opportunities for pair work and group work allowing each pupil use their strengths in collaborative activities.

Acknowledgment

Perceptions of mathematical creativity among math teachers in special education classrooms

Maya Ron Ezra and Esther S. Levenson

Tel Aviv University, Israel; maya.ronezra@mail.tau.co.il; levenso@tauex.tau.ac.il

Encouraging mathematical creativity is one of the aims of mathematics education. The present study examined teachers' perceptions of encouraging mathematical creativity in special education classrooms (SEC). Three teachers of mathematics in SEC were interviewed regarding their perceptions of mathematical creativity and their role in encouraging mathematical creativity in SEC. Findings indicated that the teachers believe in the importance of fostering mathematical creativity among their students. In general, they indicated that their role was to create a supportive environment that encouraged students to think on their own. Professional development is needed specifically to introduce teachers to tasks that can promote mathematical creativity.

Keywords: Mathematical creativity, teachers' perceptions, special educational needs.

Introduction

Encouraging mathematical creativity is an important objective of mathematics education (Levenson, 2013). Research suggests that promoting mathematical creativity can strengthen the connections between different topics both within and outside of mathematics, and extend prior knowledge (Leikin, 2009). Alongside increased awareness of classroom mathematical creativity, there is growing awareness of the importance of offering equal learning opportunities for all students (DeSimone & Parmar, 2006). Teaching that exposes students with special education needs (SEN) to a range of strategies can encourage flexibility and creativity, along with a deeper understanding of mathematics, leading to improved accuracy and foster performance among students with SEN (Peters et al., 2014).

The teacher has a significant role in fostering mathematical creativity in both, general and special education classrooms (SEC). Previous studies have shown that mathematics teachers' beliefs and perceptions can affect their teaching methods as well as decisions made in the classroom (Schoenfeld, 2011). Likewise, beliefs teachers hold about creativity can influence what they do in class. Some mathematics teachers regard creativity as an acquired skill which students can develop (Lev Zamir & Leikin, 2012), while others believe that only some students have the ability for creativity (Shirki & Lavy, 2012). The current study examines the perceptions of three mathematics teachers who teach in SEC within general education schools, regarding encouraging mathematical creativity among students with SEN. SEC have a small number of students, where each student learns according to an individual learning plan, and yet may be mainstreamed in certain subjects according to ability.

Theoretical background

Our theoretical perspective of mathematical creativity is in line with Silver (1997), who viewed mathematical creativity as "an orientation or disposition toward mathematical activity that can be fostered broadly in the general school population" (p. 75). Mathematical creativity is commonly assessed according to three criteria: *fluency*, the number of distinct solutions, possibilities, or ways of solving a given problem (Leikin & Lev, 2013); *flexibility*, breaking away from familiar and fixed patterns, posing ideas from different fields of mathematics, examining a problem from different angles, expressing solutions by means of different representations (Leikin, 2009; Levenson, 2013); and *originality*, finding a new or unusual way to interpret an idea or solution (Silver, 1997).

Promoting mathematical creativity in the classroom is the teacher's responsibility, beginning with choosing appropriate tasks. Many researchers recommend engaging students with open tasks that have many answers (e.g., Levenson, 2013). Leiken (2009) recommends engaging students with multiple-solution tasks that have one final answer but many ways to teach that answer. Another type of task is problem posing, often associated with promoting flexibility (Silver, 1997). Another responsibility of the teacher is creating an environment where mathematical creativity can thrive. For example, when a teacher relinquishes some authority as the primary source of knowledge, that teacher creates fertile ground for experimentation and investigation, encouraging students to pose questions and draw conclusions. By creating a climate that makes the classroom a safe environment for posing new and original ideas, and navigating the mathematical discourse, the teacher can encourage the development of mathematical creativity among students (Levenson, 2013).

Previous studies investigated teachers' perceptions of creativity in general education classrooms. For example, elementary mathematics teachers in general education were found to perceive mathematics as a subject with limited opportunities for creativity (Bolden et al., 2010). Although they believed that creativity is important in general, they regarded mathematics as a subject characterized more by logic than by creativity, unlike subjects such as art, music, and language (Panaoura & Panaoura, 2014). Thus, in practice, they failed to create a climate that fostered mathematical creativity in the classroom. Bolden et al. (2010) indicated that teachers believe mathematical creativity manifests itself in teaching that utilizes a range of resources (e.g., technology) and examples from daily life. Other studies found that some mathematics teachers associate mathematical creativity with tasks that are different or unusual, and tasks that have multiple answers (Levenson, 2013). At times, although teachers choose appropriate tasks that have the potential to occasion mathematical creativity in the classroom, there is a gap between the potential of the chosen task, and the way it is implemented in the classroom (Lev-Zamir & Leikin, 2013).

In contrast to the abundance of studies on teachers' perceptions of mathematical creativity in general education, few studies have investigated the encouragement of mathematical creativity among students with SEN. However, studies have examined teachers' views on teaching mathematics for these students, revealing a dispute regarding appropriate teaching methods. Some argue that for students with SEN, mathematics education should focus only on a handful of problem-solving strategies and on achieving an optimal level of proficiency in just a few calculation procedures (Geary, 2003). Others maintain that teaching procedural knowledge based on memorization and retrieving facts is difficult for some students with SEN, and therefore, those students should be exposed to a variety of strategies and encouraged to develop flexibility and creativity (Peters et al., 2014). Creating learning opportunities that encourage students to tackle mathematical challenges and find different ways to solve problems can help even cognitively less proficient students develop mathematical competence (Jonsson et al., 2014). Regarding the issue of equal opportunities in mathematics classrooms, some educators argue that just exposing students with SEN to the same content and topics as those in general classes is insufficient, and that it is necessary to provide teachers with appropriate training and support, so that they can make adjustments for their students by, for example, extending the time of learning and practice (DeSimone & Parmar, 2006).

The purpose of this study was to examine the perceptions of teachers who teach mathematics in SEC within general schools, towards promoting mathematical creativity among students with SEN. The research questions are: How do teachers of students with SEN perceive mathematical creativity? How do teachers of students with SEN perceive their role in encouraging mathematical creativity in a special education classroom?

Methodology

The study included three teachers from three different schools in Israel, who teach mathematics in SEC within general mainstream schools. As can be seen in Table 1, their training background and teaching experience were quite different, representing the reality in Israel. Some teacher colleges offer additional mathematical content training for prospective special education teachers. Ravit had such training, while Irit did not. Rachel had no formal training to teach students with SEN, but instead had a stronger mathematical content and mathematical pedagogical knowledge than Ravit and Irit.

Table 1: Background of the research participants

Teacher	Pre-service education	Years of experience teaching …			
		School, students	Mathematics (non SEC)	Special education (not math)	Mathematics in a SEC
Ravit	Special education + mathematics	Primary students with learning disorders	–	12 years	4 years
Irit	Special education	Primary students with autism spectrum disorder	–	–	12 years
Rachel	Computer science + mathematics	Middle school students with learning disorders	19 years	–	6 years

The study was conducted using a semi-structured interview. The main interview questions were: (1) Is mathematics a creative discipline? (2) Should mathematical creativity be encouraged in SEC? Why? (3) How can mathematical creativity be encouraged among students with SEN? (4) Can tasks that has been shown to encourage mathematical creativity be used for teaching mathematics to students with SEN? (5) Do you implement such tasks in your classroom and if so, how?

Each interview with the researcher lasted between 25 and 45 minutes. The teachers were asked to answer the questions based on their teaching experience, both in mathematics and in special education. For interview question (4), teachers were presented two multiple-solution tasks, a type of task that has been shown to encourage mathematical creativity (Leikin, 2009; Silver, 1997). For example, the first task showed a diagram of 25 circles organized in the form of a diamond, where the learner is required to identify how many circles are in the diagram and then find as many ways as possible to count them. The interviews, which were conducted via Zoom in the afternoon hours after the end of the school day, were recorded and transcribed by the researcher.

Findings and Discussion

Inductive analysis of the data led to three main themes: what is mathematical creativity; the teacher's role in encouraging mathematical creativity; and tasks that occasion mathematical creativity.

Mathematical creativity from the perspective of teachers who teach mathematics in SEC

To the question, "Is mathematics a creative discipline?" only Rachel responded in the affirmative, although she found it difficult to explain why. The other two teachers did not respond at all. Instead, Irit and Ravit, and later also Rachel, responded by relating how they themselves teach mathematics. For example, Irit defined mathematical creativity in the following way: "Creativity (pause) [means] bringing something different, illustrating [the mathematics] in a concrete way, and making it come alive." For Irit and the other teachers, mathematical creativity had more to do with the way they teach, than the way the students learn. Specifically, they all mentioned the use of manipulatives, as related to mathematical creativity. This finding is consistent with Bolden et al.'s (2010) study of general elementary school teachers' who believed that using a variety of methods and examples from daily life is an expression of mathematical creativity.

To understand why the teachers in this current study associated mathematical creativity with the use of manipulatives, we consider their pedagogical knowledge in the realm of special education. Students with SEN often struggle to draw connections based on previously acquired knowledge, and need mediation and curriculum adjustments in order to properly establish new knowledge (Hunt et al., 2016). In the interviews, the teachers frequently expressed those students with SEN need a lot of "manipulatives," "visualization", and "repetitiveness". The teachers' reference to manipulatives may have stemmed from their need and desire to make the mathematical content more interesting, or from wanting to illustrate the content in a way that students would be able to understand. For example, Irit stated: "[Mathematics] can be either very dull or [by using concrete manipulatives] very interesting". Rachel, who was not trained as a special education teacher, illustrates the second viewpoint: "Their (students with SEN) ability to read (understanding underlying meanings), to teach them mathematics … one has to understand that the pace is different … to encourage them to learn in a different way."

Nevertheless, when the researcher delved deeper and the teachers were asked directly whether students with SEN ever exhibit mathematical creativity, they did refer to flexibility and originality, although not necessarily using those terms. For example, Rachel related to flexibility and originality thus: "Some students solve questions in such a creative way that I'm simply stunned … in motion problems, [they] don't use the familiar formula (velocity × time = distance); they solve it in an entirely different way." Rachel is hinting at original thinking. She added, "creative students are students with a different, not rigid way of thinking". This refers to flexible thinking. Rachel also referred to unique representations of solutions, which is another characteristic of flexibility (Leikin & Lev, 2013). She said: "In geometry there is room for creativity … using building blocks, folded paper. We do a lot of creating." Ravit also related to flexibility, in the sense of breaking away from a familiar and fixed pattern and combining ideas from different fields (Levenson, 2013). She attempted to define what creativity is, saying: “using what was learned in one mathematics topic, when solving a problem in another mathematics topic.”

Interestingly, the teachers also believed that creativity in mathematics can emerge through students’ mistakes. For example, Irit said: “Even if someone (a student) says something that is incorrect but explains his reasoning and says why he thinks it’s right, in my opinion it’s even more creative.” Rachel also referred to learning from mistakes as part of the process of mathematical creativity: “If a student does something and makes a mistake, I allow these mistakes. I let them express mistakes. I think mistakes are part of the learning process, and I give a lot of credit (in the positive sense) to mistakes.” Analysing these comments from the standpoint of mathematical creativity shows that the teachers create a safe environment for their students and encourage them to raise new and original ideas (Levenson, 2013), without fear of failing.

Throughout the interview, teachers also referred to difficulties in teaching mathematics to their students. For example, Ravit said that “the students are largely set in their patterns”. The phrase “set in their patterns” was used by the two other teachers as well, hinting that the teachers believe it is difficult for their students to adopt a variety of methods for solving problems. This is in contrast to educators’ suggestions of having students solve problems using different strategies and methods, promoting fluency and flexibility (Levenson, 2013).

The teacher’s role in encouraging mathematical creativity

When the three teachers were asked if and how mathematical creativity can be encouraged in their classes, all three teachers mentioned the types of questions they ask during mathematics lessons. For example, Irit said that she asks: “How did you reach this [solution]? What did you do and how did you know to do it that way?” Ravit asked more general questions which by their generality may be said to encourage fluency and flexibility: “I ask them, ‘How can this be solved? In which ways can this be solved?’” This type of discourse encourages students to think of more than one solution method, which promotes mathematical creativity, and assists in constructing knowledge. By asking open and guiding questions, the teacher raises the level of thinking, opens new channels of thought for the students, and encourages mathematical creativity. On the other hand, none of the teachers stated that they ask individual students to solve a problem in more than one way (Levenson, 2013).

Teachers also mentioned their role as mediators in the learning process, which they believe leads to the encouragement of mathematical creativity. Rachel described what happens in class after she gives students a task to work on individually: “First of all, the student thinks, he constructs some knowledge. I give him the feeling that he’s not alone. I guide him. It’s a learning process.” Rachel continued to describe how the lesson develops and how different students describe different solutions to their classmates: “The students explain … sometimes their classmates manage to understand it better [than the teacher’s explanation].” It appears that the teachers believe that mediation and working together with the students, is an important aspect of promoting expressions of mathematical creativity, as well as constructing the subject matter.

Teachers also believed that their role is to motivate students and that mathematical creativity can be a means to increase motivation. Phrases such as “fear”, “passiveness”, “(low) self-confidence”, “challenge”, “emotional aspect” were very common among the teachers’ description of the climate in mathematics classes. Rachel suggested that the added value of encouraging mathematical creativity is a way to boost motivation: “You give students the feeling that they are doing it on their own … a sensation of learning. Rather than acquiring and ‘regurgitating’ the material … [that way] they explain how they arrived at the solution …”. This is in line with Peters et al. (2014) who suggested that encouraging mathematical creativity creates a challenge for the students and thus students are more active and involved.

As seen above, the teachers appreciate their roles in encouraging mathematical creativity in special education classrooms. They encourage students to solve problems in different ways and avoid dictating only one correct right way, thereby allowing expressions of flexibility and originality.

Incorporating tasks that occasion mathematical creativity among students with SEN

Unlike when teachers were asked about their roles in encouraging mathematical creativity, and they were immediately able to offer several responses, when asked about incorporating tasks that could promote mathematical creativity, there was quiet. Specifically, Ravit and Irit struggled to give examples of tasks that have the potential to occasion mathematical creativity. When they were shown the open tasks, they thought for quite some time if such tasks could be implemented in their classrooms and for which students, making it seem that they were unfamiliar with such tasks. That being said, they were interested to find out how their students with SEN would respond to those tasks. In contrast, Rachel gave an example of a multiple-solution task in geometry (see Figure 1) that she had implemented in her class, in which students are asked to present different ways of finding the area and circumference of a certain polygon.

What is the area of the shape? In how many ways can you find the area?	
Figure 1: Rachel’s example of a multiple-solution task in geometry

There are several possible explanations for the differences between the teachers. First, Irit and Ravit were trained as special education teachers and gained most of their professional experience in that field, rather than specializing in mathematics. Rachel, on the other hand, had many years of experience as a mathematics teacher, and had only been teaching in special education classes in recent years. Second, the teachers had experience with different age groups. Irit and Ravit taught primary school. Irit attempted to explain why she thought it would be difficult to incorporate such tasks with young students: “Because of the gaps [in knowledge] that are created, I feel that something is always missed somehow … we are in a rush to close those gaps … we are always ‘in a war’ to make it meaningful and truly develop [students’] thinking, and on the other hand, to complete the curriculum.” Irit’s thoughts may reflect primary school teachers’ perception that primary school mathematics is about acquiring and perfecting basic mathematical skills rather than encouraging mathematical creativity. By contrast, Rachel teaches middle school, where students have more mathematical knowledge, insight, and personal experience, which – alongside the challenge of solving a problem – can encourage mathematical creativity (Silver, 1997). The differences between the teachers can also be explained as a manifestation of the different approaches to teaching mathematics to students with SEN: the notion that focusing on a handful of calculation procedures and perfecting them is the optimal method of teaching mathematics to students with SEN (Geary, 2003), compared to the approach which states that encouraging students to deal with mathematical challenges and find multiple solution strategies can help even cognitively less proficient students to develop mathematical competence (Jonsson et al., 2014).

Summary and Conclusions

This study investigated the perceptions of three teachers who teach mathematics in SEC regarding mathematical creativity and their roles in fostering mathematical creativity in the classroom. All three teachers expressed the importance of incorporating creativity in SECs. In line with mathematics educators (e.g., Levenson, 2013), they expressed the need to foster an environment which encourages discussion and questioning, and allows students to solve problems in their own ways (Leikin & Lev, 2013). Their responses hinted at their recognition of flexibility and originality.

Like general primary school teachers (Bolden et al., 2010), during the interviews it became apparent that the teachers connected mathematical creativity to students' mathematics comprehension and the way they themselves teach mathematics. Building on this perception, we recommend professional development that would introduce mathematics teachers of students with SEN to various types of tasks that have the potential to occasion mathematical creativity. Teachers can then work together, using their pedagogical knowledge and experience, to integrate such tasks during mathematics lessons. For example, teachers described the importance of using manipulatives to enhance learning. Students with SEN can be encouraged to solve a problem using more than one type of manipulative or even the same manipulative but in different ways, fostering both flexibility and a deeper conceptualization of the topic being learned.

While we acknowledge that this study cannot be generalized, we see our findings as a window into the possibility of fostering mathematical creativity in SEC, offering students with SEN equal opportunities to experience mathematics as a creative domain. Further research might investigate how mathematics teachers in SEC would implement creativity promoting tasks in their classes and how students engage in such tasks, enabling teachers to understand how such tasks can be made accessible to students with different needs.

Explicit instruction and special educational needs in mathematics in early school years

Helena Roos[1] and Anette Bagger[2]

[1]Malmö University, Sweden; Helena.Roos@mau.se

[2]Örebro University, Sweden; Anette.Bagger@oru.se

This paper is an exploration of how an educational method, Explicit Instruction (EI), is used and reflected upon in research in relation to special educational needs in mathematics (SEM) in early school years. The current research front is put in relation to the Swedish curricula in mathematics and the Swedish school act (steering documents) to explore potential possibilities and challenges of the research findings in a Swedish context. The analysis was done in three steps: 1) a systematic search of research literature, 2) a content analysis of the literature 3) a relation of the results of to the steering documents. The exploration of the possibilities of EI displays that EI can contribute to every student's learning by providing a distinct structure in relation to the mathematical content. It displays challenges for special education in mathematics regarding collaboration between teachers, the competence of teachers, and time to plan the EI and time for the students working with EI.

Keywords: Explicit instruction (EI), early years, special educational needs in mathematics.

Introduction

In a systematic literature review of research on special educational needs in mathematics (SEM) explicit instruction (EI) emerged as a common educational method to support and accommodate primary school teaching in mathematics focusing SEM (Bagger et al., 2019). SEM is in this paper interpreted as a socially situated and context-dependent need of educational adjustments in the mathematics education (Bagger & Roos, 2015). In the context of this paper this implies that even though some of the research found in this study has a different perspective on SEM, we view it in the lenses of being socially situated and context dependent. Regarding the notion of EI, it is a notion used in different fields of educational research and in different educational contexts and hence defined somewhat differently depending on where it is used. Though, at its core is a systematic instructional approach of pedagogical instructions. In mathematics education this systematic instruction is used to promote students' conceptual and procedural understanding with fluency (Doabler et al., 2018). In this paper EI is interpreted as a systematic instructional approach of pedagogical instructions in mathematics education to promote students' conceptual and procedural understanding with fluency. EI could be of special interest for SEM since it focuses the need to adapt the education according to every student to promote mathematical understanding. Following, the overall aim of this paper is to explore and discuss EI in relation to SEM, and to contribute with knowledge regarding EI's possible application in a school system, in this case the Swedish school system. To be able to do this, this paper puts the current research front of EI in relation to the Swedish curricula in mathematics (The Swedish National Agency, 2019) and the Swedish School Act (SFS 2010:800). Here an exploration of the potential possibilities and challenges of research findings in this specific context is made. This exploration is made with the help of the research questions of the paper: a) How is EI depicted in research in relation to SEM? b) What are the challenges of using EI in relation to meet SEM students' needs in the Swedish school system?

Setting the scene – Swedish mathematics education

This section describes the Swedish setting in which this study is situated. Compulsory school in Sweden starts at the age of 6 when children start preschool class and start being taught mathematics. There is a national curriculum, Lgr 11 (The Swedish National Agency, 2019), from preschool class and all through compulsory school (students aged 6-15). The Swedish mathematics curriculum does not in detail regulate the teaching and learning content, materials, or methods. Rather, it regulates what areas in mathematics are to be covered in the teaching, how to approach and understand students' learning, and what knowledge, competencies, and abilities education should stimulate: "Teaching should aim at helping students develop knowledge of mathematics and its use in everyday life and different subject areas." (The Swedish National Agency for Education, 2019, p. 55) According to the curriculum, the teaching in mathematics shall give the students opportunities to develop five abilities: Formulate and solve problems using mathematics and also assess selected strategies and methods, use and analyze mathematical concepts and their interrelationships, choose and use appropriate mathematical methods to perform calculations and solve routine tasks, apply and follow mathematical reasoning, and use mathematical forms of expression to discuss, reason and give an account of questions, calculations, and conclusions. (The Swedish National Agency for Education, 2019, p. 56)

Looking at how much time students are spending in mathematics education in Sweden according to the Swedish School act (SFS 2010:800), students in lower primary school shall have 420 hours of mathematics education during their three years, and in upper primary school 410 hours.

Most mathematics teachers in primary school are general teachers. Many schools have a special teacher in mathematics employed. The special teacher works as a consultant to teachers, works with smaller groups or individual students, and sometimes co-teaches in the classroom.

Special educational needs in mathematics (SEM)

In this paper, EI is investigated in relation to SEM and the Swedish steering documents. Hence, this section describes how SEM is defined and used in a Swedish context. In relation to SEM and the context, it is important to consider that the interpretation of special educational support is always situated in culture and time, meaning the interpretation and use of the term "special needs" itself "depend[s] ultimately on value judgments about what is important or desirable in human life and not just on empirical fact" (Wilson, 2002, p. 61). The writings in the Swedish School Act (SFS 2010:800) that regulates special educational support, show that it is highly situational and relative if a student is considered to need special support or a milder form of support that is basically extra adjustments of the regular learning environment. When connecting special support to the school subject of mathematics, the judgments of special support concern how the education can help the student get access to knowledge development in mathematics (Roos, 2019).

SEM is a notion hard to define and is defined differently depending on in which situation it is used and from what epistemological field it derives (Bagger & Roos, 2015). For example, if it is used within the psychological field most often it is referred to as an individual deficiency (e.g., Pitchford, et al., 2018) but if it is used as a notion describing a specific need in mathematics education to meet diversity, the institutional environment in where it is situated is most of interest (Roos, 2019). Bagger and Roos (2015) suggest using the notion of "special educational needs in mathematics” to apply a social-relational perspective, which is adapted from Magne (2006) and used in this paper. This implies a socio-relational perspective on learning when we explore IE as a teaching strategy for the benefit of SEM students studying under the Swedish curricula.

When looking at the Swedish curriculum (The Swedish National Agency for Education, 2019) and Swedish School Act (SFS 2010:800) regarding SEM and inclusion, even though the word inclusion is not used, there are governing functions of inclusion (Roos, 2021). These functions can be described as discourses, Discourse of Democracy and citizenship, Discourse of equity, Discourse of Possibilities for participation and access, and Discourse of Knowledge and assessment in mathematics. When looking at the described Discourses, their functions are mostly ideological, and there appears to be a gap to how to actually do inclusion in the education (Roos, 2021) and how to actually work with SEM.

The analysis process

This section describes the analysis in this paper, which was done in three major steps. The first step was a systematic search of research literature to find how the current research front in SEM uses EI. The second step consisted of a content analysis of the selected research literature and the third step was to put the results of the content analysis in relation to the writings in the Swedish national curriculum (The Swedish National Agency for Education, 2019) and the Swedish school act (SFS 2010:800).

In step one, to not miss out on research in SEM using EI we searched broadly in four databases that focus on pedagogical and educational research both international and national: ERIC, Scopus, Web of science, and MathEduc. The keywords were chosen to have a broad focus on SEM and education: disabilit* and math* and learning* and education* and difficult. From here we could see which of them had research concerning some systematic instructional approach of pedagogical instructions in mathematics. The search resulted in 90 articles with no overlaps between the databases. To limit the result, we added a timespan of the last ten years to focus on the current research front. Also, only articles written in Swedish, or English were selected since we are fluent in those languages. Another limitation was that the articles needed to be published in peer-reviewed journals and focus on students from 6 to 12 years old. This left 58 articles to review. 21 out of these articles somehow discussed or used EI in relation to SEM and thus were selected.

In step two, in the reading of the selected research articles, we applied a content analysis inspired by Feucht and Bendixen (2010) to identify and categorize how EI is used in the context of SEM. Here statements about EI in the research texts were identified and summarized. This identification and summarization allowed for themes to emerge. Through the identification, categorizations were made which resulted in four themes: *systematic instructional approach of pedagogical instructions in mathematics education, word problems, mathematical representations, and working memory*.

In step three we studied the themes that emerged from the content analysis and the writings in the Swedish national curriculum (The Swedish National Agency for Education, 2019) and Swedish School Act (SFS 2010:800), the Swedish steering documents. The themes were investigated in relation to the Swedish steering documents. This made it possible to explore EIs possibilities and challenges to meet SEM students' needs in their learning process and to put it in relation to national learning targets and special support.

Results

In the two sections below the results are presented by answering the two research questions of the paper. In the first section, the focus is on how EI is used in relation to SEM, and the second section focuses on the possibilities and challenges of using EI in relation to SEM in a Swedish context.

Explicit instruction in mathematics in research

Answering the first RQ of this paper, "How is EI depicted in research in relation to SEM?", we have in the content analysis in step two identified four different themes. The first theme is how EI in mathematics can be defined as a *systematic instructional approach of pedagogical instructions in mathematics education to* promote students' conceptual understanding and procedural fluency (Doabler et al., 2018; Archer & Huges, 2011). This type of definition and usage of EI is often used in interventions in relation to SEM (e.g., Swanson et al., 2015; Kong & Orosco, 2016). The instruction is conducted by validated principles of instruction, focusing on mathematical notions and abilities the individual student needs to develop. Doabler (2018) describes that in general, EI concerns three overarching principles: (1) Instructional scaffolding; here the teacher presents the mathematical content and often a procedure. This procedure is often a model that the student can follow regarding the specific type of task. This type of guidance often uses multiple representations, and the tasks are carefully selected. "Because instructional scaffolding is intended to be temporary, the support is gradually withdrawn as students become more independent in their mathematical learning." (Doabler, et al., 2018 p. 98) (2) Student practice opportunities; here the student gets time to engage and work with the content presented and guided by the teacher in step 1. In this step, the focus is to create opportunities for the SEM student to display and explore his or her thinking. This is done through discussions and visual representations of the current mathematical content worked with. The teacher must be active and give academic feedback to support the development of mathematical proficiency. (3) Judicious review; here the focus is to take time to go back and review the concepts and procedures worked with. This is made consciously and frequently. Well-designed reviews over time open opportunities for SEM students to build knowledge with critical topics in mathematics (Doabler et al., 2018).

The second identified theme is *word problems*, which is a reoccurring object of study when investigating EI in relation to SEM (e.g., Kong & Orosco, 2016; Hord & Xin, 2013; Swanson, et al., 2013; 2015). The reason for this might be that word problems contain several steps and procedural skills, as well as reading and language skills, which often is a problem for SEM students (Powell et al., 2010). A way to go about these problems is to implement EI, with specific instructions in relation to word problems (e.g., Morin et al., 2017; Swanson et al., 2013; 2015). These studies show enhanced learning for students when teachers use EI. Although, important to point out from these studies is that EI in relation to word problems demands didactical teacher knowledge, as well as teacher knowledge about the individual learning needs of the students, to really be able to be explicit in the mathematical instructions (Kong & Orosco, 2016). Furthermore, it demands of the teacher to be able to identify different types of word problems and be able to sequence them over time to help students with structures (Powell, et al., 2010).

A third theme emerging in the analysis of studies with EI is the importance of different *mathematical representations* and helping the students to translate between representations (e.g., Kong & Orosco, 2016; Morin et al., 2017). The purpose of using representations is to help SEM students to develop conceptual knowledge in mathematics and eventually be able to translate between representations themselves (Acar, 2012). The purpose is also to help SEM students to see a connection between the conceptual and abstract strands of mathematics (Kong & Orosco, 2016). It is suggested that by using mathematical representations in the form of, for example, place value blocks in the EI students will be helped to grasp general understandings of a concept, for example, subtraction (Kong & Orosco, 2016).

The fourth and last theme identified is *working memory*. Working memory can be explained as concurrent storage and manipulation of information necessary to perform mental tasks (Acar, 2012). An argument made in research for using EI with SEM students is that the structure and explicitness of EI relieve the working memory, which has been identified as a weakness for many SEM-students (e.g., Swanson et al., 2013; 2015). Also, it is suggested that visual strategies rather than verbal strategies were more forceful in supporting SEM-students with low working memory doing problem-solving. (Swanson et al., 2015). Swanson et al. (2015, p.355) argue that "to be effective, instruction should be designed in alignment with the learners' cognitive architecture" indicating the importance for the teacher to know their students.

EI and learning mathematics for SEM students

Answering the second RQ, "What are the challenges of using EI in relation to meet SEM students' need in the Swedish school system?", we elaborate on the possibilities and challenges to meet SEM students' needs by relating the themes identified in research on EI to the Swedish context.

The way EI is thought upon in research, as a systematic instructional approach of pedagogical instructions in mathematics education, does not intervene with the Swedish steering documents negatively. If looking at the abilities in the Swedish curriculum it is stated that the education "shall give the students opportunities to develop" (The Swedish National Agency for Education, 2019, p. 56) their ability in mathematics. EI can contribute to that development for every student by providing a distinct structure in relation to the curriculum goals. Though, for EI to be able to contribute to the teaching of mathematics, teachers need to be able to connect the abilities written in the curriculum to EI and the systematical instructional approach of pedagogical actions. This to put the abilities into action in terms of EI. This is the first challenge of EI since it is not explicitly written in the curriculum how to teach so that the students develop the five abilities. The second challenge is that EI demands time, both time for the teachers to plan the EI, but also time for the students to go through the three steps of EI (Instructional scaffolding, student practice opportunities, judicious review). This could be challenging to frame within the hours of mathematics education regulated by the Swedish School act (SFS 2010:800). Another challenge is the competence of the mathematics teachers, which in primary school often are general teachers. They need to be able to plan the instructional scaffolding and carefully choose tasks in relation to the mathematical concept or the procedure to be learned. Also, they need to be able to support with feedback and give students time to think and have time to work through the steps of EI. This is connected to yet another challenge factor for meeting the SEM students' needs, the knowledge and competence of teachers and school organizations regarding SEM, and multiple representations to support learning (Roos & Gadler, 2018).

Implications

This section discusses the implications of the findings in this paper.

The specific knowledge of SEM, and knowledge of how to support learning with for instance representations is needed to be able to pay attention to every students' knowledge, prerequisites, and needs. This knowledge is needed both in school organizations and for individual teachers. If there is a lack of this knowledge, there is a potential risk for SEM students not getting the right support ending up with an education that can actually hinder learning. Here school organizations must create spaces for collaboration between the special teacher in mathematics and the regular mathematics teacher to be able to plan the EI according to the specific needs of the SEM students and the specific context. Finding these spaces to collaborate and plan for the education has been proven to be a challenge in Swedish schools (Roos, 2015). If these spaces for collaboration would be offered, there is a potential for opportunities for collaboration between teachers. This collaboration might bridge the identified gap between ideological functions of inclusion described in the Swedish curriculum and the Swedish school act about how to do inclusion in the education (Roos, 2021) and support SEM-students in an inclusive classroom. Also, since the Swedish mathematics curriculum does not in detail regulate the teaching and learning content, materials, or methods, how the EI is planned and executed is much up to the schools and teachers. This can be both a possibility and a challenge depending on the knowledge of the teachers involved and the knowledge residing in the school organization. Moreover, a challenge for the schools and teachers can be not to end up in a deficit construction of SEM students where EI is the only solution. Instead, as shown by Lambert (2018), EI can be seen as one way among others to promote mathematics learning for SEM-students. In doing so, it is core to be aware of and recognize the value of students' own strategies, knowledge, and potential to engage in mathematics using multiple strategies. As argued by Lambert (2018), this can be achieved by adopting a neurodiversity perspective, which allows for the understanding of disability as diversity than a deficit.

Important to recognize when talking about EI in relation to SEM is that there are not any shortcuts. Even though overarching principles are guiding the EI, you must take the specific context and the individual student(s) and the situation in which the EI is conducted into consideration when planning, carrying through, and evaluating these lessons with EI. Although EI may take time before, during, and after the lessons, this research shows that in a Swedish setting it has the potential to diminish difficulties and enhance learning in a way that fosters a safe and fruitful learning environment. EI also has the potential to stimulate sustainable learning for every student. Though, it is important to find the appropriate explicit instructions in relation to the mathematical content being taught, appropriate tasks, and the students taking part in the education. Then, instead of taking time from the teacher searching for different methods and tasks and taking time from the students struggling to understand or remember procedures, EI can actually save time instead. Last, but not least, when connecting this teaching method to a neurodiversity perspective on disabilities, students' equity and inclusion is more likely to be fulfilled.

Facilitator educators’ professional development for inclusive mathematics – addressing their different roles

Petra Scherer[1] and Katrin Rolka[2]

Keywords: facilitators, facilitator educators, professional development, inclusive mathematics.

Facilitator educators’ professional development and professional roles

Within the complex field of teacher education, facilitators and their professional development (PD) are of great importance. Facilitators as such are an extremely heterogeneous group: They have different backgrounds, tasks and functions in different working contexts, teach different subjects and types of learners (Dengerink et al., 2015). We focus here on persons responsible for providing PD courses for teachers (facilitators), and providing PD courses for facilitators (facilitator educators).

For qualifying facilitators, the Three-Tetrahedron Model (3T-Model, see Figure 1, Prediger et al., 2019) is of major importance. For the professionalization process, all three levels of the 3T-Model are relevant (Prediger et al., 2021): The tetrahedron on the classroom level – comprising students, teachers, classroom mathematical content, and classroom resources – will be transposed to the teacher PD level as well as to the facilitator PD level. On the facilitator PD level, facilitators are learners, the facilitator PD content comprises the whole tetrahedron on the teacher PD level which, again, comprises as teacher PD content the complete tetrahedron on the classroom level. The main level of acting concerns the facilitator PD level, but teacher PD level as well as classroom level are also touched.

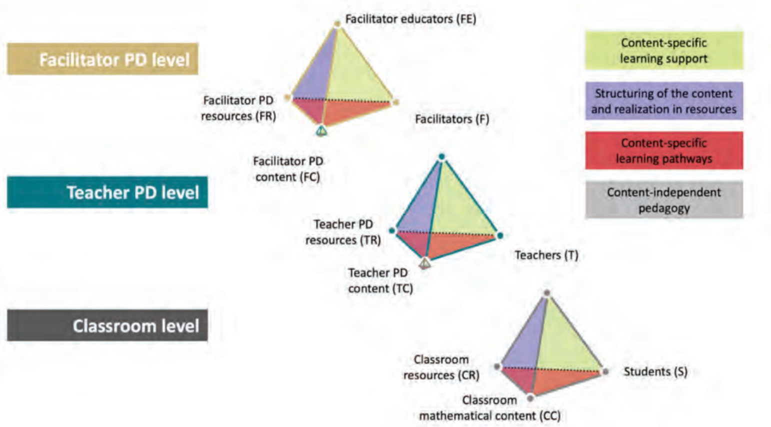

Figure 1: Three-Tetrahedron Model for content-related PD research (Prediger et al., 2019, p. 410)

Subject specific PD course ‘Coping with heterogeneity in inclusive settings’

Within the German Centre for Mathematics Teacher Education (DZLM) in cooperation with a statewide agency for teacher education, a subject specific PD course ‘*Coping with heterogeneity in inclusive settings*’ has been developed, aiming at qualifying a group of 15 facilitators (working in primary and lower secondary mathematics and special education). Exchange and cooperation of the different professions was intended for the whole course. Planned as a scaling up process, the qualified facilitators should function as facilitator educators and offer the course to other facilitators or teachers for qualifying them as facilitators. The research-based course design was grounded on various evaluated course concepts, done by the authors before. The mathematics modules were embedded in a broader concept, starting with a module, focusing on the general role of facilitators and adult learning, and followed by a module, given by the statewide agency, representing their general objectives and strategies with respect to subject specific PD. The four mathematics modules included a basic module as well as three thematic modules for inclusive mathematics, each module lasting 2.5 days. In particular: '*Basic module for deepening didactics of mathematics in the context of inclusion', 'Learning difficulties/learning disabilities/learning potentials in mathematics', 'Diagnosis and support in mathematics instruction'*, and '*Learning mathematics in inclusive settings'*. Beyond the meaningful content selection and consideration of design principles (cf. Prediger et al., 2019), the course concept put the main stress on addressing the role as facilitator educator, for example by integrating reflections as well as simulations and at the same time connecting facilitator PD level, teacher PD level, and classroom level (Prediger et al., 2019). Connecting the levels was also realized with different forms for evaluating the course quality and acceptance. One of these evaluations asked for addressing the different roles on the different levels: At the end of the mathematics modules, the facilitators had to rate the relevance of each module on a six-point likert scale, differentiated according to their role as teacher, facilitator, and facilitator educator (1 indicated 'not at all relevant' and 6 'very relevant').

Exemplary evaluation results

The overall evaluation showed that all mathematics modules mainly were assessed as very relevant or relevant for their various roles (teacher, facilitator, facilitator educator), and that the three levels (classroom, teacher PD, facilitator PD) were thus addressed (cf. Prediger et al., 2019). The primary course goal was the qualification as facilitator educator. Hence, it was expected that this level would be addressed in particular. However, all levels were addressed throughout the course: Exemplary for the module '*Learning mathematics in inclusive settings*', the participants assigned greater relevance to their role as facilitator educator and as facilitator (12 out of 13) than to their role as teacher. This is plausible and also desirable insofar as their qualification as facilitator educator and their subsequent activity as facilitator educator was intended. Nevertheless, for 9 out of 13, this module was also relevant or very relevant with regard to their role as teacher. Among other things, facilitator educators' ratings could be attributed to their individual prerequisites and acquaintance of a specific content.

The Mathematical Support Format Reproduction

Ann-Kristin Tewes[1] and Marcus Schütte[2]

[1]University of Hamburg, Germany; ann-kristin.tewes@uni-hamburg.de

[2]University of Hamburg, Germany; marcus.schuette@uni-hamburg.de

The study presented in this paper focusses on the mutual learning of mathematics in interaction for all children in inclusive mathematics classroom. Therefore, the concept of Support Systems will be adopted in order to reconstruct different Mathematical Support Systems in the mathematics classroom and to describe the possibilities for students to participate in mathematical negotiation processes. To describe mathematical learning processes, the interaction theory of mathematical learning and the cultural-historical theory, which both place social interaction at the center of (mathematical) learning, are used. This article in particular presents the Mathematical Support Format Reproduction, which develops between a teacher and a student (with special needs).

Keywords: Mathematical support systems, inclusive mathematics education, zone of proximal development, interaction theory, mathematical support format.

Introduction

With the ratification of the UN Convention on the Rights of Persons with Disabilities, the state parties have committed themselves to ensuring equal access to an inclusive school system for all people. As a result of this ratification, in Germany, more and more children and young people who were previously taught in special schools are learning in regular schools (Vock & Gronostaj, 2017). To ensure equal participation in inclusive school and the educational success of the individual, which is a fundamental principle for the realization of inclusion in the school system, teachers with different professions increasingly work together in the classroom. In this context, the different professions are assigned different areas of responsibility in the classroom: the special education teacher is more responsible for supporting and promoting individual children, while the general education teacher is assigned responsibility for the learning success of the entire class (Melzer et al., 2015; Neumann, 2019). The question now arises as to whether the different responsibilities of the teachers result on the one hand in different ways of dealing with the children and on the other hand in a different view of the mathematics classroom and mathematics learning. As learners interact with different teachers in the mathematics classroom, different *Mathematical Support Systems* and thus different learning conditions emerge between them. The aim of the broader research project[1] is to reconstruct these different Mathematical Support Systems in order to make assumptions about the multi-professional cooperation in inclusive mathematics classrooms. In this article, first results of the analysis are presented and therefore a *Mathematical Support Format – Reproduction* is illustrated as an example. For this purpose, the following sections first present the view of learning as an interactional process that underlies this study, and then derive the concept of Mathematical Support Systems and *Mathematical Support Formats (MSF)*.

[1] The research project mentioned here is from the PhD thesis of Ann-Kristin Tewes.

Learning through social interaction

Humans are dependent on or oriented towards social contacts and their environment from birth. Only through mutual interactions with others humans can develop (Vygotskij, 2003; Steffens, 2020; Miller, 1986). Through shared activities in interactive exchanges and the shared experience of these, collective meanings are increasingly built between individuals. Such social development situations have a dynamic character and are subject to constant change. They arise when individuals encounter each other in intersubjective space and are continuously renegotiated collectively. From this it can be deduced that humans always acquire (learning) objects and meanings through exchanges with other individuals, and thus learning and development processes are always social and cultural in origin (Steffens, 2020; Vygotskij, 2003). The area in which the social exchange and thus also the learning and development processes of an individual take place in relation to his environment is called the "Zone of proximal development (ZPD)" by Jantzen (2008) with reference to Vygotskij (2002) (see Figure 1). The ZPD is a special part of the intersubjective space and creates a *Space of negotiation* between intrasubjective space of the individual and intersubjective shared space of several individuals, in which individuals mutually refer to and interact with each other (Jantzen, 2008).

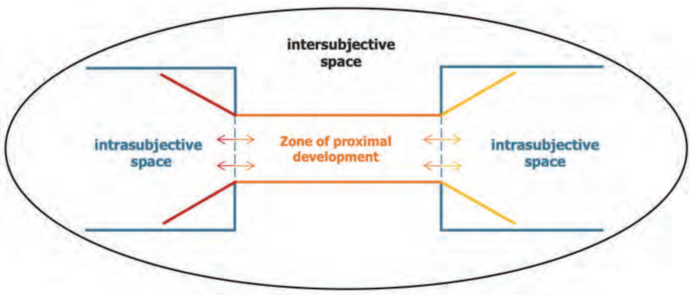

Figure 1: Social development situation between individuals

The individuals acting together in the intersubjective space mutually shape the ZPD through collective negotiation of meaning for themselves and for others (Vygotskij, 2003; Jantzen, 2008; Steffens, 2020). Once a learning or development process transcends from the ZPD – in the form of individual constructions – into an individual's intrasubjective space, Vygotsky (2002) refers to it as the "Zone of current development". The new zone of current development and the changes in the individual are then a starting point for negotiation processes in the Space of negotiation and thus also the basis for new development and learning processes within the ZPD. From this perspective, social interaction and the collective have a constitutive meaning for each subject-oriented learning process.

Mathematics learning from an interactionist perspective

Looking at mathematical learning processes in school with such an understanding of the development of learning processes, a complementary theoretical framework is needed that places interaction in relation to mathematics learning at the center of consideration. With such an interactionist perspective, mathematics learning can be understood as a process that takes place dialectically both within an individual and is located in the interaction processes in which individuals participate (Schütte et al., 2021; see also Voigt, 1995). Since the mid-1980s such interactionist approaches of Interpretative Teaching Research have been taken up and combined with subject didactic theories of mathematics learning in order to better describe everyday learning processes of mathematics (for an overview, see Krummheuer, 1992). Such interactionist approaches to mathematics learning take their learning perspective from the ideas of symbolic interactionism (Blumer, 1969; Mead, 1934) and understand social interaction as the constituting starting point of learning processes. Collectively structured learning processes give the learner the opportunity to systematically transcend his or her own mathematical abilities through exchange with others, which is then subsequently reflected in an individual process of cognitive processing. Such individualized learning then takes place in moments of reflexive deepening of what was originally collectively negotiated or learned (Miller, 1986; Schütte et al., 2021). But how does such a process of mutual learning work in specific terms? When learning in a group, such as in mathematics classes, the individual always creates his or her own interpretations of a situation based on individual experience and knowledge and in anticipation of the interpretations of others. These so-called definitions of the situation are provisional and are rejected, adjusted or stabilized in the process of the mathematical negotiation of meaning (Schütte et al., 2021). Thus, the participants in the interaction enter a process of negotiation and there continuously coordinate their mathematical interpretations of the respective situation or the respective mathematical object of other participants. From an interactionist perspective, (mathematics) learning is thus understood as a social act of interpretation in which meanings are constructed through interactive negotiation processes (Krummheuer, 1992). This negotiation process can take the form of collective argumentation (Miller, 1986; Jung, 2018), leading to the mutual production of an interpretation that is considered as taken-as-shared meaning or an *interpretive interim* (Schütte et al., 2021).

Mathematical Support Systems for participation in mathematical negotiation processes

According to the two theoretical perspectives presented above, social interaction and mutual communicative exchange are fundamental to learning mathematics. Individuals learn mathematics through social exchange in which mathematical meanings are constructed. This exchange or negotiation of meaning (Krummheuer, 1992) takes place between individuals in the Space of negotiation in the ZPD (Jantzen, 2008). Children in school also learn mathematics in interaction with others, whereby in the optimal case support in the mathematical learning process results from the interaction. Bruner (1983) developed the concept of LASS (Language Acquisition Support System) to describe such a Support System in children's language acquisition, which offers the child support in learning to use the language. A Support System not only helps the child to learn the language on the linguistic level, but also conveys the cultural context in which the language is used. According to Bruner, this Support System for the child's language acquisition is established in standardized patterns of interaction between adult and infant called formats. „A format is a standardized, initially microcosmic interaction pattern between an adult and an infant that contains demarcated roles that eventually become reversible." (Bruner, 1983, pp. 120–121) Formats are therefore routine processes with fixed roles of the interaction participants, which represent the Support System. However, by shifting roles within this system, the child can increasingly participate autonomously in the interaction (Bruner, 1983). Based on the above interactionist approaches Tiedemann describes support between mother and child as a unity of two processes. A Support System between mother and child is thus a dialectical process that is jointly shaped in interactions and is characterized by intersubjective processes (Tiedemann, 2012). Regarding the theoretical approaches of Vygotskij (2002) and Jantzen

(2008), Support Systems can be located as a dialectical negotiation process between people in the field of the ZPD (Figure 2).

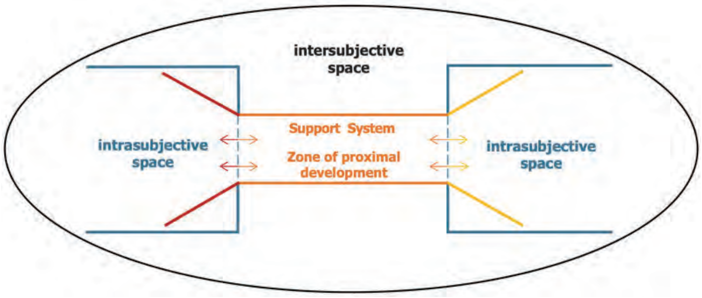

Figure 2: Support Systems as intersubjective processes in the ZPD

The involvement in a social environment and the resulting cooperation is decisive for the development of support. Statements and actions in school are thus established as a Support System when the child and the adult orient their interpretations mutually on it. Just like the ZPD, Support Systems are not fixed constructs that are developed once and then established. Support Systems are subject to constant change and constantly evolve depending on the situation. A Support System is negotiated in interaction and cannot be seen as an activity of a single person (Tiedemann, 2012; 2013). This means that there can be support efforts from the teacher, but what is established as a Support System is negotiated in the interaction in the Space of negotiation. A support system is thus a dialectical process that is shaped together. Accordingly, this also applies to *Mathematical Support Systems*. In the analyses of the collected data material, it became apparent that some Mathematical Support Systems, that could be reconstructed in the mathematics classroom, show recurring characteristics. They follow a certain recurring pattern with regard to increasingly autonomous participation and are therefore described in this paper with the term *Mathematical Support Format (MSF)* in the sense of an abductive theory development with reference to the concept of format (Bruner, 1983; Krummheuer, 1992). Accordingly, the term MSF is to be understood as an umbrella term for Mathematical Support Systems which, in the sense of the term format, occur repeatedly and are structurally similar.

Research Focus, Methodology and Procedures

The diversity of the students implies different opportunities for participation of each student in the mathematics classroom (Tewes, 2020) and thus different Mathematical Support Systems for learning mathematics between the members of the interaction in the ZPD. For this reason, the greater research project, which is located in qualitative social research following a reconstructive-interpretative methodology (Bohnsack, 2007), tries to examine different Mathematical Support Systems between students and the different professions in primary mathematics lessons. The situation from the transcript below is recorded in an inclusive primary school mathematics classroom. Thus, children with and without special educational needs learn together in this class. The diagnosis of special educational needs in Germany is carried out by a special education teacher[2]. There are two teachers working in the class – a primary school teacher and a special education teacher. In the following

[2] Whether and to what extent the diagnosis is accurate may well be debatable, but will not be discussed here.

scene, the primary school teacher works with Niklas, who has a diagnosed special educational need. To analyze the transcript concerning the Mathematical Support System and to reconstruct the mathematical negotiation process, we are doing at first an interaction analysis (Krummheuer, 1992; Schütte et al., 2019). Afterwards, the Mathematical Support System, which establishes itself between the participants of the interaction, will be reconstructed (Tiedemann, 2012).

The Mathematical Support Format – Reproduction

In the analyzed scene, Niklas and the teacher are working with a material on which colorful cards with the 'number of dots' of the numbers one and two on the left side are to be matched to the white cards with the 'number of dots' of the numbers one and two on the right side. Niklas and the teacher have already assigned the yellow card with one dot on the material on the right:

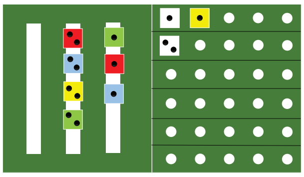

Figure 3: Material 'number of dots'

Transcript: matching 'number of dots'

08		T	[*stands up, leans over Niklas*] look at this one < [*points to the left to the red card with two dots]* > how does this look like this one or like that one\ [*points at first to the white card with one dot on the right side and after that to the white card with two dots*]
09	<	Niklas	[*looks at the card in his hand*]

19	#	Niklas	one *[looks at the 'number of dots' then looks back to the teacher and takes the card and attaches it next to the blue card with two dots in the second line on the right side]*

Interactional Analysis (Summary of the Interpretation)

The teacher leans over Niklas and points with the index finger on the left to the red card with two dots. She supports the pointing gesture with the request to look at the numbers and then to make a comparison between the white cards on the right <08>. Niklas complies with this request and looks at the card in his hand <09>. He seems to be able to determine the number of dots, since he states the number without being asked <10>. Following the naming of the number, he sticks the card to the box <11>. The teacher acknowledges this action <12>. After the teacher was involved in another conversation, she asks Niklas <15> to take a next card. Niklas again complies with this request <16> and picks up the green card with one dot. Then he looks at the card in his hand and names the number of dots. Then, he attaches the card next to the yellow card with one dot in the first row on the right side. He repeats this sequence of actions – but without naming the number of dots – with the red card with one dot, which he sticks next to the green card with one dot, and the blue card with two dots, which he sticks next to the red card with two dots in the second row on the right. After Niklas picks up the blue card with one dot, the teacher asks him again to look closely at the card <17> and then to consider where to assign it. There seems to be an interruption in Niklas' sequence of actions, because he now assigns the blue card with one dot to the second row. It may be assumed that the teacher's request might have disturbed his routine. Niklas could possibly conclude that he made a mistake before and now fixes it by naming the card again, differently from the previous cards, and placing it in the other (second) row <19>.

Support Analysis

In this scene, Niklas takes over the idea of the matching from the teacher and carries out the sequences of action increasingly independently. While the matching of the red card with two points is still more closely guided by the teacher, he independently carries out the action sequence of matching with the green card with one point, the red card with one point and the blue card with two points. The looking and active action of matching the ‘number of dots’ is taken over by Niklas in the interaction and establishes itself here as a Mathematical Support System between the teacher and Niklas. The interruption described in line <17> seems to disrupt Niklas' established routine. Niklas subsequently makes a different matching that does not seem to fit the subject content. This could suggest that this Mathematical Support System is more focused on social (organizational) participation than on professional participation. The Mathematical Support System seems to support Niklas in carrying out the matching process more and more independently. Nevertheless, it does not seem to support him subject-specific, since Niklas carries out the action sequence but makes an inappropriate matching. The teacher does not address the different matching after this scene. This suggests that the focus is more on the matching process than on the mathematical content of the matching exercise. Niklas is not given much space to make his own mathematical discoveries, but learns *to reproduce* a sequence of actions in this situation. There is no evidence of a ZPD developing between Niklas and the teacher at the subject level. The Mathematical Support System seems to effect more in the Zone of current development from the subject-oriented perspective.

Conclusion

Further analyses have shown that the structures of the Mathematical Support System, between Niklas and the teacher, could be reconstructed several times. Based on these structural similarities and with the theoretical elaborations above, it is possible to speak of an MSF. The reconstructed MSF that emerges in this interaction is intended to be an example of the *MSF – Reproduction.* The MSF - Reproduction is characterized primarily by the fact that the Mathematical Support Systems that comprise it tend to support increasingly autonomous participation at the organizational level in mathematical negotiation processes. These Mathematical Support Systems support the participants in learning or performing a procedure or an algorithm. Another characteristic of the MSF – Reproduction is that the participants of the interaction are involved in a social negotiation process in the ZPD, but subject-specific the MSF – Reproduction can be classified in the Zone of current development. Also, in the specific case of Niklas, it is not clear whether the Mathematical Support System – which is established in an interactive social negotiation process in the ZPD – enables him to learn new mathematical content or to make mathematical explorations. As the Support Analysis has shown, the focus of the scene seems to be more on the matching process than on the mathematical background of the matching exercise. Thus, the Mathematical Support System can be assigned to the MSF – Reproduction. In summary, the MSF – Reproduction supports student participation in mathematical negotiation processes, but no increasingly autonomous participation is evident at the subject-specific level. In the further course of the study, it has to be clarified how this MSF has an overall effect on the participation possibilities of the students and which different consequences result from it for students with and without special educational needs and thus for the inclusive mathematics classroom. Another question that needs to be answered is whether different MSF are person-bound to specific teachers and how this affects multi-professional teamwork.

TWG26: Mathematics in the context of STEM education

Introduction to the papers of TWG26: Mathematics in the context of STEM education

Behiye Ubuz[1], Michelle Stephan[2], Clelia Cascella[3], Nelleke Den Braber[4]

TWG26 met for the third time, this time virtually, at CERME12 and we continued the work started at CERME11 and the virtual Pre-CERME12 Event. At CERME12, 14 papers and 4 posters coming from 10 countries were presented and discussed in order to make STEM (Science, Technology, Engineering, Mathematics) subjects more relevant to students and teachers. The papers and posters were grouped under four themes: (1) M in STEM/STEAM, (2) designing for students learning, (3) processes in STEM/STEAM, and (4) STEM/STEAM professional development. Since the themes are intertwined, each paper could be assigned to multiple themes. Therefore, the assignment of papers to themes was guided by a "best fit" approach as well as practical considerations. As some of our headings below suggest, we sought research on the broader category of STEAM with little success. Thus, the headings represent the thematic areas of our conference call but with very little representation of the Arts in each category. The ideas and issues in the papers and posters will be presented under these four themes in the upcoming parts.

Thematic areas

M in STEM/STEAM

Within this theme three papers were presented. The first paper by Larsen, Kristensen, Seidelin and Svabo examined the role of mathematics in 19 developed STEM activities within the context of the framework developed by Kristensen et al. (2021). The framework based on Kristensen et al.'s review of 37 papers indicates that mathematics can be applied as a tool or can be regarded as a goal in STEM activities in different ways. The investigation of the activities reveals that the role of mathematics as a tool in these activities is to help the students develop an understanding of science or technology or help them in engineering and design processes. The role of mathematics as a goal in these activities is about the development of students' mathematical skills and knowledge. Actually, both need to be considered together as they work together in some way. They cannot be separated from each other. Mathematics sometimes can be a tool or a goal depending on the complexity and the aim of the task, a teacher's (and/or researcher's) goal, and so forth. Mainly, it is important to understand what happens in each moment in a complex task. The discussion of the papers raised several questions moving toward CERME13:

- What are the roles that mathematics plays in STEM activities?
- How can we make learning mathematics as a goal besides using mathematics as a tool in STEM activities?
- What can STEM activities do for the subject of mathematics?
- What can mathematics do for STEM teaching?

The second paper by Bennett and Ruchti analyzed students' interactions in one classroom in which they watched and discussed a video report from the National Oceanic and Atmospheric Administration on the winter outlook for the region. They also analyzed field notes from lesson planning meetings and notes from post-lesson discussions on the base of three of the nine commonly accepted perspectives for defining STEM outlined by Bybee (2013). These three perspectives are 1) simultaneous infusion, 2) temporary shift in discipline, and 3) lateral concept connection. Simultaneous infusion uses mathematical and scientific habits of mind and practices, such as the importance of using data and communicating ideas (e.g., seeing connections between the ways behavior scientists and mathematicians engage as they investigate and attempt to make sense of real-world phenomena). A temporary shift in discipline is a shift from one discipline (e.g., science) to conceptually explore a skill in another discipline (e.g., mathematics), and then a shift back to the original discipline (science) to bring new understandings to the primary science focus. Lateral concept connection is a purposeful movement between two seemingly unrelated core ideas of the same discipline (e.g., the earth science study of weather and the biological science study of birds). The discussion addressed several important questions moving toward CERME13:

- Where is the place for appropriate STEM integration? (curriculum, assessment, instruction)?
- What are the frameworks for appropriate STEM integration?
- How best to link and leverage cross-curricular learning for authentic STEM integration?
- What are the factors contributing to teachers' STEM integration? (e.g., shifting from teacher-directed pedagogy to the more student-directed nature of an integrated curriculum, the structures of school schedules, finances, strict-level or course-level curriculum, school and teacher's knowledge about what STEM is, conception of STEM education, state of anxiety and insecurity, etc.)?

The last paper by Costa and Domingos aimed to examine an experienced Mathematics and Natural Sciences teacher development and implementation of mathematical tasks (e.g., each student infects two colleagues, each student infects three colleagues, etc.) in a mathematics classroom within the context of the COVID-19 pandemic in order to highlight the role of mathematics to understand them. These tasks raised awareness and understanding about the need for measures in the context of the COVID-19 pandemic, such as social isolation or vaccination. Regarding mathematics, powers, exponential growth, variables, iteration, functions, graphics, organization of tables, and data visualization needed to be used and understood. The discussion of this paper in the TWG raised several important issues moving toward CERME13:

- Where should we leave the STEM integration? Are we going to force this "integration" into the mathematics classroom? Into the science classroom? Into the disciplinary course?
- What are the nuances, challenges, and affordances for teachers in developing/implementing STEM tasks for/in their classroom?
- Was there anything that was more difficult?
- What is the role of M in STEM in order to innovate and improve mathematics teaching?

Designing for students learning

The second theme of the submissions involved research related to designing STEM learning environments for students. Two papers focused on the meaning of mathematical models in supporting students' learning while the third investigated students' understanding of already-created models: graphs of linear functions. Regarding the modelling theme, Haier, Siller, and Vorhölter presented a framework of criteria to guide curriculum design involving Education for Sustainable Development. They introduced the notion of socio-critical modeling which refers to the activity of reflecting on one's world critically, organizing social problems mathmatically, and recognizing the role of mathematics in making the world a better place. By merging the criteria of two similar modeling design traditions and paying particular attention to socio-critical aspects, they suggested a set of eight modeling design criteria.

For their part, Just and Siller used literature on models as black boxes in mathematics, science and the work place to develop meaning for black boxes in mathematics. The term *black box* generally refers to a system of relationships, say mathematical, that is often unseen or unknown by the user. Using their carefully crafted definition, they explored ways to integrate modeling with black boxes in mathematics education using a chemistry context. They argued that designing activities to support the opening of black boxes in mathematics education is integral to the modeling process.

Finally, Knippertz, Becker, Kuhn, and Ruzika explored the ways in which students make sense of graphical models and the implications this has for designing instruction on linear function. They used eye-tracking technology to investigate what characteristics of kinematic and mathematical graphs students pay attention to and if their gaze is drawn to different areas depending on the graph type. Their findings confirmed other studies that conclude interpreting kinematic graphs is more difficult than those that are more mathematical in display.

These three papers left us with important questions moving toward CERME13.

- What are design principles specific to supporting students' modeling and socio-critical modeling more specifically?
- How do we leverage real world situations that span the S-T-E- and M disciplines to design students' STEM learning?

Processes in STEM/STEAM

The third theme of the submissions involved research related to understanding the learning processes of students in STEM/STEAM environments. Two papers and one poster explored a variety of ideas within geometrical and spatial sense making. One paper presented a theoretical argument for an extended definition of spatial thinking within STEM, and a final paper challenged current research that suggests reading and mathematical understandings are related.

The first three research projects within the geometry domain shared findings from work with students situated within classroom teaching environments involving geometrical and spatial reasoning. Eckert and Sjödahl, for example, described the tension between providing elementary students simple coding with too much structure (i.e., pre-made codes) and not enough structure, in geometry tasks, with the aim of promoting computational reasoning. Those students who arrived at a solution fairly quickly did not engage in the process of formulating problems whose solutions could be manifested in code. Students who got stuck in their unhindered exploration did not have the supports they needed to decompose the problem situation into more manageable subproblems. Eckert and Sjödahl's findings suggest that tasks need more built-in supports to promote breaking problems into smaller, more manageable pieces.

Ubuz and Aydınyer, for their part, used a Project Based Learning (PBL) approach to support students' development of geometrical reasoning as the students engaged in the engineering design process. They presented the results of a study in which 13–14 years old students re-designed a local neighborhood by first defining the engineering problem, exploring solutions by interviewing family and community members, selecting solutions and creating scaled drawings of the buildings, streets, and other structures. Ubuz and Aydınyer concluded that designing a two-dimensional scale plan of a neighborhood through PBL can strengthen students' knowledge of the engineering design processes while also developing their spatial reasoning. Furthermore, throughout designing a neighborhood plan, they learned how to design a place, the different types of professions and their duties, how to use a protractor to draw geometrical shapes, how to solve the challenges and difficulties as a group, the importance and value of geometry in real life, how the elements of a neighborhood are placed in it, and the importance of every detail such as accuracy and precision in drawings.

Lasa et al. presented a poster that documented a STEM project in which 13–14 years old students must build and calibrate an electronic weighing machine to contextualize the concept of linear functions. They found that the use of a dynamic, geometry software program was a powerful instrument for supporting students' modelling in STEM contexts because students have the opportunity to test any number of attempts before they move to a definitive physical construction. They concluded that it is not only possible, but powerful to use technology to engage students in mathematical reasoning as a primary activity rather than simply as a tool to do the work of the other disciplines (science, technology and engineering).

Zöggeler presented a more theoretical paper exploring the meaning of spatial reasoning and its location within the STEM curriculum. Critiquing current conceptualization of spatial research, they argued that most research has explored students' spatial sense in purely psychometric terms with little attention to problem solving contexts. They introduced an extended model of spatial thinking in STEM that includes two overarching facets, *spatial problem solving* and *spatial* *memory*, with six more elaborate characteristics within those. They argued for the promotion of extended spatial thinking through mathematical, physical and technical contents as well as the promotion of spatial thinking in STEM subjects.

Finally, Cascella shared the results of a study that delved deeper into the relationship between students' reading and mathematics ability. While research has shown that there is a strong relationship between students' reading and mathematical reasoning, studies rarely account for the possible intersectionality between such a relationship and other contextual variables and/or students' personal characteristics. Cascella's research results confirmed that an integrated, interdisciplinary teaching approach is necessary and can be instrumental and powerful to fight educational inequalities across gender, socio-economic status, and citizenship.

These papers left us with important questions moving toward CERME13.

- If there is something called STEM-thinking, what would it encompass?
- What are the possibilities and challenges in talking about STEM-abilities and which abilities are addressed?

STEM/STEAM professional development

The fourth theme of the submissions involved research focused on STEM/STEAM Professional Development. The four papers and the three posters leading to this theme explored a number of intertwined aspects of STEM/STEAM Professional Development, including (1) providing a critical overview on the characteristics of STEM professionalism (Møller), (2) exploring the usability of 3D modelling and printing in STEAM education in primary school (Anđić, Ulbrich, Dana-Picard & Laviza), (3) analysing teachers' views on innovative learning activities (Erbasan & Çakıroğlu), (4) documenting mathematics teachers' experience in teaching STEM (den Braber, Mazereeuw, Krüger & Kuiper), (5) developing a STEAM professional development program for training in-service teachers and exploiting the role of mathematics within a secondary STEAM context (Diego-Mantecón, Laso, Diamantidis, Kynigos), (6) detailing the relationship between STEM practices and the development of 21st century skills (Amado & Carreira), and (7) understanding what knowledge promotes the development and implementation of mathematical interdisciplinary practices within the context of STEM education (Costa & Domingos).

In particular, Møller pointed out that in Denmark, curriculum descriptions of STEM competencies do not exist. To fill this gap, Møller developed a 'concept map', based on the review of both academic and grey literature (see Monash University, 2022). So far, Møller identified three main categories to describe STEM competences: (1) computing and visualizing 'everyday' data with computers, (2) finding and solving STEM-related problems, and (3) innovative STEM thinking.

Anđić et al. discussed the usability of modern tools, such as 3D printers, by reporting on STEAM teachers' opinions and attitudes about 3D modelling and printing. Results suggested, on the one hand, that teachers from different subjects can understand differently the usability of these tools and, on the other hand, that 3D printers require a high level of computer knowledge in order to be used effectively. These results call for a reflection about the potentials and limitations of modern tools in integrated teaching approaches, and for specific training.

In line with this, Diego-Mantecón et al. described an Erasmus+ project aimed to examine and overcome the main issues obstructing the implementation of STEAM education in secondary education, by involving teachers and scholars from Spain, Austria, Finland, Greece, and Hungary.

Research reporting on teachers' experience from other countries confirmed the need to focus on STEM/STEAM Professional Development. For example, from Turkey, Erbasan & Çakıroğlu reported on teachers' experience in teaching mathematics within an integrated (STEM) approach: even though subjects integration is explicitly mentioned in the national curriculum, teachers do not consider the integrated approach as the ordinary one, and, as with other papers presented in the same section, teachers complain about a number of obstacles (such as time constraints, lack of teamwork experiences, lack of knowledge and experience, lack of equipment for activities, and so on) hindering the success of integrated teaching.

Similarly, from Netherlands, Der Braber et al. reported on mathematics teachers' experience in teaching STEM. They discussed the appropriateness of mathematics teachers' training to teach Nature, Life and Technology (NLT). According to Der Braber et al., (teaching/teachers') freedom is, at the same time, the keyword to teach NLT successfully but also a risk if/when mathematics teachers are not aware of the learning goals of such courses, or when their background and work experience causes sharp differences (between teachers) in dealing with interdisciplinary objectives. Those who plan and develop professional training should thus be aware of this, in order to better support teachers in dealing with interdisciplinarity and exploiting the role of mathematics in such an interdisciplinary context.

Finally, Amado and Carreira presented and critically discussed the effect on a group of Mathematics teachers' attitudes and perceptions about the integrated approach after attending a professional development program committed to the innovation of teaching practices. Results showed that offering teachers practical tools, ideas, and guidelines to develop an integrated approach positively affects teachers' attitudes towards integrated teaching approaches and their willingness to engage their students in solving a real-world problem, thus confirming the importance, actually the need, to focus on professional development.

These papers left us with important questions moving toward CERME13.

- What are the key competencies for future STEM teachers?
- How do we prepare teachers to teach STEM in ways that are not isolated S, T, E and M?
- How do we help teachers discuss the role of mathematics in STEM?

Conclusion

Each of the papers and posters in the TWG26 were critically discussed in small and whole groups and captured specific aspects of "STEM" from a mathematics education perspective.

From both the small groups and the plenary discussions, STE(A)M seems to be defined as both a stand-alone subject (broader than just the sum of S+T+E and M) and as a "learning environment" within which teachers (and students) can work at the intersection of different (but sharply intertwined) subjects to construct a new learning environment within which actors can develop new, innovative, and critical thinking.

Results from the research presented seem to suggest that working with real problems is the way to combine S, T, E and M. To think about STEM as a unique subject, given by the combination - rather than just the sum - of its components, we should move from an interdisciplinary to a transdisciplinary approach. In this sense, a transdisciplinary approach can help students to develop both knowledge and competence (both theoretical and empirical/practical) not just in S, T, E and M, but in STEM, conceived as a unique subject.

Teachers in different countries employ very different teaching approaches, but the perception of STEM as an integrated subject is rare everywhere. Obstacles hindering a transdisciplinary teaching approach have been reported in some of the research presented, but also emerged in the TWG26 discussions. Among these 'hindering factors', in addition to the lack of time, experience, equipment and appropriate teachers' training, scholars from different countries (such as Portugal, Spain and Italy) also mentioned the absence of enough knowledge, in the public opinion, about STEM conceived as an integrated discipline, thus raising concerns among students' relatives/parents. All these reflections confirm that teachers from different countries experience similar difficulties and call for a prompt answer/intervention from educational policy-makers, possibly in an international, common perspective.

Research about STEM, from a mathematics education perspective, should thus focus on these criticalities in the attempt to understand, for example, what STEM education is (if there is such a thing), with emphasis on the M; what the characteristics of instructional materials, teaching practices, STEM programs (e.g., classroom implementation and/or school-wide approach) are, and thus what STEM preparation is and how it can support teachers in developing a proper and effective transdisciplinary approach.

The 21st Century Skills and Competences for New Millennium Learners have been shaping curriculum reforms and educational trends around the world, including in Portugal. In this article we discuss a theoretical perspective on integrated STEM education in which practices have a central place. We consider the current importance of developing professional development programs for teachers, including mathematics, based on a conceptual framework for promoting scientific, technical, and technological knowledge and practices. Our aim is to know how mathematics teachers experience STEM activities and how they evaluate the results of their implementation in the classroom. The study uses a qualitative methodology, in the context of a professional development program. The results show that teachers performed STEM practices in a proposed task and positively evaluated the effects of their students' work on the task, namely in promoting 21st century skills.

Keywords: STEM education, teachers, practices, competences.

Introduction

The 21st Century Skills and Competences for New Millennium Learners in OECD Countries (Ananiadou & Claro, 2009) have had a strong influence in Portugal and were decisive in shaping the overall curricular design of the so-called student's profile at the end of compulsory school (Ministério da Educação, 2017). STEM education is seen as a challenging opportunity to promote the development of such skills and competences. To the public and to most of the educational community, STEM education is seen as something that is new or not yet completely known, especially regarding the ways of putting it into action. On the one hand, STEM education entails connecting science and mathematics knowledge, and their teaching in an integrated way. On the other hand, it includes scientific and engineering practices. Despite the many open questions and unknown terrain, STEM teaching and learning seems to represent a great motivational opportunity to both teachers and students. In particular, the perspective of crafting solutions to real-world problems tends to boost students' interest and curiosity.

There is no more important single factor influencing the quality of a student's educational experience in the classroom than the quality of the teaching and learning practices. Integrated STEM education is particularly relevant to the development of students' skills and competences as it involves solving real-world problems and dealing with complexity.

> Teachers make a difference. The success of any plan for improving educational outcomes depends on teachers who carry it out and thus on the abilities of those attracted to the field and their preparation (National Research Council, 2010, p.1).

Professional development programs must offer opportunities for mathematics teachers to engage in meaningful dialogues about integrated STEM education and to develop learning environments for engaging students in STEM activities (Uttendorfer, 2014). Studies have already shown that the STEM initiative is being generally well received by the teachers (e.g., Kang, 2019). In terms of increasing teacher capacity to teach integrated STEM lessons, studies found that teacher professional development courses increased teachers' recognition of the STEM approach and confidence in teaching STEM. Kang (2019) has found that there is a lack of research on the connections between teachers' perceptions of STEM and their classroom practices. In this paper, we focus on mathematics teachers' views and experiences concerning the development of a STEM activity in their mathematics classes, within the context of a professional development program.

Theoretical Framework

Moore et al. (2014) defined integrated STEM education as "an effort to combine some or all of the four disciplines of science, technology, engineering, and mathematics into one class, unit, or lesson that is based on connections between the subjects and real-world problems" (p. 38). We propose a close idea, by assuming integrated STEM education as the approach to teaching the STEM content of two or more STEM domains, bound by STEM practices within an authentic context, for the purpose of connecting these subjects to enhance students' learning.

Kelley and Knowles (2016) advocate that most content in STEM education can be grounded within the situated cognition theory (Lave & Wenger, 1991). Foundational to this theory is the concept that understanding how knowledge and skills can be applied is as important as learning the knowledge and skills itself. Situated cognition theory recognizes that the contexts, which means both the physical and social elements of a learning activity, are critical to the learning process. When a student develops a knowledge and a skill base around an activity, the context of that activity is essential to the learning process (Putnam & Borko, 2000). Often when learning is grounded within a situated context, learning is authentic and relevant, therefore representative of an experience found in actual STEM practices. When considering integrating STEM content, engineering design can become the situated context and the platform for STEM learning.

Engineering design can be an ideal entry point to work in STEM activities or projects. An engineering design approach creates an opportunity to apply science knowledge and inquiry as well as it provides an authentic context for learning mathematical reasoning for informed decisions during the design process (English, 2019). The analytical element of the engineering design process allows students to use mathematics and science inquiry to create and conduct experiments that will inform the learner about the function and performance of potential design solutions before a final prototype is constructed. Both engineering design and scientific inquiry accentuate learning by doing.

Scientific inquiry prepares students to think and act like real scientists, ask questions, hypothesize, and conduct investigations using standard science practices. Engineering and technology are closely related, and if taught in articulation with technology education can promote technological literacy. In fact, engineering and science are closely related to the way in which the technology is used.

STEM education offers students the opportunity to think through technology as a vehicle for change in culture, society, politics, economics, and environment. Studies show that students are more motivated and perform better on mathematics when teachers use a STEM integrated approach by engaging them in learning activities that include engineering design and prototyping. Incorporating STEM practices that include mathematical analysis necessary for evaluating design solutions provides a powerful basis for students to learn mathematics and to see the connections between what is learned in school and what is required in STEM careers. In this way, students develop their mathematical thinking (Kelley & Knowles, 2016).

According to Kelley and Knowles (2016), the efforts to integrate mathematics and science should be founded, in part, on the idea that knowledge is organized around big ideas, concepts, or themes, and that knowledge is advanced through social discourse. When engaging students into a community of practice, the learning outcomes can be a result of a common and shared practice. A community of practice can provide an opportunity to engage local community experts as STEM partners such as practicing scientists, engineers, and technologists who may help focus the learning.

Leung (2019) argues that teachers need to integrate the correlated STEM disciplines in ways that prevent losing the disciplines' unique characteristics, depth, and rigor. Some STEM models give mathematics and science central roles while others put engineering as the major component of STEM.

Kelley and Knowles (2016) suggest that the key to preparing STEM educators is to first begin by grounding their conceptual understanding of integrated STEM education by sharing key learning theories, pedagogical approaches, and building awareness of research results of current STEM educational initiatives. Furthermore, professional development experiences for in-service teachers may also contribute to a strong conceptual framework of an integrated STEM approach and build their confidence in teaching from an integrated STEM perspective. Kennedy and Odell (2014) claimed that STEM education programs of high quality should include (a) integration of technology and engineering into science and math curriculum at a minimum; (b) promote scientific inquiry and engineering design, include rigorous mathematics and science instruction; (c) develop collaborative approaches to learning, connect students and educators with STEM fields and professionals; (d) provide global and multi perspective viewpoints; (e) incorporate strategies such as project-based learning, provide formal and informal learning experiences; and (f) incorporate appropriate technologies to enhance learning.

Context and method

In the following, we describe and analyse mathematics teachers' experiences concerning the development of a STEM activity in their classes, within the context of a professional development program, and their views about a STEM task. The program was developed over three academic years and involved 243 middle-school (grades 7 to 9) mathematics teachers. All the participants had a professional teaching experience of more than 5 years. The aim of the program was to promote innovative classroom practices and was proposed by the regional educational authorities with the aim of reducing the rate of school failure in mathematics. It was designed according to the recommendations presented in the previous section, namely by integrating STEM practices.

In Figure 1, we present the task proposed: *Customizing paint colour*. The task was solved in small groups, where materials were made available to allow all participants performing experiments related to the re-creation of customized paint colours. The task involves some central ideas/concepts, such as: colour, mixture, ratio, volume, measurement, formulae, computation, experimentation, technological system, customer, and customizing.

MEMO

From: Sales / Orders

To: Laboratory

Subject: Recreating custom colour

We received an order of custom colour acrylic paint. It is asked to recreate the colour of the curtain sample to paint a wall of a room. The manufacturing section needs to know the composition and quantities of pigments to be used for programming the system to produce various amounts of paint. The quantity of the order is not known (1, 5, 10 liters?).

From the experience ...

You will have to find the colour as close as possible to the sample provided by the customer and obtain its composition. White base and two liquid pigments, measuring syringes and cups to make mixture trials are available.

.… to the model

From the closest possible colour obtained, find out how to manufacture any desired amount of paint, using the white base and the two primary pigments. (Consider the automated paint production system named *tintometric* system, in which a dispensing machine releases exactly the amounts of base and pastes needed to make the client's desired amount of paint).

… and to the final product…

Prepare a report of the work performed, explaining all the processes carried out, the reasoning and the conclusions obtained. You may use the proposed report template.

Figure 1. The task: Customizing paint colour

In Figure 2, we present some of the questions raised to steer discussion and reflection among the teachers, after solving the task. The reflection was intended to include the recommendations by Leung (2019) about how to pedagogically integrate the four STEM disciplines.

1. How does the task involve mathematics and the mathematical modelling process?
2. How do you see the student's learning in carrying out the task? Which ideas, contents, practices, competences are aimed?
3. Which key elements of the Educated Student's Profile do you identify in developing the task?
4. How would you integrate this task in your mathematics classes, namely what would you do before proposing the task and how would you foster subsequent learning after the task is completed?

Figure 2. Questions to guide reflection

The data collection was based on observation and documental analysis. The observation took place in some of the program sessions, in which the teachers solved the STEM task and where discussion periods with the whole group took place. After the program sessions, the teachers were challenged to propose the task to their students, in the class. The teachers were also invited to share their teaching experiences in the following sessions and to present some written reflections. Some excerpts from the teachers' reports shared in a program session will be presented in highlighting some of the results.

Results

The sessions dedicated to STEM education started with an overview and discussion of theoretical and conceptual perspectives and proposals, as suggested by the literature. Although STEM was a novel idea and concept for the participating teachers and they were not used to performing this type of tasks in their classes, the teachers showed a clear enthusiasm and interest in solving such tasks.

While working on the problem of customizing paint colour and performing experimentation with the materials provided (Figure 3), some teachers verbalized their concerns with the implementation of the task in the classroom. They were especially worried about the practical work involving the use of several materials to produce the desired colour.

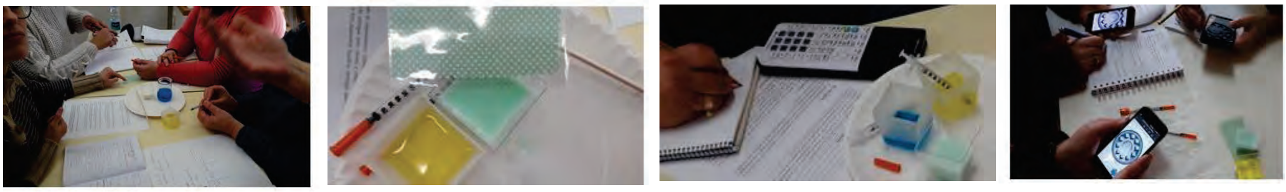

Figure 3. Images of the groups' work using materials and resources

As shown in Figure 3, one consistent finding is that the teachers systematically resorted to the digital technologies they had available. The cell phone calculator and the graphic calculator were always in use in their worktable. Some teachers also used a laptop to do some work with EXCEL. We could observe how the engineering and science practices were closely related to the way in which the technology was used. By challenging the teachers to create a possible simulation of the *tintometric* system, they mainly decided to do it with the spreadsheet (Figure 4).

Figure 4. Example of the use of Excel in a mathematical representation of the problem

Effective STEM teachers need more than just expertise in their subject matter, but they also need to be able to use instructional strategies for integrating science, technology, engineering, and mathematics into their lessons in a way that is both efficient and effective. The teachers showed great enthusiasm and dedication in solving the task, as well as they acknowledged features of the task that they found relevant to an integrated STEM activity. The idea of implementing the task in the classroom was also appealing to most of the participants. Indeed, some time later, several of the teachers used the task in their own classes. Therefore, in a subsequent session, it was possible to organize moments for sharing and discussing the results of that teaching experience.

We selected extracts of two of the teachers' statements regarding their experience with the task proposed to the students in their actual classes.

Teacher 1: Interestingly and to my surprise, the PROFIJ [vocational course] was the class that got the best results in recreating the colour and in the desired accuracy of the amounts of pigments obtained from calculations. I was surprised by the students with more learning difficulties, as they were able to overcome their difficulties with the practical activity of the recreation of the colour.

Teacher 1 proposed the task to students attending a vocational course, where students are aiming to get qualified to perform a job in the workplace. Very often, those students are characterised as highly distracted, usually chatting too much with each other, and often leaving their work unfinished. This is one of the reasons why some teachers refrain from proposing open tasks that require experimentation, collaborative work and using materials. Those students also show little interest on mathematics, have a past of school failure, and may even reject and avoid mathematics. Contrary to what this teacher expected, students' work on the task and the results achieved were unexpectedly positive and the teacher was surprised by the interest, commitment, and enthusiasm of the class in solving the problem.

Teacher 2: The task allowed the development of competencies and skills in **reasoning and problem solving**, as the students had to come up with appropriate strategies to answer the initial questions, generalize conclusions, and create **models to respond to real life situations**. This task has developed **critical thinking and creative thinking**. The students **observed**, **analysed,** and **discussed** ideas and processes by **drawing on evidence**. In groups, the students evaluated the impact of the decisions they made. The collaborative work promoted the interpersonal relationship in which the students learned to **consider different perspectives** and to create consensus. The activity carried out allowed for personal development and autonomy. The students **autonomously** designed, implemented, and evaluated strategies to achieve goals and challenges that they set themselves. The skills associated with **scientific, technical, and technological knowledge** were involved when students had to work with **resources and materials, instruments, and tools, relating technical and scientific knowledge** and identifying the technical requirements, the constraints, and resources for the realization of projects.

The comments from the Teacher 2, namely the aspects highlighted in bold, clearly illustrate the recognition of the task's potential to engage students in a STEM project and the teacher's pride on the work developed. Some of the main positive aspects that she and others highlighted after having implemented the task are here summarised: the development of a sense of responsibility, a reinforcement of collaborative work and team spirit, an increase in student's motivation, the development of students' critical thinking, promoting students' persistence in the search for strategies, and the development of problem-solving skills, mathematical communication, and creativity. Moreover, the teachers considered the work developed on the task as having facilitated and encouraged formative assessment practices aiming at developing students' skills and competences. They asked their students to produce a written report, while encouraging them to search for relevant information on the *tintometric* system. Finally, they were convinced that the work done was important to the students' appreciation of the importance of mathematics in the context of a real professional activity.

The overall results on this activity within the professional development program were quite positive in two aspects. On the one hand, it became evident that teachers formed a positive and attractive idea about the possibility of integrating STEM activities into their teaching practice. On the other hand, when putting the task into practice, many of the teachers were surprised by the way their students got involved, especially the students from vocational courses who are usually little motivated to engage in mathematical activity. In general, to all the participants, the possibilities of the task for the development of 21st century competences and skills have become salient.

Final Remarks

Our study focused on a group of mathematics teachers who attended a professional development program committed to the innovation of teaching practices. Our research methodology assumed a qualitative nature and aimed, above all, to collect evidence about the way they experienced and understood the effect of developing a STEM activity in their mathematics classes.

Regarding their involvement and interaction with the task on the creation of customized colour paint in the course sessions, we have observed that the teachers effectively assumed the scientific, technical, and technological practices involved in the solution to the problem. They have identified and worked on key concepts, namely, mathematical ones, including ratio and proportion. Moreover, they were able to integrate technological resources in their work, including the use of the graphic calculator or the spreadsheet to simulate the various trials they were performing with mixing pigments and the white base, using the materials given. Technical skills involved the need to measure the coloured liquids and to make decisions on the best ways to create the mixture. They have also engaged in discussing ideas about how colour is produced. This indicates that teachers need to be aware of the resources available, both real-world materials and digital tools, to assist them with effective instructional strategies. Using techniques such as project-based and problem-based learning show to be effective methods in STEM approaches.

In what concerns their views on the impact of the STEM activity on the students' learning, we may conclude that the teachers were not only motivated to do practical work in their classes but also to engage their students in solving a real-world problem. Their reflections reveal that after implementing the task the teachers corroborated the positive impact of the activity in their students' development of several skills and competences that are strongly connected with STEM practices. They also reported on the motivational effect observed in lower achievers, namely in mathematics, and on their engagement in finding accurate and sound solutions to the problem.

Our results, although on a limited scale, are relevant and reinforce the conclusions from other studies (Kelley & Knowles, 2016; Kennedy & Odell, 2014; Leung, 2019) in that it is possible to develop consistent frameworks for integrated STEM teacher education. Emphasising the development of 21st century skills and competences along with STEM practices in addressing the design of solutions to real-world problems appears to be a promising way of promoting integrated STEM education in our schools, at different teaching levels and with diverse students.

3D printing in STEAM education

With the increasing availability of 3D printers, their impact on various human activities from production to education began to increase (Jiang et al. 2017). In the field of STEAM (science, technology, engineering, the arts, and mathematics) education, there are various approaches to implementing 3D modeling and printing, from printing geometric shapes, molecules and cells to buildings and various buildings and similar. 3D printing has developed as an innovative pedagogical tool for enhancing STEAM learning in a number of contexts and for a variety of objectives (Hasen et al. 2020). So far, research has shown that the use of 3D modelling and printing has the following benefits in teaching: increases the active participation of students in teaching, contributes to better quality and sustainability of student knowledge, increases visualization in teaching, motivating students to learn, increases mathematical and technical skills (Leduc-Mills and Eisenberg, 2011). On the other hand, there is research that emphasizes that if students and teachers are not trained and prepared to apply 3D modelling and printing in teaching and learning, they may experience more failures in this process that can lead to frustration (Nemorin and Selwyn, 2017; Ulbrich et al. 2020). One of the last systematic literature reviews in this area (Hansene et al. 2020) suggests there is a necessity for additional research which will provide a closer insight into the benefits of 3D modelling and printing in STEAM education. This research aims to contribute to the knowledge in this area.

Methodology

We prepare our study in the form of exploratory and descriptive research. Our study uses a qualitative approach based on grounded theory to investigate teachers' perceptions of the usability of 3D modeling and printing in STEAM subject teaching. For data gathering, surveys were used. Data were collected from 200 STEAM teachers who had the opportunity to undergo training in the application of 3D modelling and printing in teaching. Grounded theory was used for data processing. In this process, open coding, axial coding and selective coding were implemented. By recommendation Strauss and Corbin (1998) line-by-line open coding was used to breaking, examining and conceptualizing the data, and gets the researcher off the empirical level by fracturing the data. In the process of open coding, we tried to give an answer on what, how and why is understood by teachers abut 3D modelling and printing. As a result of open coding, the initial codes are produced directly from the participant’s narrative. The constant comparative method (Strauss and Corbin, 1998) was employed in axial coding and selective coding in aim to develop categories and themes. In the process of axial coding, the relationship between the initials codes are established and they are classified into categories. In the process of selecting coding developed categories are refined and integrated into the theme. Examples of initial codes, categories and themes are given in the table 1.

Table 1: Initial codes, categories and themes

Theme:	Categories:	Initial codes:
Teaching contribution	Contribution to the students learning outcomes	Increasing the motivation
		Increase visualization
		Increase active learning
		Can prevent students' misconceptions

Results

STEAM teachers' opinions and attitudes about 3D modelling and printing are classified into 5 main categories named: Time, Software characteristics of 3D modelling, technical characteristic of 3D printers, teaching and learning influence, and teacher's skills. The results of our research indicate that STEAM teachers believe that 3D modelling and printing would contribute to the realization of the principles of STEAM education practice. However, teachers of different subjects within STEAM differ in what they see as difficulties in realizing the full benefits of applying 3D modelling and printing. For example, teachers of engineering and informatics have difficulty linking the implementation of 3D modeling and printing with other subjects in order to realize STEAM principles. On the other hand, teachers of mathematics, biology, chemistry, physics and art state that 3D printers require a high level of computer knowledge in order to be used effectively. Teachers agreed the successful implementation of 3D modelling and printing in STEAM education require at least basic knowledge from mathematics such as geometry– which influences students abilities to manipulate with the plane and solid, during 3D modelling, algebra– which influence students abilities to understand relations between the objects, fractions – which helps students to understand on how many parts they need to divide the figure (cube, square, circle) and which part to use for their model. Most teachers felt that good knowledge of the above mathematical areas would allow more efficient use of 3D modelling and printing in STEAM education. These and similar results will be discussed in more detail in this poster presentation.

Designing Intentional STEM Connections: An Initial Case Study in an American Curriculum School

Cory A. Bennett[1] and Wendy Ruchti[1]

[1]Idaho State University, Teaching and Educational Studies, Pocatello, Idaho, United States; corybennett@isu.edu, wendyruchti@isu.edu

Students benefit from the intentional integration of science, technology, engineering and mathematics (STEM) in ways that support deep conceptual learning in all disciplines. Elaborating on Bybee's (2013) nine perspectives of STEM, the article describes three specific and intentional methods in which integration, specifically in mathematics and science, can be effectively implemented and integrated. Each of the methods of integration has its purpose based on the context of the investigation, the intended learning outcomes, and the students' learning needs during the investigation. These methods of integration are discussed within the context of one lesson from a broader investigation on weather as it relates to the interaction of earth's major systems.

Keywords: STEM, Integration, Primary Grades, Project-Based Learning.

Introduction

Supporting science, technology, engineering, and mathematics (STEM) in the classroom has gained much momentum over the last two decades. Unfortunately, there is still no clear definition of what STEM is or means, and more importantly, what it actually looks like in the classroom (Bybee, 2013; Ring-Whalen et al., 2018). In fact, Bybee (2013) and Brown (2012) posit that a clear understanding is required because the acronym has been used in many ambiguous ways and because these ambiguities do not help educators within the reality of their practice. This means there is a need to develop methods for appropriate STEM integration, which would include such areas as curriculum, assessment or instruction so that educators can appropriately implement and integrate meaningful STEM experiences.

Review of Literature

The acronym STEM is frequently used in place of science, but how the other three content areas (e.g. engineering, technology and mathematics) are integrated varies, is inconsistent, and are often not even evident in experiences that are labelled STEM (Bybee, 2013). Mathematics, in particular, plays a fundamental and structural role in authentic science learning as seen by the description of behaviours that scientists engage in as they investigate the natural world and thus should be integrated (Michaels et al., 2008; National Research Council, 2012). Furthermore, there is an obvious overlap of the Science and Engineering Practices within the Next Generation Science Standards [NGSS] (NGSS Lead States, 2013) and the Standards of Mathematical Practice (National Governors Association, Center for Best Practices, & Council of Chief State School Officers, 2010) to promote technical ways of thinking. This overlap and alignment to technical habits of mind and interactions suggest a natural area for integration (Bennett & Ruchti, 2014).

In addition to practices, science provides multiple opportunities for students to simultaneously learn important mathematics content, especially as it relates to data analysis. However, science curricular resources rarely highlight these connections or leverage them in grade-level appropriate ways (Morris et al., 2015). Even so, educators can be well positioned to determine how best to link and leverage cross-curricular learning for authentic STEM integration. For some situations, this may mean understanding how to integrate STEM practices and habits of mind but in others it can mean purposefully injecting other STEM disciplines so that the learning can become more meaningful and applicable. This means that teachers and teacher leaders need to be aware of the specific nature of integration and how it purposefully builds students' understandings across STEM disciplines (Kelley & Knowles, 2016). However, while technical habits of mind is a good place to start integrating STEM content, the deliberate integration of STEM content at the classroom level can be more challenging.

When integrated, and when it involves a more contextual application, STEM experiences can have greater meaning and thus allow for deeper connections and more authentic learning for students (Sandall et al., 2018). Several variables in the school context can contribute to unsuccessful STEM integration. For example, many teachers struggle shifting from teacher-directed pedagogy to the more student-directed nature of an integrated curriculum. In addition, district-level or course-level curriculum alignment is often inflexible as are the structures of school schedules and finances (Margot & Kettler, 2019). Schools and teachers often do not know what STEM looks like, especially when it comes to modifying and integrating their current curriculum (Portz, 2015). This confusion leads to very different conceptions of STEM education which can cause a "state of anxiety and insecurity and, in some cases, to reject the implementation" of STEM in the classroom (Aguilera et al., 2021, p. 597).

In order to create such learning experiences, teachers often want to understand the nature of integration of the STEM disciplines. Or rather, to understand what qualifies as quality STEM learning; the knowing when and how to integrate disciplines to support greater learning. Thus, the purpose of this study is to understand how an elaboration of Bybee's (2013) integration is actualized within a primary classroom.

Theoretical Framework

Bybee (2013) outlines nine commonly accepted perspectives for defining STEM, but only six of these nine are applicable at the classroom-level. Of these six, the research team examined only those STEM perspectives that best supported a more complex integration at the classroom level; specifically, STEM means coordination across disciplines and STEM means complementary overlapping across disciplines numbers four and six above. Then, the team elaborated on these two definitions and created three specific methods for STEM integration which are referred to as: 1) *Simultaneous Infusion*, 2) *Temporary Shift in Discipline*, and 3) *Lateral Concept Connections*. In this project, *Simultaneous Infusion* uses mathematical and scientific habits of mind and practices, such as the importance of using data and communicating ideas and understandings in STEM, and are considered simultaneously during the science lesson. When using *Temporary Shift in Discipline*, is a shift from one discipline (e.g. science) to conceptually explore a skill in another discipline (e.g. mathematics), and then a shift back to the original discipline (science) to bring new understandings to the primary science focus. And lastly, with *Lateral Concept Connections* the focus of the learning moves from a primary science concept to a new science concept. The purpose of this shift is to give students new content to reinforce a mathematical concept.

In order to provide clarity and consistency, the research team established a working definition of STEM. For this project, STEM learning is understood to be opportunities, within technical content areas, to understand, create, and discuss ideas and concepts that supports students' critical thinking, analysis skills, and connections to larger concepts across and within STEM disciplines (Li et al., 2019). This focus also follows the National Council of Supervisors of Mathematics and the National Council of Teachers of Mathematics joint position paper on STEM learning (2018). Namely, that students have a strong mathematics foundation and that any STEM program or curriculum should enrich the mathematics program and also address mathematics with integrity.

Methods

The purpose of this qualitative exploratory case study (Løkke & Sørensen, 2014) was to understand how an elaboration of Bybee's (2013) integration is actualized within a primary classroom. Examining specific cases is important as it allows for the testing of theory by using multiple data collection methods in varied, yet similar, contexts to provide a more accurate and rich description of the unique, dynamic, and complex nature of classroom learning environments. With a purposeful focus for integration in mind, the research team and classroom teachers examined how the strategic integration of scientific and mathematical experiences, using the three aforementioned elaborations, allowed for a more dynamic and purposeful ebb and flow of STEM learning. That is, by using these three elaborations, the research team wanted to better understand how this elaborated framework supports the teaching and learning of integrated STEM in an upper primary classroom; this includes both challenges and affordances with respect to planning and implementation.

Participants

The primary participant in this case study was one second-year grade five teacher in their classroom, which included 23 students, from a school located in the Intermountain-west of the United States. This school serves a population with substantial social needs and financial insecurities and thus many students also often receive additional behavioural and/or social-emotional support and services. There are approximately 500 students across all grades and most teachers have between 20 and 28 students in each class and are responsible for teaching all subjects except for physical education and music, both of which are offered on a limited rotational basis. It is common to have students several years behind in reading and/or mathematics and annual test scores show that, while slightly higher than average scores across the state, only about 45% of students score at proficiency levels in mathematics.

Instructional Setting

The interdisciplinary activities described herein were developed as part of a larger, upper primary science project examining ways the geosphere, biosphere, hydrosphere and the atmosphere interact. These lessons were co-created with classroom teachers along with science education and mathematics education researchers around the intended elaborations. In the activities described below, which is a subset of the larger project on integrating STEM learning through project-based learning, the lesson objectives were to analyse and interpret weather data in order to develop understandings between weather and climate in different regions of the world.

Data Collection & Analysis

Data collected included classroom observations of students' interactions and comments, field notes from lesson planning meetings, and notes from post-lesson discussions with the teacher. Emphasis was placed on the interpretations and meaning that the researcher and the teachers had towards integrating STEM. Data were independently read and analysed to identify common themes (Paton, 2002) and were then re-categorized as needed to appropriately capture the emergent patterns.

Limitations

A primary limitation in this study revolves around the fact that it includes only one classroom, within one school. Another limitation centres on the fact that data comes from the first and only iteration of the elaborated integrations with teachers. As such, this greatly reduces the richness of the data and thus the interpretations that can be made despite promising findings for future research are limited.

Project Implementation & Findings

At the start of the lesson, students watched a video report from the National Oceanic and Atmospheric Administration on the winter outlook for the region. This was to help students contextualize how weather data can be used in their geographical area. This video report included various types of graphical data, numerical data, and a verbal discussion of the current snowpack, projected snowpack, and what this data means in terms of spring flooding forecasts. Students spent some time discussing what they heard, and what they believed were the implications of the data in their daily lives. Students were also asked to consider what knowledge and information they needed to interpret the data, based on what the meteorologist was telling them. Lastly, students were asked to consider the ways in which scientists and mathematicians think and behave in a similar fashion as they watched the video.

Next, students explored data from their own weather station. This raw data showed the daily mean temperature (F°), high and low temperatures (F°), heat and cool degree days (days when buildings needed to be heated or cooled), time, rain and average wind speed (mph) with data reported to one decimal place. Students were asked to describe what the weather was like for a week, using the raw data from one week. In small groups, students were allowed to choose any variable they wished to consider (i.e. High Temperatures, Heat Degree Days, or Average Wind Speed) and then they discussed what they noticed, wondered about, and questions they had about the data with their group to decide the "story" this data was telling. Next, they were asked to develop a statement about what their variable was "generally like for the week" and then to find a way to support the accuracy of their statement; this led to the first elaborated method of integration.

Simultaneous Infusion

Simultaneous Infusion is when the learning goals and outcomes of both content areas are well aligned and sometimes identical. This is often the case when supporting students' STEM habits of mind and is why this kind of integration was used initially to help set the context for learning. For the first lesson, the intent was for students to see the connections between the behaviours scientists and mathematicians engage in as they investigate and attempt to make sense of real-world phenomena. Thus, the local National Oceanic and Atmospheric Administration report for snowfall and the discussion on the ways in which scientists and mathematicians think and behave in a similar fashion.

Again, getting students to recognize how scientists and mathematicians use data and statistical thinking (Lane-Getaz, 2006) in similar ways is important in helping them make connections to the importance of mathematics within science.

One student indicated “All those numbers come from somewhere and they have to know what they mean before they can give a report,” highlighting the importance of keeping the context in mind when analysing and interpreting data. Another student commented, “Mathematicians make graphs and other ways to share what they know. It looks like scientists do this, too,” which further highlights similarities in how mathematicians and scientists communicate their understandings. This prompted a discussion about the relationship between science and mathematical practices.

During the whole class discussion that followed, students often described the data in more general and relative terms. Such as for High Temperature, students said that the week was warm. This created a great opportunity to discuss objectivity with the statements as the word warm alone actually cannot be used to describe the data as it is both relative and imprecise. After further discussion about how to make precise and objective statements, one student eventually recognized that they should “first try to be exact with the numbers and then figure out what those numbers mean.” This statement was agreed upon by the class and allowed the teacher to focus their attention on how mathematics can strengthen STEM learning and how both scientists and mathematicians need precision in their work. This led to the second elaboration of STEM integration.

Temporary Shift in Discipline

The Temporary Shift in Discipline pauses the learning from one discipline (e.g. science) to focus on learning a specific skill or concept in another discipline (e.g. mathematics), which will be necessary for further exploring the concepts in the initial discipline. This shift in focus allows for “just in time” learning to occur rather than teaching larger and discrete lessons on content that may seem unrelated or irrelevant to students if taught in isolation.

This part of the lesson shifted to a reasoning talk (Bennett, 2018), a process by which students reason about mathematical relationships and structures, in order to focus on key mathematical concepts that were important in exploring the science concepts. Namely, how compensation strategies can aid them in multiplying and dividing decimals. That is, by shifting to a mathematical concept, in this case the relationship between whole number operations and operations on decimals, students were able to quickly shift back to exploring the science using the mathematics in purposeful and relevant ways.

Because the intent was to help students recognize strategies for making sense of the data within a science exploration, we did not move into a formal mathematics lesson about operating on decimals but highlighted how understandings of place value used to transform the decimals into whole numbers in order to work with the data in an easier manner. Temporary Shifts in Discipline is about accessing or learning concepts from another discipline, in this case mathematics, at the right moment to make the learning in the intended discipline more meaningful, in this case the science. At this point, the final elaboration for STEM integration was used to help the students examine the weather data.

Lateral Concept Connections

Lateral Concept Connections is a purposeful movement between two seemingly unrelated core ideas of the same discipline (e.g. the earth science study of weather and the biological science study of birds). While this may seem like a *Temporary Shifts in Discipline*, it does not shift disciplines in a major way and the secondary discipline is also not a major focus. Rather, *Lateral Concept Connections* help students understand a concept within a discipline because of tangential relationships, skills, or concepts within the larger discipline that require a secondary discipline. In the weather study, numbers were presented as a mean, and students had not yet worked on measures of central tendency, there were gaps in their understanding of how to interpret the data.

For example, to help students consider how to describe the general nature of the weather for the week with their chosen variable, students were asked to consider an alternate data set on a given number of birds observed in the morning over a four-day period. This prompt was:

> "Mr. Lopez counted the number of birds he saw on his bird feeder each morning. During the 4 days he counted 8 birds the first morning, 7 birds the second morning, 9 birds the third morning and 8 birds on the last morning. About how many birds came each day? Create a model to show your thinking."

Students discussed what "about how many" meant and described it in two distinct ways. Some students used a sharing approach and talked about how "evening out" of all the birds for all of the days would tell the average while others pointed out that "we are kind of looking for the tipping point. The place where the number of birds on one side is the same as the other." For the first way of thinking about the mean (sharing), students wanted to find how to "share the birds" for the whole week. Through a purposefully orchestrated discussion, students agreed that "putting all of the birds together is liking adding them all up," which then lead another student to say that "sharing them all is kind of like dividing." All of which ultimately allowed the students to understand the process needed to describe their weather data. Students agreed that, in order to "share the weather data correctly," they needed to add up the values for their variable and then divide it by seven, as there were seven days in the week, in order to "share the data" evenly.

At this point, students moved back into the science portion of the lesson to further analyse, interpret, and report on their weather variable for the week. Note that in this case, the lesson content deviated significantly from the primary science activities in order to support a deeper understanding of the concept of mean and measures of central tendency. Again, these concepts were fundamental to their success in describing the weather for the week.

Discussion of Results & Implications

This project found that by deliberately integrating mathematics and science content through the use of Simultaneous Infusion, Temporary Shift in Discipline, and Lateral Concept Connections students were better able to develop deep conceptual knowledge in both disciplines. Attention to these elaborations, and how they appropriately scaffold learning, explicitly attend to understandings in both content areas at strategic times, and create opportunities to apply these understanding to authentic real-world problems are the heart of natural and purposeful STEM integration.

However, the initial planning was substantial and the primary teacher often relied on the other research team members to understand the nuances in the integration. This suggests that the initial planning process was not necessarily easy for the teacher, which leads to other complications with respect to implementation. Namely, if the planning is too challenging for teachers, then the elaborations may not actually help with mathematics integration in STEM learning as intended. On the other hand, and is the case with many new pedagogical approaches when initially adopted, it may be that more experience and time thinking within this framework is needed. This indicates the elaborated integration process needs to be further studied to understand the specific challenges teachers may face when implementing this elaborated integrated approach and the extent to which these challenges are a result of the conceptualization, design, or newness of the framework when implementing in classrooms.

With respect to the student learning, the data indicates that students were able to move fluidly between the different transitions to make the deliberate connections intended during the planning phase. This was even the case for shifts between disciplines (i.e. Temporary Shift in Discipline). Such results are encouraging as it suggests, from a learning perspective, the elaborated integrations support STEM learning outcomes and do so in an organic, natural manner. What is not clear at this point is the extent to which this occurs. That is, given the limitations of this case study, it is unclear if these elaborated integration experiences would be evident in other areas of mathematics and science. This is especially true given the easily accessible nature of statistics and working with data in science. It may be that other mathematical content does not lend itself to the elaborated integrations in a meaningful way.

In a time dominated by talk of STEM, and where students' ability to do STEM is critical for their success in a tech-driven globally competitive society (National Research Council, 2012), a deliberately integrated approach can provide opportunities for "more relevant, less fragmented and more stimulating experiences for learners" (Furner & Kumar, 2007, p. 186). It is time for STEM to be more than just any isolated discipline or an arbitrary accumulation or tangentially related experiences. It is time for STEM to be a transformational process to explore learning in a manner that may not otherwise be realized; a dynamic process that intentionally builds connections for students across and within disciplines through a more organic process.

Improving students’ reading skills to improve their performance in math: empirical evidence from Italy towards the development of integrated approach to math education

Clelia Cascella

University of Manchester, UK; clelia.cascella@manchester.ac.uk

Understanding the role of Math in STEM and designing an approach to teach math in a STEM context is a timely topic. Nonetheless, research has to understand what STEM means before planning any teaching approach and identifying any prerequisite students need to have/develop to avail themselves of such an integrated approach. In the present paper, I focused on the latter aspect. Starting from previous studies claiming that the higher the students’ reading skills the better their performance in S, T, E, and M, I analysed Italian data to explore the relationship between students’ reading skills and math performance, and how such a relationship interplays with students’ characteristics. Results showed that reading skills predicts math performance and mediate the negative effects of some students’ sociodemographic characteristics, thus calling for the development of integrated teaching approach that also focuses on the improvement of students’ reading skills.

Keywords: STEM integration, Math, Reading and Text Comprehension.

Introduction

Studying STEM (Science, Technology, Engineering, and Mathematics) from a mathematics education perspective has received an increasing attention from both scholars and teachers. Some of the most frequently asked questions are about the definition of STEM and about the role of math in STEM. For example, is STEM a unique subject that is somehow “more” than just the sum of its components, to be taught as a stand-alone topic? Or is it a “learning context” within which math can be used as a tool to teach S, T and/or E, or is it a “learning context” within which math can be find new perspectives and stimulate new lines of reasoning by interacting with real (scientific, technological, engineering) problems? Moreover, what kind of abilities/skills students need to have or to develop to benefit from such an interdisciplinary or transdisciplinary teaching approach?

Answering these (research) questions is not easy at all and calls for more research, also aimed to understand the possible *interaction effects* between students’ performance in math and their characteristics, such as their reading skills, their personal characteristics and the characteristics of the context students inhabit (here included peers’ characteristics). Nonetheless, little research has been carried out to date to understand if (and, if yes, to what extent) the relationship between students’ performance in math and their characteristics and skills can interplay with, and thus being (positively or negatively) affected by the characteristics of the school and the classroom attended by students. The current paper aims to fill this gap.

The relationship between students’ characteristics and their performance in math

There are several factors affecting students’ performance in math, such as schools’ characteristics (facilities, didactical protocols, etc.) (e.g., Fowler & Walberg, 1991) that can enhance or hindering learning, or students’ background characteristics, such as their sex (e.g., Cascella, 2020), citizenship, (Cascella & Giberti, 2020), and socioeconomic status (SES) (Coleman et al., 1966), or other skills, such as reading skills (e.g., Cascella, 2021) that can predict their performance in math. In the educational literature, there is a full agreement that students’ socioeconomic status (SES) can significantly affect their performance and, in particular, that low-SES students develop performance more slowly compared with higher-SES students, across countries (e.g., Organization for Economic Cooperation and Development, 2019; Reardon et al., 2006).

Another background factor significantly associated with students’ performance (both in math and reading) is sex: girls outperform boys in reading and text comprehension, in all the countries around the world. Such a superiority in reading counterbalances female relative underachievement in math (Ajello et al., 2018), that is sharper in some countries (such as Italy, Spain, etc.) (Guiso et al., 2008). Similarly, foreign students’ performance is different (often, but not always, lower) compared with native students and, according to results from the Programme for International Students Assessment (PISA), their relative disadvantage in math compared with native students is primary due to their disadvantage in reading (Organisation for Economic Co-operation & Development, 2016).

In addition, recent research has shown that all the relations described here above interplay with the characteristics of the learning contexts (schools and classrooms) students live in. Peers’ characteristics affect individual academic performance, sometime even more than individual characteristics. Such a phenomenon is more frequent in secondary education (Kessels, 2005). Previous studies have shown for example that, in secondary schools, “the social composition of the student body is more highly related to performance, independent of the student’s own social background, than is any school factor” (Coleman et al., 1966) and, more precisely, that students’ individual performance is more strongly associated with classroom and/or school SES than with student’s individual SES.

Research aims and questions

Even though previous studies have identified some factors affecting students’ performance in math, it seems that these associations can dramatically change depending on the characteristics of the (learning) context students attend. In absence of research aimed at quantifying the effect of external factors, designing innovative teaching approach is taught and may lead to unexpected results.

In the current paper, I investigated the mediating role of students’ reading skills on the relationship between students’ SES and students’ performance in math, and used students’ sex, citizenship status, regularity throughout the academic pathway as control variables. Census data collected in Italy at Grade 10 in 2017 have been used to answer the following research question: Does the relationship between students’ performance in math and their background factors and skills interplay with the characteristics of the school and the classroom students attend? And, if yes, to what extent?

Methodology

Data

In 2017, the Italian national institute for the evaluation of educational system (*Tr. Istituto nazionale per la valutazione del Sistema di istruzione e formazione* - INVALSI hereafter) administered two achievement tests to the Italian students' population to measure their competence in (i) reading and text comprehension, and in (ii) math.

In this paper, I analyzed data collected at Grade 10 (on average, 15 years old students), at census level (427,465 students in 24,870 classrooms, in 3,986 schools). Italian data are particularly suitable for the purposes of the present study because, at Grade 10, there are three school types (i.e., Lice, Tecnici, and Professionali[1]): all of them are embedded in the same educational system and have the same math curriculum, but they are usually attended by students with very different characteristics in terms of socioeconomic status, gender, citizenship, and regularity of academic pathway. (For a description of the sample analysed, please see the 'Data description' section).

The differences between different school types allowed for the investigation of the possible interaction between personal and contextual factors. Results based on such a sample are thus of help to answer my research questions and can be used as an example - of interest for the international reader - of how the mediating role of reading skills on the relationship between students' performance and students' characteristics change depending on contextual factors.

Analytical strategy

A multilevel model (MLM) of students' performance in math (estimated via the Rasch model - Rasch, 1960) against students' characteristics (i.e., sex, socioeconomic status, citizenship, regularity throughout the scholastic pathway, reading skills) and contextual factors (peers' socioeconomic status aggregated at classroom and school level), has been estimated by using MLwiN, a software for multilevel analysis (Rasbash et al., 2017), used to account for data hierarchy (i.e., students nested in classrooms and schools).

Multilevel modeling is very adequate for the purposes of the current study as it models the interdependency within levels under the theoretical assumption that students from the same context share something more as compared to students from other contexts (Hox, 2010).

In the present study, multilevel models have been estimated with random intercepts and fixed slopes (Hox, 2010). School type has been added as a predictor to verify that the difference between school types was statistically significant. In order to observe how the relationship between students' characteristics and reading skills and students' performance in math varies by school type, I

[1] Although all school types allow access to university, Tecnici and Professionali offer a specific education/training and a direct access to the job market in a variety of sectors that do not require an academic degree (but that are more focused, for example, on technological competences or on the development of manual abilities), whereas Licei offer a broader education preparatory for university.

performed three separate analyses[2]: one for Licei (224,791 students), one for Tecnici (132,954 students), and one for Professionali (65,120 students).

Such a decision is statistically robust as the INVALSI national sample is statistically representative of the Italian students' population at regional level and by school type. Moreover, each school type shows unique characteristics: each of them thus represents a unique learning environment (See 'Data description'), and the differences between school type worth a separate analysis.

Results

Before performing the multilevel analysis, in the next sub-section, I presented a description of the data analysed in the present study. Tables and figures have been saved in a separate file, available online[3].

Data description

Students' characteristics sharply vary by 'school type' thus characterizing Licei, Tecnici and Professionali as different, highly segregated learning contexts.

Schools' composition varies in terms of the proportion of enrolled boys and girls, the proportion of enrolled native compared with foreign students, in terms of students' socioeconomic status and performance levels, both in reading and in math, and in terms of the proportion of 'regular' students (i.e., those attending the expected grade) compared with 'retained' and 'in advance' students.

In 2017, at Grade 10, 51.3% of students attending Licei is female. Such a percentage decreases in Tecnici (30.3%), and in Professionali (15%). Moreover, around 85% of students attending Licei are Italian citizens. Such a percentage is slightly lower in Tecnici but drops down to less than 80% in Professionali. In addition, the proportion of retained students over the total is less than 10% in Licei, around 20% in Tecnici and more than 35% in Professionali.

Students' socioeconomic status and students' performance (both in reading and in math) sharply vary by school type. Students' SES is higher in Licei (mean = 0.31, SD = 0.97) than in Tecnici (mean = -0.19, SD = 0.95) and in Professionali (mean = 0.54, SD = 0.96). Students' performance in math is above the national mean in Licei, in line with the national mean in Tecnici, and sharply below the national mean in Professionali. As with it, students' reading skills are above the national mean in Licei, in line with the national mean in Tecnici, and below the national mean in Professionali (Figure 1, in the Supplementary File) (INVALSI, 2017).

[2] In each model, all continuous variables (i.e., 1. students' reading skills, 2. individual, 3. classroom, and 4. school SES) were centered on the grand mean (Hox, 2010). For categorical variables (i.e, sex, citizenship, regularity, and school type), 'Boy', 'Second generation student', 'In advance' and 'Tecnici' have been used as reference category.

Multilevel analysis

Before performing the multilevel analysis, I estimated the null-model, i.e. a model without predictors used to calculate the variance of students' performance in math (the dependent variable) at different levels of the data hierarchy. The variance calculated at each hierarchical level is also used to calculate the variance partition coefficient (VPC - Hox, 2010) (Table 1, in the Supplementary File).

The model intercept expresses the overall mean of math performance (measured by using the Rasch model (Rasch, 1960) in Licei, Tecnici, and Professionali, and thus serves as a benchmark with which other models are compared with[4].

The proportion of variance in math performance explained by individual factors sharply changes by school type, and it is higher in more disadvantaged contexts (more than 40% in Licei and 50% in Tecnici, and around 60% in Professionali) (Table 2, in the Supplementary File).

To better understand if and, if yes, how the relationship between reading skills and math performance changed depending on the learning context, I analyzed data collected in Licei, Tecnici and Professionali separately, as reported in the next three sections.

Licei

Consistently with previous literature (Ding & Homer, 2020), the regression analysis indicates that boys outperform girls in math, and that female disadvantage increases after having accounted for reading skills, thus confirming the hypothesis that reading skills mediate the relationship between gender and math performance. As with this, regular students are slightly advantaged compared to 'in advance' students whereas retained students are sharply disadvantaged. Nonetheless, these differences decrease after accounting for reading skills.

Reading skills also mediate the relationship between citizenship and math performance. More precisely, higher reading skills are associated with higher performance in math and, after having accounted for reading skills, the retained students' disadvantage significantly decreases. Such results are stable across hierarchical levels but different in magnitude because the proportion of variance explained by individual factors decreases when the hierarchical data structure is accounted for: at classroom and school level, the magnitude of effects related to individual variables is smaller than that at individual level. Such a result is not surprising as the individual level model does not account for data hierarchy, and thus wrongly attributes to the individual level the variance actually explained by factors at the higher hierarchical levels (Hox, 2010).

[4] The difference in the -2*loglikelihood between models, in each school type, is statistically significant - as assessed via a Chi-Square test -, thus confirming that the model accounting for data hierarchy fits better than that does not (i.e., the 1-level model): 1-level model captured the variance actually explained by variables at the higher hierarchical level (i.e., at classroom (models 2) and at school (models 3) levels), and thus wrongly attribute such a variance to individual students' characteristics (Table 1, in the Supplementary File), biasing results interpretability.

In addition, the effect of individual SES decreases when peers' SES (aggregated at classroom and school level) is added to the model. Reading skills also mediate the effect of peers' SES on individual math performance. In particular, the effect of individual SES is statistically significant but very low, thus confirming that peers' SES affects individual performance in math even more than individual SES (Cascella, 2020; Coleman, 1966), and showing that reading skills mediates the effect of both individual and aggregated SES on math text score.

Tecnici

In Tecnici, where students' ability both in text comprehension and in math is lower than in *Licei*, reading skills explain most of the variance in students' performance in math, thus suggesting that even small increases in reading skills can help students to perform better in math. Moreover, reading skills mediate the effect of all students' background factors and aggregated SES. In contrast with Licei, aggregated SES (and, in particular, classroom SES) explains a low proportion of variance in the dependent variable as shown by its regression coefficient that is statistically significant but low.

Professionali

Reading skills mediates both individual and aggregated SES. Moreover, individual SES effect drops down when aggregated SES is added into the model thus suggesting that peers' SES (aggregated at classroom level) is more strongly associated with individual math performance than individual SES. Such an association is statistically significant but less strong than in Licei. Such a result may suggest that the association between contextual factors is stronger in higher-SES contexts (i.e., Licei) than in low-SES contexts (Professionali).

Conclusion

In the present paper, I presented an empirical study based on Italian data and aimed at investigating how the mediating role of reading skills on the relationship between students' characteristics and their performance in math changes depending on the characteristics of the "learning context" students attend. Therefore, even though I showed that students' reading skills have to be taken as a prerequisite to learn and perform well in math, the results presented in the current paper also suggest that the effect of reading skills on students' performance in math does not work for all students exactly in the same way: the association between contextual factors and individual performance in math is stronger in higher-SES contexts than in low-SES contexts.

So, if by a side the results presented here suggest that teachers and/or researchers, in developing an integrated teaching approach, should not ignore the importance of reading skills but rather should include the improvement of students' reading skills as part of such an integrated approach, on the other side, they should (i) be aware of how the relationship between students' reading skills and their performance in math interplays with the external context, and (ii) work to tailor their teaching approach to their own students.

The study presented in the current paper shows some important limitations. First, I used students' performance in math as measured via INVALSI achievement tests as a proxy of students' attainment in math. As with this, reading skills as measured by INVALSI tests can capture just a part of students' reading skills. More investigation about how and why reading skills can affect students' performance in math is necessary to advance the existing knowledge.

Nonetheless, results based on INVALSI data allowed for a comparative analysis between different school types that represent very different learning environments, suitable to understand how the mediating role of reading skills on the relationship between students' characteristics and their performance in math changes by context.

The current paper can thus contribute to the ongoing debate about the construction of an integrated teaching approach by providing an empirical investigation of the possible intersectionality between the relationship between reading skills and math performan with students', classrooms', and schools' characteristics (Aikens & Barbarin, 2008; Caldas & Bankston, 1997; Marks et al., 2006; Perry & McConney, 2013). Understanding how the effect of factors affecting students' performance change depending on the context students inhabit is necessary in order to design an effective teaching approach.

Specialized knowledge to develop interdisciplinary tasks in the context of STEM education

Maria Cristina Costa[1,3] and António Domingos[2,3]

Keywords: Teachers' knowledge, professional development, STEM education, hands-on.

Despite increasing recommendations for implementing STEM (Science, Technology, Engineering and Mathematics) education, the literature identifies difficulties about its implementation by teachers (English, 2017; European Schoolnet, 2018). Appointed reasons are related to the need for teachers to acquire a robust Content Knowledge about the subject matters to be integrated (English, 2017). Therefore, it is necessary to offer them with a Professional Development Programme (PDP) that provides them with knowledge and skills to implement this approach in class. Recently, several authors refer the need for highlighting the role of the M in STEM, which also brings added challenges to teachers (Beswick & Fraser, 2019; Stohlmann, 2018). Therefore, it is crucial to understand what knowledge promotes the development and implementation of mathematical interdisciplinary practices within the context of STEM education. Concerning teachers' professional knowledge, the literature presents several studies such as Shulman (1986) that distinguishes three categories of Content Knowledge (CK): Subject Matter Content Knowledge (SMCK), Pedagogical Content Knowledge (PCK) and Curricular Knowledge (CuK). Other authors refer to the subject matters to teach such as mathematics (Ball, Thames and Phelps, 2008), science (Park & Oliver, 2008) and technology (Mishra & Koehler, 2006). However, there is a lack of research about the necessary knowledge for promoting STEM education, in particular by highlighting the role of the M. Therefore, our research question is: what knowledge is necessary for teachers to develop an integrated approach of STEM education with a focus on mathematics? Because the characterization of this knowledge is missing in the literature, this study is crucial for teachers, researchers, and also teacher educators who need to design PDP related to this approach.

This research is inserted in a broader project that includes a PDP, targeted to primary and middle school teachers, with the aim of providing them with knowledge and skills to develop and implement hands-on practices in class that promote an integrated approach of STEM education (Costa et al., 2020). To answer the research question, an empirical study was developed in the framework of the referred PDP for three school years. This training context brings added challenges for teachers to innovate their practices in class, namely mathematical practices related to STEM. With a qualitative methodology and an interpretative approach (Cohen, Lawrence, & Keith, 2007), data collected for three school years include participant observation during PDP and teachers' portfolios developed during the programme. Based on this data and teachers case study, it is concluded that there exists specialized knowledge dimensions that are crucial for teachers to be able to develop and implement the required approach. First, there is theoretical knowledge for example associated with some science themes such as electricity, sound or astronomy: TheoCK_S (Theoretical Content Knowledge to teach

Science). But to be able to implement hands-on experiments related to Science, teachers also need to know how to handle the equipment and materials to implement the hands-on tasks, which requires TechCK_S (Technical Content Knowledge to implement Science experiments). In addition, teachers need to have PCK to transform the specialized theoretical and technical knowledge in order to make them understandable to students, which leads to new dimensions: TheoPCK_S and TechPCK_S. Extending these new dimensions to tasks that integrate all the STEM subjects we propose the following dimensions of knowledge as presented in Table 1.

Table 1: Knowledge necessary to implement hands-on STEM experiments in class

SMCK		PCK	
TheoCK_STEM	TechCK_ STEM	TheoPCK_ STEM	TechPCK_ STEM

Based on our research, it is concluded that to effectively implement hands-on STEM integrated tasks in class, teachers need to acquire specialized knowledge as stated in Table 1. Finally, we suspect that the same knowledge is necessary for other grade levels such as secondary school, but more research needs to be developed in this matter.

What can be learned from mathematics teachers' experiences who teach an interdisciplinary STEM course

In the Netherlands, it is common that teacher training courses for upper secondary education educate for a single school discipline, such as mathematics. At the same time, teachers with a mathematics qualification are also formally competent to teach an interdisciplinary school course called Nature, Life and Technology (NLT), regardless whether it has been addressed in the teacher training programmes. However, teaching NLT is substantially different from teaching mathematics with respect to, for instance, pedagogy and objectives. In this paper we report on a study on experiences of mathematics teachers who, in addition to teaching mathematics, teach NLT. The experiential knowledge is meant to inform mathematics teacher educators who prepare students for interdisciplinary courses such as NLT.

Keywords: mathematics teachers in STEM, secondary education, teacher education, interdisciplinary

Introduction.

In the Netherlands, most teachers in secondary education are trained to teach a specific school discipline, such as mathematics. Although cooperation between and integrating of school courses are frequently encouraged in the Netherlands (Folmer, Koopmans-van Noorel & Kuiper, 2017), teachers collaborate mainly with colleagues of their own discipline, unless there is a need for cross-curricular collaboration within a school, due to thematic project work or a specific course. One course in which this is different is the interdisciplinary STEM course Nature, Life and Technology (NLT).

Nature, life and Technology is an elective course in upper secondary education. The objectives of the course are to strengthen the cohesion between science and mathematics and to increase the attractiveness of science education (Stuurgroep NLT, 2007). In this course, students work on complex real-life problems for which they need knowledge from mathematics, physics, chemistry, biology and physical geography to solve these. The course has a modular structure. With each module, students are working on new problems around a topical issue using teaching materials developed through collaboration between teachers and universities or organizations specialised in the topic. Teachers work within a team of teachers with different competences and backgrounds, mainly mathematics, physics, chemistry, biology and geography. Such team of teachers is called an NLT-team.

Teachers who participate in these kinds of activities are confronted with other learning and teaching situations as in their disciplinary course and as a consequence will have to relate to these experienced differences. For example, NLT requires attention for overarching ideas such as the interplay between the natural sciences and technology, and not merely attention for specific disciplinary concepts, such as finding an exponential formula given two points. The usual pedagogical approaches in NLT are also different from those in mathematics school courses, since a lot of coaching of group work is done in NLT. In addition, NLT often uses different assessment formats than the exercises that are customary in mathematics (Den Braber, 2020). Knowing that there are such differences between the courses, it can be argued that mathematics teacher training should prepare future teachers for teaching NLT and for dealing with these differences. Especially, when these differences should indeed be dealt with according to mathematics teachers that teach NLT and knowing that it is considered important that mathematic teachers participate (Stuurgroep NLT, 2007).

However, it has become clear that preparation for NLT is marginal in most mathematics teacher training programmes. Consequently, dealing with the differences will in most cases have to be learned after the teacher training course, during working life, if a teacher chooses to participate in NLT. However, opting for teaching NLT requires some lived experiences in NLT and experiencing the differences with teaching mathematics. However, it is known that mathematics teachers do not seek such experiences in working life easily. Mathematics teachers participate less in NLT than teachers of the other related disciplines such as physics or biology (Den Braber et al. 2020). Mathematics teachers indicate that they do not always see a role for themselves in NLT. Teachers who are unfamiliar with NLT may find it difficult to envision what is required to teach NLT and compare teacher requirements to their own knowledge, skills and attitude to determine whether participation is even feasible, let alone appealing. Teachers who have taught NLT will have formed an image of what is required to teach a course such as NLT and will have found ways to act accordingly.

Despite the fact that mathematics teachers currently participate less in NLT than teacher of sciences, there are some mathematics teachers who are successfully part of an NLT-team. The fact that it is possible and can be successful raises the question whether we can learn from the experiences of these mathematics teachers to help prepare future mathematics teachers. It is this question that led to a study with the underlying research question: How do qualified mathematics teachers shape their role within a NLT- team and deal with mathematics in NLT?

In this paper we will describe results regarding to what the experiences teach us about the possibilities for mathematics teacher training programmes to enable lived experiences in teaching NLT for future mathematics teachers.

Conceptual framework

Analysing the experiences of a teacher within NLT requires a framework that describes a learning process of a teacher in his or her work in the broadest sense. It is not only about the knowledge of the teacher but also about the actions, feelings, motives and foresight within the context of a person's working environment. Roth & Lee (2007) indicate that cultural-historical activity theory (CHAT), because of its focus on processes and individual and collective agency, can be the analytical lens for learning processes in lifelong learning, both in formal and informal (work) situations as well as in educational settings.

It is for this reason that we make use of a CHAT-based analytical perspective on learning processes while engaged in work processes (Mazereeuw, 2020). This perspective depicts a process in which experiences at the workplace are internalised (Zittoun & Gillespie, 2015) and, depending on the interpersonal dialogue are stimuli for envisaging new action possibilities and actions within the work process. Acting on these new perspectives and action possibilities through experimenting can also create new experiences. Hence, experiential learning processes are not linear. Because of the reciprocal nature of the interpersonal process and the social and material consequences in context it is much more dynamic. To emphasize the reciprocal nature of the process we included insights of the Dialogical Self Theory (Hermans, 2001).

The idea of the dialogical self is that a person mirrors experiences with ones knowledge, perspectives, norms and values in an internal dialogue and that these experiences can be re-lived and re-framed beyond the actual experience itself. So, the internal dialogue is an interpersonal process -within the mind- in which a person relates to the lived and re-lived experience. CHAT emphasizes that an internal dialogue can result in the desire to act, especially when frictions are experienced. For instance, a person perceives that contributing to the work calls for knowledge and skills that the person does not feel confident about. When that person wants to continue to participate in the workplace, new action possibilities will be sought out. Therefore, frictions, or the commonly used term contradictions, are often a source of change and development as described by Engeström (2011). We tried to capture the internal dialogical process in four compact questions someone asks aware or unaware. The first question is ‘How do I understand what is going on (with me, others in the environment)?’. Understanding includes ones own perceptions of knowledge of the workplace, division of labour and workplace goals, norms, emotions and values. The second question is ‘How do I value this?’. Here a person mirrors this conception of the experience with what matters to the person, what the person finds important. The third question is ‘Should I do something about this or not?’. This question refers to the motive to become an actor and to contribute to the workplace. The fourth and final question reads ‘What can I do to contribute and/or to engage the friction?’. This question refers to the way a person depicts his or her own role in the situation and how that person envisages action possibilities that might help to contribute to a solution or to engage the friction.

The questions above show that this process may well be influenced by previous work and teaching experiences. That is probably also the case for NLT teachers who have experiences in another school course or have worked in different fields before entering the educational system. Figure 1 schematically represents the dialogical processes when interpreted for teaching NLT.

In order to provide insight in the possible frictions that initiate internal dialogue in teachers we conceive teaching of NLT as an activity within an activity system. To portray the activities we make use of the commonly used model of Engeström (1987), which builds on the ideas of Vygotsky and Leont'ev. The model shows that human action can be seen as an interaction between a person (*subject*), a certain goal (*outcome*) and cultural artefacts that support and shape this action (*mediation*). Furthermore, the goal-directed actions of an individual cannot be separated from its social and material context. An activity system consists of relevant others (*community*), with values and norms (*rules*) and with a division of labour.

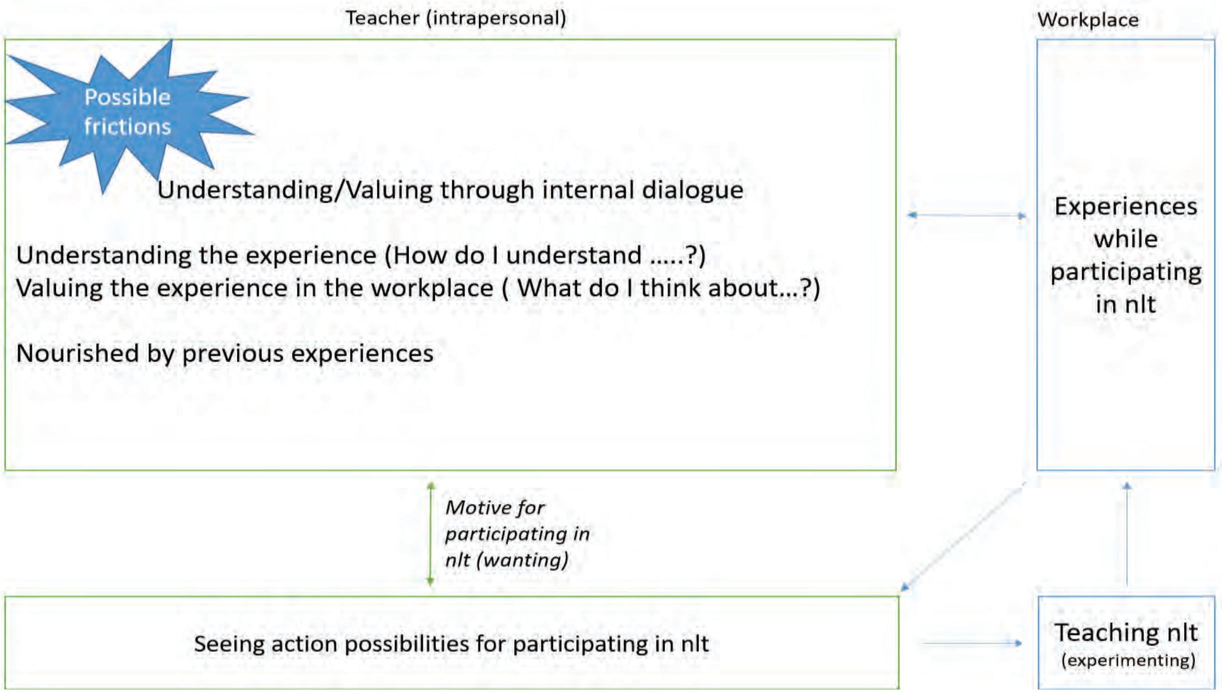

Figure 1: Processes of learning through experiences, based on Mazereeuw (2020) exemplified for teaching NLT

Unlike Engeström, we use the model as a means for portraying a teachers' thinking about the activities in which they participate, shown in figure 2. As indicated above, a person ones social and material work environment and places oneself within it. In this study Engeström's model is used to guide the data collection and analysis and find out how teachers think about their own discipline and NLT and the frictions therein. Teaching NLT in a secondary school can be conceived as a goal-oriented activity in an activity system in secondary education. This is done by using certain teaching materials and supportive (digital) resources (*instruments*) which are in accordance with a national examination program and a plan for assessment, etc. (*rules*). Teachers are part of a professional group of teachers. They have to deal with parents, colleagues within the school who all want NLT to be taught (*community*). Mathematics teachers can be part of an NLT-team which is another community with another set of (informal) rules, and another division of labour compared to the activity of teaching mathematics.

The outcome of the activity deserves a closer look because the outcome of the activity system NLT is still ambiguous. Even though there is an examination programme, it leaves a lot of room for teachers and NLT-teams to formulate their own objectives, objectives that they feel are fitting for NLT. Moreover, Braber et al. (2019) made clear that the general aims of NLT are still debated on and when it comes to mathematics in NLT are not clear to both mathematics teachers and students. So, looking at the way teachers view NLT we can assume that the outcomes pursued are diverse. It is therefore of interest to find out what mathematics teachers view as the outcome of teaching NLT especially with regards to the role of mathematics. In school mathematics learning mathematical skills is seen as the outcome of the activity system. Within NLT mathematics can be described as an instrument, a means to an end. William and Roth (2019) claim that the more disciplinary courses are a goal by itself, the more difficult it becomes to work interdisciplinary.

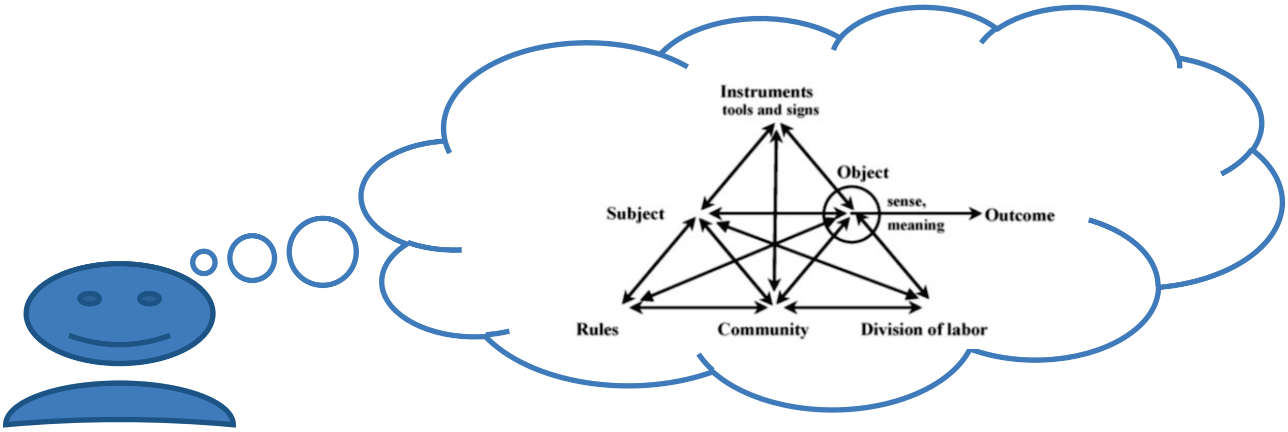

Figure 2: The envisaged activity system by the NLT teacher of the activity in which the teacher participates.

We started with the idea that through an internal dialogue a person mirrors experiences with ones knowledge, perspectives, norms and values. We portrait the envisaged activity using the model of an activity system where the teacher is the subject.

Data collection and analysis

In order to find out how qualified mathematics teachers shape their role within a NLT- team and deal with mathematics in NLT six male and four female qualified mathematics teachers all teaching NLT were interviewed. The teachers varied in age, work and teaching experience and work in different schools around the country. Following the first interview, an additional interview was conducted with a second member of the same NLT-team to triangulate the data of the first interview and evaluate the interview set-up. This led to small changes in the preferred order of the interview questions.

The interviews were meant to provide insight into how mathematics teachers conceive their role within NLT and what thoughts existed about the role of mathematics within NLT. Questions were asked about frictions that teachers experience when teaching NLT, and whether or not these were due to possible differences with the teaching of mathematics. We also asked how they have dealt with these frictions.

The interviews had the character of a conversation about NLT in which the interviewer also provided information about NLT and gave background information when needed. For example, sometimes the teachers asked questions about the organisation of NLT in other schools. The interview can best be characterized as a semi-structured interview. The interview set-up contained a number of topics and questions related to the conceptual framework. The order in which the questions were asked depended on the course of the interview. However, it always started with a few practical questions about background, teaching experiences, current teaching tasks and past work experiences. This was followed by questions about the experience with NLT, their role in the NLT-team and the possible differences between activities when teaching mathematics and NLT. For example, they were asked whether they experience differences in the use of teaching materials or teaching methods (*instruments*), collaboration with colleagues (*division of labour*) and which agreements concerning NLT have been made within the school (*rules*). When frictions were put forward by the teachers, questions were asked about the teachers' views of knowledge, skills and attitude towards interdisciplinary teaching and NLT. The role in the NLT-team and the connection between curricula of mathematics and NLT were also addressed. The interview ended with questions that invited the teachers to talk about their thoughts on the role of mathematics in NLT.

The recorded interviews were transcribed. Semantic units (Aviv, 2001) were categorised using elements of the activity system, and the labels (personal) beliefs, knowledge and skills and attitude towards NLT based on a division by Ernest (1989). For instance, a teacher stating which teaching materials are used in the classroom is labelled under *instruments*. Frictions experienced by teachers were noted as well as previous experiences when stated by a teacher. For instance, the following semantic unit illustrates an experienced friction concerning the subjects knowledge for teaching NLT compared to teaching mathematics.

Teacher: Mathematics, you can just ask me about that, I know it, but with NLT I sometimes doubt my answers are completely correct. […] makes me less comfortable.

Data analysis further focused on the role of each mathematics teacher within NLT. First, we looked at their view on the role within the NLT- team to see if there are similarities or differences. Then we looked at the relationships between how teachers describe their own teaching in NLT and what they see as objectives for NLT. i.e. the subject-instruments-object/outcome relationship. A third analysis focussed on each teacher's orientation towards the objectives of NLT. The emphasis was the teachers' views on intended objectives of mathematics within NLT and views on the overall objectives of teaching NLT. A fourth analysis concerned the frictions each teacher experienced. All frictions mentioned by the teachers were gathered and positioned in an activity system to see if there were similarities or differences in the experienced frictions. Peer-debriefing was used in the process of coding and interpretation.

Results

When we look at division of labour in the NLT-teams, the role of the mathematics teachers vary from teaching a statistical module by themselves, to teaching a science module with a physics teacher. Some are teaching modules with a strong biological component involving the brain or navigation of birds which they had to make their own. With the exception of one, the teachers seem comfortable with what they do because of earlier experiences in which they have acquired knowledge or skills before teaching NLT. The one teacher that was not comfortable assisted teachers from other disciplines only for a few lessons. She was asked to help students with differential equations and modelling with in a spreadsheet. This teacher felt a friction due to her view of her own knowledge of science and the lack of overview of the teaching module.

NLT is seen as a course where mathematics is applied and where mathematics can be useful, especially with regard to mathematical modelling to help solve the problem at hand. So the view of most teachers seems to be consistent with the objectives of NLT. However, often the teachers thoughts of these objectives themselves and their personally desired outcomes do not always correspond with the intended curriculum of NLT. Teachers seem to formulate their own objectives as the formal objectives of NLT are not really known. The latter is specifically the case when it comes to the use of mathematics or the reflection on the role of mathematics in the examination program.

Most teachers are not familiar with objectives in NLT that focus on the importance of mathematics. The ones that do report difficulties translating this for students.

The frictions teachers experience also seem to vary. Much of these frictions have to do with conditionalities. In some schools it is hard to have meetings with the NLT-team because disciplinary faculty meetings are held at the same time and require a teachers attention. Nevertheless, working with other colleagues is viewed as worthwhile and desirable even though it can take some getting used to. Working with and preparing the teaching materials of lessons in NLT generally takes more time than preparing mathematics lessons. On the other hand, teachers also seem to appreciate the freedom they get as they are free to adjust materials, add or skip parts of the content and assignments. Some experience difficulties with the motivation of students because students seem to give priority to the disciplinary courses for which they also take exams. Some teachers indicated that seeing that they only teach one or two modules a year, building a relationship with students can be more difficult than in mathematics lessons.

What stands out in the analyses is that teachers with previous experiences in actual interdisciplinary work environments or with mathematical modelling experience less frictions teaching NLT. In fact, two of those teachers commented that they experience frictions with the way they have to teach mathematics instead of with teaching NLT as it is so different to what they are used to.

Discussion

The freedom to find ways to teach NLT that align with a teacher's personal point of departure has been important for teachers. Especially, since this freedom has been a way for teachers to deal with frictions they experience while teaching NLT. This may indicate that teacher training should focus on the flexibility of working with teaching materials and to encourage experimenting with their pedagogical choices. Even though this is also encouraged in mathematics teacher training, research shows that mathematics teachers are still mainly focused on the textbook (Woldhuis et al., 2018). This is not possible within NLT if a teacher wants to feel comfortable teaching. NLT offers a lot of freedom to make pedagogical choices and many different roles are possible as a teacher, but a teacher has to be aware of the objectives of NLT. Specifically, when it comes to the role of mathematics and the idea of interdisciplinary work. This may have consequences for teacher training programmes, knowing that we saw differences between teachers in dealing with interdisciplinary objectives depending on their background and work experience. This could mean taking into account the different personas in teacher training and take advantage of the lived experience with applied mathematics when present. Teacher training should also support reflection on the role of disciplinary mathematical knowledge when working on an interdisciplinary problem. Seeing mathematics more as an instrument than a 'product'. Something that the some interviewed teachers found difficult to do. Training programs could therefore pay attention to beliefs on mathematics in relation to the sciences. Starting, for instance, with one discipline that is closely connected to mathematics, like physics (Nguyen & Krause, 2020), but perhaps ending with letting students experience mathematics or mathematical modelling in corporate life or interdisciplinary working environments. This could support teachers in letting their students experience how mathematics can help with real-life interdisciplinary questions and discuss the contributions mathematics can make in solving real-life problems.

Introduction

Following European Union recommendations, many countries have incorporated the competence-based learning approach in their curriculum. This approach aims to prepare citizens for current and future challenges in Science, Technology, Engineering, and Mathematics (STEM, Diego-Mantecón et al., 2021a). To provide citizens with the necessary competences, there exists an increasing interest to integrate Arts into STEM, in the so-called STEAM Education.

STEAM education entails teachers crossing boundary disciplines to adequately integrate content. In countries like Spain and Greece, secondary education teachers are usually qualified to teach a single discipline. In an integrated context, it means that teachers must design and implement activities involving content from disciplines in which they did not receive specific training. In STEAM activities science and engineering disciplines often take a dominant role (Martín-Páez et al., 2019), whereas mathematics appears in a basic and utilitarian manner (Lasa et al., 2020). Recently, Diego-Mantecón et al. (2021b) found disparities in the characteristics of the STEAM activities implemented by in-field and out-of-field mathematics teachers as well as in the manner they exploit mathematics. In-field mathematics teachers, unlike the out-of-field ones, seem to avoid transdisciplinary projects (based on real experiences) because of the difficulty in addressing school mathematics. Even when implementing interdisciplinary projects (contextualized based experiences), mathematics teachers encounter problems to meaningfully exploit mathematics and promote high cognitive demands. As consequence, Diego-Mantecón et al. (2021b) suggest developing training programs focused on reproducing experiences in collaborative environments, where both in-field and out-of-field mathematics teachers cooperate to construct and deliver knowledge.

The study

Following Diego-Mantecón et al.’s (2021b) suggestion, we attempt the so-called STEAMTeach project (https://www.steamteach.unican.es/), which is a Teaching Professionalism European-funded initiative based on the Erasmus+ Programme. The objective is to design a cross-cultural STEAM professional development (PD) program for training in-service teachers to exploit mathematics within a STEAM context at middle and high schools. To design this PD program, we firstly interviewed 25

STEAM trainers in five countries: Spain, Austria, Finland, Greece, and Hungary. The interviews helped to identify issues obstructing the implementation of STEAM activities in school classrooms. In the next, we report a preliminary framework emerging from the Greek and Spanish data.

Results

The analysis revealed that trainers agreed on the importance of introducing teachers to theoretical aspects of the integrated STEAM education approach and to the following four active methodologies: (1) collaborative learning, (2) design-, (3) inquiry- and (4) problem-based learning. Based on these outcomes, we devised a preliminary PD framework comprising three blocks: a theoretical block in which, through different sessions, teachers are introduced to STEAM education and the methodologies listed above; an experimental block where teachers, grouped in teams, have to attack a series of STEAM activities in the same way that their students would do it; and an implementation block where teachers are requested to design and implement activities in their classroom with the trainers' support. After executing the first round of training courses, we observed that this preliminary PD framework allows teachers to gain insights into the meaning of STEAM education and its application in the classroom, as they were forced to experience the difficulties that arise in different STEAM contexts. This in turn increases teachers' confidence to implement their STEAM activities and exploit school mathematics. Importantly, this preliminary PD framework is under an iterative process of implementation and evaluation, and hopefully subsequent training courses will provide us with extra data to refine the initial framework into a more consistent and reliable instrument.

This study examines how a tinkering task in visual programming environments can provide opportunities for developing problem solving skills. We pursue this by analyzing eleven students in year 8 working with a tinkering task in a visual programming environment during a mathematics class. They were asked to create repeating patterns. Their work and discussions were analyzed through a lens of abstraction and decomposition, two elements of computational thinking. The analysis reveals how some students became thoroughly engaged in problem solving while others had a shallower experience of randomly manipulating the pre-made code. Since it was not the difficulty of the task but rather the random outcome of their manipulation of the code that determined whether they became engaged or not suggests that there is a need for support structures to fully tap into the potential of tinkering tasks to elicit problem solving.

Keywords: Problem solving, tinkering, computational thinking.

Introduction

Coding is now, by the year 2020, incorporated in elementary school curricula in many countries around the world. Sweden, amongst others, has incorporated it into the mathematics curriculum and transforming the curriculum into an integrated science, technology, engineering and mathematics (STEM) curriculum in the process. Feurzeig et al. (2011) envisioned a school system where coding could be viewed as a means toward learning mathematics and developing problem solving skills. This cross-section of coding and mathematics situates coding in a STEM-context in Sweden. Coding has since then become framed within the bigger idea of computational thinking (CT), problem-solving by drawing on the concepts fundamental to computer science (Wing, 2006). The educational research literature does not adhere to one conceptualization of CT, nor how one can operationalize CT in the classroom practice for young pupils (Brennan & Resnick, 2012).

Problem solving is highlighted in both mathematics education research and the classroom practice as an important skill and a means for developing understanding (Hiebert & Grouws, 2007). It can be viewed as moving from the world we live in, to the world of symbols, that can be shaped and manipulated (Freudenthal, 1991). Problems are interpreted in the language of mathematics, creating models that has potential to say something about the real world. CT implies that this can be done by applying technical solutions through a process of breaking down the problem into decontextualized subproblems (abstracting and decomposing) which are interpreted in the language of digital technology (code). There are several similarities between problem solving skills in mathematics and programming, and a potential for mutual benefits in terms of learning (Feurzeig et al., 2011). Bråting and Kilhamn (2021) discuss this by pointing out intersections between algebraic thinking and CT with tasks for young children, e.g., that both contexts use variables, but also points out that they are not necessarily understood in the same ways in both contexts and therefor introduce a potential conflict for learners.

Programming has a steep learning curve as it entails learning a new language to express oneself in. Kotsopoulos et al. (2017) suggests tasks where students modify pre-made code to make the learning experience more accessible and there are also visual programming environments (VPE) where code is represented as building blocks (Figure 4). A recent review of research on CT in the VPE Scratch[1] concluded that there is need for studies that make sense of the quality of understanding that students develop while programming (Fagerlund et al., 2021). However, problem solving that requires creative reasoning is hard and requires careful design of tasks and instruction (Jäder, 2019). There is a need to better understand design-elements of tasks to design instruction to engage primary schools' youngest students in tasks with potential to develop their CT. Our guiding question is *how can tinkering tasks in visual programming environments provide opportunities for developing problem solving skills?*

We will pursue the question by analyzing students' CT in a tinkering task which was a part of a design research project in mathematics education. We will use a lens of abstraction and decomposition to analyze students' actions in a VPE and discuss opportunities to develop CT from a STEM perspective.

Abstraction and decomposition

Solving a problem is a process of analyzing the problem, devising a plan and carrying out the plan (Polya, 2004). A way to approach this process is to make the problem more accessible (ibid.), e.g. by drawing a picture, find an analogous or auxiliary problem or break down the problem into more manageable subproblems and later recombine the solutions to a solution for the original problem. Burke (2012) describe similar processes in how middle school students can be taught to solve programming problems. The whole concept of CT can be thought of as "thought processes involved in formulating problems so their solutions can be represented as computational steps and algorithms" (Aho, 2012, p. 832). Kalelioglu et al. (2016) propose a framework for CT based on a systematic literature review that starts in Abstraction and Decomposition. Abstracting is the ability to focus what is essential and ignoring what is not (Wing, 2008) and thereby making the problem more accessible. What is then abstraction when speaking about young students' ability to abstract? Let us imagine a student that want to include a fish swimming from point A to point B in a VPE project. The student realize that the code needs to include the movement of the fish and the direction of the movement, but it doesn't really matter if the fish is green or purple. The problem to solve is how to get from point A to point B. The student must manage to see what is important and what is not (abstracting), to be able to solve the problem. Decomposing into

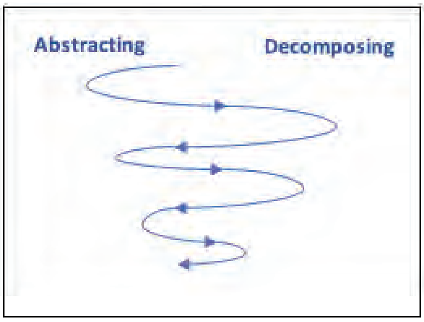

Figure 1. A spiral representing how we conceptualize the computational thinking processes abstraction and decomposing

[1] Scratch is a visual block-based programming environment developed by MIT. It is developed to be suitable for introduction to programming for young students since the pre-made blocks of code lowers the threshold of learning syntax to be able to code.

subproblems is the ability to solve problems by breaking them down into smaller more manageable problems. The student with the swimming fish needs to break this problem down into smaller pieces in order to solve it. One part of the problem is to make the fish move just far enough to get from point A to point B. The other part of the problem is to figure out which direction will get it to the right spot. Two subproblems to solve one problem. Whether one views these two processes as one, e.g. the CT practice (Brennan & Resnick, 2012), or as two, e.g. two tools when attacking large and complex tasks (Wing, 2008), they are closely intertwined. We choose to visualize this in a downward spiral, see figure 1, as we envision it having a direction towards the solution of the problem.

Solving a mathematical problem involves analyzing the problem, devising a plan and carrying out the plan (Polya, 2004). We connect this to our visualization of CT in three practices, visualizing an idea, formulating a plan, and translating into code, see figure 2. Steps of abstracting and decomposing moves the student forward towards a solution of the problem within a computer environment. The student with the fish starts in an idea, wanting to create a scene from the ocean. Acts of abstraction enables the student to figure out what parts of the idea are essential to create the impression of an ocean and every essential part has to be decomposed into solvable sub-problems to devise a plan. This plan, as an intermediary step towards writing an instruction that a computer could understand, is sometimes called a pseudo code (Weintrop et al., 2016). The plan is then carried out within the syntax of the coding environment, i.e., code-blocks in the VPE case.

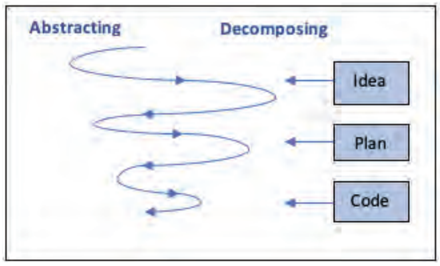

Figure 2. The computational thinking spiral with three stages of problem solving written in, Idea, Plan and Code

This spiral movement visualize the student getting deeper into the problem-solving process, working towards solving subproblems that eventually adds up to a complete solution. The student shift back and forth between the practices, modifying the *idea*, formulating and revising a *plan*, and produce *code*. The student in the example had an idea to create an ocean. The ocean was abstracted into a few essential parts that would make the viewer understand it is an ocean, for example a couple of moving fishes. Those essential parts constitute the plan. As the student start to deal with a problem one at the time, abstracting and decomposing in an iterative process, the processes lead to coding.

The type of subproblems that students engage in depends on the type of task (Eckert & Hjelte, 2021) and whether the subproblem constitutes a problem or not depends on the student. We adhere to the definition of a problem as when the solution method is not known in advance to the learner but require creative reasoning (Lithner, 2008). Tasks where students program for motion, typical to VPEs, tend to put programming subproblems in the foreground and mathematical subproblems in the background (Eckert & Hjelte, 2021). Bråting and Kilhamn (2021) question whether VPEs developed for the purpose of developing students' CT is the future of mathematics education. Even though there are similarities between algebraic thinking and CT, objects such as variables exists in both worlds, how we make sense of those objects differs. Benton et al. (2017) provide evidence for how carefully designed tasks have potential to develop both algebraic thinking and CT, e.g. the idea of the 360° total turn. The risk is though that one or the other gets lost in the process of creating code (Bråting & Kilhamn, 2021; Eckert & Hjelte, 2021).

Method

The present paper focuses on reaching an understanding of how tinkering tasks in VPEs provide opportunities for developing CT. The analytical process of this paper is that of an abductive approach (Alvesson & Sköldberg, 2009). We propose an analytical lens to view the data through, and then allow for the emerging insights into the students' CT process to influence the initial theorization. The idea of the CT spiral is meant to inspire cycles of future design experiment (Cobb, Confrey, diSessa, Lehrer, & Schauble, 2003) on programming in mathematics classes in the first years of primary school. The CT spiral is used here as an analytical framework in a retrospective analysis using constant comparisons (Gravemeijer & Cobb, 2013). Instances of data are compared to find similarities and differences related to abstraction and decomposition in the data. Looking for indications for when students relabel an object by focusing on certain aspects (abstraction) and when students try solving a subproblem by focusing on one aspect of the object (decomposition).

The data set used in this analysis are video screen captures of student work in the VPE and recordings of their verbal communication, generated within a larger design project concerned with digitally enhanced mathematics education. The tasks utilize the idea of engaging students in actual programming tasks and asking them to reason about the results. The design hypothesis was that the tasks would trigger students to develop their ability to solve mathematical problems using computers. The empirical study was performed with a class of 20 students in year 8 (aged 13/14) in Sweden using a tinkering task. For this particular task, eleven out of those 20 students' screens and discussions were captured through a screen capturing tool for analysis. The students were given a pre-made code in scratch (https://scratch.mit.edu/projects/250218077/) that drew a shape we called a snowflake. Figure 3 and 4 depict the code and result. The inner loop, that repeats twice, contain moves and turns that create the shape of each point of the snowflake. The outer loop, that repeats 8 times, creates the number of points and the angle between them. The task was to create their own repeating pattern based on the pre-made code. This type of task is called a tinkering task (Kotsopoulos et al., 2017) and is an established task design as students immediately are confronted with the intended problem-solving process. Students are meant to make simple modifications to an existing computer program to elicit questions such as "What if I change this part of the code?". Visual programming environments are especially suited for such tinkering because of its low threshold regarding programming syntax (Resnick et al., 2009) and its focus on exploration (Kotsopoulos et al., 2017). The result section in this paper includes a summary of the analysis of all eleven students as well as an in-depth analysis of one student's work. Transcripts are translated from Swedish to English by the authors. Names used are fictional.

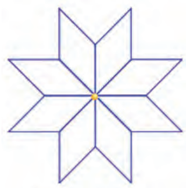

Figure 3. The snowflake

Figure 4. The tinkering task's pre-made code

Results

Our analysis indicates that tinkering tasks in visual programming environments provide both opportunities and challenges for developing CT in terms of abstraction and decomposition.

Reviewing all eleven students showed that in cases where we could detect a formulation of both an idea and a plan in the students' work, the task managed to engage the students in CT during the allotted time. In cases where either an idea, plan or both were missing, there were few indications of CT. The task type seemed to encourage CT in cases where random changes in the code produced new unfinished patterns that interested the students. In cases where the random changes either produced a finished pattern, or a pattern that was not pleasing to the student, the process came to a stop and did not elicit further CT. Following is Nevin's work, who together with Jasper produce interesting unfinished patterns in their random changes that they pursue and try to complete. Their random changes of the turn-blocks of the original code (see figure 3) resulted in a open snowflake shape (see figure 5). Their actions thereafter indicate that they have an idea what they want to accomplish. The idea seems to be to create a closed version of the open new snowflake shape.

Nevin:	It has more repetitions.
Jasper:	You need more repetitions.
Nevin:	I know.
Jasper:	12, pick 12.
Nevin:	Do you think 12 is enough.
Jasper:	I think 12.

Nevin and Jasper analyze their snowflake shape and we interpret Nevin's utterance It has more repetitions as him identifying that the new shape has more repeating shapes than the original snowflake. We interpret Jasper's call for more repetitions as abstracting the notion of points and decompose their idea into the subproblem of filling the gap in the shape with more points. Nevin agrees that this is their plan. Together with their actions on the screen when they place the marker in the outer loop, the plan of adding more points to the snowflake is abstracted into being about repeating particular chunks of code more times, and they settle on twelve. Twelve repetitions are however too much so they try with ten. The change to ten repetitions does not close the shape completely, and this exchange follows.

Jasper:	There is one more needed.
Nevin:	No … we can try but I don't think so.
Jasper:	But, like this. It is one line that is not used. This line. Get it Nevin.
Nevin:	They must connect at the end.
Jasper:	Yes.
Nevin:	But it isn't possible.

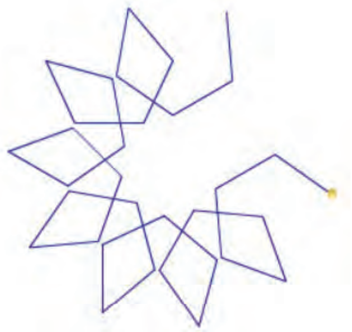

Figure 5. An open snowflake shape that requires more points to close

Jasper is set on their original plan of adding repetitions to close the shape. However, Nevin has spotted that even if they do so, the lines will not line up perfectly. To make the lines connect after one lap, the rotation-block in the outer loop needs to be a devisor to 360. Nevin seems to have spotted this visually from the picture and insinuate that they need to revise the plan.

Jasper:	Maybe have to … do more steps. No, nothing will happen. Maybe more degrees or something.
Nevin:	No, I don't think I will change anything.
Jasper:	But I think so because 65 65 65 does not add up to 360. That's why.
Nevin:	What is it then? How should I change it then?

To revise the plan, Jasper searches for aspects of the idea of a closed snowflake shape to abstract. He rejects the aspect of size and instead abstract the aspect of angles between each point of the snowflake.

Nevin does not agree but Jasper has decomposed the aspect to a subproblem of divisibility. In a previous task with simpler geometrical shapes, the key feature was to make the turn-blocks add up to 360. Their new plan is to use angles that are divisors to 360. Jasper and Nevin start by changing all the turn-blocks to 120 with the argument three times 120 is 360 but change their minds.

Jasper:	120 … you have to split it.
Nevin:	Yes. [whispers: I thought] … but what does 120 become then … 60 60 60. Otherwise it doesn't add up to 120. Does it add up to 120.
Jasper:	No
Nevin:	No. If I do 60. No I need to have the same or.
Jasper:	Yes but this must be higher.
Nevin:	Why.
Jasper:	It must be. What must it be … it must be … 90 it will be then. Wait. It was 45 from the start. Then that one was 135. So I think you need to have it to 180. Yes try 180.
Nevin:	How about this one?
Jasper:	It should be 60.

We see how the CT process elicited by the tinkering task has engaged the students in a mathematical reasoning. Their plan is to use divisors to 360, i.e. 60, 120 and 180 degrees. However, their understanding of the code is lacking which shows when the attempt to abstract elements of the plan into code. Based on the original code, they use 120 and 60 degrees in the inner loop since it adds up to 180 just as in the original code. The turn-block in the outer loop is set to 60 degrees. The end result is a shape very similar to the original snowflake, but at least it is closed which was in line with their idea and the time for the task runs out.

Analyzing the eleven students resulted in three different categories of actions, 1) students who maintained a CT process throughout the activity, similar to that above. Six students ended up in this category. In the other two categories did students not engage in a CT process, but those are difficult to showcase with transcripts. However, they both had in common that the task did not elicit a formulation of either an idea or a plan or both but their reasons why were different. 2) Students who, by mere chance, generated what was deemed by the student as an acceptable repeating pattern never got the chance to formulate an idea to continue working with. Two students were in this category and figure 6 shows an example of how such shape looked like. The engagement with the task stopped when the student achieved this shape from the first manipulation of the code. 3) Students who generated a shape that had potential to start a CT process but did not take time to abstract what were key aspects of their idea of the emerging shape that could be decomposed into manageable subproblems. Those did not formulate plans. Working without plans resulted in aimless manipulation of the code which either made the students give up or resulted in completely different shapes and a reformulation of the idea. Three of the analyzed students were in this category.

Figure 6. A closed shape produced on a student's first try

Discussion

Tinkering tasks in visual programming environments provide both opportunities and challenges for developing CT in terms of abstraction and decomposition. On the one hand, the pre-made code provided limited freedom to create a clear idea of what to achieve and the accessibility encourage a planless revising of code did not elicit abstraction and decomposition. On the other hand, the low threshold of working with a pre-made code provided opportunities for some students to quickly engage in solving subproblems of both programming reasoning and mathematical reasoning. Such opportunities for integrated STEM learning merits further discussion.

Tinkering as a pedagogical activity in a VPE can be summarized as exploration (Kotsopoulos et al., 2017). It aligns with our findings, that students explore different randomly generated shapes. However, there were big differences in their engagement in problem solving. Students who immediately arrived at a shape they were happy with, hindered them from formulating problems which solutions could be manifested in code, essential to CT processes (Aho, 2012). Students who got stuck in unreflected exploration, who never formulated a plan connected to an idea, were not supported enough to decompose their idea into more manageable subproblems. Only students who were lucky enough to arrive at acceptably unfinished shapes were engaged in abstraction and decomposition. Those 6 students in the analysis created subproblems related both to coding and mathematics and thus had similar experiences as those in the Benton et al. (2017) study. The remaining 5 students never engaged in problem solving or mathematical reasoning and thus had the lesser experience pointed out by Bråting and Kilhamn (2021).

This tinkering task's advantage and disadvantage was the low threshold to coding. It was not the difficulty or novelty of the task that usually elicit creative reasoning (Lithner, 2008) but rather the random outcome of the low threshold exploration. The task itself seemed to fulfil the criteria of not having a known solution method and was engaging to the students. It leads us to believe that it is not the task itself that needs the careful designing to elicit creative reasoning proposed by Jäder (2019) in similar settings, or the positioning of mathematics as proposed by Eckert and Hjelte (2021) but rather support strategies that can help those students that for one reason or the other never engages in the problem-solving process. There are more aspects of STEM related problem solving activities in the cross section between coding and mathematics to explore. We invite researchers to use our model of analyzing a CT process to evaluate how support structures connected to tinkering tasks in VPEs can elicit STEM related problem solving experiences to a higher degree in the classroom.

Investigating middle school mathematics teachers' views on innovative learning activities

Elçin Erbasan[1] and Erdinç Çakıroğlu[2]

[1]Middle East Technical University, Faculty of Education, Ankara, Turkey; erbasan@metu.edu.tr

[2]Middle East Technical University, Faculty of Education, Ankara, Turkey; erdinc@metu.edu.tr

This paper describes a phenomenological study exploring middle school mathematics teachers' views, enablers, and barriers regarding innovative mathematics learning activities by investigating their experiences. The study also aims to determine their suggestions that may lead educational stakeholders to increase the quality of instruction and student learning. Data collected from the interviews and qualitatively analyzed reveal that the enablers mainly were related to receiving support and positive feedback from others. The barriers were associated with time, students' learning habits and classroom learning culture, work environment, and preparing activities. There is a need for providing training and resources for teachers for better mathematics education. Integrating such activities into the curriculum, developing effective training programs, and supporting teachers for successful implementation are the implications based on the findings.

Keywords: Innovative mathematics learning activities, STEM education, mathematical modeling, middle school, teaching practices

Introduction

Today's societies are expecting qualified individuals equipped with 21st-century skills to keep up with the era since technology and information are rapidly produced, developed, changed, and consumed. One of the most crucial factors in achieving the goal of developing individuals with 21st-century skills, identified by educators and economists, is education. However, formal education institutions that mostly use teacher-centered instruction which promotes rote learning and memorization, may negatively affect the need for a qualified workforce and inevitably become insufficient to integrate real-life into the instruction (Akgündüz et al., 2015). In other words, traditional educational practices are insufficient and ineffective to raise individuals as required by the 21st-century (Borich, 2017). As a result of the rapid changes in the globalizing world based on technology, business, and industry, countries have been forced to implement innovative policies in their educational systems as an inevitable result of the change.

There are many approaches in which 21st-century skills can be targetted, including inquiry-based learning, discovery learning, problem-based learning, project-based learning, technology-assisted learning (Westwood, 2008), and STEM education (Barakos, Lujan & Strang, 2012) in the educational literature. The theoretical and practical background of problem-based learning (Hung, Jonassen & Liu, 2008), project-based learning (Condliffe et al., 2017), and STEM education (National Research Council [NRC], 2010) may help students to become skillful at critical thinking, collaboration, communication, creativity, productivity and problem-solving for being up-to-date, having scientific and technological literacy and living in 21st-century.

There is a need for research studies that examine the applicability, strengths, and disadvantages of the activities related to STEM education or mathematical modeling in schools. Approaches that aim to enhance 21-st century skills of students have been implemented by some Turkish middle school teachers. In this regard, exploring their experiences and perspectives by focusing on the enablers and barriers they faced while implementing such activities may provide insights for designing future professional development efforts in many other contexts. Therefore, the current research was designed to investigate the views and experiences of middle school mathematics teachers who have some degree of experience in implementing innovative mathematics activities, such as STEM education or mathematical modeling, in their classrooms.

The current study used the term "innovative mathematics activities" as an umbrella term based on literature review and preliminary informal communications with middle school mathematics teachers about their STEM or mathematical modeling activities. Many of the teachers did not name their implementations as STEM or mathematical modeling as given in the literature and there are blurring boundaries between such relatively new approaches in the Turkish context. In this study, this term referred to non-routine educational activities that emphasize the real-life connections of mathematics and integrate mathematics and other disciplines such as science, technology, and engineering to maximize student learning, help them gain positive attitudes towards mathematics, and develop their 21st-century skills. These integrated activities require planning, implementing, and evaluating student-centered innovative mathematics instruction. We used the term "innovative" to refer to *relatively* new methods in mathematics learning activities rather than teachers discovering "new" educational methods. In summary, we use this term to refer to middle school mathematics teachers' all "relatively new" mathematics learning activity implementations related to non-traditional and non-routine educational approaches. In some educational contexts, the term evolved into including only STEM education and mathematical modeling activities since the participants of the study made a connection between innovative mathematics learning activities and them.

The specific research questions of the study were:

- What views do middle school mathematics teachers have for innovative mathematics learning activities they implement?
- What are the enablers and barriers for the innovative mathematics learning activities implemented by middle school mathematics teachers?
- What are the middle school mathematics teachers' suggestions for implementing innovative mathematics learning activities to other educational stakeholders?

Method

We use a phenomenological research design. The thirteen participants of the study were selected through a snowball approach among middle school mathematics teachers who had knowledge and experience about innovative mathematics activities. Three of them were working in public schools, and ten of them were in private schools. All of them -except one- were female. All of them had teaching experience at all grade levels of middle school, including their internships. Their teaching experiences ranged from 2 years to 20 years.

Data were collected through semi-structured interviews. The interview protocol included 19 questions and follow-up questions for some of them. The interviews included questions related to the participant teachers' thoughts about (i) the nature of their mathematics teaching in general, (ii) their implementation processes, including enablers and barriers to their work, and (iii) reflective interpretations about the activities and recommendations for other teachers.

Data were collected in face-to-face and online environments on a volunteer basis. We followed six steps recommended by Lodico and her colleagues (2010) to analyze data. The interviews were transcribed, redacted, and studied. Then they were analyzed utilizing the content analysis method. The similar views, experiences, enablers, barriers, and suggestions about innovative mathematics learning activities under the codes formed by the researchers. The data analysis process was guided by the research questions.

Examples of innovative mathematics learning activities implemented by the participant teachers

The activity implemented by P2 can be given as a representative example of innovative mathematics learning activities. She formed Caretta Caretta Nest Activity for 6th-graders. The activity included designing a nest for caretta caretta to prevent their egg loss by designing a nest for them after searching their sizes and living conditions. The students needed to use their knowledge related to ratio-proportion, area of polygons, and volume of prisms in the design process. The process required considering using the given whole area effectively, creating nests properly, and placing them productively.

Another example is Oil Spill City Activity formed and implemented by P10 in 6th-grades. She asked her students to design barriers to prevent oil spills after an environmental disaster by using their ratio-proportion and area of polygons-related knowledge. She stated that they used saltwater, olive oil, and bottles filled with to represent seawater, oil, and barriers to experiment with the process. She mentioned that her students connect their knowledge on density and ratio-proportion by changing the amount in these materials to stop oil spills by holding barriers at a certain level.

Findings

Teachers' perceptions regarding innovative mathematics education

In the interviews, the participating teachers were asked what they understood of the term "innovative mathematics education." Their descriptions were mostly based on non-traditional educational approaches. They linked it with student-centered instruction, having real-life connections, emphasizing learning by doing and active participation, involving technology use, and being activity-based and interdisciplinary.

Attributes of implemented innovative learning activities

The participants were asked to explain the characteristic features of the innovative mathematics activities they implemented with their students. The teachers mentioned the grade levels they targeted, the mathematics concepts covered, the physical setting, concepts covered from other disciplines, the average duration, how their students work on the activities, their assessment techniques, and their resources while preparing for the activity. The following table summarizes an overview of the participant teachers' responses to the characteristics of innovative mathematics learning activities.

Table 1: Attributes of innovative mathematics learning activities the teachers implemented

Note. The number of total responses is greater than the number of the participants since they mentioned more than one innovative mathematics learning activity implemented by them, and some teachers' responses include more than one category. So, the frequency represents the number of teachers who point out the given categories. This is valid for the rest of the tables.

Emotion perceptions during innovative mathematics learning activities

Many of the teachers asserted that they have positive emotions such as being satisfied, having fun, motivated, and excited while implementing innovative mathematics learning activities. Almost all of these emotions were related to students' reactions and emotions that were commented as positive by the participants. More explicitly, the participants feel satisfied when their students learn the topics they covered in the activities, and correspondingly when their students feel happy. They felt themselves as enjoyable teachers and did not get bored during the lessons in which such activities were implemented because of their active role and high interaction with their students compared with their traditional lessons. They are motivated more in the lessons they use such activities because of their students' positive reactions such as excitement, happiness, and active participation. Similarly, -but changing roles with their students- they feel excited when their students are motivated to make an effort to learn and participate during the implementations.

Some participants describe their experiences as exhausting, which depends on their role in these activities. According to interview data, this was not a complaint but more of a description of the nature of the workload these activities had. More specifically, they found that planning and implementing such activities requires more effort than their traditional lessons.

Perceived effects of innovative mathematics learning activities

The teachers explained how they perceive the effects of their activities on students based on their observations and experiences. They interpreted these effects as having positive contributions to change students' attitudes and enhancing their 21st-century skills, affective skills, learning of concepts, and psychomotor skills.

All of the participant teachers argued that the students became more aware of their future professional options, social and environmental issues, and gender issues. The participants believed that their students' attitudes towards participating in mathematics lessons and learning mathematics changed positively. Also, they believed in a positive contribution of innovative mathematics learning activities to their students' 21st-century skills. The specific skills they mentioned include collaboration, communication, problem-solving, critical thinking, researching, creative thinking, and curiosity. The positive effects of these activities were stated as motivation, attention, self-confidence, and a sense of achievement. Almost all of the teachers highlighted the improvement in student learning of the concepts and an increase in students' achievement in mathematics due to the interdisciplinary nature and real-life connection of such activities. Lastly, since the teachers implemented mostly modeling or designing activities, they observed the development of their students' psychomotor skills.

Enablers of providing innovative mathematics learning activities

The teachers explained their enablers by connecting to themselves and other people involved in the educational process. Students, colleagues, school managers, parents, and other people contribute to planning their lessons. The following table presents an overview of the enablers of providing innovative mathematics learning activities.

Table 2: Enablers in the process of innovative mathematics learning activities

Enablers	Frequency
Collaborating with colleagues	10
Receiving support from school management	8
Receiving positive feedback from parents	5
Thinking students' possible questions	5
Receiving positive feedback and reactions from students	4
Talking with an expert from a different profession	3

Barriers in the process of innovative mathematics learning activities

The difficulties or barriers the teachers encountered in the process of innovative mathematics learning activities were grouped under four categories: (i) time, (ii) students' learning habits and classroom learning culture, (iii) work environment, and (iv) preparing activities. The following table summarizes these categories and their sub-categories with the frequencies of the difficulties mentioned.

Table 3: Barriers in the process of innovative mathematics learning activities

Main Category	Sub-category	Frequency
Time	Time constraints for covering the curriculum	10
	Need for teaching to test	6
Students' learning habits and classroom learning culture	Being familiar with teacher-centered instruction	7
	Lack of teamwork experiences	6
	Difficulty in classroom management	5
Work environment	Teachers having too much workload	5
	Lack of equipment for activities	4
	Destructive criticism of colleagues	3
Activity preparation	Difficulty in integrating other disciplines into mathematics	5
	Teachers' lack of knowledge and experience	4
	Difficulty in simplifying complex concepts for students	3

Teachers' suggestions about innovative mathematics learning activities

The participants expressed their suggestions about innovative mathematics learning activities by considering their supporting factors and difficulties. When they were asked what would their recommendations to other teachers be, they mentioned keeping themselves up-to-date, knowing students' characteristics and interests, observing and leading students during the activities, becoming persistent in implementing such activities, implementing the well-known basic activities, getting opinions of others, and learning a foreign language. They suggested that the ministry authorities should simplify the mathematics curriculum, provide training and resources for teachers, and put sample activities in the curriculum. They also mentioned that mathematics teacher educators need to contribute by providing teachers resources and professional development opportunities.

Discussion and implications

The participants stated that student-centered instruction, the real-life connection of mathematics concepts, learning by doing strategies, active participation of students, integration of other disciplines (especially science, technology, engineering, and design) with mathematics, and activity-based learning make their mathematics lessons innovative. Usually, the Turkish middle school mathematics curriculum covers and recommends these approaches in Turkish schools (Ministry of National Education [MoNE], 2018). So, these approaches should not be called innovative. However, the teachers perceived themselves as teaching mathematics out of the ordinary when they implemented activities related to such approaches. Although these activities are given a place in the curriculum as regular practices at the policy level, they are seen as non-routine and innovative practices by the teachers. Teachers have restricted educational practices in accordance with policies even though these policies include innovative suggestions. So, policymakers should be careful about how national educational policies are perceived and implemented among teachers.

Although the teachers did not explicitly mention any theoretical point of view, their descriptions and implementations can be interpreted in line with the constructivist and constructionist learning theories, related to STEM and mathematical modeling approaches. It can also be argued that most of the teachers' perceptions of innovative learning activities were in line with the recent rhetoric of STEM education, mathematical modeling, project-based learning, problem-based learning, cooperative learning, or technology-integrated instruction. This indicates that the teachers were up-to-date on the relatively current educational theories and were willing to implement the ideas and approaches in these theories into their classroom practices. It may be because most of the teachers attended professional development seminars and in-service training programs.

The teachers stated one of the most critical factors in maximizing the quality of their activity implementation was their interaction with other people –namely students, colleagues, school managers, parents, and domain experts– who get involved in the activities from beginning to the end by sharing their views, comments, knowledge, and experiences. Therefore, teachers need a collaborative mindset for learning to implement such activities. Regarding the barriers to implementing the innovative activities, the findings of the study confirm the other previous studies on STEM and mathematical modeling (Herro & Quigley, 2017; McMullin & Reeve, 2014; Stohlmann, Moore & Roehrig, 2012).

Since the STEM and mathematical modeling integration into mathematics lessons are relatively new for many teachers, it is considered that there is a need for informing educational stakeholders about the integration for better implementation. The findings of the study demonstrated that some enablers such as collaborating with colleagues and professionals from other disciplines, being supported by colleagues and school management, and receiving positive feedback from students and parents make the process of innovative mathematics learning activities easier. These factors enable teachers to implement well-planned STEM and mathematical modeling activities. Correspondingly, teachers should be encouraged to implement their activities by creating a collaborative working environment and taking moral and material supplies. So, professional development opportunities can be designed to increase communication and collaboration between mathematics teachers and others. On the other hand, the current study put forward that teachers get into several barriers while implementing their activities. They primarily focused on the lack of time for planning and implementing the activities due to their workload and requirement of covering the curriculum in regular classes, the lack of students' familiarity with these types of activities, the lack of equipment required in the implementation of these activities, and the lack of knowledge that teachers experienced in STEM and mathematical modeling activities. The authorities can develop strategies to overcome these barriers for better mathematics education by developing policies about teachers' workload, mathematics class hours, and mathematics curriculum by revising them in accordance with STEM and mathematical modeling activities.

Criteria for sociocritical modeling tasks in sustainable development contexts

Karoline Haier[1], Hans-Stefan Siller[1] and Katrin Vorhölter[2]

There is a broad consensus that Education for Sustainable Development (ESD) should be integrated into all core subjects to enable learners to acquire the necessary knowledge and competencies for a SD in a comprehensive way. How ESD can be integrated in mathematical modeling has not been clearly defined yet. Sociocritical modeling can be one possible way for implementing SD in mathematics lessons. In this paper, we develop criteria for sociocritical modeling tasks based on previous empirical findings and theoretical considerations. To conclude, the task textile consumption, that was designed based on these criteria, is presented here.

Keywords: sociocritical modeling, sustainable development, task design

Introduction

In an era of globalization, digitalization, climate change and crises, a growing number of educators and employers are united around the idea, that students need to learn special skills to deal with these kinds of global issues[1]. These issues require a shift in our lifestyles and a transformation towards a more sustainable way we think and act (UNESCO, 2014). According to Bakker et al. (2021) “the big question is what role mathematics education can play in meeting these challenges” (p. 7).

Education for Sustainable Development (ESD) is increasingly demanded from many sides (Nationale Plattform BNE, 2017). This requirement applies to all areas of education and to all subjects, including mathematics education. In terms of educational theory, the relevance of ESD in mathematics education can be justified, among other things, by Winter's basic experiences (Winter, 1995). The first states that "Erscheinungen der Welt um uns, die uns alle angehen oder angehen sollten, aus Natur, Gesellschaft und Kultur, in einer spezifischen Art wahrzunehmen und zu verstehen" [phenomena of the world around us, which concern or should concern us all, from nature, society and culture, are to be perceived and understood in a specific way] (p.17). One goal of ESD is to empower learners with the knowledge, skills, values, and attitudes to address the above-mentioned challenges and take informed decisions and make responsible actions. Therefore, students need to gain competencies such as critical thinking and reflection, both for ESD and in math education (Gutstein, 2006; Skovsmose, 2021).

A great deal has been assumed and researched about modeling in math education to include real-world contexts in teaching mathematics. What has been little studied is the extent to which students are also able to acquire competences that will help them become responsible citizens via working on modeling tasks. This includes, among other things, the competence to make

[1] https://www.unesco.de/sites/default/files/2018-08/unesco_education_for_sustainable_development_goals.pdf

decisions that promote SD (also called *decision-making for SD*). Bakker et al. (2021) published answers from all over the world to the question: "On what themes should research in mathematics education should focus in the coming decade" (p. 2). Many of the responses, especially after the pandemic outbreak, strongly emphasized the importance of teaching mathematics in the context of these global challenges (Skovsmose, 2021). Increased interdisciplinary teaching or problem-based learning to learn competencies such as critical thinking or decision making can be mentioned here as an example. It can be claimed that the demand for a socio-critical orientation of mathematics education is constantly increasing the more crises society has to cope with (Skovsmose, 2021).

This leads to our research question: *What might be useful didactical criteria for designing tasks to establish reference to SD contexts in mathematics lessons?*

Theoretical Framework

The idea of integrating ESD into mathematics education is a more or less young one (UNESCO, 2014). Therefore, it is necessary to briefly address different theoretical aspects from both sides, mathematics education and ESD, to be able to compare and combine later.

Understanding, questioning, and critically reflecting on global issues using sociocritical modeling in mathematics education can be seen as a way to initiate a critical orientation within mathematical modeling. "Modelling is a powerful vehicle for bringing features of twenty-first century problems into the mathematics classroom" (English, 2016, p.10). From this it can be deduced that there is a need for tasks in mathematics education that are oriented towards socio-scientific issues and, in addition to modeling competencies, also offer the opportunity to critical reflect on the context and develop decision making for SD. Because all relevant contexts and issues are composed of content from STEM subjects, this goal cannot be achieved without including STEM (Maass, Geiger, et al., 2019). Furthermore, including SD contexts in mathematical modeling is an important opportunity "to integrate science, technology and engineering in meaningful ways as students tackle problems involving mathematics in relevant settings" (National Council of Supervisors of Mathematics & National Council of Teachers of Mathematics, 2018).

What exactly is meant by socio-critical modeling, how modeling tasks can be designed, and what is understood by contexts of sustainable development is explained in the following sections.

Mathematical Modeling

The goals of modeling in math education can be considered in different ways. A distinction can be made between content-oriented, process-oriented, and general goals. The content-oriented goals include the development of the environment with the help of mathematical means. Process-related goals include general mathematical competencies (e.g., problem-solving skills) and the heuristic strategies. Finally, the general goals include culture-related arguments. Here, the focus is on the image of mathematics as a science and on conveying the importance of mathematics for active participation in society (Greefrath & Vorhölter, 2016).

In addition to the goals of modeling presented here, various theory-based perspectives have emerged over time in the national and international discussion on modeling (Kaiser & Sriraman, 2006). The goals pursued can differ greatly in each case, depending on the aspect under which modeling tasks are developed, selected, and used. The perspective of socio-critical modeling, as one of seven, pursues the intention to promote discourses that are stimulated by mathematics and come from the learners' lifeworld. Barbosa (2006) describes this modeling perspective as a way of critically reflecting on the role of mathematics in society. Here, the goal of modeling is primarily to generate interdisciplinary thinking (special relation to STEM education) and critical discourse among learners. The crucial role, the context of the task can have, is particularly evident in this form of modeling.

Socio-critical modeling can deal, among other things, with socio-scientific issues (e.g., cloning or stem cells) and social issues (e.g., gender-pay-gap). Real problems like these often include ethical, moral, social, or cultural dimensions and thus challenge us to become aware of the subjectivity of modeling processes. This is done by critically reflecting on all steps of a modeling process. However, the outcome of such modeling can lead students to critically reflect on their own behavior and make recommendations based on their own modeling.

Sustainable Development Contexts

The difference between an issue and its context is that the context can be far more complex and considers more perspectives and information (Sadler, 2004). One important question when it comes to realistic contextualized tasks is the amount of reality on the one hand and mathematics on the other hand. So, with SD contexts in modeling, it is rather important to address both. It has been noticed that “it can be difficult to identify and address the mathematics involved in the contexts” (Maass, Doorman, et al., 2019, p.1001). We entirely agree that this difficulty points out the necessity to include such issues and the inherent mathematics. As an example for SD contexts that should be more present in mathematics education, a discourse from science, politics and society led to the identification of central problem areas for the design of SD. According to them, the socioscientific core problems of the 21st century include: *climate change, world food supply, soil degradation, drinking water* and *biodiversity* (Reid et al., 2010; UNESCO, 2014). Of course, there will be many more challenges, especially of a social nature, such as racism or migration, which will not be discussed further here for the time being.

The Guide for embedding ESD in textbooks presents a first orientation to place SD contexts at the core of school subjects through the implementation in textbooks. The authors outlined 15 guidelines for creating mathematics curriculum resources that support ESD which include among others: real contexts, current issues, complexity, values, access to data, interdisciplinarity, opening dialogue, collaboration and courage (MGIEP & UNESCO, 2017).

Modeling task design

To encourage students to engage in mathematical modeling, suitable problems and tasks are required. Several theoretical approaches for the design of modeling tasks exist but will not be further outlined here (Blomhøj & Kjeldsen, 2006; Maaß, 2010).

Another possibility for the conception of good modeling tasks is the orientation at criteria, based on which their quality can be classified. At this point it should be emphasized that there are no "the" criteria of modeling tasks. The goal, which is followed with the processing, is in the focus. Even a good modeling task does not have to fulfill all criteria equally. The criteria according to

Maaß (2007) will be considered here, which she names as "typical" for modeling tasks are *1. open, 2. complex, 3. realistic, 4. authentic, 5. problematic and 6. solvable by carrying out a modeling process*.

For the design of modeling tasks that support decision making for SD, one needs real contexts and current issues. SD is thus considered a new context generator for mathematics education. Therefore, it must be ensured that the SD context is accessible using mathematical methods. As already stated above, scholarly studies and societal experiences have been able to identify some core problem areas in the discourse that are of particular importance for the design of a SD. These core problems now serve as a thematic orientation framework for the task design. Accordingly, the issues to be addressed should be *1. central to SD processes, 2. locally or globally, 3. have potential for action, 4. have long-term significance* and *6. can be dealt with in an interdisciplinary manner*.

Based on these theoretical thoughts we here report our approach for the design of SD context modeling tasks. For this purpose, the process of the criteria merging is shown first. Subsequently, the exemplary task based on these results is presented.

Merging Criteria

Comparing both sets of criteria, some overlap can be found in what seem to be characteristics of good modeling tasks. The design of the tasks should succeed in such a way that modeling competencies are promoted and at the same time interest in the concerns of SD is aroused in the students. Additionally, they should be stimulated to reflect critically or argue concerning SD issues. For this purpose, criteria from the two different domains were compared (see Figure 1). In addition to the criteria for modeling tasks (Maaß, 2007) (green box), the guidelines for embedding ESD in textbooks (MGIEP & UNESCO, 2017) (orange box), were considered. In the process of merging, similarities and differences of both guidelines were worked out. An attempt was made to create a catalog of eight criteria that would include both guidelines in equal parts (see arrows Figure 1). The result of the comparison of the criteria are eight characteristics for modeling tasks in the context of ESD (yellow box).

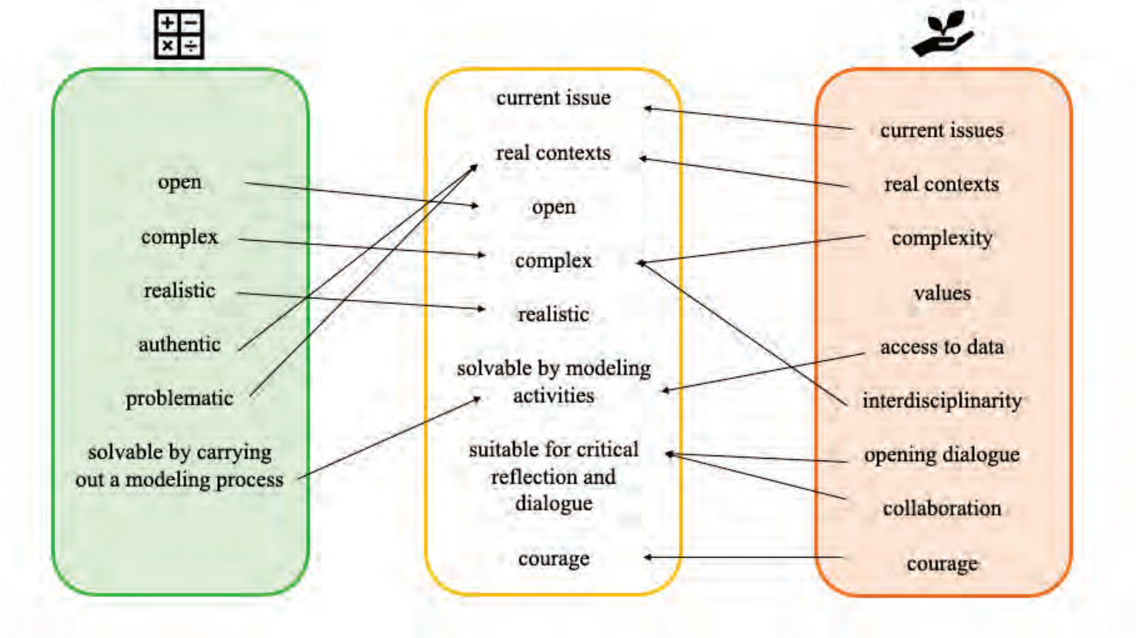

Figure 1: Process of merging of criteria

SD context modeling task design – an example

In the following, we show how these criteria can be applied to a selected current issue for the design of a modeling task. Starting with a current issue like "Fast Fashion" and embedding the problem in a real context of global development like climate change is one possible way to begin with the task design. Based on the problem and context chosen, the corresponding values should be named, and open and realistic question should be formulated, that is solvable by modeling activities and in some way suitable for a critical reflection. If possible, a longer-term potential for action should be able to be defined from the task.

Table 1: Exemplary application of the criteria

current issue	Fast Fashion
real context	Climate Change
open	individual assumptions and solutions
complex	interdisciplinary nature of the problem
realistic	use of real data
solvable by modeling activities	understand/simplify, mathematize, interpret, validate
suitable for critical reflection and dialogue	reflection on one's own consumption behavior
courage	leaves judgment to the students based on their mathematical investigation and knowledge of the relevant context

For the context of the modeling task presented in this paper, the issue "Fast Fashion" has been chosen (see Table 1) which, on the one hand, has a strong connection to the youth reality and, on the other hand, is related to the core issues of SD. Since, in addition to modeling competencies, it is primarily that critical reflection and arguing are to be promoted, the potential for personal action must be apparent to the students. Therefore, the guiding theme *consumer behavior* has been chosen, as it effects every student, has multiple effects on socio-scientific and social issues and provides mathematical content to work with (see Table 2).

Table 2: Textile consumption as an exemplary SD context modeling task

Task	Textile Consumption
Question	How big would your closet have to be in 10 years if you don't sort out or dispose of anything in between and continue to shop the way you have been?
Mathematical Content	Convert units, rule of three, rounding, estimating, calculate with volume
Learning target	Trigger AHA effect about own consumption behavior and effects

Preliminary experience with the modeling task "Textile Consumption" (see Table 2) was gained with 50 grade 10 students. They worked in small groups of 3-5 people, and after completing the tasks, group interviews were conducted for qualitative data collection. The use in a 10th grade mathematics class has shown that the students were able to reach a result with the task through modeling activities (understand/simplify, mathematize, work mathematically, interpret, and validate). In addition, the results of the interviews showed that a critical reflection of the given issue took place at several points. It should be mentioned here that the way the interviews were conducted, and the limited time frame did not allow for further discussion and reflection of the results. Nevertheless, all groups critically reflected on the problem of Fast Fashion and their own consumption. At this point, we would like to provide two quotes from the interviews as examples.[2]

> In any case, the task has made it clear to me that I should perhaps reduce my consumption a bit. My clothes are really a lot, and I might also look in the next few years that I sort things out and give them away...it's always difficult to separate, but that you then get rid of clothes and give them to people who need them. (Diana)

Through this quotation it becomes clear that the student has recognized for herself, due to the work on the task, that she should limit her clothing consumption. However, it can be noted that she does not necessarily aim to buy less new clothing, but rather to pass on existing clothing. Nevertheless, it can be stated that the processing of the task has led to a critical reflection on and examination of the context. This connection becomes even more apparent in the following second quote. In this quote, the student himself makes a direct connection between calculating the amount of clothing and initiating reflection on his own clothing consumption:

> Because you have calculated how many clothes you buy and how big your closet should be, you start thinking that you buy a lot of clothes that you might not even need...not that much. (Enya)

[2] The quotes are translated by the authors and the names of the students have been changed.

These two quotes show that mathematics can certainly be used for critically reflecting on a context in a meaningful way. They show two different kinds of a critical reflection based on the students' experiences while working on the modeling task textile consumption. The students interpret their mathematical solution in the given context and start to substantiate their arguments for reduced textile consumption with their mathematical results.

Summary & Outlook

Based on the question, what role mathematics education can play in meeting global challenges like crises, globalization, and the urgent need of a sustainable development, we started with SD contexts in socio-critical modeling creating content for mathematics classrooms. The research question to be answered here related to possible criteria for the design and implementation of tasks that support arguing for decision making for sustainable development.

The literature research has shown that so far, no criteria for tasks in general as well modelling tasks in particular have been formulated, which are to promote explicitly competencies such as decision making for SD. Thus, the set of criteria elaborated in this work could be usefully applied in further research for the design of SD context modeling tasks. Designing and evaluating further teaching materials based on these criteria is a worthwhile task for future research.

The quotations of students presented make it clear that by working on the task, the students have begun to question their own textile consumption, even though the intentions for action expressed by both are subjective and different. This shows that tasks with an SD context have the potential to stimulate critical reflection and promote arguing even outside of mathematics. Future research is needed to determine how, why, and to what extent this approach can work in general.

Towards implementing Black Boxes in Mathematical Modeling an epistemological Approach

Adapting models from science and science education

Janina Just[1], Hans-Stefan Siller[2]

[1] University of Wuerzburg, Germany; janina.just@mathematik.uni-wuerzburg.de

[2] University of Wuerzburg, Germany; hans-stefan.siller@mathematik.uni-wuerzburg.de

This article explores the concept of black boxes within mathematical modeling. First, we perform a literature-based clarification of the term black box, the use of a black box, and explore the use of this construct in science, and workplace. A black box is characterized by the following issues: (a) being believed to be distinct, (b) having observable (and relatable) inputs and outputs, (c) being black (that is, opaque to the observer). Afterwards, we demonstrate the uses of black boxes within mathematical modeling. We generalize these uses to a model of how black boxes can be implemented in mathematics education. Based on this model, we derive educationally relevant activities for using and opening such a black box. The application of these activities is illustrated in more details using an example of physical chemistry: the Arrhenius Equation.

Keywords: Black box, mathematical modeling, STEM

Introduction

Mathematical modeling is an important part of mathematics education (Kaiser, 2020). English (2016) described modeling as a powerful tool to implement 21st century skills in mathematic classrooms. This is because real-world problems connect mathematics with aspects of the world, and are often linked with mathematical modeling and mathematical models (s.f. Artigue et al., 2007; Kaiser & Stender, 2013; Lingefjärd, 2006).

In practice, many models use black boxes. For example, they serve as simplifications of phenomena or approximations in modeling tasks (e.g. Bissell, 2004; Buchberger, 1990; Hoijnen et al., 1992; Straesser, 2007; Williams & Wake, 2007). Black boxes are often used, especially in work places and science models (Straesser, 2007; Williams & Wake, 2007). In order to understand how the term black box is used and whether or how it can be utilized for mathematics, we have used an epistemological approach and analyzed tasks of science. Because of these findings, we argue that we should include teaching about black boxes in mathematics education. However, there is no consensus (yet) on how exactly we should do that. Hence, the aim of this paper is to give an overview of possible approaches, to present our own concept, and to deepen existing approaches in the process.

Theoretical background: Black Boxes

Kaiser and Stender (2013) proposed two different directions for mathematical modeling: "*mathematics for applications, models and modeling*" (p. 278), and "*applications, models and modeling for the learning of mathematics*" (p. 278). The second headline emphasizes the goal of learning mathematics. In this paper, we want to implement black boxes into mathematical modeling in the context of STEM. Therefore, we will refer to the first headline. The realistic or applied approach of mathematics puts the solution of the real-world problem in the center. To describe the processes while working out the solution different modeling cycles have been developed (e.g.Blum & Leiß, 2007; Kaiser & Stender, 2013). In the following, we will refer to the modeling cycle proposed by Kaiser and Stender (2013). This corresponds the mathematical modeling cycle in physics education of Redish and Bing (2009) excluding the real-world situations and fits the later presented problem.

Modeling with Black Boxes

As described above assumptions are obligatory during modeling. These can be interpreted as black boxes. In addition, well-accepted mathematical models can work as a starting point of further real-world problems. Therefore the problem solver must not have fully understood the origin model or its emergence, but its input and output behavior. Accordingly, this mathematical model is used as a black box. In our contribution, we give an overview of black boxes in general and in particular in the context of mathematical modeling. We will present a way to open black boxes, but without giving an answer to the question if and when one should open a black box.

The term black box is usually used without a precise definition, but in a kind of intuitive understanding (e.g. Bissell, 2004; Buchberger, 1990; Fojo et al., 2017; Hoijnen et al., 1992; Straesser, 2007; Williams & Wake, 2007). We use the definition of black box provided by Glanville (1982). Following a philosophical approach he characterizes a black box as: "[…] (a) being believed to be distinct, (b) having observable (and relatable) inputs and outputs, (c) being black (that is, opaque to the observer)" (Glanville, 1982, p. 1). We want to emphasize how we understand this definition and give an example. One aspect that we want to enhance is that even though the definition claims observable inputs and outputs, it does not mean that the researcher is already fully aware of its input-output behaviour. Notably, the fact that a black box is both observable and relatable does not necessarily imply that it is also deterministic. Indeed, statistical systems can also be understood as a black box.

State of the art: Black Boxes in Mathematics Education

In mathematics education, black boxes are associated with Computer-Algebra-Systems or other technical systems (Buchberger, 1990; Peschek, 1999; Williams & Wake, 2007). For this usage of black boxes, Peschek (1999) defines a black box as something "[…] in denen operatives Wissen so materialisiert ist, dass es als Ganzes aufrufbar und einsetzbar wird, ohne dass ihre innere Funktions-weise verstanden werden oder auch nur bekannt sein muss" [in which operational knowledge is materialized in such a way that it can be called up and used as a whole without its internal functioning being understood or even having to be known] (p. 1). This mathematical perspective on black boxes is not sufficient. On this account, the focus in the following is not on trivialized mathematics that is taken over by computer systems, but on the usage of black boxes in modeling and STEM education (e.g. Krell & Hergert, 2019; Krell & Krüger, 2017; Upmeier zu Belzen, Krüger, & van Driel, 2019).

Modeling with Black Boxes

In later approaches in science education, a model-based approach is often chosen and the terms *model of* and *model for* are mention in this discussion (Gouvea & Passmore, 2017). The aspect *model for* something means using the model to gain more information about the real world or to make predictions. Therefore they turn into epistemic tools (Gouvea & Passmore, 2017). In this application, it can be useful or even necessary to use a model as a black Box. The idea of black box might emphasize the fact, that a model is a useful thinking tool, but not a precise description of reality. This misconception can otherwise lead to difficulties understanding more complex systems that cannot be explained with the origin model or even prevent scientists to gain new epistemological knowledge (Taber, 2017). But a black box in science education can not only be used to emphasize the model as a tool but is also an approach for modeling itself, by using a black box activity (e.g. Ruebush et al., 2009; Warren, 2001).

Opening a Black Box

The metaphor of opening a black box represents the precise exploration and questioning the inner functioning for which the black box stands for. There are two reasons for opening a black box. The first reason is to gain scientific knowledge about the black box itself. The motivation to gain scientific knowledge about the black box can be research or education. In the context of research, the scientist wants to gain knowledge about the unknown. In science or mathematic education, the incentive to open a black box can be versatile. By opening a black box students can learn something about the model itself, the modeling process and lead to a deeper understanding about the black box, for example, a model that serves as a tool. This can and should prevent application errors. The second reason is that the black box cannot be distinguished.

Black Box Concept

In this section, we explain how we should include black boxes into mathematics education. Therefore, we want to distinguish between a black box that evolved from a white box and a black box that should only represent the unknown. The first, for example, involves mathematical models whose modeling is not apparent to the user, but the user knows about their validity. The second one implies for example phenomena in nature that have not yet been explored in detail. The later criterion of Glanville's definition mentions the user's point of view, and brings both kinds of black boxes together. This view of using a black box is illustrated in Figure 1.

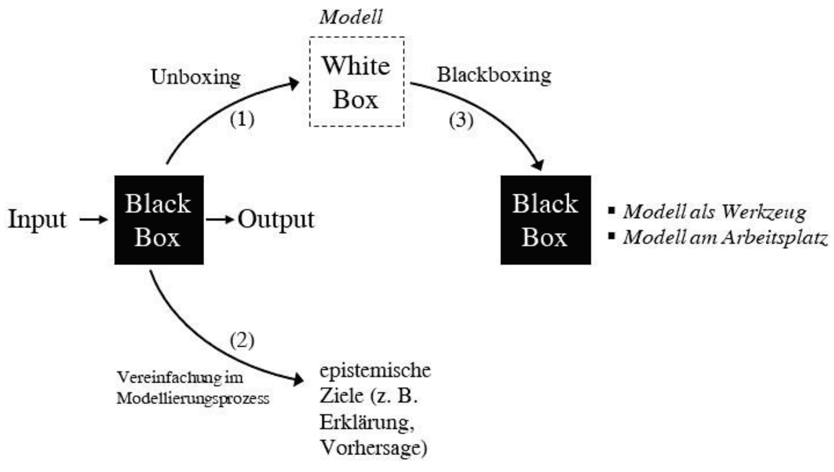

Figure 1: Extended Approach: illustration of the black box, refined from Glanville (1982, p. 1)

We justify this distinction due to their vocational use. By studying unknown phenomena, researchers are trying to unbox the unknown (1) (Glanville, 1982). After unboxing the unknown, it might be useful to turn the white box into a black box (3). Williams and Wake (2007) point out two reasons for black boxes: time and space. However, for mathematics, only time is relevant.

Time represents the black boxes that changed models and/or mathematical work into instruments, and tools (Williams & Wake, 2007). This leads to efficient use of those models but goes along with the leakage of knowledge. For example, the model designer knows the simplifications they made, but the user does not. This is a typical situation at work (Straesser, 2007). CAS-Systems are self-constructed by the designer who is fully aware of the underlying algorithm, the technic, and mathematical knowledge, but it is opaque to its observer/user. The command for differentiation or integration serves as an example. In this application, the software is taking over the mathematical work (Williams & Wake, 2007).

In contrast to opening the black box, it might be useful, not to unbox the black box (2). This may seem to contravene the aim to study the unknown, but "[…] our ability to overcome and cope with ignorance and thus is a primitive of learning and, hence, of science" (Glanville, 1982, p. 1). This can be for example a simplification and is therefore essential in the work of modeling (Bissell, 2004; e.g. Hoijnen et al., 1992). Hoijnen et al. (1992) depict an application for the black box as an approximation in mathematical modeling in a scientific context. He describes the use of a black box to estimate the energy that is gained out of biomass. This enables to calculate auto-and heterotrophic biomass yield the without studying the microorganisms that are not relevant for the modeling (Hoijnen et al., 1992).

One reason for those simplifications is the fact, that exact scientific research is determined by the limits of the measurable aspects (Ortlieb, 2008). Another reason is the intricacy of parts of phenomena that turn out irrelevant compared to the phenomena. Bissell (2004) gives an example in the context of communication and control engineering and points out that:

> In this approach, a complex linear electrical network is represented by its input-output behavior; at this level of abstraction, the precise nature of the interconnections of components inside the black box becomes irrelevant (p. 312).

This leads to the conclusion, that in the scientific context it is necessary to leave some phenomena opaque as a black box to achieve epistemic aims. Therefore, this way of working with models and modeling has to be part of the scientific and mathematic curriculum.

Activities to open a Black Box in Education

The result of an opening process for example by modeling is a more specific model, which still leaves a part of the real word opaque. Latour (1994) describes this endless process as follows: "Each of the parts inside the black box is a black box full of parts" (p. 37). An endless process is incompatible to gain results, efficiency, and education. Therefore, the necessity of a *temporary ending* is essential. In the following, we want to picture relevant activities to work with black boxes, and an option to bring the endless process of opening with a temporary ending together. We try to identify boxes in boxes. This leads to a new modeling cycle, which is illustrated in Figure 2.

The first level represents the black box itself, for example, an equation that is used as a tool. The reasons for this usage have been explained in previous sections. The target itself defines the different underlying levels and can appear in different ways. By opening a black box students can learn something about the model itself, this might be by the interpretation of the model or learning about the modeling process itself. While doing so, assumptions or underlying models appear in this process, which are represented by the smaller boxes below, and defined as new black boxes. Due to this definition, there is a point, where the opening process is finished due to its target, even though not everything is visible to the observer. The most difficult part of this is to know the point of whether to stop the process, or to go further to fulfill the target. This topic needs further research.

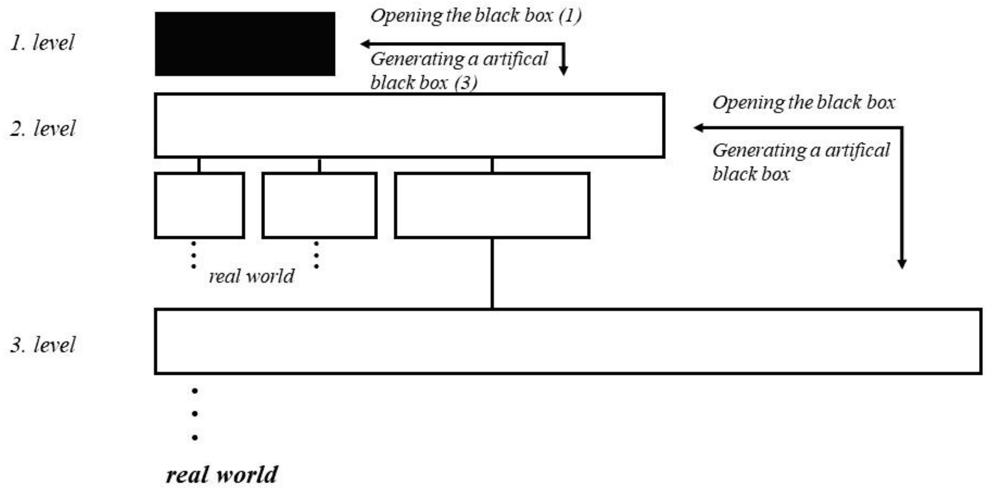

Figure 2: How to open and generate a Black Box.

Another activity to open the black box is that the students interfere it, and make assumptions from the input-output performance. This modeling access is called a black box activity in science education (Krell et al., 2019). This activity can be applied in a different way. It can be linked to a real-world model or applied on a black box for educational reason.[1] The usage of this black box is only to foster students' understanding of models and modeling in science showed positive effects (Krell & Hergert, 2019). Here, modeling serves as a tool for opening a black box.

The described modeling tasks retrieve in the atomistic approach of mathematical modeling, that is besides the holistic approach consensus on the teaching and learning of mathematical modeling (Kaiser, 2020). In the following section, we illustrate the benefit of our model by applying it theoretically to the Arrhenius equation.

Application: The Arrhenius Equation

The Arrhenius Equation (1) is one example in science (education), how a model is used as a black box. The equation is one of the most important equations in physical chemistry (Logan, 1982). For example, it is used in material research for battery technology (Breuer et al., 2015; Ren et al., 2015).

$$k = A \cdot e^{-\frac{E_A}{R \cdot T}} \overset{Linearization}{\Longleftrightarrow} \ln\frac{k}{A} = -\frac{E_A}{R} \cdot \frac{1}{T} \qquad (1)$$

A common application in science education is the ascertainment of the activation energy of the sucrose inversion. To do so the students only need the scientific model as a tool. In this process, the

[1] e.g. Freie Universität Berlin. Modelle der Biologie. https://tetfolio.fu-berlin.de/web/440484 29.08.2021

model is embedded as a black box and will not be opened, which is an example for the first level of Figure 2. The modeling steps for the ascertainment are described in Figure 3 based on the modeling cycle of Kaiser and Stender (2013), in which the real situation is replaced with the black box. In this example the Arrhenius Equation is the black box.

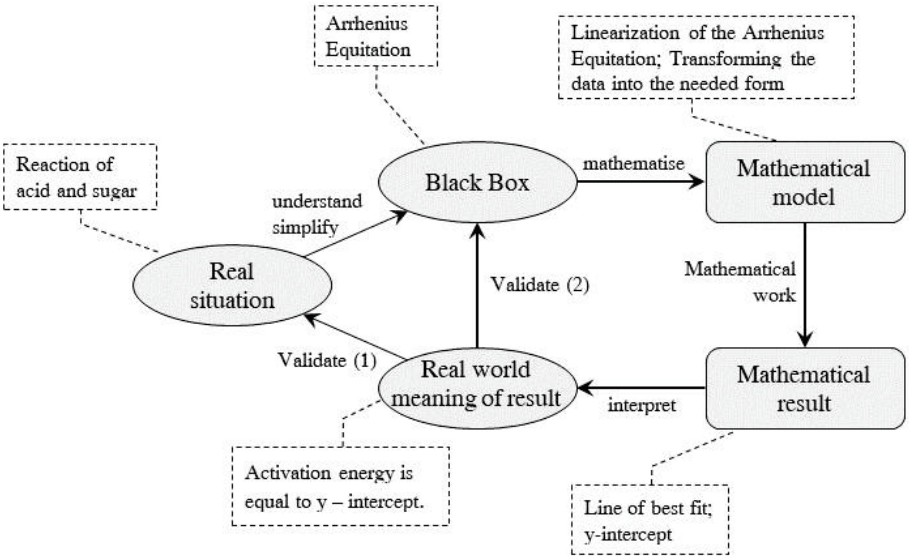

Figure 3: modeling cycle to ascertain the activation energy of the sucrose inversion according to Kaiser and Stender (2013, p. 279)

The modeling task is the ascertainment of the reaction of acid and sugar that cannot be measured directly. The students need to consider, how they can ascertain the activation energy only with measurable data. The Arrhenius Equation is a tool to determine the wanted quantity. To do so the reaction rate is necessary. This one is ascertainable with the changing turning angle of the liquid during the reaction. These results are the base of the following usage of the Arrhenius Equation to determine the activation energy. In the next step, the data is transferred to fit into the mathematical model. This data set is mapped to a coordinate system and the line of best fit is plotted. This leads to the so-called Arrhenius slope (Figure 4). The students have to read off the y-intercept of the slope that corresponds to the activation energy. After this, the results are validated (2) by approximating possible mistakes during the measurement and its analysis. Therefore, every step of the modeling is revised. Following the steps of the modeling cycle can help to structure the propagation of uncertainty. After that the results are compared with the literature value (validate (1)).

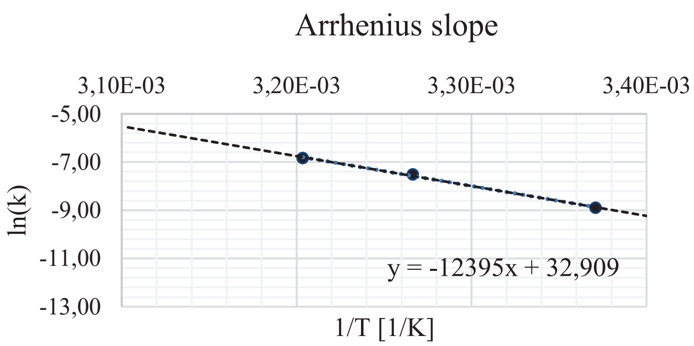

Figure 4: Arrhenius slope

In this described usage, the equation is used as a black box. In the context of education, a reason to unbox the equation is to gain knowledge about the model. This takes us from knowing 'how' to knowing 'why'. The interpretation reveals the connection between the different variables but does not explain the different parameters themselves. This leads to an underlying level. For example, the activation energy and its factors can be interpreted as another black box.

Summary

In this paper, we focused on how we can apply black box techniques in mathematical modeling. By using literature-based normative approach, we developed a model to implement black boxes in mathematical modeling, and argued for its benefits in mathematical education. These benefits show themselves in the necessity for application in science and workplaces, and within the modeling of real-world situations. However, the critical reflection of this process is an open question for future research. This, most importantly, includes deciding when and where to apply these techniques ("critical opening"), both in an educational setting and in the real-world.

Graphs are an important interdisciplinary and everyday tool for visualizing and interpreting information and communication processes and, thus, an essential part of 21st Century Skills. In particular, linear functions are a fundamental component of school and university education, but students often have difficulties interpreting this type of function, in mathematics as well as in physics – especially in kinematics. This paper presents first results of an eye-tracking study, which compares learners' visual attention during the interpretation of linear graphs in mathematical and physical contexts.

Keywords: Eye tracking, graphs, context, problem solving.

Introduction

Graphs are a typical representation to show the dependencies between different quantities and therefore play an essential role in conveying information in the natural sciences. They are typically introduced in mathematics in secondary school and are part of both the school and university curriculum in different STEM contexts (Glazer, 2011; Leinhardt et al., 1990). Beyond the purely mathematical understanding of the functional relationship, graphs are an important tool, e.g., for visualizing trends in measurement data and are thus an interdisciplinary tool for interpreting quantitative information in the context of 21st Century Skills (National Research Council, 2012).

In recent decades, however, research has shown that many students have difficulties interpreting graphs (Glazer, 2011). This is especially true for kinematic graphs (Beichner, 1993; Ivanjek et al. 2016; McDermott et al., 1987). Since the cognitive processes involved in graph interpretation are closely linked to visual perceptual processes, e.g., extracting relevant information from graphs, eye tracking opens up the possibility of gaining insights into learning or problem solving processes involving graphs (Klein et al., 2021; Susac et al., 2017).

In this work, we use eye tracking to investigate visual strategies of students while solving line graph problems in a mathematical and kinematical context. To this end, we recorded their gaze data to investigate their visual attention while solving item pairs of a test instrument validated by Ceuppens et al. (2019) that require the same mathematical solution procedure. On a selected item pair, we show that gaze behavior differs significantly between the mathematical and kinematical contexts.

State of Research

Students' learning difficulties concerning graphs in the contexts of mathematics and physics can be grouped into three main aspects: First, although mathematics and physics are deeply connected (Redish & Kuo, 2015), students have difficulties linking both disciplines adequately (Ivanjek et al., 2016). Reasons for this are a domain-specific learning (Pollock et al., 2007) and a lack of the ability to transfer knowledge from mathematics to physics (Christensen & Thompson, 2012). Second, students have problems using multiple external representations competently (e.g., Ainsworth, 2006), especially when switching between different representations back and forth (Even, 1998). Third, in particular the high degree of abstraction of graphs poses difficulties since learners need to relate mathematical entities to real world processes (McDermott et al., 1987).

Eye tracking is a method to investigate visual attention by recording eye movements. The eye movement can be described as a sequence of fixations (eye stop points) and saccades (jumps between fixations). Predefined areas in the field of view, so-called areas of interest (AOI), are used to define eye-tracking metrics such as the total visit duration (TVD, cumulated times between first fixation in and first fixation outside an AOI) and transitions (saccades between AOIs). To get an adequate understanding of line graphs, learners have to extract information from the graph and combine this with prior knowledge. Such processes of information extraction and constructing meaning with graphs are described by the Cognitive Theory of Multimedia Learning (CTML, e.g., Mayer, 2009). CTML describes three main processes concerning problem solving and learning: selection (extraction of sensory information from graphs), organization (building a coherent internal representation through information structuring) and integration (combining internal representations such as axis values or axis intervals in graphs with the long-term memory).

The following connection between CTML and eye tracking allows a theory-based interpretation of the eye-tracking data: Gaze durations (TVD, fixation durations) are associated with processes of the selection and organization of information extracted from the processed material, gaze shifts (transitions) are related to integration processes (e.g., Alemdag & Cagiltay, 2018). In summary, eye tracking is a non-intrusive method to obtain information about visual attention and cognitive processing in problem solving processes. So far, to our knowledge, there is no eye-tracking study of the comparison of visual attention processes on linear graphs in the context of mathematics with other contexts, especially with physics in high-school. In general, there is a gap in analyzing mathematical problem-solving processes and representations using eye tracking in secondary school (Strohmaier et al., 2020). This study aims to fill this gap.

Research Questions

For our eye-tracking study, we used the validated test instrument of Ceuppens et al. (2019) because it contains items in both kinematical and mathematical contexts. While Ceuppens et al. (2019) examined 9th grader, we used the test instrument with students in the entry phase of upper secondary school. The aim was to check whether the difficulties in interpreting linear graphs are still present in the upper grades. The background is that the competent handling of graphs in general and of linear graphs in particular is assumed in the upper school and can be seen as a basis for the development of

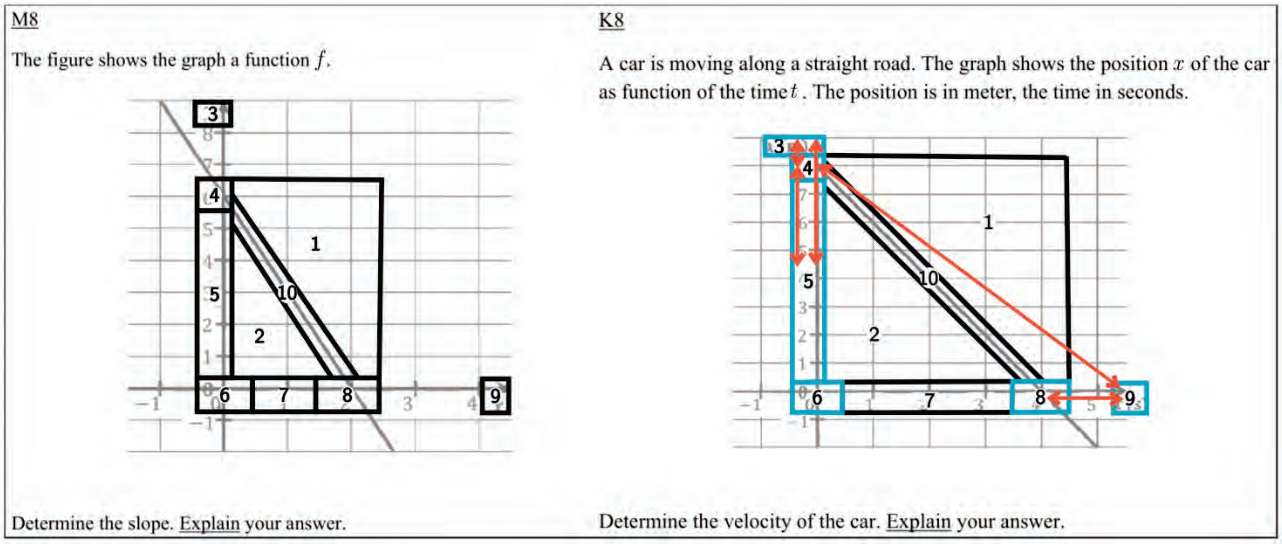

Figure 1: Isomorphic item pair no. 8 from the test instrument used; on the left: mathematical context M8), on the right: kinematical context (K8). The diagram-area of each item is divided into AOIs 1-10. AOIs with significantly longer TVDs than in the isomorphic item are marked in blue. Red arrows indicate transitions between AOIs that appear significantly more often than in the isomorphic counterpart

many new learning contents in the STEM context. The research questions of the study were as follows.

RQ1: Do the difficulties of 9th grader, particularly in solving kinematic items, also occur with students in upper secondary classes?

RQ2: Do selection and organization processes analyzed by gaze behavior in solving isomorphic items differ between mathematics and kinematics contexts?

Methodology

The test instrument consists of 24 items taken from a validated test by Ceuppens et al. (2019) and translated literally into xxx (details redacted for review). The instrument consists of pairs of items in mathematics and kinematics contexts that are isomorphic to each other, i.e., have the same surface features and require the same mathematical solution procedure. In order to avoid sequence effects, all items were presented to the students in arbitrary order and an alternating start either with physics items or mathematics items. In the context of this paper, we focus the eye-tracking based analysis on item pair number 8 (cf. Figure 1). Here, students evaluated the negative slope of a linear graph once for a mathematical function and once for a time-position function.

A total of 35 upper secondary students (14 male, 21 female, all with normal or corrected-to-normal vision) from a secondary school in xxx (details redacted for review) participated in the study. The students voluntarily took part in data collection either in free periods or in regular classes (with teacher permission). At the time the study was conducted, kinematics had already been covered in the courses of all participants. The students were rewarded with a 5 €-voucher for participation. Item pair no. 8 was completed by 24 students only. In the context of this paper, we are interested in why students with mathematical knowledge exhibit problems in the physics context. Therefore, we only consider students who answered the mathematics item correctly and failed solving the physics item (N = 14, 8 female, 6 male).

The study took place in the school's library where two identical eye-tracking systems (Tobii X3-120) were set up. First, the participants answered a short questionnaire about their demographics. After that, a 9-point calibration was performed to obtain a full-customized and accurate gaze point calculation. Subsequently, the 24 items were shown on the computer screen (1920 x 1080 px; refresh rate 75 Hz). If students were ready to give an answer, they pressed a key to move to the next slide. After they had answered, they were asked how confident they were about the correctness of their answer (4-point Likert-type rating scale, ranging from very high confidence to no confidence). The students could take as much time as needed to answer a question. They did not receive feedback after completing a task and could not return to previous tasks.

Performance data: The answers were coded dichotomously (0 for wrong solution, 1 for correct solution) following Ceuppens et al. (2019). Answers for which the participants stated that they had guessed were marked as incorrect. To compare the difficulty of the items, the item difficulty P (proportion of participants who answered the item correctly) was calculated.

Gaze data: The data collection and the definition of AOIs was done with the software Tobii Studio. For the assignment of the eye-movement types, the default I-VT (Identification by Velocity Threshold) algorithm of the software was used (threshold: 30°/s for the velocity; Salvucci & Goldberg, 2000). One participant's results were excluded due to poor quality eye-tracking data. For the gaze data analysis, the items were restricted to the diagram area. The AOIs were chosen such that graph relevant structures are covered by one AOI each (cf. Figure 1). For example, areas of the axis intersection points or areas below and above the linear function are summarized in AOIs. The eye-tracking metrics TVD (selection/organization) and transitions (integration) were considered. A non-parametric Wilcoxon signed rank test was used to test whether the central tendencies of the TVD / number of transitions of the participants in the dependent samples (M8 correct, K8 incorrect) were different. The analyzed datasets met the assumptions required to perform the Wilcoxon test. A threshold of $p = 0.05$ was used to determine the effect significance level within all tests performed. To control the false discovery rate due to multiple testing, the p-values were corrected using the Benjamini-Hochberg procedure. The effect size r (for non-parametric data, cf. Fritz et al., 2012) with 95% confidence interval (calculated using Bootstrapping with 1000 replications) was determined for all Wilcoxon tests with significant results and can be interpreted after Cohen's guidelines (small effect: $0.1 \leq r < 0.3$; medium effect: $0.3 \leq r < 0.5$; strong effect: $0.5 \leq r \leq 1.0$; Cohen, 1988).

Results and Discussion

In this section, descriptive results of all study participants are analyzed first. Afterwards, results of the analysis of the eye-tracking data for item pair no. 8 are presented. This item pair was selected for the eye-tracking based analysis because it shows the greatest difference in terms of item difficulty in the mathematics and physics contexts (cf. Figure 2).

Descriptive results

The results of the item difficulty analysis for all test items are shown in Figure 2. The task description of the item pairs is placed at the top and right-hand side of the diagram. For example, in item pair no. 1 (IP 1), participants were asked to compare the y-intercepts of two linearly increasing functions in mathematics or the initial positions of two objects with linearly increasing $x(t)$-graphs, respectively. Item pair no. 6 required the determination of the slope of a linearly decreasing function or the velocity of an object with a linearly decreasing $x(t)$-graph, respectively. Except for item pair no. 3, the item difficulties of the mathematics items are higher than those of the respective isomorphic kinematics items. Extremely difficult items are kinematical items dealing with negative velocities and with the representation form formula (P_{K4} = 0.15, P_{K8} = 0.08, P_{K9} = 0.20, P_{K10} = 0.10, P_{K11} = 0.15, P_{K12} = 0.05) (Bortz & Schuster, 2010). Whereas the items K2, M2, and M6 are extremely easy items (P_{K2} = 0.89, P_{M2} = 1.00, P_{M6} = 0.83) (Bortz & Schuster, 2010).

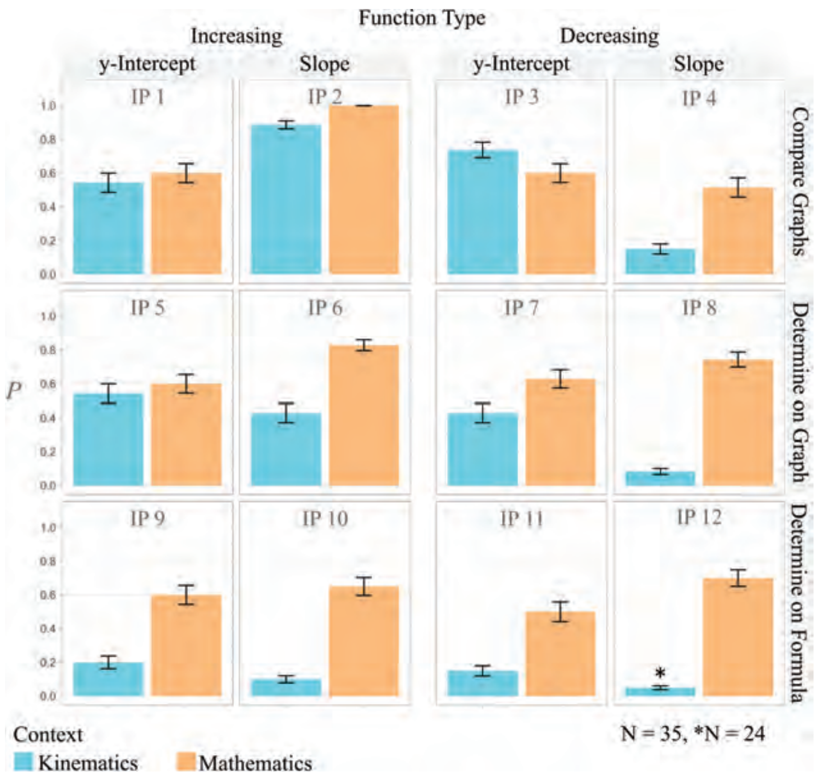

Figure 2: Comparison of item difficulty level *P* of all item pairs (IP) in the test instrument

Item Pair No. 8

The results of the Wilcoxon test (p-values with effect sizes r for significant results) are presented in Table 1 together with the mean TVD for each AOI of item pair no. 8. All significant results relate to longer TVDs in item K8 than in item M8 and are visualized in Figure 1. The two axis labels (AOIs 3 and 9), the x-axis (AOI 5) and the intersections with the axes (AOIs 4 and 8) were viewed significantly longer in item K8.

The number of transitions between AOIs with significant TVDs in both items of item pair no. 8 were analyzed. Table 2 shows the results of the Wilcoxon test (p-values with effect sizes r for significant results) together with the average number of transitions between two AOIs.

Table 1: Average TVD (Mean) per AOI with standard error (SE), adjusted *p*-values of the Wilcoxon Test and effect sizes *r* with 95% confidence intervals are given for all Wilcoxon tests with *p* < .05

AOI	$Mean_M$	SE_M	$Mean_K$	SE_K	*P* (adj.)	*r*
3	.05	.02	2.22	.38	.004	.882 [.877; .882]
4	1.86	.37	4.30	.91	.020	.663 [.441; 1.000]
5	1.24	.19	2.29	.49	.011	.714 [.543; 1.000]
6	.11	.04	.73	.44	.011	.748 [.643; 863]
8	.92	.21	2.65	.69	.020	.663 [.471; 1.000]
9	.03	.02	1.13	.19	.004	.850 [.815; .914]

Table 2: Average number of transitions (Mean) with standard error (SE), adjusted *p*-values of the Wilcoxon Test and effect sizes *r* with 95% confidence intervals for all tests with significant results

AOI	$Mean_M$	SE_M	$Mean_K$	SE_K	*P* (adj.)	*r*
3 | 4	.07	.07	5.53	1.01	.016	.852 [.793; .888]
3 | 5	.00	.00	1.00	.22	.018	.744 [.627; .878]
4 | 5	.87	.41	3.40	.87	.018	.736 [.529; .865]
4 | 9	.00	.00	.67	.27	.044	.653 [.421; .816]
8 | 9	.13	.09	1.73	.51	.018	.772 [.627; .888]

All significant results refer to more frequent transitions in item K8 than in item M8 and are visualized by red arrows in Figure 1. Transitions along the axes that link information between axis labels and other axis content occur significantly more often in item K8 than in item M8. Other gaze shifts along the upper *x*-axis area and gaze shifts between the *x*-axis intercept and the *t*-axis label also occur significantly more often in item K8 than in item M8.

Conclusions and Outlook

In this study, a test instrument validated by Ceuppens et al. (2019) on linear graphs in a mathematical and kinematical context was used with upper secondary students. Our results confirm for the described sample from grade 11 the following main findings of the study by Ceuppens et al. (2019) with students from grade 9: Difficulties in the context of kinematics, with formulas and in the interpretation of functions with negative slopes. This shows that the difficulties also exist with older students and are not remedied by teaching in the classes in between. To gain more insight into the solution process, the eye-tracking data from a selected item were examined in more detail.

Using a selected pair of isomorphic items to quantify a negative slope, it was shown that gaze behavior differs between kinematical and mathematical contexts. In detail, the results of the eye-tracking analysis show a higher dwell time of the gaze from the axes in item K8 than in item M8, which speaks for a stronger focus of the information extraction on the axis sections. In addition, changes of view between time- and position-axis happen more frequently in item K8 than in item M8, which means a stronger linking of the information on the axis sections. The analysis of the gaze data suggests that in the kinematical context mostly the attempt is made to form the quotient of place and time, which leads to the fact that the negative sign of the velocity is not taken into account and the task is thus solved incorrectly. The reason for this could be the physics lessons, in which an algorithmic procedure for calculating the velocity from the location and time data is taught, so that the application of mathematical procedures is no longer taken into account. These assumptions are supported by isolated interviews conducted as part of this study. For example, one student commented as follows in his description of the solution strategy for item K8: “The distance divided by time is the speed, so I just calculated at the distance 8 divided by time 4, 8 divided by 4 and that was 2 meters per second.” To remedy these transfer difficulties, teachers should be sensitized to this, and this should be done early in their curriculum. A targeted linking of mathematics lessons and physics lessons could on the one hand help to promote the transfer of mathematical procedures for solving physical problems, but on the other hand also connect mathematics to an application.

It seems that students struggle interpreting graphs independent of their age. As graphing is one important, ubiquitous and everyday 21st Century Skill, we will study this question in a broader sample. In addition, based on this important preliminary work, we will collect interview data for triangulation in a follow-up study.

Mathematics as the focal point of STEM teaching

Dorte Moeskær Larsen, Mette Als Kristensen, Lars Seidelin and Connie Svabo

University of Southern Denmark; dmla@imada.sdu.dk; metteals@imada.sdu.dk; lds@imada.sdu.dk; svabo@imada.sdu.dk

The role of mathematics in STEM teaching is often described as limited or unclear, and more or less always conceived as a tool. This paper examines the role of mathematics in 19 STEM activities developed in the research and development project LabSTEM, the goal of which includes developing STEM activities where mathematics is the focal point. All 19 activities include mathematics, and they target students from kindergarten to lower secondary school. The analysis contains a categorisation of the different roles that mathematics plays in the 19 STEM activities. The results show that teachers manage to present mathematics not as abstract and decontextualised but as integrated and relevant in most of the 19 activities. Nevertheless, there is a persistent tendency for them to place mathematics learning in the background, relegating mathematics to a supporting role in STEM.

Keywords: STEM education, role of mathematics, 21st-century skills.

Introduction

As STEM teaching has advanced from being mostly a political goal in many countries to gradually becoming a larger and richer component of the classroom. It is important to consider and reflect on the role that mathematics plays or should play in STEM teaching. The acronym STEM does not automatically mean that all four disciplines (science, technology, engineering and mathematics) are included in teaching activities or are included to the same degree. There is no widely accepted agreement on whether STEM education refers to the promotion of knowledge *within* its individual disciplines or an *integrated* interdisciplinary approach. The disciplines can be combined and integrated in various ways. Some scholars argue that even if only two STEM disciplines are included, they are sufficient to constitute STEM teaching (Stohlmann, 2019). Other scholars contend that mathematics is a critical component of any teaching activity labelled STEM teaching (Doğan et al., 2019).

STEM teaching is often described as having a dual purpose. It must both provide students with the skills to perform tasks in complex and interdisciplinary contexts *and* ensure increased competency and skill level in STEM subjects (Maass, 2019). This dual goal poses the risk of a deep understanding of individual subjects being overshadowed by interdisciplinary, context-driven ways of working. Furthermore, a specific concern in the literature is that mathematics, in particular, will not occupy a distinct position because it figures as a background subject in STEM teaching (Shaugnessy, 2013), and STEM approaches seem to have a less positive impact on mathematical outcomes than science outcomes (Honey et al., 2014).

Consequently, the objective of the Danish development and research project, Laboratory for Integrated STEM (LabSTEM), is to develop STEM teaching activities where mathematics is in focus.

The aim is for teachers to balance between addressing real-world problems that students perceive as interesting and relevant and ensure that they do meaningful work with content, skills or methods from mathematics in combination with the other three STEM areas. In this paper, we ask the following research question: RQ: How can mathematics be integrated as the focal point of STEM teaching?

Different ways of integrating mathematics in STEM activities

In the literature, the relation between mathematics and STEM can be understood in various ways (Bybee, 2013). The question that mathematics teachers often ask is what STEM-integrated activities can do for the subject of mathematics. One of the answers is to make mathematics content and teaching more meaningful and relevant by creating a scenario or context for mathematical problem-solving. However, we also need to ask what mathematics can do for STEM teaching. Science provides mathematics with interesting problems to investigate, and mathematics provides science with powerful tools with which to analyse different scientific problems and concepts; thus, the relationship is reciprocal (Fitzallen, 2015).

Pang and Good (2000) reviewed studies that integrated mathematics and science in the 1990s and stated that, at the time, the dominant approach focused primarily on scientific content, with mathematics assuming a supporting role. The authors even posed an interesting question, which remains relevant today: Is the focus on science a much more natural and productive approach for integration? In contrast, Isaacs et al. (1997) suggested that mathematics should form the primary basis of the integrated curriculum because of its inherently logical structure. Other researchers have pointed to engineering as a good starting point for integrating mathematics into STEM activities (Berland & Steingut, 2016). Bennet and Ruchti (2014) suggested the integration of mathematics into STEM activities using mathematical practices as a common framework, and several scholars have also described mathematical modelling as a way of integrating the disciplines, thereby making mathematics the focal point (Auning, 2021; Doğan et al., 2019; Maass et al., 2019).

Kristensen et al. (2021) developed a framework describing the various roles that mathematics can play in STEM activities. The framework is based on the authors' review of 37 papers, all of which included different STEM activities in which mathematics was integrated.

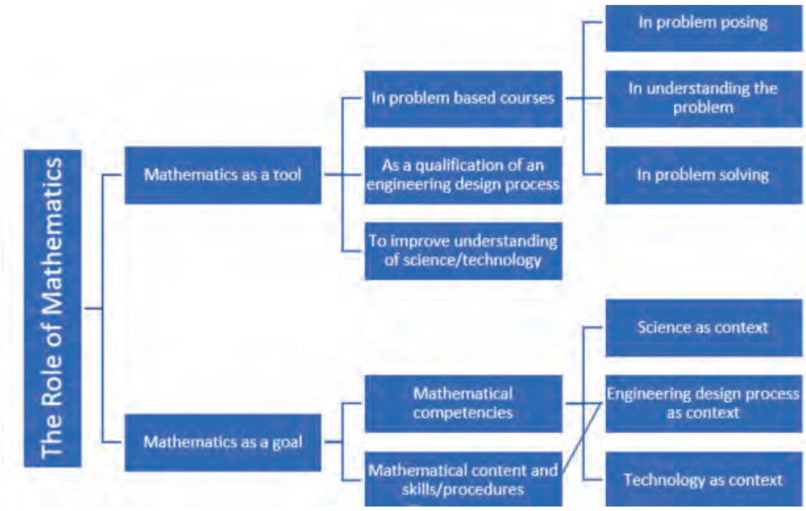

Figure 1: The role of mathematics (Kristensen et al., 2021)

The framework in Figure 1 shows that mathematics can be variously applied as a tool in STEM activities, for example, to qualify an engineering design or improve students' understanding of a specific science. When mathematic is a tool, mathematical skill, contents and competencies are not the focal point of the activity; however, mathematics is included, for example, to solve a problem in science or to develop something in engineering processes. Students do not necessarily learn new mathematics concepts/competences, but they are able to see that their mathematics knowledge can be used in other contexts. Figure 1 also shows that mathematics can be regarded as the primary objective and aim in a STEM activity, for instance, to develop students' mathematical skills and conceptual understandings of mathematics or mathematical competencies (Niss & Højgaard, 2011). When mathematics is the goal, students' learning of mathematics in the activity must be made clear. In these activities, science/engineering/technology is the context for mathematics learning. Mathematics can simultaneously serve as a tool and a goal in specific learning activities, and therefore, the dual roles are not mutually exclusive. More follows on this below.

LabSTEM – mathematics as the focal point of STEM

LabSTEM is a three-year research and development project which began in January 2020. Its purposes are to develop a STEM approach to teaching that is tailored for Denmark and to make it available for teaching and learning practice in order to support sustainable and interdisciplinary STEM teaching from day care to secondary school. Organisationally, temporary communities of practitioners and researchers were established in the form of STEM laboratories. These are not actual, physical laboratories but event-based gatherings of people. In 2021, 17 such laboratories were established, with approximately 250 participants, including kindergarten, primary and secondary school teachers. The aim of these laboratories is for teachers to develop STEM-teaching activities, with mathematics as the focal point. Furthermore, the aim is for these activities to be empirically tested in practice, with guidance from lecturers/researchers from university colleges or the University of Southern Denmark. Throughout the first year, the laboratories developed 19 STEM teaching activities, which we analyse in detail in this paper. These activities explicitly describe how mathematics is included and demonstrate noticeable differences in the ways in which they present mathematics. It is noteworthy that among the participating teachers, some were mathematics teachers, others were science teachers, and many were both.

Methods

The STEM activities were developed in teams of two to six members in the different laboratories. Afterwards, the teachers described each activity, including its title, level, theme, duration, prerequisites, relation to the national curriculum, goals, assessment, the learning process and how the different disciplines (S, T, E and M) operate. The 19 activities were then coded by the first and second authors of this paper in an Excel spreadsheet under different categories: mathematics content from the course description; how mathematics is applied, including a description of student work; a short description of the teaching activity and a description of which STEM discipline was included and its focus. The research group then discussed each activity in relation to the model of Kristensen et al. (2021) (see Figure 1). In this paper, our analysis of the 19 activities is not based on empirical observations from classrooms; it is based exclusively on the teachers' course descriptions.

The 19 activities come from different levels of the school system: two from kindergarten, 12 from primary school and five from lower secondary school. This distribution pertains to the fact that the majority of the STEM laboratories are at the primary school level. The STEM activities deal with myriad contexts, from designing homes for hedgehogs to sorting waste or growing potatoes. A table of the 19 activities can be accessed here: http://kortlink.dk/2dv9k (each of which is numbered; these numberings will be used in this paper). The first two authors of this paper jointly conducted the analyses and categorisations of the different activities. Each activity description was read and discussed with regard to the different categorisations in Figure 1. In the following sections, we first describe one of the activities to clarify our analytical approach, followed by an overall analysis of the 19 activities.

Case – germination and growth of sunflowers and watercress

A first-grade activity called Plants and Germination was developed in one of the laboratories. The focus was on sunflowers and watercress and what their seeds needed in order to grow. The activity began with a walk in the woods, focusing on observing normal conditions for the plants in the forest. Each student was then given a sunflower seed to embed in a cotton ball in a plastic bag, each of which was then taped onto the classroom window, resembling a cardboard greenhouse (see Figure 2a). Each student then kept a schedule of how many millimetres the plant grew from day to day. Additionally, watercress seeds were sown in milk cartons (see Figure 2b), which were positioned in different places in the classroom, with or without light and with more or less water.

Figure 2. Pictures of growing seeds: a) sunflower; b) watercress

In the days that followed, the students observed and documented the seed germination. How many watercress seeds sprouted? By how many millimeters did the sunflower seeds grow per day? The students systematically reported their results on Excel spreadsheets. Clear descriptions were provided that specific focus had to be placed on measuring with a ruler and the concept of measurement. The purpose was to make groups of students find some patterns showing the best conditions for the seeds. At the end of the activity, the students held dialogues in class and then in groups about their results and prepared a short video where they used their data to explain their results while showing the seeds and plants.

The following target outcomes for mathematics are listed in the course description: i) "The student can make a statistical inquiry with simple data". ii) "The student has knowledge of simple methods of collecting, arranging and describing simple data". iii) "The student has knowledge of and can measure units of length" (English translation). Based on the model (Figure 1) of Kristensen et al. (2021), we identified the role played by mathematics in this activity. First, we observed that mathematics was used as *a tool* to develop the students' scientific understanding of photosynthesis. By measuring the sprouts with a ruler, the students learnt more about what the seeds needed to grow. Second, mathematics was a specific *aim* of the activity. As stated in the course description, one of the target outcomes was the development of the students' mathematical skills (by using a ruler) and knowledge about the concept of measurement (as described, e.g. by Lehrer, 2003).

The role of mathematics in the 19 STEM activities developed

Similar to the case discussed in the preceding section, we examined the 19 above-described STEM activities from year one in LabSTEM. In almost all the activities, mathematics was used as a *tool in the STEM activities* (see Table 1). In relation to our RQ, this means that the role of mathematics in these activities was to help the students develop an understanding of science or technology or help them in engineering and design processes. Only in one activity was mathematics not defined as a tool (activity 16). Here, it was the main aim; the focus was on pi and the symbol's history and meaning in everyday life.

Mathematics as a tool and the aim of the mathematics (activity number is in parentheses)

Table 1: Overview of the role of mathematics in the developed activities

As mentioned earlier, all course descriptions explicitly listed the mathematics-specific goals of the various activities (this was a requirement in the guideline form), but it is important to clarify that we do not know whether the students actually achieved these goals in practice. Moreover, the descriptions were not all clear about how the students would achieve these specific goals.

By studying the mathematics-specific content comprising the explicit aim of the 19 activities, we observed a wide spectrum. It was difficult to judge whether the content was about reviewing known concepts/skills or learning new concepts/skills in mathematics; however, we found a prevalent focus on the application of known mathematics, mostly because the goals described were often included in the curriculum of lower classes. However, in these activities, the students tried to apply the mathematical concepts as tools in other as well as new contexts. Three activities described a specific focus on problem-solving, but in many of the others, mathematical modelling competence was very central, albeit without this being explicitly described. Often, only the mathematical skills were explicitly written, including practising counting, learning or reviewing skills in measuring time, handling data (e.g. with frequency tables) and measuring length with a ruler. Table 2 below presents an overview.

Mathematics as an aim	
Competence	**Skills and concept knowledge**
problem-solving	counting, writing numbers, scale ratio, geometric shapes, spatial figures, curves in the coordinate system, concept of functions (slope), measurement, statistics, spreadsheet, time, data comparison, pi, area and volume, angles, economics

Table 2: Mathematics-specific goals in the developed activities

We include statistics as part of mathematics because it is part of the mathematics teaching curriculum at these grade levels. This is despite the fact that these subject areas can also be viewed as separate from each other (Capaldi, 2019). Table 2 demonstrates that it is not accurate to say that some mathematical topics feature more frequently as aims in STEM courses than others as there is no one-sided focus on specific topics.

Discussion and conclusion

Overall, the LabSTEM teachers developed activities in which mathematics is part and parcel of the aim and where the participating students engage with mathematics as a tool to gain a deeper understanding of science/technology/engineering. It is less clear the extent of the role of mathematics as this is not explicitly stated in the LabSTEM activity descriptions.

In many STEM activities, mathematics has no clear role (Kristensen et al., 2021; Martín-Páez et al., 2019). However, in the 19 activities discussed in this paper, mathematics is not abstract and decontextualised. It is clearly part of the activity, and it is relevant and integrated to a greater or lesser degree. Interestingly, when teachers are assigned the specific task of making mathematics the focal point, they almost always use mathematics as both a tool *and* a goal, which leads to the question of whether it is possible *not* to make mathematics a tool in STEM activities (making it only the aim) and still integrate all the disciplines.

To answer the question of how mathematics can be integrated as the focal point of STEM teaching, we argue that teachers need to have a clear focus on this when planning the teaching activity and need a great deal of support if this is to happen. At the same time, mathematics must figure as both a goal and a tool in the activity itself. The kind of tool that mathematics is, however, is an interesting question, and the precise meaning of *tool* could well be up for further research – for example, is tool a language or a context?

The mathematics-specific goals of the 19 activities are widespread, but they are often characterised by reviews of mathematical concepts, skills training or applications of learned mathematics. Gravemeijer et al. (2016) discussed how mathematics may prepare students for the future and argued for a shift *from* competencies that compete with what computers can do *to* competencies that complement computer capabilities. They suggested a greater focus on developing 21st-century skills such as critical thinking in mathematics, posing mathematical problems and mathematical communication. This is in line with the argument that STEM teaching aims to prepare for 21st-century skills (Maass et al., 2019). There is, however, little connection between the mathematical content that Gravemeijer et al. (2016) proposed and the mathematical content forming the aim of the developed activities. For example, none of the activities have creativity or the posing of problems as aims. However, in addition to the explicitly described mathematical content, other mathematical processes will probably be included when the activities are enacted in practice. Examples include whether students need to make argumentations for their mathematical answers (mathematical reasoning competence) or work with different mathematical representations (mathematical representation competence) (Lim & Seldom, 2010).

An additional theme worth discussing is the clarity of the target outcomes for students. Is it problematic if students are not explicitly told that mathematics competencies are included in the activities? Although we, as researchers in mathematics education, can perceive mathematics as central, it is probably more doubtful that all students will be cognisant of this. In this case, therefore, the activity would not help solve the problem of viewing mathematics as abstract and isolated from students' everyday life (Niss & Højgaard, 2011).

One of the tendencies of working with integrated STEM activities is to relegate the specific subjects to the background and bring the case/problem to the fore (the problem, rather than the subjects, as the aim) (Klausen, 2011). This may form the basis of critical reflection towards our own study since, in one sense, it contains a degree of "silo thinking": focusing on mathematics in integrated activities. Nevertheless, if the most important part of mathematics is invisible to students, there is a great risk that they will not experience the significance of these competencies. Obviously, the teachers in the LabSTEM project do not present mathematics as abstract and decontextualised but as integrated and relevant in most of the 19 activities. In many ways, however, they are still inclined towards pushing mathematics learning to the background, relegating it to a supporting role as a tool in the STEM context rather than important in its own right.

Construction and calibration of an electronic weighing machine

Aitzol Lasa[1], Adolfo Lizarraga[2], Álvaro Sáenz de Cabezón[2] and Iker Irañeta[3]

[1]Public University of Navarre, Faculty of Education, Spain; aitzol.lasa@unavarra.es

[2]Salesians College, Spain; a.lizarraga@salesianospamplona.net; a.saenz@salesianospamplona.es

[3]Mendillorri Secondary School, Pamplona, Spain; iiranetunz@educacion.navarra.es

We present the structure of a STEM project in which middle school students (i.e., thirteen to fourteen-year-old mandatory secondary school students) must build and calibrate and electronic weighing machine to contextualize the mathematical notion of linear function. During the calibration process, the didactical situation may overcome students' algebraic knowledge; therefore, dynamic software is used to aid what students cannot do for themselves.

Keywords: Secondary school mathematics, STEM education, 8th grade.

Theoretical frame

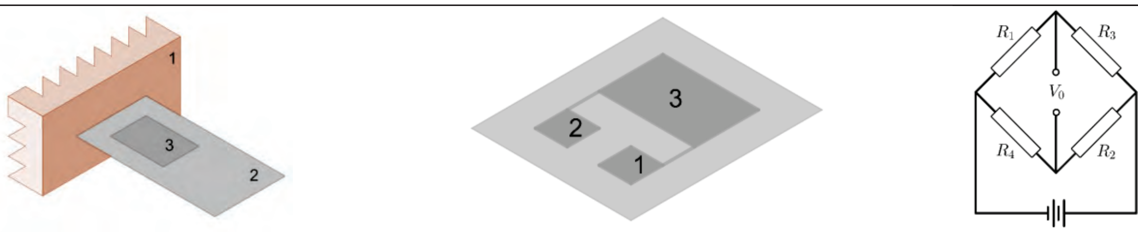
Let's consider a STEM project as a *didactical situation* (Brousseau, 1997) where students apply their personal mathematical knowledge and use a number of basic strategies to solve a particular task. The mathematical knowledge students are required to face in STEM problems mostly regards measurements, elemental geometrical language and arithmetical operations with numbers (Lasa, Abaurrea & Iribas, 2020). Finally, the STEM notion of *technological literacy* in a mathematical context naturally brings us to Instrumental Theory, since dynamic models can operate as antagonistic milieu, giving students the necessary feedback of their performance (Lasa & Wilhelmi, 2013).

Experimentation

Laboratory work (science) involves measurement of quantities in scientific notation and the use of the international unit-system, laboratory work (technology) to design an electric circuit prototype, the calibration of the scale by technological means (engineering) and the modeling of linear functions in real contexts, where students obtain numerical values out of algebraic expressions (mathematics).

Theoretical basis

The experiment is based on the assumption that the scale can be calibrated from a linear relationship between the known weigh of predetermined objects and the variation in the resistance of an electric circuit embedded on the metal piece, which forms the deformation gauge (figure 1).



a) Deformation gauge. 1, structure support; 2, aluminium gauge; 3, extensiometric gauge.

b) Detail of the extensiometric gauge. 1, input terminal; 2, output terminal; 3, electrical circuit.

c) Outline of a Wheatstone bridge

Figure 1: Outline of a deformation gauge and Wheatstone bridge

Experiment

Predetermined experimental phases in both schools avoid phase-order variability:

Global discussion of shapes	→	Software modeling (DGS)	→	Physical construction	→	Mathematical formal study

Figure 3: Project steps (Lasa et al., 2021)

Results

Students have built a personal knowledge regarding the equation of the line, and are receptive to address the mathematical formalization of the line from a theoretical point of view. The mathematics teacher will now assume leadership and institutionalize the notion of linear function.

		a) Staging	b) Calibration	c) Measure

Figure 5: Student working at the lab

Conclusions

This experience confirms that it is possible to integrate formal mathematics in the context of STEM projects, beyond its usual assistant character. Furthermore, the key notion of didactic situation has led us to an adapted structure for STEM project with a final formal mathematical component.

What characterizes STEM professionalism?

Maria Møller

Aarhus University, Danish School of Education, Denmark; maml@edu.au.dk

*STEM education and the development of children and young people's STEM competencies are on the political and educational agenda worldwide. In Denmark, curriculum descriptions of STEM competencies do not exist. Before composing such descriptions, it is relevant to investigate what characterizes STEM professionalism (Danish: STEM-*faglighed*). A hermeneutic framework provides the basis for a literature and document review, examining how international research, ministries, and the business community, characterize STEM professionalism. The analysis takes place through a concept map. Three categories characterize STEM professionalism: computing and visualising 'everyday' data with computers, finding and solving STEM-related problems, and innovative STEM thinking. These categories can form a starting point for identifying and describing STEM competencies. A prototype of a STEM competency flower with three petals is presented.*

Keywords: STEM competencies, STEM professionalism, literature review, hermeneutical approach

Introduction: Relevance and research question

The international community aims to ensure that more children and young people acquire competencies in STEM (science, technology, engineering, mathematics) (Bybee, 2018; E. Council, 2006; N. R. Council, 2011; Regeringen, 2018; Zollman, 2012). Competence descriptions can be the starting point for formulating concrete competence goals, which are essential for students to develop specific STEM competencies (Højgaard & Sølberg, 2019). If policy actors, principals, and teaching staff explicitly want to improve students' competencies in STEM, competence descriptions are essential (Sølberg et al., 2015).

In Denmark, academic competence descriptions in the curriculums define the professionalism of all courses in the primary and lower secondary school. For example, six competencies define the professionalism of mathematics (Børne- og Undervisningsministeriet, 2019b), and four define natural science[1](Børne- og Undervisningsministeriet, 2019a). In a Danish curriculum context, no descriptions of STEM competencies exist. With the object of making descriptions of such STEM competencies, it would be relevant to investigate what is understood when talking about STEM professionalism. A well laid-out characterization of STEM professionalism may subsequently identify some STEM competencies which can form the basis for future STEM education in Denmark.

Professionalism in an educational context

What is meant by professionalism in STEM is not clearly defined. Therefore, this paper examines how the community, such as international research, ministries, and the business community,

[1] Natural science includes the courses in nature/technology, physics/chemistry, biology, and geography

characterize STEM professionalism. In that light, the following research question arises: *What characterizes STEM professionalism according to international research and texts from ministries and the business community?*

Methodology

When, in 2020, I completed a Ph.D.-proposal (Møller, 2020) for a scholarship within educational research, I gained knowledge of several texts relating to STEM education and teaching. My search for literature for the project proposal used 'non-systematic' and 'deliberate-random' searches in Google Scholar, with keywords such as 'STEM', 'science', 'mathematics', 'education' and 'teaching' in English and Danish, respectively. Knowledge from this search process forms the basis for my initial thoughts and ideas about my upcoming literature search for STEM professionalism.

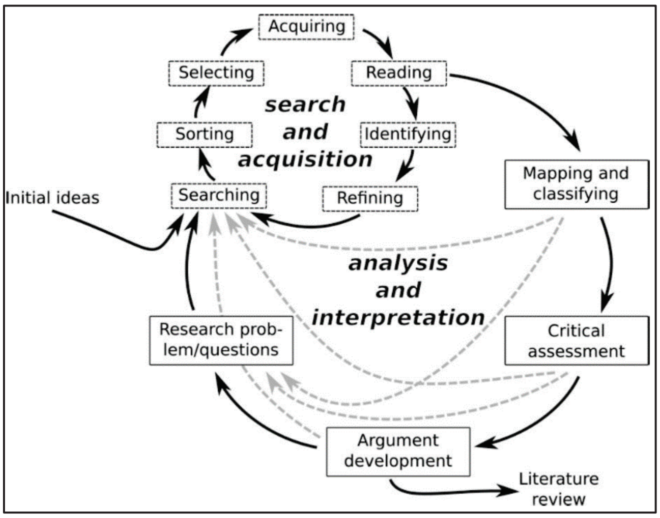

Figure 1. A hermeneutic framework for the literature review process

Based on a hermeneutical view of science, I chose a hermeneutic approach to rule the review process. A hermeneutic approach for a literature review is carried out by iterations between the two circles *search and acquisition* and *analysis and interpretation*, illustrated in Figure 1 (Boell & Cecez-Kecmanovic, 2014, p. 264). The two circles are mutually independent. New knowledge achieved in one part of the process can give a new understanding of the field, and a new understanding of the field can change the perspective of well-known sub-elements. From a hermeneutic viewpoint, you can say that the part gives an insight into the whole, which provides an understanding of the part (Brinkkjær & Høyen, 2018).

The review process

The wording in the research question '*What characterizes STEM professionalism…*' gives reason to be interested in how texts describe and relate to elements that can characterize STEM professionalism. A 'characterization' is a description of a given object's distinctive features or fundamental characteristics. In that light, I am interested in finding characteristics and features of STEM professionalism described in international research and texts from ministries and the business community. The purpose of the review process is, therefore, to assemble a corpus of literature that, through analysis, will develop some arguments for the characterization of STEM professionalism.

Search and acquisition – sorting and identifying core literature

I commenced my review process by rereading the 29 references in my PhD proposal (Møller, 2020). The texts served as *initial ideas* for going in the upper circle in Figure 1. In the texts, I explored keywords and issues that can describe features and characteristics of STEM professionalism; e.g., descriptions of STEM-related competencies, goals for teaching STEM to pupils, and central knowledge and skills in a STEM context. I included the publication if I thought its content could contribute to a characterization of STEM professionalism. An example is Barcelona (2014) because the publication articulates the importance of students' ability to solve STEM-related problems.

I include seven references from my PhD project proposal in the review; see Table 1.

Analysis and interpretation - a concept map as a tool for analysis

As I read the included texts, I shifted to the bottom circle in Figure 1. While I read the individual texts, I organised essential concepts, topics, or content that described scientific elements concerning STEM professionalism in a digital concept map. A concept map can process and structure a collection of concepts and themes with complex interrelationships (Steen et al., 2020). An example of texts that contribute with content in the concept map is the National Research Council (2011) with 'handling a large amount of data' and Holdren et al. (2013) with 'creativity' in the context of solving problems.

As I read more texts and obtained several subject elements, I organised the elements in groups, which related to or impacted each other. I explained the groups' relationship with arrows. When I perceived that the grouping had a certain kind of consistency, I gave them a header. I may have created a header or decided that one of the subject words was descriptive for the grouping. I printed the digital concept map and used analogue Post-It to place new concepts or replace concepts into new groups. I wrote analogue Post-It notes in the digital concept map at natural moments in the analysis process. For example, I would do this at the end of the working day, or if I knew that I could not continue to work on the review process for a few days. Thus, the online concept map was dynamic and continuously changing, and developed as I worked through the first iteration.

Iteration two, three, four …

The purpose of doing more than one iteration is to find more texts that deal with the field and reach a point of saturation (Boell & Cecez-Kecmanovic, 2014). When no new literature or significant arguments arrive in further searches, saturation is reached.

I identified different texts through a snowball effect and citation searches. In the second iteration, I looked back at the seven included texts from my first iteration by noting relevant texts from their lists of references. Currently, I am working with the phases: sorting, selecting, acquiring, reading in the top circle in Figure 1. I also look forward to finding recent texts that refer to the given publication; e.g., Holdren et al. (2013) Carneval et al. (2011). This may also lead to the inclusion of Carneval et al. (2011).

In addition, through iterations three and four, relevant texts will be retrieved by searching in library databases, talking to colleagues and other STEM stakeholders, participating in webinars, and looking into relevant project descriptions; e.g., European project proposals like Erasmus+ (CiSTEM, 2021). The dynamic hermeneutic process leads to a deeper and more wide-ranging overview and understanding of texts dealing with sub-elements to characterize STEM professionalism. I will work in the phases: mapping and classifying, critical assessment and argument development, which belong to the bottom circle in Figure 1. The second, third, and fourth iterations include 13, nine, and 32 texts. The 61 included texts are illustrated in Table 1. In Møller (2021), an exhaustive reference list is available.

Table 1. Included texts in four iterations. In Møller (2021), *a reference list is available.*

Iteration	**Included publications**	**Total**
1: Identify relevant key concepts in STEM professionalism	Re-read publications from my ph.d.-project description – select overview texts (Undervisningsministeriet, 2018) (Erhvervsministeriet, 2018) (E. Council, 2006) (N. R. Council, 2011) (Holdren et al., 2013) (Barcelona, 2014) (Becker & Park, 2011).	7
2: Expand text material	Snowball and citation searches, talk to stakeholders, European projects proposals, webinars (Carnevale et al., 2011) (Arikan et al., 2020) (English, 2016) (Bybee, 2013) (Jensen, 2007) (Wing, 2006) (De Meester et al., 2020) (Halász & Michel, 2011) (Københavns Universitet, 2019) (Jang, 2016) (Johnson et al., 2020) (Carracedo et al., 2018) (Siekmann & Korbel, 2016)	13
3: Systematic search in databases	Search string with keywords found in 1st and 2nd iteration (Baron et al., 1989) (Berns & Erickson, 2001) (Bingman & Stein, 2001) (Harvey & Charnitski, 1998) (Shaw, 2000) (Stull, 1998) (Velez et al., 2015) (White & Berlin, 1985) (Sølberg, 2020)	9
4: Transversely expand text material	Snowball and citation searches, talk to stakeholders, European projects proposals, webinars (Aldron & Soury-Lavergne, 2016) (Augustine et al., 2005) (Berry & Csizmadia, 2016) (Connecticut State Dept. of Education, 1991) (Council on School Performance Standards, Frankfort, 1989) (George, 1996) (Government Office for science, 2017) (Grgurina, 2016) (Howard et al., 2000) (Hõlm et al., 2016) (Hurd, 2000) (Karis & Andersson, 2016) (Kiselova & Gravite, 2017) (Kjelvik & Schultheis, 2019) (Li et al., 2019) (Linney & Walshe, 2016) (N. R. Council, 2014) (Smith & Moore, 2014) (Steele, 2013) (Yeung et al., 2000) …	32
Saturation	**When no new literature or significant arguments arrive in further searches, saturation is reached.**	**61**

Findings

As the review process evolves, groupings in the concept map appear. In the analysis and interpretation of the groups, I use the term ‘category’ for a unit that brings together key concepts and contents that deal with STEM professionalism. I use the word ‘theme’ to describe the analytical units that crystallize within each category. No categories are thus determined in advance but stem from the literature and the documents found through the review process.

Categories and themes found

After four iterations in the review process, I will designate five groups in the concept map. Out of consideration of the limited extent of this CERME-paper, I include arguments for the first three categories with associated themes. I mark the first three categories with a blue oval in Figure 2. Each category is distinct from but overlaps every other category and cover-up several themes. Some themes relate to more than one category.

I take a normative stance on the categories in the descriptions, but I am conscious that the review process aims to characterize STEM professionalism for future STEM education.

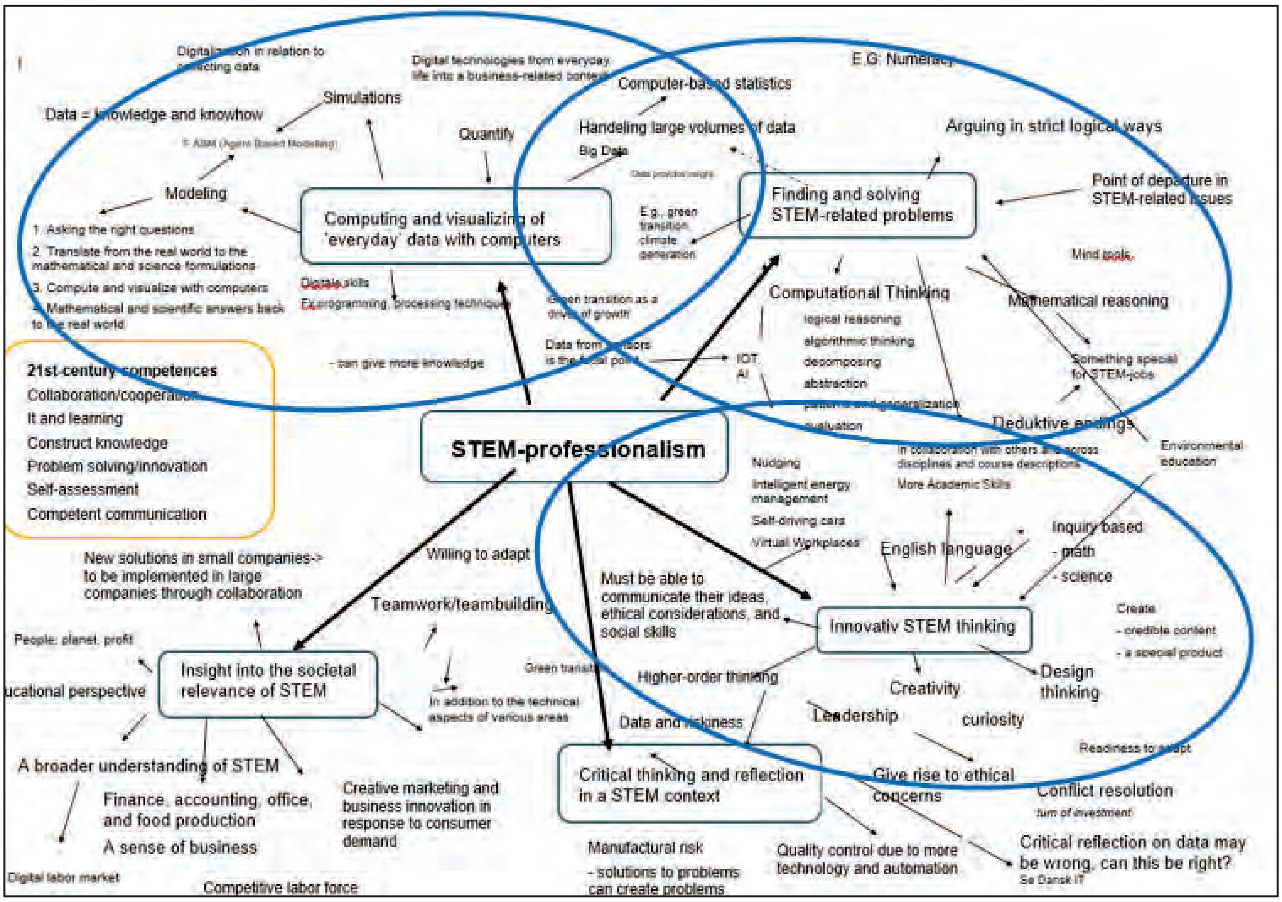

Figure 2. A draft of the concept map of STEM professionalism divided in five groups. Three categories are marked with blue ovals.

Computing and visualising 'everyday' data with computers

The first category I present from the concept map is c*omputing and visualising 'everyday' data with computers*. Computers are necessary to work with and can handle large volumes of data. In a STEM context, authentic data from everyday life is essential (Kjelvik & Schultheis, 2019). Authentic data are accurate, quantitative, or qualitative information collected from real-life phenomena. Computers and associated programs have several advantages to quantify this kind of data (Linney & Walshe, 2016). A way of getting an overview of data is to visualise it with graphs and computer-based statistics (Howard et al., 2000, Hõlm et al., 2016). Modelling is relevant for visualising data in a usable way and becomes a theme in the first category. Modelling in a STEM context is about asking the right questions, translating from the real world into mathematical and science formulations, computing and visualising with computers, and formulating a mathematical and scientific answer back in the real world (De Meester et al., 2020; Jensen, 2007; Steele, 2013, Aldron & Soury-Lavergne, 2016). Simulations can support modelling in STEM by imitating minor or more prominent parts of reality—for example, a cell's interior or how the oceans' ecosystems are affected by acid pollution. An insight into such active representation of reality can contribute to learning and understanding relatively abstract STEM-related phenomes (Karis & Andersson, 2016). Simulations also become a theme. To visualise data with computers, you must manage and handle a large amount of data (E. Council, 2006; Karis & Andersson, 2016) and have some digital skills. These form the last two themes in the first category.

Finding and solving STEM-related problems

Problem-solving skills involve the identification of complex problems based on STEM-related issues and related information required to develop and evaluate options and implement solutions (Bingman & Stein, 2001; Carneval et al., 2011; Carracedo et al., 2018; E. Council, 2006; Halász & Michel, 2011; Howard et al., 2000; Jang, 2016; Shaw, 2000; Steele, 2013; White & Berlin, 1985). This leads to the second category: *Finding and solving STEM-related problems*. One way of solving STEM-related problems includes computational thinking (CT) (Becker & Park, 2011; Wing, 2006). CT becomes the first theme in this category. CT is a problem-solving process that encompasses several sub-processes For example, logical reasoning, algorithmic thinking, decomposing, abstraction, patterns and generalisation, and evaluation (Berry & Csizmadia, 2016). CT, modelling, simulations, and handling a large amount of data with computers can provide new knowledge to find resolutions to STEM-related issues. For example, these include disease control, nutrition, global warming, new energy sources, and understanding the universe (Hurd, 2000). This problem-solving process assumes mathematical reasoning and deductive endings, which becomes the second theme (Augustin et al., 2005). With the language of math, science, and technology, you can argue in strictly logical ways, which is notable for solving STEM problems (Connecticut State Dept. of Education, 1991; Council on School Performance, Frankfort, 1989). Solving complex problems in a STEM context requires an interdisciplinary approach (Arikan et al., 2020; De Meester et al., 2020) and opens the possibility of cooperation between different STEM disciplines (Berns & Erickson, 2001). An interdisciplinary approach is the last theme in this category.

Innovative STEM thinking

When we want to find resolutions to STEM-related issues, thinking innovatively in a STEM-minded way is essential (Barcelona, 2014). *Innovative STEM thinking* is the third category. Innovative thinking is about having an idea and carrying it out. However, it is also about thinking in different ways and involves various perspectives. Creativity, design, and design thinking are themes in this category. Creativity is an important way of thinking in a STEM context (E. Council, 2006; Holdren et al., 2013; Jang, 2016; Regeringen, 2018; Steele, 2013). Design and design thinking can be approaches that encourages different perspectives in viewing and solving problems, and they are vital to creativity and innovation (Li et al., 2019). When you work creatively and innovatively, you need to collaborate with others within and across disciplines. To do that broadly helps communicate ideas to others and to understand inspiration and explanations from international sources, such as the internet (Jang, 2016; Yeung et al., 2000). In this situation, mastering the English language is advantageous (Berns & Erickson, 2001; Bingman & Stein, 2001; Baron et al., 1989; Yeung et al., 2000). Communication and interdisciplinary collaboration are the last two themes in this category.

To summarise, the first category with associated themes is: computing and visualising ‘everyday’ data with computers (modelling, simulations, handling a large amount of data, digital skills). The second category with associated themes is: finding and solving STEM-related problems (computational thinking, mathematical reasoning and deductive endings, interdisciplinary approach). The third category with associated themes is: innovative STEM thinking (creativity, design and design thinking, communication, interdisciplinary collaboration). A complete overview of the included texts related to the categories and themes is registered in Møller (2021).

Concluding remarks

The findings of this paper indicate that it is possible, using a review with a hermeneutical approach, to develop some arguments for the characterization of STEM professionalism. Because of limited space, this paper includes arguments for the first three categories with associated themes. However, it is reasonable to think that the concept map's last two groupings can also be described. When that is properly carried out, the five categories can constitute an identification of STEM competencies. The competencies can be represented in a so-called competency flower, known from mathematics in the KOM framework (Niss & Højgaard Jensen, 2002). In Figure 3, I have designed a prototype of a STEM competency flower with the first three petals: *STEM data handling competency, STEM problem handling competency, and STEM innovative thinking competency*. When the last two competencies are found, it is reasonable to assume that a STEM competency flower with comprehensive descriptions can be a starting point for competency-oriented STEM education.

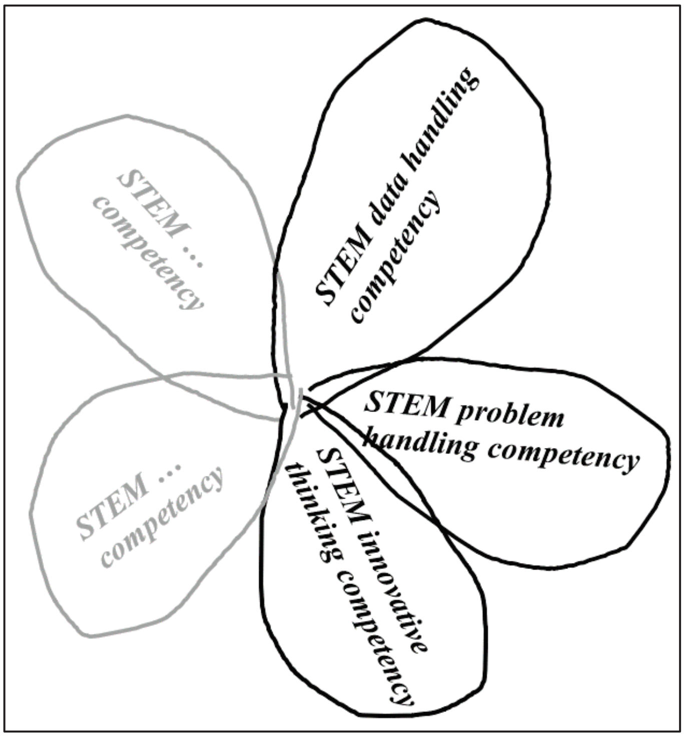

Figure 3 A prototype of a STEM competence flower with the first three petals

Suppose ministries, stakeholders, and teachers take such STEM competence description as a premise. In that case, the STEM competence descriptions can be the gateway for future competence-oriented STEM education, possibly explicitly developing pupils' STEM competencies.

Exploring the engineering design process on designing a neighborhood in project-based learning environment

Behiye Ubuz[1] and Yurdagül Aydınyer[2]

[1]Middle East Technical University, Faculty of Education, Turkey; ubuz@metu.edu.tr

[2]TED Ankara College Foundation Schools, Turkey; yurdagultoka@hotmail.com

Abstract: In this paper we explore 7th grade students' engagement with engineering design processes while designing a two-dimensional scale plan of a neighborhood in Project Based Learning environment. To do this, verbal protocols throughout classroom observations and interviews were collected from 97 seventh-grade students. We analyze these protocols to document the students' engagement with engineering design processes together with opportunities to learn and apply mathematics. The results show that project-based learning engages students in engineering design processes while designing a two-dimensional scale plan of a neighborhood as a project.

Keywords: Engineering design process, geometry, project-based learning.

Introduction

The project-based learning (PBL) approach engages students actively in pursuing solutions to authentic (driving) question that serves to organize and guide instructional tasks in both the presentation (benchmark lessons) and practice of selected topics (project) (see Ubuz & Erdogan, 2019 for the definition of presentation and practice of selected topics). PBL scaffold learning and build meaningfully powerful Science, Technology, Engineering, and Mathematics (STEM) concepts supported by language, social studies, and art (Capraro & Slough, 2013). PBL builds on engineering design process as the cornerstone (Capraro & Slough, 2013). While engaged in a project, following an engineering design process (EDP) allows systematic learning, simultaneously exposing students to experience the cognitive processes of an engineer (Tate, Chandler, Fontenot, & Talkmitt, 2010).

The key features of PBL (e.g., Markham, Larmer, & Ravitz, 2003) are to encourage students' learning and develop the essential knowledge and skills to engineer a personalized solution to the design problem (Chua, Yang, & Leo, 2014). Even though many works have been conducted on PBL, none has specifically tailored to document students' engagement with EDP. To do this, this paper focuses on documenting students' engagement with EDPs while designing a two-dimensional scale plan of a neighborhood in a PBL environment. EDP model followed in the current paper is composed of the following four characteristics: 1) Defining the problem, 2) generating and selecting between multiple possible solutions, 3) modeling and analysis, and 4) iteration (Berland, Steingut, & Ko, 2014). Specifically, this paper is guided by the following research question: How do students engage with the EDP in the PBL environment?

Methodology

Participants

The participants in the present study included those students for whom Project Based Geometry Learning (see Ubuz & Aydınyer, 2019) were instructed for five 40-min periods per week over the course of six weeks (altogether thirty 40-min periods). A total of 97 seventh-grade students, consisting of 57 females and 40 males, in three intact classes from a private school in Ankara, Turkey were the participants.

Description of the Project in Project-Based Learning Environment

In the PBL environment, students faced a challenging project, including the following problem situation to specify the well-defined outcome and ill-defined task:

> "There is a so-called contest entitled Neighborhood Renewal Project for redesigning a neighborhood replacing old buildings (not historical ones) with new ones. When you begin to design your scale plan, keep in mind that you have some design requirements."

The project was conducted during the last 14 lesson hours. To mirror real-world engineering, the students had to accommodate the following requirements to design their scale plan:

- Designing a two-dimensional scale plan of a neighborhood located on a rectangular smooth surface with actual dimensions of 120 m and 170 m on an empty white cardboard with the corresponding dimensions of 48 cm and 68 cm.
- Considering the needs of the residents and environmental problems encountered by them.
- Including different positions of three lines in a plane representing roads as well as certain polygons with some dimensions representing ground areas covered by buildings and other areas.

Students were expected to design their scale plan mainly using their knowledge of geometry and mathematics. The students were assigned to small groups composing three or mostly four students on the basis of the data from Group Embedded Figures Test. Each group included at least one student from each cognitive style (field dependent, field mixed, and field independent) Once the problem, "How do you design your neighborhood plan?", was posed to the class at the beginning of the PBL, some sample scale plans of different neighborhoods were shown by projecting them on a large screen to discuss the positions of the roads with respect to each other and the types of polygons used for buildings based on their existing knowledge. Then, they were asked to conduct some preliminary research to design their plan, including:

- Finding some scale plans of different neighborhoods to investigate their location, population, climate, economy, industry, history, and natural vegetation; the environmental problems that their residents encounter; and their roads, buildings, and other areas, and possible actual dimensions of them; and
- Investigating different people's involvement in designing a neighborhood.

By reference to information collected through their investigations and discussions throughout their outside classroom work, each group decided their groupmates' professional roles and their group leader. Following this, each group started to construct their scale plan considering the requirements provided above.

Throughout creating their scale plan, the classroom teacher interacted with the groups, answered the students' questions, and prompted them to explain their choices and consider different alternatives. Although the project was set up as a contest between the groups, they were introduced that every project can win the contest as long as it fulfills all requirements.

Data collection and analysis

Classroom observations (abbreviated as O) and interviews (abbreviated as I) with the students depending on their available time during the treatment let us document students' engagement with EDPs. Classroom observations and semi-structured interviews were conducted during and after the treatment. Each class was audio-recorded. Each interview conducted individually was also audio-recorded. There was no time limitation for the interviews. Interview questions are as follows: "What resources did you use while making the outside-classroom search? What information did you find?", "Did you encounter any difficulties while creating your scale plan? If any, what kind of difficulties did you encounter? What did you do to overcome them?", "How did you decide the types of polygons for ground areas covered by buildings and other areas of your scale plan?", "Did you like/dislike creating your scale plan?", and "What did you learn from creating your scale plan?" Please refer to the paper on the PBL environment (see Ubuz & Aydınyer, 2019) for the other details about interviews.

The tapes from the classroom observations and interviews were then transcribed. The transcripts were then segmented into units of text in preparation for coding. Each segment represents one idea. Segmenting was done independently by the two researchers, checked for reliability, and any inconsistencies were resolved. The average reliability for segmenting was 94%. Once the segmenting was completed, data analysis was conducted. Each segment was coded with respect to EDP characteristics and their key aspects in the coding scheme (Berland et al., 2014). This process was fluid—a single utterance could speak to multiple EDP characteristics, and each characteristic could be addressed multiple times throughout the observation and interview.

Findings

The findings are provided around the aforementioned four characteristics of the EDP.

Defining the problem

After the teacher provided the driving question, each student simultaneously communicated with their parents, relatives, social studies teacher, and headman, and conducted research from various sources (e.g., the Internet, books, or other sources). From their parents and relatives, he/she received information regarding their profession (e.g., engineering, architecing, landscape architeching, city planning). From their social studies teacher, he/she got information about the geographical position, population, climate, economy, industry, history, and natural vegetation of some places. From the headman of their neighborhood, he/she got a sample plan of their neighborhood and information about the requests and complaints of the residents. Through searching the Internet, books, or other sources (e.g., atlas, maps, encyclopedias), he/she found (1) some sample scale plans of different neighborhoods, (2) articles on designing a place, (3) the standards of designing a neighborhood (e.g., the number of floors of buildings should be adjusted according to the population of a neighborhood, wider streets are needed to be established if the neighborhood is close to the city center to be reached quickly and easily), (4) the elements of a neighborhod (e.g., roads, buildings and other areas), and (5) actual side lengths of the ground areas of the buildings and other areas as well the width of the roads. Regarding to a particular neighborhood, he/she found its (1) geographical position (e.g., latitude and longitude, neighboring places, whether it is mountanious or by the sea, a town belongs to which city), (2) population, (3) climate (e.g., average highest and lowest temperature each month, continental or Mediterranean climate), natural vegetation (e.g., woodland bush), (4) growing products (e.g., fruit trees, vegetables), economy and main sources of income (e.g., agriculture, tourism, industry), (5) history (e.g., historical and cultural buildings and other areas in it), and (6) environmental problems that the residents encounter.

I-S17: I have learned what professional owners of city planners, architects, engineers, and landscape architects do. We are going to choose black pine for green areas [for our scale plan] because we learned that it produces more oxygen compared to other types of trees.

Upon their investigations, they realized that the main environmental problems were air pollution, noise pollution, lack of green areas, traffic congestion, global warming, and unplanned urbanization; and different elements (e.g., roads, buildings, other areas) needed for the residents of a neighborhood regarding residence, health, education, administration, shopping, transportation, entertainment, doing sports, recreation, eating-out, and religion. Additionally, they realized what professions should be included in a common project to design a place, what they do, and their training process at a university. Upon this, each groupmate decided his/her profession. They mostly chose to be an engineer, an architect, and a city planner. Then, the groups decided where to design a neighborhood. Most of them decided to design it in different places (e.g., big cities, small towns, seaside, island, etc) in Turkey and a few in abroad.

To accommodate a neighborhood they wanted to design that is sustainable, walkable, vibrant, social, and livable, the groups started to make decisions to solve the issues the residents of the neighborhood encounter regarding the location, population, climate, economy, industry, history, natural vegetation, environmental problems, roads, buildings, and other areas.

As emphasized above, the main goal was to improve existing residential communities. The problems raised in the context of this main goal can be listed as follows:

1. What could be the elements of the neighborhood and the places of them?
2. What could be the polygonal shapes of each building and other areas?
3. What could be the side lengths and angle measures of polygonal shapes representing ground areas of the buildings and other areas in real life and on the plan considering the scale together?

4. What could be the positions of roads with respect to each other using positions of three lines in a plane?
5. What could be the width and length of the roads on the plan?
6. How can we draw and place polygons and roads agreed upon on the scale plan using a protractor and a ruler?

The first problem is about deciding the issues related to the scale plan and the following four problems are about deciding geometric representation of the physical environment in the neighborhood, while the last is about drawing the scale plan.

Generating and selecting between multiple possible solutions

Regarding the first problem, the students decided the elements of a neighborhood and the placement of them in it based on their communication, search and investigation emphasized in the previous part. Regarding the elements of a neighborhood, they mostly decided to include houses for residence; buildings of health clinic and pharmacy for health; schools for education; bank, headman's office, fire department, police office and post office for administration; market place and shopping center for shopping; bicycle routes, bus station, parking lot, petrol station, roads and taxi rank for transportation; theatre and cinema for entertainment; areas to do different kinds of sports; green areas and playgrounds for kids for recreation; and restaurant for eating-out. They also included different cultural and religious areas in their plan to be respectful to people from different cultures. They planned to protect existing historic and cultural places as well as natural beauties. Furthermore, depending on the place of the neighborhood, they included other areas such as a harbor if it is by the seaside. It was interesting to observe that some groups decided on cultivating particular fruit trees and vegetables according to the climate of the neighborhood so that the residents can do their own organic farming. They also decided to have buildings that are not too high to solve unplanned urbanization.

In determining the placement of the buildings and other areas in the scale plan, students usually made suggestions within their professional roles. The suggestions of the students in different roles were discussed within the groups and then a common decision was reached. Throughout the presentations of their project to the class, for example, they said the following as a group:

> As a landscape architect and the group leader, I (O-S12) advised to design green areas as large as possible…The reason that we chose this neighborhood was its unplanned urbanization. We tried to give importance to the aesthetic [appearance of it]... As a city planner, I (O-S13) advised to place buildings such as a pharmacy, a fire department, a police office, and schools in the center of the neighborhood so that the residents could be able to reach them easily… As an architect, I (O-S16) advised not to include the two houses very next to each other… We have learned how to design a place while developing this project… As an engineer, I (O-S21) decided the measurements of buildings and roads in real life and on the plan…

Regarding the second problem, they determined polygonal shapes of the buildings and other areas to be placed in the plan by considering the ground areas of the buildings and other areas in reality (e.g., squares and rectangles for football field, houses, and administration buildings). Furthermore, to fit the polygons into the plan and to fill the blanks on it, they considered the polygons' number of sides, angle measures, and positions with respect to each other and with respect to the positions of the roads. They also included regular polygons (e.g., squares for houses which are symmetrical to each other and a regular hexagon for a theatre) to have a pleasing and attractively appearing and architecturally good-style neighborhood. They chose a triangle for having small areas such as a museum and a bus station, and some polygons having more than three sides to have larger areas (e.g., for green areas). They also used nested polygons for buildings used for similar purposes (e.g., for education). They chose trapezoids, parallelograms, and rhombi for buildings which had narrower and wider parts (e.g., for taxi ranks).

Regarding the third problem, they considered the interior and exterior angle measures and the side lengths of polygons representing the ground areas of the buildings and other in real life. They had difficulty with estimating the lengths of the ground areas of the buildings in real life. For example, O-S23 asked, "Is the width of this class 25 meter-long? I want to visualize how long 25 m is." The teacher let her and her groupmate O-S25 measure the length of the classroom using a 1-m ruler and they found it to be approximately 8 meters. Regarding the fourth problem, they decided to include parallel and crossing roads to solve traffic congestion and unplanned urbanization.

Modeling and analysis

Regarding the third problem, they needed to realize that a polygon to be placed on the plan and its shape in real life are similar. Then, first, considering that all corresponding angles of two similar polygons are congruent, they decided to have equal corresponding angle measures of a polygon to be placed on the plan and its shape in real life. Second, considering that all lengths of corresponding sides of two similar polygons are proportional, they decided the scale of the plan (i.e., 1:250) by thinking about the side lengths of the rectangular white cardboard to be used to draw their plan (48 cm by 68 cm), and the side lengths (120 m by 170 m) of the rectangular smooth surface they want to make a neighborhood. To do that, they converted the side lengths of the rectangular smooth surface from meter to centimeter to make the units the same and calculated the ratio of the length of the rectangular white cardboard to its corresponding actual side lengths in the rectangular smooth surface. Third, considering their decisions regarding to the actual side lengths of the polygons representing the ground areas of the buildings and other areas, they calculated the side lengths of the polygons to be placed on the plan using the scale of the plan (1:250) by first converting the actual side lengths of the polygons in real life from meter to centimeter. Regarding the fifth problem, considering their decisions regarding to the actual width of a road (e.g., 10 m), they calculated the width of a road (e.g., 4 cm) to be placed on the plan using the scale of the plan (1:250) by first converting the actual width of the road from meter to centimeter.

Regarding the last problem, to draw their scale plan using a protractor they did not know how to use it to measure a particular angle and/or how to draw an angle having a particular measure. The teacher or groupmates helped the students who did not know how to use it. Besides that, minor mistakes in their drawings regarding to the angle measures or side lengths of polygons made them unable to draw the shapes they wanted to make.

O-S4: We could not draw a parallelogram with 100 and 80 degrees of angles, could you show us?

O-S4: We tried to draw a regular hexagon whose side [lengths] are 2.5 cm. We were careful with [drawing] its angle measures but the sixth [side] length became 3 cm instead of 2.5 cm.

Iteration

Although the students mostly worked in a definite order to create their scale plan (i.e., deciding the issues related to the scale plan, constructing two-dimensional geometric representation of the physical environment, making a rough sketch of the plan, and drawing the scale plan, respectively), they sometimes needed to reconsider previously made decisions and make some adjustments to improve their scale plan. The first remarkable iteration needed when the teacher noticed the errors in students' decisions regarding to the angle measures and side lengths of the polygons representing the ground areas of the buildings and other areas. Based on the teacher warning (e.g., "Be careful about the …"), they needed to reconsider their incorrect decisions regarding to the angle measures and/or side lengths of polygons. This incorrect decision is due to three reasons. The first is the confusion of the exterior and interior angle measures of a polygon (e.g., deciding 60 degrees rather than 120 degrees for each interior angle measure of a regular hexagon). The second is not realizing that the polygons that represent ground areas of the buildings in real life and their corresponding polygons on the plan are similar. For this reason, they calculated the side lengths as well as the angle measures of the polygons on the plan on the basis of the scale. They then noticed that the polygons representing ground areas of the buildings in real life and their corresponding polygons on the plan are similar. That is, the angle measures of polygons representing ground areas of the buildings in real life and their corresponding polygons on the plan are the same. The last is a mistake on converting a unit to another unit (e.g., converting a side length from meter to centimeter by dividing rather than multiplying by 100). The second remarkable iteration occurred when they encountered difficulties while drawing the scale plan (e.g.., not being able to draw the polygon they want to construct, having some polygons not fitting into the plan, having more empty space in the plan). Not being able to draw the polygon they want to construct made the students realize the importance of accuracy and precision in measurements, as mentioned in the previous part. Not fitting into the plan or having more empty space in the plan made them revise their rough sketch and prior decisions regarding the polygonal shapes and their angle measures and side lengths.

I-S20: I realized that drawing is not an easy work, and even a small error can destroy everything if architects do not pay attention to their drawing.

O-S20: We thought this building of the neighborhood as a parallelogram, but it did not fit into the plan. We changed this parallelogram into a trapezoid.

Conclusion

This study has proven that designing a two-dimensional scale plan of a neighborhood in the PBL environment engages students in EDPs and in turn probably deepen their EDP capabilities. This result is expected considering the structured PBL environment developed according to the key features of PBL. To achieve the goal of graduating students who are competent in EDPs, we need to continue to use PBL in schools. In sum, PBL environment builds on EDP as the cornerstone and as the foundation on which students bring their compartmentalized knowledge of science (e.g., types of trees that produce more oxygen compared to other ones), technology (computer, ruler, protractor), mathematics (angle and side properties of polygons, inclusion relationship between the polygons , e.g., "Is square a rhombus?", similarity and concurrence of polygons, angle and side properties of regular and irregular polygons) to bear on solving real-world problem. Furthermore, throughout designing a neighborhood plan, they learned how to design a place, the different types of professions and their duties, how to use a protractor to draw geometrical shapes, how to solve the challenges and difficulties as a group, the importance and value of geometry in real life, how the elements of a neighborhood are placed in it, and the importance of every detail such as accuracy and precision in drawings.

The movement in spatial thinking in STEM-subjects

Marion Zöggeler

Paris Lodron University Salzburg, School of Education - Department of Mathematics, Austria; marion.zoeggeler@plus.ac.at

This research project relates to the core of spatial ability linking to the STEM-subjects. Well-developed spatial abilities may lead to better comprehension of scientific and technical matters and to solving current real-world issues by thinking spatially in a variety of ways. The purpose of the study is the application of spatial abilities in the sense of spatial thinking as an entirety, which interacts in a broad way in the fields of science, mathematics, physics and technology. We have developed a new model of the extended Spatial Thinking for STEM, within we have underlined the movement as an essential element of spatial thinking. The various perspectives on movement in spatial thinking are combining elements, which show the interrelation between the subjects of STEM. This is described by selected examples.

Keywords: Experience and space, movement, visual perception, spatial thinking, problem solving.

Spatial thinking – the application of spatial abilities

Spatial thinking as an entire ability

> Spatial thinking is the mental process of representing, analyzing, drawing interferences from spatial relations […] between objects […] or relations within objects, […] analyzing spatial relations and transforming spatial relations. (Uttal et al., 2013, p. 367)

Spatial thinking, the “visual processing and spatial cognition” (McGrew, 2009; p. 5; Buckley et al., 2019, p. 168) is a complex ability, which reveal the various spatial thinking processes. They are used individually and are changed within the solving processes of tasks (Barratt, 1953; Just & Carpenter; 1985; Schultz, 1991).

One of the first researchers, who named various aspects of spatial thinking, is the British scientist and mathematician Francis Galton.

> Much instruction on these matters can be derived from those who possess the power of what is called the visualising faculty, in a high degree. The objects of their memory are conspicuous images; they can retain them for a long time before the eye of their mind, they can dismiss or change them at will, and they can, if they please, subject them to careful examination from every side. (Galton, 1879, pp. 158)

In this description, Galton implied three steps in the process of spatial thinking: the perception, the memory as the possibility to retain and to retrieve a recognized object and the imagining and operating with spatial pictures. This indicates an entire view on spatial thinking, as we can find also in novel definitions, for example the visual and spatial capacity of the intelligence is “the ability to generate, store, retrieve and transform visual images and sensations” (McGrew, 2009, p. 5). Furthermore, McGrew (2009) relates in his description to the perception and imagination of shapes, images and spatial orientation of objects, which change their shapes and positions in space by movement. Also in the actual research, spatial memory is a central element in spatial thinking, which is expressed in the following explanation “largely determined by the capacity to represent and manipulate mental information (spatial cognition) and to hold sufficient amounts of pertinent information (working memory)” (Buckley et al., 2019, p. 166).

Thinking about and with space in STEM

Spatial thinking includes thinking about space and thinking with space (Hegarty & Stull, 2012). The former means the experience in real space, in large-scale environment in which you can only see part of the whole at the same time. Further, it means the mental operating with real and imagined objects in space, in the small-scale. Thinking with space relates to the use of spatial objects and spatial mental processes for the imagining of non-spatial contents, for example the use of symbols and of graphs in coordinate systems, the representation of abstract contents in diagrams and the structure of terms (Malle, 1993).

Spatial thinking needs to be promoted for problem solving in the subjects of STEM. Many studies reveal that students have more success in attending courses and finishing their study on the academic level when they have a good developed ability to think spatially. Also in the further professional working, they can arrive higher aims. (Uttal & Cohen, 2012; Sorby et al., 2018)

Wai et al. (2009) highlight the interaction of the three abilities, spatial ability, mathematical ability and verbal ability. This necessitates a change in mindset in favour of spatial thinking for the curricula. Young adults with well-developed spatial abilities seem to handle better images and shapes in the imagination than those who think in verbal and numerical symbols (Wai et al., 2009; Mix et al., 2016). Probands with less-developed spatial abilities and well-developed verbal skills try to solve mathematical problems with verbal description, while others prefer a spatial representation in the problem solving (Fennema & Tartre, 1985). This relates to the usual structure of the logical thinking: a deductive and verbal process and a structured, global, intuitive spatial and inductive process (Tartre, 1990). Even though “reasoning thinking” with verbal and analytical processes is sometimes elevated above the spatial perception and imagination, spatial thinking is the core of thinking (Duffy et al., 2018, p. 273). Only the interaction of the two mental areas, the abilities of the spatial and of the rational thinking, leads to the expected success in STEM-subjects (Duffy et al., 2018; Sorby, et al. 2018).

Studies reveal that a higher spatial ability combined with a visual working memory supports the success in academic learning and the understanding of subject contents in the beginning of study. However, on a higher level specialist knowledge and experience are more used and successful in problem solving in STEM-subjects. (Uttal & Cohen, 2012; Duffy et al., 2018; Xie et al., 2020)

Spatial thinking extended to problem solving in STEM

In the following, we describe the development of a new model in Spatial Thinking for STEM. The aim of this attempt should be the application of spatial mental processes in mathematical, physical and technical issues.

From visual perception and spatial imagination to further reasoning

Previous research has primarily focused on exploring visual perception (Vernon, 1962; Frostig et al., 1972) and spatial ability (Thurstone, 1938; Linn & Petersen, 1985; Maier, 1994) as two distinct pillars of spatial thinking. Most models on spatial thinking and spatial abilities, and the related tasks have concentrated on artificial, theoretical situations in psychometric tests, and they have rarely considered scientific subject contents. To fill this research gap, there is constructed a model combining neurological findings of visual perception and spatial ability with the application on real problem solving in STEM-subjects. Spatial thinking and acting includes the two areas, visual perception and spatial ability.

Visual perception is the anatomical and neuronal process from the sensory stimulus to the cortical cognition. It is the ability for seeing the world around us recognizing and identifying objects and situations. Other sensory stimuli, especially motoric and auditory ones complete the visual perception, which is the most involved in spatial ability (Nänni, 2009). From the psychological literature (Vernon, 1962; Bak, 2020) and from neurological research (Burgess, 2014) we outline three fundamental components of visual perception: the perceiving of objects, movements and depths.

Spatial ability is the capacity to operate mentally with the images arising from visual perception, for instance, transforming, rotating, cutting and combining them. Sensory impressions are processed and reorganized mentally. We have to work actively on these mental images. (Thurstone, 1938; Maier, 1994)

In addition to the combination of visual perception and spatial ability (Maresch, 2020), a further component is necessary. This relates to the applying of spatial processes in spatial and non-spatial contents, including a higher level of thinking for arguing, reasoning and problem solving on abstract mathematical contents. This level includes expedient analyzing and creating individual solving steps (Figure 1). The "Movable Thinking" (Roth, 2005) in mathematical and geometrical contents can be seen as a further aspect of the higher spatial thinking. It is the capacity to find a movement and movable parts inside a geometrical constellation and to use them for arguing and proving.

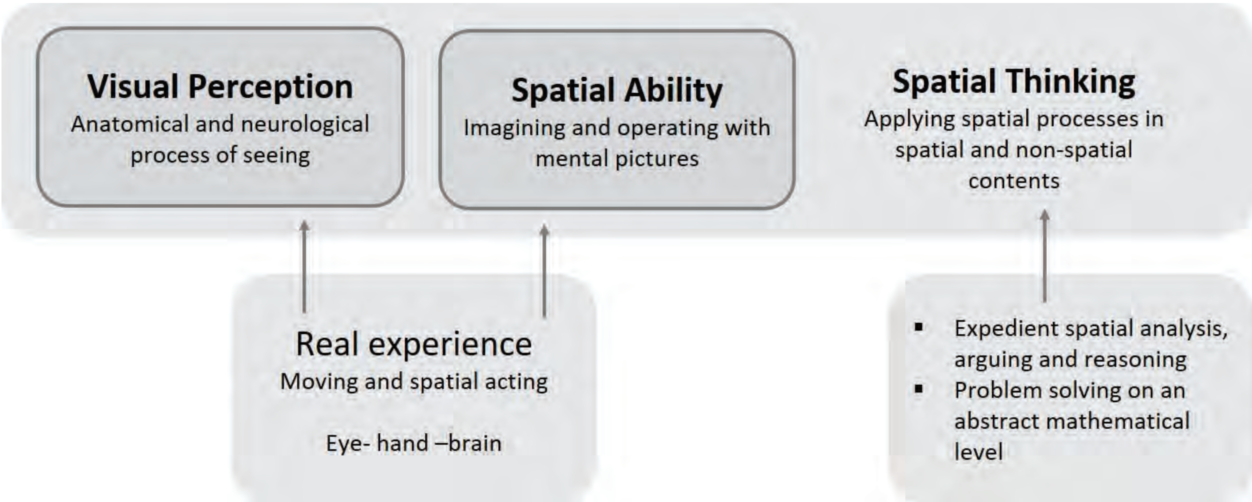

Figure 1: Spatial Thinking in STEM

The extended model of Spatial Thinking in STEM

The model is composed of six fundamental and two overarching facets (Figure 2). They relate to contents of space and take place on every level of spatial thinking, namely the visual perception, the spatial imagining and the expedient thinking.

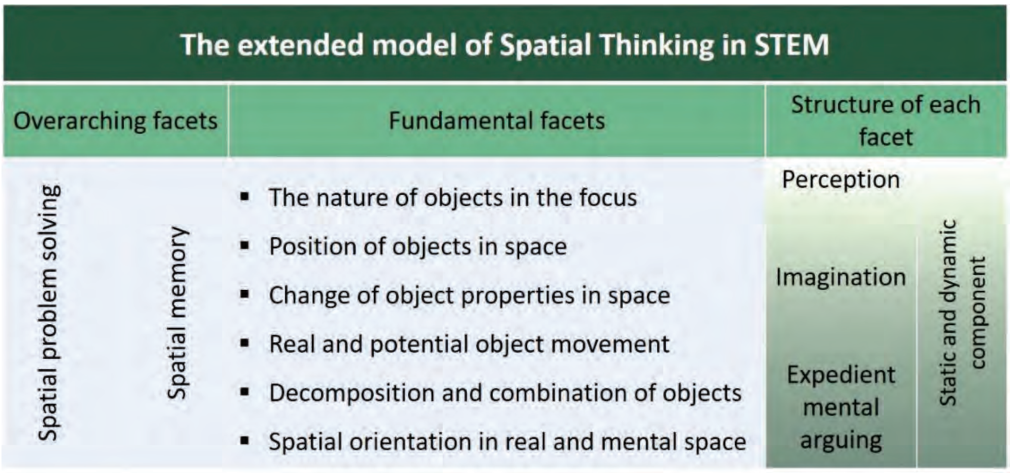

Figure 2: The facets of Spatial Thinking

The nature of objects in the focus relates to the comprehending of a constellation as a whole, from which single objects or parts are distinguished. The objects should be recognized in their relevant properties as constancies for identifying them and removing them from the background. Referring to mathematics, this facet includes arguing with geometrical properties, such as invariances, orthogonality and parallelism.

The position of objects in space deals with the perceiving and imagining of the location and position of one or more objects in a spatial constellation, in relation together and to the viewer. For example, it includes the spatial relations of elements of areas and solids, such as the relation between lines, edges, and angles. The combination between the geometrical imagination and the algebraic representation of straights and planes in a metric space requires this facet using coordinate systems.

The change of object properties in space is the changing of objects and parts of them through mirroring, rotating, shifting and scaling. This happens by the imagining of movements to recognize the changing process between the initial and the final state of the object. As an example, we can name the varying aspect of variable quantities.

The real and potential object movement relates to a real movement in space and a possible movement in a mechanical configuration with movable parts, not to a fictive movement in a mathematical constellation. This facet has a concrete reference to various fields of physics and technology, while it is related indirectly to mathematics via the similarities with the facet of the change of object properties. For imagining the deflection of a moving object, e. g. a rolling ball (Kozhevnikov et al., 2007) or a moving charged particle in a homogeneous magnetic field (Fulmer & Fulmer, 2014), we should be able to follow mentally the path of the movement.

The facet of decomposition and combination of objects involves breaking down an object or a configuration into parts and combining the parts into a whole object or a new configuration through

Boolean operations. In a further sense, it relates also to the structuring of terms and the imagining of fractions, as a part of the whole.

The spatial orientation in real and mental space is about the orientation of a person in the real space and in the mental imagination, whereby it is necessary to put themselves into the space. By changing the perspective, an object or a constellation of objects can be seen from different angles. Referring to physics, for instance, this facet is important for the imagination of movements in astronomy (Cole et al., 2018). As a viewer from different points on earth, as well as from outside the earth we see different movements, which we have to combine for understanding the interrelation, for example the apparent movement of the sun and the real movement of the earth.

The spatial problem solving and the spatial memory flow in into all fundamental facets, in understanding the task, in mental and concrete processing of solving the task, in assessing the solution steps and in finding further possible solutions.

The movement as a central element of spatial thinking

Movement, as the change in location and position of an object in space and as the change of properties of an object, as well as the movability as a possibility for changing, pervades the spatial thinking as a whole. Movement appears in various ways, as imagining and anticipating a sequence of movements, as a mental process of changing an image or as a mental process for solving problems. Based on the real movement and orientation in the space to explore it and on feeling the movement of one's own body occurs the transfer of perception into the imagination. (Stückrath, 1955; Piaget & Inhelder, 1971; Glück et al., 2005; Wolbers & Hegarty, 2010)

We have found four perspectives on movement, which are important in the imagining of mathematical, physical, technological and scientific contents:

- the movement which can actually be experienced in space and which is comprehensible in the imagination,
- the potential movement of a movable part of a mechanical configuration, for example the movement of gearwheels, screws and pulleys,
- the mental movement of an entire object to change its properties,
- the mental movement to change single parts in a mathematical constellation as an internal displacement, for example folding a solid by its surface. This relates also to the movement which is applied in abstract mathematical and geometrical contents, as movable thinking.

In the following, we present two examples, one for the spatial imagination of potential movement in a mechanical constellation (Thurstone, 1938) and one for the spatial imagination of real movement in an astronomical context.

The movement in a mechanical configuration

A rightwing screw engages a gearwheel in the signed direction. The gearwheel rotates on a fix axis. We have to imagine spatially how the rotating movement of the rod is combined with the translation movement. In which direction does the gear rotate when the threaded rod engages the gear in the indicated sense of rotation? In which direction does the gear move, when the worm is put on the rod inversely, from the right side to the left side in this perspective?

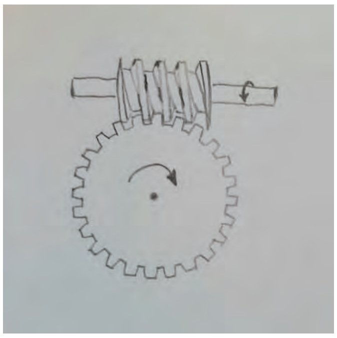

Figure 3: Gearwheel and threaded rod

To solve the task, we fix distinct features in the representation, like the teeth of the gear and the rotating direction of the threaded rod. We can mentally imagine the relation between the rotation and the translation movement of the rod. The picture of a screw turned into a wall can serve as a practical help. When the worm is put inversely on the rod the spatial relations are conserved and the direction of each spiral is unchanged, as the thread remains a right-hand thread. The spatial thinking relates to the recognition of the spatial relation between the parts of configuration and their movement.

The movement in an astronomical task

A further example to improve the imagination of movement in science deals with the path of the sun, seen from diverse places on the earth. The content of the task refers to the daily rotation of the earth around its axes, whereby other movements and astronomical phenomena are neglected. In which direction do you see the path of the sun in Rome on the North Hemisphere and in Cape Town on the Southern Hemisphere? The absolute cardinal points of the sunrise, the sunset and the peaking of the sun have to be recognized, moreover the reference points to the body of the viewer, such as left or right when looking at the sun. This problem can be seen from the earth at rest, the large scale of experience, and from a fictive point in the universe on the moving earth, the small scale of a geometric model. For simplifying the task, two places outside the tropic are chosen, because otherwise the local and seasonal conditions have to be considered. As spatial approaches can be used: putting oneself into the reference frame through mental change of viewer's position and spatial orientation or considering properties of objects and their relation using geometric quantities in an analytical way. As interesting statements of students for explaining their mental processes can be named the following answers: "I have thought about the earth as a sphere with one half in the shadow", "The earth rotates in certain points in the direction of sun and in others away from it", "I have mentally imagined a person living near Cape Town." (Zöggeler et al., 2021).

Space and movement in space are the background of spatial thinking.

Rationale

Thematic Working Group 27 focuses on research concerning the role of Mathematics Teacher Educators (MTEs) in fostering mathematics teacher learning, both during the pre-service and the in-service periods of teachers' careers. The need for this group emerged in CERME11, when several papers submitted to TWG18 (Mathematics teacher education and professional development), focused on teacher educators. The rationale for opening a new group for this topic stemmed also from the accumulation of research on MTEs witnessed in recent years. This growing interest is reflected in conferences (e.g., Educating the Educators), books dedicated to MTEs (e.g., Goos & Beswick, 2021), journals and special issues on MTEs' professionalization and their role in scaling up sustainable interventions (e.g., ZDM 46(2), 2014; ZDM 47(1), 2015; Int. Jr. of STEM Ed. 4(27), 2017; IJSME (1), 2021), and a host of papers focusing on this issue in leading journals such as ESM, JMB and JMTE. Our goal in creating this TWG is to support further development of this emerging field.

First steps of TWG27: The CERME12 meeting

As TWG27 is new, it met for the first time in CERME12. Twenty-three participants attended the TWG27 sessions, 16 contributions (13 papers and 3 posters) were presented and discussed. Figure 1 shows the distribution of contributions by countries, with about 57% coming from Europe, 25% from North America, 12% from South America and 6% from the Middle East.

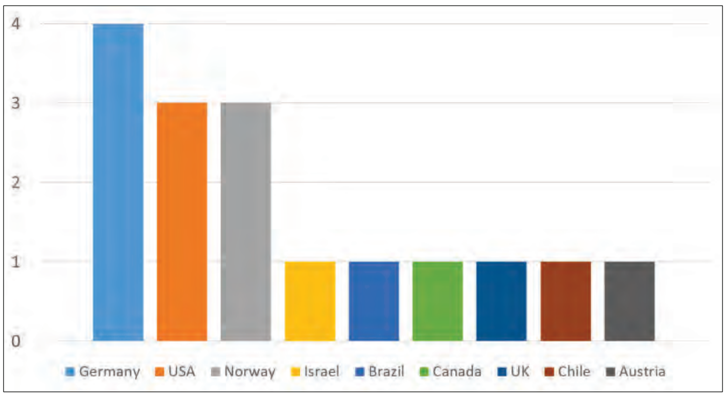

Figure 1: Distribution of contributions to TWG27 by countries

The call for papers proposed the following themes to initially form the scope and focus of the group:

1. Conceptualizing the profession of MTEs: Adapting theoretical frameworks from the teacher level to the MTE level; integrating generic and mathematical aspects within the work of MTEs;
2. Knowledge, beliefs, skills and practices of MTEs: Theoretical models and empirical studies;
3. Preparing MTEs (including formal and informal qualifications): Conceptual frameworks and empirical studies;
4. Designing professional development for MTEs; tools and resources for supporting MTEs;
5. Scaling up programs for mathematics teachers: Building institutional capacity through focusing on facilitators; institutional factors that support or hinder the effectiveness of PD facilitators;
6. The influence of current global issues on the role and practices of MTEs.

The majority of contributions related to themes 2, 3 and 4, one paper related to theme 6, and one to theme 5, while theme 1 was not directly addressed but mentioned in contributions with other foci.

A vocabulary note: MTEs are referred to in the literature by many different terms. For the purpose of coherence of the TWG27 work, we use the terms *facilitators* and *educators* to denote MTEs who support the learning of practicing teachers and prospective teachers, respectively.

Characterizing TWG27 contributions: A brief summary of different aspects

Main issues addressed

Theme 2 was the focus of many contributions, presenting studies on the knowledge, beliefs, skills and especially the practices of MTEs. Several papers focused on facilitators' practices with regard to different PD contents (e.g., conditional probability, Griese et al.; supporting at-risk students, Laschke et al.; algebraic thinking in early years, Ferreira et al.), while others centered on how PD goals are achieved (e.g., enacting norms, Schwarts et al.; modeling, Nolan; theory of change, Eriksen & Solomon). Different tools were suggested to examine MTEs' practices (e.g., scriptwriting tasks, Shure et al.; productive disciplinary engagement, Elliott & Lesseig; disruptive pedagogy, Bjerke & Nolan). Themes 3 and 4 were addressed by several contributions as well: Nieman et al. investigated how a tool, designed to provide insight into mathematics teachers' experiences within a PD course, can be used by facilitators to inquire into their facilitation practices. Rojas et al. examined the impact of "critical friendship" experiences between MTEs on their professional development, and Mayerhofer et al. introduced the idea of personas as yet another means to support MTEs. Bruns et al. investigated the effects of an extensive facilitator PD program, while Opheim et al. discussed the design of PD experiences for MTEs with varied backgrounds. Theme 5 was addressed by Seago and Knotts, who reported on asynchronous online video-based PD modules, which can be flexibly adapted to various facilitation formats, and are therefore highly scalable. Finally, Theme 6 was uniquely represented by Coles, describing MTEs' work with teachers who bring questions of global challenges into their classrooms.

Theoretical and conceptual lenses used

A range of theoretical and conceptual tools or lenses were used across the studies in this TWG. They can be categorized broadly into three groups (with some papers drawing on ideas across more than one group). In the first group are papers which drew on particular notions of teacher expertise, or teacher learning, and used them to reflect on the role of the MTE. For example, Seago and Knotts drew on Ball and Bass's (2003) notion of Mathematics Knowledge for Teaching, as did Elliott and Lesseig (who particularly looked at Specialized Content Knowledge). Griese et al. used a model of teacher expertise in their study of facilitators, while Ferreira et al. used a model labelled Professional Learning Opportunities for Teachers, and Bruns et al. employed Prediger et al.'s (2019) three-tetrahedron model of professional development designed to investigate teacher learning. A second group drew on conceptualizations of MTEs' expertise. Shure et al. used Prediger et al.'s (2021) framework for the expertise of PD facilitators, and Laschke et al. used a model of teacher orientations which they develop into one of MTE orientations. Schwartz et al. analyzed facilitator decisions using a framework of MTEs' resources, orientations, goals and identity (Karsenty et al., 2021). There were fewer papers in this second group than in the first, perhaps reflecting the relative recency of theorizations of MTE expertise. Finally, some papers drew on theoretical frameworks that support the analysis of MTEs' actions and contexts. For example, Eriksen and Solomon used the notion of boundary objects (within Communities of Practice) to conceptualize MTEs' practices, and Elliott and Lesseig mobilized the notion of productive engagement. Rojas et al. conceptualized and analyzed the self-study of MTEs. Sharing a critical perspective, Bjerke and Nolan drew on ideas of disruptive pedagogy to study the practices of MTEs and Coles used ideas from critical mathematics education with the same aim. This diversity can be seen as reflecting how the study of MTEs often draws on ideas from the highly diverse field of the study of teachers. We view it as encouraging that conceptualizations of MTEs' practices are emerging and being shared.

Methodology employed in the studies reported

Most of the presented studies were small-scale studies, following a qualitative research paradigm, sometimes involving only single cases investigated in an in-depth manner, or self-studies (e.g., Nolan). Many of the studies used a variety of data sources to investigate MTEs' work. These included the following: interviews (Bjerke & Nolan; Eriksen & Solomon; Griese et al.; Nieman et al.; Seago & Knotts); facilitators' journal entries (Schwarts et al.); teachers' weekly online logs and teacher community walls (Seago & Knotts); written records from teachers and facilitators (Ferreira et al.); summative memos (Elliot et al.); audio and/or video data from PD sessions (Elliot et al.; Ferreira et al.; Laschke et al.; Schwarts et al.); dialogues from a scriptwriting task (Shure et al.); and video data from stimulated-recall interviews (Schwarts et al.).

As opposed to the aforementioned qualitative studies, Bruns et al. reported on a classical quasi-experimental intervention study, using quantitative methods to investigate the effects of facilitator PD on teachers' learning in the context of early mathematics education.

It can be conjectured that the focus of almost all the contributions on qualitative approaches is another indication that the field of research on MTEs is still emerging, with qualitative studies providing findings that can later be used as springboards to more diversified research approaches.

New emerging issues

Several issues emerged during the course of our group discussions. Here we summarize the most frequent ones.

- *MTEs’ role in bridging between theory and practice.* We considered what conceptual lenses we might use to analyze MTEs’ practices that support the link between theory and practice. One suggested idea for exploring this issue was to conduct a workshop in which participants use different lenses to examine sets of data from multiple projects.
- *The role of reflection as a learning mechanism for MTEs.* We identified several questions for future consideration, for example: How can MTEs use reflection to better attune their practices to teacher learning? How do issues of status and power influence MTEs’ reflection with others such as their peers, researchers, and critical friends? What is the role of criticism or emotional reactions within MTEs’ reflections?
- *Role-modeling as a practice used by MTEs.* We discussed the idea of modeling and the design of research that can address questions such as: How central is role-modeling to the practices of MTEs? To what extent do MTEs model the pedagogical practices that they support in theory? What are possible implications of a lack of coherence between the practices MTEs aim to support and the practices they use?
- *The role that TWG27 might play in moving the field forward.* As pointed out earlier, most studies reported in our group were small-scale, qualitative studies. We recognized the need to develop a more comprehensive picture of the field, for example by identifying areas of research that can benefit from larger-scale studies and an extended range of methodologies.

These issues, as well as other questions raised during the meeting, are reflected in the Call for Paper and Poster Proposals for CERME13.

In summary, the collection of TWG27 papers and posters presented in this volume reflects an effort to capture current themes within the developing research on the profession of MTEs. We look forward to the continuation of this group’s activities in future ERME conferences and aspire to expand this TWG27 in terms of participants, represented countries, topics and types of studies.

Developing a *disruptive pedagogy* theoretical lens for studying the practices of mathematics teacher educators

Annette Hessen Bjerke[1] and Kathleen Nolan[1,2]

[1]Oslo Metropolitan University, Norway; Annette.Hessen@oslomet.no

[2]University of Regina, Canada; Kathy.Nolan@uregina.ca

In this paper, we explore the notion of disruptive pedagogy, and propose a disruptive pedagogy theoretical lens to study the practices of mathematics teacher educators (MTEs) in their post-field courses. While much is known about prospective teachers (PTs)' transition from university to field experience, less is known about the under-researched transition from field experience and back to university. We propose that perspectives borrowed from literature focused on disruptive pedagogy can shed light on this transition and help MTEs to better understand their role in unpacking PTs' field experiences. The lens consists of four key areas of focus (two on challenging current practices and two on promoting new practices). We close this paper by exemplifying what these 'challenges' and 'promotions' might look like in the context of MTE post-field practices.

Keywords: Mathematics teacher educator, disruptive pedagogy, theory-practice, theoretical lens.

Introduction

Improving teacher education is a constant concern. In that respect, research on the theory-practice transitions has been extensive (Allen & Wright, 2014; Britzman, 2003; Gainsburg, 2012), including transitions from university (theory) to field experience (practice), as well as transitions from the process of becoming a teacher (university) to the first few years of being a teacher in schools (Nolan, 2014). Another key transition in teacher education programs is the under-researched transition from field experience back to university, where "[l]ittle is known about the way in which teacher educators integrate prospective teachers' actual experiences when they return to university after fieldwork" (Eriksen & Bjerke, 2019, p. 9). This 'unpacking' of field-back-to-university transitions is relevant to the community of teacher educators since teacher education programs, and corresponding field experiences, are frequently critiqued for being steeped in technical-rational approaches (Nolan & Tupper, 2020). Mathematics teacher educators (MTEs) in particular struggle with the tensions implicit in these transitions, as they seek to disrupt dominant 'technique-oriented' discourses of school mathematics and becoming a teacher.

We acknowledge that the use of theory and practice to describe transitions between university teacher education courses and school-based field experiences creates a false binary and hierarchy (Zeichner, 2010). While we draw here on theory-practice language, in reality our interests are positioned within a hybrid space of research where we study the role of MTEs in disrupting and reimagining knowledge constructed in the crucial movement from university to field and back to university. Within this movement, it is the post-field context of teacher education that we focus our attention.

Drawing on Anderson and Justice (2015) and their way of seeing a pedagogy as disruptive if it "requires students to challenge or change their epistemologies and participation in their learning" (p. 400), we propose a theoretical lens of disruptive pedagogies that enables us to better understand the roles and practices of MTEs in post-field contexts and to re-conceptualize post-field possibilities in teacher education. We suggest that such a lens can be applied to study a central question underpinning theory-practice transitions: What are MTEs' roles in unpacking prospective teachers’ (PTs’) field experiences?

Disruptive pedagogies

The use of the term *disruptive* first emerged in juxtaposition with the introduction of new technologies in companies, where “the degree of disruptiveness” was crucial in predicting its success or failure (Christensen, 1997, p. 169). Acknowledging that technological disruptions may provide the opportunity for new ways of thinking, learning, and teaching (despite possible internal resistance to adoption) resulted in Christensen and Raynor (2013) expanding the idea of disruption and introducing the term *disruptive innovation*, where innovations were seen as disruptive if they replaced a dominant current technology.

These lines of inquiry sparked an interest in exploring more generally the impact of new technologies in educational settings (Christensen et al., 2011; Hedberg, 2011; Stevenson & Hedberg, 2011) and also within teacher education contexts, where the possibilities that emerge from the uptake of new technologies were investigated as a *disruptive pedagogy* (DP) (Anderson & Justice, 2015). In this way, DP emerged out of innovation with respect to technologies (Christensen, 1997), not more general pedagogies. To date, however, few teacher education studies have a non-technology focus with respect to DP, and fewer still (if any) turn the lens of DP toward mathematics teacher education and MTEs in particular.

Anderson and Justice (2015) define disruption as “an analytical construct that allows for the investigation of how individual learning and changes in local practice mutually influence the other within a purposefully designed learning context” (p. 401). As with our work, these authors express interest in “disruptive innovations within teacher education contexts” (p. 401); however, they do so with an explicit focus only on pedagogies that engage prospective teachers with technology; that is, they “do not attempt to examine pedagogy independently from technology or technology independent from pedagogy” (p. 401). Thus, our exploration here contributes more generally to the theory and practice of DPs in teacher education as we, in this paper, expand upon that work in DP and propose a theoretical lens to investigate MTEs’ post-field pedagogical practices. We propose that such a DP lens can be used to view post-field contexts to understand the extent to which MTE practices address practice-theory gaps and contribute to a wider goal of improving mathematics teacher education.

Introducing the Research Study

As noted previously, our research interest is in exploring the question: What are MTEs' roles in unpacking PTs’ field experiences? In a recent paper (Nolan & Bjerke, 2021), we discuss and present a list of barriers/challenges encountered in theory-practice transitions (from university to field experience). Primarily based on findings from our own research on theory-practice transitions in teacher education, these barriers/challenges formed the basis for the construction of research interview questions designed to study the roles and practices of MTEs in the next transition – the practice-theory transition (from field experience back to university). The interview questions included asking MTEs to share their own professional challenges with respect to practice-theory transitions, the pedagogical strategies and theoretical tools they draw on to challenge and/or disrupt these transitions in working with PTs in post-field courses, and what they view as their primary role(s) in the post-field context of mathematics teacher education. Hence, we focus here on the work of teacher educators, not so much the actions of PTs, within teacher education.

As MTEs, we know that PTs bring countless stories of success and failure from different mathematics classrooms to their post-field courses, many of which can serve as starting points for reflections – at least for the one who *owns* the story. However, reflection is challenging for PTs (Stiler & Philleo, 2003), and such individual-level reflections are found to have little real value in bringing about lasting change within complex school environments (Forde et al., 2006). Instead, PTs must be skilled at reflecting critically, with a depth and quality that challenges the teacher education community and allows for "disruption" (Anderson & Justice, 2015). Given the shortcomings of a reflection-focused post-field context, we saw a need to develop a lens for analysis in conjunction with collecting our data, as a way to move beyond reflecting on single field experiences, and to move toward a way of detecting those disruptive and transformative practices initiated by MTEs. Here, we offer a theoretical lens that highlights the promising concept of disruption in the context of MTE practices.

Introducing the theoretical lens

Our aim in this section is two-fold: To describe our methods in selecting and reviewing research literature on DP and to present the lens itself.

Once the need to construct a DP theoretical lens was established, we proceeded to locate research texts focusing on DP. Our aim in this engagement with the research literature was to learn about the diverse ways in which authors defined or described disruptive pedagogy. That is, our intention was to return to the roots of DP, not to conduct a comprehensive literature review. Thus, from each of the research texts located, we synthesized key ideas that spoke specifically to how the authors defined/conceptualized the pedagogy, including its aims and examples of what it might look like in practice in classrooms. Through careful study of these synthesized ideas, we noticed that, in some cases, the researchers sought primarily to *challenge* current status quo or traditional practices through DP while, in other cases, the goal was focused more on *promoting* different practices which were intended to disrupt and/or replace these current practices. In this way, it became clear how the literature suggested the existence of certain current pedagogies and practices teacher educators want to shift away from, and also pedagogies they want to promote, or 'shifts towards'. In the end, our synthesis of ideas directed us toward the construction of four key areas of focus, or themes, across the literature on DP: two focused on challenging current practices and two focused on promoting new practices. When we introduce and describe the themes below, we maintain more general teacher educator language; however, after describing each theme with a summary of its focus, we outline a key question that directs our attention toward practices specific to MTEs. The four themes and their accompanying MTE-question constitute our DP lens.

I. Challenge traditional and technical-rational approaches to teaching and learning

The body of research on DP provides us with some helpful insights on 'what currently is'. Acknowledging that something important is lost when inquiry/problem-based teaching and learning are marginalized (Anderson & Justice, 2015), we want to disrupt the conservative nature of traditional teaching cultures (Hedberg, 2011). Instead, we want to push PTs “to challenge ideas, beliefs, and practices that they were not comfortable with, providing them with the opportunity for a re-examination of their own beliefs, values, and practices in the classroom” (Anderson & Justice, 2015, pp. 406-407). This re-examination should include challenging assessment practices associated with traditional, linear ways of “defin[ing] pedagogical content and reduc[ing] learning to the tools which measure it” (Beighton, 2017, p. 114). As well, DP challenges the reducing of “teaching and learning to the application of ‘recipes’ of ‘good practice’” (Beighton, 2017, p. 117). We need to go beyond a focus on simple recall, recognition and reproduction of ideas and performances (Mills et al., 2009, pp. 72-73), which support a deterministic view of learning (Iftody & Sumara, 2010). In this regard, we can learn from Vratulis et al. (2011) who highlight the importance of moving away from those ‘additive’ pedagogies which are “integrated to support existing, often teacher directed, classroom practice” (p. 1180). Taken together, this leads us ask: To what extent do MTEs work toward a (mathematics) teacher education that challenges pedagogies based on traditional and technical-rational approaches to teaching and learning?

II. Challenge practices informed by non-critical approaches

Evidence of teacher educator practices which make knowledge problematic, and demand that PTs critically reflect on their own belief systems and learning experiences, is important due to “the culture of resistance for pedagogical change” that is embedded in schools (Vratulis et al., 2011, p. 1181). To unpack such resistance, Weis and Fine (2001) propose that teacher educators stage “act[s] designed to disrupt the asymmetric relations embedded in a capitalistic economy and racism” (p. 520), and draw attention to how schools “serve to perpetuate and indeed legitimize widespread structural inequalities” (p. 497). Sidebottom (2019) calls for teacher educators to challenge “the neoliberal, performative constraints on our abilities to realise socially-just academic organisations” (p. 233).

To legitimize and promote social justice processes, Mills (1997) proposes a disruptive pedagogy to challenge “the legitimacy of school processes which produce and reproduce oppressive relations of power” (pp. 35-36). Such a critical perspective calls for a pedagogy which moves beyond ‘valuing’ diversity and a culture of tolerance “to a critical understanding of difference that … recognizes micro and macro power relations, and problematizes knowledge about ‘community’” (Mills et al., 2009, p. 75). In this regard, Beighton (2017) offers the idea that “teacher educators can examine how non-diversified practices at the local [micro] level constitute barriers to meaningful student participation and undermine teachers’ responses to issues of equity and social justice” (p. 113). Hence, we ask: To what extent do MTEs work toward a (mathematics) teacher education that challenges current practices from perspectives informed by critical mathematics education?

III. Promote non-traditional and participatory approaches to teaching and learning

While the two first themes were concerned with what DP aims to shift away from, we now turn to two themes that are more concerned with what DP promotes, or ‘shifts towards’. Generally speaking, this third theme is concerned with promoting pedagogies which introduce “new ways of thinking, learning, and teaching” (Anderson & Justice, 2015, p. 405), which frequently imply the “[n]eed for teachers to unlearn traditional teaching beliefs and practices” (Hedberg, 2011, p. 2). The theme embraces a disruptive view of learning which highlights how learning can only be provoked, not predicted (Iftody & Sumara, 2010, p. 105). In addition to provocation, an invitation to PTs to share their insights and stories is also key in this dimension of DP (Sidebottom, 2019); that is, inviting students into teaching and learning conversations is an important step in replacing the "formulaic deficit models" of teaching with "a creative engagement of and crucially *with* learners" (Beighton, 2017, p. 120). Anderson and Justice (2015) advocate for disrupting traditional practices of teacher education courses by creating "a participatory environment that publicly challenges [PTs'] epistemologies and the community practices in the learning process through both their engagement with the content and interactions with their peers" (p. 404).

In sum, a key aim of this DP theme is to mentor/support PTs to "fully engage in transformative, radical educational acts… required to constantly reposition, redefine, and rethink their roles and to deconstruct and redesign their objects of study" (Bastos, 2009, p. 5). Moreover, and above all, this third theme seeks evidence of teacher educator pedagogies that encourage PTs to "experiment with pedagogical approaches learned in their teacher education programs… [even] if they are not evident in schools and may not be supported by sponsor teachers on practicum" (Vratulis et al, 2011, p. 1181).

In light of this theme description, we return our attention to mathematics teacher education, and ask: To what extent do MTEs work toward a (mathematics) teacher education that promotes pedagogies focused on non-traditional and participatory approaches to teaching and learning?

IV. Promote practices informed by equity and social justice aims

Here, we seek evidence of teacher educator pedagogies that promote an agenda grounded in equity and social justice aims. To promote such an agenda, teacher educators are called upon to model pedagogies that "challenge inequities and social injustice rather than… projecting a vision of an ideal school" (Mills, 1997, p. 39). This means teacher educators are called to work toward teaching practices that promote change in the existing relations of power that appear throughout the routines of life within a school Mills, 1997). It also means emphasizing the importance of providing challenging work for students from traditionally underachieving backgrounds (Mills et al., 2009) while paying "more attention to our own agency and responsibility" (Sidebottom, 2019, p. 233) in the face of systemic barriers to social justice. Given the critical and equity-focused aims of this theme, we ask: To what extent do MTEs work toward a (mathematics) teacher education that promotes practices from perspectives informed by equity and social justice aims?

The DP lens in the context of MTE post-field practices

With the four DP inspired themes established, and the way in which they raise questions that directs us to the practices of MTEs, we return to the language of mathematics teacher education and ask: What might these pedagogies—those that 'challenge' and 'promote'— look like in the context of MTE post-field practices? As it would be an impossible task to provide a comprehensive list, we aim here to suggest a few examples. At the same time, we remind the reader that this is a work in progress, and that the next step is to examine our study's data through the four themes of this DP lens with a goal of understanding the pedagogical strategies and theoretical tools MTEs report to draw on as a way to bring about disruptions in their post-field work with PTs; that is, we aim to understand the extent to which there is evidence of disruptions in the post-field approaches of MTEs that set out to effect lasting changes in PTs' practices.

Drawing on the points raised within our theme summaries, a disruptive pedagogy in mathematics teacher education would involve, for example, MTEs *challenging* different instrumentalist technique-oriented approaches, for instance what Skovsmose (2001) refers to as the “exercise paradigm”. DP might also be characterized by MTEs providing opportunities for PTs to challenge their belief systems and learning experiences that have an impact on their ability to consider alternative discourses for what it means to know and learn mathematics. This would necessarily include challenging systems and structures of mathematics education that continue to colonize the learner toward deficit views with respect to who can succeed at mathematics, including misrecognizing the power of mathematics and its uses in schools and in society more generally (Andersson & Nolan, 2021).

In the same manner, a disruptive pedagogy in mathematics teacher education would involve MTEs *promoting*, for example, more experimental task- and inquiry-based mathematics teaching and learning, thus “emphasizing that planning can be about inquiry and joint discovery rather than prediction and transmission” (Beighton, 2017, p. 119). Additionally, in keeping with an equity and social justice focused agenda, MTEs would move “critical mathematics education forward… with the goal of educating critically aware students who have power to question the mathematics that influences and formats their lives” (p. 45). Admittedly, it is no easy task for MTEs to practice disruptive pedagogies; however, Beighton (2017) reminds us, as “teacher educators [we] need to understand that learning, with all its difficulties and complexities, is not a problem to be fixed or a weakness to be confessed, but an ongoing process of engagement with what is becoming” (p. 120).

Implications for the existing research in the area – and for MTEs

Situating their work in the context of PTs working with technological innovations, Anderson and Justice (2015, p. 408) found that the practices of PTs in response to pedagogical disruptions fell into three distinct categories: transformative practices (where PTs took up the disruptive practices), performance of untransformed practices (where PTs participated to ‘get it done’), and practices that were resistant to the disruption (where PTs pushed back) (p. 408). In this way, their findings “provide a starting point for examining the implications of disruptive pedagogical practices within pre-service teacher education programs” (p. 416). Our lens construction is a recent development initiated to engage with MTEs’, rather than PTs’, perspectives on DPs. It remains to be seen whether MTE practices brought forth by our disruptive theoretical lens fall into categories similar to these, or perhaps very different ones.

Our next step of data analysis will provide insights into how we may improve upon and enhance this DP theoretical lens by grounding its application in research data. In addition, presenting our lens for discussion in a community of MTEs (as in this CERME-12 TWG 27 focused on the professional practices, preparation and support of MTEs) will provide opportunities for us to further reflect on our conceptualization of this DP lens, as well as provide a desirable context for sharing this innovative theoretical lens for other MTEs to consider in their own research and practice.

Effects of Facilitator Professional Development on Teachers' Learning – An Intervention Study in the Context of Early Mathematics Education

Julia Bruns[1], Maike Hagena[2] and Hedwig Gasteiger[3]

[2]University of Hamburg, Hamburg, Germany; maike.hagena@uni-hamburg.de

[3]University of Osnabrück, Osnabrück, Germany; hedwig.gasteiger@uos.de

A fundamental question in the context of professional development is whether teacher professional development (TPD) can be scaled up successfully using facilitator professional development (FPD) programs. Studies that link effects of FPD programs to teacher learning are, however, rare. The presented study addresses this research gap by examining effects of an extensive FPD program in the context of early mathematics education (EmMa^M). To examine effects of EmMa^M, a quasi-experimental intervention study with two intervention groups was conducted: While in group A the TPD course was enacted by the program developers, in group B the TPD was enacted by facilitators. Results show that teachers in group B achieved comparable learning gains to teachers in group A. This result supports the idea of scaling up professional development using FPD – if facilitators are qualified accordingly.

Keywords: Facilitator professional development, in-service professional development, teacher learning, early mathematics education.

Facilitator Professional Development Programs and its Effects

Teacher professional development (TPD) is essential to improve teaching quality and support teachers' lifelong learning (e.g., Borko, 2004). Therefore, a shared aim of school administration, developers of professional development (PD) programs, and researchers is to scale up effective PD programs (e.g., Roesken-Winter et al., 2015). This scaling up can be realized by qualifying facilitators to enact TPD at several sites (Borko, 2004). To support facilitators in their (new) role, several authors suggest facilitator professional development (FPD) programs which include PD materials and activities for teachers as well as support materials for facilitators to enact the PD program (Borko, 2004; Koellner et al., 2011; Prediger et al., 2019).

Prediger et al. (2019) developed the *Three-Tetrahedron Model of professional development* "to capture the complexity of PD courses in a multifaceted way and to connect the different levels of (1) teaching and learning on the classroom level, (2) PD on the teacher level, and (3) PD on the facilitator level" (p. 408). The *Three-Tetrahedron Model of professional development* suggests a cascadic approach to scale up PD programs. In cascade models a group of facilitators, who are mostly teachers themselves, is trained to conduct TPD programs (Krainer, 2015).

Different authors question the effectiveness of cascade models: They criticize that cascade models follow a transmissive approach and do not take the context of the individual facilitator into account (e.g., Hayes, 2000; Kennedy, 2014). Additionally, for example Krainer (2015) expects a dilution of expertise with each level of the cascades. In summary, it is assumed, that facilitators might have less developed mathematical expertise and/or less accomplished facilitation practices then their trainers which in turn leads to less expertise at the teacher level. Whether this is the case has yet to be examined.

Therefore, a key question is whether TPD programs enacted by facilitators in FPD programs achieve effects on teachers' learning (Koellner et al., 2011; Perry & Boylan, 2018; Prediger et al., 2019; van Driel et al., 2012). The few research results on the effects of FPD on teachers' learning available in the field of mathematics education indicate that teachers that were trained in a PD course enacted by facilitators increased their knowledge in comparison to untrained teachers (Bell & Higgins, 2010), but show less competence than their facilitators (Koellner & Jacobs, 2015; Lange, 2014; Turner et al., 2017). Additionally, effects of TPD differ with respect to the facilitator (Bell & Higgins, 2010; Carney et al., 2019). In summary, these results support the assumption that the scaling up of TPD using FPD is possible. However, the results do not clarify the extend of these effects and thus do not address the criticism of the dilution of effects with each level of the cascades. This is especially true as there is a lack of research comparing the effects of TPD courses enacted by facilitators and TPD courses enacted by experts in the field with more expertise then the facilitators (i.e. the originators/developers of the PD courses). The present study starts out to address the questions of the dilution of effects with each level of the cascades by examining FPD in the context of early mathematics education exemplified by the FPD program *EmMa*^{M} (Bruns et al., 2021).

The Context of this Study: *EmMa*^{M} – A FPD Program for Early Mathematics Education

A key feature of the *Three-Tetrahedron Model* is to base FDP on TPD. To realize this, we firstly developed a TPD course on early mathematics education called *EmMa - Erzieherinnen und Erzieher machen Mathematik* [EmMa – Early childhood teachers are doing mathematics] (Bruns et al., 2017), secondly examined the effectiveness of this TPD course (Bruns et al., 2017) and thirdly developed the facilitator professional program *EmMa*^{M} (Bruns et al., 2021). The development of the facilitator professional program *EmMa*^{M} was guided by key features of facilitators learning as indicated in the literature (Jacobs et al., 2017; Koellner et al., 2011; Schifter & Lester, 2005):

- **Considering all aspects of teaching and learning on the teacher and the classroom level:** To realize this first key feature, the structure and content of the FPD program *EmMa*^{M} is based on the structure and content of the TPD course *EmMa*. *EmMa*^{M} comprises of an introductory module and four in-depth modules which each lasts two days. Additionally, *EmMa*^{M} integrates various activities from the TPD course *EmMa*, which are firstly carried out by the facilitators themselves and afterwards reflected on with regard to the aims of the activities. *EmMa*^{M} thereby addresses the content of the TPD course *EmMa* from a higher level which also includes typical teacher misconceptions and reflection of teaching strategies.
- **Integrating and modeling activities of the teachers PD program**: As all activities as well as all theoretical aspects from the modules of the TPD course *EmMa* are enacted by the leaders of the FPD course, these leaders also function as a model for the facilitators.

- **Supporting the preparation, implementation as well as the follow-up of the TPD course:** In practical phases between the FPD modules, the facilitators independently lead TPD courses on early mathematical education. Through these practical phases, *EmMa*^{M} realizes an accompanied implementation of the TPD program as advised by Jacobs et al. (2017). Facilitators are supported in the preparation, implementation and follow-up of their TPD course during the FPD.
- **Offering supporting materials to enable facilitators to conduct the PD course in alignment with the intended goals of the PD program:** The fourth key feature of supporting materials is realized by a set of guiding materials. These materials include suggestions for the methodical structuring of the TPD course, a commented set of presentation-slides for each TPD module and templates for several teacher activities. In addition, the leaders of the FPD provided further literature as well as a set of games and play materials used to foster early mathematical learning in kindergarten (games, pattern blocks, etc.) which is used to plan different learning opportunities for children in the TPD program.

All in all, the FPD program extends over a period of 10 months and includes 85 hours of presence time and at least 100 hours of time to prepare and implement the TPD course in the practical phases.

Design of the Study

Research Question and Research Approach

To examine effects of *EmMa*^{M}, a quasi-experimental intervention study with two intervention groups was conducted: While in group A the TPD course was enacted by the program developers (first author of this paper and a colleague), in group B the program was enacted by facilitators. According to the aims of our study and the TPD course *EmMa*, we focus on the effects on teachers' mathematical pedagogical content knowledge (MPCK) and their beliefs. The leading research question is: Are there significant differences in the development of early childhood teachers' MPCK and beliefs between early childhood teachers that undertook the PD course EmMa enacted by facilitators in comparison to early childhood teachers that visited the PD course EmMa enacted by experts (the program developers)?

Sample

The sample of the experimental group A, the expert group, comprises of n = 76 early childhood teachers (n = 65 female, n = 4 male, n = 7 missing) that visited a TPD course *EmMa* on early mathematics education enacted by the program developers between 2014 und 2016. The early childhood teachers were between 24 and 59 years old, on average 43.97 years (SD = 10.81). All early childhood teachers were trained at vocational schools and were working in Germany.

The sample of experimental group B, the facilitator group, comprises of n = 83 early childhood teachers (n = 76 female, n = 7 male) that visited a TPD course *EmMa* on early mathematics education enacted by nine different facilitators. The early childhood teachers visiting these TPD courses were between 21 and 62 years old, on average 42.27 years (SD = 11.08). The early childhood teachers were also trained at vocational schools and are working in five different federal states with comparable frameworks concerning early childhood education.

The developer of the *EmMa* program leading the TPD courses of experimental group A are the first author of this paper, currently a junior professor for mathematics education and a colleague, who is an early childhood teacher himself and currently professor for early childhood education. The nine facilitators leading the PD courses of experimental group B were all visiting the FPD program *EmMa*$^{M.}$. The TPD courses were conducted as a part of this FPD program (practical phase) in 2018. The facilitators were between 31 and 57 years old, in average 43.33 years (*SD* = 9.83). Six facilitators were trained as early childhood teachers themselves and had between 11 to 30 years practical experience as an early childhood teacher. The other three facilitators had a Master's degree in educational studies, one with mathematics as a major field of her studies. Yet, none of the facilitators had been significantly involved with early mathematics education during their training or studies. Most of the facilitators (7 out of 9) additionally reported prior experience in leading PD courses to different topics relevant to early childhood teaching (e.g., language and literacy) but not to early mathematics education. Experience in PD ranged between 3 to 300 days (*M* = 70.13; *SD* = 101.42).

As described facilitators were supported intensively in these practical phases by the leaders of the FPD program. In addition, results of a qualitative study on these practical phases of *EmMa*^{M} using the same sample showed that facilitators all stayed very close to the suggestions for the methodical structuring of the TPD course (Bruns et al., 2021). From this it can be followed, that the TPD courses visited by the early childhood teachers in experimental group A and B were comparable concerning content and structure but not necessarily concerning the thematic depth and mathematical correctness.

Instruments

Early childhood teachers' MPCK was measured by a standardized Rasch-scaled test consisting of 35 items (Blömeke et al., 2015). Each item on MPCK was coded dichotomously (0 = not correct/ not reached; 1 = correct). The Rasch scaling model was applied to the coded data. The z-standardized early childhood teachers' WLEs are used as performance values for any further analyses. In our study, the test showed an EAP reliability[1] of .58 which is comparable to earlier studies (ibid.).

The beliefs towards mathematics in general were assessed by a questionnaire (Blömeke et al., 2017) using 27 items and a 6-point Likert scale. The items distinguish five beliefs facets: (1) a static orientation towards mathematics (7 items, Cronbach's α=.83, (2) a process-related orientation towards mathematics (4 items, Cronbach's α=.82), (3) an application-orientation towards mathematics (6 items, Cronbach's α=.80), (4) gender stereotypes regarding mathematics (5 items, Cronbach's α=.92) and (5) enjoyment of mathematics (5 items, Cronbach's α=.87). Every single item ranges from 1 to 6, mean scores have been computed for the different scales. Higher scores indicated that participants had a higher agreement in the mathematics-related statements.

[1] When calculating IRT reliability using Rasch modeling, each participant is assigned an estimated ability value expressed as a score distribution. The predictive reliability is 1 minus the ratio of the variance of a participant's score distribution relative to the sample variance. EAP represents the mean of such predictive reliabilities in the sample and is thus a measure of the overall reliability of the sample that can be interpreted similarly to Cronbach's α (see e.g., Neumann et al., 2010).

Procedures and Analysis

Data on experimental group A was collected in TPD courses led by the program developers in the years 2014 to 2016. Due to missing data, we have 54 (MPCK) respectively 49 (beliefs) complete data sets for the analysis in group A. The facilitators started their FPD program *EmMa*^{M} in March 2018. As a part of this FPD program the facilitators lead one *EmMa* TPD course with 10 to 12 early childhood teachers in the practical phases (see Figure 1). The early childhood teachers visiting these *EmMa* TPD courses led by the facilitators in training form experimental group B. Due to missing data, we have 82 (MPCK) respectively 81 (beliefs) complete data sets for the analysis in group B.

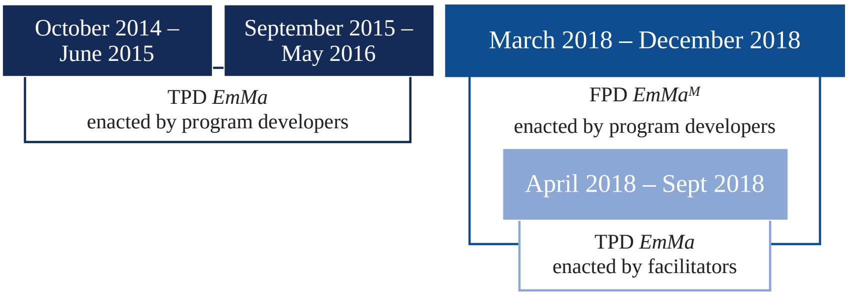

Figure 1: Interconnections between the TPD enacted by the program developers (group A), the FPD and the TPD enacted by the facilitators (group B)

In order to assess whether the early childhood teachers' MPCK and mathematic-related beliefs changed from measurement point 1 to measurement point 2, we used a t-test for dependent samples. Based on these findings, for each competence facet a repeated measure ANOVA was used to determine the extent to which changes differ depending on the experimental group. The absence of significant differences would indicate comparable effects in both groups.

Results

The results of a paired t-test confirm significant increases in MPCK for both groups. The early childhood teachers from experimental group A score a mean of 46.81 points on the pre-test for measuring the MPCK and a mean of 49.89 points on the post-test ($t(53) = -3.03$, $p < .01$, $d = 0.26$). The early childhood teachers from experimental group B score a mean of 47.39 points on the pre-test for measuring the MPCK and a mean of 50.21 points on the post-test ($t(81) = -2.23$, $p < .05$, $d = 0.27$). The results of the repeated measure ANOVA reveal a significant main effect of the measurement point ($p < .01$, $\varepsilon^2 = .08$) but not of the experimental group. There was also no interaction effect. In other words, early childhood teachers in both experimental groups increased their MPCK equally.

Concerning the beliefs, the results of paired t-tests confirm significant increases in the agreement to process (EG A $t(48) = -2.16$, $p < .05$, $d = 0.30$; EG B: $t(81) = -4.41$, $p < .001$, $d = 0.50$) and application orientation (EG A: $t(48) = -4.41$, $p < .001$, $d = 0.55$; EG B: $t(81) = -3.07$, $p < .01$, $d = 0.40$) statements towards mathematics and in the agreement to statements concerning the enjoyment of mathematics (EG A: $t(48) = -5.37$, $p < .001$, $d = 0.76$; EG B: $t(81) = -6.28$, $p < .001$, $d = 0.78$) for both experimental groups. Furthermore, significant decreases in the agreement to static orientation statements towards mathematics (EG A: $t(48) = 6.73$, $p < .001$, $d = 0.86$; EG B: $t(81) = 6.45$, $p < .001$, $d = 0.78$) and in the agreement to gender stereotypes (EG A: $t(48) = 4.69$, $p < .001$, $d = 0.58$; EG B: $t(80) = 4.60$, $p < .001$, $d = 0.42$) statements regarding mathematics are also confirmed for both experimental groups. The results of the repeated measure ANOVA reveal significant main effects of the measurement point but no main effects of the experimental group. There are also not given any interaction effects. In conclusion, early childhood teachers in both experimental groups succeeded equally in positively changing mathematics-related beliefs.

Discussion

Limitations of the study

Our study bears limitations regarding the sample of early childhood teachers in the two groups. The TPD courses in group A and B were time-shifted by about three years. We did, however, find no differences between the groups on the pre-test scores and therefore concluded that the differences in the sample seem to be neglectable for this study. Secondly, limitations can be traced back to the instruments used to measure early childhood teachers' mathematical pedagogical content knowledge. To compare the facilitator and the expert group regarding their learning effects, we used the same instrument to measure teachers' mathematical pedagogical content knowledge (Blömeke et al., 2015). The test score interpretation of this instrument is, however, validated for a sample of pre-service not in-service teachers and the test instrument follows a rather cognitive and broad approach regarding mathematical pedagogical content knowledge. Further limitations occur concerning the sample of the facilitators. This group was very heterogenous regarding their education, experience with TPD in general and their experience with mathematics and mathematics education (in early childhood settings). Likewise, it should be mentioned that facilitators followed the suggested structure, content and activities of the TPD course *EmMa* quite closely (Bruns et al., 2021). It can therefore be assumed that the effects we found can partly be attributed to the concept of the TPD course *EmMa*.

Interpretation and Conclusion

To our knowledge this is the first study that addresses the criticism of expertise dilution with each level of the cascades by comparing effects of TPD courses enacted by facilitators to effects of TPD courses enacted by experts in the field. As did previous research (Bell & Higgins, 2010; Carney et al., 2019; Koellner & Jacobs, 2015; Lange, 2014; Turner et al., 2017), our study found that TPD courses enacted by facilitators can achieve effects on teachers' learning concerning their MPCK as well as their beliefs – if facilitators are qualified accordingly for the job and supported by experts in the field. Adding to the state of research, our study found that these effects are comparable to effects of experts in the field. Our study did not indicate any differences in the effects of the TPD course between the expert group and the facilitator group regarding the development of teachers' MPCK nor their mathematics-related beliefs. This result supports the idea of scaling up PD using FPD (Borko, 2004; Koellner et al., 2011; Prediger et al., 2019) as it reveals that experts and facilitators can achieve the same effects on teachers' learning through TPD.

However, this result must be considered in the light of the FPD concept: The effects found in this study are not only based on quality of the TPD courses lead by the facilitators and the expertise of the facilitators, but also on the extensive resources and specific materials used to support facilitators in leading TPD courses (s. a. Borko, 2004; Koellner et al., 2011; Prediger et al., 2019). It can therefore not be ruled out that there is a dilution of expertise with each level of the cascades. In fact, in an accompanying qualitative study, we found that the facilitators make a lot of incorrect statement during their TPD courses (Bruns et al., 2021). Our results of this study do, however, indicate that this lack of expertise can be compensated by the close monitoring of the facilitators and the high quality of the TPD resources. Our results therefore support those critical perspectives on the cascade model that direct their criticism towards the implementation of the cascade model in practice (Hayes, 2000; Wedell, 2005). Still to be investigated is the extent to which the effects of the TPD courses differ depending on the facilitator (see also Bell & Higgin, 2010; Carney et al., 2019). Nevertheless, we conclude from this that scaling up TPD by qualifying facilitators to enact TPD at several sites can be successful – but probably has to be accompanied not only by extensive facilitator training but also high-quality resources to facilitate the TPD.

The role of the mathematics teacher educator in supporting engagement with global issues in the mathematics classroom

Alf Coles

University of Bristol, UK; alf.coles@bristol.ac.uk

The world is in a period of rapid change. Climate chaos is leading to floods and droughts and exacerbating inequality. A recent global survey indicated a majority of young people are 'very' or 'extremely' worried about climate change. This paper asks, in such a context, what is the role of mathematics education and, in particular, what can mathematics teacher educators (MTEs) do, in supporting teachers who want to engage in bringing global issues into their teaching? I report on work taking place in one university in the UK where, for the last 6 years, MTEs have been encouraging teachers to address global issues in their classroom. One role which has emerged for a MTE is in supporting the translation of scientific work on climate change into classroom tasks. In the UK, the spaces for such work are being squeezed in an increasingly politicized education system. The lens of critical mathematics education offers a mechanism for reflection on the role of the MTE.

Keywords: Global challenges, climate change, learning to teach mathematics, role of the mathematics teacher educator, critical mathematics education.

Introduction

The effects of climate change, or the climate emergency, are visible across the world. The year 2021 has seen extreme weather in the form of tornadoes, droughts leading to wildfires, rainfall leading to unprecedented flooding and more. Mathematics is deeply implicated in climate change and other global issues, for example, in how events are communicated and how they are modelled. Mathematical models of climate, pollution, virus spread, the economy have real world effects and so mathematics is also implicated in the creation of some of the global challenges facing humanity. For instance, mathematical models of the economy, which place no value on materials before they are extracted, facilitate exploitation of natural resources and the depletion of environments which have historically sustained communities. A report on a survey, about to be published (but trailed in the media) by Caroline Hickman at Bath University, UK, looked at the views of 10,000 16-25-year-olds across 10 countries and found high levels of eco-anxiety: 60% of young people surveyed said they felt 'very' or 'extremely' worried about climate change. In such contexts, a mathematics education which continues its business as usual, in isolation from the world outside the classroom, seems increasingly jarring. This paper aims to investigate what mathematics teacher educators (MTEs) might do. What role might a MTE take, in working with prospective or in-service teachers, in order to support a re-thinking of the kinds of topics or discussions which take place in mathematics classrooms, to include global issues and challenges such as climate change? My way of approaching such questions is informed by critical mathematics education and I set out this perspective in the next section. I then report on work that has taken place over the last 6 years, at the University of Bristol, in the UK, in which MTEs have been working with teachers to encourage and support tackling global issues in the mathematics classroom.

Critical mathematics education

Critical mathematics education refers to work which brings insights from critical theory into the specific sphere of mathematics education. Andersson and Barwell (2021) offer a summary, that critical mathematics education: "is *driven by urgent, complex questions*; is *inter-disciplinary*; is *politically active and engaged*; is *democratic*; *involves critique*; and is *reflexive and self-aware*" (p.3, italics in original). This characterization says to me that critical mathematics education is particularly appropriate to a consideration of how issues such as climate change might be relevant to the work of a MTE. Global challenges such as the climate emergency, and other ecological disasters are certainly urgent and complex and inter-disciplinary. Addressing such questions as a MTE (in the UK) is a political statement since there is now a mandated curriculum for teacher education which is focused on the techniques and craft of teaching, with no mention, for instance, of our role in preparing citizens for a precarious future. And, as I hope to demonstrate in this paper, the use of critical mathematics education for MTEs can provide a tool for reflexivity.

Andersson and Barwell (2021) identify three broad schools of work within critical mathematics education (acknowledging that such divisions are a simplification): Freirean; Foucauldian; and a Nordic school. They characterize the Freirean school as focused on the use of mathematics for consciousness raising, for "reading the world", in a way that draws parallels to Freire's (1970) work on literacy as consciousness raising. Within this tradition there is often an explicit aim to challenge oppression and effect change (Gutstein, 2006). The Foucauldian school investigates the (often invisible) uses of the discourses of mathematics in the "organization of human affairs" (Andersson & Barwell, 2021, p.9), for instance, the way in which middle class assumptions about what constitutes child development can become accepted as what it means to be "normal", or the way in which differences between girls' and boys' relations to mathematics are constructed (Walkerdine, 1988). In the Nordic school, Skovsmose (1994) explores the use of technology in society and argues for the need for students in school to not only be taught to do mathematics but also to critique how mathematics is used and how it gets embedded in technologies which have real social effects, such as algorithms for welfare payment distributions.

Perhaps surprisingly, there has been relatively little work linking critical mathematics education to issues such as climate change, with exceptions such as Renert (2011) and Barwell (2013); although this is a situation that now appears to be changing (e.g., Barwell & Hiis Hauge, 2021; Steffensen et al., 2021). There also appears to be little work bringing critical mathematics education into discussions of the work of mathematics teacher educators. This article brings both of these strands together. I do not adopt one particular school of thought within critical mathematics education but rather use the range of meanings in order to investigate evidence and possibilities for critical mathematics education in the role of a MTE. I use the broad characterization of the three schools of critical mathematics education as a set of ideas, offering opportunities for reflection and critique of the practices of MTEs. I will be reporting on a long-term project which is on-going at the University of Bristol. This is a project that embodies a process of curriculum innovation within our teacher education course and it has not been guided explicitly by ideas of critical mathematics education. In the next section, I offer a description of this project, before reporting on some of its outcomes via a reflection on three professional journal articles.

The Green Apple Project

The name "Green Apple" came from the internal funding scheme which helped kick-start the project in 2015 at the University of Bristol, UK. The funding was to support innovation in our 1-year teacher education course for secondary school, which leads to a Post Graduate Certificate of Education (PGCE). The idea was to support teachers bringing questions of global challenges into their subject teaching, or their work as form tutors (a pastoral role required of teachers in England). Two (or more) "Green Apple representatives" (reps) are recruited from each of the 8 subjects offered on our PGCE course and these reps meet with a group of teacher educators (including MTEs) on three occasions over the year. The reps are responsible for disseminating outcomes from meetings to the rest of their subject group. Meetings introduce reps to ideas (such as the framing of "wicked problems", or of education for sustainable development) and allow time for discussion between and across subject groups and offer prompts for action between meetings. Classroom resources are shared and previous years' work is available. Over the last 6 years, the project has introduced and run sessions with all prospective teachers, provoking thought on the role of global challenges in their subject teaching.

In order to present some of the outcomes of the project and to focus on the role of the MTE, I report here on three articles, which have been written by mathematics members of the Green Apple Project, and which have appeared in (or are soon to appear in) the professional journal *Mathematics Teaching*. These are the only publications from the group in a professional journal. In what I report here, I focus on the tasks offered in the articles, and reflect on the role of the MTE in each case, linking to ideas of critical mathematics education.

Sustainable futures, from 2018

Karl Bushnell wrote an article for Mathematics Teaching (Bushnell, 2018) based on resources he had developed and trialed for his own classroom. Karl had done his PGCE at the University of Bristol and taken an active role in the Green Apple project. The work he wrote about was conducted when he had taken up a job in a school near Bristol. Karl continued his Master's in Education (with a specialization in Mathematics Education) at the University of Bristol and developed an approach to offering tasks which paralleled standard exercise questions, with questions that led students to answers which told them something about the global environment. An example is given in Figure 1, which shows the worksheet for students, involving a sequence of tasks leading them to calculate the sea-level rise that would be caused by the Greenland icesheet melting.

In Figure 1, tasks are paired, to have one question, or set of questions, with no context and one question drawing on the same skills but in the context of melting ice sheets. For example, the second task (top right of the sheet) has three prisms and asks students to find their volume. Then the prompt is: "Given that the global water [sic] surface area is 361,132,000 square kilometres, and using your answer to Question (1) [which was to convert 50 metres into kilometres], calculate the volume of water needed to cause a 50m rise in sea levels". The final question invites students to write down their thoughts having done the calculations, i.e., to reflect on the implications of the predicted change.

The tasks were developed entirely by Bushnell, i.e., without direct MTE involvement. The role of the MTE, in the case of the work written up here, was one of supporting the raising of issues (via the Green Apple work on the PGCE course) and then subsequent support via a flexible Master's programme that allowed teachers to follow their own classroom interests. Bushnell was an engaged and passionate individual who took the initiative to continue to develop themes from the Green Apple project after he had left the PGCE course as a qualified teacher.

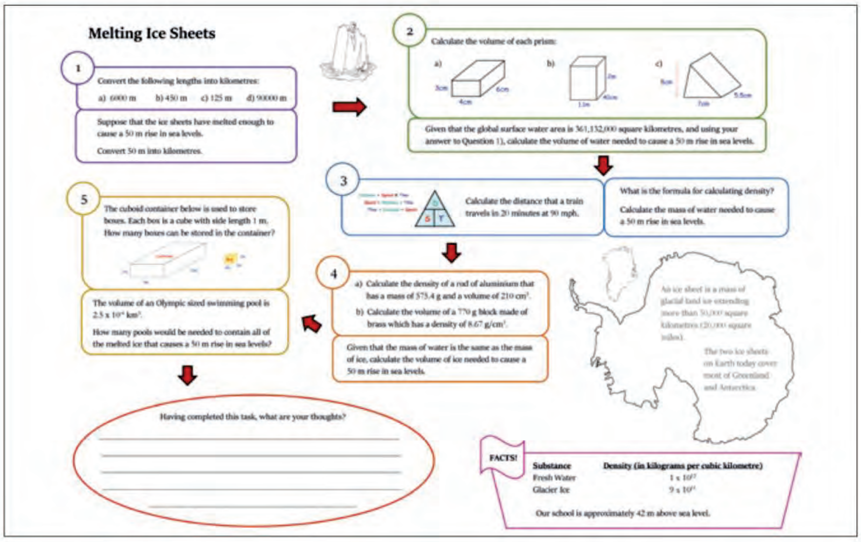

Figure 1: A sequence of tasks calculating sea-level rise from the Greenland icesheet melting

This task, and the MTE support, do not appear to attempt to offer a critique of the mathematics being used (as in the Foucauldian or Nordic schools). The mathematics is presented as a neutral tool and the assumptions behind the model being used are not discussed, for instance. The MTE did not provoke questions about this neutrality, nor prompt reflection on possible links to social action, or oppressions which are entailed in the causes of sea level rise (e.g., consideration of the almost incalculable human suffering which would ensue). There seems to be an aim to raise consciousness (edging towards a Freirean idea); in the classroom task the aim is to raise consciousness of the consequences of the melting of the Greenland icesheet. And the MTE role appears to have raised consciousness, or awareness, for the teacher, of possibilities for the use of global challenges in mathematics teaching and allowed space for reflection on how this could be done, while also maintaining a focus on the curriculum that needs to be taught in secondary school.

Global challenges, from 2019-20

Across two articles (Brown et al., 2021 Part 1; Brown et al., 2021 Part 2) 9 prospective teachers on the PGCE course (in the 2019-20 cohort), supported by their 3 MTEs, each wrote about one task they had either created or found and then used (or planned to use) with classes they were responsible for in their placement schools. By this time, several years into the Green Apple project, global challenges were involved in one of the mathematics programme's Master's assignments on the PGCE course, and so every prospective teacher had to engage, in at least one lesson, with thinking about how to incorporate an issue such as climate change into their classroom teaching. I relay below 5 of the 9 tasks reported on across the articles. Two tasks began with simply stated challenges to provoke discussion, which then developed into more extended activity.

“How does a country’s GPD affect a person’s life?” (Part 1, p.9)

"How many trees could fit in this room?" (Part 2, p.9)

The other tasks got students doing some work or calculations that did not necessarily initially relate to a global challenge and then led into a key question. Here are three examples.

Based on data about incomes in England and Romania: "Which country has a bigger pay gap between male and female workers?" (Part 1, p.10)

Based on drawing paths and associated loci (to model a potential Covid transmission distance of 2m): "assess potential transmission points" (Part 1, p.13)

Having worked out the area of the school grounds and, based on aerial photographs of deforestation in Brazil: "find the area that had been cut down, and how many 'areas of the school' that this represented" (Part 2, p.11)

Several of these lesson ideas came from the prospective teachers' engagement in their Master's studies, where they had to plan a topic (around 5 hours of teaching) which involved at least one global challenge being addressed. For other teachers, these tasks were developed in response to a session given to all prospective teachers on the course, on Green Apple issues. The role of the MTE has shifted here, to one of mandating some exploration of global issues. As MTEs, having seen and been impressed by the work developed by these teachers, my two colleagues and I then proposed some joint writing. As MTEs we helped edit and structure the writing and supported its submission.

As with the previous example, these tasks, and the MTE support for them, appear primarily focused on consciousness raising (Freirean school) without perhaps drawing attention to the uses of mathematics (the Nordic school) and hardly pointing towards more Foucauldian questions around the organisation of society. In other words, the tasks appear focused on raising awareness of issues such as deforestation and the MTE role appears, as before, primarily focused on raising awareness of possibilities within the classroom. The write-ups of the tasks suggest wider implications about society, and links to social activism, were left implicit and that would also be true to say about the MTE support being offered (i.e., consideration of such wider issues was not prompted or provoked).

Climate science, from 2021

In early 2021, I began a collaboration with a scientist (Joseph Darron) from the UK Met Office, after this scientist was given a secondment of a day a week to work at the University of Bristol. Joseph's research centres around questions of how climate models and statistics are communicated (e.g., to politicians). After a few months of intermittent discussions about making his research into something usable in the classroom, we invited a local partner school to see if they would like to join us. One teacher (Barney Rolph) volunteered and worked on adapting and trialing the tasks that we were developing. Barney had been on the PGCE course at the University of Bristol and been involved in the Green Apple group. The task Barney adapted to use in his classroom was the following (Coles et al., 2022, p.7):

Climate models are used to simulate the climate and predict changes. We will be focusing on models that can be used to predict how much wetter or drier a place might be in the future. There are different models, made by different scientists.

> Botswana (in Africa) currently averages around 34mm of rain per month.
>
> Here are 9 projections for the change in rainfall in Botswana (in mm per month) in the coming years:
>
> +17; +13; +6; -2; -2; -6; -6; -6; -14
>
> Your task:
>
> Imagine you are an advisor to farmers in Botswana. You are going to prepare a written summary of this data advising farmers of future risks and changes to the climate. Think about different mathematical techniques that you have learnt that might help analyse and/or present this data.

In the article, Barney offers some of the response of his class to this prompt and further work he went on to do with them using climate data. The MTE role is quite different in this case, compared to the previous two. Here, the MTE acts as a conduit between a climate scientist and a teacher. As the MTE involved, I remember recognizing, in Joseph's presentation of his research, its classroom potential. The questions he was grappling with – to do with what the consequences are of different presentations of data for how they are interpreted – seemed like ones that students in schools could access. I also recognized that the data Joseph was using seemed accessible for quite young students and, in my experience as a teacher, it is not easy to find real data in a form that is suitable for a classroom.

The task here, in contrast to the previous ones, feels more aligned to the Nordic school idea of inviting reflection on the use of mathematics and how complex data might be summarized mathematically. And hence, I also interpret the MTE role in this case as provoking awareness of the use of mathematics. There may be elements of consciousness raising also, in the task and in the work of the MTE, but again little attention to wider societal questions and connections to possibilities for action.

Discussion

Having presented the work of the Green Apple project, as it has manifested in three professional journal articles, and offered a description of the role of the MTE in each case, I now summarise and then reflect further on these outcomes.

My aim in offering the work of the Green Apple project has been to allow reflection on the question: *What role might a MTE take, in working with prospective or in-service teachers, in order to support a re-thinking of the kinds of topics or discussions which take place in mathematics classrooms, to include global issues and challenges such as climate change?*

As alluded to above, I interpret the MTE roles in the first two cases as being most aligned to a Freirean perspective on critical mathematics education, with a focus on consciousness raising. However, having said that, compared to examples offered in Freire (1970), the roles of the MTE in these cases are relatively limited examples of consciousness raising. Nonetheless there is a linking of reflection and action, in the work of the teachers, to implement changes in their classrooms and a hope, on the part of the MTEs, that such work will continue into the future. The final example, of the MTE in the role of conduit or bridge building, edges into more of a Nordic school version of critical mathematics education, in raising questions about the use of mathematics in communicating data about climate change, and the huge uncertainty of current models (despite the certainty that change is happening).

Considering the second example, there seems to be a power in mandating engagement in considering global challenges, as part of a teacher education programme, and supporting further engagement of those who show interest by setting up and coordinating a co-writing opportunity. In the final example, the use of mathematics by politicians, policy-makers and scientists is beginning to be explored in the task, in contrast to the previous two articles.

In all cases, the Foucauldian school of critical mathematics education points to possibilities for the role of a MTE that were not taken. In Bushnell's work, a possible MTE provocation might have been to invite consideration (on the part of the teacher and/or students) of who is in danger from sea-level rise and where do they live? In the case of the 2019-20 writing, similar provocations might have been, who benefits from de-forestation? how fairly spread is a country's GDP? In the climate model scenario, again, we did not address questions of the impacts of drought or flood on difference sectors of society. In a UK context it is unlikely such wider question would be addressed in a mathematics classroom but, in reflecting on MTE roles not taken, these seem like potentially significant provocations for teachers, in forcing a consideration of how global issues link to the organisation of societies and the inequalities which are exposed by global forces such as climate change.

As demonstrated here, the three lenses of critical mathematics education offer a mechanism for recognising what is *not* being done, as a MTE. Questions I might ask myself (e.g., in planning to work with prospective teachers) from each of the different perspectives are:

> What are the global challenges that teachers I am working with care about? What tasks and mechanisms (e.g., as part of a teacher education course) can I offer, to support them acting on their interests, in their own classrooms? (a Freirean perspective).
>
> When does mathematics teaching reinforce, or remain silent about, inequalities embedded in the wider organisation of society? Do I call attention to such absences? What might teachers' lived experiences of inequality be and what sensitivities will be needed to explore this (e.g., the space and safety to express reactions and know they have been heard)? (a Foucauldian perspective).
>
> In any context of mathematics teaching (including my own), do I invite reflection on the uses of the mathematics being learnt? Can I link with a professional, who is working on a global challenge, and explore the reality of their use of mathematics? How might I make resources available for teachers in a form that provokes reflection on the uses of mathematics? (Nordic school).

Despite the developments evident over the six-year period of the Green Apple project, I am left with a sense that the resources developed by teachers and the related work of MTEs remains on the margins. The tasks developed seem to represent likely one-offs in the teachers' practices. Similarly, for the MTEs, a mandated "core content" of initial teacher education precludes any sustained focus on global challenges and hence support for such work also has a "one-off" feel.

For both teachers and MTEs there are demands that are hard to ignore (exam success of their students, for the teachers; and, prospective teachers passing a teaching qualification, for the MTEs) both of which, in the UK, pull away from a focus on global challenges. So, although I have provided some answers to my question about what are possible roles of a MTE in supporting such work, I am struck by the limited nature of the roles I have been able to embody, in comparison to the complexity and depth of the issues facing the planet, and amidst a politicization of educational decisions in the UK that, to take one example, mandates against discussion of “anti-capitalist” perspectives in schools.

One thought that sustains me, however, is that we are developing MTE practices, roles and resources to support a curriculum-in-waiting. COVID has shown how rapidly changes can be made in education systems. Over the six years of the Green Apple project I have sensed prospective teachers increasingly wanting to work on inter-disciplinary and global issues, through the lens of their subject teaching. I suggest that critical mathematics education offers a ready, and perhaps untapped, set of resources to help MTEs think about possibilities for transformation in their roles and practices and, one hope I have is that prospective and in-service teachers will increasingly demand for such change.

What makes doing mathematics in PD productive: Lifting and adapting a framework for insights on leader PD and facilitation

Rebekah Elliott[1] and Kristin Lesseig[2]

[2]Washington State University Vancouver, USA; kristin.lesseig@wsu.edu

Well-prepared facilitators of mathematics PD are essential, yet few studies offer nuanced insights and content-specific practices for how facilitators support teachers' productive mathematical engagement. This study utilizes a framework of productive disciplinary engagement (PDE) to investigate the social and mathematical practices of 48 aspiring facilitators and two expert PD leaders across a two-phase design-research study. We found that the PDE framework allowed us to identify participant and facilitation practices that afforded and constrained productive engagement with disciplinary content and practices. We discuss the use of PDE as an analytic and design framework for facilitator and teacher PD. This study contributes insights on content-specific PD practices applicable to a wide range of mathematics PD models.

Keywords: Facilitators, professional development, mathematics education, facilitator practices.

Introduction

Decades of U.S. policy and international research advance that effective professional development (PD) must actively engage participants in disciplinary work. In mathematics PD, this means offering opportunities for teachers to engage in the mathematics relevant to their classrooms. Previously, we have argued that goals for doing mathematics are underspecified, advocating for PD to attend to teachers' specialized content knowledge (SCK) (Ball et al., 2008; Elliott et al., 2009). Well-prepared facilitators of mathematics PD are essential to realizing these goals and advancing PD research (Karsenty, 2021; Lesseig et al., 2017). Over the past decade, attention has been paid to the growth of PD facilitators (Krainer et al., 2021); however, few studies offer nuanced insights and content-specific practices for *how facilitators support* productive mathematical engagement when working with teachers in PD (Borko et al., 2014). We take up this aim by examining a nested context of facilitator PD focused on teacher PD, in which two expert leaders (ELs) worked with aspiring facilitators. Knowing how and what moves to support teachers' productive engagement is vital to high-quality PD (Tekkumru-Kisa & Stein, 2017).

This study is situated in a two-phased design research project, *Researching Mathematics Leader Learning* (RMLL). The paper examines participants' collective work on one mathematics task across four small groups and two whole group discussions using a framework of *productive disciplinary engagement* (PDE; Engle & Conant, 2002). We use this framework to understand what makes "doing mathematics" in PD effective and ways facilitators might guide collective mathematical activity toward particular goals for teacher learning.

Theoretical perspective

Elsewhere we have argued that teacher learning of mathematics differs from students' learning in at least two specific ways (Elliott et al., 2009). Teachers have experienced the content at least once as students and often have revisited the mathematical ideas as teachers or PD participants. Second, in PD, teachers are working with peers and are often colleagues of the facilitator, resulting in different authority arrangements than those among teachers and students. These differences, coupled with the understanding that teachers come into PD with varied orientations toward mathematics, mathematics teaching, and learning, can create tensions as social positioning is negotiated among colleagues when doing mathematics (Holland & Lave, 2009). As a result, we have argued that a goal for teachers' mathematical learning in PD is to develop SCK (Ball et al., 2008). With this goal, facilitators must anticipate and navigate the range of ways teachers may leverage mathematical concepts while simultaneously holding teachers accountable to the practices of the discipline and supporting their authority by positioning them as competent. Facilitators must also negotiate what constitutes a mathematical explanation, how errors and uncertainty are valued, and how social relations and positioning are mediated. This study utilizes the PDE framework as a lens to consider the dynamic interplay among social and mathematical aspects of the work accomplished by aspiring facilitators (teacher leaders) in a PD setting. Our analysis provides an empirical argument for the utility of the PDE framework addressing how productive disciplinary engagement is afforded or constrained in collective mathematical work in facilitator PD.

Adult learning involves cognitive, social, and cultural dynamics inseparable from contexts and content. Consistent with this situative perspective, we use PDE to examine the activity system - actors engaged with one another, using practices and resources to enact activity - as our unit of analysis (Holland & Lave, 2009). A vital feature of the study context of facilitator PD is that these actors belonged to at least three communities of practice central to doing mathematics - aspiring facilitators, previous participants in mathematics PD, and mathematics teachers. The complexity of these overlapping communities frames the collective work of doing mathematics in this setting and the social positions occupied by participants. Awareness of the practices nested within these multiple communities is vital to evaluate the productivity of PD engagement.

Productive Disciplinary Engagement

Engle and Conant (2002) describe *productive engagement* as the intensity and extent to which learners progress on a problem over time. *Disciplinary engagement* involves working toward goals by individuals and groups using the concepts and practices of that discipline. PDE frames how we make sense of ideas, practices, and discourse when a group of aspiring facilitators solve and share solutions to mathematics tasks meant to support them in developing mathematical knowledge for teaching and leading. Engle and Conant (2002) operationalize PDE as a dynamic system of four coordinated tenets: problematizing–resources and authority–accountability, suggesting that when any tenet is more dominant or missing, PDE is in jeopardy.

Problematizing refers to efforts where disciplinary uncertainties arise. Uncertainty involves questions or indecision regarding what to do, conclude, or justify. Productivity increases as learners reflect on uncertainty and employ *resources* to alleviate it. Resources might be tools, artifacts, or practices needed to do particular kinds of disciplinary work. Problematizing is advanced when learners have sufficient resources and are encouraged to question and make proposals or challenges. As learners assert *authority*, they express their agency to define, address and resolve disciplinary problems. Authority is expanded as learners take control over problematizing the disciplinary content. Learners' authority needs to be balanced by *accountability* to how one's ideas make sense and are relevant to the work of one's peers, others, and to the discipline. PDE was conceived as a set of design principles to understand the quality of learning settings (Engle & Conant, 2002). We extend PDE's application to focus on the supporting conditions of facilitation in the context of PD. We consider the framework's utility as an analytic and design tool across facilitator and teacher PD.

Context

RMLL's five-year design-research project prepared facilitators to lead mathematical tasks in PD using a series of PD videocases to support productive mathematical discussions (Elliott et al., 2009). In six seminars in Phase I, facilitators solved mathematics tasks, discussed solutions, and analyzed facilitation features within PD videocases (c.f., Lesseig, et al., 2017). Math tasks were identical to those in student textbooks or PD curriculum. In eight seminars in Phase II, facilitators again solved mathematics tasks, discussed solutions, and analyzed videocases, but there was an increased emphasis on teacher learning goals to develop SCK. In Phase II, we redesigned mathematical tasks to foster and focus mathematical conversations on concepts and practices critical for teaching (Lesseig et al., 2017). With these "reframed–tasks," we aimed to invoke uncertainty by foregrounding mathematical structure while simultaneously providing facilitators with resources to coordinate representations as they explored mathematical patterns and offered conjectures and justifications.

Methods

We analyzed two small groups in Phase I (three and four members), two small groups in Phase II (four members each), and two whole group discussions (Phase 1, n =11, Phase II, n = 37) as facilitators worked on the *Staircase Task* (Noyce Foundation, 2005). This task is a visual patterning task in which facilitators were asked to determine the number of cubes needed to build the n^{th} staircase (i.e., the sum of consecutive integers). In Phase II, after facilitators worked on the Staircase task, they were given the *reframed* task, which pressed them to coordinate representations (visual models, expressions, and tables) to illustrate solutions to the quadratic relationship that can be generalized as [n(n+1)]/2. We were not looking for evidence of individuals' cognitive resources; instead, we examined patterns of practices and how PDE was afforded or constrained.

First, we viewed the video records to develop a consistent idea unit of leading speaker and focus. Our coding scheme captured the mathematical and social interactions in each idea unit. Disciplinary codes included claims, justifications, and representations. Social codes noted whose ideas were made public and traced how the groups took up these ideas. We also noted how individuals positioned themselves or were positioned by others. Based on this coding, we wrote summative memos of small and whole groups examining how work was accomplished in light of the four PDE tenets to illuminate similarities and differences across groups (Miles & Huberman, 1994). We report on critical ideas across phases to illustrate the interaction of facilitators' mathematical and social work (given pseudonyms initials) and the two ELs (noted as L in the transcript).

Results

Across both phases of small groups, most facilitators revealed their uncertainty with the Staircase task identifying a recursive relationship in their table (figure number and total cubes). Patterns were described as adding the figure number to the previous staircase, the sum of consecutive addends, or a generalized sequence. Facilitators' discussion revolved around various explanations for the recursive pattern and their attempts to find a formula that directly related the figure number to the number of cubes in the staircase. Most facilitators could not coordinate resources within their group to find the summation or move to a closed-form solution. A Phase I small group narrated a part of their uncertainty in the following interchange.

CK:	This might be too long and cumbersome, but I'm thinking n+n-1+n-2 ((GT saying it at the same time))
GT:	I wonder if there's another way to state that?
CK:	I don't have any idea.
LN:	But that's what it is
GT:	Yeah, but isn't there an easier way to put it?
CK:	There's gotta be.
LN:	But how do you show a sequence?
CK:	Well, I started writing out the actual numeric equation, so for 3, it equals 3+2+1, and so for 4, it equals 4+and the quantity 3+2+1. Do you see what I'm saying?…
LN:	I don't know how to show sequencing in algebraic thinking except for parentheses
GT:	Yeah, I don't know either. I can't remember.

Mathematical uncertainty made public

As illustrated above, facilitators willingly made their uncertainty public, pushing papers into the center of the table to show their reasoning and sharing different patterns they noticed. Additional resources were needed to move forward within groups where uncertainty coalesced toward the same strategy (e.g., remembering how to sum a sequence). The compressed knowledge of previous mathematics and the various ways that different mathematical concepts were coordinated perpetuated uncertainty unless further resources were recruited into facilitators' discussions.

When uncertainty was public, facilitators often positioned themselves in terms of mathematics. When attempting to generalize patterns, we heard facilitators suggest that they were "visual thinkers," not "formula queens," and label peers as "the Algebra teacher," which conferred higher status. The positioning of facilitators often provided insights into the uncertainty they faced. We also noticed that this social positioning could result in facilitators *deflecting their authority and hampering the accountability* of the facilitator's ideas to the discipline. This showed up in various ways, such as presenting strategies but not knowing how to continue because of faulty understandings ("remembering") or in compressed solutions that were not pressed on to examine the mathematical claims and unpack justifications.

A counter-narrative to the deflecting of authority and accountability to the discipline emerged when facilitators asked how a strategy works, whether it always works, and how a variable was defined. In Phase I we noted that these questions were potentially powerful, yet justification wasn't normative, and incorrect mathematical responses were not probed. However, we saw the expert leader press for accountability in the whole group by prompting facilitators to define variables and coordinate representations (visual model with expressions) to justify claims. Facilitators, in turn, challenged mistaken ideas pressed for further elaborations of mathematical concepts, and the expert leader continued to press for accountability to the discipline. This created opportunities to slow down conversations and connect resources to the uncertainty that had emerged in small groups.

The following are illustrative interchanges from the Phase I whole group.

NC: ...So first, if you start with a 3 by 3, so when I looked at that, you could just divide this. So, this would be x-squared.
L: And why is it x-squared?
NC: If you complete the whole square…(pointing to the additional squares added to figure 3 staircase).
L: So, what's x?
NC: X would be one dimension, one side. In this case, x would equal 3.

Moments later, in NC’s solution discussion

L: So, I'm curious as to why you subtract the [pointing to quantity ½ x^2 - ½ x]…
SL: Okay, so I don't get, okay, here I am again. I don't get why that's ½ x, those three little chunks.
NC: Well, x is 3 squares, right?
SL: Ok. Yes, yes.
NC: And so, ½ x would be one square and a half square so if this (points to the squares on diagonal that have been cut in half) equals x, then this (points to the portion of squares on diagonal that needs to be included to create staircase) equals ½ x.

In Phase II, pressing questions in small groups like those in Phase I resulted in accountability to one another. Yet, we also found that the reframed task served as a resource to push facilitators toward greater accountability to the discipline. As the excerpt below illustrates, we heard facilitators share solutions, solicit support to co-create solutions and revoice each other’s answers until they felt mathematically confident with the ideas.

SJ: Okay, I’ve got another one, ½ of n^2 + ½ of n. So which one of these models shows half of the square plus half of the number? How can we show that? I know it works. You guys have to help me!
ED: That’s different; let me think that through.
BK: Yea, let me write it down, say it one more time.
SJ: Half of n^2 + half of n
ED: But that just goes back to that is the same formula (pointing out that if you simplify [n(n+1)]/2, the expressions are equivalent).
SJ: But if we look at the square (SJ picks up blocks to recreate the 3 x 3 square). Here’s the square, right? So, half of that would take it to that.
ED: Plus…
SJ: Plus half of the 3 (continues rearranging the cubes to add back on and recreate 3rd staircase).
ED: So, half of the square is that much, and then the half of n is that much (pointing to subset of the blocks)
SJ: Is that what b is showing? (pointing to the square model in the reframed task)
ED: Yea, I think that is what that is showing because that is that half (pointing to the diagonal in figure b).

Here we see how the additional resources of the reframed task supported accountability to the discipline – enabling facilitators to coordinate symbolic and visual representations of the quadratic relationship and move beyond verifying that an expression works to justifying and making sense of expressions coordinated across representations. Small *and* whole group discussions were opportunities to coordinate uncertainty and resources and hold themselves accountable to one another and the discipline. Our analysis documents facilitators unpacking mathematical concepts and reasoning across representations to challenge ideas.

ELs played pivotal roles in both phases

In Phases I and II, ELs drew upon two facilitation practices to support reconciling facilitators’ uncertainty to catalyze resources. One method was to *confer authority on the facilitators to address* *their uncertainty* by inviting facilitators to ask questions, press for justification, and compare reasoning across groups. In the exchange from Phase I, below, the expert leader acknowledged the viability of facilitators' reasoning (a recursive solution) and encouraged them to seek additional resources to address their articulated uncertainty.

GT:	Yeah. We're all stuck here.
L:	Well, what you might want to do is literally go in pairs and eavesdrop on the other two tables because they've actually got two different approaches. So what I would suggest is going and just listening for a couple of minutes and then…
GT:	We have an approach
L:	You do! And I think that you might hear some things that would help you build on your approach.

A second practice the ELs utilized to support facilitators was to *reposition resources generated via facilitators' agency but not fully explored*. This practice allowed facilitators to address uncertainty and hold themselves accountable to the discipline by coordinating the closed-form expression, the pattern in their table, and a visual representation of the algebraic ideas of multiplying the dimension of an n by n+1 rectangle and dividing the figure in half.

In Phase II, the second set of coordinated leader practices emerged, *extending the facilitator's agency* by inviting facilitators to connect representations in the reframed task and *fostering facilitators' rehearsal of partial or incomplete understandings*. For example, when facilitators noticed connections between the visual rectangle model and a table showing Gauss' counting method, the expert leader invited them to explore (extend their agency) and rehearse using the fourth Staircase to articulate the correspondences across the representations.

Although some might suggest that these leader practices are not unique to PD (i.e., similar to classroom practices), we contend that because the goals for learning are geared toward SCK, they are unique from goals for students and, as a result, demand particular sensibilities from ELs that are equally different. We expand upon those differences in the discussion that follows.

Discussion

Our analysis revealed critical insights on facilitators' practices and ELs' practices. One of the necessary conditions for PDE was fostering facilitators' accountability to one another and the discipline when coordinating crucial resources. Persistent accountability amongst facilitators wasn't enough to foster PDE. Facilitators needed access to resources to hold themselves accountable to the discipline. In Phase I, ELs conferred authority and strategically repositioned resources to balance facilitators' uncertainty with resources. With access to these resources, we saw facilitators use a range of socially and mathematically effective practices such as pressing for clarification, mapping correspondences amongst representations, and creating the shared meaning of each other's methods, critical markers of PDE. Similar to Borko et al. (2014), when facilitators took up this kind of social and mathematics work, we saw groups make progress on their uncertainty and productively engage with key concepts and practices in the task.

Our results led us to claim that collective agency to press on uncertainty is a supportive condition to foster PDE. When facilitators collectively asserted their authority to share, add-on, and connect ideas, they could access resources to address their uncertainty. Further, when ELs offered opportunities to slow down conversations via practices of repositioning resources, extending agency, and rehearsing partial understanding, we saw facilitators reveal their errors, refine reasoning, and revoice solutions until they were confident with solutions. These were also spaces for peers to support accountability by asking pressing questions, pointing out insights provided thus far in an explanation, and connecting methods (Tekkumru-Kisa & Stein, 2017).

ELs' practices of conferring authority and repositioning resources were strategically deployed in ways that either re-centered facilitator authority to disrupt status or leveraged facilitator authority in invitations to examine additional resources and share reasoning. These practices pressed facilitators for accountability to one another, and the discipline, and thus were vital to advancing productivity beyond engagement (Engle & Conant, 2002). To consider PDE as a framework for teacher and facilitator PD, we must understand the ways that teachers' and facilitators' social and professional positioning frames how authority and disciplinary uncertainty afford and constrain productive engagement.

The PDE framework allowed us to understand the resources needed in PD, the role of facilitator agency and accountability, and how ELs can foster PDE. Facilitators' engagement with the reframed task highlighted the need for "just enough" uncertainty to create productive struggle alongside resources to accelerate and focus discussions on critical mathematical ideas for teaching. Strategic leader practices of extending agency and fostering rehearsals of understanding were foundational to facilitators expanding their productive engagement with SCK.

Essential to a PDE lens for PD is to consider how mathematics is framed by specialized content central to mathematics teaching and learning (Ball et al., 2008). While related to what Engle and Conant (2012) call the critical content and practice of the discipline, PDE accountability in PD would mean something slightly different. For facilitators to be accountable to the discipline, they need to leverage and connect multiple mathematical structures, examine correspondences across representations, and coordinate various solutions. The EL practices we identified in our analysis fostered this type of facilitator activity and thus advanced these goals.

Conclusion

We used the PDE construct (Engle & Conant, 2002) to examine the dynamic interactions among social and mathematical aspects of doing mathematics in facilitator PD. The study offered empirical evidence for the framework as an analytic tool for PD research. The PDE framework revealed the nuanced ways that aspiring facilitators' authority and accountability were at play as they accessed resources to address uncertainty. Moreover, we identified how ELs supported PDE via a set of strategic practices related to the four tenets of PDE. We offer insights on strategic facilitation practices of doing mathematics that can inform future studies of facilitation (Krainer et al., 2021).

While we did not use PDE as a design framework in RMLL, our emerging research suggests that "lifting" the tenets of PDE to inform PD designs is a viable lens to guide task design and practices. Our analysis of ELs' practices revealed how their support of facilitators taking up resources in response to their uncertainty and fostering authority in balance with accountability was a means for cultivating SCK. Frameworks to support PD design and formative feedback are essential for advancing content-specific facilitation across PD models (Karsenty, 2021). As a potential design framework, we can imagine how the adaptation of the PDE classroom framework could orient PD designs and advance productive social and mathematical norms while doing mathematics in PD. This study contributes insights on content-specific PD practices beneficial to a wide range of PD models where teachers engage in mathematics.

The mathematics teacher educator as broker: boundary learning

Elisabeta Eriksen[1] and Yvette Solomon[1,2]

[1]OsloMet University, Norway; elriksen@oslomet.no, yvsol@oslomet.no

[2]Manchester Metropolitan University, UK; y.solomon@mmu.ac.uk

We analyse how two co-teaching mathematics teacher educators (MTEs) describe and justify the enactment of their theory of change in a course for practicing teachers. Applying concepts from Communities of Practice, we identify a shared view of the key boundary objects highlighted in the design of the course in our two MTEs, alongside divergent but complementary means of brokering learning at the boundary during enactment. Prominent in our analysis is a working relationship in which one MTE brokering through coordination appears to allow the other to work towards radical transformation, by seeking confrontation that allows her to define the problem space. We consider the implications of this dynamic for their emphasis on teaching as a pair.

Keywords: Boundary learning, brokers, mathematics teacher educators.

Introduction

Mathematics teacher educators (MTEs) were oddly absent from earlier research on teacher education, perhaps because they were frequently those doing the research. Although they are now a research subject in their own right (see Goos & Beswick, 2021), as Jaworski (2021) notes in her response to contributions in that volume, in many studies of MTE learning and development, “the course or programme is very much in the background” (p.420). In this paper, we bring the course into focus in an exploration of two MTEs’ theory of change as they intervene in mathematics teachers’ practice.

Theoretical/analytical framework

Many of the studies in Goos and Beswick’s collection share a theoretical orientation towards communities of practice (Wenger, 1998). Jaworski (2021) notes the usefulness of this approach as a way of understanding not only teacher learning and change but also MTE learning and development. In particular, she notes the power of the idea of boundary crossing in analysing the process of professional development, drawing on Akkerman and Bakker’s (2011) seminal review of the literature. Briefly, Akkerman and Bakker identify four mechanisms of learning potential at the boundary between practices – for example, when MTEs are university researchers, the boundary between MTEs (academic expertise) and teachers (practitioner expertise). These mechanisms are:

Identification: The differences between communities' practices are made explicit without attempting to reconcile them.

Coordination: A dialogue is established to translate between the communities, and these can co-exist without noticeable discontinuities.

Reflection: Comparing and contrasting brings about (new) insights into the practices of both communities.

Transformation: Confrontation with a problem triggers reconsideration of existing practices, resulting in recognition of a shared problem space. Sometimes this results in hybridisation, a new practice emerging creatively from the meeting of diverse practices. Finally, crystallisation is the rare phenomenon where the hybrid practice has real consequences and results in new routines.

These learning mechanisms are made possible by *boundary objects*, objects that have different local meanings but enough interpretative flexibility to allow communication across the boundary between communities (Star, 2010): an assignment in teacher education, for example, could be interpreted by students as a requirement that must be met and by the teacher educators as support for future practice.

Literature review

This framework has been used to explore how a diverse group of MTEs (academic researchers and science/mathematics teachers) worked on professional development for teachers which linked authentic workplace situations with mathematics teaching (Bakogianni et al., 2021). Analysis revealed that a range of boundary objects (tasks, course objectives, etc.) enabled a change in MTEs' learning mechanisms over time, as they moved from identification to reflection and coordination. While in this example the boundary learning occurred spontaneously, it can also be fostered by brokers (Wenger, 1998). Goos and Bennison (2018) observe that MTEs frequently enter into explicit brokering between practices, and that this is enhanced by diversity among collaborating MTEs. In their study, MTEs were either specialists in mathematics or mathematics pedagogy, and success was defined as the integration of their respective disciplinary paradigms, mathematics content and pedagogy. In this paper, we focus not on MTE's disciplinary backgrounds but on differences in how they describe enacting the shared goals in their theory of change. Hence, we ask our research question: What changes do two mathematics teacher educators set out to realise through a course for in-service teachers, and which features do they highlight as essential for realising change?

Context of study

The context for this study is a one-year part-time credit-bearing (30 credits, half of a full-time load) course for in-service teachers in a Norwegian university. Many – but not all – are primary teachers lacking the necessary credits to satisfy recent requirements for teaching mathematics. The course aims to introduce teachers to student-centred, inquiry-based mathematics teaching. It promotes a Realistic Mathematics Education (RME) approach to teaching, highlighting a number of key principles, particularly the importance of context in emergent mathematics and the transition from informal to pre-formal to formal models (e.g. Van den Heuvel-Panhuizen, 2003), and guided reinvention (Stephan et al., 2014). In this paper we report on data from two of the MTEs teaching the course, Silje and Daniel (pseudonyms). Both are experienced MTEs (Silje is more senior) who conduct research in mathematics education, and have experience as mathematics teachers in schools.

The course was designed by Silje more than 15 years ago, and has been implemented at this university (cohorts of up to 200 divided in up to 5 classes) for the past 8 years (updating the reading list, modifying the tasks, etc.) by a group of MTEs working in pairs and led by Silje. Over the years, Silje has co-taught the course with a number of MTEs. Currently, she works with Daniel, who at the start of the data collection was beginning his second year teaching the course but had previously taught a course for prospective mathematics teachers that had adopted materials from Silje's course. The two had asked to co-teach the course for the second time, as they consider their collaboration particularly fruitful.

Methodology

This paper presents an analysis of a written statement and interviews with Silje and Daniel, as part of a larger project analysing a community of practice of ten MTEs involved in the course. The idea of theory of change in teacher professional development had been raised at a research group meeting, so we asked Silje and Daniel to write down their version for this course so that we might understand the connections between their goals for teacher change and the design and enactment of the course. They did this exercise together, and we reproduce their account here, translated into English by the first author (Table 1). Silje and Daniel were then interviewed together by the first author. The interview focused on the background to their document, and Silje and Daniel's views on what they believed the teachers brought to the course and how the MTEs built on this to achieve their aims. They were also asked about the nature and extent of teacher change they hoped might happen. A follow-up interview with Silje aimed to clarify points arising in the first interview including her emphasis on having two MTEs in the classroom during teaching. Both interviews were transcribed in Norwegian and translated into English by the first author. In our translations we have aimed to keep as close as possible to our understanding of intended meaning in the original Norwegian.

We analysed the data by first identifying boundary objects in Silje and Daniel's written statement and then classifying the relevant interview extracts in accordance with Akkerman and Bakker's (2011) four mechanisms for learning opportunities. There are at least four potential communities of practice at play here: the teachers-as-students, the teachers as members of the wider community of teachers, the MTEs as educators with a reform purpose, and the course members as a whole, engaged in a joint inquiry. We limit our interest here to examining the change that the MTEs aim to achieve at the boundary between teachers as members of a wider community and their own community of education reformers. In our analysis, we looked for references to these communities and the differences between them (identification), and references to actions taken by Silje and Daniel in terms of the establishment of dialogue which aims to translate between communities (coordination), comparison/contrast between practices (reflection), and presentation of problems which disturb practice (transformation).

Analysis

In this section we report first on Silje and Daniel's written statement, identifying three boundary objects, followed by an analysis of their interview, highlighting their justification of the theory of change and their account of how the three boundary objects support their goals. We notice who introduces new perspectives, and how the other disagreed, supported or elaborated. We focus in the discussion on the relationships between them as brokers on the boundary between practices.

Theory of change (Table 1)

We identified three boundary objects in Silje and Daniel's account: research-based course literature (while only one conceptual tool is referenced [Ulleberg & Solem, 2018], Silje and Daniel draw on technical vocabulary - pre-formal methods, talk moves, learning landscapes etc - from the field of RME and inquiry learning, which they know we are familiar with); teachers' lived experience of being in the classroom led by the MTEs ('gatherings'); and written assignments on engaging with their school students' mathematical thinking ('missions'). There is an emphasis on creating a learning experience for teachers which they will mirror in their classrooms, and on understanding the student point of view. In addition to exposing teachers to close investigation of student work and of their own practice, Silje and Daniel seek to model the practice that they promote; in this sense their "theory of change" suggests that they aspire to transform in their work on the boundary by confronting teachers with new experiences which will lead to reconsideration of their existing practice.

Table 1: Silje and Daniel's "theory of change" document

Our overall goals	How
That teachers experience learning through a reform-based approach, and develop this in their own practice That teachers can facilitate practical, inquiry-based and theoretical work that nurtures and develops students' mathematical knowledge and mathematical thinking To develop teachers' dialogical approach to mathematics so that the use of talk moves and opportunities for oral mathematics increase To develop mathematical and didactic competencies so that discussion of student work is nuanced and teachers are explicit about their didactic tools. To create, as an example of practice that teachers can use in their own classroom, a safe learning environment in mathematics, where we listen to each other, dare to ask questions, dare to make mistakes, learn to persevere and give each other thinking time	By discussing authentic student work and directing attention to what the student can do, what lies on the student's closest learning horizon, and how the teacher can challenge students to develop their thinking by: • discussing the learning landscape / learning trajectories of the students, cf. RME • analysing and discussing the work of their own students in written assignments • becoming acquainted with, work with and be able to account for, informal and pre-formal methods that can eventually be used as teaching tools By using Solem and Ulleberg's model of questioning as analysis and reflection tools to develop conversational features / rich discussion in teaching By getting the teachers to work investigatively in and with mathematics throughout the course That we ourselves have a practice that reflects the overall goals of the course

Learning opportunities: bringing about transformation

The interview analysis suggests considerable complexity in this transformative aim. Asked to explain their theory of change, Silje embeds her account in her personal history as a teacher, and deep convictions about what is involved in learning mathematics. She identifies the core goal of the course as promoting mathematics teaching where students see themselves as sense-makers:

> From the moment I started teaching mathematics and discovered that people found it a very authoritarian subject – they didn't understand anything, they felt stupid – I realized that several generations were deprived of the opportunity to feel [...] that they could think for themselves.

Silje justifies the theory of change primarily based on experience, while the research perspective is secondary. Daniel relates it to both his experience as a school teacher and research:

> I initially taught as I was taught myself ... it was really these [materials] of Malcolm Swan that were a revelation to me…What occurred to me was that the students started talking in a different

> way. It led to a kind of dialogue in the classroom that one could lift up. [The materials] gave me an idea of how I could ask questions and function in a different way in the classroom.

Here, Daniel foregrounds the research (Swan, 2005), spotlighting specific elements of the theory of change (the classroom dialogue). Silje's more holistic perspective emphasises values that she sees as encapsulated in Kierkegaard's writing. Elaborating on this in the follow-up interview Silje explains:

> That's what I see in […] Kierkegaard […], to meet the student where the student *is* and to lead him by the hand ... By 'lead' [I mean] that we go together and the premises are yours. You are the starting point... your path is not the same as hers! Now it's *you* we're talking about.

This idea captures Silje's ethos, and the essential quality of the community of practice she wants teachers to become part of through the course. For her, the shift towards making the student the starting point of teaching entails a radical transformation that must start with a confrontation; she rejects a passing suggestion from Daniel that the course might rely on teachers wanting to change:

> Most of them *don't* want to change. [...] I meet them full of prejudice and assume they will convert, so to speak; [prejudice] that they come with traditional beliefs and experiences of mathematics teaching. And - as far as I can see - it turns out to be largely correct. … As [one teacher] said, it's a paradigm shift. Something happens during the first gathering, they experience something they never experienced before. [...] So, no, I don't think they need to *want to*. On the contrary.

While Silje's strong identification of difference is not at all concerned to reconcile practices, Daniel takes a less radical view, seeing participation in the course as an opportunity for development, a coordination between the teachers' present practice and the goal of the course. He doesn't see the teachers as "necessarily problematic", but concedes that "one wants to develop their ways of teaching mathematics". In this sense, Daniel speaks more readily as a broker concerned to promote dialogue and reflect on practices both old and new. Next, we analyse Silje's and Daniel's justifications of the three boundary objects - missions, course literature and gatherings – as opportunities for learning.

The 'missions'

Silje describes listening to students as a crucial but unfamiliar practice for the teachers:

> We want [...] teachers to learn to listen. Learn to see the student. Understand how this student thinks before going in with my understanding of what I think this student is thinking. That's why we spend so much time on these 'missions'. To get [teachers] to take the student perspective.

The 'missions' create learning opportunities through transformation in which teachers are confronted with a problem space they weren't aware of, valuing and building on students' surprising ideas. She stresses their role as confrontations between reform teaching and their habitual practice:

> I believe it is because of these missions, where they have to sit with the students and have to analyse what they say and think about what to answer, that they discover sometimes – and they write so in the assignments in the start – that they took the answer out of the mouth of the student. This is something they need to experience, too. You need to discover how *not* to do it. And the joy to discover how incredibly lush children are! They think about so many fun things that we've forgotten to think about. I am very happy every time I discover it!

While Silje emphasises missions as opportunities for new discoveries and sheer difference which is not (and cannot be) reconciled with existing practice, Daniel describes them as enabling coordination in the sense of demonstrating the day-to-day 'reality' of theory:

> For the teachers, it's the 'missions' that truly pull together all the threads of the course. In the oral exam they reflect on the missions and [say] that "we read about all these things, and then we did the observations – and the students said exactly the things we had read about!" It was almost a surprise for them that the theory could actually happen in their own day-to-day reality [laughs].

The research-based course literature

The role of the substantial research-based reading list generates similar differences in Silje's and Daniel's accounts of brokering. Although she values the opportunities for reflection that this brings for teachers, Silje believes it is necessary but not sufficient for impacting practice ("it's lethal to assume that literature alone can persuade teachers"), thus justifying the inclusion of missions. This is not to say that Silje thinks that engaging with literature is not important. She recalls her excitement, as a novice MTE, on discovering literature on mathematics pedagogy and its usefulness as a tool for thinking. The RME orientation of the course, too, stems from literature that fits her ethos ("I had read the books from the Netherlands and took in ideas […] – they hit me right in my thinking"). For Silje, rooting the course in research is a given, but it must connect to prior or ongoing experience. Daniel, too, is selective: since joining the course he has consolidated the theoretical aspect of the RME orientation ("I read a lot on RME. [Including] the idea of learning landscapes was a bit my influence") but stresses that the aim is not mere alignment - choices are based on their own assessment ("there is some influence from others, for instance Malcolm Swan … we are free to mix in other things").

Silje returns to missions and Daniel's coordination argument, adding that translation is bi-directional:

> If it's going to be research-based, […] reading is valuable, also to go back and get the theory confirmed. Isn't this what we try to achieve with the missions? They read something - they have the experiences from the gathering - and then go out [to do the 'mission'] and go back and read the theory again?. [...] I claim that the value is in the back-and-forth between theory and practice.

While Silje focuses on the details of this dialogic relationship between reading and experience as part of a process of reflection, Daniel focuses on specifics of what the literature can contribute, pursuing his theme of coordination as translation between practices:

> We take examples of student work ... and try to lift the conversation about what the students did, what they thought - and frame it in the context of theory: both mathematical theory, say associativity and distributivity for multiplication, but also [theory] on development. […] Where they are in a mathematical landscape. [...] Even though the metaphor is limited, it helps! Because I think nobody is in a point in a landscape, but it helps teachers to think "What are the possibilities for this student now? What can he do and how can he develop from here?"

The 'gatherings'

During gatherings, Silje is less concerned with theory, focusing more on defining the problem space by modelling the practices she promotes, with the teachers experiencing the student perspective:

> We go around and listen... It gives us an insight into the dialogue in each group […] and it teaches us an awful lot about how we interact with them - when you jumped in too soon, when you didn't really know what to say, when you were wondering about … when you left that group to make time for another. We can't teach them another practice if we aren't participating and helping them.

However, she is mindful of the danger of the experience amounting to identification rather than transformation and the need to broker the process through articulating her choices:

> We can design a session that [they] experience as very good. And it may well be good as a session where you teach mathematics. But if the goal is for them to learn to be teachers, then they need to know about the decisions behind. They can't see it unless we say it, I think.

Daniel sees the interaction between MTEs and teachers as coordination, an opportunity to translate between theory and practice. Interactions between the teachers are also important as they allow hybridisation, the emergence of new practice as they discuss their responses to students' ideas:

> When we discuss and analyse a case for example […] this dialogue becomes their own, so that when something unexpected happens they will have developed another way of thinking. The dialogue going through their heads and the questions they will ask the student will be different because they had a dialogue with others about that. [...] And then they can use it in their teaching.

Both MTEs value being two in the classroom. For Daniel, it allows identification as decisions and dilemmas become visible in a dialogue between the MTEs where they query each other's choices. Silje elaborates in the follow-up interview that the spontaneity of dialogue is key:

> I love the dynamic […] from Daniel [interrupting me to clarify] – so much fun! [...], to my saying to him "I completely disagree with you and here's why", to someone suddenly jumping in because what I said made them think of something that fits perfectly. But spontaneously! [...] We need to stand together and be in dialogue and talk to each other and talk to the audience.

Discussion: partnering in change

In this paper, we have drawn on concepts from Wenger's (1998) Communities of Practice to understand two MTEs' justification for their practice as they co-teach a course for teachers. Conceptualising the MTEs' roles as brokers (Star, 2010; Wenger, 1998) for teachers' boundary learning, analysis of their written theory of change allowed us to identify three key boundary objects: 'gatherings', research-based course literature, and missions. Interview data showed that the two positioned themselves as members of both communities of practice (mathematics teachers and MTEs) as they shifted between justifying the theory of change from the perspective of practitioners or academics, with Silje foregrounding the first and Daniel the second. Akkerman and Bakker's (2011) framework for boundary learning enabled a distinction between Silje's holistic manner of justifying the theory of change (an aspiration to radical change, to transform the practices of the teachers) and Daniel's more analytical approach picking out specific items from the theory of change (e.g. teacher questioning, Table 1) and unpacking these. The next layer of analysis identified similar contrasts in their accounts of enactment: Silje tended to initiate accounts of pursuing identification and transformation through the three boundary objects, while Daniel concentrated on coordination between practices. This characterisation of the complementary roles they take on as brokers supports their sense that their collaboration is fruitful. To return to our research question, and the issue of Silje and Daniels' justification for their overall goals of the course, these complementary roles and aims perhaps provide some indication of ways forward for understanding mathematics teacher educators' evolving practice in more detail, and the nature and extent of their role in teacher change and development.

Towards an approach to teachers' professional development: Creating learning opportunities for teachers who teach mathematics

Miriam Criez Nóbrega Ferreira[1], Alessandro Ribeiro[2] and João Pedro da Ponte[3]

[123]University of Lisbon, Institute of Education, Portugal; criezmiriam@gmail.com; a.ribeiro@ie.ulisboa.pt; jpponte@ie.ulisboa.pt

This paper presents the first intervention cycle of a design-based research on teacher professional development carried out in Brazil. It aims to understand how the formative process helped teachers to understand what algebraic thinking means and how to work with it in the early years of elementary school. Data analysis was based on three principles of design concerning the Role and actions of the teacher educator, Professional learning tasks for teachers and Discursive interactions among participants. The results indicate that the design principles contributed to the teachers' understanding of the meaning of algebraic thinking and how to promote it in elementary students.

Keywords: Professional development, early algebra, teacher educator, professional learning tasks, discursive interactions.

Introduction

The development of teacher knowledge is a condition for improving the quality of education (Borko et al., 2008), and teacher education (initial or continuing) is a cornerstone of this process. Often, the professional education offered to teachers is superficial, disconnected from the ways in which they learn and far from the practice of teaching. This indicates the need to develop research that can contribute to a greater understanding and, consequently, a better organization of teacher education (McDonald et al., 2013). With a design-based research (DBR) approach (Cobb et al., 2016), a teacher education program was developed with the objective of promoting professional learning opportunities for teachers of the early years of elementary school, related to working with algebraic thinking. Thus, the present study seeks to answer the following question: *"How does the teacher educator's role in preparing professional learning tasks and conducting discursive interactions in a formative process, contribute to creating learning opportunities for teachers who teach mathematics in the early grades of elementary school?"* Although the teacher education process focuses on a specific mathematical theme, this study intends to contribute to the construction of general guiding principles for planning and carrying out teacher education processes, based on characteristics of effective professional development (Desimone, 2009) and from a model made to design and assess teacher education processes (Ribeiro & Ponte, 2020).

Theoretical framework

Over the last decades, the introduction of algebra in the school curriculum in the early years of elementary school has been a trend in Mathematics Education (Russel et al., 2011). This is because research has shown that, from an early age, children are already able to think algebraically (Blanton & Kaput, 2005) and that the development of this skill can favor the future learning of abstract algebra (Kieran et al., 2016). In this sense, teachers need to hold knowledge that enables them to work with algebraic thinking. Considering that elementary school teachers have little experience with classroom practice that can support work with algebraic thinking (Hunter et al, 2018), and how recent the inclusion of this topic in the Brazilian national curriculum is (Ferreira, 2017), continuous development programs are critical to creating professional learning opportunities for teachers (Ribeiro & Ponte, 2020). Research points to the need for five characteristics to be present for a teacher education process to be of high quality and thus effective (Darling-Hammond et al., 2017; Desimone, 2009; Kennedy, 2016): (1) focus on knowledge of the subject and on how students learn this content; (2) active learning, in which teachers participate in the knowledge construction process; (3) coherent with the curriculum and school objectives, teachers' previous knowledge and beliefs; (4) duration of meetings with continuous and intensive opportunities; and (5) collective participation, in which groups of teachers participate and build an interactive learning community.

Kennedy (2016), in addition to pointing out the importance of the motivation of teachers to participate in these programs, also suggests that their effectiveness depends largely on the pedagogy adopted (how they are carried out). In this sense, the PLOT model (Ribeiro & Ponte, 2020) (Figure 1) highlights the Role and Actions of the Teacher Educator (RATE), the Professional Learning Tasks for Teachers (PLTT) and the Discursive Interactions Among Participants (DIAP), as domains which, in an integrated way, contribute to the creation of Professional Learning Opportunities for Teachers (PLOT), in a certain context.

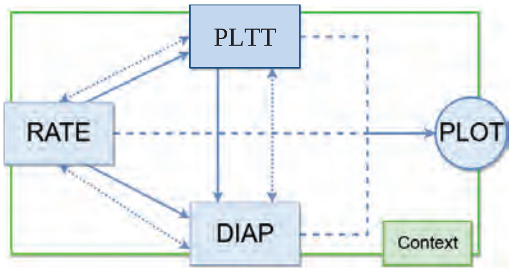

Figure 1: PLOT Model (adapted from Ribeiro & Ponte, 2020)

Although they do not directly refer to high-quality teacher education processes, the domains of the PLOT model consider many of its characteristics. The Role and Actions of the Teacher Educator (RATE), when designing formative processes that consider the characteristics of the local context (characteristic no. 3 of high-quality teacher education programs), takes into account conduction and mediation actions (Stein et al., 2008) through exploratory teaching (Ponte, 2005) in order to create professional learning opportunities for teachers (Ribeiro & Ponte, 2020). The role of the teacher educator, in addition to proposing tasks and creating a collective work environment, has to do with providing adequate and relevant feedback for each situation, ensuring the active and collective participation of all involved (characteristics 2 and 5). The teacher educator's actions and questions should contribute to the reflection on the subject, seeking to establish a relationship between theory, experience and practice (Silver et al., 2007). The Professional Learning Tasks for Teachers (PLTT), which are strongly influenced by practice, focus inseparably on mathematical and didactical knowledge (Ribeiro & Ponte, 2020) (characteristic 1), and can be defined as tasks "that involve teachers in the teaching work, which can be developed in order to meet a specific objective for teacher learning and take into account the prior knowledge and experiences offered by the teachers" (Smith, 2001, p. 8). Smith (2001) points out that materials such as videos of classes (Borko et al., 2008), student work (Kazemi & Franke, 2004) and high cognitive level mathematical tasks (Ribeiro & Ponte,

2020) portray teaching practices and can create opportunities for teachers to analyze and evaluate real classroom scenarios (Silver et al., 2007).

Discursive Interactions Among Participants (DIAP) are directly associated with collective participation (characteristic 5). It assumes that professional learning opportunities can materialize from exchanges between peers, through dialogical communication (Craig & Morgan, 2015). One way to provide discursive interactions is through the exploratory teaching approach, as it presupposes the circulation of mathematical and didactical experiences and knowledge among teachers (Ribeiro & Ponte, 2020). Some authors suggest exploratory teaching should take place in four phases (Stein et al., 2008): introduction, realization in students' autonomous work, whole-class discussion and systematization.

Research Methodology

The present study was carried out in a qualitative-interpretive perspective with Design-Based Research (Cobb et al., 2016), in which data collection from the first design cycle was carried out in a continuing education program developed in the first half of 2019 in a São Paulo State education network, Brazil. Audio and video records of the meetings were collected, as well as written records from the teachers. The participants were 14 teachers from the early years of elementary school. The program lasted 32 hours, with 8 4-hour meetings, in an in-person format, and 32 hours of individual work. The entire teacher education process was video recorded with two cameras, one focused on the teacher educator and the other on the participants. The subgroup discussions were recorded in audio and written records of the teachers and the PLTT used were also collected. The teacher educator, with extensive professional experience at this level of education, is the first author of this paper.

Considering the central aspects of effective teacher education program and the domains of the PLOT model, we established the following factors as design principles (main characteristic of a DBR) (Cobb et al., 2016)): (i) the Role and Actions of the Teacher Educator (RATE), which indicates the importance of considering the articulation between mathematics and didactics in and for teaching, the construction of an exploratory teaching-learning environment (Ponte, 2005) and the orchestration of discussions (Stein et al., 2008); (ii) the Professional Learning Tasks for Teachers (PLTT), which, by involving different practice records, promote the exploration of mathematical and didactical knowledge (Silver et al., 2007); and (iii) the Discursive Interactions Among Participants (DIAP), which, by affirming the importance of collective participation through dialogical communication (Craig & Morgan, 2015), involve teachers in an environment of reflection and discussion. Thus, the hypothesis of this research is that an intervention based on these principles contributes to promoting professional learning opportunities for teachers of the early years of elementary school regarding understanding the meaning and development of work with algebraic thinking. We used the three design principles as analytical lenses to consider the reflections brought by teachers and the ways in which the formative process provided teachers with opportunities for professional learning (Ribeiro & Ponte, 2020).

Results

Design Principle: Discursive Interactions Among Participants (DIAP)

In its design, the PLTT *Generalization* asked teachers to discuss the students' productions, analyzing their justification regarding the veracity of the mathematical sentence (Figure 2). This part of the PLTT focused both on the mathematical knowledge demonstrated in generalizations and on the didactical knowledge, considering how students think, as teachers needed to interpret and give meaning to the different justifications made by students. Regarding the first mathematical sentence in Figure 2, which the students answered is false because "*Calculations are not made, the result never has multiplications*," the teachers made some observations during the whole-class discussion:

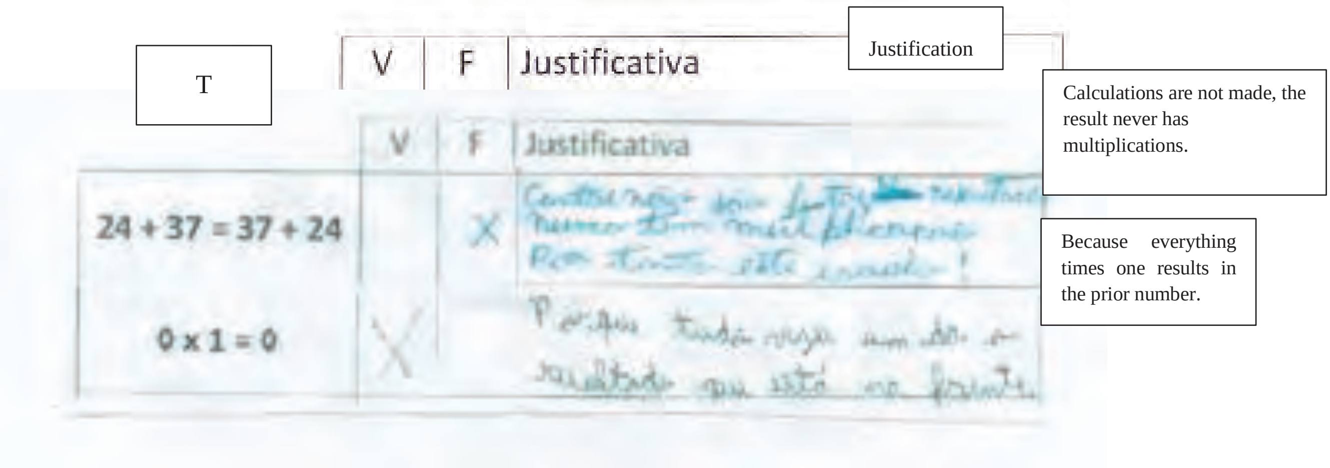

Figure 2: Part of the practice record of the PLT Generalization

Moisés: There's no coherence...
Marina: Usually, they never see calculations with prior numbers. The teacher will give them the expression, not the result. They need to seek the results.
Adriana: Wow, I didn't think of that...

For both Adriana and Moisés, the student's answer made no sense, since the justification was unusual for them. On the other hand, Marina identified that students believed that after the equal sign there could be no other expression, only a result, considering the operational perspective of the equal sign. For Adriana, this discussion provoked a new way of looking at the situation:

Adriana: I didn't think of it like she [Marina] said... in my head she didn't understood [that] if I add 24 and 37, it's the same as adding 37 and 24. She didn't understand what was proposed there, that the result can't have expressions...

By sharing her interpretation with the teachers, Marina contributed so that everyone could look at the student's response from another point of view, motivating the emergence of a professional learning opportunity arising from discursive interactions between participants (DIAP), a situation planned by the teacher educator in the design of the professional development process, from an active and collaborative process, through dialogic communication.

Design Principle: Professional Learning Tasks for Teachers (PLTT)

In the first meeting, the teachers were asked to consider the work of a few students (Figure 3) and analyze the knowledge they demonstrated and what procedures they had adopted to solve the mathematical task: *Pedro was very happy because he finally managed to complete his fourth sticker album! Each album has 225 stickers. How many stickers does Pedro have in all?*"

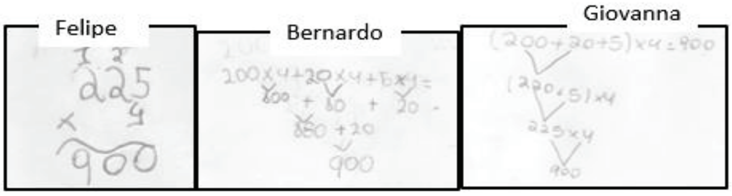

Figure 3: Records of the PLT "Analyzing a multiplication task"

After the analysis of this record of practice, carried out by the subgroups of teachers, the teacher educator asked, during the whole-class discussion, in which of these representations it was possible to perceive algebraic thinking. This questioning sought to survey the teachers' knowledge about the main content addressed by the teacher education program. Teacher Débora selected the Bernardo's representation and justified her choice by saying:

Débora: Because it demonstrates that it is a numerical expression, it has more than one operation, so it is generalizing, it left a specific calculation... See, there [in Bernardo's representation] he used multiplication and he also used sum, so he is using more than one operation to get to the result.

In this excerpt, Débora associated generalization with the presence of more than one operation, in addition to linking it to numerical expressions, expressing your initial knowledge. After working with the PLTT *Generalization* (Figure 2), Débora expressed her concept of generalization, associating it with patterns and regularities:

TE: What is generalization in mathematics?
Débora: It's when you have a situation... that serves not only a specific situation, but for more than one, there is a pattern, a regularity... for example, when they notice the regularity of the multiplication tables…

The PLTT *Generalization* prepared by the teacher educator, using records of practice, that were specially chosen to promote teachers' reflection, promoted the analysis of students' productions and contributed to the emergence of professional learning opportunities, in which Débora redefined her concept of generalization.

Design Principle: Role and Actions of the Teacher Educator (RATE)

In another situation, faced with a difficulty presented by Eliana, the teacher educator, in addition to seeking to contribute to the reflection, offered feedback:

TE: What was easier, what was more difficult, what would you do differently?
Eliana: What I think would be more difficult in this task would be reaching all students.
TE: The groups were made up of how many children?
Eliana: Four.
TE: If you start in pairs, a task for two [students]. Because in groups of four, one does the work, another helps, another pretends to help, and the last one doesn't even pay attention.

The question posed by the teacher educator, promoted reflection because the teachers needed to think about what worked (or not) and what reformulations could be made. In addition, the teacher educator established a direct relationship with the teacher's position when considering her concern, suggesting that, if students were arranged in pairs, this could favor the understanding and performance of the mathematical task. This position of the teacher educator provided adequate feedback to the situation, based on her knowledge of didactic knowledge, establishing a direct relationship with practice.

From the perspective of orchestration of the discussions, the teacher educator proposed reflections when the teachers discussed the division algorithm in a task done by the students:

Débora: [The students thought] of the multiplication tables of the numbers that were in the brackets [divisors], that any number multiplied by number 1 will always result in the dividend.

TE: But... only by number 1? [...]

TE: I would put this on the board and ask the group. Look, this group found this, do you agree, does everyone agree? But just for number 1? Because, for example, when I divided, I had this number [in the quotient], if I multiply it [by the divisor] I have this number [dividend]. This goes for any division.

Débora: I didn't notice that.

In this excerpt, the teacher educator assumes the role of guiding problematizations and calls attention to a rule, which although valid for number 1 would also be valid for other numbers, and that Débora said that she hadn't noticed. The teacher educator's action, articulating mathematical and didactical knowledge, drew attention to a mathematical regularity, causing the teacher to look at the division operation differently.

Discussion

The results show that the professional development process designed and carried out, considering the three design principles, supported the creation of professional learning opportunities in which teachers reflected on the meaning of algebraic thinking and didactics in mathematics classes, advancing in their perspectives. The PLTT *Generalization*, by presenting records of students' work on a mathematical task (Ribeiro & Ponte, 2020), focusing on knowledge of students' reasoning (Desimone, 2009), encouraged the teachers to discuss collectively (Darling-Hammond et al., 2017) the presence of generalizations in the students' justifications (Figure 2). In this case, together with the aforementioned PLTT, the other two domains of the PLOT model, the Role and Actions of Teacher Educator (RATE) when designing the PLTT and promoting the analysis of the students' records, and the promotion of Discursive Interactions Among Participants (DIAP), contributed, as stated by Débora, to reframe her understanding of the meaning of generalizations. The results show us that the design of the PLTTs and, especially, how the teacher educator led them through questions and actions (Stein et al., 2008) created opportunities for teachers' professional learning as they provoked reflections in Débora, who realized that there was a regularity in the division algorithm and how this could be worked with students. In addition, by giving a suggestion on how to proceed to reach all students, the teacher educator provided pertinent feedback (Darling-Hammond et al., 2017) on the situation posed by Eliana establishing a bridge between teachers' theory and practice (Silver et al., 2007).

In addition, during the discursive interactions, Marina presented her interpretation that for the student there can be no other expression after the equal sign. This position by Marina may have contributed to the creation of an opportunity for professional learning, by leading Adriana to make a new interpretation, showing that situations of professional learning can arise from the exchange between peers through dialogic communication (as in Craig & Morgan, 2015).

Conclusion

In addition to the design principles adopted by this study (Role and Actions of the Teacher Educator (RATE), Professional Learning Tasks for Teachers (PLTT), and the Discursive Interactions Among Participants (DIAP) pointing to the creation of learning opportunities, there is a strong interdependence between them, as both PLTTs design and its conduction are the teacher educator's tasks. The teacher educator thus gains a prominent role considering that the professional development process can be more in-depth and interconnected with practice depending on his/her actions. It is up to the teacher educator to carefully plan the teacher education learning processes (Kennedy, 2016), defining objectives, content and strategies organized in PLTTs (Ribeiro & Ponte, 2020), and to orchestrate (Stein et al., 2008) discursive interactions (DIAP), provoking reflections and providing appropriate feedback for each situation (Darling-Hammond et al., 2017). To create professional learning opportunities, it is not enough to place teachers in discussion groups (Kazemi & Franke, 2004); there is a need to carefully plan what to discuss. Thus, the teacher educator's knowledge is emphasized, both with regard to the knowledge of the content discussed in the teacher education program and to how it is led (Desimone, 2009). Although the present study has a mathematical focus on working with algebraic thinking in the early years, we suggest that the design principles that we use can be generalized to other mathematical themes or even other disciplines, which could give rise to further research.

Facilitators’ views on content goals, learning obstacles, and teaching resources in reference to conditional probability

Birgit Griese, Ralf Nieszporek, Rolf Biehler

Paderborn University, Germany; birgit.griese@math.upb.de, ralf.nieszporek@math.upb.de, biehler@math.upb.de

Facilitators of teacher professional development (PD) courses mediate the course ideas conceptualized by the PD course designers. It is relevant to research what views facilitators hold in reference to the content goals, the learning obstacles, and the teaching resources that constitute the heart of a PD course. In our current study, we analyze one facilitator’s deliberations in an interview conducted after a PD day on conditional probability, based on a framework of expertise on the classroom and the PD level. The results reveal which elements of the PD course were adopted wholeheartedly, and which remained more or less superficial. The analysis also suggests reasons for this distinction and how to rethink facilitator qualification and PD course material.

Keywords: Professional development, facilitators, expertise, conditional probability.

Introduction: Challenges in teaching conditional probability

With curriculum changes and the growing relevance of data in the modern world, stochastics (statistics and probability calculation) has moved into the spotlight of mathematics education (Batanero et al., 2011). This has led to a growing need for teacher professional development (PD) for stochastics in general, as teachers are the agents in lesson development, just as facilitators are the agents of teacher PD. Stochastics presents a challenge for numerous reasons (Burrill & Biehler, 2011): There are uncertainties to deal with, e.g. when predicting future frequencies from probabilities. And modelling must be taken seriously; the step from reality or real data to the world of mathematics involves an awareness of idealizations, and the necessary interpretation of results requires considering restrictions of the model.

In this paper, the challenges are exemplified by the content of conditional probability, which is connected to the concept of stochastic independence and Bayes’ theorem. The common mistakes respectively misconceptions in this area (Bar-Hillel, 1983; Gigerenzer & Hoffrage, 1995; Kahneman & Tversky, 1973; McDowell & Jacobs, 2017) cover confusing condition and event, misinterpreting stochastic dependence as causality, and underestimating the relevance of the base rate $P(A)$ for the calculation of the conditional probability $P(A|B)$. Substantial knowledge of common mistakes and misconceptions is prerequisite for choosing suitable teaching resources and supporting students in reaching the respective learning goals. Conducting a teacher PD, however, is accompanied by additional challenges. While providing necessary content knowledge or illustrating misconceptions, facilitators need to address aspects which are specific for a PD, like participants’ heterogeneity or their pre-formed opinions on learning pathways. A framework for design of and research on teacher PD, the three-tetrahedron model for content-related PD research (see Prediger et al., 2019) covers these aspects comprehensively: The four corners of a tetrahedron, referring to educator, learners, content, and teaching researches respectively, are specified for three levels, the classroom level, the PD level, and the qualification level. On the PD level e.g., the facilitators are the educators of the learners, who are the participating teachers. This model also illustrates the connections between the different levels. Classroom level issues are nested in the PD level insofar as the content goals and learning obstacles for students are, together with suitable teaching resources, the content at the PD level. Therefore, facilitators should be experts in the content goals, the learning obstacles, and the teaching resources of both the classroom and the PD level. In how far this is the case and what might be the reasons behind, is the focus here.

Theoretical considerations: Expertise for teaching conditional probability

We base our considerations on a situated approach and chose a framework for teaching expertise (Prediger, 2019, adapting Bromme, 1992), which distinguishes between *jobs*, *pedagogical tools*, *categories*, and *orientations*. These concepts allow to describe and explore what teachers or facilitators focus on doing in a specific situation (*jobs*), which thinking *categories* they activate, what they utilize in order to reach their goals (*pedagogical tools*), and which *orientations* influence their choices. The thinking categories, in particular, cover specificities of the content, e.g. the procedural and conceptual learning goals, the possible learning pathways, and the learning obstacles. The framework is tuned towards the actual teaching / learning situation, with its carefully orchestrated resources and its *ad hoc* reactions and decisions.

For this paper, we focus on content goals and learning obstacles (which are parts of the thinking *categories*), and on the *pedagogical tools*, which are closely connected to content goals and learning obstacles – as teachers / facilitators choose their pedagogical tools (e.g. specific tasks or activities, visualizations, software applications) with the aim of supporting their students / the participants in their PD course in reaching the intended content goals, keeping possible learning obstacles in mind, i.e. finding ways to overcome them. In our PD setting, a content goal is to comprehend the relevance of the base rate $P(A)$ for the calculation of the conditional probability $P(A|B)$, which is often underrated when the corresponding calculations are executed with probabilities and Bayes' rule. Using natural frequencies and an easily accessible representation, e.g. a double tree diagram, can help to overcome this learning obstacle (Gigerenzer, 2011; Wassner et al., 2007). Our PD also aimed at generally promoting the use of simulations as a teaching resource, which has been shown to "have the potential to make learning statistics easier" (Lane & Peres, 2006, p. 6). On the one hand, simulations were presented to foster the frequentist view on probability. On the other hand, we introduced simulations as an adequate tool for calculating probabilities where learners' analytic means are insufficient.

The thinking categories at classroom level cover, among other aspects, the content goals that are to be addressed and the learning obstacles that might hinder reaching these goals. In the course section focused here, the content goals can be described as knowing the definition for conditional probability, understanding the sense of this definition, calculating conditional probabilities (via the definition or by using Bayes' rule or other strategies), and being aware of the impact of different base rates. At PD level, knowing how to introduce conditional probability and stochastic independence by utilizing appropriate tasks, activities, simulations, and visualizations, as well as considering misconceptions when planning lessons, would be added to this list.

At classroom level, various learning obstacles should be considered by the teacher, e.g.

- modelling issues as a result of idealizations involved in probabilistic models
- sampling issues, sampling variation and differences between population and samples
- motivation issues that might hinder students from grasping or memorizing the content,
- misconceptions like confusing condition and event, misinterpreting stochastic dependence as causality or underestimating the relevance of the base rate, and
- a high level of abstraction that could present a learning obstacle in itself.

At PD level, additional learning obstacles comprise the heterogeneity of the group of participating teachers (e.g. referring to their individual knowledge or their respective professional learning groups), pre-formed opinions on certain teaching approaches, or previous (positive or negative) experiences when teaching the same or a similar content. For example, teachers might infer from their own learning history that the use of digital technology is not worth the time needed to come to grips with it. Or they might not consider modelling issues as relevant enough to discuss explicitly.

The pedagogical tools comprise teaching and learning resources, which can have a close connection to the content goals. For the content of conditional probability at classroom level, these are: the reflected use of absolute (natural) or relative frequencies, traditional tree diagrams with probabilities, (double) tree diagrams with absolute frequencies, 2x2 tables, linguistic scaffolding, hands-on experiments, digital simulations, data from digital simulations, ideal simulation (gaining natural frequencies by using artificial population sizes), authentic problems, and problems with artificial stories. The resources listed here, taken from the PD course at hand, share the characteristic that they address conceptual understanding, rather than procedural skills (see Binder et al., 2020 for an explanation of the different tools for visualization).

At PD level, these pedagogical tools can also be utilized, in a reconfigured form with a perspective on the PD situation: For example, the content and its associated pedagogical tools from the classroom level can be arranged in possible sequences, to present a range of teaching options. Then, the PD participants can be asked to work on the tasks and materials belonging to the different options, from a student perspective. This, in turn, can be followed by group discussions to reflect upon the teaching options, led by the facilitator who can incorporate his own experience with the material into the discussion, integrating participants' concerns and misgivings.

There are various possible connections between the content goals, the learning obstacles, and the teaching resources; and teachers' or facilitators' more general (and less content-specific) orientations can reveal the underlying reasons for their interpretation and the performance of their jobs: For example, an orientation to actively address misconceptions influences the choice of an activity or a teaching resource; an awareness of modelling issues implies integrating validation considerations; the belief that language matters encourages offering content-specific language learning opportunities. The exemplary connections in Figure 1 also illustrates the interconnection of the classroom and PD level. Using (ideal) simulations in class is an adequate tool to create an awareness for the impact of base rates. Promoting the use of simulations in the classroom implies addressing their advantages in the PD by pointing out their usefulness in e.g., group discussions.

Our research goal is to learn more about facilitators' views connected to the content goals, learning obstacles, and teaching resources – so we aim to answer these questions:

RQ1: Which content goals, learning obstacles, and teaching resources are mentioned by the facilitator and how are they accentuated?
RQ2: Which connections between the content goals, learning obstacles, and teaching resources are mentioned by the facilitator and how are they elaborated upon?

As a perspective, we are interested in exploring in how far the facilitator's notions coincide with the conceptual ideas of the original PD designers. Therefore, our research interest is in knowing which orientations can be inferred from the above, in particular in reference to the facilitator's adaption of the teaching concept. This also includes exploring if and when the facilitator focuses on student learning and / or on teacher PD.

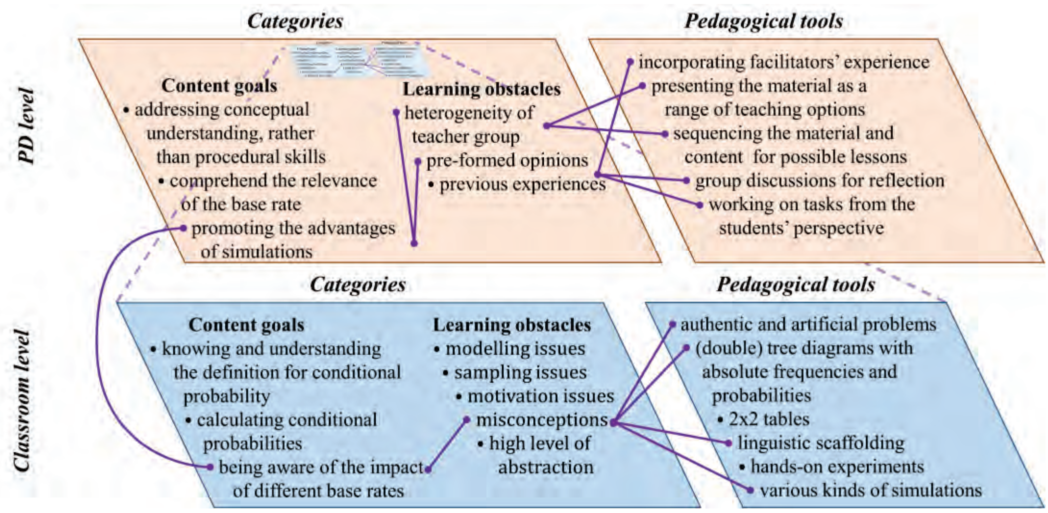

Figure 1: Nested facilitator expertise (categories, pedagogical tools) for teaching conditional probability, with exemplary connections

Context of the PD course

The PD course is part of a five-day PD program on stochastics for upper secondary level, developed at Paderborn University, Germany (Barzel & Biehler, 2017). The PD program envisions a teaching approach based on the principle of consistently promoting concept formation, e.g. via the use of simulations, digital tools, authentic examples and real applications. During the PD course on conditional probability, stochastic (in)dependence, and Bayes' theorem, the teaching recommendations focus on the use of natural frequencies, e.g. gained in simulations, and their use in double tree diagrams, which are regarded as an innovation in the German school context. A more traditional form of representation, 2x2 tables, is mentioned along the way.

The whole PD program was discussed at length and re-designed with four experienced facilitators over a period of three years, in cooperation with a regional education administration. Afterwards, the facilitators moderated the program more than once in teams of two.

Methodology

Directly after each PD day, guided interviews with the facilitators were conducted, audio-recorded and later transcribed. Among other aspects, the interviews covered the PD learning goals (both from the facilitator's and from the course designers' view), possible learning obstacles and how to overcome them, and the teaching resources offered by the PD course for the classroom level. In the course of the interview, facilitators were asked to elaborate on a printed list of PD goals.

In this paper, we concentrate on one facilitator, who we call "Mike", who was involved in the re-design of the PD program, and on the part (on day 2 of the program) on conditional probability, stochastic independence, and Bayes' theorem. Mike is male and has 16 years of experience as teacher, and 13 years as facilitator (mostly for other content than conditional probability). The interview with Mike lasted 70 minutes and has 178 turns; the interviewee's turns ranging in length between short comments of very few words and extensive elaborations of over 450 words.

The transcribed interview was analyzed in three steps: First, the passages relevant for content goals, learning obstacles, and teaching resources were identified, respectively, by the first and second author separately. Second, a consensus was reached between them about which interview passages belonged to which aspect. Third, a qualitative analysis was conducted (Kvale, 2009) in order to dissect the relevant text passages and phrase answers to the research questions.

Results

The research questions (RQ1: Which content goals, learning obstacles, and teaching resources are mentioned by the facilitator and how are they accentuated? RQ2: Which connections between the content goals, learning obstacles, and teaching resources are mentioned by the facilitator and how are they elaborated upon?) can be answered as follows (see Figure 2 for an overview):

Mike mentions the contents conditional probabilities and Bayes' theorem as the most important goals for the PD day, without specifying what exactly is relevant for these topics (turn M_002). He emphasizes that the PD concept is to promote students' understanding and argumentation skills (M_004, M_010, M_014, M_018, M_064) and sees this aspect as an indication for better teaching (M_010, M_012, M_022). There is no mention of procedural skills. Mike connects the advancement of understanding with an awareness of common misconceptions (M_010, M_018, M_111, M_121, M_127, M_165, M_171, M_175) and finds that the most relevant general problem is that "students show very many misconceptions, even with everyday relevance" (M_010), where at the same time he assesses everyday applications as beneficial for students' motivation (M_010). Mike has noticed that PD course participants often hold misconceptions themselves (M_107, M_167), so addressing misunderstandings is an issue both at the classroom and at the PD level (for the connections between the different aspects of expertise, see Figure 2). Mike does not mention simulations, an adequate tool for fostering students' understanding.

The teaching resources Mike specifies can all be located on the classroom level and mostly refer to specific tasks (M_010, M_012, M_127, M_128, M_145, M_157, M_173) that have an authentic background and touch upon the common mistakes. Other pedagogical tools that Mike mentions are double tree diagrams (M_022, M_149, M_151) and 2x2 tables (M_121, M_149, M_151), again with a perspective on classroom teaching, not on teacher PD. He explains at length that he prefers 2x2 tables (M_149, M_151) and gives as reasons that they help students to connect absolute and relative frequencies, and to bridge the transition from a tree diagram to the reversed tree diagram (M_149), therefore connecting a teaching resource to a content goal. Although double tree diagrams, as presented in the PD course, comprise didactic advantages, Mike states he would use this resource only subsequently (M_151). In addition, Mike sees the advantages of using absolute over relative frequencies (M_129, M_131) for the content goal of promoting understanding, but comments on this teaching / learning resource only when hinted by the interview material. He stresses the fact that, in a PD course, the aim is not to offer an ideal teaching approach that works perfectly in every setting (M_127), but to present a range of teaching options (often in the form of tasks, M_052) teachers can choose from. Therefore, a lesson plan is not regarded as an appropriate teaching resource at the PD level, but a collection of tasks and activities is. Mike outlines that he would conceptualize his own lessons following the principle to orchestrate an easy access, stressing connections to previous knowledge elements, and introducing more complex considerations only when students feel secure on the new ground (M_141). The scenario he refers to particularly attends to weaker students and examination situations (M_121, M_145, M_147).

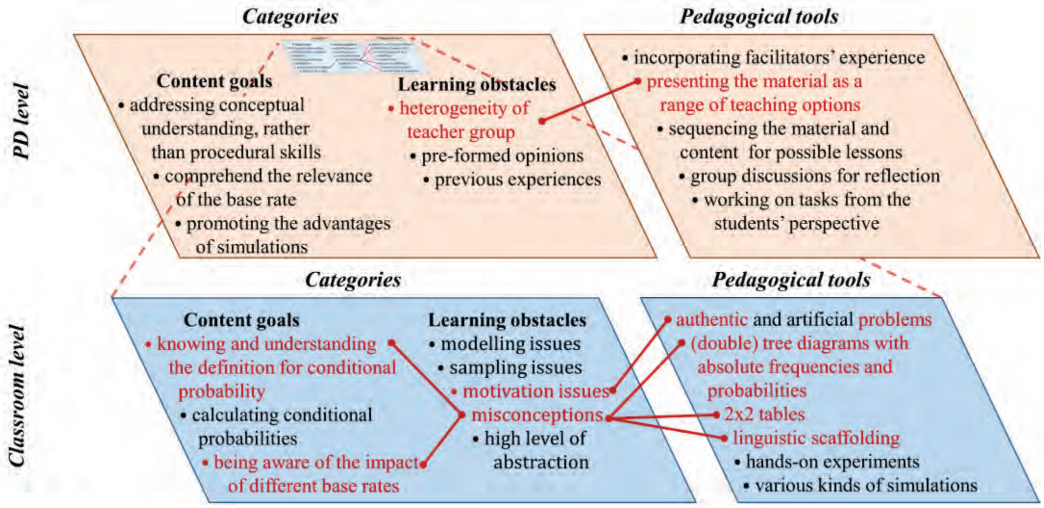

Figure 2: Aspects of expertise and their connections mentioned by facilitator Mike (highlighted)

The use of hands-on experiments or digital simulations triggers questions for Mike, as to when (or if, the German language does not distinguish this) these are helpful (M_109, M_143), and he finds that the result matters, independent of coming from a simulation or from a calculation (M_018). In this context, Mike is keen to refer to hands-on experiments (M_014), thus indicating a certain reserve towards digital simulations. More importantly, Mike always connects digital simulations with the technical skill of handling Graphing Calculators (M_024). As simulations require predetermining the number of overall experiments, Mike does not see the advantage of simulations over 2x2 tables – and he is unaware that these can indeed represent ideal simulations (M_143-145). He would utilize simulations when the probabilistic model is unclear, though (M_018, M_145).

Particularly here, it becomes clear that Mike's argumentation routinely refers to the decisions he has made or would make for his own teaching (M_097, M_145), the PD course participants do not feature in his deliberations as active agents of their own teaching. He visualizes himself teaching, not qualifying the PD participants teaching their respective students (M_141). This is a key point in our analysis, as it not only reveals Mike's self-concept of himself as a facilitator, but also provides a method to spark reflections on this self-concept (via visualizing the prevalent scenes in one's mind when leading a PD course), and categories for facilitator self-concepts (e.g. as teacher, as agent for the PD of the participating teachers, or even as erstwhile learner) in general.

Conclusion

Mike, one of four facilitators, expresses his views openly in the interview. What he does and does not mention in reference to content goals, learning obstacles, and teaching resources allows insights into a facilitator's views on the specific PD course at hand and on teacher PD in general.

Mike's utterances indicate an orientation to stick to teaching strategies that yielded satisfying learning results in the past, e.g. preferring 2x2 tables (a standard form of representation) over double tree diagrams (rather uncommon in German textbooks, but suggested by didactic research and successful teaching experiments). It is remarkable that Mike mentions of his own accord only teaching resources that he either favors (e.g. 2x2 tables), or that are both innovative *and* stand the test of him introducing them into his own lessons (e.g. double tree diagrams). He comments on other resources (like digital simulations) when these are mentioned by the interviewer, but does not introduce them into the conversation himself. This shows that he has remained skeptical of using digital simulations for improving learning in the classroom, and he states that he would only take recourse to them if there is no other way of establishing a probability.

All in all, it becomes obvious that Mike favors the perspective of focusing on the classroom level (M_026, M_125, see Figure 2). He sees the main purpose of PD in teachers discussing and reflecting on concrete teaching situations, himself as *primus inter pares* – albeit acknowledging parallels between the PD course and a mathematics lesson. Mike switches to reflections on the PD level in the later parts of the interview (M_127 onwards), but retains his focus on his own suggested teaching, and on teacher professional development only indirectly via the intended student learning.

Consequently, it remains doubtful how far certain aspects the PD course ideas have been conveyed successfully, in spite of intensive and prolonged cooperation between course designers and facilitators. It seems that orientations are not easily changed, in particular if they are based on previous experience, and addressing them should be planned very carefully. Introducing new teaching resources or pedagogical tools, on the other hand, might be presumed successful up to a certain level. And it we hope that these can impact on orientations in the long term.

What is more, Mike's focus on lessons and students leaves the issue unresolved if the PD courses he leads concentrate on teacher PD in the sense of advancing teacher expertise – which is more than reflections on advancing student learning. Mike emphasizes that teachers are presented with a range of tasks and activities to choose from or to adapt, but does not address the necessary skills for this selection or adaptation process. Ideally, these skills should be promoted during phases of discussion and reflection in the PD course, and the facilitator would disengage from the role of a colleague and view the PD course participants as individuals whose learning processes are also his responsibility.

It will be interesting to explore if this interpretation can be supported by Mike's actions and utterances during the PD course, which was audio-recorded. Although acting as a team, the analyses of the other three facilitators' interviews and moderation will probably reveal different aspects and thus paint a more differentiated picture of facilitators' views.

Facilitator practices during PD courses in response to teacher orientations for supporting at-risk students

The orientations that teachers possess impact their instructional decisions. Accordingly, PD facilitators need to be able to identify and respond to these orientations, especially when teachers demonstrate orientations contradictory to PD principles. Facilitators are thus faced with the challenge of balancing PD content goals and atmospheric goals. We first examine teacher orientations at the beginning of a PD. Second, as facilitators' situative goals and orientations become apparent in facilitators' practices, we examine facilitators' practices applied in response to teachers' orientations. Results reflect previous evidence of teachers' procedural, syllabus bound, short-term, and individual orientations. Our research furthermore revealed various practices facilitators use to respond to teachers' various orientations such as confirming teachers' statements, implicitly and explicitly referring to PD principles, and using examples from their own lives or instruction.

Keywords: Professional development, facilitator practices, teacher orientations.

Introduction

Teacher orientations are crucial for instructional decisions in the classroom. Thus, if teachers view, for example, mathematical proficiency as implementing different mathematical procedures, they will highlight different instructional goals in comparison to teachers who accentuate conceptual understanding (e.g. Schoenfeld, 2011; Zohar & Dori, 2003). In the PD program *Mastering Math*, which represents the context of our study, the focus centers on fostering teachers' ability to enhance at-risk students' understanding of mathematical concepts. As orientations such as diagnostic, conceptual, long-term and communicative were identified as decisive to enhance at-risk students' understanding (Prediger et al., 2019), these are the focus of the PD. Accordingly, the facilitators need to identify what orientations teachers possess and consider how they can respond in order to move forward towards the content goal of the PD. In the theory section, we first elaborate on teacher orientations for supporting at-risk students and, second, on goals and orientations as part of facilitator practices. In the empirical part of the paper, we present data from three PD courses to scrutinize teacher orientations and patterns of facilitator practices in response to these orientations.

Teacher orientations for supporting at-risk students

Teacher orientations can have consequences for supporting at-risk students, especially in building conceptual understanding. In expanding upon prior conceptualization of orientations, for instance by Schoenfeld (2011), Prediger (2019) created a framework of mathematics teacher expertise that includes orientations as one of five facets: “Orientations refer to content-related and more general beliefs that implicitly or explicitly guide the teachers’ perceptions and prioritisations of jobs“ (p. 370). Evidence on teacher orientations and practices connected to at-risk students, revealed that teachers often focus on assisting students in developing procedural knowledge and less so on constructing conceptual knowledge (Beswick, 2007; Wilhelm et al., 2017; Zohar et al., 2001). Furthermore, teachers tend to base requirements on those dictated by the school syllabus, highlight short-term mastery instead of working toward long-term goals (Moser Opitz, 2007; Prediger et al., 2016), and emphasize individual student issues (Krähenmann et al., 2019) as opposed to rich discourse including all students and their products (Karsenty et al., 2007). According to these results, the following contrasting orientations can be used to identify the practices teachers show to support at-risk students’ understanding: diagnostic or syllabus-bound orientation; conceptual or procedural orientation; long-term or short-term orientation; and communicative or individualistic orientation. Thereby, empirical studies identified orientations based on a diagnostic, conceptual, long-term and communicative approach as supportive to enhance at-risk students understanding (Prediger et al., 2019).

Goals and orientations as part of facilitator practices

In terms of what (novice) PD facilitators need to know and do to be able to provide successful PD programs for mathematics teachers, researchers have increasingly examined what constitutes necessary PD facilitator knowledge and practices (Borko et al., 2014; Lesseig et al., 2017). In view of diagnostic, conceptual, long-term and communicative orientations as the basis for the PD guiding principles and forming the content goals of the PD within the context of *Mastering Math*, the facilitators need to deal with diverse teacher orientations while targeting these PD content goals. Whether the PD content goal is reached depends on the practices that are “recurrent patterns of a facilitator’s utterances and actions” (Prediger et al., 2021) when conducting a PD. Practices are characterized by pedagogical tools facilitators use such as PD activities and their categories for noticing and thinking that can be based on the content knowledge and pedagogical content knowledge facilitators bring to the PD. Furthermore, the situative goals facilitators pursue, such as content goals or atmospheric goals, depend on facilitators’ orientations, such as goal orientation, participant orientation, or esteem for participants, and are part of facilitators’ practices (Prediger et al., 2021). According to prior case studies on facilitators’ practices in a PD, situations can occur that let different goals compete with one another and challenge facilitators to navigate between them or turn from one to another (Prediger & Pöhler, 2019). In the light of the PD program *Mastering Math*, facilitators may be faced with such a situation, in that teachers show orientations contradictory to the PD guiding principles (for example a procedural instead of a conceptual orientation), challenging facilitators to balance content goals and atmospheric goals. As facilitators’ situative goals and orientations become apparent in facilitators’ practices, we examine the practices applied in response to teacher orientations and the patterns of practices facilitators show. Against the aforementioned theoretical background, we pursue the following research questions:

RQ1: What orientations for supporting at-risk students do teachers show during PD courses related to this topic?

RQ2: What practices do the PD facilitators apply to respond to teachers’ orientations?

RQ3: What patterns of facilitator practices and underlying situative goals can be detected?

Methodology

Participants

Three PD groups (PD 1: N=17, PD 2: N=10; PD 3: N= 9) of the *Mastering Math* PD program participated in the study. The participating teachers possess different mathematical or non-mathematical backgrounds and different experiences in teaching primary students, as some attended a primary teacher education program and completed their internship, and some are teaching out-of-field. For each of the three PD groups, two PD facilitators were responsible to conduct the PD as a tandem. The facilitators are teachers themselves, and teach mathematics either in primary or secondary school. They also draw on different teaching experiences and various educational backgrounds, ranging from primary teacher education programs including an internship, to a major in mathematics or in special education. All facilitators received the same preparation to conduct the PD, then provided similar PD content and used similar methods.

Data collection and analysis

Within each PD group, a group discussion was conducted, videotaped and transcribed. Within this PD activity, teachers were asked to situate themselves in relation to the juxtaposition of all orientations (for example "It is important for at-risk students to find out if they have mastered basic arithmetic skills" for procedural orientation, or "It is important for at-risk students to find out if they have understood basic concepts and representations" for conceptual orientation).

As a first step, the individual teacher utterances were analyzed utilizing a coding system with the aforementioned teacher orientations for supporting at-risk students (see table 1) following a deductive approach. The transcripts were coded by two experts in the field of mathematics education. Intercoder-reliability over all groups showed sufficient consistency (Kappa=0.98) (McHugh, 2012). Absolute and relative frequencies are reported to quantify the orientations. As a second step, all statements of facilitators in response to teachers' statements were coded by two researchers, using an inductive approach. First, the two researches coded the transcript of PD group 1 independently. Second, the identified categories where discussed and revised, resulting in codes seen in the first column of Table 2. Third, the transcripts of the three PD groups were coded, according to the intercoder-reliability with a sufficient consistency (PD group 1: Kappa=1,0; PD group 2: Kappa=0.89, PD group 3: Kappa=0.93) (McHugh, 2012). Additionally, we coded the facilitators' practices in response to the teacher orientations and report absolute frequencies. An inductive approach was used and resulted in four categories (see first column of Table 3, applied by two coders who fully agreed).

Results

According to the analysis of teacher orientations that were visible in the group discussions in the three PDs (RQ1), some teachers had, to an extent, internalized some of the guiding principles of the PD program (see the green marked orientations), including supporting conceptual learning, focusing on long-term mastery, and establishing a communicative atmosphere that involves all students. These orientations were most visible overall in the PD groups (see Table 1). In regard to the individual PD groups, however, differences can be seen in terms of the main orientations.

Table 1: Teacher orientations overall and in the three PD groups in percentages

Teacher orientation	All PD groups (in %)	PD group 1 (in %)	PD group 1 (absolute instances)	PD group 2 (in %)	PD group 2 (absolute instances)	PD group 3 (in %)	PD group 3 (absolute instances)
Conceptual	15.56	22.73	5	0	0	12.50	2
Both	6.67	4.54	1	0	0	12.50	2
Procedural	6.67	9.09	2	0	0	6.25	1
Diagnostic	2.22	4.54	1	0	0	0	0
Both	4.44	4.54	1	0	0	6.25	1
Syllabus-bound	2.22	0	0	14.29	1	0	0
Long-term	15.56	22.73	5	14.29	1	6.25	1
Both	11.11	9.09	2	14.29	1	12.50	2
Short-term	6.67	4.54	1	28.57	2	12.50	2
Communicative	13.33	13.64	3	14.29	1	12.50	2
Both	6.67	4.54	1	0	0	12.50	2
Individualistic	4.44	0	0	14.29	1	6.25	1

While PD group 1 (n = 17) tended to display both a conceptual and a long-term mastery orientation, PD group 2 (n = 9) showed more of a short-term orientation, followed by syllabus-bound, both short-term and long-term, communicative, and lastly, individualistic orientations. PD group 3 (n = 10), in contrast, displayed all orientations with less emphasis on any particular orientation. In all of the PD groups, teachers showed contradictory orientations. Even when a teacher or some of them showed orientations that agree with the guiding principles of the PD program Mastering Math (see the green marked orientations), usually there was also at least one another teacher who revealed orientations that do not agree with the guiding principles (red marked), such as "(…) has mastered the task, even if the background knowledge may not change, but it is a success for them (…)" or who weighed the pros and cons of both contradictory orientations (orange marked) by referring, for example, to the need to take into account the different perspectives students and teachers have, such as "[…] the current material can't be understood, if there are gaps before that are too big (…) for the short-term success of the children this is here [short-term] much better and for the motivation also, but […] as a teacher I have them but then rather the longer-term development in view".

Teachers' statements that, in some cases, point to orientations contradictory to the PD guiding principles represent the starting point of the PD with which facilitators need to deal with when targeting the PD content goals. We examined the practices and patterns of practices facilitators showed in response to teachers' orientations as a next step (RQ 2 and RQ 3). The analysis of the facilitator practices in reaction to the statements made by the teachers in the three PD groups revealed a variety of practices in the three groups (RQ2). When analyzing facilitators' reactions and responses to orientations teachers articulated, the number of statements that agree, disagree or weigh pros and cons were considered (see table 2). Facilitators in PD group 1 most often needed to react to teachers' statements that were in agreement with PD guiding principles. Accordingly, the number of facilitator statements providing confirmation is the highest in that group. However, the facilitators did not provide confirmation to all of the agreeing statements, but instead took note of them, recognizable through verbalized acknowledging.

Table 2: Absolute instances of facilitator practices in response to teacher statements in the PD groups

Facilitator practice in reaction to a teacher statement that	Group 1 facilitators	Group 2 facilitators	Group 3 facilitators
is in agreement with PD guiding principles	(=14 statements)	(=2 statements)	(=5 statements)
• Acknowledging	4	2	2
• Providing confirmation	9	3	2
• Taking a neutral position	0	0	0
• Not commenting	0	1	0
• Invalidating a statement	0	0	0
weighs pros and cons of PD guiding principles	(=5 statements)	(=1statement)	(=7 statements)
• Acknowledging	0	0	1
• Providing confirmation	3	1	1
• Taking a neutral position	0	0	1
• Invalidating a statement	2	0	1
• Reinterpreting a statement	1	0	0
is in disagreement with PD guiding principles	(=3 statements)	(=4 statements)	(=4 statements)
• Acknowledging	0	0	0
• Providing confirmation	1	1	0
• Taking a neutral position	0	0	0
• Invalidating a statement	2	3	1
• Reinterpreting a statement	1	2	0

If teachers' statements were in disagreement with the PD guiding principles or the teachers weighed pros and cons, the facilitators, in most cases, invalidated or reinterpreted teachers' statements, pursuing the content goal, but also provided confirmation when teachers weighed pros and cons, preferring to keep a good atmosphere as a situative goal. The facilitators' practice of providing confirmation, even when a teacher's statement did not agree with the PD principles, is part of a pattern we identified also in PD group 3 (RQ3). Facilitators first showed esteem for participants by providing confirmation as a first step, presumably to maintain a good atmosphere. As a second step, they invalidated or reinterpreted the teacher's statement, to stick to the content goal, by referring to PD guiding principles when highlighting the important role of understanding:

Facilitator: "Absolutely. And exactly it always depends on the person. […] In the short term I totally agree with you that you should build up self-confidence and strengthen the child a bit. But the understanding is […] and according to the concept of being able to do math safely is really the absolute crux. […] I can't understand the small, I can't understand the big – never. Ability. And then this child will always have failures his whole life long in mathematics lessons. […] That we think about it that understanding is really the absolute basis."

In sum, the facilitators in PD group 1 used the chance to refer to PD guiding principles implicitly or explicitly eight times when responding to teachers' statements (see table 3) and additionally illustrated one of the principles by means of driving a car as an everyday example.

The facilitators in PD group 2 pursued another pattern to respond to teachers' statements. Only two teacher statements in this group were in agreement with PD guiding principles. The facilitators did not comment on the two statements directly but acknowledged the statement and returned to it later on to provide confirmation more than one time in order to pursue the content goal of the PD. Furthermore, when all teachers showed nonverbal agreement with the PD guiding principles, the facilitators did not ask them to provide an argument, resulting in a lower number of statements in agreement with the PD principles. Instead of asking teachers for arguments, the facilitator used the chance to praise the orientations of the teachers and additionally to refer to the PD guiding principles implicitly (see Table 3), using an alternative way to target the content goal. In the case of teacher statements in disagreement with PD guiding principles, the facilitators invalided and/or reinterpreted the statement, and, in one case, they provided confirmation. Also, in regard to the one statement that weighed pros and cons, the facilitators provided confirmation of it. In these cases, facilitators pursued an atmospheric goal instead of the content goal.

The facilitators of PD group 3 responded to one of the five statements with the PD guiding principles, agreeing with teachers' orientations by providing confirmation two times, but missed responding to four of them. Instead of directly providing confirmation with PD principles to agreeing statements, the facilitators provided anecdotes from their private lives or from their own teaching experiences. The same occurred in response to disagreeing statements or statements that weighed pros and cons (in sum 7 times, see Table 3). The facilitators referred implicitly or explicitly to PD guiding principles in response to all kinds of statements in six cases. Both contributed to maintaining a good atmosphere in the PD course. In sum, very often, they referred to examples out of their private lives and own instruction, as well as to PD guiding principles, explicitly or implicitly, pursuing an atmospheric goal. Instead of responding to teachers' statements directly, they decided to let the discussion between teachers flow, looking for statements of other teachers that invalidated the disagreeing statement. Furthermore, they avoided direct responses that invalidated or reinterpreted teachers' statements, also contributing to a good atmosphere and, at the same time, preserving the PD content goal.

Table 3: Absolute instances of facilitators reference to practice in the three PD groups

Facilitators use of	Group 1	Group 2	Group 3
• anecdotes or everyday examples	1	0	2
• examples from own instruction	0	0	5
• explicit reference to the PD guiding principles	5	1	4
• implicit reference to the PD guiding principles	3	3	2

Discussion and conclusion

The orientations teachers showed when they started a PD course on fostering the ability to monitor and enhance students' understanding of basic concepts are to some extent in line with previous evidence that points to a more procedural (Beswick, 2007; Wilhelm et al., 2017), syllabus bound, short-term (Prediger et al., 2016), and individual orientation (Krähenmann et al., 2019), instead of a conceptual, diagnostic, long-term and communicative orientation. The latter orientations build the principles of the PD program and inform the content goals facilitators need to target when conducting the PD. The study revealed various practices facilitators use to respond to teachers' various orientations. Facilitators in PD group 1 mostly invited teachers to make a statement or bring an argument to the discussion. In the light of the PD guiding principles, the facilitator succeeded in being a good role model in that he or she exemplified a communicative orientation. Facilitators in PD group 2, in contrast, let many chances pass to invite teachers into a discussion or to ask them to bring arguments for their orientation and therefore missed examining whether teachers actually have conceptual orientations or whether they hold procedural orientations. Facilitators in PD group 3 faced many disagreeing statements as well as statements that weighed pros and cons and they responded to these statements with various examples from their daily lives and their own teaching practices, combined with explicit or implicit references to PD guiding principles.

In regard to the typical facilitators' patterns we identified, first, in many cases, the facilitators avoided reinterpreting or invalidating teachers' statements directly, but started their responses by providing confirmation before invalidating or reinterpreting them, presumably in order to maintain a good atmosphere. An additional pattern was found, also probably aiming to maintain good atmosphere within the PD groups: Instead of responding directly to statements that were not fully in agreement with PD guiding principles, the facilitators in two of the groups often used anecdotes or examples of their own instruction or referred to PD principles. Recourse to examples and principles seems to help the facilitators to pursue the content goal with a simultaneous preservation of a good atmosphere.

The study reveals the variety of facilitator practices used to respond to teachers' orientations and contributes to the understanding of multiple ways and patterns that appear in facilitators' moderation strategies when conducting PD courses. In line with the results of further case studies (Prediger & Pöhler, 2019), the challenge facilitators face when navigating between different PD goals they need to manage becomes obvious; in our study, facilitators' practices in all three of the PD groups demonstrated how facilitators attempted to balance content goals and atmospheric goals. As a next step, we suggest the investigation of whether facilitators' abilities to focus more strongly on the content goal while simultaneously considering atmospheric goals can be fostered by discussing PD incidents in video clubs and probing PD situations in simulated learning environments.

Introduction

Modern pedagogies place increasing emphasis on individualized learning to address student diversity. This is also required by new educational policies. Providing future teachers with relevant knowledge and fostering the development of their competencies to implement individualized learning settings is a challenge for mathematics teacher educators (MTEs). In this work, we suggest personas as a way to support MTEs in conveying the diversity of characteristics, needs, and conditions of mathematics learners. Personas are concise data-driven descriptions of fictional representatives of learners who share similar characteristics and needs. In our recent work, we have identified the potential of personas to facilitate student-centered teaching and learning of mathematics. We have collected data on students' goals, needs, challenges, joys, fears, and strategies, and have developed personas of students in Austrian academic upper secondary schools to provide teachers with a resource to facilitate individualized learning. In this project, we expand upon that work towards teacher education courses suggesting personas as a new resource for MTEs to facilitate rendering the development of mathematical pedagogies more student-centered and promoting individualized teaching and learning opportunities. We aim at answering the following questions with regard to mathematics teacher education: (a) Which student characteristics should be portrayed by personas to promote decisions on designing individualized teaching and learning settings? (b) What are the scenarios for applying personas?

Theoretical and methodological framework

In Austria, teachers are required to align their teaching to the diversity of students by educational policy documents. In practice, however, teachers tend to consider highly specific and stereotypical student characteristics to decide how to address diversity in lesson design (Larina & Markina, 2019). To reduce subjectivity and bias in design contexts, Cooper (1999) claims that it is beneficial to have one specific person in mind and tune the design to their goals and needs. He suggests to use personas as a portray of the target group and as a communication tool for designers when discussing design ideas and drafts.

Personas are "hypothetical archetypes of actual users […] defined by their goals" with fictional names, fictitious personal details, and a portrait (Cooper, 1999). Originally, they were used in user experience research to present characteristics, goals, skills, and interests of homogenous user groups. While Cooper (1999) introduced personas for product optimization processes with the goal to promote sales, the goal in the context of education is to enhance design processes for more efficient teaching and learning.

There has not been comprehensive research on applying persona development techniques to teacher training contexts although the use of personas has the potential to facilitate preparing teachers to implement individualization in their classrooms.

In recent research, we collected data from mathematics teachers in Austrian academic upper secondary schools about the characteristics and needs of their students and created student personas based on these data. These personas have been utilized in teacher training courses to design materials for teaching mathematics. We plan to refine the personas by conducting a quantitative questionnaire study among school students. Including the teachers' expert views and using standardized questionnaires for surveying students should help minimize subjectivity and bias. To identify potential applications of personas for MTEs, we review current approaches of MTEs to foster individualized mathematics teaching. We then propose applications of personas for MTEs based on the findings of this review.

Results and discussion

Recent literature on individualized teaching and learning states that for successful learning the demands on the students have to match their individual learning conditions (attitude, interests, level of knowledge, misconceptions, skills, self-concept) to avoid a decrease in cognitive activity; therefore, decisions on the demand level of students and on appropriate teaching and learning methods have to be made (Prediger & Aufschnaiter, 2017). As a consequence, when developing personas for use in mathematics teacher education, the learning condition of students should be portrayed.

Personas of such kind can be a valuable resource for MTEs to train how to implement individualized learning in classrooms by promoting well-founded decisions for designing individualized materials and settings for teaching and learning mathematics. In particular, personas can serve as a basis for discussions about design approaches proposed by participants of mathematics teacher education courses. Thereby, personas meet Gueudet et al.'s (2012) demand for resources for MTEs to foster collaborative work. They facilitate including the students in discussions and have the potential to establish individualization as a premise for designing learning settings while reducing the bias stemming from stereotypical beliefs of the discussants.

Developing the complex practice of facilitation requires participation in a professional community and the use of tools that make key aspects of facilitation concrete. We report on an ongoing empirical analysis of how professional development (PD) facilitators[1] used a tool designed to provide insight into teachers' perceptions of aspects of mathematics PD that prior research has linked to teachers' learning. Findings indicate that the tool, when used in a professional community, can support facilitators to inquire into and make decisions about their facilitation practice, and to assess whether changes in facilitation result in improvement.

Keywords: Facilitators, professional development, tools.

Skillful facilitation of collaborative professional development (PD) focused on ambitious mathematics teaching is complex work (e.g., Prediger et al., 2019; Sztajn et al., 2017). Facilitators must support teachers to engage in authentic inquiry focused on mathematics, students' learning and experiences, mathematics teaching, and relations among these elements (e.g., Jaworski, 1994; Lefstein et al., 2020). Further, they must support teachers to deprivatize their practice for collective inquiry (e.g., Little, 2002), view the PD as relevant to their own instructional contexts (e.g., Putnam & Borko, 2000), and see themselves as valued members of the group (e.g., Grossman et al., 2001).

Given these demands, a critical issue for the field concerns supporting facilitators' ongoing learning and improvement of their facilitation practice (Krainer et al., 2021). Developing complex practice, like facilitation, requires *participatory* as well as *material supports* (Wenger, 1998). Facilitators deepen their practice by co-participating in a professional community with others focused on investigating and experimenting with targeted forms of practice; tools play an important role in making concrete what is valued in the intended forms of practice (van Es et al., 2014).

In this paper, we report on an ongoing empirical analysis of how PD facilitators used a tool our team designed to support facilitators to inquire into and make decisions about their facilitation practice. To our knowledge, few tools currently exist to support facilitators to *assess* and *improve* their ongoing

[1] Our use of the term *facilitator* in this manuscript denotes a mathematics teacher educator who supports the learning of practicing teachers.

practice. We focus on the case of a facilitator in a supportive context to "evoke images of the possible" (Shulman, 1983, p. 495) for using this tool to inform facilitation.

A practical measure of collaborative professional development.

We focus on facilitators' use of a tool that was designed as a *practical measure* (Takahashi et al., in press). Distinct from research or accountability measures, practical measures are intended to support practitioners in quickly gathering data about processes they want to inquire into and improve. Key characteristics of practical measures include that "what is being measured is meaningful to its users," administration of the measure and analysis of resulting data is "minimally burdensome," and "data collection and analysis processes are timely" (p. 9). Users administer practical measures at multiple timepoints as part of inquiry cycles to assess whether deliberate changes to their practice result in desired improvements, and to set goals for their future work.

Our team developed a practical measure of collaborative PD that takes the form of a teacher-facing survey and that assesses teachers' perceptions of aspects of mathematics PD that prior research has linked to teachers' learning. The measure takes teachers three to five minutes to complete and can be used across a range of PD contexts. It was designed to make connections between teachers' experiences and facilitators' practice visible and available for inquiry with others.

To develop the measure, we first identified key aspects of PD that research indicates make a difference for teachers' learning opportunities. One aspect concerns the *discussion practices* employed by a group of teachers. This includes the extent to which teachers feel able to share and revise emergent thinking, press one another for reasoning/evidence, and challenge ideas (Lefstein et al., 2020). A second aspect concerns teachers' *deprivatization of practice*, or the extent to which teachers open their own teaching practice for inquiry and see value in doing so (e.g., Little, 2002). A third aspect concerns *relevance*, or the extent to which teachers experience the PD as responsive to and possible in their own instructional contexts (e.g., Putnam & Borko, 2000). A fourth aspect concerns teachers' sense of their *membership in the community*, or whether teachers feel valued in the group (e.g., Grossman et al., 2001). See our team's annotated measure (Practical Measures, Routines, & Representations, 2021) for elaboration on each of the aspects in relation to research on teachers' learning.

We then generated initial survey items that assess the critical features of each aspect of PD. After generating these items, we engaged in 18 cycles of design, analysis, and revision to ensure that the items assessed what they were designed to measure and that they communicated well and were meaningful to teachers and facilitators. In each cycle, researchers observed a PD session and generated field notes specific to the focus of each item. The then-current measure was administered to teachers at the end of the session. The research team then conducted cognitive interviews with three to five teachers, in which they asked the teacher to explain their response choices and probed the teacher's interpretations of the items. Further, after each session, researchers shared the resulting data with facilitators to understand their interpretations of the items and whether they perceived the data as helpful for informing their practice. They then conducted a qualitative analysis of the various forms of data, resulting in revisions to the survey, including eliminating, adding, and/or modifying particular items. This process resulted in ten survey items (see Table 1).

Table 1: Overview of the practical measure of collaborative PD

Key aspects	Teacher-facing survey items
Discussion practices	1. I feel like I can share a *mathematical idea* I am unsure about with this group of teachers and leaders. ○ *Yes* ○ *No* 2. I feel like I can share an *idea about teaching* I am unsure about with this group of teachers and leaders. ○ *Yes* ○ *No* 3. I feel like I can ask others to elaborate on an idea with this group of teachers and leaders. ○ *Yes* ○ *No* 4. I feel like I can push back on an idea with this group of teachers and leaders. ○ *Yes* ○ *No*
Deprivatization of practice	5. In today's session, I felt like I could share something I'm wondering about my own teaching (examples: a question, a dilemma, a challenge). ○ *Yes* ○ *No* 6. I would be open to sharing the following with this group of teachers and leaders: (Select all that apply.) ☐ *an anecdote about what my students said or did* ☐ *an anecdote about something I said or did when teaching* ☐ *samples of my students' written work (examples: exit tickets; photos of students' work)* ☐ *a math task or activity* ☐ *video of my students solving problems* ☐ *video of my teaching* ☐ *I would not be open to sharing any of the above.* 7. I would be open to inviting members of this group of teachers and leaders to join a lesson of mine. ○ *Yes* ○ *No*
Relevance	8. Today's session was relevant to my work as a teacher. ○ *Yes* ○ *No* If yes, what did you find relevant? If no, why not? 9. I feel ready to try something I learned today in… ○ *All of my math classes* ○ *Some of my math classes* ○ *None of my math classes* If applicable, what are you planning to try? If applicable, in which classes are you hesitant or not ready to try something, and why?
Membership in community	10. In today's session, I felt like my ideas were valued. ○ *Yes* ○ *No*

Methods.

In the 2019-2020 and 2020-2021 school years, facilitators administered the measure in 18 PD sessions across 10 distinct contexts. In this paper, we focus on how one PD facilitator, Reina, used the measure to inform her ongoing work with a middle-grades mathematics department. Specifically, we ask: How does a facilitator use the measure to inquire into and make decisions about their facilitation practice? Reina's use was of special interest because she worked for an extended time with a consistent group of teachers and was engaged in professional inquiry about her practice with other facilitators. Her use provides "images of the possible" (Shulman, 1983, p. 495) for use of the measure in a supportive context to set goals and assess whether deliberate changes resulted in the intended improvements.

Research context.

Reina worked for an organization that provided ongoing, job-embedded mathematics PD to districts and schools around the USA, with a focus on supporting teachers' development of ambitious pedagogical practice and content knowledge (Lampert et al., 2013). The organization's leaders provided ongoing, structured opportunities for facilitators, like Reina, to inquire into and further deepen both their facilitation practice and teachers' learning.

As of 2020-2021, Reina had facilitated teacher PD for three years; two years as an instructional coach in a school district and one year as a facilitator with the PD organization. Prior to this, Reina worked as a secondary mathematics teacher for 28 years. During 2019-2020 and 2020-2021, Reina facilitated PD for a five-person mathematics department at a middle school in the Northwest USA. In 2019-2020, the PD focused on leading whole-group mathematics discussions; in 2020-2021, given COVID-19, the five-session PD sequence focused on how to lead discussions during virtual instruction.

Data sources.

During the 2020-2021 school year, Reina administered the measure at the end of Sessions Two (March) and Five (May). Members of our team attended these sessions, took field notes, and collected artifacts, including teachers' responses to the practical measure.

Interviews with Reina serve as the primary data source for this analysis. After both Sessions Two and Five, members of our team conducted a one-hour semi-structured interview with Reina, in which she interpreted teachers' survey responses. The PD organization's two leaders also participated in the interview. These interviews focused on understanding Reina's interpretation of teachers' responses and modifications she considered making to the facilitation of future sessions. The interview following Session Five involved looking at teachers' responses to the surveys from Session Two and Session Five, side-by-side. In addition, we conducted a follow-up semi-structured interview with Reina two weeks after Session Five that focused on understanding her background, facilitation goals, and perspectives on how, if at all, the measure informed her work.

Data analysis.

Qualitative analysis focused on how Reina interpreted teachers' survey responses and identified goals for her practice. We first generated an initial codebook assessing the range of ways facilitators used the practical measure to inquire into and make decisions about their facilitation practice, based on analysis of Reina's interviews as well as those of another set of facilitators from the broader data set. Our team then used an iterative coding process in which we independently applied codes from the codebook to Reina's interviews, discussed and resolved disagreements in our coding, modified the codebook where necessary, and then returned to the transcripts to update our coding to reflect changes to the codebook. Lastly, we turned to the follow-up interview to further understand Reina's decision-making and to triangulate with what we had identified as the range of uses of the measure.

Results.

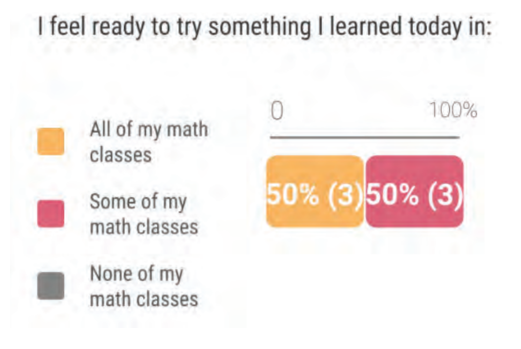
Reina used the practical measure to inquire into and make decisions about her facilitation practice in four ways: to (1) provide insight into critical and otherwise hidden aspects of teachers' perspectives and experiences; (2) prompt reflection on key aspects of the PD; (3) prompt ideas for a change in the preparation for or facilitation of an upcoming session; and (4) consider whether deliberate changes to her facilitation practice resulted in desired improvements. Given space limitations, we focus on two examples selected purposefully to illustrate this range: Reina's interpretation of teachers' responses to Survey Item 9 after Session Two, and to the same item after Session Five.

Example 1: Gaining new insight into teachers' perspectives and experiences, prompting reflection on key aspects of the PD, and prompting change.

In each of the five sessions, Reina facilitated the teachers' engagement in a mathematics task and their discussion of mathematics ideas. She then facilitated their discussion of instructional strategies for facilitating whole-group discussion in their virtual classrooms, and teachers met in small groups to plan for an upcoming lesson. During Session Two, Reina led a 1.5-hour virtual session focused on supporting students to share rough draft thinking by using "discussion frames," sentence starters to scaffold students' sharing in discussion. Reina administered the measure at the end of the session, and all six teachers present (the five department members and a student teacher) completed the survey. The next day, Reina, the PD organization's two leaders, and members of our research team met for an interview.

Reina's interpretation of teachers' responses to Item 9 is illustrative of three uses of the measure. As shown in Figure 1, half of teachers indicated that they only felt ready to try something in some of their math classes following the session. Reina read their responses to the follow-up prompts on the survey (What are you planning to try? In which classes are you hesitant to try something and why?) and said, "that [the use of discussion frames] is not applicable in classes just blows me away, you know?" She emphasized this surprised her given that the teachers eagerly participated in the session. She then reflected on her facilitation, saying:

> Those comments … are concerning to me, because I apparently haven't pressed that this is good teaching and good teaching happens every day … it's not something that we pick and choose. … I need to focus on that with this group – that this is good for all [students]...



What are you planning to try?

Teacher A: I plan to work with discussion frames for my [advanced] class. [My advanced] class works the most collaboratively, so there are opportunities to try the new skills.

In which classes are you hesitant to try something and why?

Teacher B: 4th period … they are so unwilling to participate openly

Teacher C: Algebra … we are taking tests and studying for the final … I'm not sure if it is the right time to learn from each other

Figure 1: Teachers' responses to Item 9 in Session Two (n = 6), with select open-ended responses

As evidenced here, Reina used teachers' responses first to *gain insight into critical and otherwise hidden aspects of teachers' perspectives and experiences*. She interpreted the selected open responses as indicating that some teachers saw ambitious instructional practices as appropriate only for some classes or under some circumstances. Second, she used the data to *prompt reflection on key aspects* *of the PD,* in this case her own facilitation. She focused especially on the extent to which she had supported teachers to connect the PD focus to "good teaching" which "happens every day."

In addition, we see evidence that she used teachers' responses to *prompt change in her planning for and facilitation of a subsequent session* ("I need to focus on that with this group – that [good teaching] is good for all [students]"). Reina described the changes she made in the follow-up interview. One key change concerned engaging teachers in discussing key excerpts from *Principles to Actions: Ensuring Mathematical Success for All* (NCTM, 2014). She described discussion prompts she had posed to teachers: "What are we doing when we don't provide deep rich math conversations and we exclude kids from those? What are we doing to their futures as mathematicians?" Another key change concerned her framing of the mathematical tasks teachers engaged in during the PD sessions as providing access for their students. For example, she described saying the following to the teachers as she introduced a task:

> [This task is] set up in ways that allow students to stop and think privately, share their ideas in a small group, and then come together and share the groups' ideas or individual ideas out loud. It gives [students] more access and more comfort.

Reina modified Sessions Three, Four, and Five to account for what she learned. In what follows, we illustrate Reina's interpretation of the resulting change in teachers' responses.

Example 2: Assessing whether changes in facilitation resulted in improvement.

During Session Five, Reina and the mathematics department met again virtually for 1.5 hours. They focused on learning an instructional routine aimed at supporting students' argumentation. Reina administered the measure at the end of the session, and all five teachers present completed the survey. Two days later, Reina, the PD organization's leaders, and researchers met for another interview.

In this example, we see Reina use teachers' responses in a fourth way: *to assess whether deliberate changes in her facilitation practice result in desired improvements*. Consider Reina's interpretations of the change in teachers' responses to Item 9 from Session Two to Session Five (Figure 2).

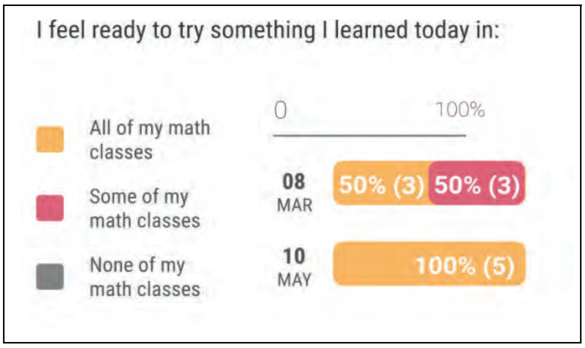


Figure 2: Teachers' responses to Item 9 in Sessions Two (08 MAR; n = 6) and Five (10 MAY; n = 5)

In seeing that in Session Five all five teachers indicated they were ready to try something in all their math classes, Reina said:

> … I'm almost relieved to see that change … It looks like we've reached a little more to [teachers] believ[ing] that they will implement this with all students, in all classes.

Reina used the longitudinal data to assess the changes she had made between Sessions Two and Five: engaging teachers in discussion about their role and responsibility, and carefully framing mathematics tasks as providing access to students. She regarded the shifts in teachers' responses as indicating that the changes she made to her planning and facilitation of the PD resulted in desired improvements, namely, that teachers increasingly viewed ambitious instructional practices as appropriate for all their students.

Discussion and conclusions.

We have provided an image of how a facilitator used a practical measure of collaborative PD designed to provide insight into teachers' perceptions of aspects of mathematics PD that prior research has linked to teachers' learning. Findings indicate that the facilitator used the measure to inquire into her facilitation practice and set goals for her future work. These findings contribute to the burgeoning literature on PD facilitators' learning by highlighting the potential of using a particular tool to inform facilitators' practice, and by association, the improvement of PD.

While these findings suggest the potential value of this tool, it is important to attend to key features of the context in which the facilitator interpreted teachers' responses. An important question for future research concerns the *routine of interacting* with the tool – the "patterned ways of engaging together" (Coburn & Russell, 2008, p. 217) which guide conversations about facilitation practice. For example, it is likely that questions posed in the sense-making interviews ("What do you notice about teachers' responses to this item?" "Why do you think teachers responded the way they did?"), as well as interjections from the PD organization's leaders, impacted the focus and quality of Reina's interpretations of teachers' responses. In future analyses, we plan to analyze the relationship between the role of the PD organization leaders and Reina's use of the data, and the extent to which the range of Reina's uses of the measure is evident in other facilitators' interpretations in other contexts. Understanding a range of uses of the tool will inform the design of supports for facilitators' learning.

Acknowledgment

The work described and the writing of this manuscript was supported by the Spencer Foundation's Research-Practice Partnership Program and the National Science Foundation (No. DRL-1620851). The opinions expressed do not necessarily reflect the views of either foundation. We are grateful to our many collaborators.

The role of pedagogical modeling in being/becoming a culturally responsive mathematics teacher educator

Kathleen Nolan[1,2]

[1] University of Regina, Canada; kathy.nolan@uregina.ca

[2] Oslo Metropolitan University, Norway; katheno@oslomet.no

Keywords: Mathematics teacher educator, culturally responsive pedagogy (CRP), pedagogical modeling, prospective and practicing teachers.

Introduction

Lunenberg et al (2007) writes, "at present one must have serious doubts about the competence of teacher educators to serve as role models in promoting new visions of learning" (p. 586). Others have suggested that teacher educators are not clear or consistent in what conceptions of teaching are most important to be modeled in teacher education (Montenegro, 2020; Timmerman, 2009). However, just as K-12 teachers cannot teach in ways that they themselves did not experience as learners (Nolan, 2014), teacher educators are also challenged to model pedagogies that they have not experienced as learners or through professional development. For mathematics teacher educators (MTEs), this idea applies to topics of reform and inquiry-based pedagogies as well as other key approaches such as culturally responsive pedagogies (CRP). I draw on Ladson-Billings (1995) to describe CRP as "a theoretical model that not only addresses student achievement but also helps students to accept and affirm their cultural identity while developing critical perspectives that challenge inequities that schools (and other institutions) perpetuate" (p. 469). The research that I describe in this poster begins from the premise that MTEs must develop their *own* CRP as an essential step toward working with prospective and practicing teachers (PTs) to develop *theirs*. That is, MTEs need to grow their own practice as culturally responsive pedagogues (Nolan & Keazer, 2021).

Research Study and Methods

This poster describes a study I conducted while teaching a "CRP in Mathematics Classrooms" course to a group of practicing and prospective teachers (PTs) who were enrolled in a *Teaching Elementary School Mathematics* certificate program. The study was designed to explore PTs' understandings of CRP at various points throughout the one-semester course. In total 38 students took the course over three offerings, with 31 students consenting to participate in the study and allowing their course journal assignment to be used as data; additionally, nine of these 31 participants agreed to participate in a post-course interview. This poster focuses on data gathered from one interview question in the study where I asked about my role as the course instructor and how/if I modeled CRP in the design and teaching of the course: *In addition to teaching about CRP in mathematics, one of my goals is to teach through CRP. Can you think of any ways that I modeled CRP through teaching this course?*

Data and Discussion

Analysis of this one interview question, posed to the nine research participants, yielded several themes which express how (according to the students) I successfully modeled CRP to my students. Examples of these themes are: My use of distributed expertise model (guest speakers invited to present on topics within their realm of experience and/or research); how I positioned myself as a learner in the same field as I am instructing; I conveyed an image of CRP which clearly illustrated that there are many ways to define and enact CRP (what it means and looks like is as varied as the classrooms involved); I made a strong effort to privilege the voices of students throughout the course, from a pre-course survey on student needs/desires through to an opportunity to 'personalize' the course through an open-ended project.

Viewing the data through a critical lens, interesting points can be noticed. For example, the post-course interviews occurred within a few weeks of course completion, so one wonders if these PTs had internalized and processed for themselves what CRP might look like in their own classrooms as teachers, let alone have the capacity to reflect at the level of someone else's classroom practices.

Closing Thoughts

Regrettably, the technical-rational practices teacher educators are expected to model are more widely studied (Aleccia, 2011) than teacher educator pedagogies which promote an agenda grounded in equity, social justice, and culturally responsive aims. To promote such an agenda, teacher educators are called upon to model pedagogies that "challenge inequities and social injustice rather than… projecting a vision of an ideal school" (Mills, 1997, p. 39). Critical analysis of this research study's themes in light of current research on CRP in mathematics teacher education and K-12 schools will be presented in the context of MTEs modeling CRP.

Keywords: Teacher educators, professional development, higher education.

Two decades ago, Tzur (2001) was surprised to notice that research on development of mathematics teacher educators was almost non-existent. More recently, Lloyd (2020) notes that research on mathematics teacher education still tends to emphasise the prospective teachers or participating teachers more than the mathematics teacher educators. Still, there is little support for teacher educators, and no common education for mathematics teacher educators. MatRIC, which is a Centre for Research, Innovation and Coordination of Mathematics Teaching in Norway, has collaborated with the Norwegian Centre for Mathematics Education to develop a national study programme for mathematics teacher educators. The study programme is designed to be two academic years, part-time and gives 30 ECTS points. This poster presents the design of this programme.

The study programme is designed to include teacher educators with varied backgrounds, so that they together can work and develop their teaching of pre-service teachers in collaboration. The pilot of the programme started in August 2021, with 26 participants from twelve different teacher education institutions in Norway. Some participants have PhD's in applied or pure mathematics, but little or no experience from teaching mathematics in schools. Other participants have taught mathematics in primary or secondary school for many years but have less formal education in mathematics. We brought them all together with the aim of developing their teaching of pre-service teachers in mathematics in collaboration.

The education of mathematics teachers involves mathematics as a scientific field, the practice field, and the mathematics education research field. The goal of this programme is that teacher educators will develop the competence to establish strong(er) connections between these three fields. Participants in this programme will gain insight into central mathematical ideas and central themes in mathematics education. Furthermore, the programme will engage participants in research into a variety of approaches for mathematics teacher education. In collaboration, participants will discuss and research mathematics teacher education, and the goal is for participants to develop their own practice as mathematics teacher educators. Participants will undertake a research and development project with their own pre-service teacher students. This will entail the development of research design, generation and analysis of data, and the production of a research article.

The programme in Mathematics Education for Teacher Educators is divided into four parts.

Part 1: Mathematical thinking in the foreground. Participants will collaboratively:

- investigate "big" ideas in mathematics (e.g., functions, associative property, relation)
- investigate pre-service teacher's understanding of big ideas in mathematics and relate these to pupils' learning
- investigate teaching of big ideas in mathematics teacher education – and relate these to pupils' learning

Part 2: Practice in the foreground. Participants will collaboratively:

- investigate the nature of mathematics teachers' practice and how this may be developed
- investigate practices in teacher education that support the development of meaningful engagement in mathematics for pre-service teachers and pupils – and relate these to pupils' engagement, learning and experience
- analyse, reflect on, and develop teaching and mentoring in mathematics teacher education

Part 3: Research (mathematics education) in the foreground. Participants will collaboratively:

- Investigate some major research themes in mathematics teacher education, for instance through self-study or action research
- Reflect about how research in mathematics teacher education can be applied in participants' own teaching in mathematics teacher education
- Investigate and reflect about how one's own research can be integrated within teaching and supervising in the education of pre-service mathematics teachers

Part 4: Individual research project. Participants will collaboratively:

- Research and undertake systematic inquiry into their own practices
- Author texts that can be further developed into publishable articles
- Discuss and contribute towards each other's research projects and texts

The quality of the study programme – in particular how it was received, and to what extent participants consider it relevant for mathematics teacher educator practice – will be evaluated and explored by conducting interviews and questionaries among the participants, in addition to the reports and research articles written by the participants. The first cohort of the programme is considered a pilot, and it will be evaluated and further improved. However, this is a study programme which is designed to be able to last beyond the extra funding from MatRIC on the pilot, and where the teacher institutions see the value in investing this for their employees.

While the community highly values critical friendship experiences between teacher educators, there is little evidence regarding what happens within such experiences. In this study, we report a Self-Study developed by two mathematics teacher educators (MTE), focusing on their critical friendship sessions on preparing and implementing a sequence of classes by one of them. Data collection occurred by recording three critical friendship meetings conducted at the end of implementing a sequence of classes related to quadratic equations. Results discuss different types of questions focused on understanding MTE's pedagogical reasoning and teaching practice. On the other hand, the analysis of the corpus allowed characterizing their level of depth (descriptive or analytical) and the type of content (professional or didactic-mathematical). These findings enable unpacking the critical friendship relationship and invite to explore in-depth the interactions between MTE and critical friend and the possible impact on both professional learnings.

Keywords: Mathematics teacher educator, critical friendship, reflective practice, pedagogical reasoning, professional development.

Introduction

Several studies, especially those referring to the practice of teaching (Beswick & Goos, 2018; Castro Superfine & Li, 2014), have reported that mathematics teacher educators (MTE) have a crucial role in the development of complex learning in their prospective teachers. Through their teaching practices, MTEs offer prospective teachers opportunities to learn mathematics as their future students should learn that subject (Chapman, 2008). As a result, the quality and effectiveness of mathematics teacher education depend on mathematics teacher educators' expertise (Goos & Beswick, 2021; Ping et al., 2018). However, studies about the development of mathematics teacher educators and the challenges they face in their work are scarce. Masingila & Olanoff (2021) highlight that most mathematics instructors in teacher education programs do not have professional support or training in becoming teacher educators. Although several studies have noted that studying one's teaching practice is a powerful tool for teacher educators to reflect on and improve their practices (Schuck & Brandenburg, 2020), Liang et al. (2019) claim that MTEs have little opportunity to study and develop their teaching practices.

To contribute to this discussion, we present a part of a Self-Study to go deep into the reflection on the practice of a novel MTE promoted by a critical friend (Schuck & Russell 2005), a colleague experienced in mathematics teacher education. This kind of collaboration in self-study is crucial for going beyond their initial background and expertise. In fact, this strategy supports the practice of reflecting on their own teaching as an inherent part of the work of mathematics teacher educators (Chapman, 2008). However, little is known about the practice of being a critical friend, exploring how to manage the questions, tensions, and dilemmas through appropriate support. To understand this collaborative process, we seek to answer the following research questions: what kind of questions does the critical friend promote to elicit the MTE's thinking? From the conversation with the critical friend, what characterizes the reflections of the MTE? This self-study is expected to unpack the reflection generated in a critical friendship between a novel and an experienced MTE and give new instances of reflective practices.

Conceptual Framework

In studies on the professional development of MTE, the notion of reflective practice as a means of linking theory and practice has been relevant (Goos & Beswick, 2021). In this way, different studies state that self-study allows MTEs to improve their teaching practices (Schuck et al., 2008; Schuck & Brandenburg, 2020). For example, Tzur (2001) researched his own professional path, tracing his experience as a mathematics learner, mathematics teacher, mathematics teacher educator, and mentor of fellow mathematics teacher educators, identifying crucial events and experiences that advanced his professional knowledge and practice. Schuck et al. (2008) point out that teacher educators can improve their teaching practices through reflective practice and learning conversations with critical friends. In the literature on self-study, critical friends can be from the same discipline area or different areas. They can be colleagues at different stages of their careers (Schuck & Russell 2005), and commonly reflection on practice involves collegial expert-novice partnerships (Goos & Beswick, 2021). On the other hand, an explicit goal of MTEs' research of their practice should be self-understanding and professional development (Chapman, 2008). Therefore, we need to include in the research how the teacher educator-researchers reflected, inquiring in different kinds of questions reflective practices are developed in the interaction between MTE. To what extent can this practice become unpacking and sharing with other mathematics teacher educators to implement this process as a professional learning practice.

Methods

This paper reports a collaborative research project in two voices based on a critical friendship between Author 1 and Author 2 and is part of a broader self-study. Samaras (2010) states self-study as the critical examination of one's actions to achieve a more conscious mode of professional activity. Hence, it is a self-focused and interactive approach that seeks meaning rather than solutions to a specific problem. In this research, Author 1 who takes the role of critical friend is an experienced university-based MTE. He teaches method courses in primary and secondary mathematics teacher education programs connecting permanently theory and practice in mathematics education, and investigates the role model practices held by mathematics teacher educators. Author 2 is a school-based novel mathematics teacher educator who teaches a method course (Mathematics Teaching and Learning) in a secondary mathematics teacher education program and works as a practicum supervisor of prospective teachers. The double role of Author 2 makes him permanently connect his teaching as a MTE with his practice as a school-teacher.

Data collection occurred by recording three critical friendship meetings before and after implementing a sequence of classes related to quadratic equations and functions teaching. In weekly meetings, Author 1 and Author 2 engaged in critical dialogue around MTE's teaching experience. During the first session, the focus was on establishing critical friendships and exploration of the issues which the MTE wanted to address in this self-study. During the second session, the MTE had to communicate the planning of classes that would be the object of analysis in the study and discuss the same with the critical friend. Finally, the third session addressed implementing the previously analyzed classes, delving more deeply into various topics.

The data analyzed were the transcripts from audio-recorded meetings. We conducted a thematic analysis (Braun & Clarke, 2006) to identify themes related to personal and professional tensions in Author 1's experience of becoming a mathematics teacher educator and his teaching practice. For doing so, a constant comparative method (Corbin & Strauss, 2015) was used to code the data, starting with open coding iteratively. A second coding round was conducted to collapse codes into themes such as recurrent questions, recurrent reflections, and foci of reflection. A third coding round was completed using the refined codes to understand where those themes were expressed or addressed. Several cross-data triangulations were made across this coding scheme, with the collaboration of another researcher (Author 3) to validate codes, themes, and consistency (Cohen et al., 2000). Also, we discuss the main finding with the whole research team.

Results

Based on the analysis conducted, we were able to identify various types of questioning undertaken by the critical friend, and diverse types of answers and reflective practices used by the MTE.

Role of the critical friend: delving further into some assumptions

In general, we observe two major modes of asked questions during dialog and discussion. The first mode, referred to as questions asked to attempt to understand pedagogical reasoning, focuses on the MTE's reasoning about the phenomenon under discussion, promoting explanations regarding adopted decisions. Instead, the second type of questions, identified as questions attempting to understand the MTE's teaching practice, focuses on getting the teacher educator to establish relationships between his experience and decisions made that lie at the basis of his teaching practices, either in a higher education or primary or secondary school context, both at the present time as well as within other time frameworks.

We distinguished three types of questions that focused on pedagogical reasoning: Exploration questions, Discussion questions, and questions aimed at Deepening Insight. Exploration questions sought to open up topics of conversation meant to enable the MTE to begin his reflective practices dealing with said topics. For example, in the first work meeting, the critical friend makes the following statement to get the teacher educator to clarify what he expects to get out of these collaborative work sessions.

CF: Then, the first issue is what it is you would expect to get out of a process of joint reflection such as this self-study. ¿What is it you would expect based on what we have already read and gotten to know of this methodology regarding the meetings with the Critical Friend?

On the other hand, Discussion questions enabled the teacher educator to comment on his reasoning about making decisions, or on the topic under discussion. A clear example is a discussion about the content of classes. The critical friend questions the MTE about the reasons he must incorporate the concept of the didactic variable into his classes.

CF: And why is the didactic variable interesting?
MTE: Why is the didactic variable interesting!? [CF: Yes, why?] In other words, the didactic variable, just as a concept who cares whether it is called didactic variable or whatever it's called.
CF: OK, but why does dedicating a full two-module class to this content seem interesting to you?

Finally, the last type of question was the one aimed at deepening insight, which attempted to get the MTE to reflect on his own explanations or reasoning regarding the phenomenon under discussion. For example, a broad debate about the teacher educator's role as a model develops in the second session, and about what the latter thinks is being modeled in his classes. In this context, the critical friend engages more extensively in reflective practice and formulates questions that enable him/her to delve deeper into the MTE's thinking.

CF: [...] when you are teaching the class on equations or on some other mathematical subject you have taught, what is it you meta-communicate when you teach your classes? You told us you had classes that were more about the content of primary and secondary level math, others that were more about professional performance, such as planning, etc. When you are in classes that are more about primary and secondary level math content, what do you expect to model, or what have you seen yourself modeling?

From the point of view of focus on practice, we distinguish three types of questions: those having to do with Personalization, with Experience, and with Assumption. In the personalization questions, the critical friend seeks to inquire into the MTE's motivations or personal connections with the subject under discussion or into decisions he has made for the class. During the first session, for example, discussions take place in connection with theorizing about certain teaching practices the MTE feels are effective, and the critical friend seeks to understand how those practices affect him.

CF: And how do you feel about that when you are standing in front of our students?
MTE: How do I feel about needing a theory to back me?
CF: Mmm? Do you feel more confident, do you feel calm?

Another type of questions is those aiming to evoke the MTE's practice. These experiential questions made it possible for the teacher educator to bring into the conversation different past experiences or those from other contexts, to be discussed in terms of the phenomenon in question. During the first session, the discussion develops around the modeling role the teacher educator feels he has for his students. To inquire why this is relevant, the critical friend invites the MTE to engage in reflective practice about his experience.

CF: Can you think of an episode in which you were impacted by the lack of coherence on the part of your teacher educators? At what point does [coherence] begin to be important for you?

Finally, the third type of questions focusing on practice is the one having to do with assumptions. These are questions in which the critical friend puts the MTE in situations he/she has not necessarily lived or experienced. The purpose is for the MTE to project a decision or reflection about a phenomenon, in spite of the fact he denies having lived that experience in particular. In the following quote from the third session, we observe an episode where this type of question is being posed, and in which the teacher educator and critical friend discuss what happens to students when subjects are left open in class, which is a habitual strategy of the MTE.

CF: But if you had a different group next year, this could happen to you, right? [MTE: Of course] Because in the final analysis, going beyond the group, your style of teaching leaves things open. So, there could be a group with which that doesn't work … [MTE: How would I address that? what would you do in that case?]

Types of teacher educator reflection practices during critical friendship sessions

It was possible to identify two types of reflection practices dealing with questions and discussions triggered by the critical friend. On the one hand, in terms of depth, we found some reflective practices to be superficial, where the MTE did not engage in introspection with respect to what was being discussed, as opposed to some deeper ones in which the MTE engaged in introspection regarding the phenomenon under discussion. On the other hand, there were reflective practices related to the type of content of the MTE's reflections, some related to professional aspects, and others of a didactic-mathematical type.

With regard to level of depth, the quote below comes from a moment in which the MTE gives an account of what he expects to get out of this critical friendship relationship and of the presence of questions that trigger the surfacing of beliefs. Even though one can observe a certain positioning on the part of the MTE, he does not delve much into the types of questions that he would like to explore.

MTE: No, that seems perfect to me, but I would specifically add to that [...] that if the change with respect to certain beliefs is made explicit, beliefs about which we have no prior idea what they are going to be, but if there is some change or at least a certain…if certain doubts arise in me, at least that. Because I don't expect to clarify here all the doubts, I may have [...] but perhaps, to the contrary, generate more questions.

Nevertheless, when the MTE continued his narrative, we observed an example of increased analysis and depth in his reflective practice, in which he contrasted his vision of the teaching role as a guide with the student's autonomy. This vision reflects the evolution of the MTE's role as a teacher educator resulting from his professional experience, from staking his experiences, expectations, and challenges on that role.

MTE: I believe that I have become aware that, at least during certain moments, independently of classroom contexts, the student is to be the protagonist. I need to be more like a guide [...]. I believe that generating autonomy, I don't know if it can be said that way, but I believe that generating autonomy of thought or freedom of thought [...] I believe in that in my role as a teacher –I am thinking of the classroom – I believe that generating that freedom is of key importance.

On the other hand, in terms of the specific content of the MTE's reflective practice, we observed an increase in statements having to do with professional aspects such as classroom experience related to curricular decision-making, or expectations regarding the vision of teaching that future teachers begin constructing during their formative years. Didactic-mathematical aspects, such as decisions with respect to teaching and learning functions, or a design proposal for a specific mathematical task, were discussed to a lesser extent. The following quote is an example of a MTE's professional response while alluding to the importance of installing decision-making and questioning as a permanent professional practice, especially when working with student teachers:

MTE: Then how that decision-making act has an impact on designing a mathematical task with a specific purpose. The understanding that the fact of posing certain questions conditions your teaching, conditions the way you will be planning your teaching, and what the impact is I am going to have on my students. I believe that is what I would mostly expect to get out of this session with them. And what I would like to remain with, is the knowledge of having evidenced that the above [process] is taking place.

In connection with statements aimed at didactic-mathematical topics, the following quote is extracted from a moment in the second session in which the MTE analyzes the notion of a didactic variable and his role in decision-making:

MTE: That in itself is what is interesting, that one can handle that, manipulate that deliberately with a purpose, depending on the student, and that it makes an impact in the way that student learns. That's the point. So, I understand that the didactic variable is an answer to that process. I believe that it is transcendental. What happens is that if you have not been taught what the didactic variable is, that does not necessarily make you consider it or not consider it. But it is important to make the student aware that this is present in their decision-making in the manner in which they design a mathematical task. It is present, and it is important to consider that.

Discussion and Conclusion

The results obtained show that the critical friend (Author 1) as well as the MTE (Author 2) develops a variety of strategies that allow them to build the critical friendship. On the one hand, the MTE is capable of articulating different levels of depth in his reflective practices and of diversifying their content in order to address professional aspects of a teacher's work, as well as specific aspects of the teaching and learning of mathematics. This makes it possible to enrich Chapman's approach (2008), to the extent of specifying the ways in which to examine the dilemmas of classroom practice. The questions voiced by the critical friend offer the teacher educator an opportunity to consider different points of view and to thus question his beliefs (Schuck & Brandenburg, 2020). At the same time, these results allow us to offer an unpacking of internal dynamics at work in the critical friendship relationship between MTEs. Table 1 summarizes the different types of questions posed by the critical friend and the different types of reasoning displayed by the MTE.

Table 1: Categories of questions and answers tables

Purpose of the Questions (Critical Friend)		Types of reflective practice (Mathematics Teacher Educator)	
Understanding pedagogical reasoning	Understanding teaching practices	Level of Depth	Content
Exploration Discussion Delving into the topic	Personalization Experience Assumption	Descriptive Analytical	Professional Didactic-Mathematical

The relationship between questions and answers, and definitely between the purpose of questions posed by the critical friend and what the MTE displays during the conversation in connection with said questions, becomes a strategy that makes it possible to provide support to the professional learning of both actors within the critical friendship relationship. At the same time, it enables them to be aware of the personal resources they make available during the discussion, which they can project onto their own experience, thereby contributing to the improvement of their teaching practices. In addition, critical friendship is a tool that causes the teacher educators involved to evolve, as happened in this case in which they went from a dynamic based on questions to one in which they shared experiences, both mathematics teacher educator and critical friend having engaged in reflective practices that can potentially impact their teaching practices.

Although this study has contributed to unpacking some crucial aspects of critical friendship, it is important to establish the limitations and scope of the findings. For example, this study focuses on a particular case; therefore, it does not allow it to be generalized to the broader group MTEs. Nonetheless, the findings of this study may contribute to starting new discussions about generating spaces for MTE professional learning supported by collaborative work among them. Based on our experience in this self-study, and particularly in this critical friendship, we consider it necessary to articulate the existence of these relationships between teacher educators of the same program, safeguarding the time and conditions to make them happen. In addition, inclusion of various profiles of MTE has turned out to be an enriching element in the ensuing discussions and their analysis, which leads us to think that critical friendship may be used among other actors (practice tutors and students, teacher educators and students, etc.) for purposes of improving and growing the complexity of their professional learning.

Ignoring, upholding, redirecting, provoking: Ways of enacting norms in a video-based professional development

Gil Schwarts[1], Ronnie Karsenty[2] and Abraham Arcavi[3]

[123]Weizmann Institute of Science, Dept. of Science Teaching, Israel; gil.schwarts@gmail.com; ronnie.karsenty@weizmann.ac.il; abraham.arcavi@weizmann.ac.il

The enactment of norms is a key challenge for professional development (PD) facilitators, particularly in video-based programs where teachers tend to be judgmental. This study follows seven novice facilitators of a video-based PD program that aims to promote reflection on practice while downplaying criticism on the filmed teachers' actions. We describe how the novice facilitators enacted norms and responded to teachers' judgmental comments, in order to unpack this challenge. The findings show that although the facilitators underwent the same preparation, considerable variations were found in their decision-making concerning this issue. We describe possible reasons for the different decisions, and suggest implications.

Keywords: Novice facilitators, PD norms, video-based PD.

Background

All social interactions are built on certain norms, which constitute an implicit or explicit contract by which participants agree upon what is acceptable, what is less acceptable, and what is definitely unacceptable (Forsyth, 1995). In mathematics education, classroom norms have been thoroughly investigated (e.g., Yackel & Cobb, 1996), including teachers' instructional norms (e.g., Herbst & Chazan, 2011). By contrast, norms in the PD context have received less attention. PD courses for practicing mathematics teachers are based on social interactions, and as such, are also conducted according to norms that are meant to be accepted and shared by the PD facilitator and the participants. Facilitators are the dominant actors in introducing and maintaining these norms (Karsenty et al., under review), since they design the sessions, lead them, and have the authority to indicate what courses of action, comments, and directions to pursue are acceptable and valuable for the discussion. They often do so according to guidelines, and perhaps also tools or moves, provided by the PD program they facilitate. Since evaluative comments are prevalent in teachers' talk when watching other teachers' lessons (Coles 2013; Jaworski, 1990), the enactment of norms is a key challenge for facilitators in video-based PD programs (Karsenty et al., 2019). It follows that it is even more challenging for novice facilitators who need to make decisions during unfamiliar situations. When novices facilitate PDs to their colleagues, as often occurs in the upscaling process of a PD, the enactment of norms is also shaped by their sense of credibility and their multiple identities as teachers, colleagues, and facilitators (Knapp, 2017). In this paper, we focus on this challenge by exploring the following research questions:

How do novice facilitators of a video-based PD respond to teachers' judgmental comments? What underlies facilitators' decisions with respect to this issue?

Context

The above questions are investigated in the context of a PD project called VIDEO-LM (Viewing, Investigating, and Discussing Environments of Learning Mathematics), developed at the Weizmann Institute of Science in Israel. The program aims to enhance secondary mathematics teachers' reflective skills, along with their mathematical knowledge for teaching (MKT; Ball et al., 2008), via collective guided analysis and discussions of videotaped lessons (hereafter VLs) of unfamiliar teachers. A six-lens framework is used to focus participants' observations and analysis of VLs (Karsenty & Arcavi, 2017), including: *mathematical and meta-mathematical ideas* in the lesson; the filmed teacher's *goals*; the *tasks* used; the *interactions* in the lesson; the filmed teacher's *dilemmas and decision-making*; the filmed teacher's *beliefs*. To enhance reflections and decenter criticism, the project team determined several core norms for these discussions (adapted from Karsenty & Arcavi, 2017, p. 438-9): (1) Maintain a non-evaluative and respectful conversation about the filmed teachers, assuming that they are acting in the best interest of their students and that they have the knowledge needed for teaching the observed lessons; (2) Instead of criticizing the filmed teachers, practice "stepping into their shoes" in order to understand the goals and beliefs underlying their decisions; (3) Discuss alternative teaching decisions not as better or worse courses of action, but rather as a way to enrich the span of possible options while considering the *gains and losses* involved; (4) Under the assumption that there is no one best practice, observe lessons not as models to imitate but as rich artifacts that are aimed at stimulating discussions on issues of teaching; (5) Substantiate arguments raised in the video-based discussion, for example by using evidence from the VLs. To achieve the project goals as well as the local goals of the groups they work with, the facilitators of VIDEO-LM PDs choose which videos, lenses, and activities to use in each session. It follows that two central roles of the facilitators are *designing sessions* and *leading discussions* around VLs, and that the VIDEO-LM context is a rich setting to explore the research questions posed above: firstly, since discussion norms are central to the program design, and secondly, because facilitators have the latitude to choose how to maintain these norms, and to monitor the extent to which they allow them to be breached.

Method

Participants. This study is part of a broader research project, consisting of a multiple case-study investigating seven novice facilitators, who are also mathematics teachers, in their first year of practice. During the VIDEO-LM project's upscaling, new facilitators who previously participated in the PD as teachers were recruited. They were prepared in a one-year course and were supported by a personal mentor and by facilitators' group meetings during their first year of facilitation. All the facilitators led school-based yearly VIDEO-LM courses in 2016-17 that lasted 21-30 hours, spread over 6-11 sessions. From the seven novice facilitators (named hereafter FacA, FacB, etc.), five facilitated the PD in their school (FacA-FacE) and two were external facilitators (FacF and FacG).

Data collection. To examine facilitators' decisions as well as their own view of them, the following data was used for this paper: (1) journals written by facilitators before and after each PD session, where they responded to guiding questions regarding goals, decisions, challenges, and more; (2) videos of two PD sessions per facilitator, one early in the year and another towards the end of the PD; (3) videos of stimulated-recall interviews (SRIs) held with every facilitator a few days after each of the filmed PD sessions. In these SRIs, the facilitator and the first author jointly watched the PD videos, and the facilitator was asked to stop the video whenever s/he noticed a decision to reflect on.

Data analysis. All the research project's data was coded according to five macro-categories which we named *issues of facilitation*, one of them is "enacting norms", namely, how facilitators introduced norms and responded to judgmental comments. The data presented in this paper are those that were coded under this issue, namely, transcripts of (a) PD discussions where facilitators initiated the enactment of norms and/or responded to their breach, (b) facilitators' reflections on these episodes in SRIs, and (c) reflections in journal entries. The PD sessions were further segmented according to decisions, using the methods presented by Schoenfeld (2010). The criterion for coding a sequence as a "decision" was that it refers to *something the facilitator initiated* that consists of several turns that allow for capturing the context and meaning. To analyze facilitators' decisions we used the ROGI framework (Karsenty, et al., 2021) comprising *Resources*, *Orientations*, *Goals*, (ROG, Schoenfeld, 2010), and *Identity*, as defined by Gee (2000): "Being recognized as a certain 'kind of person', in a given context" (p. 99). By employing these four constructs and pointing to their interplay, we constructed interpretations of the facilitators' decisions. We found four different ways in which facilitators responded to judgmental comments, and possible reasons underlying these decisions. Although facilitators may perform different decisions during one session, we assigned each PD session to one of the four decisions according to the most common decision identified in the session.

Findings: ways to respond to judgmental comments, and their possible reasons

Despite the centrality of discussion norms in VIDEO-LM and the fact that all the facilitators were highly familiar with them (first as PD participants themselves and then in the VIDEO-LM facilitation course they took), considerable variations were found when addressing this issue. Four different decisions were identified: (1) The facilitator **leaves judgmental comments unaddressed**; (2) The facilitator **strictly upholds** the norms; (3) The facilitator **redirects** judgmental comments; (4) The facilitator **deliberately provokes** criticism to stimulate the discussion. In the presentation of each decision we mention which cases were assigned to it: the numbers "1" and "2" refer to early and later sessions, respectively. For example, the notation FacB2 refers to FacB in her later PD session. Three sessions out of 14 analyzed (FacE1, FacC1, FacF2) were omitted since no judgmental comments were raised by the PD participants. Below, each decision is described using examples from different cases, (yet, due to space limitations, we do not represent all of the identified instances in each decision). The notation "I1-4" refers to the facilitator's 1st SRI (interview), line 4. "T2" refers to Teacher 2.

Leaving judgmental comments unaddressed (FacA2, FacD1, FacB1)

This decision, which was identified in three cases, relates to facilitators' non-enforcement of norms and avoidance of dealing with judgmental comments. When such comments appeared, the facilitators either ignored them or tried to move on to a different topic. This decision stemmed from one of the following reasons: (1) limited resources to handle such comments, coupled with ambiguous orientations on how and when to enforce norms ("When I heard these comments, I felt really bad, and I didn't know how to relate to them, how to react", FacD, I1-158); (2) an orientation that the norms should be introduced gradually ("This is only the second session, I want to let them get things out", FacD, I1-178); (3) For a facilitator with a strong *colleague identity*, an aspired goal of maintaining good relationships with the teachers ("I constantly remember that not all teachers participate in the PD with the highest desire and motivation. Since I am their colleague, I want to acknowledge their position", FacB, 2nd Post-session journal); (4) a goal of letting teachers express themselves, in order to ensure their cooperation later on ("I think it was a good decision to let him say whatever he wanted […] afterwards there were some parts where he contributed enormously to the discussion", FacB, I1-59,61); (5) fear of reacting to judgment raised by the teachers by using further judgment towards the teachers themselves, which might lead to an unpleasant atmosphere ("I don't want to be involved in confrontations […] I'd rather avoid such frictions", FacA, I2-6).

Strictly upholding the norms (FacA1)

Interestingly, although norms are essential in the VIDEO-LM design, this decision – in which the facilitator does not allow the violation of norms – was assigned only to one session out of 14. The decision was expressed as follows: a) mentioning the norms explicitly before screening a VL; b) reacting *immediately* when a norm was breached. Both these sub-decisions can be seen in the following illustrative examples from FacA's early PD session:

48	FacA:	Last time I said we have norms of discussion, I said that what guides us is respecting those who stand in front of us [the filmed teachers], but I did not define what "respect" is. When I say "respect" [...] it's the state of mind I want you to get into every time we watch a lesson: assume that whoever is standing in front of us, especially since they knew they are going to be filmed, and they prepared the lesson – assume that they always act in the best interest of their students. And we are not supervisors, we are not instructors, we are not here to evaluate them, we only want to see things that happened in their classes and learn from them.
495	FacA:	[Context: the facilitator responds to a PD teacher that criticized the filmed teacher for only writing the positive solution $x = 13$ for the equation $x^2 = 13^2$] Why do you think, why didn't he [the filmed teacher] correct it? Obviously, he knows that it's [supposed to be] ±.

The main reason underlying this decision appeared to be FacA's goals "to make the teachers assimilate the VIDEO-LM language of gains and losses" (I1-182) and "to have a non-judgmental discussion" (2nd Pre-session journal). These goals, together with Josh's strong adherence to the VIDEO-LM resources and values ("my definition of what a good [PD session] is […] it's whether during the discussion the issues from the Observer's Guide[1] appear", I1-273), have probably caused him to respond immediately to every violation of norms. This decision resonates with the approach that norms should be clear from the outset (Coles, 2013; Jaworsky, 1990) to determine the direction the discussion will take.

Redirecting judgmental comments (FacC2, FacD2, FacE2)

Whereas the previous decision relates to an immediate reaction to non-compliance with the norms, *redirection* is subtler; here the facilitator gradually steers the conversation into ascribing goals to the filmed teacher's actions, using open-ended questions that are directed to the entire group.

[1] The Observer's Guide (OG) is a document linked to each VL in the VIDEO-LM website, that includes a suggestion of how the VL may be analyzed using the six lenses.

Nonetheless, these decisions often go together: the facilitator may reassert the norms and then try to redirect the discussion. The decision to redirect allows for other participants' opinions to be heard, including those which contradict the criticism that was voiced. However, this entails the risk that the non-enforcement of norms may lead to an increasingly judgmental discourse. The following discussion from FacD's later session is an example of a successful redirection:

[Context: The teachers had just observed a teaching episode from an 8th-grade probability lesson that consisted of games. When analyzing the mathematical ideas in one of the games, the filmed teacher asked the students to share their strategies and wrote their answers in a table. In the following PD discussion, Teacher 2 and Teacher 6 criticize this move].

366	T2:	Filling out this table was just a waste of time.
367	FacD:	Filling out this table was a waste of time, what do you think?
369	T1:	No.
370	FacD:	Not a waste of time, why?
371	T1:	Kids love to give their answers. If you were to ask me what my strategy for the game was, I would want to share it very much.
372	FacD:	That was his [the filmed teacher's] consideration, letting all the students share their strategies?
373	T6:	[...] [in a criticizing tone] I think that if he had used technology here, he could have gotten faster and clearer results.
374	FacD:	Why do you think so?
375	T6:	If everyone were sharing their data in a common document [...] he would have seen it [the table of strategies] right away.
376	FacD:	Still, what... what's the gain in what he did?
378	FacD:	What does this allow?
379	T1:	That everyone can share.

The judgmental comments in Turns 366 and 373 were followed by the facilitator's open-ended questions (Turns 367, 370, 374, 376, 378), which encouraged the voicing of a different opinion (Turns 369, 371, 379), even if expressed by only one teacher. The facilitator herself was pleased with the course of the discussion when observing it during SRI-2:

I2-148	FacD:	[Refers to T2's comment in Turn 366] She prepared the groundwork for me [laughs]. Because many teachers think that filling out the table or discussing multiple strategies is a waste of time, and I think that's one of the nicest things in this VL.
I2-149	GS:	This teacher said something that you objected to, so why did it make you happy?
I2-150	FacD:	Because it was an opportunity to see how others feel and let the others think about it too. Also, she herself [T2] could have tried to answer [my question], I don't know if she thought about it that way.

FacD's articulations indicate that she views judgmental comments as a resource for the discussion that enables her to put out feelers about the issue at hand and encourage multiple opinions. Therefore, according to her orientation, such comments should not be immediately rebutted, as the ensuing discussion may provide an opportunity for the critical teacher to change her mind, in light of the other teachers' comments and the open-ended questions posed by the facilitator.

Deliberately provoking judgment (FacB2, FacF1, FacG1, FacG2)

This decision relates to elicitations of judgmental comments, for example by deliberately choosing a controversial VL, by asking judgmental questions, or by probing a teacher who seems dissatisfied with a VL. Here are two examples from FacF's early session:

88	FacF:	[Turns to a teacher who made gestures of dissatisfaction while the group re-watched a 20-minute segment from a VL] Before we talk about the lenses, I want to start with you, Teacher 1. To hear about your experience of watching the same segment for the second time.
92	FacF:	I'm just terribly curious about this question, Teacher 2, I'm looking at you [...] you seem to be a little opposed.

While these excerpts may have different interpretations than the one suggested above, FacF's reflection on his PD video shows that his goal was to stimulate the discussion:

I1-76	FacF:	I was ready for criticism on the VL because my mentor had prepared me. I wanted the teachers to be evaluative, because criticism elicits conversation, and that was needed. Here, I saw Teacher 1 sitting uncomfortably [while watching the VL], and I wanted to get him agitated, I wanted them all to get angry, to get upset, to talk.

A similar stance was expressed by FacG in her final session. In SRI-2 she reflected on a PD episode where the group was 'sleepy' and she used provocative questions (such as "are you sure the students understood what the filmed teacher did there?") to enliven the discussion:

I2-44	FacG:	It was very important to me that they would not just give me the answer that they thought I wanted to hear. I wanted critical thinking. [I asked them if all the students understood] and they answered "yes, they all understood", and I thought, '*are you sure* all these 30 students understood?' That's what's important to me, to constantly elicit their thinking.

This decision lets facilitators control (to some extent) the volume of judgmental comments in the discussion, in the sense that: (1) they will not be caught by surprise when criticism emerges; and (2) the very fact that the facilitators themselves bring up the controversy may reduce teachers' antagonism ("I decided to tell them in advance before watching, 'you are going to squirm in your chairs', because otherwise, [...] they would have been even more judgmental and the discussion would not have been productive", FacB, I2-48). Regardless of this sense of control, facilitators may have little idea as to what to do with such comments when they appear. Thus, a further decision is to prepare for the kind of comments that may emerge, including thinking about possible responses to use in real-time, as FacB described in SRI-2:

I2-62	FacB:	This VL makes people uneasy […]. I wrote in my session plan that the teachers would probably ask "what is she [the filmed teacher] doing this for?". [...] My role as a facilitator is thinking about what criticism could come up, and thinking what answers I can give.

All the above excerpts suggest that as in the previous decision, the facilitators hold the orientation that judgmental comments are a useful resource that provides the spark to kindle a lively and engaging discussion. What distinguishes this decision is that the facilitators are those who initiate or elicit judgment, with the aid of prompts they purposefully chose.

Synthesis and implications

This study set out with the aim of shedding light on how novice facilitators enact norms within a specific video-based PD, in particular how they respond to criticism, which is known to be an inhibitor of teachers' learning and reflection (Coles, 2013; Karsenty & Arcavi, 2017). The four decisions presented above show different responses to judgmental comments that were identified within seven novice facilitators' practices. There are several similarities and differences between the decisions, that can illustrate the complexity of deciding on a course of action: The last three decisions are similar in the sense that they all show how facilitators steer evaluative talk into a discussion about gains and losses which can lead to teachers' reflections. However, they differ in terms of the facilitators' capacity to withstand judgmental discussions, or, the extent to which facilitators see these comments as fruitful. The first decision, i.e., facilitators allow for judgmental comments but do nothing about them, may look on the surface very similar to the decision to redirect judgmental comments: in both cases, criticism towards the filmed teacher is enabled. However, in the *redirection* decision, judgmental comments are used by the facilitators as a resource, thus the liability to the program's norms and the filmed teacher is preserved. In the first decision, in contrast, the criticism is never addressed. Overall, the findings contribute a delineation of different ways to execute the PD's main goal, suggesting that there are multiple "best-practices" to do so, which are shaped by the different contexts. The ROGI analysis assisted to show the complexity of decision-making during facilitation, especially for newcomers who do not have well-established scripts to work by. For each decision, we described various underlying reasons, which are related to the goals of facilitators (e.g., to teach the VIDEO-LM language), their orientations (e.g., criticism can advance the discussion), their resources or lack thereof (e.g., inability to respond immediately to judgment), and their multiple identities (e.g., a facilitator who is also a colleague who prefers to maintain a pleasant atmosphere rather than get into confrontations while enforcing norms). Identifying the complex considerations underlying facilitators' decisions contributes to a better understanding of novice facilitators' practices. Accordingly, this work suggests immediate implications for facilitator educators: (a) to acknowledge that facilitators' practices are shaped by multiple elements. Thus, alongside supplying them with adequate resources for the enactment of norms, it is worthwhile to ponder on their orientations and goals with respect to this issue and to understand what challenges and affordances are generated by their identities as teachers and colleagues; (b) to discuss the idea that there are various ways to accomplish the PD goals, each carries its own gains and losses; (c) to delve on how teachers' criticism can enhance the discussion and turn into a resource for facilitators; (d) to discuss the possible consequences of a non-enactment of norms. In general, it could be of benefit for the field to understand more on how norms may influence mathematics teachers' learning, and on the facilitators' role in this process.

Designing asynchronous video-based professional development for mathematics teacher educators

Nanette Seago[1] and Angela Knotts[1]

[1]WestEd, San Francisco, U.S.A; nseago@wested.org; aknotts@wested.org

The Video in the Middle (VIM) project is creating forty two-hour video-based professional development modules that can be combined in a variety of ways to form personalized pathways that meet the unique needs of a wide range of professional learning settings and contexts. The VIM asynchronous modules are designed to be used in three flexible facilitation formats: locally facilitated, expert facilitated, or independent/non-facilitated. VIM modules aim to support teacher noticing of student thinking and increase their mathematical knowledge for teaching linear functions. Preliminary research results indicate that teachers appreciated the variety of facilitation formats, found the online modules useful and engaging, and noticed, compared, and analyzed a variety of visual and numeric methods for solving linear function problems.

Keywords: Mathematics teacher educators, facilitation, online professional development, video-based learning, teacher noticing, mathematical content knowledge.

Introduction

Incorporating video within a professional learning environment offers great potential for mathematics teacher educators to support teachers in unpacking the relationships among pedagogical decisions and practices, students' thinking, and the disciplinary content (Borko et al., 2011). With video, teachers can observe and study the complexity of classroom life, reflect on their own instructional decisions, and to integrate multiple domains of knowledge to solve problems of practice (Blomberg et al., 2013). Recent reviews of the literature on video use in professional development (PD) point to the value of video as a tool for improving instructional practice (Gaudin & Chaliès, 2015).

As video technology and online video sharing have become more accessible and widespread, video-based PD is well-positioned to leverage the benefits of digital platforms (Teräs & Kartoglu, 2017). Online platforms can allow teachers access to professional learning resources that may not be available to them locally and can also support those who are reluctant to share ideas in face-to-face settings in becoming more comfortable doing so in digitally mediated interaction. Online PD is considerably more scalable than comparable face-to-face PD, and in many cases is subject to fewer monetary and logistical constraints for teachers (Killion, 2013). Research to date on online PD has shown some positive effects for teachers, even compared to face-to-face formats (O'Dwyer et al., 2010). Most research comparing online, and face-to-face versions of PD has found that well-designed online courses utilizing high-quality learning materials intended for individual use can produce learning outcomes that are like or better than face-to-face options (Fishman et al., 2013).

There is a general recognition of the critical role facilitators play in leading PD and the need for knowledgeable PD facilitators, leaders, and coaches (Bates et al., 2011). As PD shifts to address challenges such as COVID-19, facilitators are increasingly engaging with online platforms. To flexibly respond to teachers' complex and rapidly changing circumstances, new types of facilitation roles will become necessary (Koellner et. al., 2022). This paper reports on the design and preliminary findings from a project that is adapting face-to-face mathematics PD materials to an asynchronous digital format that was pilot tested with mathematics teachers in three facilitation conditions (local facilitated, expert facilitated and non-facilitated) to examine the impact on teacher and student knowledge. The paper will focus on findings related to the three facilitation conditions.

The video in the middle project

The Video in the Middle (VIM) project is designing and researching asynchronous PD modules. The asynchronous format allows participants access to PD at any time, in any location, and can potentially eliminate the often-mentioned roadblocks to participation—lack of scheduling flexibility and geographic distance. The VIM project draws upon the face-to-face *Learning and Teaching Linear Functions: Videocases for Mathematics Professional Development* video and ancillary resources (e.g., lesson graphs, transcripts, mathematical and video commentaries) to develop 40 two-hour modules intended to develop teachers' noticing skills and mathematical knowledge for teaching linear functions. These modules offer flexibility by allowing mathematics educators to design a variety of module sequences to fit their professional learning needs.

Conceptual frameworks

The design and development of the VIM asynchronous modules are conceptually grounded in two main bodies of research related to teacher learning in PD. First, the development of professional knowledge that consists of deep and connected mathematical content knowledge, the knowledge of students' thinking and how students learn the content, and knowledge of pedagogical practices and norms to support student learning. Second, the development of a professional vision that consists of teachers' ability to notice, analyze, and reason about features of student thinking and classroom interactions. In this section, we briefly discuss these two research areas with a focus on how they relate to the design and impact of the VIM asynchronous PD.

Mathematical knowledge for teaching

Ball and colleagues have identified and elucidated "mathematical knowledge for teaching" (MKT) as the professional knowledge that mathematics teachers must have to do the mathematical work of teaching effectively (Ball & Bass, 2002). This conception of knowledge of mathematics for teaching is multifaceted and includes both content and pedagogical content knowledge. MKT includes a sophisticated understanding of effective instructional practices and student thinking related to specific mathematical content and comes into play during all phases of teaching. For mathematics teacher educators, incorporating video within the learning environment supports opportunities for teachers to develop their MKT by unpacking the relationships among pedagogical decisions and practices, students' work, and the disciplinary content (Bloomberg et al., 2013). Collectively viewing and discussing video clips allows for the complexities of classroom practice to be stopped in time, unpacked, and thoughtfully analyzed, helping to bridge the ever-present theory-to-practice divide and support instructional reflection and improvement. The VIM module design incorporates MKT by providing multiple and varied experiences to examine and compare a variety of mathematical methods and representations, and to analyze the complex relations between content, pedagogy, and student thinking.

Professional vision and noticing

One unique aspect of mathematics teacher educators' knowledge is their "professional vision", which refers to their ability to notice and analyze features of classroom interactions, make connections to broader principles of teaching and learning, and reason about classroom events (Seidel & Stürmer, 2014). Over the years, diverse conceptions of noticing have emerged in the literature, but in general most discussions of mathematics teacher noticing involve two main processes: (1) *Attending* to particular events in an instructional setting (i.e., teachers choose where to focus their attention and for how long) and (2) *making sense* of events in an instructional setting (i.e., teachers draw on their existing knowledge to interpret what they notice in classrooms) (Sherin et al., 2011). Sherin et al. (2011) argue that these two aspects of noticing are not discrete, but rather interrelated. Teachers attend to events based on their sense-making, and how they interpret classroom interactions and students' thinking influences where they choose to focus their attention. A noticing conceptual frame is used within the VIM asynchronous module design to support the analysis of classroom interactions and reason about teaching and student thinking within the viewing and analysis probes of the video clips embedded within the modules. In addition, the bridge to practice activities that end each module are designed to connect teachers' learning to their classroom practices.

VIM module design and development

Many, but not all, video-based mathematics PD programs have teachers are designed to engage teachers in specific activities before and after watching the focal video (Borko et al., 2011). For example, prior to watching a clip, PD facilitators may ask the teachers to solve and discuss the math problem shown in the video to develop content knowledge, motivate teachers to notice elements of the content contained within the clip, and attend to specified activities such as a unique solution method or teacher questions that prompt extended student reasoning. After viewing the video, facilitators may guide a discussion and in which the teachers relate what they have seen on the video to their own classroom practices. The discussion and follow-up activities extend teachers' thinking and analysis by probing more deeply into topics or issues presented within the video.

We label this intentional sequencing of video viewing such that it occurs between designated activities with specified learning goals a 'video in the middle' design (Seago et al., 2018). In video-based mathematics PD that incorporates this design feature, video is in the middle of the learning experience, sandwiched between activities such as mathematical problem-solving and pedagogical reflection. Our goal is not to argue that this design feature is new to the field of professional development, but simply to highlight and label it, and consider how the design is likely to support pre- and in-service teachers' learning.

Each VIM module contains the same set of activities embedded in the video in the middle design, placing a video clip at the center, or "in the middle," of professional learning as teachers take part in an online experience of mathematical problem solving, video analysis of classroom practice, and pedagogical reflection (Figure 1). The overall structure of this design is consistent across all VIM modules and is intended to support teachers' professional learning opportunities around mathematical knowledge for teaching (Ball & Bass, 2002) and teacher noticing of student thinking and teacher-student interactions (Sherin et al., 2011).

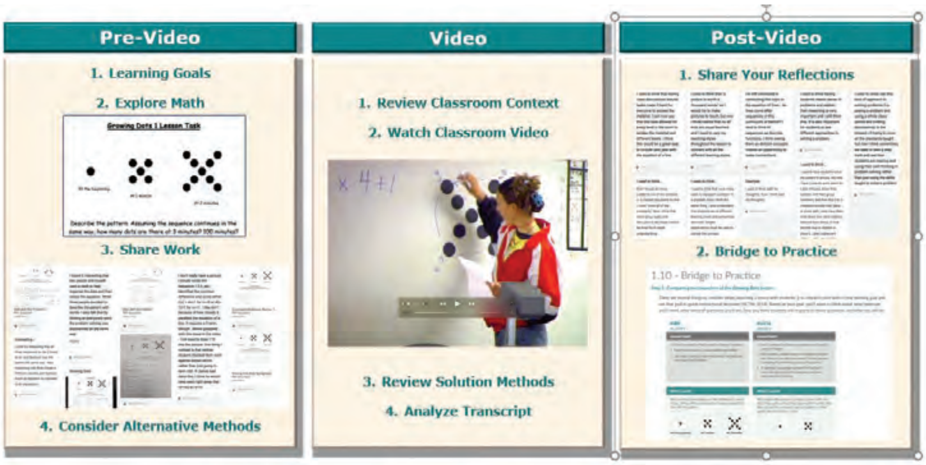

Figure 1: Video in the middle PD activities

The VIM modules are designed to be offered in three asynchronous facilitation formats: (1) locally facilitated, (2) expert facilitated, and (3) independent/non-facilitated. The different formats provide unique affordances for teachers and provides users with both flexibility and choice in their professional learning. Some teachers may prefer to work independently at their own pace and on their own time schedule; others may prefer to work with colleagues at their school with local facilitation from a coach. Or districts may want to offer their teachers the opportunity to participate with other teachers nationally in an expert facilitated experience. VIM's final design will offer a variety of suggested pathways through the modules depending upon goals, grade levels, and mathematics content, with options to personalize a professional learning plan (depending on one's goals) or swap a particular module with another from the bank of VIM modules.

Methodology

During Spring 2020, middle and high school teachers were recruited across the state of California to participate in a pilot efficacy study to address the following research questions:

> *What is the impact of teachers' participation in the three delivery formats on teachers' mathematical knowledge for teaching, their noticing skills, and their teaching practice? What is the impact on their students' performance?*

In this paper, we report on the impact of participation in the three delivery formats on teachers' mathematical knowledge for teaching and noticing skills.

Participants. Mathematics coaches/leaders from two school districts with which researchers had existing relationships were recruited for the locally facilitated condition. The coaches/leaders in each district recruited teachers and then served as the local facilitators for groups in their districts. For the independent /non-facilitated condition and the expert-facilitated condition, teachers were recruited from districts across California and randomized into two groups. Where multiple teachers were recruited from the same district, teachers were split between the two groups. Of the 68 teachers who began the study, 56 (82%) completed all or nearly all study activities, including all four VIM modules

(16 local facilitated, 16 expert facilitated, 24 independent). All three conditions had 80% or higher completion rates—local facilitated (83%), expert facilitated 80%, and non-facilitated 83%.

Intervention. All teachers experienced the same four sequenced, two-hour modules for a total of eight hours of professional development over the course of eight weeks (February-March 2020). While the modules are structured alike and contain a consistent set of activities and resources, each individual module is focused on a set of three unique learning goals (mathematical, pedagogical, and instructional) that are designed around each VIM mathematical task and video clip.

Facilitator training. In January 2020 two project staff designed and facilitated a 90-min zoom facilitator orientation for the two expert and three local facilitators. During the orientation, staff gave an overview of the RCT study and timeline, the VIM module structure, tools (such as Canvas, NowComment and Padlet), and a web-based facilitator guide. Additionally, a video tutorial focused on the journal tool was created for the facilitators to learn how to comment on participants responses and provide feedback to their teacher participants within the asynchronous format.

Measures. A variety of measures were used to gather impact data on teachers and students. Teacher measures included an online pre-post video and student work analysis task, weekly online self-report teacher logs focused on what teachers used in their classroom practice related to the PD, teacher interviews focused on usefulness, engagement and facilitation conditions, classroom observations and PD embedded pre-post community wall posts and comments. A student online quiz was developed to assess shifts in content knowledge. The focus of this paper will be on the analysis and results of the mathematics community wall pre-post data and interview data across the three facilitation conditions.

Analysis and results

COVID's impact on data collection, analysis, and results. Weeks seven and eight of the RCT were impacted by COVID-19. In both facilitated groups there was less interaction among participants in the fourth module than the previous three modules. Typically, there were four-five participants who commented on colleagues' posts. For the fourth module, there were one or two people who completed the module around the same time and interacted with each other. For teachers who completed the fourth module, they completed all the activities and journal entries but didn't comment or interact much with their colleagues. In addition, while ~5000 pre student quiz data was successfully collected, post student quiz data was not able to be collected. Teacher observations were not completed and therefore teaching practice impact data was not collected.

Teacher community walls. Within each of the VIM modules, teachers worked on the mathematical task that the students in the video clip engaged with. After solving the problem, they uploaded an image of their work and colleagues and facilitators commented or asked questions. Two project staff independently examined and categorized the various mathematical methods posted by teachers and analyzed the responses by the teachers on each other's methods. They compared and agreed upon their categories, analysis, and calculations. Community mathematics wall participation was high in all three conditions. In the locally facilitated condition, 80% of participants posted their mathematical work in the first VIM module and 95% posted their work in the final VIM module. In the self-paced group, 88% of the participants posted their mathematical work for the first module and 100% posted in the final module. In the VIM project facilitated group, 100% of the participants posted their work in both the first module and last modules. The VIM project facilitated group had the smallest number of pre-non-facilitator comments, but a similar number of total comments to the other two conditions. The most notable pre-post results emerged in the analysis of the visual versus numerical methods used by teachers. Specifically, by condition:

- *Locally facilitated*: Visual methods increased from 3% of the total methods posted in module 1 to 89% in module 4; numerical methods decreased from 70% of the total methods posted in module 1 to 11% in module 4
- *Expert facilitated:* Visual methods increased from 6% of the total methods posted in module 1 to 94% in module 4; numerical methods decreased from 82% of the total methods posted in module 1 to 6% in module 4
- *Non-facilitated:* visual methods increased from 18% of the total methods posted in module 1 to 85% in module 4; numerical methods decreased from 82% of the total methods posted in module 1 to 6% in module 4

The preliminary results in the analysis pre-post methods not only showed improved MKT with a substantial shift from numerical to visual methods, but their comments indicated an increased appreciation for visual methods in general by mentioning use of color, modeling of expressions, etc.

<u>Teacher interviews</u>. Of the 56 teachers who completed the study, nine were randomly selected for guided interviews in June and July 2020, three from each condition. All interviews were audio-recorded and transcribed. Two project staff identified passages related to teachers' engagement in the PD, the usefulness of module features, the content and resources, their thoughts on the facilitation conditions and the impact on their practice. All nine expressed that they found the VIM PD modules engaging and useful. When asked to comment on features or elements of the VIM modules they found most beneficial, the videos, lesson graphs, and community walls were all mentioned by most teachers. In relation to noticing, many teachers commented that watching a video of a real classroom helped them better understand what teacher moves described in the PD would look like and how 'real' students might respond mathematically. In relation to MKT, teachers mentioned that they learned a variety of ways linear functions tasks can be approached or solved, whether from the analysis of the videos, the solution methods document, or in other participants' work posted on the community walls.

When asked about their experiences, teachers in different conditions described distinctive affordances of each. For example, most teachers in the facilitated groups appreciated receiving feedback from a coach in their district or an expert facilitator, while those in the independent/non-facilitated group enjoyed the flexibility of being able to complete the modules at their own pace. As one independent participant said,

> 'I like this particular experience because I can go at my own pace, and it was still almost like it was facilitated because there were questions that you had to answer.'

Most participants in the facilitated groups felt that the facilitation was supportive and helpful. They appreciated the comments and questions posed on the Padlet wall and said that it helped them reflect on their own learning and perspective of the task. Some shared that it helped them to be accountable and get the work done.

> 'I liked the group I was in because it held me accountable to do a lesson a week, or in the time constraints. I might not have managed my time as efficiently... I wouldn't have gotten as much out of them. I feel I was able to get more out of them by being in the structured setting.'

One person in a facilitated group shared how supportive the facilitator was in helping her understand some of the content of the lesson as well as the postings on the Padlet wall. Almost all the participants in the facilitated groups appreciated being in a facilitated group and said that they would choose that option again. One participant felt ambivalent about the facilitation and said she could be in either a facilitated or independent condition, as the facilitation felt minimal and not very helpful. Participants in the independent condition were divided regarding whether they would prefer having been in a facilitated group instead.

> 'I kind of liked the independent group because I was able to adjust my weekly schedule, but I also like to socialize with colleagues and talk about what we are learning. I would like to have tried the other part, but I don't think I have a preference'.

Discussion and conclusion

The VIM asynchronous video-based PD modules are designed to meet the increasing need for online PD options that include flexibility and choice for teachers and facilitators (Koellner et.al., in press). The preliminary analysis of the community wall and interview data show impact of the three facilitation conditions on teacher noticing and MKT in the teacher's examination of student thinking, classroom interactions, and mathematical representations/methods.

A surprising result was the fact that there were no substantial differences in the RCT study across the three conditions regarding teacher engagement and interaction on the community mathematics task wall. We hypothesized that the facilitated group would be more engaged and post more comments in response to their colleagues' methods and facilitator probes. This did not turn out to be the case, as teachers across all three conditions commented in similar numbers and shifted from numeric to visual methods from pre to post. We wonder if the design of the video in the middle experiences—the opportunities provided to teachers to access multiple perspectives of each other, mathematicians and mathematics educators and engage with their peers within the community wall activities—may have provided teachers with more similar than different experiences across the three conditions. We anticipate learning more as we analyze more data (journals, community wall reflections).

The asynchronous, online nature of the VIM modules makes them highly scalable; unlike many face-to-face and synchronous online PD options, mathematics educators do not need to limit participation due to space or cost concerns. At the same time, the various facilitation options allow for interaction and collaboration among teachers.

Utilizing a scriptwriting task as a tool to examine facilitator practices in response to teacher orientations for at-risk students

Teacher orientations influence instructional prioritizations and how teachers attend to students, particularly those at risk of being left behind. In PD programs, facilitators' practices to recognize and respond to such teacher orientations for supporting at-risk students are thus an important aspect of content-related facilitator expertise. Extending the use of scriptwriting tasks to the PD facilitator level, we present two contrasting cases of how facilitators employ practices to respond to teachers' orientations in a PD simulation. One facilitator avoids direct opposition with conflicting teacher orientations, while the second facilitator challenges the teachers' orientations that do not contribute to supporting at-risk students' learning. By discussing the contrasting practices in the facilitators' written scripts, we demonstrate how the scriptwriting task can be used to investigate content-related facilitator expertise in terms of practices in response to teachers' orientations.

Keywords: Scriptwriting tasks, facilitator practices, teacher orientations, professional development.

Introduction

Mathematics represents a cumulative content area with basic concepts laying the foundation for later understanding. It is crucial that students can be supported in gaining knowledge from previous years or units, so they can develop deeper conceptual understanding as they move forward in later grades. The orientations that teachers have in response to less-privileged students who are at risk of being left behind are important to understand and necessary for PD facilitators to be able to identify and respond to. Such facilitator practices are part of their content-related expertise as conceptualized by Prediger et al. (2021). In this study, we draw on the Prediger et al. (2021) framework and utilize a scriptwriting task to examine facilitators' practices for responding to teachers' orientations for supporting at-risk students' learning processes. We examine these practices in the context of a PD for teachers to monitor and enhance at-risk students' conceptual understanding of basic concepts. In the theory section, we first address teacher orientations as part of their teaching expertise. Particularly, we elaborate on four sets of orientations pertinent to the context of fostering at-risks students' mathematics performance. Second, we describe the framework of facilitators' content-related expertise, with a focus on the facets relevant for our study. Third, we expound upon the tool of a scriptwriting task, the instrument we applied. Thereafter, we present and discuss the data we gained in the context of the teacher PD project *Mastering Math*, which is built around supporting at-risk students' mathematics learning. Especially, we report how two facilitators were immersed in a PD simulation by the scriptwriting task and what practices they applied to deal with different teacher orientations.

Theoretical background

Teacher orientations as a part of teacher expertise

Various studies showed how teachers' orientations, respectively beliefs, regarding the nature and meaning of mathematics are manifested in their teaching practices. Schoenfeld (2010) examined the components that impact how a teacher acts in the classroom and developed the theory of goal-oriented decision making, which considers resources, goals, and orientations as essential components. Such orientations and accompanying practices can have consequences for supporting students, especially those in need of additional assistance, if teachers prioritize, for example, procedural fluency over conceptual understanding. In expanding upon this conceptualization of orientations, Prediger (2019) created a framework of mathematics teacher expertise that includes orientations as one of five facets: "Orientations refer to content-related and more general beliefs that implicitly or explicitly guide the teachers' perceptions and prioritisations of jobs (e.g. beliefs about the content or students' learning processes)" (p. 370). Findings from empirical studies revealed four sets of contrasting orientations. First, teachers often focus on the development of procedural knowledge as opposed to conceptual knowledge (Wilhelm et al., 2017). Second, in terms of diagnosing individual student challenges, teachers often follow the school syllabus regardless if students fall behind, and, third, maintain short-term mastery in contrast to emphasizing long-term goal mastery (Prediger et al., 2016). Fourth, teachers concentrate on individual student issues (Krähenmann et al., 2019), instead of facilitating rich discourse with all students. These four sets of orientations are addressed in the PD course *Mastering Math* that constitutes the context of our study.

Facilitator practices as part of their content-related expertise

In terms of what PD facilitators need to know and do to be able to provide successful PD programs for mathematics teachers, researchers have increasingly examined what constitutes necessary PD facilitator knowledge and practices (Borko et al., 2021; Lesseig et al., 2017). In putting different knowledge domains in action, facilitators need to employ practices that are conducive to working productively with adult learners and construct environments in which teachers can collaborate about relevant topics and can feel safe and supported to share information (Borko et al., 2014). Accordingly, Prediger et al. (2021) provided a framework for content-related facilitator expertise. The framework consists of jobs, which are conceptualized as typical and often complex situational demands of facilitating a specific PD, and practices as recurrent patterns of facilitators' utterances and actions for managing the jobs. These practices can be described and analyzed by revealing the underlying facilitator orientations and situative goals on which the facilitator implicitly or explicitly draws:

Orientations: Generic or content-related beliefs and pedagogical attitudes (e.g., about teachers' thinking or about the PD content) that implicitly or explicitly guide the facilitators' perceptions and prioritization of jobs (e.g., participant orientation).

Situative goals: The goals that the facilitators pursue in a respective situation can directly refer to PD content learning goals (in brief, PD learning goals), can address process qualities (e.g.,

> cognitive activation, briefly, process goals), or can be of an atmospheric nature (briefly atmospheric goals). (Prediger et al., 2021, p. 8)

Thus, goals and orientations determine how facilitators act in a specific situation, and it is important to make them visible in facilitators' practices. For that purpose, scriptwriting tasks are a useful tool, which allow for creating a fictional context in which facilitators need to simulate their practice.

Scriptwriting tasks as approximation of PD practices

So far, scriptwriting tasks have been employed on the teacher level as a tool that functions as a bridge between planning and the actual course of action in the classroom by providing classroom situations for teachers to react to learners' utterances and provide possible explanations (Zazkis & Sinclair, 2013). By using scriptwriting tasks, one can draw on a situated approach to enable the approximation of the actual act of supporting students, but instead in a fictionalized situation. Scriptwriting tasks have been accordingly implemented as a means of investigating pre-service teachers' understanding of content and facilitating of learning (Lim et al., 2018); and with in-service teachers (Kontorovich & Zazkis, 2016) to assess how teachers deal with student alternate conceptions. Scriptwriting tasks, however, have not yet been utilized as a tool for assessing facilitators practices in response to teachers' orientations in a situated fictional PD context.

Aims and research questions

To examine PD facilitators' practices in response to teachers' orientations for supporting at-risk students, we employed a scriptwriting task to first provide facilitators with a fictional situation in which teachers in a PD are provided with a student dialogue of three students working on a task and then with a discussion between three teachers concerning how they would continue the conversation with the students. The facilitators were then given the task to first complete the dialogue with the fictional teachers and guide them to in discussing how to support the fictional students and, second, to provide rationale as to why they ended the dialogue at the chosen moment. We pursued the following research question:

RQ: What practices do facilitators apply to respond to teachers' orientations for supporting at-risk students in completing the scriptwriting task, and what situative goals are behind these practices?

Methodology

Instrument: scriptwriting task

The scriptwriting task was developed based on a classroom-level task concerning filling in the tens between 0 and 100 on a number line that contained the following prompt: How can you plot and label numbers on the number line? What can help you? The scriptwriting task included a fictional dialogue of three students with alternate conceptions of the task discussing their solutions followed by a fictional teacher dialogue of three teachers discussing how they could support the students in completing the task (Figure 1).

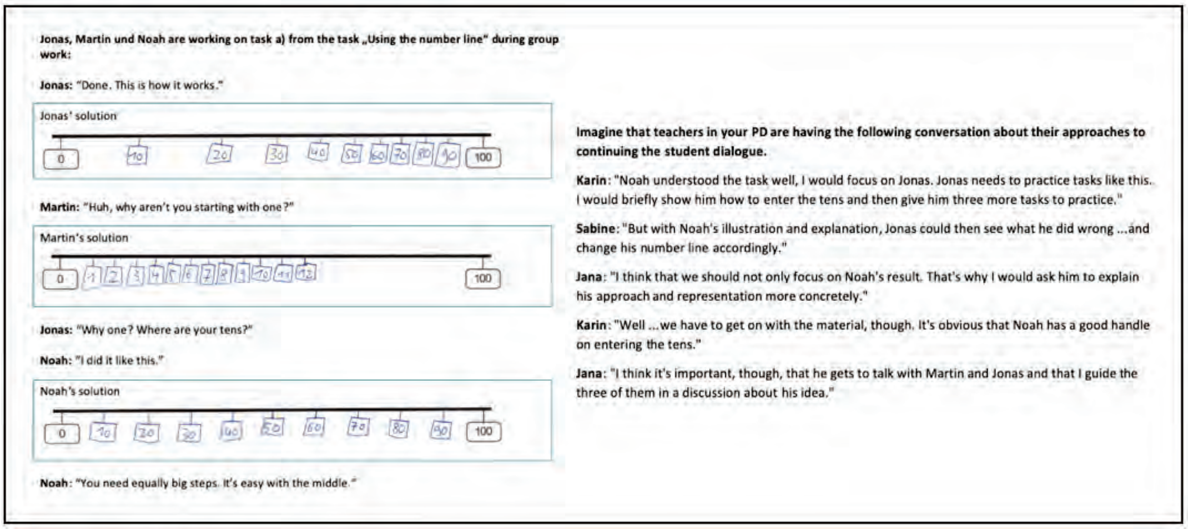

Figure 1: The scriptwriting task student dialogue (on the left) and teacher dialogue (on the right)

After reading the fictional dialogues of the three students and the three teachers, the facilitators were asked to complete the dialogue with the three teachers (Karin, Sabine and Jana), thereby demonstrating how they will address the teachers' orientations for supporting at-risk students and help the teachers to foster student understanding of the basic concepts in the task. The four contrasting sets of teacher orientations for supporting at-risk students were embedded in the scriptwriting task.

Participants, data collection and data analysis

In total, a group of 14 PD facilitators from the federal state of Berlin were asked to participate in this study and were provided with the number line scriptwriting task described in the previous section. Six facilitators agreed to participate. All of the facilitators led PD courses in the program *Mastering Math* for primary school mathematics teachers, which focuses on means of supporting students at risk of being left behind. The *Mastering Math* PD program centers on the four sets of principles: (1) diagnostic vs. syllabus-bound orientation; (2) conceptual vs. procedural orientation; (3) long-term vs. short-term orientation; and (4) communicative vs. individualistic orientation. We selected these unique written scripts from two of the facilitators, in particular, as these two contrasting cases of facilitator practices illustrate how two facilitators react differently in the same fictive PD situation to enhance teachers' learning processes.

Results

The two written scripts demonstrate the facilitators' contrasting approaches in the extent to which they attempt to convince the teachers of the guiding principles of the PD program for supporting at-risk students. While the first facilitator poses questions and encourages the three teachers in the fictional PD situation to discuss the student misconceptions from the task without visibly advancing the guiding principles of the PD, the second facilitator more directly challenges the teachers who are not convinced by the guiding principles and engages them in a discussion surrounding long-term mastery achievement and diagnosing individual student capabilities in order to help move students forward. The two transcripts of the written scripts and the contrasting practices are presented in the following sections.

Case one: A hands-off approach to conveying PD guiding ideas

The facilitator in the first transcript encourages the teachers to provide their opinions concerning the challenges the students in the fictional dialogue encountered by posing questions as to the students' different approaches and different problems they faced. The facilitator responds to the teachers either by demonstrating agreement with the comments concerning Martin's problem that interferes with his understanding of the task and adding to the teachers' ideas with a short commentary that reflects the guiding ideas of the PD, or by remaining neutral by closing the discussion without further comment.

1	Facilitator:	The three students have different bases of understanding. What is the difference between Noah's and Martin's solutions?
2	Jana:	Noah has a strategy. He knows that he first has to look for the middle and then has to record the remaining numbers at equal intervals.
3	Facilitator:	And Martin? […] And what is Jonas' problem?
7	Karin:	Jonas obviously doesn't know what is meant by tens. That is why I would first quickly explain it to him.
8	Jana:	I don't think explaining will help. He could discover it for himself by showing him the work of the other two children. The children could then make comparisons themselves.
9	Facilitator:	Exactly. Martin has a fundamental problem. He may not yet have an understanding of place value. According to MSK, sustainable learning especially for at-risk students should be oriented towards building understanding. One of the guiding ideas of MSK is to promote communication. So what would have to happen for me to catch Martin up?
11	Karin:	Well, with some students it's really hopeless. I wouldn't waste so much time, but rather concentrate on the better-performing students.
12	Jana:	I believe that children have only really understood a subject when they can explain it in their own words.
13	Facilitator:	Thank you very much for your contributions and your assessment. At this point I would like to end the discussion for now and show you a short film.

The facilitator continues the dialogue in such a manner echoing the main elements of the dialogue beginning such that Karin expresses a distinct opinion concerning how to support at-risk students, reiterating that short-term, quick approaches are necessary, especially for such "hopeless" students when support can instead be focused on "better-performing students." It is evident that the facilitator identified the teacher orientations from the scriptwriting task dialogue and extended these to the continuation of the dialogue. The facilitator does not respond to Karin's comments, however, but makes it clear that such orientations can be expressed in the PD. In response to the follow-up question regarding why the facilitator ended the dialogue at that specific moment, the facilitator explained:

Facilitator 1: Karin is obviously still of the old school, according to the motto: Explain quickly and then continue with the material, don't waste any time. It is more important for her to support the better-performing students. The other two participants are more oriented towards the principles of MSK. In the first round of discussion, I would not try to persuade them. It is not about persuasion, but especially such teachers like Karin should be able to make their own discoveries and not be discouraged […]

Thus, the facilitator reiterates her strategy of first assessing the orientations of the participating teachers, before engaging them or encouraging them to think about their viewpoints and their actions in the classroom. The facilitator creates an atmosphere in which the teachers are encouraged to express their opinions, at this stage, however, the facilitator does not push the teachers to reflect on their positions and reasoning behind such viewpoints or have the teachers focus more deeply on the mathematics behind the students' different representations from the student dialogue.

Case two: A direct approach to conveying PD guiding ideas

The second facilitator takes a different approach in the continuation of the dialogue with the three teachers in the written script and provides evaluative comments (see turn 24) of one of the teacher's comments concerning spending too much time on the process of remediation for students considered not capable of doing math.

7	Karin:	But that can take a long time until Martin understands it. What if he doesn't realize that 50 has to be in the middle...then we'll still be sitting together the day after tomorrow.
8	Facilitator:	You're really making an important point here. There are children for whom MSK is ultimately not suitable either. And this would be a good time to find out what Martin's situation is like. If it's not clear to him that 50 is half of 100, and if he's not able to think in tens, then he needs a different kind of support. We would have to take a closer look at that in any case […]
21	Facilitator:	…But why (looking at Karin) is that so important anyway, that we take so much time for this whole process? […]
23	Karin:	But that takes an infinitely long time. And there are simply children where I don't know if that really helps. Math is also a bit like that - either you can do it or you can't.
24	Facilitator:	Yes, that's still a widespread belief. And there really are kids for whom it's very difficult to achieve. But there are also many who just need a little more time and visualization and action. And time for visualization....so...they need to be able to link what they see to their thinking. And when they get that, it clicks pretty quickly. Then they replace their misconceptions with more appropriate ones. If you have experienced this yourself a few times, then you can comprehend it better. You just have to do a few remedial lessons, and then you realize that. But it also takes a bit of time to develop a feeling for which children they really make a difference and for which ones you still have to look for other forms of support. But when you get the children further along, it's totally satisfying for everyone. Can you live with that for now, Karin?
25	Karin:	[nods]
26	Jana:	And luckily we don't have any time pressure in remedial lessons. It just doesn't make sense to keep going if the kids haven't understood it yet.
27	Facilitator:	Exactly, that's the great thing about remedial lessons! But unfortunately we do have a bit of time pressure...we're going to get on with our program now. Anyway, I'm really looking forward to your reports from your first remedial lessons.

The second facilitator responds directly to Karin and even states that the idea that some children cannot do mathematics is "still a widespread belief," and then explains how to support children who struggle with more time and visualizations. While the facilitator does provide an evaluative response to Karin's statements, the facilitator asks Karin if she can try "to live with" the principle of long-term mastery for the time being, and moreover, the facilitator suggests that once Karin has completed a few remedial lessons, she will better understand the process of remediation. Thereby, the facilitator creates an atmosphere in which teachers with opposing orientations to the guiding principles of the PD are not completely discounted. In response to ending the continuation of the dialogue, the PD facilitator explains that such beliefs or orientations cannot be changed in one discussion as they are deeply rooted and will hopefully change with experience and observation:

Facilitator 2:	Jana and Sabine are on the right track already and the essentials for conducting support discussions have been said. Karin still has doubts. But they can't be dispelled with a single conversation. These are deeply anchored beliefs about learning that - hopefully - will gradually disappear once Karin has gained her own experience and realizes that her colleagues are more convinced.

The facilitator thus acknowledges that changing a teacher's orientation to reflect the PD principles will not happen immediately and notes the role of the other members of the PD as relevant for influencing orientations. While the facilitator did respond to Karin's comments concerning some children who just cannot do mathematics, the facilitator does not press Karin further and instead provides an opportunity for another teacher in the PD to express support for long-term mastery.

Discussion and conclusion

The exemplifying cases show how facilitators could react differently in a PD in response to teachers' orientations. Facilitator 1 creates a situation when completing the scriptwriting task in which the facilitator pursues the *content goal* by directing the teachers' focus to students' thinking and challenges in solving the task, to then diagnosing students' learning processes in light of PD guiding principles. Facilitator 1 therefore purses the *content goal* by illustrating one of the PD guiding principles by analyzing the students' potential and challenges. The assertion of one of the teachers that it is important to avoid wasting time on students who are not able to understand is left uncommented. The facilitator thus seems to demonstrate the need to show *esteem for participants* and therefore, especially at the beginning of the PD, purses *atmospheric goals* instead of the *content goal*. In contrast, facilitator 2 discusses and confronts the orientation the teacher shows who insists on avoiding wasting time. Moreover, the facilitator consequently defends the PD guiding principles, thus focusing on the *content goal*, despite repeated objections of the teacher. Moreover, the facilitator seems to try to provoke the teacher to reinterpret or invalidate her own orientation. At the same time, the facilitator engages the teacher in the discussion process and shows esteem for her, presumably to maintain a good atmosphere. The practices of facilitator 1 match facilitator 2 practices to some respect, as both seem to recognize and take teachers' orientations into account. Furthermore, both facilitators refer to the PD guiding principles, with a focus on the *content goal*, albeit to different extents. In addition, both facilitators are anxious to maintain a good atmosphere.

As there have been calls for ways to expand research on expanding the professional growth of facilitators (Borko et al., 2014; Lesseig et al., 2017), this research responds with a research tool that can be utilized to fill this gap. The scriptwriting task as a tool for professional development of PD facilitators of mathematics represents a situated form of practice. First, as a tool for facilitator educators to examine facilitator practices in responding to teachers' orientations, and second, as a means of discussing such responses to help facilitators continue on their path of professional growth.
