This paper aims to characterize the processes in which mathematics teachers engage while solving non-routine mathematical problems and express their reasoning with technology. The descriptive model Mathematical Problem Solving with Technology was used to analyse an experienced teacher's utterances and actions while solving a mathematical problem with a spreadsheet. Our findings reveal the complexity of expert problem solving with technology, through regulation processes and several micro-cycles involving the processes integrate and explore. The teachers' techno-mathematical fluency seems crucial to solving the problem and expressing the reasoning with technology.

Keywords: Mathematical problem-solving, techno-mathematical fluency, experienced mathematics teachers, expert problem solving.

Introduction

Digital technologies provide significant opportunities for enhancing mathematical thinking processes. Yet, the literature shows that most of the technology uses in mathematics learning consist of forms of replicating traditional classroom approaches with some improvements (Bray & Tangney, 2017).

Mathematical problem solving (PS) has been over decades a fertile field of research (Santos-Trigo, 2020). However, the role and impact of digital tools in the processes of solving mathematical problems remains an underexplored topic. Some studies address the strategies and ways of reasoning developed by means of digital tools (Santos-Trigo & Reyes-Martínez, 2019; Silva et *al.*, 2021). Rott et *al.* (2021) propose a model of PS processes that can be used to characterize students' processes with dynamic geometry. Still, it is strongly influenced by Schoenfeld's (1985) model, which was based on paper-and-pencil work and did not account for the affordances of digital tools nor does it provide ways of explaining their role in the PS processes. In this paper we report on an exploratory case study developed to answer the following research question: what is the role of technology on mathematics teachers' processes of PS and how does it support their mathematical thinking?

Theoretical framework

Cognition in digital settings has been conceptualized as stemming from the interactions between individuals, technology, and the media; hence, *humans-with-media* entails the transformational and reorganizational power of the digital tools with which one thinks and acts (Borba & Villarreal, 2005). Technology plays a significant role in the development of mathematical thinking; it allows innovative ways of accessing information and affords new styles of thinking and knowing, producing a reorganization of cognitive activity, namely, in the PS processes.

Our research has been focusing on non-routine mathematical problems, i.e., challenging situations to which the solver does not have a straightforward mathematical process that leads to the solution. Solving these problems by means of digital tools requires the engagement in a mathematisation activity that leads to a productive way of dealing with the challenging situation (Lesh & Zawojewski, 2007), entailing both mathematical and technological knowledge. The development of a conceptual model is consistent with a progressive mathematisation activity, where a *model of* a particular situation evolves into a *model for* explaining or justifying the solution (Gravemeijer, 2005). As the conceptual model portrays the mathematical reasoning developed, it becomes difficult to establish a clear boundary between the solving activity and the explanation of the reasoning. Often, they are so entangled that *solving-and-expressing* summarizes the synchronous processes of mathematisation and expression of mathematical thinking (Jacinto & Carreira, 2017).

Regarding teachers' use of technology in PS, Silva et *al.* (2021) discuss the ways of thinking-with-technology developed by collectives of teachers-with-media, concluding that the tools brought to the fore, GeoGebra and a Spreadsheet, influenced the exploration of the problem, not only visually, but also numerically and experimentally. Hernández et *al.* (2020) analysed pre-service teachers' mathematical understanding when dealing with problem solving in GeoGebra. They found that GeoGebra played a fundamental role in articulating different approaches and in the effective use of control strategies (such as, evaluating the solution or finding support for their conjectures). This leads to consider teachers' proficiency in using digital tools in their problem-solving-and-expressing activity.

The ability to articulate mathematical and technological skills, such as 'techno-mathematical literacies' (Hoyles et *al.*, 2010), is seen as relevant to efficiently solve a problem from a mathematical perspective and to communicate its solution. The term 'fluency', adopted from Papert and Resnick (1995), seems appropriate to describe the ability of articulating a complex idea by means of a tool, being able to do or construct relevant things with it. Thus *techno-mathematical fluency* (TmF) refers to the ability to combine mathematical and technological knowledge for solving-and-expressing non-routine problems (Jacinto & Carreira, 2017). It entails bringing together digital tools and mathematics to create new understandings of the situations, develop techno-mathematical thinking and express it effectively. As with digital fluency, TmF involves to be able to select a useful technological tool from a pool of possibilities, the recognition of particular affordances in the tool, and knowing how it can be used to reach a mathematical outcome.

Research Method

This study investigated the processes of an experienced mathematics teacher, Sofia (pseudonym). A qualitative approach was used in collecting and analysing data. Data collection took place online, through Zoom. At first, in a semi-structured scoping interview the teacher was invited to talk about the role of PS and technology in mathematics teaching and learning. Then, she was asked to select one non-routine problem among four possibilities provided, and to solve it using the digital tools of her preference. She was asked to verbalize every thought and to make explicit every action, and to share her computer screen which enabled the video recording of actions and utterances while solving the problem. Data includes the video recording and the files produced by the teacher.

The teacher's processes were analysed, using NVivo, based on the transcript (utterances) and the video recording (actions), aiming to identify critical events (Powel et *al.*, 2003) that would allow to segment the activity. Deductive coding was performed on the segmented data, based on the ten processes of the descriptive model of Mathematical Problem Solving with Technology (MPST) developed earlier (Carreira & Jacinto, 2019; Jacinto & Carreira, 2017).

A keystone of the MPST model is the inseparability between the subject and the digital tool in solving the problems and expressing the solver's techno-mathematical thinking. The MPST model results from the combination of two theoretical lenses: Martin and Grudziecki's (2006) model for solving a technological problem, and Schoenfeld's (1985) mathematical problem-solving model. The MPST model includes ten processes: i) *Grasp* refers to the first encounter with the problem, either by reading or stating it, to an appropriation of the situation and early ideas involved; ii) *Notice* entails an initial attempt to understand what is at stake, the mathematics and the digital tools that may be useful; iii) *Interpret* is about placing affordances in the digital resources to ponder mathematical ways of approaching the solution; iv) *Integrate* refers to the combination of technological and mathematical resources within an exploratory approach; v) *Explore* entails the use of technological and mathematical resources to explore and analyse conceptual models that may enable the solution; vi) *Plan* involves the outlining of an approach to achieve the solution based on the analysis of the conjectures previously explored; vii) *Create* refers to carry out the outlined approach, recombining resources in new ways to enable the solution and synthesise new knowledge objects that will contribute to solve-and-express the problem; viii) *Verify* involves engaging in activities to explain and justify the solution based on the mathematical and technological resources available; ix) *Disseminate* refers to presenting the solution or outputs to relevant others and pondering on the success of the PS process; and x) *Communicate* comprises the interactions with relevant others while dealing with the problem.

The processes were used to code the segments and their analysis supported the writing of the case of the teacher Sofia solving-and-expressing a problem with the spreadsheet. In the next section, we describe the segments of her problem solving activity by summarizing, in the form of tables, the processes that she carried out at each stage.

Results and discussion

Sofia is a secondary mathematics teacher, with over 20 years of experience. She is highly enthusiastic about the use of technology, as she uses and promotes her students' use of digital tools (e.g. the calculator, GeoGebra, Kahoot). She thinks some tools are suited to particular kinds of problems and that the teachers' familiarity with such tools is fundamental to their successful integration. A detailed and clear explanation of the reasoning process is essential, and Sofia urges her students to do it.

Selecting the problem and grasping the conditions

Sofia started by reading the given problems but spent more time in some parts of the one she would choose (Figure 1), by reading out loud fragments of the statement.

Leonor borrowed the video camera from her mother to film the general rehearsal of the play she is preparing with her colleagues at the Theatre Club. She knows that the camera's battery lasts 2 hours if it is in recording mode and lasts 3 hours in playback mode. Leonor wants to record the rehearsal and immediately watch that video with her colleagues, but cannot re-charge the battery. What is the maximum amount of time of the rehearsal that she can record, in minutes, to be able to view everything she recorded, right after?

Don't forget to explain your problem-solving process!

Figure 1: The problem chosen by Sofia: "How long does the battery last?"

It became clear that it was a new problem for her: "I'm not seeing a way to solve it. At first sight, I would say least common multiple… no, the greatest common divider… I don't know… but it's interesting. I might try this one out!" (*grasp*) (Table 1). Sofia notices that the spreadsheet is an appropriate tool to deal with the problem. Realizing that, if the recording lasts 2h, it will not be possible to play it (*interpret*) she begins to consider recording only 1h, and creates a table with Excel inserting titles and colouring cells A1 and B1, resizing the columns, and formatting boundaries (*integrate*). Then she tests the previous hypothesis, filling 1 in the recording column and 1 in the playing column, although she thinks this experiment will not lead to the solution (*interpret*).

Table 1: Utterances and actions of Sofia during the initial approach

What Sofia did or said	MPST processes
- reads the problems to appropriate the notions that may be involved, identifies a situation as familiar, chooses the problem to solve: "*I like this one… it looks more challenging*"	Grasp
- "*I'm opening an Excel*", says, while overlapping that window with the page that contains the problems - reads the problem again: the battery lasts 2h when in recording and 3h when in playing mode	Notice
- hypothesis 1: "*let's see, a possibility… if she records 2h, she's not able to see it. If she only records 1h…*"	Interpret
- starts by organizing the information on a table: types "recording" in cell A1, and "playing" in cell B1 - formats the table: adjusts the cells dimensions, colours them in orange, formats table's boundaries - inputs 1 in A2 and 1 in B2	Integrate
- "*this is so basic… but I think this way won't take me there*"	Interpret

Testing with an erroneous approach

Sofia's subsequent activity is characterized by a micro-cycle between the processes *integrate-interpret* (occasionally, *explore*) which entails introducing formulas in the spreadsheet using its syntax, testing concrete cases and analysing the results obtained in light of what she was expecting.

She assumes that 5h is the total battery duration and writes 2/5 and 3/5 in her spreadsheet model, meaning the ratio of the recording time and of the playing time, respectively. After some attempts, she decides to test a familiar case: if the recording takes 2h, she knows that the battery will be empty. But the result obtained with her model in Excel (0.8h of playing time) is not what she expected (0h). The tests, based on the initial erroneous assumption, disregard that the battery fully charged lasts 2h in recording mode and the same full charge lasts 3h in playing mode. These experiences support a perspective that will become crucial in the development of the solution: the *time left* after a certain recording. However, another difficulty seems to persist which is related to the perception of the existence of two variables of the same nature – the "*amount of time* spent using the camera" and the "*amount of time* that the battery lasts", entailing an inverse proportion.

Testing and developing the conceptual model: "the percentage of the battery left"

The *exploratory* phase of Sofia's activity (excerpts in Table 2) entails the test of a familiar case (1h in recording mode) and a new way of looking at the problem: the percentage of the battery left. When recording 1 hour, half the battery is spent and the remaining half allows watching a 1h30 video (*explore*). Realizing the potential of this approach, she adds a column - "LeftB" - where she considers the percentages of battery left after a certain recording time. That column is a new techno-mathematical object that reveals how she is conceiving the path towards the solution (*planning*).

Table 2: Utterances and actions of Sofia during the development of the conceptual model

What Sofia did or said	MPST processes
- *"hum... 2h… I record 2h, its over, I can't, I can't watch it. (…) but if I have something previously recorded during some other time, I can play it for 3h. I can watch 3h of recording"*	Interpret
- *"If I record for instance 1h, let's see, I recorded 1h then I spent half of the battery. I recorded 1h, so 50% of the battery is left… 100% of the battery would allow to record 3h, 50% will allow for an hour and a half. There!"* - *"I'm in another line of thought now"*	Explore
- Inputs 1.5 in cell B3 (testing) and explains *"there will be 1h left of recording… the battery is left… if in here I record 1h, there will be 1h left"*	Interpret
- Inserts 'LeftB' (what is left of the battery) in C1 and in C3 inputs '1' justifying *"just to see if this allows me to generalize something faster"*	Plan
- *"there is 1h left, no, I have half of the battery left"*	Interpret
- In the cell C3 she records 50% and in D3 she computes the percentage of the battery that is left to play the video, that is $D3 = C3 * B2$ 	Integrate
- *"I have 50% left of the battery… so I recorded 1h, half is left, I kept half of the battery and that half battery will give, will be 50% of the 3h (…) I will have an hour and a half. An hour and a half to play the video"*	Interpret
- Inputs 1.5 on A4, which corresponds to 1.5h in recording mode	Integrate
- *"If I record 1h30 it is left…* [sighs] *I get a quarter of the battery left"* - *"I'm computing without generalizing and this should be generalized completely… so… I'm left with 25%..."* 	Interpret
…	…
- *"is it enough to play? I don't know, I'll see… I don't want to make one by one"* - Replaces the percentages of battery left after the recording with a formula, that is, C3=50% is replaced by $C3 = 1 - A3/2$ - *"I have 50% left. This is what is left and here* [C4], *it will have to be 25%"* - Drags the fill handle from C3 to C4 and confirms that the result is 25%. 	Explore
- *"I have 25% left, now what do I have to do? I have to calculate 25% of the 3h"* [using the spreadsheet]	Interpret
- *"let's see if it's enough, 1.7... 1.7"*, says, inputting 1.7 in cell A5 - inspects the formula, asking *"What percentage is left?"* and by dragging the fill handle from C4 to C5 concludes *"15%"* 	Integrate
- *"at the first sight there is still a little left over. Oh, but it's not enough to see, because then I need to play... I have to see what I recorded* [laughs]. *I was forgetting that detail of the problem, wasn't I? Then it's not working there* [1.5 in recording mode]*… right?"* - *Look, I think I've moved ahead but now I'm finding myself stuck somehow...*	Interpret
- engages in reviewing the steps taken so far and her reasoning, explaining the meaning of lines 1 and 2 in the spreadsheet and going through the several experiments made with particular cases	Verify

Sofia's conceptual model (a *model of*) is being developed as she tests other values even if, at this point, they are worked out mentally and manually inserted on Excel. The processes integrate, interpret and explore follow each other in a cyclical way (Table 2), while Sofia keeps aiming to find a more robust approach that takes advantage of the spreadsheet affordances: "now how do I put it this here in a formula? (…) this should be completely generalized". The process interpret includes observations regarding the testing of particular cases, whilst the process explore is related to the use of those experiences in the refinement of the conceptual model.

The exploratory activity continues until she obtains a formula for the case corresponding to the recording of 1.5h, in which the battery is left with 25% of its capacity, and uses it to test 1.7h. She concludes that the solution must be somewhere between 1h and 1.5h but, as she fills stuck, she decides to review her reasoning and processes (*verify*).

Finding and expressing the solution

After concluding that the overall reasoning is correct and confirming that the formula used throughout column C (to compute what is left of the battery after a certain recording time, “LeftB”) is correct, Sofia realizes that she is looking for two equal values in different columns (A and D). She then colours these two columns in orange for her own “guidance” which is a critical action that sets the *creation* of the solution (Table 3), that is, she will continue her approach by carrying out the plan using the spreadsheet model to test between 1h and 1.5h. She finds the solution in the second attempt: the camera may record a video of 1.2h and its battery will allow to play the whole film.

Table 3: Utterances and actions of Sofia finding and expressing the solution

What Sofia did or said	MPST processes
- about to finish the review, she inserts “play” in D1 to become clearer what the values in the column refer to - *“now, hold on… let me do just one thing for guidance”*, says, formatting the colour of cells A2 to A8 to orange - *“to organize my ideas… here and here…”* and formats cells D3 to D7 with the same colour - tests 1.1 in A5 and obtains 1.35 in the column B (view) and claims *“they must both be equal”* referring to the orange shaded cells - tests 1.2 in A6 and drags the fill handle from C5 to C6 and from D5 to D6 while saying: *“hold on… technology could still be of more assistance to me… I could take further advantage if I worked will with Excel”* - *“Look, 1.2… 1.2… I think that the maximum is 1.2… She could record 1h, 1h, and the 0.2 times 60… hum…”* - She starts to insert a formula in G4, but computes mentally first: *“12 minutes!” Oh, this is it! So… I think it is 1h and 12 minutes”*	Create
- *“Now I have to recapitulate everything to see if this makes sense again”*	Verify
…	…
- *“You have all the reasoning recorded, so it’s not necessary to explain it all”* - going back to statement, describes that she started by testing a concrete case because she already knew the solution, and then moves to explain how she obtained the formulas - Corrects the heading in the cell C1 changing it from “LeftB” to “%battery” to better adhere to the content - *“I think it’s fine now! I’m convinced!”* [laughs] - opens a text editor file and writes “Problem” as the title - uses the Snipping Tool to take a snapshot of the spreadsheet table and pastes it on the text file - starts typing and reading out loud a description of the processes followed, disregarding the initial erroneous path - presents the solution as 1.2 hours	Verify
- *“now a confirmation is needed, oh, not a confirmation, the calculations confirm... a process, a mathematical formula to reach this value”* [the solution] - sends the spreadsheet and the text editor files to the researcher via e-mail	Disseminate

As requested, Sofia engaged in explaining her problem solving processes by recapitulating, again, her thoughts and actions with Excel (*verify*). While doing so she revises the table, changing C1 heading from “LeftB” to “%battery” as she finds it to be more explicit. Even though she is continually seeking for a “mathematical formula”, she includes in the written explanation that she was “computing the percentage of the battery left after the recording (1- recording time/2)”, which worked as a *model for* explaining how the solution was achieved. Her reflections on the success of the activity and the files sent to the researcher containing the solution, characterize the process disseminate.

Conclusion

The Mathematical Problem Solving with Technology model allowed to analyse the role of the spreadsheet in the teacher’s processes. It also accounts for the complexity of expert successful problem-solving activity by revealing that metacognitive skills, namely control and regulation strategies are of paramount importance to progress (Schoenfeld, 1985; Hanin & Van Nieuwenhoven, 2020).

PS with technology takes place trough micro-cycles of several processes, as others suggest (Carlson & Bloom, 2005; Jacinto & Carreira, 2021). Initially, within an erroneous approach, the processes *integrate-interpret* support experimentations that will disclose the basis of the conceptual model: the battery time that is left. Then, other cycles comprise the processes integrate-explore-interpret, as she perceives a different approach in using the spreadsheet to organize the testing of particular cases. The conceptual model evolves through cycles of integrate-explore, from testing with cases (model of) to a confirmation that the approach works and the spreadsheet supports a general solution (model for).

The teacher used the spreadsheet output to create the final answer, as a solving and an expressing tool. Even though the exploratory activity has induced a plan based on the percentage of battery left, the solution emerges from a retrospective analysis of her reasoning, that lead her to look for equal values of the recording time (column A) and the playing time (column D). This reinforces the idea that the 'solving' and the 'expressing' are simultaneous activities of mathematisation.

Sofia's techno-mathematical fluency is revealed by her familiarity with a diversity of digital tools useful in mathematics teaching and learning. In this case, the spreadsheet was chosen because she is familiar with its syntax, recognizes several of its affordances (tabular representations, formulas, automatic fill) in organizing and developing a numerical approach. Later on, a more robust conceptual model emerges as she is constantly seeking a generalization, a formula. The spreadsheet's numerical feedback encouraged conjecture generation and exploration, by easily testing the effects of changing values or relations. By incorporating the formatted table on the text file, she created a techno-mathematical answer to the problem that represents her conceptual model of the solution. Her techno-mathematical fluency includes the recognition of affordances in the digital tools used with several purposes: to interpret the situation from a techno-mathematical point of view, to explore a conceptual model, and to produce the techno-mathematical solution.

Technology plays a paramount role throughout the mathematical problem solving and expressing activity, which suggests that techno-mathematically fluency is an essential skill for mathematics teachers to engage in successful problem solving with technology.

Keywords: Task design, formative assessment, silent video tasks

Introduction

This poster reports on results from a design-based research project (e.g. Bakker, 2018) focusing on the definition, design, implementation, and development of silent video tasks–tasks were students watch and add their voice-over (in the form of explanations, descriptions, narrative) to short, silent animated mathematics films. Experiences made with teachers in the first phase of the research project formed the basis of the first drafts of a definition of silent video tasks and a description of their instructional sequence that were presented in the form of comics on a poster at CERME11 in Utrecht (Kristinsdóttir, 2019). Based on reactions from participants in TWG15 at CERME and at ICTMT-14 in Essen, a second phase of the design-based research project was prepared and conducted in fall 2019 with the aim to develop further the process of assigning silent video tasks. The second phase of the research project–which could be viewed as a case study–was conducted in collaboration with three Icelandic upper secondary school mathematics teachers, who had some previous experiences with the use of formative assessment. This poster presents the refined instructional sequence of silent video tasks, in the form of comics, based on results from the case study.

Methodology

Prior to the case study, some potentials of silent video tasks to be used as a tool for formative assessment had been identified, using a list of technology-based formative assessment strategies by Wright, Clark, and Tiplady (2018). Hence, teachers with experience of formative assessment practices were purposefully selected to take part in the case study. It so happened that all three teachers, that accepted participation, taught a course for low-achieving students entering grade 11 (age 16-17) in upper secondary school. Based on teachers' suggestions and in accordance with the course curricula, I (the first author) created three one-minute-long silent videos on the topics of coordinate geometry and linear equations. Teachers planned to implement all three videos within the course of one semester. They were encouraged to suggest refinements to the tasks' instructional sequence already in the first interview prior to the silent video task implementation.

Data collection was mainly in the form of teacher interviews that were conducted before and after each implementation of a silent video task and classroom observation notes written during each implementation of a silent video task. Furthermore, during three of the interviews, the teacher who tried out all three silent video tasks was asked to do some think-aloud exercises to prepare and reflect on his task implementation. These think-aloud exercises proved to be helpful to understand the reasons behind his actions and decisions regarding the task implementation.

All interviews were transcribed verbatim in Icelandic. Analysis started immediately after the first interview, focusing on the instructional sequence design and development. After transcribing the last interview, an iterative process of open coding and detailed notes-writing was used to gain an overview of how teacher's ideas, experiences, and expectations developed over time. Thus, creating a base for forming the design principles of silent video tasks, using a format suggested by van den Akker et al. (2013, p. 67) that included characteristics, procedures, and underlying theoretical and empirical arguments for the design.

Results

In the end, only one of the participating teachers implemented all three videos, and the other two teachers both implemented one of the videos in their teaching. Based on teacher interviews, think-aloud reflections, and classroom observations, the instructional sequence of silent video tasks was further developed. Prior to the case study, the silent video tasks' instructional sequence involved the selection of a silent video; whole class viewing of the video; students working in pairs to prepare and record their voice-over for the video in a first lesson, teacher preparation (listening to all students' responses) before the follow-up lesson, and a group discussion based on a part of students' task responses in the follow-up lesson. Teachers in the case study, however, wanted feedback to be immediate and instead of only listening to selected task responses, they wanted a whole group listening and discussion as a reaction to all students' responses to the task. This proved to be challenging for teachers. Nevertheless, the teacher who implemented all three silent video tasks developed his ways of conducting the group discussion and during the third implementation, he was observed to make connections between students' discourse (as presented in students' responses to the task) and the mathematical discourse (as had been presented in classes before the silent video task implementation). This might be connected to the process of reification (Sfard, 2008, p. 44), which involves a transition from describing processes towards talking about objects.

*This paper reports an exploratory qualitative study conducted within the FLINK (*German acronym for *supporting learners for developing sustainable mathematics skills by using interactive materials) project in Austria. We present an overview of the study, its theoretical framework, initial findings from FLINK-based resource designs and the development of our TPACK-inspired professional development course focusing on assessing, designing, and implementing digital materials. Starting in the school year of 2021/22, all Austrian pupils in 5th and 6th grades will be equipped with digital devices. FLINK aims to support mathematics teachers in this digital transformation. In the pilot project, seven pre-service teachers participated in developing interactive, open-access learning and teaching resources for Austrian lower secondary mathematics courses, and initiated a design-based research project aiming to design a pre-service teacher training course within a masters program.*

Keywords: Professional development, digital materials, technology integration.

Introduction

In Austria, digitalization in teaching and learning is becoming increasingly important especially due to impacts of the Covid-19 pandemic. The ministry of education reacted by providing a digital work environment for (lower) secondary schools (BMBWF, 2018). Since autumn 2021, most 5th and 6th grade students will be equipped with digital devices (laptops or tablets with a digital pen and keyboard). According to Clark-Wilson et al. (2020), one key issue for the successful integration of technology in mathematics classes is teacher training (TT). For example, in Uruguay *Plan Ceibal* (a government policy to provide a laptop for each student and teacher) revealed the need for TT programs to support teachers in the integration of digital devices for teaching and learning (Vitabar et al., 2019). However, identifying key factors for a sustainable TT, which have an impact on teachers' everyday lessons, is an ongoing research topic (Zehetmeier & Krainer, 2011).

The joint mathematics TT program at Johannes Kepler University (JKU) and colleges of education includes two courses on the use of technology in mathematics classes. However, these courses mainly focus on software skills, and they do not include the intense didactical feedback necessary to enable students' professional development in this field (Zehetmeier & Krainer, 2011). Research also suggests that it takes more time than often anticipated for teachers to gain enough confidence to use digital materials in teaching (Clark-Wilson & Hoyles, 2017). Supporting Austrian teachers' longer-term integration of digital materials into classroom teaching includes several phases of work. First, we aim to develop a pre-service TT course in our master program that focuses on designing and/or creating digital materials and the accompanying task design, which should enable students to select digital resources and plan for their use. The second important part of implementation into regular teaching will have to be addressed in a later phase as part of our long-term research plans.

Theoretical considerations

Technologies could support teachers' work in various ways, such as assisting the organization of teachers' work or offering new ways of communicating, connecting, sharing, and doing mathematics (Clark-Wilson et al., 2020). In this study, we focus on the role of technology as a new way to represent and learn mathematics and in particular on the digital materials to be used. With digital materials, we mainly utilize dynamic objects in GeoGebra that enable pupils to engage in dynamic interactions with the material and/or provide automated feedback. These objects are embedded in a GeoGebra-based online worksheet additionally comprising of further tasks or explanations for pupils. We chose this software as it: is an open-source mathematics software for educational purposes; allows an interactive combination of several semiotic representations of mathematical objects; and is widely employed in Austrian schools. Due to the age and grade of the pupils first equipped with technology and their limited experience with GeoGebra, we focus on material with pre-designed configurations.

After reviewing several possible alternative models, we selected Koehler and Mishra's (2009) TPACK model as the most appropriate framework. According to this model, teachers need to develop skills not only concerning technological, pedagogical, and mathematical knowledge but especially on the respective interactions of these themes. TPACK encompasses teachers' knowledge of challenges and changes in teaching when using technology, factors that make mathematical concepts easy or difficult to learn, ways to overcome learning difficulties by using technology, and the basis for a sound, meaningful teaching with technology (Koehler & Mishra, 2009). In the following, we interpret professional knowledge in the sense of the TPACK framework.

The TPACK model covers a wide variety of factors relevant for integrating technologies successfully into teaching, its latest version also includes teachers' knowledge *of* their sociocultural environments as contextual knowledge (Mishra, 2019). However, for designing pre-service TT, also sociocultural environments *in which* these skills are to be acquired should be considered. In terms of networking theories, we additionally utilize Goos' (2005) adaption of Valsiner's (1997) Zone theory to cover a broader range of possibly relevant factors to complement the TPACK model. Goos adapted the framework suitable for examining factors influencing teachers' use of technology in secondary mathematics classes. The zone of proximal development (ZPD) can be interpreted as the zone where (future) teachers can develop skills guided by more experienced persons, and the zone of free movement (ZFM) refers to environmental issues constraining a teacher's development (e.g., access to hardware). While the ZFM implies possible actions of future teachers, the zone of promoted action (ZPA) represents professional development (e.g., pre-service TT) which promotes their teaching practices. Considering the interplay of these zones, novice teachers' ZPA has to be within their ZFM, and promoted actions must be within a novice teacher's reach, that is within their ZPD (Goos, 2005). In sum, Zone theory and TPACK together provide a more holistic view on content-related, contextual, sociocultural, and individual factors relevant for implementing and researching a pre-service TT course focusing on technology integration in mathematics teaching.

FLINK – Digital materials design

Our exploratory study is situated within the FLINK project at JKU, which aims to provide mathematics teachers with digital materials to be used alongside mathematics textbooks. The pre-designed interactive materials aim to support pupils' learning of mathematics and therefore focus on the following functionalities: (i) developing concepts and (ii) practicing skills (Drijvers, 2019). Teachers can implement specifically selected materials either during their lessons, or provide them for pupils' homework. A guiding objective in the design process is that each digital material offers a technology-added value compared to paper-and-pencil tasks, which means exploiting functionalities offered by technology such as: automated feedback; dynamic visualizations; or task randomization. For future materials, we also plan to examine the potential of technology for implementing more open-ended tasks, for instance tasks focusing on modelling or problem-solving.

Four mathematics teacher educators selected 18 high-achieving students (6^{th} to 10^{th} semester) enrolled in their university courses, seven of whom worked within FLINK project in July 2021 for an average of 28 hrs/week). These students designed digital materials for topics of grade 5 with a strong focus on the technology-added value. Their workflow is structured as follows: Firstly, students choose a particular small topic from the 5^{th} grade curriculum. Then they work through a checklist (guided by an accompanying script), which requires students to summarize relevant information on their topic (e.g., literature research, learning goals, design ideas, and technology-added value). The script provides additional information for selecting and designing digital materials and for task design, in particular information about: the introduction of the mathematical topic in a learning sequence; the structure of finished materials; the use of language; and references to curriculum and mathematics educational literature. Students are required to analyse the chosen topic from a content-specific pedagogical perspective. Afterwards, they (re-)design digital materials and review their ideas together with an experienced teacher and teacher educator. This review and redesign process takes place two to three times. In parallel, the students discuss their ideas with an 'authoring team', which comprises those who implement their ideas in GeoGebra. Finally, the finished materials are reviewed again by another experienced teacher.

All materials currently completed can be found at www.geogebra.org/flink. One exemplary GeoGebra Book is *Fractions as part of a whole* (https://www.geogebra.org/m/pge8d4x3). Each book consists of digital materials for exploring mathematical concepts and practicing skills. The first part ('Entdecken') consists of interactive tasks about new concepts accompanied by guiding questions. The second part ('Üben') provides self-checking tasks with immediate responses, hints, prepared solutions, or new tasks at the push of a button. Figure 1 presents one task, where pupils must decide if a given fraction is coloured blue. They receive feedback (correct, false) and can choose the next task by pushing 'Neue Frage'. Furthermore, a counter displays the number of already correctly solved tasks.

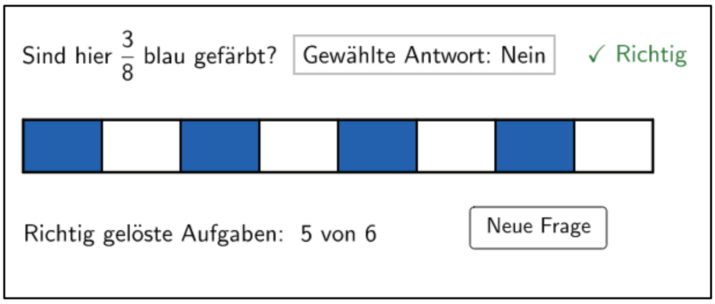

Figure 1: Task 'Can this be correct? – Level 2'

The project is framed by the following research questions: How can a pre-service TT course within a master program focusing on designing digital materials for lower secondary education support future teachers in (i) assessing the quality of digital materials, (ii) designing or (iii) implementing design ideas with technology, and (iv) planning lessons integrating digital instructional materials? We concentrate on the master program because it offers opportunities for students to integrate their prior mathematical knowledge, mathematical content knowledge for teaching, pedagogical knowledge, and knowledge about technology integration acquired in their university courses and school internships. The above-described structure will be the starting point for the design of the TT course. Hereby, we currently have two major priorities: First, we consider it important to provide students with relevant literature-based information about technology-integration in school and to guide them in conducting an intensive literature research about the chosen topic in terms of relevant content knowledge for teaching (e.g., typical errors of pupils, options for visualizations). This should result in an awareness of relevant quality issues in the design and use of digital materials as for example outlined by Trgalova and Jahn (2013). Second, we want to implement a structural collaboration between students and more expert practitioners from mathematics education and technology implementation (Clark-Wilson & Hoyles, 2017).

Research design

From a long-term perspective, this study focuses on developing pre-service TT, thus integrating theoretical findings into practice. According to Cobb et al. (2003), design-based research (DBR) aims at developing domain-specific theories about learning with a designed learning environment and improving this environment by conducting an experiment in an iterative, hypothesis-driven way. DBR involves multiple cycles of hypothesis-based design of learning environments and aims at bridging the gap between practice and research. Therefore, DBR is suitable for our research questions.

For our first cycle, we selected an explorative qualitative approach (data collection by means of students' learning diaries and working notes). It aims to develop inductively a local theory about the development of the professional knowledge of the participating students, which should inform our deeper understanding of the processes involved, and relevant criteria for the design of a pre-service TT course - our *local theory* (Teppo, 2015). This first exploratory study of DBR intends to examine how the participants' self-assessed professional knowledge evolved according to the TPACK model. In addition, we plan to identify crucial – and missing – factors that are relevant for supporting students in assessing, designing, and creating digital materials with technology and thus important for designing a TT course. In this phase, we focus on the first three sub-questions of our research aim.

Preliminary results

In this section, we present exemplary analyses of data collected from FLINK project students' learning diaries over a period of approximately five weeks. Students were encouraged to self-assess the evolution of their TPACK knowledge over time, which factors were helpful and what additional kind of support they needed. Our data analysis followed thematic analysis coding procedures (Braun & Clarke, 2012), which revealed several themes. In this paper we concentrate on: evolving students' professional knowledge; supporting and constraining factors, and the changing beliefs of students.

Students' professional knowledge

The emerging themes span the TPACK model; however, the participating students highlighted especially their evolving knowledge in two fields: pedagogical content knowledge (PCK) and the interaction between technological and pedagogical content knowledge (TPACK). This result also gives an account of the project structure, which focuses on students' intense work with mathematics educational literature.

Students' PCK includes: deepening understanding of PCK issues; how to enhance mathematical understanding for pupils; introducing mathematical topics in teaching; conceptualization in teaching, enhanced knowledge about typical pupils' errors and learning obstacles; topic-specific options for supporting pupils; and further topic-related themes. Most of the themes concentrate on a certain topic (e.g., typical errors when multiplying decimal numbers) but others cover more general aspects. Laura (all names are pseudonyms), for instance, noted:

Laura: Engaging with it [literature] opens new forms of conveying content. [21-08-16]

As the students' ideas are implemented in GeoGebra, one specific theme considers representation and visualization issues. Students discovered additional forms of representations (e.g., how to visualize rational numbers) and remembered rules for visualization (e.g., using various colours for visualizing a certain geometric object). Especially, they started to consider how related representations with technology and paper-and-pencil could interact; for example, Barbara's notes about possible representations of points or Flora's comment about the different representations of commas (in German as comma, in GeoGebra as dot).

Barbara: [Using] cross or point when constructing? Advantage of a cross: a compass can pierce it very accurately. Disadvantage of [using a] point: since it is quite large in GeoGebra, it could happen, that pupils draw thick 'dumplings' on paper. Therefore, … points will be represented as a cross. [21-08-23]

Flora: GeoGebra does not recognize a comma as such, but one must enter a dot … on paper, never dots but commas are made. [21-08-19]

Two further categories concerning PCK emerged from students' notes: language use and task design. We do not have space to expand on the theme task design, which obviously is an expected issue when designing materials. However, several comments revealed issues about language use, indicating the importance of this category, which included: the importance of formulating mathematically correct statements; using language precisely and sensibly; enhancing readability; and using inclusive wording (e.g., according to pupils' gender or cultural background). In addition, supported by an experienced teacher, students also evaluated inexact wording that occurs in schoolbooks. Here, one exemplary student comments about multiplication of decimal numbers, which reflects an expert's well-thought considerations:

Flora: Not the decimal point but the digits shift – [something] often described 'incorrectly' in schoolbooks. [21-08-06]

Finally, we discuss two technology-related knowledge categories: technology from a technical perspective and technology-related views on learning and teaching. The first category contains codes mainly concerned directly with the chosen software, its tools, and technical possibilities to implement students' materials ideas, which can be summed up as technology knowledge (TK) and technological content knowledge (TCK). The second theme relates to TPACK and mainly focuses on dynamic features and visualizations and especially on technology-added value (or limitations) of digital materials, which the following comments show:

Barbara: Dynamic visualization directly shows the effect of varying parameters. This can be very helpful for representations of solids or oblique projections. [21-08-05]

Julia: There are many tasks … that can be carried out particularly well with digital technology because they contain direct feedback, solution paths, and new tasks. Also, the aspect of dynamic variation can be particularly helpful ... [21-08-03]

Furthermore, there are some tasks with more value if they are solved with non-digital means. For example, construction tasks in which children should use ruler and compass. [21-07-28]

Additionally, results reveal various themes representing quality issues for technology integration similar to those outlined by Trgalova and Jahn (2013) (e.g., design and presentation or technical aspects, didactical implementations), showing an increasing awareness of students towards quality aspects. To summarise, the data analysis results in a broad range of issues especially concerning students' PCK and TPACK, which indicates that the structure of FLINK project supports students' professional development and thus provides a profound starting point for organizing a TT course.

Supporting and constraining factors

Supporting factors most frequently mentioned are discussions with colleagues and reflecting and discussing their ideas with experienced teachers and teacher educators. Laura, for instance, wrote:

Laura: … exchanging ideas with each other, being able to ask short questions. Sometimes, a short thought-provoking remark from a colleague is enough. [21-07-15]

Like Ida, all participating students highlighted the importance of discussing their ideas with experts:

Ida: I always find discussions with teachers … particularly useful. It is helpful to discuss other thoughts, perspectives, and experiences on various topics. [21-07-29]

Further supporting factors are: studying schoolbooks and literature about mathematics education; researching existing digital materials; the provided accompanying script and checklist; and the students' prior knowledge. One student in particular mentioned that after reviewing content-specific literature, structuring her knowledge and ideas, proved to be helpful. This can be interpreted as one step of 'decompressing' mathematics to make it explicit for learners as mentioned by Clark-Wilson et al. (2020). These factors support elements of students' ZFM. As most of these factors – except student discussion – are already implemented in the structure of FLINK project, they also are part of their ZPA. A finding is that student discussions should be integrated in the planned pre-service course.

Finally, we discuss findings concerning the main constraints. As mentioned before, the participants mainly design digital materials and tasks and other students (authoring team) implement their ideas with GeoGebra (authors). While students find it supportive to discuss their ideas with the authors as suggested in the project structure, they highlight the need for earlier and more regular discussions:

Christina: To start planning digital materials, it would have been helpful to learn … which ideas are implementable and which not, or what is particularly cumbersome and should be avoided, if possible, since I do not have so much experience with GeoGebra apart from basic knowledge. [21-08-04]

This theme indicates participants' missing TK and TCK, which only partly evolved in this project. Furthermore, it represents a constraining issue on students' ZFM, and there is a tension between students' ZPA and ZPD because designing the digital materials (promoted action) is not fully within their reach (ZPD). Therefore, a further aim for designing a university course must be to provide a setting and structure to enlarge students' knowledge about implementing design ideas.

Beliefs and attitudes

Interestingly, before the project we did not consider how students' beliefs and attitudes may change in this project. Ida's comment about the value of intensive literature already indicates such change.

> Ida: Before, I was not aware of how important it is to deal with mathematics educational literature to enable a topic for teaching to be prepared. [21-07-16]

In addition, Laura recorded after only two weeks:

> Laura: The intensive study of digital implementation possibilities, its technology-added value, and, above all, the already implemented materials are constantly changing my mind and my attitude towards it. I can very well imagine using some of these materials in teaching myself. [21-07-15]

Data analysis revealed a change in: students' attitudes about how to approach a new topic for teaching; the value of the literature review to inform their PCK; and their beliefs about added value of technology integration in teaching. Furthermore, one student commented that she felt more secure about using digital materials in the classroom, even though she was yet to use them. From the perspective of Zone theory, beliefs and attitudes are part of the individual student's ZPD; therefore, such change is one factor for a possible successful technology integration in teaching and learning.

Discussion and conclusions

The results indicate that various factors implemented in the FLINK project's structure support students to develop their TPACK and thus provide a basis for a pre-service TT course. Supporting factors are among others: providing students with a checklist and script as guideline in the beginning; emphasizing literature review on the topic involved; and – most important – enabling regular discussions with experts (experienced teachers, teacher educators, and software experts). Based on these experiences, we could recommend common supervision by experienced teachers and mathematics educators, as they bring different perspectives into discussions: While students adopt the role of learners of technology used in teaching, the involved experts act as guides in the process of designing digital tasks. Furthermore, for each topic students should be encouraged to structure their ideas and knowledge about teaching mathematics (e.g., mathematical concepts, introductions, typical mistakes) and to formulate precise learning goals; the latter is something we introduced during the project as it helped students to focus on the intention of each digital material. One further major issue for us to consider in our study is how to deepen students' TK/TCK, possibly through collaboration with software experts. Finally, it seems crucial that the course structure enhances peer discussions, and it will be important how to embed these factors in a university course's time frame, which differs from this project in terms of structure and especially in the amount of time required.

Results indicate that students' knowledge mostly evolved concerning PCK and TPACK. Hence, it may be advisable to use the MPTK framework (Clark-Wilson et al., 2020) in our next research cycles as it takes a specific stance towards mathematics and also includes teachers' beliefs and attitudes. In addition, students' self-assessment of skills may not always correspond to their actual knowledge, a fact to be considered in the next phase. Furthermore, quality issues emerged during data analysis implying that we already identified some crucial factors for a course design that supports students in assessing and designing digital materials and thus provides first answers to our research questions. Next we will concentrate on how to integrate the findings of this study into our master's program.

Preservice mathematics teacher's learning trajectories of Technological Pedagogical Content Knowledge (TPACK) in an online educational technology course

Irina Lyublinskaya[1] and Xiaoxue Du[2]

[1]Teachers College, Columbia University, New York, NY, USA; il2369@tc.columbia.edu

[2]MIT Media Lab, Boston, MA, USA; xiaoxued@media.mit.edu

This case study examined mathematics preservice teachers' (PSTs') learning trajectories of discipline-specific Technological Pedagogical Content Knowledge (TPACK) in a non-discipline-specific online educational technology summer course. The study showed that all three PSTs followed a similar pattern of continuous TPACK growth with some variations. Annotated digital timelining of TPACK trajectories suggested that growth of PSTs' discipline-specific TPACK could be attributed to the course design, while variations could be explained by a variety of personal and contextual factors moderating the effect of the course on their TPACK development.

Keywords: Learning trajectories, Mathematics preservice education, Online learning, Technological Pedagogical Content Knowledge, Timelining.

Introduction

The need to prepare preservice teachers (PSTs) for teaching with technology, specifically in virtual environments, is widely recognized by the teacher education community. However, according to OECD (2020) on average, fewer than half of all teachers feel well prepared to use technology in their classrooms. The discussions about teacher preparation for technology integration started about two decades ago and led to the development of the Technological Pedagogical Content Knowledge (TPACK) framework, first proposed for mathematics education (Niess, 2005) and then extended to different subjects and contexts (Mishra & Koehler, 2006). The central component in this framework, an integrated TPACK, is the knowledge that relies on the interaction of content, pedagogy, and technology and is specific to the teaching context. Further, Niess et al. (2010) proposed the developmental model of integrated TPACK through five progressive levels: Level 1 (Recognizing) where teachers recognize alignment of the capabilities of technology with subject content; Level 2 (Accepting) where teachers form a favorable or unfavorable attitude toward teaching and learning a subject with technology; Level 3 (Adapting) where teachers adopt or reject teaching and learning a subject with technology; Level 4 (Exploring) where teachers actively integrate teaching and learning of a subject with appropriate technology; and Level 5 (Advancing) where teachers evaluate the results of integrating appropriate technology into teaching and learning a subject. This model is based on Roger's (1983) diffusion of innovation theory, which also served as a theoretical basis for the Stages of Adoption of Technology (SOA) model that was developed to understand the trends of technology adoption by preservice and in-service teachers (Christensen & Knezek, 1999). SOA model includes six stages in which teachers rate themselves: Stage 1 where teachers mostly avoid technology, Stage 2 where teachers are frustrated and lack confidence when using technology, Stage 3 whet teachers begin to understand the process of using technology, Stage 4 when teachers become self-confident with technology, Stage 5 when teachers start using technology as an instructional tool, and Stage 6 when teachers become creative in using technology as an instructional tool. This model provides an affective lens into teachers' trajectories towards technology integration that could provide additional insights into understanding of individual TPACK trajectories.

Growing body of research indicates that development of TPACK with new technologies is a complex and multifaceted process (Niess & Gillow-Wiles, 2021), but little is known about the ways PSTs' TPACK learning trajectories are shaped by external factors, such as practices and experiences in their teacher preparation courses or by internal factors, such as attitudes toward and confidence with technology integration. Therefore, this study combined the learning trajectories approach with developmental model of TPACK (Niess et al., 2005) and Stages of Adoption of Technology model (Christensen & Knezek, 1999) to analyze TPACK learning trajectories of mathematics PSTs participating in an online educational technology summer course. Specifically, the purpose of this study was to analyze how various contextual and personal factors influence TPACK development of mathematics PSTs.

Literature review

Studies indicate that TPACK framework-based courses support mathematics PSTs' TPACK development (Açıkgül & Aslaner, 2019); however, there is no consensus on what is the most effective approach to TPACK development. While many TPACK studies focus on factors that affect overall TPACK development, little is known about PSTs' daily experiences in programs that aim to develop their TPACK, specifically in and for online environment. Research shows that individual teacher learning trajectories are non-linear, complex processes developed over time through the active engagement with a set of ideas (Shavelson, 2012). The studies that focus on TPACK learning trajectories acknowledge the diversity of patterns in mathematics PSTs' TPACK development. For example, Niess & Gillow-Wiles (2021) showed that mathematics PSTs' learning trajectories of TPACK for teaching online are multifaceted in building knowledge for teaching and learning with technology. Özgün-Koca et al. (2010) demonstrated that engaging secondary mathematics PSTs in iterative design and implementation of technology-rich inquiry-based materials led to their shifts in identity from learners to teachers and their TPACK development. However, PSTs' TPACK learning trajectories were also influenced by their beliefs about the role of digital technologies in mathematics.

More studies are needed to understand mathematics PSTs' development of TPACK *in* and *for* online environments. Therefore, this study was guided by the following research questions: 1) In what ways online course practices influenced mathematics PSTs' individual learning trajectories of TPACK? 2) What factors contributed to variations in mathematics PST's learning trajectories of TPACK?

Methods

Study context

The educational technology course in the study was non-discipline-specific pedagogy course and therefore the whole-class instruction focused on the purpose and the role of instructional technology in non-discipline-specific teaching and learning, while tasks for small groups were subject-specific. The course content was delivered in a synchronous mode via Zoom video-conferencing and Nearpod platform (nearpod.com). The course met for seven weeks with two 1.5-hr sessions per week, one led by the STEM education faculty and another one – by a doctoral student-mentor with degree in politics, literacy and instructional technology. During faculty-led sessions PSTs experienced pedagogical practices with technology through both, student and teacher perspectives. Each immersion experience engaged PSTs in high cognitive demand tasks and guided or open inquiry to illustrate both the role of specific type of technology and the specific teaching strategy. Then this experience was analyzed from a teacher's perspective based on theoretical considerations. During mentor sessions PSTs learned how to use technology and engaged in developing their own technology-based activities while the mentor provided necessary scaffolding.

Each assignment aimed to assess PSTs' ability to use technology tools to facilitate specific high-impact instructional strategy for teaching a topic of their choice in online settings. During the 2nd week, PSTs developed a blog task for student research and communication. During the 3rd week, they developed a multimedia concept map task. In the 4th week, PSTs developed a small group exploration using Google Apps to support student discourse and collaboration. For the final project PSTs developed a full online lesson on a topic of their choice using Nearpod. Each assignment required PSTs to include subject-specific technology tools in their tasks.

An earlier study (Lyublinskaya & Du, 2021) demonstrated that the increase in PSTs mean TPACK scores in this course was statistically significant and with large effect size. The study suggested that the PSTs' overall TPACK growth could be attributed to the program design, specifically, inclusion of immersion - theory - analysis - digital content development cycles and focus on high-impact teaching strategies. The study also suggested that PSTs' individual learning trajectories fall into a limited set of distinct patterns. However, question remained how this non-discipline-specific educational technology course supports the PSTs' discipline-specific TPACK development. Thus, this study attempts to gain a more in-depth understanding of the factors affecting mathematics PSTs' learning trajectories of TPACK in such course.

Out of 25 PSTs' enrolled in the course, three PSTs were preparing to teach mathematics, and therefore were selected for this case study. PSTs A and B had no prior instructional technology or teaching experience, PST C had some K-12 teaching experience including experience with technology.

Data collection and analysis

The TPACK levels rubric (Lyublinskaya & Tournaki, 2012) was used to score PST-generated digital artifacts that included weeks 2-4 assignments and a final online lesson. The rubric measures the level of TPACK in four specific components: overarching conception, knowledge of curriculum, knowledge of instructional strategies, and knowledge of student understanding (Niess et al., 2010) and the range of possible scores for each component is from 0 to 5. PSTs' individual scores across four components of TPACK were averaged and plotted against time to visualize TPACK learning trajectories. Nearpod reports were collected and analyzed for completion of activities and understanding of the material.

The TPACK Likert-scale survey (Chai & Koh, 2017) was modified to collect PSTs' beliefs about their TPACK and design beliefs, that include four constructs: new culture of learning (NCL), attitudes towards technology (ATT), design dispositions (DD), and views about themselves as teacher-designers (TAD). The survey was administered in weeks 1 and 7. The Stages of Adoption (SOA) survey was administered during weeks 2-7 to collect self-assessment of stages. Three open-ended questions about challenges in using specific technology tools were added to the survey. Open-ended responses were coded in relation to SOA.

The study used annotated digital timelining to explore contextual and personal factors that affected mathematics PSTs' TPACK learning trajectories (Figure 2).

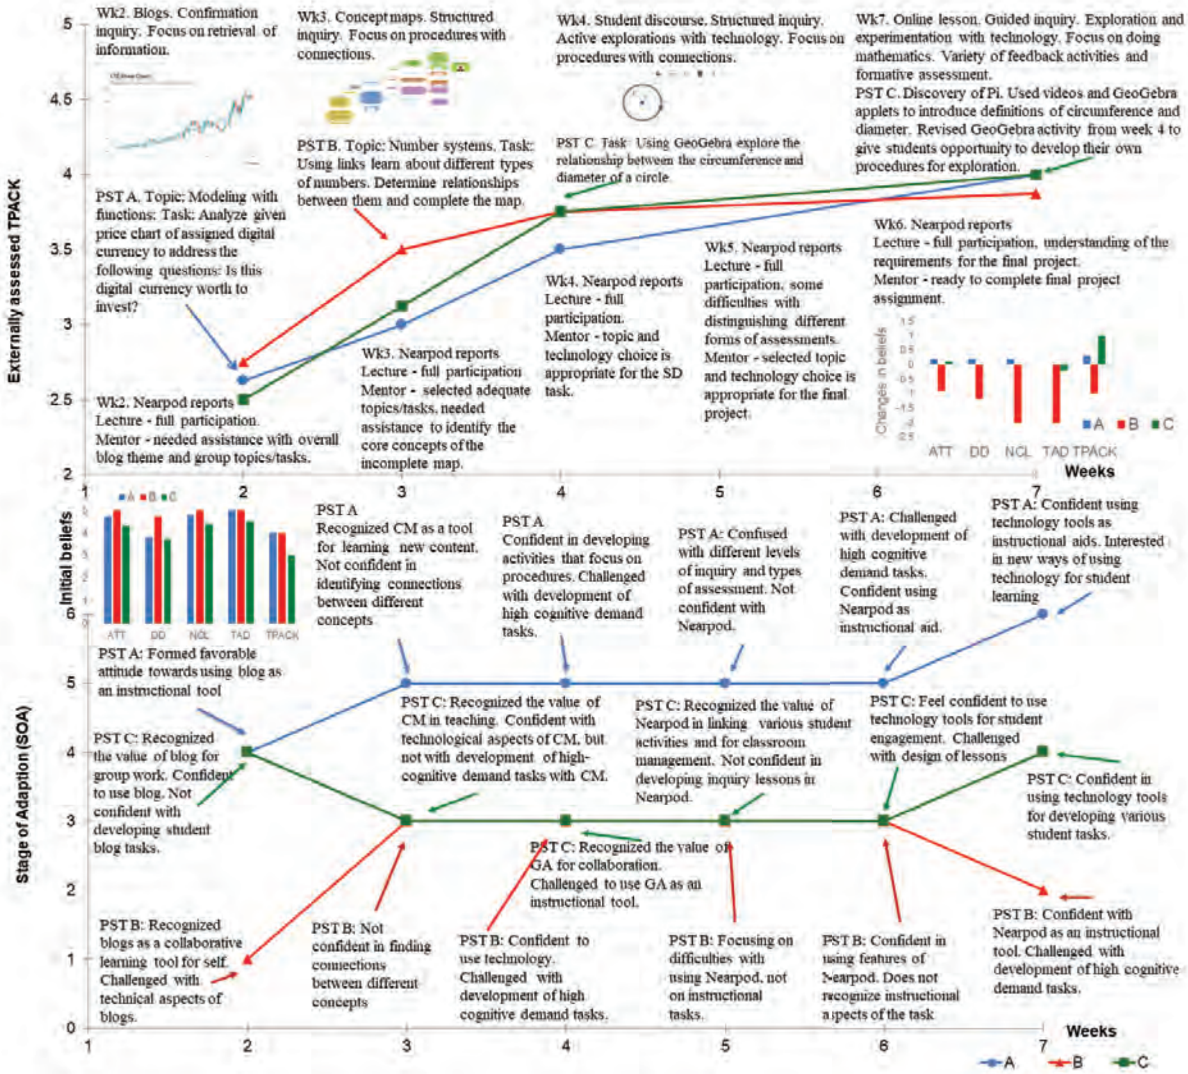

Figure 1. Timelining analysis of PSTs' trajectories of TPACK and SOA

Timelining is a visual research method that focuses on a time-based representation of one or more constructs of interest. The power of a timeline as an analytic resource is in the way that it allows to use multiple type of data from multiple sources on the same display that extends and deepens understanding of the observed changes in the constructs of interest over time (Chamberlain & McGuigan, 2019). In this study, the TPACK and SOA trajectories annotated with the summaries of the analysis of collected data. In order to do that, TPACK and SOA scores were first plotted for each PST to create simple timelines with aligned horizontal axes. Digital artifacts were analyzed for features reflecting the TPACK score. One artifact per assignment was selected to illustrate these features on the TPACK timeline. Nearpod reports provided records of participation and collected PSTs' questions for the mentor. The SOA timeline was annotated with summaries of individual responses to the survey open-ended questions. In addition, two bar graphs were added to the timelines: the first week's TPACK and design beliefs scores calculated from the survey and changes in these scores from the week 1 to the week 7.

Results/Discussion

All three mathematics PSTs demonstrated TPACK growth by one (PST B) or two (PSTs A and C) TPACK levels, which indicates that this non-discipline-specific educational technology course supported development of subject-specific TPACK. Comparison of their TPACK learning trajectories show that all three PSTs followed a similar pattern of continuous TPACK growth with some variations in actual scores and rates of change. In a previous study (Lyublinskaya & Du, 2021), this pattern was found for only 25% of the PSTs enrolled in this course. This continuous growth by mathematics PSTs could be attributed to their full participation in all course sessions as evident from the analysis of Nearpod reports. The analysis of mentor session reports indicated that PSTs recognized their challenges and reached out for support as they were developing their artifacts. That also could have contributed to the positive shifts in TPACK demonstrated by PSTs.

Analysis of PST-generated blog tasks (week 2) showed that all of them were at the Accepting level of TPACK. This level is characterized by confirmation inquiry with low level of cognitive demand tasks that focused mostly on retrieval of information and basic facts (Stein & Smith, 1998). Illustration of this level is a blog developed by PST A with the intent to address the topic of modeling with functions by using online price charts of different digital currency. However, the actual student tasks did not include modeling, trend lines were already included on the price charts that students accessed on the Internet, and questions did not ask for analysis of trend lines or identification of functions used as trendlines, mostly focusing on reporting information found on the websites. This level of TPACK was observed for a large majority of PSTs in the course, therefore course sessions put more emphasis on discussions about levels of inquiry and cognitive demand of tasks.

The following week all three PSTs reached the Adapting level of TPACK as evident from the analysis of concept map tasks. This level is characterized by structured inquiry with higher cognitive demand tasks that include procedures with connections. As an example, consider PST B's task for students to develop a map illustrating the real number system. She provided students with incomplete map that had 5 nodes – natural numbers, whole numbers, integers, rational numbers, and irrational numbers – each linked to an internet source. Students were expected to use provided Internet resources to explore the properties of different number sets in order to establish their hierarchy and complete the concept map. However, her instructions were very prescriptive and did not provide students with opportunities to explore their own questions about the numbers. These results were representative of the large majority of PSTs in the course, thus course sessions put more emphasis on developing guided and open inquiry tasks with technology.

By week 4 all three mathematics PSTs shifted towards using technology for more active explorations, focusing on student thinking and development of conceptual knowledge. However, student tasks with technology were still at the structured inquiry level and often just replaced non-technology-based tasks. As an example, consider a student activity to explore the relationship between the circle's diameter and circumference developed by PST C. She created a Google Document handout linked to an online GeoGebra App. Students were to draw five circles, measure their diameters and circumferences, calculate ratios of circumference to diameter, and arrive at conclusion about the relationship between the two measurements. Asking students to draw five circles similar to a pencil and paper activity indicated that PST C did not understand the dynamic nature of GeoGebra. Students could have varied the radius of a single circle to observe changes in the diameter and circumference. Moreover, instructions to calculate the ratio of the circumference and diameter took away student opportunity for discovery.

In the following weeks, while PSTs were working on their online lessons, the course sessions focused on the various models for technology-infused lessons, with continued emphasis on inquiry and cognitive demand tasks. Analysis of mathematics lessons indicated that all three PSTs incorporated guided inquiry by engaging students in experimentation with technology through high cognitive demand tasks. By week 7, PSTs A and C achieved the Exploring level of TPACK with PST B falling short of that level by a small margin. As an illustration, consider the lesson "Discovery of Pi" developed by PST C. The lesson started with interactive review of the concepts of radius, diameter, and circumference of a circle using GeoGebra applets followed by a matching activity and multiple-choice quiz to check student understanding of definitions. The next part of the lesson was a revised GeoGebra activity from the previous assignment. At the beginning of the activity students were asked to make a prediction about the relationship between the diameter and the circumference of a circle. They were then instructed on how to construct a circle, measure its circumference and diameter, and change its size. Students were to develop their own procedure to determine the relationship between these two measurements and record their work in the group's Google Document. The lesson concluded with student presentations of their discoveries and teacher's summary.

While the overall pattern of the TPACK learning trajectories was similar for the mathematics PSTs, there were some variations in TPACK scores over the course of the study. Therefore, the study analyzed PSTs' responses to surveys. As can be seen from the bar graph on Figure 2, PSTs had different initial beliefs about technology in teaching and learning mathematics and the role of the teacher as designer. PST B had the most positive attitudes, while PST C, the only one who had prior teaching experience, was the least positive. Starting week 2, PSTs self-assessed their SOA of technology and reflected on their experiences in the course. The summaries of qualitative analysis of these responses shown on SOA timeline (Figure 2) clearly indicate that PSTs had different challenges throughout the course.

PST A had the highest SOA self-assessment, mostly indicating his confidence in using technology for teaching. He consistently explained his lower performance by the lack of time rather than understanding: "Sometimes I don't have enough time to prepare for the lecture or finish my assignment perfectly." (PST A, week 3). However, his reflections about his struggles with instructional tasks suggest that he might have been overconfident during the first half of the course. During the second half of the course, he had the largest TPACK growth and by the end of the course, his attitudes slightly improved across all five categories, including self-assessed TPACK. Even though PST B had the most positive attitudes at the beginning of the course, she was the least confident in the group about her ability to use technology in teaching, even though her TPACK scores were highest during the first half of the course. This lack of confidence is evident from her comments: “It's hard for me to brainstorm a topic [for student tasks with technology].” (week 3), “Coming up with high cognitive [demand] activity ideas is challenging.” (week 4), “the workload is a bit heavy” (week 7). By the end of the course she had the lowest self-assessed SOA and her attitudes towards technology worsened (see the changes in beliefs bar graph on Figure 2). The lack of confidence and feelings of being overwhelmed might have affected her overall performance. As a result, her final TPACK only slightly improved, remaining at the Adapting level.

PST C started with relatively high SOA self-assessment, and throughout the course she consistently expressed confidence with using technology. At the same time, she was regularly challenged with pedagogical aspects of the tasks, as can be seen from her survey comments: “I'm confident in setting up and publishing a blog, but I’m not sure about the content of my blog” (week 2); “I think the main challenge at the moment is the [lesson] design” (week 6). Thus, her self-assessed SOA decreased early in the course and did not come back until the very end of the course, when she finally gained confidence in her abilities to design technology-infused lessons. Her increased confidence is reflected in highest growth in self-paced TPACK among the three PSTs as well as her reaching the Exploring level of TPACK by the end of the course.

These results suggest that level of confidence, attitudes towards technology, and design dispositions could have affected the variations in PSTs’ learning trajectories of TPACK.

Conclusions

The study results suggest that a non-disciplinary-specific educational technology course could support the development of PSTs’ subject-specific TPACK by organizing PSTs’ learning as the cycles of immersion – theory – analysis – digital content development, with the first and the last stages being subject-specific, while the theory and analysis aspects were discussed across different subjects. The study findings also indicated that mathematics PSTs’ learning trajectories were influenced by the focus on high-impact teaching strategies. Variations in the individual PSTs’ learning trajectories could be attributed to their attitudes towards technology, beliefs about the role of the teacher as a designer, self-regulating skills, and the level of confidence with technology and pedagogy.

This study contributes to the field in two ways. First, the study extends an innovative visual research method, timelining analysis, commonly used in forensics to an education mixed-method study. The use of timelining extends and deepens understanding of the observed changes in the PSTs’ TPACK over time by visualizing the links between multiple data. Second, the study contributes to the field by examining individual learning trajectories of PSTs’ TPACK *for* online teaching of mathematics and conceptualizing the variations in the paths taken by PSTs. More studies are needed to understand the complexity of developing TPACK for teaching mathematics online.

Interactive Whiteboard: View of prospective primary and secondary math teachers

Lea Marie Müller[1] and Lukas Wachter[1]

[1]Saarland University, Saarbrücken, Germany; leamarie.mueller@uni-saarland.de; wachter@math.uni-sb.de

Many schools possess interactive boards, which can be especially beneficial for teaching mathematics. This paper examines the attitudes of prospective primary and secondary math teachers towards the use of interactive whiteboards. It also shows the requirements they perceive to be important for the school, teachers, and students, and the different areas they would use interactive whiteboards for their lessons. The results showed that many prospective teachers, either for primary as well as for secondary school, have a vague intention of how they can benefit from interactive boards in their classroom. However, it can also be seen that these prospective teachers in most cases do not know about specific applications and overall (dis-)advantages of this technology.

Keywords: interactive whiteboard, prospective teachers, mathematics education, technology

Introduction

Over the past ten years, interactive whiteboards (IWB) have become increasingly popular in German classrooms. This trend spiked after a decision in 2019 to actively finance the introduction of new technology in German schools. Similar developments can be seen internationally as well, such as in North America, East Asia, Australia, and several European countries. For example, Denmark has already introduced digital whiteboards in about 40% of the classrooms by 2015 (Balta & Duran, 2015). Most likely, the number has increased even more in recent years and in the future, IWB will be used almost exclusively in schools. Since the preparation of teachers for future challenges is essential, such as the use of digital media and especially the IWB, this study aims to research on prospective teachers' attitudes towards IWBs and how they are implemented into the education at a German university. To gain an insight into the current situation in Germany, we decide to ask prospective teachers for their own opinion of experience.

Theoretical framework

IWBs are touch-sensitive boards, that can be connected to a computer and projector (Nejem & Muhanna, 2014). More recent models combine both of these functions integrated into the IWB (Saltan, 2019).

Along with tablets and computers, IWBs play a central role in the digitalization of school education. The effect of IWBs have been widely researched by several authors. There are also positive effects of IWBs on all levels of education (e.g. pre-kindergarten: Cozby, 2018; secondary education: Cabus, Haelermans & Franken, 2017; school and university: Jacob, 2014) have been repeatedly shown. In particular the motivational effects of technology, which might only be an illusion (Knaus, 2013), are highly regarded. Studies such as Türel's (2012), which focused on teaching with IWBs, show, that the majority of the 140 Turkish middle school teachers examined lacked the technical and pedagogical knowledge to teach with this technology. Knaus (2013) found similar results in a survey of German teachers. Regarding the usage of IWBs, The IWB is often used merely as a digital notepad (Cabus et al., 2017); a projection surface (Knaus, 2013); a communication, demonstration and presentation device or as an instrument for teacher organisation (Northcote et al., 2010) in schools.

Ellis (2010) researched the effects of technology in the classroom with the SMART board as a prime example and stated that "the impact and implementation of the technology is only as strong as the teachers' understanding of the materials being used" (Ellis, 2010, p. 12). This highlights the need to educate teachers in how to effectively use technology in the classroom. Teachers do not necessarily share this view however. As shown in Knaus' (2013) research on the use of IWBs in German schools and universities, some teachers believe that the use of technologies by one colleague is sufficient for its introduction in a new school. It is clear, that every teacher will have to deal with IWBs – which undeniably hold potential for improvement – in the near future, even though most of them were not trained on how to use them in their university courses (Jacob 2014). Therefore, it is not quite clear how (prospective) teachers are *using* these installments for their lessons. Teachers need to be educated such that they can use technologies like the IWB in a way from which pupils actually benefit.

With that in mind and because of the rapid development of digital technology, it is important that we check, and not just assume, if prospective teachers know the application and limitations of digital technologies like the IWB, especially in the context of mathematics education, and whether such technologies are being utilized in university education.

A desideratum exists regarding the education of prospective mathematics teachers concerning their experiences with IWBs and the usage of this technology in mathematics classes. This inspired the following research questions, that should be answered via a survey within the body of mathematic students at Saarland University – also having possible implications for teaching students in mind:

1. To what extent were students able to gather experience with IWBs?
2. Which digital technologies, particularly with regards to IWBs, would students use in mathematics lessons and how would they use them?
3. To what extent have these experiences influenced students' ideas for using IWBs in school?

Methodology

The survey consisted of an open questionnaire to find out if the prospective teachers are adept at using IWBs and how they would employ them in teaching mathematics. Therefore, prospective teachers enrolled in mathematics courses for primary and secondary schools were asked to participate voluntarily in an online survey. No specific selection was made by age or semester attended. The online survey was open for responses for three weeks.

The first section of the questionnaire asked for sociodemographic data. This was followed by open-ended questions on the subject of digital technologies, in particular the use of IWBs. For this, students were asked which digital media in general they had become familiar with during their studies, whether they have already gained experience with the IWBs, and about their attitude toward this technology. Furthermore, they were asked to name prerequisites for the use of digital technology in school, both at a teacher and at a student level.

After the survey period had expired, both authors independently performed a qualitative content analysis according to Mayring (2015) to identify categories based on the answers given by the students. Next, these categories were compared by both authors. Then, the answers of the prospective teachers were revisited again to ensure the reliability of the categories. Finally, the two authors' classifications of the answers were compared again and their agreement verified. Only data from prospective teachers who indicated mathematics as a studied subject and completed at least thirty percent of the questionnaire were included in the analysis – see next section. In the following section, we will present our results: the main- and subcategories we found as well as the number of students who mentioned each of these categories.

Results

A total of 48 respondents participated in the publicly available survey during the three-week period, whereof 31 met the aforementioned criteria and were thus included in the analysis. Slightly more primary education students (n = 17) than secondary education students (n = 14) participated. The percentage of women was noticeably higher in both groups. Most students in both groups participated in an internship at school. However, only one participant in the primary education group reported having worked as a homework assistant, while three students in the secondary education group have already taught a class, and one of them was a language instructor.

To answer the first research question, the prospective teachers were asked if they had come in contact with IWBs and could gather experience with IWBs and their applications. Table 1 shows that more than 80 percent of respondents have gained some type of experience. Most of this experience was reportedly gained in practical settings such as during the students' own school years or during an internship. Less than half of the students reported having encountered the technology in seminars or lectures at university and only one person during their free time. Almost equal numbers of students indicated that the IWB was used as a projection screen or as a blackboard replacement. The blackboard replacement is usually used at school, while the projection surface, such as for presentations, at university. Only a few students mentioned specific applications or operational scenarios (see Table 1).

Table 1: Experience with IWBs of primary and secondary prospective teachers

No experience (5)	
Experience (26)	- in practise (school) (18)
	- university (13)
	- free time (1)
Insert format (11)	- projection surface
	- blackboard replacement (8)

	- others (6)	- internet - DGS - presenting results - oncoo - writing in graphics - videos

After respondents were inquired about their accumulated experience, they were asked to indicate how often they would use an IWB for teaching. The majority of both prospective primary and secondary school teachers indicated that they would always or almost always use IWBs. Next, participants were asked (to predict) how often they would use IWBs. Students with positive attitudes toward IWBs, were asked how they would use them. Those who did not, were asked why they do not want to use it. Table 2 details how they planned to use this technology in their mathematics class, divided into three categories: *representation medium*, *communication medium,* and *working tools.* As previously shown in the results on this topic, there was a consensus that most participants would use it as a blackboard replacement or to present content. Both groups stated that geometry is a topic that could highly benefit from using IWBs. The respondents from the secondary school group also explicitly mentioned functions as an additional topic where they can find advantages in the use of the technology. More detailed insights into teaching content or scenarios were not mentioned.

Table 2: How prospective teachers would use IWBs

	Use of interactive whiteboards in school			
	never	sometimes	almost always	always
primary	1	1	8	7
secondary	0	1	6	7

Applications in school		
Representation medium (11)	Communication medium (6)	Working tools (6)
- geometry (4)	- board replacement (3)	- apps (Geogebra) (1)
- functions (3)	- teamworking (1)	- online elements (1)
- 3D-models (2)	- interexchange (1)	- presenting results (1)
- complex learning (1)		
- drawing (1)		
- pictures, movies (1)		

Finally, the survey asked about the requirements that must be met at the school level, student level and teacher level to enable the usage of this technology. In Figure 1, the blue side represents the categories of the primary prospective teachers, while the orange side represents the categories of secondary prospective teachers. Subcategories were formed first, which were then grouped into main categories. For this reason, the number of main categories and subcategories are not equal, since some people named several subcategories but were only included once in the main category, or only named the main category. In most cases, the categories from both groups are similar and differ only in a few points.

In total, three main categories could be identified. Almost all respondents indicated that financial resources must be available. Under the category of *technical precondition*, both *hardware*, such as equipment, and *infrastructure* were also frequently mentioned. However, it can be seen that the prospective primary school teachers consider both to be somewhat more necessary than the prospective secondary school teachers. Other subcategories include *teacher training*, *anchoring in curriculum,* and *development of teaching materials*, which can be combined into the main category *educational aspects*. Especially for primary education students, further training of teachers was an important requirement. *Supervisor*, *university cooperation* and *time for lesson planning were* subcategories mentioned by one person and categorized as *other*.

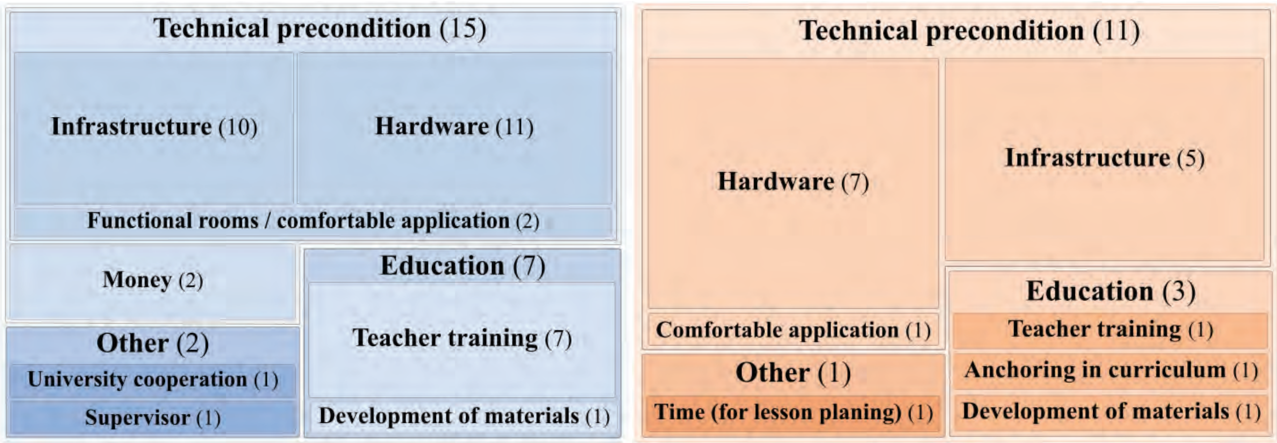

Figure 1: Requirements at school level of primary (blue) and secondary (orange) prospective teachers

Figure 2 shows the requirement at the teacher level. The three main categories *digital media knowledge*, *positive attitude* and *technology enhanced teaching skills* (TET skills) were established. While both groups of prospective teachers surveyed frequently mentioned digital media knowledge in particular. Primary school group focused on it even more frequently than secondary school students. Another important criterion mentioned is attitudes toward digital media, which we refer to as positive attitude. Many respondents expressed the belief that open-mindedness and a willingness to educate oneself further on digital technologies are necessary for their use them in classrooms. TET skills could be identified as another category, which include the subcategories teaching flexibility and application ideas. However, this was only mentioned by a few respondents.

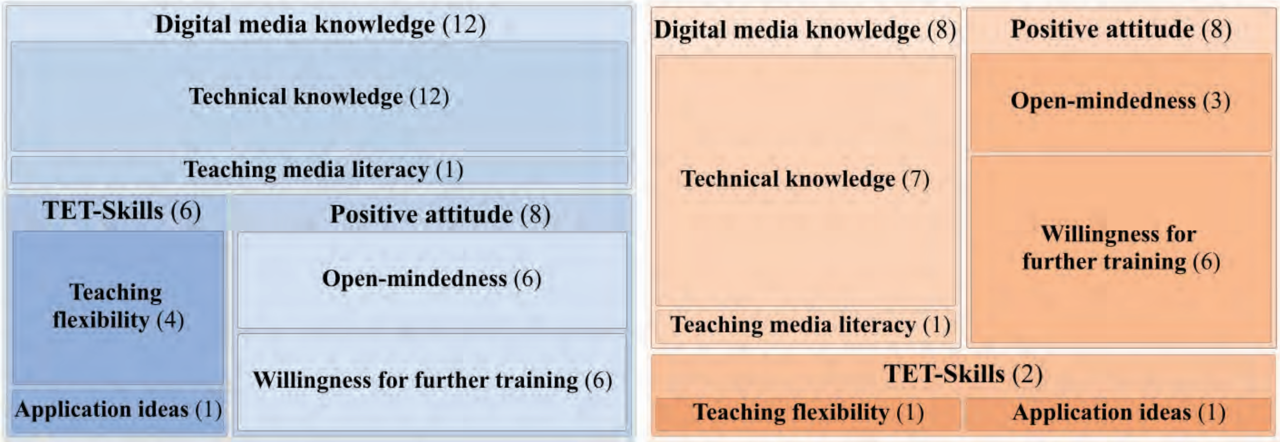

Figure 2: Requirements at the teacher level of primary and secondary prospective teachers

The results of the students' reported requirements for using the IWB are shown in Figure 3. Two main categories can be identified. In the primary school group, the results show disagreement between prospective teachers as to whether or not students need to have prior experience and knowledge of digital media. On the other hand, the majority in the secondary school group agreed that students need previous knowledge and experience. Two respondents in both groups commented that the students already have previous knowledge and experience to build on. Furthermore, the social skills of the students are also considered important, with prospective teachers from the primary school group citing motivation most frequently.

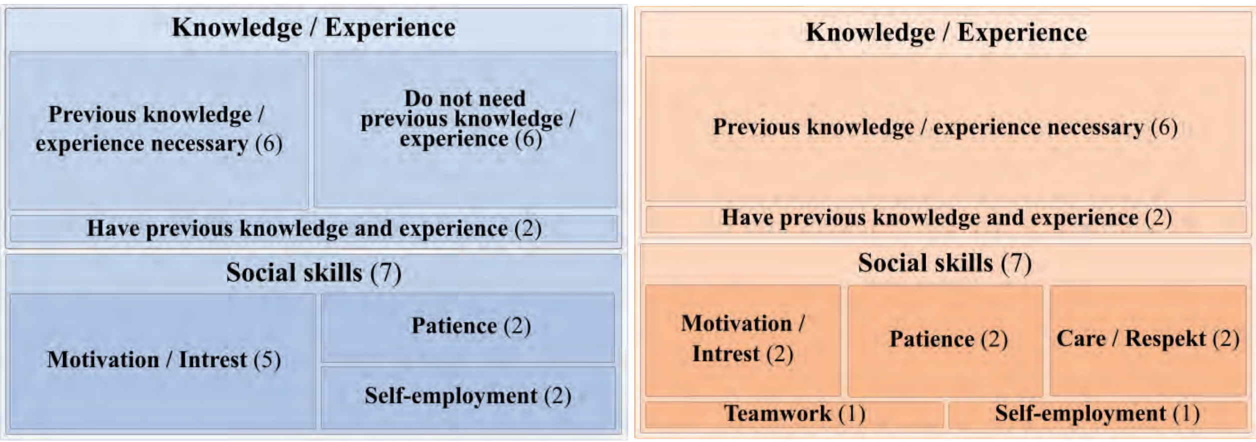

Figure 3: Requirements at the student level of primary and secondary prospective teacher

Overall, we can see that most of the interviewed respondents have some idea of what is needed (by the teachers, students and authorities) to succeed at using IWBs in the classroom, even if the number of explicitly named ideas for use-cases is pretty low. These results and their implications will be discussed in the following section.

Discussion

The results show that almost all surveyed prospective teachers have a positive attitude toward IWBs. This matches the findings of other authors (e. g. Warwick & Kershner, 2008; Littleton, Twiner & Gillen, 2010). While the majority of the respondents would use the IWB for teaching, they are only familiar with a few applications. Interestingly, although many participants chose infrastructure as a requirement for utilizing IWBs, only two respondents said they will use them for *online elements* and *movie / pictures,* where internet is most likely needed. However, it should be noted that there are also negative sides to the ability to live-research things during class, such as misinformation among various websites. Furthermore, teachers can show videos in the classroom. Online mathematics tutorials, which claim to provide quick and easy explanations for certain topics, also often contain oversimplifications and mathematical errors. This shows that prospective teachers have to learn how to correctly handle IWBs and the consequences of their application, such as quick access to online information just as students have to do at school. Given this fact, it is good to see, in this study a lot of respondents know the relevance of advance training. This result also underlines the importance of further training, because the teachers are uncertain about whether the students need previous knowledge and experience, which was probably not addressed in their previous study at the university.

Although we have to consider the rapid development of technologies like IWBs, a short comparison of the categories found in this paper and the research of Northcote and colleagues (2010) shows that the main ideas regarding working with IWBs are closely related to each other and seemingly stable over time. It follows that universities should properly integrate the technical knowledge and competencies needed to work with IWBs in the classroom into prospective teachers' training, just like didactic knowledge. This includes, for instance, discussing their advantages and disadvantages in certain situations, giving examples on topics that could be adapted for this technology, and also teaching about how the IWB is operated so that technical errors during classes can be reduced to a minimum. Especially in mathematics education, diverse applications exist to utilise the IWB as more than just a surface for presentations or as a blackboard replacement. In maths teacher training, there are benefits to using simple applications, which are more comfortable and intuitive. The majority of all surveyed students already mentioned presenting and operating with 3D-Models in the context of teaching geometry, e. g. using the software GeoGebra. One key advantage of this software is that it allows the user to operate on the models, e. g. to rotate them or zoom in and out. This can be done *directly* on the board in front of the students, in contrast to the software found on laptops, beamers or tablets (e. g. Kohls, 2012) and does not require any additional instruments.

Applications exist for other topics of mathematics as well. For example, in primary education, the students learn to read the clock. Showing an analogue clock on an IWB enables the teacher to hide and unhide certain elements of the clock and change its appearance and alter other functions without having to deal with the downsides of a homemade clock (not as precise, fragile, etc.). In the area of probability, an IWB can be useful to show a wheel of fortune with adjustable sections. Details can be hidden or revealed and sections can be replaced. In addition, the graphics, together with dynamic calculations related to them, can be integrated directly into the 'classic' chalkboard painting. Furthermore, not only for special mathematics applications, the IWB has the advantage of saving these panels and chalkboard presentations so to use and modify them repeatedly.

This study shows that there is a need for further debate on digital media such as the IWB. Therefore, more exploration into this topic is necessary, which might result in the cooperation with schools or universities to develop further ideas. It should be kept in mind that this is a relatively new topic for many fields and institutes, even at the university level and a knowledge of such research should be transferred to other digital technologies and media. The rapid development of digital technologies and their applications constitutes a major, novel challenge for everyone. Because of this, it is also a central purpose of the university and further research to find fields of applications and examine them carefully. Only in this way can prospective teachers of mathematics, but also of other subjects, be prepared for their further school life and accompanying tasks.

What pre-service teachers observed from their virtual mathematics teaching practice

Paola Ramírez G.

University of Talca, Chile; paola.ramirez@utalca.cl

This paper presents the preliminary findings of an ongoing project regarding what pre-service teachers and facilitators learned while teaching in an online environment during the COVID-19 pandemic in 2020. Using narrative inquiry as a methodology, this initial analysis suggests a need to examine their general descriptions in detail to recognise which actions pre-services teachers specifically identified in their own practice and what they noticed about their mathematics teaching.

Keywords: Observations, pre-service teacher, noticing, facilitator, online lesson.

Introduction

For pre-service mathematics teachers, one of the main components of their education is teaching practice, which enables them to gain experience, practice their professional skills and develop knowledge of how to conduct mathematics lessons at the school level. Teaching practice thus plays a crucial role in the learning of pre-service teachers (Guyton & McIntyre, 1990; Le Cornu, 2012) by enhancing their professional development. Pre-service mathematics teachers are supported during their teaching practice by experienced mathematics teachers and other academics, who function as 'mentors', 'supervisors' or 'facilitators'. However, little attention has been paid to facilitation (Even, 2008; Kelchtermans et al., 2017). By contrast, rich and varied research has considered pre-service teachers' professional identities; their influences during lessons (Zhao & Zhang, 2017), and their teaching values (Mergler, 2012). Moreover, it has been recognised that experienced teachers must improve and update their knowledge (Genç, 2016) to support pre-service teachers effectively.

Research has shown that concerning teaching practice, "pre-service teachers adopt survival strategies during this stage, avoiding risks or taking the initiative so as not to reveal their weak points; consequently, they do not develop the real professional competence that is expected to develop at this stage" (Correa Molina, 2011, p. 78, translated from Spanish). In particular, in the Chilean context, where this study is ongoing, one of the weaknesses noted about pre-service teachers is their failure to link practice and theory (Comisión Nacional de Acreditación (CNA), 2018). This points to a lack of knowledge about what is learned by pre-service teachers during teaching practice and specially in online environments. Even more, recent research shows that "pre-service candidates did not have the opportunity to demonstrate mastery of specific teacher performance expectations within the distance learning format" (Hill, 2021, p.1); therefore, knowing that there is an "evolution and transformation of the classroom with the growing integration of the internet and interactive digital devices into mathematics teaching and teacher mathematics teacher education" (Engelbrecht et al., 2020, p. 825) there is an urgent need to understand in greater detail what is learned through teaching practice, to include virtual mathematics teaching practice. One way of doing so is for the facilitator to note the details of pre-service teachers' actions when teaching and supporting pupils. The aim of this paper is to present the preliminary analysis of a study on what pre-service teachers and facilitators learned while teaching in an online environment during the COVID-19 pandemic in 2020. Our research question is: When pre-service teachers conduct their mathematical practice virtually in a school, what characterises their learning? Using narrative enquiry as a methodology, we examine what pre-service teachers noticed about their own practices, including whether and how these observations were linked to the discipline of mathematics. The three participants were pre-service teachers who were doing their final teaching practice in a school virtually, and the author of this paper was the facilitator of these participants.

Theoretical Framework

To consider the teaching practice of pre-service teachers as a situated professional experience that leads to a lack of articulation of the link between practice and theory, I examined what the pre-service teachers. and the facilitator. learned about what they learned about their own skills in their teaching practice and what this revealed about their learning during interactions with others (experienced teachers, students, and facilitators). As a theoretical framework, I referred to the discipline of noticing (Mason, 2002, 2011), which has been considered a means to promote professional development (i.e. Barnes & Solomon, 2013) and an essential part of pre-service mathematics teaching practice (Llinares, 2013).

Studies of noticing are usually carried out from a first-person perspective, as this way of approaching learning involves looking at one's own professional practices, thus allowing for the observation and investigation of professional pedagogical practice. This enables pre-service teachers in their professional practice to identify more feasible ways of working, consider incidents they experienced during their pedagogical practice, and discuss what they have noted professionally, as well as which characteristics others have recognised (Mason, 1989). Such an approach validates the observed actions that differ between pre-service teachers' own practices and those of others and allows teachers to become mindful of their own actions so they can act differently in the future and make effective changes (Mason, 2011). For example, if a student asks what 'definite integral' means, an 'automatic' answer is often 'the area under the curve', but noticing and applying the professional gaze involves "arranging to alert oneself in the future so as to act freshly rather than automatically out of habit" (Mason, 2011, p. 37); thus, providing a different type of answer becomes possible. Learning to notice professionally allows pre-service teachers, through the observation of their teaching practice, to distinguish the professional components of actions and avoid using generalities, such as 'it was an adequate class'. This is done by paying attention to the details of mathematics-related actions, which in turn helps them to give professional answers to mathematics questions from students.

Finally, although it is expected that future mathematics teachers will professionally consider their mathematical knowledge and while there are analytical models allowing this knowledge to be studied (e.g. the mathematics teacher specialised knowledge [MTSK]; Carrillo et al., 2013), the aim of this ongoing research was not to examine pre-service teachers' knowledge; rather, by working with the discipline of professional noticing, the study considered the actions that promoted learning during mathematical teaching practice, enabling pre-service teachers to act consciously.

Methodology

I used narrative inquiry (Clandinin & Huber, in press) as a methodology, which means the researcher sought to understand the experiences of the participants during their mathematics teaching practice in an online environment, as expressed by their stories. In this paper, I present their experiences through stories told by Sue, Jonah and Harry, considering the meaning of their experiences through the stories they told and the actions they observed.

To conduct the analysis, I used a modified version of Mishler's typology, which is a method of narrative analysis, which means "focusing on making meaning of events and experiences through the researcher's tellings" (Kim, 2016, p. 198), "imposing a told on the telling: identifying a story pattern" (Kim, 2016, p. 205) looking for emerging patterns in stories, chosen it without predetermined themes for the story to tell in advance.

Methods

The participants of this ongoing research were pre-service teachers doing their final teaching practice in two different Chilean schools during 2020. The criteria for their selection were that the teacher conducted their practice in an online teaching–learning environment using tools that involve access to live chat, audio and video conferencing, shared whiteboard, virtual "hand raising" and a break room; and the teaching took place in "real time" via the internet. For pre-service teachers in Chile, this teaching practice usually occurs in the last years of their study towards becoming a mathematics teacher.

The lessons taught by the participants took 45 minutes each. Two of the three participants were in a school that received only students with special needs, so the number of pupils that they have per lesson varied between three and four. The third participant was in a school where the number of pupils per lesson was 30 on average. In addition, the participants oversaw designing and teaching their mathematics lesson to their students over a period of three months and they attended to presentation on the discipline of noticing in mathematics classes.

I observed three lessons per pre-service teacher within the online teaching–learning environment and although it is recognised that one of the practices to support pre-services teacher on their lesson is through the use of observing a video of their own practice (i.e., Segal et al., 2018), I gave to them the observations of each lesson in a written manuscript to be read by them. The written transcripts consisted of a detailed dialogue of what the teacher and students were saying to each other). The reason for given those transcripts to the participants is because "transcripts can help reveal details that are easily missed when watching a video" (Reid et al., 2014, p. 373)

Having given the observation manuscript of the lesson to the participants, bearing in mind the discipline of noticing, I asked to them read it previous to collect research data through three separate conversational interviews about what the participants had observed during each online classroom, the length of each interview was on average one hour, and each was video-recorded within the video conferencing platform. After that, each participants wrote reports of what they had noticed in their own mathematical teaching practice and they submitted this document to an online platform. Following Mishler's typology the method of finding common patterns in the transcript from the interview as well on the written report was highlighting and coding the common characteristics that constituted a pattern of noticing on the data collected.

Results

The following analysis constitutes the preliminary findings regarding the common patterns of noticing among the three students—Sue, Jonah and Harry—based on the interviews and the written reports about what they observed about their own practices as pre-service teachers in charge of online classrooms.

The tension of teaching as a pre-service teacher

Sue was sitting at her desk waiting to start her class. She had to wait until the teacher stopped speaking before she could start her lesson; afterwards, she told me in the interview, '*I realised that when I read, according to my observations, Mary* (referring to the teacher responsible for the class in which she was doing her practice) *interrupted me sometimes. I waited to speak because she was saying something, and I thought I would make my point later, but by then she had already made it*'. I noted Sue's concern about the tension involved in being a pre-service teacher with another teacher close to her.

This tension of being a pre-service mathematics teacher was also experienced by Harry, but in a different way. His concern was, '*I always feel that students don't look at me as a friend…I know when, someday, I'm in a school, they will want to speak about their problems with me*'. He had the idea that a teacher should be a friendly person who can speak about things other than mathematics, but he noted that he was not yet a teacher; he identified himself as only a pre-service teacher who will become a teacher in the future, but for me, he is a teacher now, because he is teaching.

The importance of reflecting on details

By asking '*What do you think about the observation? I don't know what type of observations you have experienced before but…*', I was trying to provide the context for beginning to speak about the mathematics observations, bearing in mind the discipline of noticing and how to give sensible and professional mathematics answers. Sue said, '*I like that you generated a dialogue because, in general, when other teachers observed me previously, they only noted key things; that's all*'. She added, '*You gave us every detail*'. Harry commented, '*I was expecting a critique of my work, more judgments*'. His experiences of other instances of practice feedback were structured observations that seemed to him to be criticisms.

Going back to the details given in the transcript, Sue explained something about 'c'. Not knowing to what she was referring, I asked her to go to the relevant page of the transcript and explain a little more about 'c'. She found the point and exclaimed, '*Here*!' and relayed the following dialogue about Pythagoras' theorem in her class:

> Sue: We use a little formula to calculate c. Who is c?
> Students: The results.
> Sue: Hypotenuse or cathetus?

She added, '*I realised that I was asking about c as a person*. *I should have asked "What is c?"*' Sue was concerned about her mathematics expression and what she could do about it. How could she examine her own speech while being aware of the mathematics happening in that moment? Were there enough questions? I asked: '*What draws your attention in your observation?*' Her first observation was that although it was a story relating to mathematics, she was identifying the long side of the triangle, apparently working from her memory as a student and seeing that the ‘c’ in the ‘little formula’ (as she referred to Pythagoras’ theorem) was the result of an operation. Despite the richness of the details given by Sue to observe her action, I recognised that she was perhaps only noting the specific mathematics around the ‘c’ but not providing more information about a possible action that could be undertaken concerning the ‘c’ idea.

Jonah stated, ‘*I would like to extract some part of the observations of my facilitator*’:

Jonah: D (referring to the problem level); It looks a bit complex.
Student: Teacher, let me think about it, because I’m sure I have seen it before.
Jonah: It is interesting. I wanted to give you this [question] because…
Student: I’m sure we have seen it before.
Jonah: You bet. Let’s…

He noted Regarding this dialogue, we can see that *the student was interested in solving a complex problem*[1]*… At that moment, I took the decision to give him more time, but half of the class time could be lost, so I decided leave the problem to the end, but that didn’t happen … Looking back, I see this as an important chance that I lost.* Jonah wrote about his actions, reflecting on his own mathematical knowledge, his interruption of the student, and his concern when looking back on the class. He also observed, “*it looks like an error in the transcription* (shown below)*, but it’s not. I´m speaking about the whole problem, answering my own questions, and this type of action will never be favourable for promoting the autonomy* (of my students). *It has started to become something automatic’* (referring to probability lessons).

Jonah: That’s the thing about probabilities; three can come out many times on one day, but not on another.
Jonah: What are the favourable cases?
Jonah: Let’s look here. For every number that I get here, I have six chances of getting it. That’s 36
Jonah: So the probability that I get Tom …
Jonah: You understand? It wasn’t an easy problem to solve, but if you want to solve it, you must pick numbers close to seven.

He observes the transcript and from there, he took account that in his lesson, he was speaking all the time (which he acknowledges). Reflecting on his actions, as prompted by the transcript, he was able to understand more deeply his own learning without me saying, ‘You have been speaking all the time in your lesson’. I wanted them to learn from their own observations, avoiding compulsory descriptors, such as, ‘Does the teacher give the goal of the class? Are the students participating in the lesson’? In a similar way, Harry said, *I realised there is a lot of Harry speaking (in my transcript). I literally take the microphone…and I don’t allow the others to speak. I said to her* (referring to a student), “*We are seeing ratio. It’s a ratio,” and I didn´t give to her the opportunity to speak*. After going back and

[1] In the Chilean context, it is very common to encourage students to writing in the third person. Although, in this study, the participants were allowed to write in the first person, some of them wrote in the third person or used a hybrid of the first and third person.

reading his transcript, he noted what he had done on their teaching, seeing its importance in the way as he teaches his mathematics lesson.

Decisions and mathematical consequences

The students spent time speaking about their actions but without directly mentioning mathematics, so I started trying to direct the questions towards actions relating to mathematics in the transcript. Sue told me: *I knew the difference between eight to the power of two and eight times two, and I think they understood that, but I think they forgot it because, when I asked them, they still said that eight to the power of two was eight times two*. She observed she did not have the mathematics resources to correct the errors. How should she start giving professional answers about mathematics? Why did she give the same answer to the students if they were still making the same error? I was concerned with this situation, so I asked her, '*How can we give a different mathematical answer while considering the idea of doubling or the power of two?*' Sue replied, '*Developing the power*', detailing her own knowledge of the power and what she brings to her lesson.

Harry, in a similar way, seemed to decide to stop talking about mathematics because '*I didn't want to add more concepts to what they already had…I know what I said about the addition rule, but it is not as I said*'. This showed the paradox of deciding 'the best' mathematics for students, but what were the consequences of this decision? Is there a 'best' mathematics to be learned? Who decides this? Jonah said, '*I was thinking a change of measurement was trivial and the students must know this, because it is usual for me to know this as a Chilean citizen, but I failed on this activity*'; thus, he took responsibility for his mathematics actions. *I asked*, '*Thinking about the change of measurement and ratio that were part of your lesson, how would you take account of them?*' Jonah replied, '*In my next lesson, I will start with the change of measurement and ratio, presenting some double entry tables so that they can see they are ratios*'.

Discussion

In an on online mathematics teaching context, what the pre-service teachers noticed in these initial findings reflects the importance of discussing the details of their practice, recognising the tension between becoming, but not yet being THE teacher, and I ask 'who defines being a mathematics teacher?' 'are we considering what type of pedagogical identity is happening on the pre-services teachers?' Is it enough to teach mathematics to be considered a mathematics teacher? As van Gogh (2017, p. 45) asserted, 'One becomes a painter by painting'; likewise, one becomes a teacher by teaching".

This initial analysis suggests a need to move from general descriptions towards giving specific details of pre-service teachers' actions to encourage them to reflect on their own actions and what they notice during mathematical teaching practice, such as seeing the mathematical consequences of their decisions during teaching practice, as the stories in this narrative analysis have shown.

When presenting observations of the practices of pre-service teachers, moving to uncontrolled (but no less effective) noticing by each participant regarding what the pre-service teachers observed about their own practices in their reading of the transcript, allows them to link their own mathematics with their pedagogical practice and perhaps foster effective learning in their students.

Finally, the use of technological tools that involve video conferencing and recording in a research context facilitated the collection of the data. However, providing the transcript to the pre-service teachers allowed them to detail their own mathematical practices and their own learning. The pre-service teachers' awareness of the use of this type of technology in their lesson seems low, perhaps because they are building a windmill instead of a wall concerning technology in their own teaching practice. That is, as Brunetto et al. (2021) argue, a teacher can build a wall or a windmill when the wind changes the usual class environment into a virtual one, such as with the current pandemic.

A videogame for supporting teachers' scaffolding in whole-class discussions

Cintia Scafa Urbaez Vilchez[1] and Alice Lemmo[2]

Videogames are becoming a topic of interest in mathematics education. However, research in the field does not seem to clearly highlight the role that a videogame environment has in supporting teachers in promoting teaching-learning processes. The aim of this paper is to analyse how a videogame for learning can support a teacher in scaffolding relational thinking during whole-class discussions. We observed that the videogame does not explicitly seem a benchmark for offering scaffolding interventions, but the teacher states that observing students playing is relevant for orchestrating discussions, especially in anticipating and monitoring students' processes during the classroom activities.

Keywords: Game based learning, relational thinking, scaffolding.

Introduction

In recent years, the widespread use of digital games for learning has opened new frontiers for research in education, whereas Connolly, Boyle, Hainey, McArthur and Boyle (2012) show that this interest is frequently speculative and a lack of empirical evidence about the effectiveness of games. Concerning mathematics education, several research studies address the potential, promises, and pitfalls of digital games for mathematics learning by measuring, monitoring, and analysing the development of students' sense-making as they engage in games technologies, both in and out of school (Lowrie & Jorgensen, 2005).

In literature there are different and independent definitions of videogames for learning. For our purposes, we choose to consider the one provided by Perrotta and colleagues (2013), who describe game-based learning (GBL) as "[…] the use of video games to support teaching and learning." GBL could become a tool that supports teachers specific teaching and learning targets. However, it is important to select a specific area to investigate from both a mathematical and educational perspective.

In this study, we are interested in exploring the role of a GBL in supporting teachers' scaffolding during classroom discussions on relational thinking.

Theoretical framework

To achieve our goal, it is necessary to clarify what relational thinking is and what types of scaffolding teachers could carry out during classroom discussions.

Carpenter, Franke and Levi (2003) describe *relational thinking* as examining two or more mathematical ideas or objects, looking for connections between them and analysing or using those relationships to solve a problem, to decide, or to learn more about the situation or concepts involved. Carpenter, Levi, Franke and Zeringue (2005, p. 54) define relational thinking as "looking at expressions and equations in their entirety rather than as a process to be carried out step by step". In other words, relational thinking regards the use of fundamental properties of numbers and operations to manipulate numerical expressions rather than following sequences of procedures for reaching a result.

Carpenter and colleagues (2003; 2005) mentioned many times the importance of teachers' effort in designing suitable teaching and learning environments. The authors suggest engaging students in the solution and subsequent discussion of specific tasks; in particular, solving true/false and open number sentences could provide a flexible context for representing relations among numbers and among operations. However, involving students in well-designed tasks is not enough (see for example Lampert, 2001); one of the goals of research on relational thinking is how teachers might foster its development and its use to learn arithmetic. Therefore, the role of the teacher is crucial, and it could be defined as scaffolding, that is the "[...] support given by a teacher to a student when performing a task that the student might otherwise not be able to accomplish" (Van de Pol, Volman & Beishuizen, 2010, p. 274)

Carpenter et al. (2003; 2005) highlight the relevance of scaffolding, but it seems that the role of teachers and how they could scaffold students are not clearly defined. However, in most of their papers the authors present examples of interviews with students and transcriptions from discussions with their teachers. Such examples allow us to identify four kinds of strategies that teachers could use to provide scaffolding: (1) choosing suitable task to administer and then discuss with students; (2) inviting selected students to intervene during the discussion; (3) inventing or introducing new tasks to clarify or share the emerging mathematical ideas; (4) encouraging students to invent new tasks to clarify or share the emerging mathematical ideas.

In this scenario, a GBL could offer several scaffolding opportunities; for example, it could present a large number of suitable tasks in line with the ones proposed by Carpenter and colleagues (2003) (1). This large body of tasks could also allow teachers (3) and students (4) to invent new examples of similar tasks based on reasoning by analogy. Finally, the log files collected by the digital environment could permit teachers to select students for discussion considering their achievement in the game (2).

Methodology

To understand if and how a game-based learning could help teachers scaffold activities on relational thinking, we structured a field trial as follows.

1. We planned a teacher training focused on how to use the videogame, on relational thinking and the role of the teacher during whole-class discussions. Furthermore, we provided the teacher with some theoretical and methodological guidelines.
2. We designed the videogame tasks to be equivalent to those proposed by Carpenter and colleagues (2005).
3. We provided the teacher with worksheets to highlight the solution processes, which are not visible from the videogame log files. Moreover, she could use a web interface, where scores, access and play time and other useful information are reported.
4. We asked the teacher to present the videogame and the worksheets to her students and then to orchestrate a classroom discussion. Finally, we interviewed the teacher.

SuperFlat Math

"Matematica Superpiatta" (SuperFlat Math) is a game-based learning (GBL) about Mathematics developed by Prof. Leonardo Guidoni, from the Department of Physical and Chemical Sciences of the University of L'Aquila. It consists of a sandbox videogame that enables primary and lower secondary school students to explore a blocky, procedurally generated 3D world. This videogame is divided in mathematical activities, which are composed of different "minigames", that are short puzzles at increasing levels of difficulty.

In our trial we asked students to play two activities: "Parkour" and "Swimming Pools". The first one (Fig. 1) consists of a perilous uphill path, which in some points presents a number sentence or an expression with two possible solutions. Players should choose the correct one in order to advance in the path. The first half of Parkour minigames presents number sentences in which students should find the correct solution, whereas the second half contains an equivalence between two expressions.

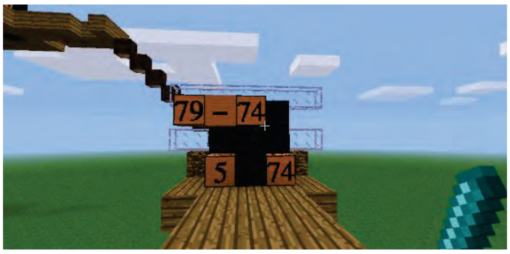

Figure 1: A Parkour minigame

The minigames in Swimming Pool (Fig. 2) consist of a pool full of block numbers from 0 to 100 and an open number sentence. The goal is to find the correct block number within the pool and place it in the sentence. The first half of Swimming Pool minigames contains an open number sentence with two operations and one missing number, whereas the second half presents expressions with parenthesis and two or more different operations.

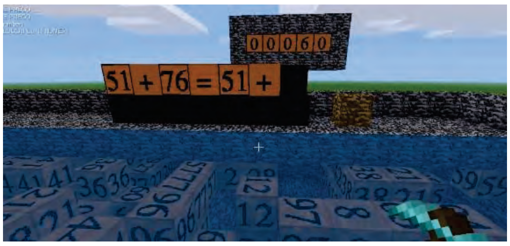

Figure 2: A Swimming Pool minigame

An additional feature of SuperFlat Math is the message given to players on the correctness of their answers. If the answer is correct, players gain points that could be converted in rewards.

A web interface has been developed, called "CLARAS" (CLAssroom Report And Supervision), which enables teachers to monitor students' achievements and to collect useful information about access and play time, scores, number of correct answers, number and type of wrong answers, number of attempts, and so on. This interface helps teachers and researchers identify students' misconceptions and solutions to the given tasks.

Worksheets

According to Carpenter, Franke, and Levi (2003), the easiest way to start a classroom discussion on relational thinking is to assign students true/false and open number sentences. For this trial we structured two worksheets, which were focused on specific number properties and ways of thinking about number operations: the first one was composed of 17 true/false number sentences, while the second one was composed of 13 open number sentences. We asked students to justify their answers for each task so as the teacher could understand the process carried out to solve it.

The true/false tasks concern three main topics: conception of equal sign, properties of addition of natural numbers, and properties of multiplication of natural numbers (Table 1).

Table 1: True/False tasks in worksheet1

Conception of the equal sign	Properties of addition	Properties of multiplication
1. $3+5=8$ 2. $8=3+5$ 3. $3+5=3+5$ 4. $8=8$ 5. $4\times 2=0+8$ 6. $9+5=14+5$ 7. $8\times 2+5=8\times 2=16+5=21$	8. $3+5=5+3$ 9. $10+2+8=10+10$ 10. $3+5=2+1+5$ 11. $20+7+33=37+40$	12. $8\times 6=8\times 5+1$ 13. $10\times 2=8\times 2\times 2$ 14. $15\times 2=3\times 10$ 15. $6\times 5+6\times 3=6\times(5+2)$ 16. $3\times 11+7\times 3=18\times 3$ 17. $7+14=7\times 4$

The open number sentences regard three main topics: properties of addition/subtraction of natural numbers, properties of multiplication of natural numbers, and more complex expressions with the four operations (Table 2).

Table 2: Open number sentences in worksheet2

properties of addition/subtraction	properties of multiplication	more complex expressions
1. $25+16=25+\cdots$ 2. $25+32=27+\cdots$ 3. $\ldots+60=57+83$ 4. $30-25=20-\cdots$	5. $7\times 3=\cdots+7$ 6. $8\times 3+8=8\times \ldots$ 7. $2\times 3\times \ldots=6\times 5$ 8. $2\times \ldots\times 7=14\times 5$ 9. $25+20=5\times \ldots$	10. $32+(20-7)=32+\cdots$ 11. $25+75=25+(30+\cdots)$ 12. $(\ldots+\cdots)-17=28-15$ 13. $25+\cdots=25+36:3$

Some of the tasks proposed in the worksheets were also added in Swimming Pool and Parkour minigames.

Teacher training

We structured the teacher training in three meetings. In the first one we asked the teacher to play SuperFlat Math as to familiarise with the game environment, the instructions, and the kind of proposed tasks. In the second meeting we presented to the teacher some examples about relational thinking taken from the textbook by Carpenter and colleagues (2003). Finally, in the third meeting we showed her CLARAS and its main features. We also provided the teacher with guidelines, where the fundamental topics of each meeting were summarised.

Sample and data collection

The sample is a fifth-grade classroom of a primary school located in a region of central Italy. The classroom is composed of 22 students, 14 males and 8 females. The whole-class discussion was orchestrated by their mathematics and science teacher.

The teacher lets students play for about 2 hours, then she assigns them the worksheets to be solved in small groups (composed of three students) and finally she orchestrates a whole-class discussion.

We asked the teacher to observe students play, collect, and read all the worksheets and record the whole-class discussion.

Results

The teacher conducted several classroom discussions involving all the topics proposed in the worksheets. In this result section we focus on the description and analysis of the classroom discussion about the conception of the equal sign. The discussion lasted 1 hour and 23 minutes and almost all present students got involved.

In the following we report and describe some discussion transcripts. We selected those that highlight the key role of teacher's scaffolding. We present a first example in which the teacher picks out some of the 7 tasks related to the conception of the equal sign, a second one in which she calls some students out to intervene in the discussion and a last one in which she introduces new tasks in order to clarify the emerging mathematical ideas. In the first example, we show an excerpt in which the teacher effectively selects only few tasks from the worksheet1 in the following order: $3+5=8$; $8=3+5$; $8=8$ respectively the task 1, 2 and 4 in the worksheet1. She starts by pointing out the difference between the first two sentences.

Teacher:	Student A, how do you read that [referred to $8=3+5$]?
Student A:	Eight equals three plus five.
Teacher:	Ok, Student A. And how do you read the first one [referred to $3+5=8$]?
Student A:	Three plus five equals eight.
Student B:	They [referred to the numbers] have been changed.
Teacher:	What have been changed?
Student B:	The results... Because in the first one it was in the first place, in the second one it was in the last one.
Teacher:	Do you agree? We all agree, do you all think that between the two [referred to $8=3+5$ and $3+5=8$] the results have been changed?
Student C:	To me, it is easier to decompose the second one [referred to $3+5=8$], 8 in $3+5$ and $3+5$ is equal to three plus 5 because we know that one can put the equal sign when either the first or the second part give the same result, so it is like $3+5$ is equal to 8 ...

The discussion goes on, and all at once the teacher asks some students if they have already met sentences of the form $8 = 3 + 5$ and if they consider it as equivalent to $5 + 3 = 8$. Thus, she encourages the class to invent new equalities equivalent to $5 + 3 = 8$ and $8 = 3 + 5$. In this case, almost all students answer autonomously with different examples like $2 + 2 + 2 + 2 = 1 + 1 + \cdots + 1 = 0{,}9 + 7{,}1 = 13 - 5 = \cdots$ During this part of the discussion, we noted that the teacher exhorts students to continue suggesting equivalent sentences. Then, we report a second transcript example in which the teacher selects certain students based on their answers in the worksheets. In the following, the classroom is discussing about the sentence $9 + 5 = 14 + 5$. The teacher calls Student E out because her strategy is the same as that of another one.

Teacher:	Since we are dealing with small numbers, we know which is the result of both sides of the equal sign. But before, when I asked if the sentence [referred to $9 + 5 = 14 + 5$] was true or false, Student D explained why it was false without telling the result. Has someone reasoned in the same way? Student E?
Student E:	I did not compute $9 + 5$ either. I saw that five was in both the additions, only 9 and 14 changed. Since 14 is greater than 9, the results could not be the same.
Teacher:	Ok. Student F.
Student F:	I saw that five was in other positions, it was the number that was always present in both operations, so I look at the first two addend of both operations and I realize that, since 14 is greater than 9, the result [in the right side] should be greater...

After discussing with Student E, the teacher explicitly calls Student F out, because she remembers she used a relational strategy to solve the task in the worksheet1: she compared the addends 14 and 9 without any computation.

Finally, in the subsequent example the teacher does not look for a task in the worksheet or among those proposed in the videogame, but she invents a new one, in order to consolidate the reasoning explained in the previous transcript by Student F.

Teacher:	According to you, this reasoning... Now we have small numbers... But let's try to think with bigger ones. According to you, could this reasoning help us in solving: $3527 + 1528 = 3682 + 1528$? Are they the same?
Student F:	No!
Teacher:	$3682 + 1528$. Are they [referred to the sentences] the same?
Chorus:	No!
Student G:	No, no, no. It is the same... It is the same...
Student H:	It is the same.
Student G:	Because... 3527 is smaller than 3682, but the other addend is the same.

At first, students do not easily understand teacher's example, but afterwards one of them realises that there exists a similarity between the invented task and the one from the worksheet1. Then, the teacher carries on the discussion emphasizing the potentiality of the student's observation: $a + b = a + c$ if and only if $b = c$. Finally, a student concludes with the following remark: if $b > c$, then $a + b > a + c$.

Discussions

In this section, we analyse the results described previously by exploring the role of a GBL in supporting teacher's scaffolding during classroom discussions on relational thinking.

In the three examples, we highlight when and how the teacher uses the four scaffolding strategies described in the theoretical framework. Therefore, in all the three examples, the teacher chooses the tasks to discuss with students without following the order of the tasks in the worksheets (1) and she invites selected students to intervene during the discussion considering their responses in the worksheets (2). In the first excerpt, the teacher encourages students to invent new tasks to clarify or share the emerging mathematical ideas (4), while in the last example she invents a new task to clarify the emerging mathematical ideas (3).

We assumed that a GBL could have offered several scaffolding opportunities. Thus, it could be interesting to observe the role of the videogame in this trial. During the interview the teacher reports she did not rely on the web interface, because it only displays correct and wrong answers. Indeed, she calls students out during the discussion considering their answers in the worksheets and not referring to game scores. We also supposed that the large body of tasks could have allowed teachers and students to invent new examples of similar tasks based on reasoning by analogy. In fact, the examples provided by students are not like the ones presented in SuperFlat Math ($2+2+2+2=1+1+\cdots+1=0{,}9+7{,}1=13-5=\cdots$) but probably they seem to have been invented considering other contexts. However, the teacher invents a task very similar to the ones proposed in the videogame. In line with this data, it seems that GBL offered to the teacher only one of the four scaffolding strategies, but we asked her if the videogame was useful in this trial. She answers affirmatively: in particular, she states it was remarkably interesting to observe students while they were playing in order to discover their strengths and weaknesses on equalities. Furthermore, the teacher maintains the videogame was an essential feature in the trial because of its motivational aspects, such as its power to captivate students' attention or the goals and rewards within the game. Finally, the teacher declares that the discussion would not have been the same without the videogame.

Teacher:	To us, as primary school teachers, the videogame is very important. We should intervene more during play time so that the following activity with worksheets enables students to consolidate all concepts emerging from the game. In this way, with the worksheets we can verify if all our work was profitable. For me, the videogame is essential, and it should become a pleasant practice.

Conclusions

The aim of this paper is to analyse whether and how SuperFlat Math could support teachers in scaffolding activities that involve relational thinking. To do so, we organized a field trial which involved three phases: playing the videogame, written activities with worksheets and a whole class discussion. Before the trial, we structured a three meetings teacher training in which we proposed some theoretical references on relational thinking, and we presented the videogame and the web interface. From the discussion analysis we can determine that in several scenarios the teacher performed all kinds of expected scaffolding. The excerpts reported in the above section are unambiguous evidence of what we have already described. However, the presented results seem to show that the videogame was used by the teacher as a tool for scaffolding only in the case of inventing new tasks (3). For the other strategies, she preferred to use the worksheets to select specific tasks, students, and students' answers to be discussed. In addition, students did not refer to videogame tasks when they invented new ones. For our analysis we refer only to the four strategies presented by Carpenter, Franke, and Levi (2003; 2005); probably, a more general framework on teachers' scaffolding (e.g., Van de Pol, Volman & Beishuizen, 2010) could be more useful. The teacher states that the motivational aspect of the videogame plays a particularly significant role in promoting classroom discussions; it could be considered as two of the six scaffolding intentions (Van de Pol, Volman & Beishuizen, 2010): Recruitment and Contingency. In addition, SuperFlat Math seems a remarkably interesting tool in monitoring students' activities for designing the discussion. Indeed, the teacher reported that observing students play allowed her to conduct informal observation of students' arithmetic knowledge and skills. According to the theoretical framework by Stein and colleagues (2015), the act of observing students' behaviour could be included in both "anticipating" and "monitoring" practices, which are the first two phases of the model for orchestrating productive discussions. For this reason, we propose that observing students play might implicitly help teachers orchestrate the discussion, but we should investigate this hypothesis further, for example by conducting a new trial using the thinking aloud method (Fonteyn, Kuipers & Grobe, 1993). Finally, there are some aspects that could be interesting for future research. For instance, we could develop sequences of adaptive tasks within the videogame to emulate teacher's scaffolding. Moreover, the videogame could propose more structured feedbacks that partially help teachers and researchers discover students' processes. For this purpose, we could ask students to keep a "diary" during play time, where they could write down the strategies used to solve the proposed tasks.

Acknowledgment

We are incredibly grateful to the primary school teacher Arianna Fiorenza and prof. Leonardo Guidoni for their support. For more information: http://www.matematicasuperpiatta.it/

Teachers' perceptions of teaching and learning mathematics in the WhatsApp environment through the "Bagroup" project

Ruti Segal[1,2] and Yaniv Biton[2]

[1]Oranim Academic College of Education, Tivon, Israel; rutisegal@gmail.com

In this study, we investigated what opportunities for learning and teaching could be created using WhatsApp as a social network to help students prepare for the final secondary-school Bagrut (matriculation) exam in mathematics. Launched by the Center for Educational Technology three months before the Bagrut examination, we initiated WhatsApp groups meant to provide an online review project during which teachers integrated blended learning, and students presented problems with which they were having difficulties. During this initiative, we applied a quantitative and qualitative research model to analyze the teacher's perceptions about what learning and teaching opportunities were created. In this particular report, we focus only on the quantitative.

Keywords: Social network, communication, mathematics teachers' knowledge

Introduction

Communication is a necessary and essential component of learning and teaching processes. Plentiful, diverse communication allows students to organize their mathematical thinking; analyze, evaluate, and enhance their ability to express their mathematical thinking consistently and clearly alongside those of others; and make proper use of mathematical language to accurately express mathematical ideas NCTM (2000). During lessons, it is important that mathematics teachers initiate a discourse to promote communication between students and use diverse tools for explaining, making connections, solving problems, and raising persuasive arguments (NCTM, 2019).

"Orchestrating such discourse presents a unique challenge in online settings where discourse usually takes the form of discussions about shared readings or experiences rather than collaborative problem-solving of a mathematical task" (Morge et al. 2020, p. 216).

Teaching and learning mathematics with social networks

Learning via social media can take place in many settings. It invites learners to collaborate in meeting their learning goals by communicating with colleagues over the Web, learning in any environment that social network learning allows, expedite learning as a result of exposure to many, varied learning interactions between the group’s partners, anonymous learning, and active or passive learning, among other things (Naidoo & Kopung, 2020; Moodley, 2019). Social networks can also be integrated into student learning processes, and the interactions that occur between teacher and student and between the students themselves allow immediate feedback, improvement of thinking and reasoning skills, more focus on addressing learners' difficulties in learning and understanding processes, and exposure to the mathematical ideas of their peers (Biton & Segal, 2021; Freeman et al., 2016; Greenhow & Askari, 2017). Thus, it is important for mathematics teachers to acquire appropriate technological knowledge about teaching over the social networks, options offered for teaching in this environment, and methods for integrating appropriate pedagogy for optimal mathematics instruction.

Technological pedagogical and mathematical content knowledge

Based on Shulman’s work (1986), Ball and Bass (2003) defined the term “Mathematical Knowledge for Teaching” (MKT) as the knowledge that encompasses areas and levels of school mathematics, supports mathematics teachers’ connected ideas, and emphasizes their ability to plan, evaluate, integrate, and manage appropriate mathematical content for teaching. Subsequently, Ball et al. (2008) proposed six different components of MKT, one of which – Knowledge of Content and Students (KCS) – combines knowledge about students and about mathematics. It entails knowing how students think, what mathematical tasks may be easy/ difficult for them, and so on. This type of knowledge requires interaction between specific mathematical understanding and familiarity with students’ mathematical thinking. Koehler and Mishra (2009) coined the term “Technological, Pedagogical, and Content Knowledge” (TPACK), which is an amalgamation of the three types of knowledge. The concept of TPACK implies that these bodies of knowledge intersect at various levels of complexity, and it encompasses the knowledge teachers require to effectively integrate technology into their teaching (Schmidt et al., 2009). One component of TPACK that is relevant to this particular study is TPK−Technological Pedagogical Knowledge. This is familiarity with the range of technologies that can be integrated into teaching and understanding how their use can affect teaching methods.

Clearly, making use of any web-based social platform requires the teacher to have TPACK: the technological capacity to operate within the platform, the pedagogical skills to use it effectively, and (as goes without saying) the content knowledge they aim to impart to their students.

The "Bagroup" project

The Bagroup project was initiated by the Learning Center for Education Technology for the Ministry of Education to offer the use of the WhatsApp application to high school students preparing for their math matriculation exams (“Bagrut”) at all levels. WhatsApp groups of approximately 100 students from across the country (who were not necessarily acquainted with each other) were set up and overseen by a professional, experienced teacher. The project ran approximately two to three months before the date of the exam, during which hundreds of thousands of messages were sent that included scholastic content, questions and solutions, and explanations. The WhatApp-based project offered the advantages of immediacy (students could get an immediate, professional response from a teacher or peer), equality (the entire student body had access), mobile learning (the smartphone supplemented classroom instruction anywhere and anytime), encouragement (strengthened understanding, feelings of capability, and self-confidence) and variety (exposure to a myriad of learning and problem-solving methods).

The study’s aim was to determine teachers' and students' perceptions of the project. For this purpose, five research questions were posed, but in the present framework, we focus only on the question: What are teachers’ perceptions of the WhatsApp “Bagroup” project learning environment?

Method

Setting

Learning in each of the WhatsApp “Bagroup” groups was based on the “blended learning” format, which includes synchronous and non-synchronous sessions (Schwartz et al., 2017; Tella, 2014). The group was overseen by a professional teacher to ensure consistency, but most of the learning was peer-to-peer. A learning program was designed specifically for the project, and every day, questions in one of the pre-defined topics were raised and solved within the group. For each subject, two or three 45-minute-long WhatsApp lessons were held in which the teacher presented the topic and emphasized significant points of knowledge. Learning was continuous (24/7) and facilitated in a variety of ways: text messages, voice messages, photos, video, questions, presentations, and more.

Sampling method

A nonprobability sampling method was used based on the availability and willingness of participants to reply to the questionnaire.

Research tools

Four data collection tools were used: (1) Teacher questionnaire distributed at the end of the three-month learning period that included 11 six-point Likert-type statements and open-ended questions. The questionnaires were constructed together with and validated by a team of mathematics education experts to monitor and evaluate the actions of the participants, particularly because they were strangers to each other at the outset. Out of the 40 participating teachers, 24 responded; (2) informal semi-structured interviews at the end of the learning period (friendly conversations via video chat with three teachers and two project managers); (3) the content of the WhatsApp messages; and (4) observations of four groups of students (chosen at random).

Data analysis

Four-stage data analysis was both quantitative and qualitative and included (Corbin & Strauss, 2014; Creswell, 2014): (1) quantitative analysis of closed statements in questionnaires; (2) qualitative analysis of open questions in questionnaires and interviews; (3) cross-matching information obtained from quantitative and qualitative analyses; and (4) searching for evidence/episodes from the students' and teachers' messages to corroborate the findings obtained in the previous stages.

Findings

Our quantitative findings of the responses to the teachers’ questionnaire are presented in Table 1 (list of statements, and average score and standard deviation of each; (internal reliability, α =0.785).

Table 1: Averages and standard deviations of the components and statements that relate to teachers' experience in teaching mathematics via the WhatsApp “Bagroup” project

Statement	Av.	SD
Category 1. Contribution of the WhatsApp environment to learner's emotional needs	**3.56**	**0.89**

I managed to track the students’ progress via the WhatsApp discourse.	3.83	1.17
I managed to explain the material just as much as in a regular class.	3.33	1.05
WhatsApp allowed students to participate without fear of committing mistakes.	4.14	1.39
Written discourse in WhatsApp is preferable over verbal discourse in regular classes.	2.50	1.41
Teaching through WhatsApp allowed me to meet the specific needs of each student.	4.04	1.20
Category 2: Factors that promote learning in the WhatsApp environment	**4.20**	**0.86**
The lesson setup with WhatsApp differs from that in a regular lesson.	4.92	1.10
The WhatsApp method made me more familiar with available math-teaching math technologies.	3.96	1.27
Students seem to invest more time and effort in learning compared to in a regular classroom.	3.38	1.47
I believe that WhatsApp will become an integral tool for teaching math in the future.	4.61	1.34
Category 3: Factors that inhibit learning in the WhatsApp environment	**3.10**	**0.97**
Some mathematical content cannot be explained via WhatsApp.	3.29	1.43
I could not manage to generate students' collaboration like I do in a regular class.	2.92	1.35

Figure 1 illustrates the distribution of answers. For ease of presentation, the Likert scores were divided into three levels (agree, somewhat agree, disagree) and the respective percentages are indicated.

In the first category, “Contribution to learner’s emotional needs,” all the teachers agreed or somewhat agreed that it reduced students’ fear of making mistakes, the majority agreed or somewhat agreed that it allowed them to meet the specific needs of each student, and they all agreed or somewhat agreed that they were able to successfully track their students’ progress. However, the matter of written vs. verbal explanation did trouble the teachers as only about a quarter believed that written discourse is preferable over verbal discourse (a little over a third somewhat agreed).

In the second category, "Factors that promote learning in the WhatsApp environment," all the teachers agreed or somewhat agreed that the lesson setup with WhatsApp was quite different than a regular lesson, that WhatsApp would become an integral tool for future mathematics instruction, and that teaching through WhatsApp improved their familiarity with the technologies available for teaching math. However, there was some difference of opinion regarding whether students invested more time and effort in learning compared to students in a regular classroom": although over four-fifths agreed or somewhat agreed, almost a fifth disagreed.

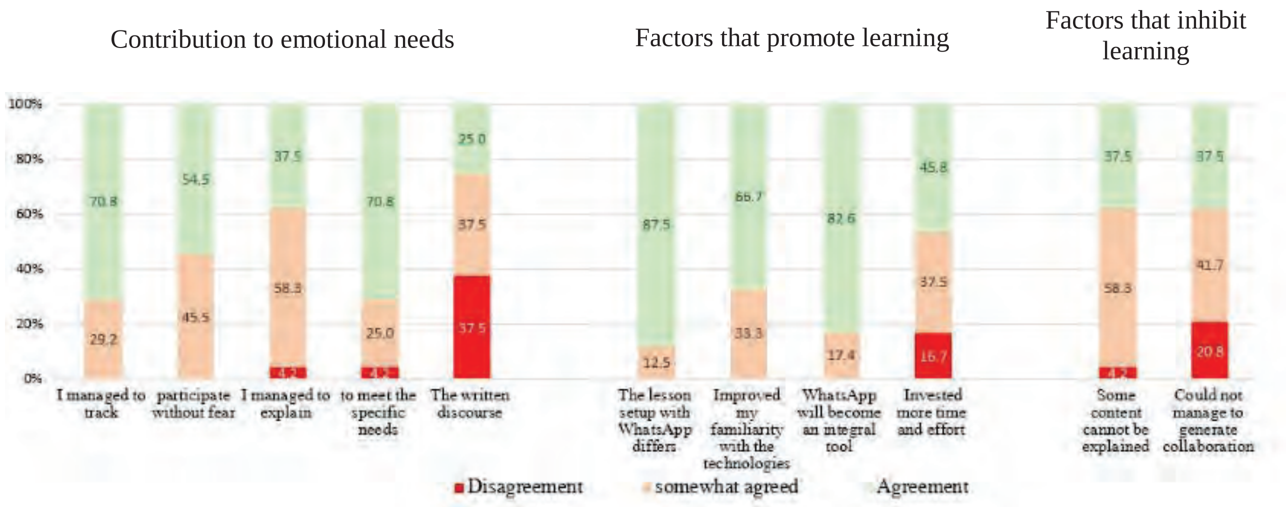

Figure 1: Levels of teachers' agreement with statements concerning their experience teaching mathematics via WhatsApp

In the third category, "Factors that *inhibit* learning in the WhatsApp environment," about a third of the teachers agreed and over half somewhat agreed that some mathematical content **cannot** be explained via WhatsApp." With respect to the last statement, "I could not manage to generate collaboration between students like I do in a regular class," note that this is a "negative statement," meaning that agreement illustrates a disadvantage. Almost 80% agreed or somewhat agreed with the statement meaning that only about a fifth did not find encouraging collaboration to be a problem.

Discussion

Because learning opportunities are created through the interactions of (at least) tasks, teaching, and students, measures of learning opportunities will need to develop through analyzing interactions among these factors and describing how some interactions help students achieve a specified learning goal more than others (Cai et al., 2020. p. 19).

The aim of this study was to investigate teachers' perceptions of the WhatsApp Bagroup program environment as a lever for learning and teaching opportunities. Analysis of the teacher questionnaires gives the overall impression that the teachers feel the program does indeed address students' emotional and scholastic needs perceived by them.

Emotional needs

The program involved interaction between students and teachers and between students and their peers through respectful communication. Each student's ideas were taken seriously and everyone had the opportunity to ask questions, make statements, and express their ideas. These have been shown to be necessary for a successful learning atmosphere (Chapin et al., 2013).

The first category of statements was to determine whether the teachers believed this platform met the learner's emotional needs. Overall, the response was favorable. Teachers believed that it allowed them to meet the specific needs of each student (4.04): most (70.8%) agreed; 25% somewhat agreed with the relevant statements. Only 4.2% disagreed. Similarly, fully 94.8% felt that the platform allowed them to successfully explain concepts or understand their students' difficulties (37.5%:

agree; 58.3%: somewhat agree) and only 4.2% did not. Results also showed that 100% of the teachers managed – either fully (70.8%) or somewhat (29.2%) – to properly track their student's progress through the WhatsApp discourse (3.83), a factor that would help meet students' emotional needs.

All the teachers either fully (54.5%) or somewhat (45.5%) agreed that the platform freed students from the fear of making errors (average 4.14), clearly a factor in meeting students' emotional needs. However, there seemed to be some hesitancy regarding whether the written discourse was efficient enough to meet student needs, as over a third (37.5%) disagreed with the statement "The written discourse in WhatsApp is preferable over the verbal discourse in a regular class" (average 2.5). Only 25% of the teachers fully agreed that it was preferable and 37.5% somewhat agreed.

Overall, it seems that the teachers' personal approach to the students, meeting needs, and providing a feeling that any question is valid encouraged learning and provided emotional support.

Scholastic needs

Most of the teachers expressed satisfaction with their ability to track students' responses and explain mathematical concepts over the platform, thus meeting their students' scholastic needs. However, many did not agree that written discourse was preferable (see above).

Regarding how much students invested in learning in this platform, most of the teachers agreed (45.8%) or somewhat agreed (37.5%) that the students in this project invested more time and effort in learning compared to students in a regular classroom" (3.38); about a fifth (16.7%) disagreed.

Challenges to teachers

It is not surprising that 87.5% of teachers fully agreed with "The lesson setup with WhatsApp differs from that of a regular lesson" (average 4.92), as an internet chat platform is clearly different from frontal teaching (even over the internet, such as with ZOOM), since all answers must be composed in writing. Regarding their success (or not) in explaining the content over the platform, it seems that the majority of teachers had difficulty, as a third of teachers agreed (37.5%) and over half of them somewhat agreed (58.3%) with "Some mathematical content cannot be explained via WhatsApp" (average 3.29). Only 4.2% seemed to have no problem explaining content over the platform.

Finally comes the issue of successful student collaboration (average 2.92). Only 20.8% of the teachers responded that they had no problem getting their students to collaborate, 41.7% seemed to have some problems with this, and over a third (37.5%) reported that they could not manage to generate collaboration between students like they do in a regular class.

Nevertheless, despite these challenges, all teachers believed (82.6%) or somewhat agreed (17.4) that WhatsApp (or similar) will become an integral tool for teaching math in the future (average 4.61). Furthermore, all the teachers responded that teaching through WhatsApp improved their mastery with technologies available for teaching math (66.7% agreed, 33% somewhat agreed, average 3.96).

Conclusion

Naidoo and Kopung (2020) emphasized the contribution that collaborative learning via WhatsApp made to pre-service mathematics teachers: it encourages ubiquitous, prompt, and anonymous mathematical learning. In the present study, in-service mathematics teachers are teaching students whom they have not met before, and the teachers identified a similar contribution to the students alongside its contribution to them as mathematics teachers. The majority of teachers reported satisfaction with the program: it allowed them to track student progress, assisted them inefficiently in solving problems, and helped them identify where students were having difficulty. They also felt that it helped meet students' emotional needs because students were not afraid to make mistakes, and they received an appropriate and immediate response to any difficulties according to their specific needs.

The teachers seemed to feel that the program increased their TPK (Schmidt et al., 2009) because they were forced to become familiar with a variety of innovative teaching-learning processes in technological environments and gain experience in how to teach, explain, and present mathematical processes and concepts. Nevertheless, the environment posed some challenges: for example, not all mathematical content is appropriate for this environment and written discourse is not always an alternative for verbal discourse to fully explain some concepts.

These and similar programs may help predict learning or teaching responses that have not yet been identified. Similar studies may assist in shaping future research into technological integration into formal education, leading to the introduction of solutions to ongoing educational problems or altering prevailing educational norms and methods towards more beneficial applications.

Implementing the 5E inquiry model in an online platform of a flipped classroom environment

Halima Sharkia[1] and Zehavit Kohen[2]

[1]Technion - Israel Institute of Technology, Israel; halima@campus.technion.ac.il

[2]Technion - Israel Institute of Technology, Israel; zehavitk@technion.ac.il

In light of COVID-19 outbreak and the subsequent closures of educational institutions, the need for online environments has significantly increased. This study sheds light on the online component of a mathematics flipped classroom (FC) and aims to investigate if, and to what extent, it can effectively utilize inquiry-based learning (IBL). Based on the 5E inquiry model, the study focuses on an advanced mathematics course for high-school students taught in an FC environment. Analysis of seven filmed lectures on the subject of complex numbers was conducted using a validated 5E inquiry model scoring instrument. Results indicate promising findings for a wisely planned virtual platform that answers the 5E model requirements and may successfully demonstrate an IBL-supported environment.

Keywords: Inquiry-based learning, flipped classroom, 5E Model, mathematics education

Introduction

The difficult period resulting from the COVID-19 outbreak, which includes, among other things, the closure of educational institutions, has highlighted an urgent need for a worthy alternative to the traditional teaching method (Dhawan, 2020). Most recently, and due to COVID-19 pandemic, a huge variety of online learning environments have emerged. A potential alternative approach is the Flipped Classroom (FC), with the goal to provide students with a supportive environment alongside a deep and meaningful learning experience (Sharkia & Kohen, 2021). The research environment that served this study is a MOOC called Campus IL, an Israeli national digital learning venture, which offers the users the opportunity to experience an advanced and individualized learning process, by providing a huge variety of online content. Particularly, the FC method can be an ideal venue for transforming traditional learning into an engaging, inquiry-based learning (IBL) environment (Love et al., 2015). The FC approach includes two phases, of which the first phase occurs out of class, where students are expected to undergo an independent learning process, while the second phase takes place inside the classroom and involves extensive practice exercises of the materials learned outside of class (Bergmann & Sams, 2012). Previous studies in the field have explored the application of IBL in the physical classes, as the FC approach frees up class time for IBL-type activities (Sharkia & Kohen, 2021). Yet, limited research had been done on the application of IBL in the online component of the FC environment (Love et al., 2015). Thus, the current study aims to investigate the application of IBL in the online platform of an FC learning environment. We aim to explore whether, how, and to what extent an online platform for a mathematics FC utilizes IBL in the most effective way.

Theoretical Background

The FC Approach

Two components comprise the FC approach; the first is the independent learning process that takes place outside of the classroom, and the second is the active and collaborative lessons inside the classroom (Bergmann & Sams, 2012). The FC approach utilizes various technological means to provide students with instructional materials and related exercises. These technological resources allow students to learn the content outside of class (Dori, Kohen, & Rizowy, 2020), hence offer teachers considerable time in class to provide deeper explanations and practice alongside the students (Bergmann & Sams, 2012). The online component of the FC is where teachers provide filmed lectures, presentations, online assignments, and more, and expect students to independently learn the provided content before arriving to the class. With that, and according to Lo and Hew (2017), this approach promotes student-centered learning experience. Additionally, it allows a wiser management and exploitation of class time, by enabling teachers to roam around the classroom, identifying various individual difficulties, detecting different challenges and misconceptions among the students, and finally react accordingly by giving these students the support and encouragement they need (Lo & Hew, 2017). A main advantage of the class component of the FC approach is that it provides students with adequate amount of class time to extensively and collaboratively work on exercises alongside their teacher, which is considered an essential condition to master mathematical skills and achieve comprehensive understanding of the material (Kaiser & Vollstedt, 2007). A main advantage for the online component of the FC approach is that the instructional content is available for students out of class any time and place, hence they can access it countless times until they accomplish full comprehension (Lo & Hew, 2017). As a result of the COVID-19 pandemic, the "traditional" flipped classroom, in which students meet with the teacher in person, was almost impossible to adopt. Instead many institutions have integrated online teaching with FC. Research has shown that this combination resulted in positive effects on students, including increased learning, comprehension and attention, as well as positive evaluations of a variety of taught courses (Tang et al., 2020).

The 5E Inquiry Model

According to the 5E model (Bybee et al., 2006; Bybee, 2009), learning through inquiry follows five phases, which are identified as follows: (i) engagement, (ii) exploration, (iii) explanation, (iv) elaboration, and (v) evaluation. These phases can be implemented to various levels when planning and constructing different curriculum materials, lesson plans, and instructional strategies (Bybee et al., 2006). Classroom inquiry is composed of five essential characteristics (National Research Council, 2000), which can be addressed by applying the 5E model during the learning process (Schallert et al., 2020). The first characteristic is engaging the learner in scientific questions (National Research Council, 2000, p. 29). This feature can be found in the first phase of the 5E model, namely, engagement, which enables students to engage in the learning activities. In this phase, teachers need to motivate and engage students by presenting a certain problem that requires students' attention. The next phase is exploration. As soon as students are engaged and motivated in a certain activity, they should be able to explore their thoughts and abilities. In this phase, classroom inquiry is characterized by prioritising the evidence in response to questions, and formulating explanations based on evidence (National Research Council, 2000, p. 29). The next phase of the 5E model is explanation, in which concepts, ideas, procedures, and skills become clear and understandable. This phase relates to another inquiry characteristic that comprises explanations connected to scientific knowledge and communication and justification of explanations (National Research Council, 2000, p. 29). The explanation phase describes these features, offering students the opportunity to create connections between their explanations to scientific knowledge and further justify them. The next phase is the elaboration of the problem and its solution(s). In this phase teachers provide students with further experiences, tasks and challenges aiming to expose them to new but similar situations. The final phase of the 5E model is the evaluation, in which teachers are expected to provide their students with the appropriate feedback on the quality of their performance. Figure 1 presents visually the 5E inquiry model.

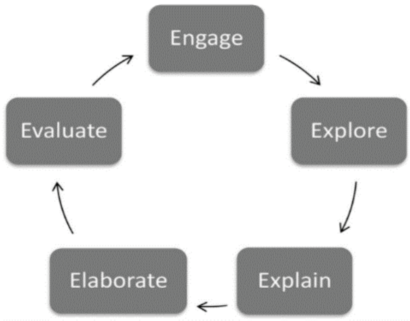

Figure 1: The 5E inquiry model (Schallert et al. 2020, based on Bybee and colleagues' model, 2006)

The research question of this study is: How, and to what extent, the online platform of the FC can effectively utilize the IBL approach.

Method

Research Environment - Campus IL

The current study focuses on one course that is held in Campus IL. Campus IL is a joint venture from Digital Israel and the Council for Higher Education that aims to provide all Israeli citizens the opportunity to pursue education and engage in intellectual development. This environment includes a huge variety of courses and resources from highly respected colleges, universities and other academic organizations. Having gained access to Campus IL, the user can benefit from a personalized and unique learning experience. The current study utilizes an advanced mathematics course in Campus IL. This course is designed for high school students who study advanced mathematics, and aims not only to prepare them for the final matriculation exam in mathematics that takes place at the end of 11^{th} and 12^{th} grades, but also to expand their horizons and nurture their mathematical thinking and prepare them for first year college mathematics.

All the content of this course is conveyed through short, filmed lectures that were filmed and produced in a specially designed studio at the Technion institution, under the supervision and direction of a professional photography and editing team. The average length of each video is roughly 5 minutes, and it is mostly followed by short assessment tests and quizzes that aim to assess students' comprehension of the mathematical content they have recently watched. Dr. Aviv Censor, one of the outstanding lecturers in the Technion institution (according to national and institutional instructional surveys) is the teacher who delivers the content in all the filmed lectures. In addition, an academic team under his supervision has developed, created, and written all the evaluation tests in a manner that suits the level taught in the videos. Figure 2 presents a screenshot taken of a filmed lecture about the subject of complex numbers.

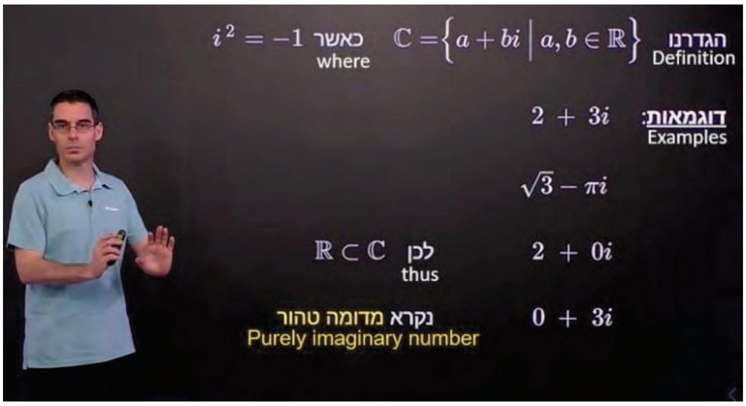

Figure 2: The teacher in a filmed lecture about complex numbers

Research Tools and Analysis

Research tools include a scoring instrument that was developed and validated in a research study conducted by Goldston and colleagues (2013). This scoring rubric was designed to evaluate IBL lesson plans according to the 5E model by Bybee et al. (2006) and is considered a reliable tool for its total reliability score that reached 0.98. It consists of several items for each one of the 5E model phases. Each item is given a score that ranges from 0 to 4, based on a 5-point Likert scale, where 0 stands for unacceptable, 1 is poor, 2 refers to average, 3 means good, and 4 represents excellent. This rubric was also found to help teachers and educators to revise their strategies of how to design a 5E-based lesson. The current study mainly used several sections of this rubric to assist in evaluating filmed lectures, in an attempt to investigate if and to what extent these lectures employ the IBL method. The elements of all phases were considered except for the explanation phase, which is basically based on assessing student perspective, therefore could not be taken into account in the scoring process which evaluates the teacher perspective in the filmed lectures. In the present study, we chose to present the analysis for the first seven filmed lectures which provides introduction to the subject of complex numbers. This subject is part of the advanced mathematics curriculum, that is required in the second matriculation test conducted at the end of 12th grade. These lectures started with three introductory videos, the next two videos explained the emergence of the groups of numbers and provided a definition of a complex number, and the last two videos illustrated the algebraic and geometric representations of a complex number. The videos were transcribed and evaluated quantitively according to the scoring rubric described above. We also present qualitative analysis of the videos, for examining the narratives of IBL that were captured in the videos.

Findings

In order to reveal the exemplification of IBL in the online platform of the mathematics FC Campus IL, a thorough and comprehensive analysis of several filmed lectures was completed. A score was given to each one of the different elements that are characterizing the various phases of the 5E model. Figure 3 below illustrates the means and standard deviations of the scores obtained to the seven filmed lectures. Scores were calculated separately for each one of the four considered phases.

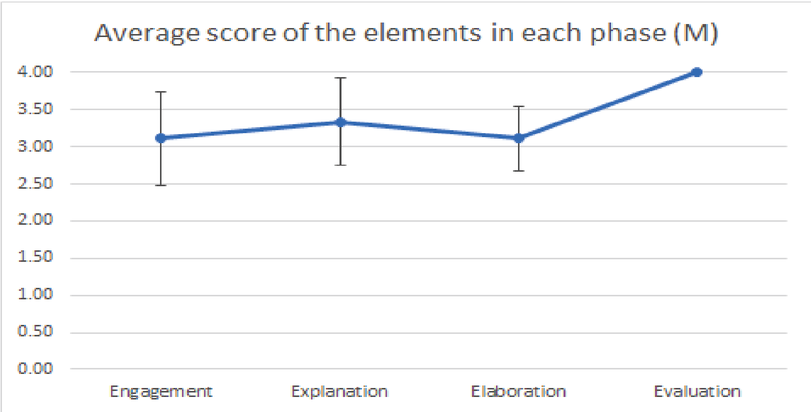

Figure 3: Average scores of the elements composing each phase of the 5E model

Figure 3 shows that all the examined elements were evident in the lectures and reached a score that is higher than 3, meaning that these lectures highly fulfill the requirements for implementing IBL during a mathematics lesson. Besides means and standard deviations, frequency distribution of scores that were given for each component was calculated. See Table 1 reflects the frequency distribution of scores that were given for each component, for all the seven explored filmed lectures.

Table 1: Frequency distribution of scores that were given for each component

Phase	Score (2)	Score (3)	Score (4)
Engagement	22.22%	44.44%	33.33%
Explanation	16.67%	33.33%	50.00%
Elaboration	11.11%	66.67%	22.22%
Evaluation	0.00%	0.00%	100.00%

It can be seen that score (4) has the highest frequency in both explanation and evaluation components while they have different means. Similarly, score (3) has the highest frequency in both engagement and elaboration components. These differences in the distribution can explain the differences in standard deviation in each component. Specifically, when comparing all four phases, it can be seen that the explanation and evaluation components were the most prominent in the examined lectures. This indicates that the explanation phase that is adopted in the videos largely promotes and contributes to inquiry in the classroom. Particularly, aiming to encourage and promote profound understanding, throughout this phase it was evident that the teacher was determined to introduce concepts that students were unfamiliar with or not aware of. Presenting a great variety of examples and strategies in the filmed lectures, the teacher was able explain these concepts and theories. Another interesting finding that is revealed is that classroom inquiry can be more efficient when the teacher performs evaluation and assessment activities at the end of the lecture.

From a qualitative perspective, we now describe some utterances that were observed in the filmed lectures, which illustrate the appearance of the inquiry components in part of the videos that were analyzed. In the introduction lecture (#1), the teacher opens the lecture with an interesting starting point in an attempt to gain students' engagement. He asked the students the following: "Did you know that bears can count to 4?!”, then continues: “When walking in bear-inhabited areas, the instructions recommend staying in groups of at least 5 people, as bears tend to avoid groups of more than four”. Following the intriguing introduction about counting natural numbers, the teacher refers to negative numbers, and asks: “what is -3?” and immediately tries to bring real life examples to illustrate the meaning of negative numbers. He then asks students an interesting question that stimulates students’ knowledge from their early years of study: “Back in 6th grade, you were taught that multiplying two negative numbers results in a positive number. Why is this true? I would like you to pause the video for a moment and try answering this question yourself”. The teacher tries to raise simple yet challenging questions to motivate the students and attain their attention and engagement, this is crucial to assure students will be intrigued to continue watching the next lectures seeking for logical answers. Following, in the second introduction lecture (#2), the teacher enters the explanation phase, in which he intends to answer the previously raised question, and thoroughly explain it to the students. At this stage, the teacher chooses a creative explanation of the answer, and uses a filmed example attempting to convey the concept of “the product of two negative numbers is a positive number”. He gradually poses a variety of questions to help students develop their understanding and skills, such as: “In this video, you can see Maya walking at a speed of 3 km/h. What if we run it twice the original speed? What happens if we run the video backwards? what if we run it backwards twice the original speed? etc.”. After the explanation phase the teacher moves to the next phase of elaboration revealed in lecture (#3) of the introductory films, in which he presents new problems, yet related to the previous parts of the introduction. This lecture aimed to elaborate the concept of square root of a negative number. He uses simple explanations, examples, and graphs to illustrate that no square root exists for a negative number. And from this point, he mentions the main subject of complex numbers by saying: “There were some who believed differently and raised the idea of imaginary numbers”. He concludes this video by adding that: “Let us consider complex numbers, without which there would be no Einstein relativity, no quantum theory, no autonomous cars, and no noise-cancelling headphones”. Doing so, he emphasizes the importance of mathematics in general and the significance of the complex numbers subject to students’ real life. All the above examples of this teacher’s lectures demonstrate the actual use of IBL in the online platform of the FC, through a variety of wise questions, certain metaphors, and unique delivery methods of the mathematical content. These examples supplement the quantitative findings which indicate a high degree of IBL applied by this teacher in the various online filmed lectures.

Discussion

According to the Principles and Standards for School Mathematics (National Council of Teachers of Mathematics, NCTM, 2000), an IBL approach should be integral to and at the core of good instructional practices. Yet, to promote rigorous and meaningful IBL, teachers should constantly strive to improve the quality of inquiry instructional practice (Marshall et al., 2006). In the present study, we provide insights into implementing IBL in mathematics flipped classrooms. It investigates if, how, and to what extent the online platform of the flipped classroom can effectively utilize the IBL approach. Using a validated scoring rubric (Goldston et al., 2013), analysis and scoring of several filmed lectures were accomplished. The findings indicate that the instructional process in these examined lectures exemplify the characteristics of an IBL method. Specifically, findings reveal that the explanation phase was prominently observed. This finding aligns with several characteristics for IBL defined by the National Research Council (2000). It was evident in the lectures that the teacher tried to raise questions that require the students' exploration, and subsequently offered them explanations that are science based. Thereby, teaching them to link their own explanation to scientific knowledge which leads to further comprehensible justifications. Another significant finding is that once evaluation process was observed, it indicated an excellence implementation of IBL. According to Bybee (2006), this is a critical phase, which enables not only teachers but also students to evaluate and assess their comprehension. Through applying short quizzes and a variety of tests, teachers may be able to evaluate the improvement of students' understanding and abilities (Schallert et al., 2020).

From a theoretical perspective, the study contributes to the limited literature about the interrelationship between IBL and FC, particularly referring to the online component of FC. From a practical perspective, we present promising findings indicating that when designed wisely according to the 5E inquiry model, the virtual component of the flipped classroom can represent an IBL environment which students will benefit from, especially in difficult periods such as the current COVID-19 period.

This paper examines what misconceptions about geometric similarity (GS) teachers can attend in their curriculum scripts and how they use dynamic mathematical technology (DMT) in the classroom to promote students to encounter, reflect upon and address their misconceptions. The Structuring Features of Classroom Practice (SFCP) construct of ‘curriculum script’ guided the collection and analysis of the data presented in the paper. The research worked with three teachers with different levels of experience and expertise in using DMT. Data collection involved video-recorded observations, audio-recorded, semi-structured post-lesson teacher interviews and lesson resources. The findings suggested there were differences in the quantity of misconceptions the teachers anticipated and/or identified and in the ways in which they used the DMT to help students confront, reflect upon and address their misconceptions.

Keywords: Geometric similarity, misconception, dynamic mathematical technology, teacher.

Introduction

Researchers have underlined that there is still little understanding of the phenomenon of the integration of dynamic mathematical technology (DMT) into classroom practice and we need more case studies guided by the available different theoretical lenses to explore teachers’ DMT-enriched practices within ‘real’ classroom settings (e.g. Ruthven, 2014). In our research, we aimed to contribute to addressing this gap by investigating secondary teachers’ actual classroom practices as they teach the key mathematical domain of geometric similarity (GS) with a carefully designed DMT. We focused on GS since it is a key but also difficult concept for students (Clark-Wilson & Hoyles, 2017). For instance, research has documented that the improper use of additive reasoning is one of the most common student misconceptions about GS (Noss & Hoyles, 1996). However, despite its importance in school mathematics and the difficulties that it poses to students, GS has been neglected in research on the integration of DMT into practice. This is surprising as the research evidence suggests that students’ engagement with DMT could help them overcome their (possible) misconception(s) with GS (Clark-Wilson & Hoyles, 2017).

The current paper presents part of a broader PhD study (Simsek, 2021), conducted by the first author and supervised by the co-authors. The paper concerns particularly teachers’ use of DMT in their practices to support students to confront, reflect upon and address their (possible) misconception(s) about GS. We formed our research question for this paper as follows: *What student misconceptions about the topic of geometric similarity can teachers attend in their curriculum scripts and how do they use dynamic mathematical technology in their classroom practices to support students to encounter, reflect upon and address them?*

The 'Curriculum Script' Construct of the SFCP Framework

We selected and used the Structuring Features of Classroom Practice (SFCP) framework to guide the entire research process of the broader study including both data collection and analysis. The lenses of this framework specifically concentrate on the five key structuring features of classroom practice that shape how teachers incorporate (new) technologies into their practices, namely *curriculum script*, *resource system*, *activity format*, *working environment* and *time economy*. The framework underlines how these features pertain to teachers' integration of technologies into the classroom and identifies the examples of the associated teacher craft knowledge in relation to integration of technologies (the full description of the framework can be found in Ruthven (2014)). Ruthven (2014) discusses teachers' craft knowledge is mainly tacit, illustrating why many teachers find it difficult to articulate or might not even be aware of. Teachers develop this type of knowledge, which is dynamic and evolving, primarily through "their own practical experience of learning and teaching the topic" or from "available curriculum materials" (Ruthven, 2009, p. 138). The SFCP framework therefore serves to identify and analyse teachers' craft knowledge that underpins successful classroom practice with (new) technologies.

Due to the focus of the present paper, we briefly describe *only* the construct of *curriculum script* as it also involves student misconceptions about a topic teachers anticipate and/or identify and how teachers address them using different pedagogical tools including DMT(s). The concept of *curriculum script* can be defined, in the psychological sense, as an event-structured organisation of knowledge incorporating well-defined sets of learning objectives, expectations and actions in a loosely logical sequence for a mathematical domain, likely misconceptions related to the domain, together with resources, activities, associated language and questions, and pedagogic strategies (Ruthven, 2009). When teachers implement (new) technologies in their practices, they need to draw on their knowledge to develop and adapt their curriculum script for teaching a topic. This script guides the ways teachers create the overall structure for a lesson (i.e. the dynamic plan or set of goals and actions for a particular lesson) and enact it in a flexible and responsive way (Ruthven, 2014). It is important to highlight a curriculum script goes beyond a lesson plan created by teachers in the written form in advance a lesson. In this sense, while a lesson plan seems to be fixed and contain details that teachers are able to articulate, a script can be considered as dynamic and evolving in light of what happens in the classroom and encompass content of teachers' craft knowledge that many of them are not be able to articulate or might not be aware of.

Design and Methods of the Study

This research adopted a multiple case study approach. We were able to identify and work with three teachers who had been previously involved in the original Cornerstone Maths (CM) project in England (see the details of the project in Clark-Wilson and Hoyles (2017)) and expressed an interest in being part of the research. We recruited them from the community of the project as they had engaged with a particular DMT tool, the CM software, and they were committed to use the DMT in their own classroom practice to teach CM curriculum unit on GS (including the CM software, the student booklet and the associated teacher guide) to students aged 13-14 years. The participant teachers were from the two different London-based co-educational secondary schools. While Jack (pseudonym) taught in a school in the east London, Alex and Lara (pseudonyms) were colleagues and taught in the north-west London. We expected Jack to exemplify characteristics of an *expert teacher* in the use of DMT for teaching and learning of mathematics as he had high-level of involvement in the original CM project and considerable experience and expertise in the use of DMTs. Whereas, we expected Alex and Lara to exemplify characteristics of an *advanced beginner teacher* as they had mid-level of involvement in the original CM project and some experience and expertise in using DMTs (Berliner, 2004). We assumed such selection would be helpful to elucidate differences in the characteristics of teachers' practices with DMT in relation to GS.

The CM software is a web-based DMT designed to support students' understanding of the set of three CM curriculum units for lower secondary mathematics in England. The units include GS, algebraic patterns and expressions, and linear functions. The software was designed by exploiting the dynamic, visual and multi-representational potential of digital technology. It contains several carefully designed dynamic tasks related to each of CM units and promotes the use of the 'predict-check-explain' pedagogical approach. These tasks were created on the basis of realistic contexts in a learning environment in which there are dynamically linked multiple mathematical representations such as geometric shapes, ratio checker and measurement tables. The CM software is therefore intended to offer the potential for students to make conjectures and test them by manipulating such representations and to explore the underlying mathematical concepts and relationships in a realistic context. In terms of GS, the tasks allow students to engage with, for example, shapes, ratio checker and measurement table by using several key features (e.g. scale factor slider, angle slider, dragging) in the dynamic learning environment. Therefore, they could potentially recognise and explore the embedded variant and invariant properties of mathematically similar shapes and how the properties are used to determine similarity. The CM software is also intended to help students encounter, reflect upon and overcome their (possible) misconceptions about GS.

Data collection involved video-recorded lesson observations, audio-recorded, semi-structured post-lesson teacher interviews and lesson resources. The first author observed eight each of both Lara's and Jack's lessons and seven of Alex's lessons. In the case of Jack, he conducted his lessons in his normal classroom with laptops. In the cases of Lara and Alex, they both taught their lessons either in a pre-booked computer room with desktop computers or in an ordinary traditional classroom with iPad computers. Moreover, the first author interviewed Alex and Jack six times and Lara eight times, which lasted between 35-45 minutes. Lastly, we collected teachers' interactive whiteboard or PowerPoint slides, examples of their task sheets, photographs of students' DMT screens and their associated written work in the workbook in response to the DMT-enriched tasks. For data analysis, a *within*-case analysis was carried out first to create an individual detailed description of each case in written form that helped examine each case in depth. The within-case analysis led to the identification of what student misconceptions about GS each case study teacher attended in her/his curriculum script and how (s)he used the DMT to help students address them. Then, using spreadsheets, a *cross-case analysis* was conducted by comparing and contrasting the cases based on the results of the within case analysis. The cross-case analysis resulted in the identification of the key differences between the teachers in terms of their anticipation and identification of student misconceptions about GS and their exploitation of the DMT to tackle them in the classroom.

Findings

In this paper, we present findings emanated from our data analysis that concern the case study teachers' anticipation and identification of student misconceptions regarding GS and of the ways through which to enable students to confront, reflect upon and address their (possible) misconceptions using the DMT. The within-case-analysis revealed the following student misconceptions about the topic of GS evident in the teachers' curriculum scripts.

1. If two shapes look similar in appearance (e.g. rectangles), they are mathematically similar;
2. An enlargement results in the creation of a mathematically similar shape which is *always* larger than the original;
3. A scale factor makes a shape only doubled and/or halved;
4. The use of additive strategies within GS is appropriate when determining whether shapes are mathematically similar;
5. If the lengths of a shape are multiplied by a scale factor of k, then the area of this shape is multiplied by a scale factor of k, too;
6. The proportionality of all corresponding pairs of sides is by itself sufficient to prove the similarity for shapes; and
7. The angles of a shape are multiplied by a scale factor along with its side lengths.

The cross-case analysis indicated that compared to Alex and Lara, Jack, as an expert teacher, showed more awareness of the likely misconceptions about GS and of the potential teaching strategies incorporating the use of the DMT in a dynamic mode to tackle them. While Jack anticipated and identified a total of six of the above stated seven key misconceptions and made dynamic use of the DMT to provide opportunities for students to address them, Alex and Lara predicted only three and two different misconceptions of them, respectively, and did not necessarily use the DMT in the same way as Jack did. In the following, we present results for each case to provide an insight into what misconceptions out of the above given ones each teacher attended in their curriculum script and how each used the DMT in their classroom practice to support students to encounter, reflect upon and address them.

Case Study 1: Lara

In her curriculum script, Lara identified the first and second misconceptions underlined above that her students faced when engaging with the DMT-enriched tasks. However, she did not make dynamic use of the DMT herself in the observed lessons to assist students in addressing them. Below, we present analysis of the second misconception to provide an insight into how she addressed a misconception with (and without) the DMT.

Promoting students' understanding that an enlargement does not only result in the creation of a similar shape larger than the original

In her post-lesson interview, Lara expressed students struggled to understand an enlargement may also result in a shape being smaller than the original as they were inclined to think an enlargement is a mathematically similar shape that should be *always* larger than the original. She outlined she recognised this misconception when interacting with a pair of students as they asked her to confirm what she had said in the previous lesson regarding the possible impact of an enlargement on the sides of shapes. She also stated students' engagement with one of the DMT-enriched tasks, where students predicted, tested and explored if the rectangles were mathematically similar to the original on the basis of visual and numerical cues, helped them realise an enlargement may create also a smaller similar shape than the original.

> They [students] cannot connect that an enlargement also makes a shape smaller because, in their mind, an enlargement is something getting bigger. They told me [that] "You said yesterday an enlargement can make the shapes smaller as well". So, for them, by themselves, they are not connecting it until we have done this [the DMT-enriched task]. So, from the original to copy 2 [the names of the shapes being enlarged in the task], they can see the bigger shape [the original shape] is getting smaller. Before that, they could not, that is how I assumed or observed.

However, Lara herself did not use the DMT dynamically to help students realise and explore that an enlargement is a similar shape which may be also smaller than the original. Instead, she only allowed students to use the DMT during their independent work with the DMT to confront and reflect upon this misconception by themselves.

Case Study 2: Alex

In his curriculum script, Alex anticipated the second, fourth and sixth misconceptions given above and addressed them with (and without) the DMT in the classroom. We present how he addressed the third misconception with the DMT to offer an insight into this aspect of his curriculum script.

Promoting students' understanding that the proportionality of all corresponding pairs of sides is not by itself sufficient to prove the similarity of shapes

Alex was aware students need to understand the need to consider both the corresponding angles and sides when determining if shapes are mathematically similar.

> If they [students] do not bring corresponding angles and corresponding sides together, they can go into an error. When they just focus on the [corresponding] sides, they might miss the fact that the corresponding angles [in mathematically similar shapes] need to be the same. They [students] need to be aware of both.

In the lesson that featured Task 5.2 (see Figure 1), during the subsequent whole-class discussion, Alex himself used the DMT dynamically to promote students' emergent understandings that inequivalent corresponding angles do not result in a similar shape to the original. From his computer desktop, he used the DMT to demonstrate and share students' responses with the class and to stimulate a discussion. For example, in the dynamic learning environment, Alex first measured the corresponding angles of the original and the parallelograms named Copy 1 and Copy 2 and then dragged the angle slider to change the angles of the original and Copy 1, followed by two questions he posed to the class: "What did you notice about all the angles?" and "What is going on with the angles at the moment?".

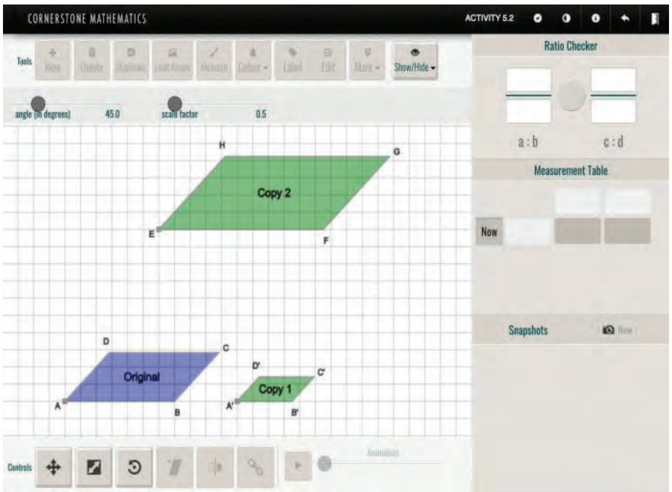

Figure 1: Task 5.2 in the DMT where students drag the angle and scale factor sliders and compare the three parallelograms as they change

Alex also used the types of geometric transformations (e.g. translation, rotation, enlargement) to superimpose Copy 1 on the top of Copy 2 and then dragged the angle slider. His aim was to show and confirm that since the corresponding angles were the same initially, Copy 1 and Copy 2 were mathematically similar, as the angle slider was dragged, the corresponding angles did not remain the same, which made Copy 1 and Copy 2 not mathematically similar. In his post-lesson interview, Alex outlined the DMT enabled students to identify and examine both the corresponding angles and sides, especially through the use of the types of transformations, which would not be possible with an exam-style question in a paper-and-pencil environment.

> If you get a shape where the shape is oriented, and you can use the software [the DMT], for example, you can use this software to orientate the shapes differently to see where corresponding sides and angles are. I think those types of things are useful in the software because you can use the software to rotate the shape to find, as I said, where these angles go. If you use an exam question [in a paper and pencil environment], it is hard for students to understand what they are focusing on the angles and the sides.

Case Study 3: Jack

In his curriculum script, Jack anticipated and identified all of the seven misconceptions provided above (except for the first one) and aimed to address them through the use of the DMT in a dynamic mode during the observed lessons. We particularly focus on the fourth misconception in detail below to give an insight into this aspect of his curriculum script. This misconception was spontaneously spotted and identified by him during a lesson and resulted in him making *ad hoc* decisions to address it using the DMT dynamically.

Promoting students' understanding that if the lengths of a shape are multiplied by a scale factor of k, then the area of the shape is multiplied by a scale factor of k^2

Jack identified this misconception in a lesson when interacting with students during their independent work with the DMT to check their written explanations in the workbook. He instructed students to engage with Task 2.1 (see Figure 2) in which they were instructed to play an animation, watch and decide which quadrilaterals (if any) were always mathematically similar to the original and then produce their written justifications in CM workbook. He noticed one pair of students used the concepts of perimeter and area in their written explanation to justify why the orange and red rectangles were always mathematically similar. The students had concluded the orange and red rectangles remained mathematically similar to the original as the area and perimeter of the rectangles increased by a scale factor of 3 when the animation slider came to the end.

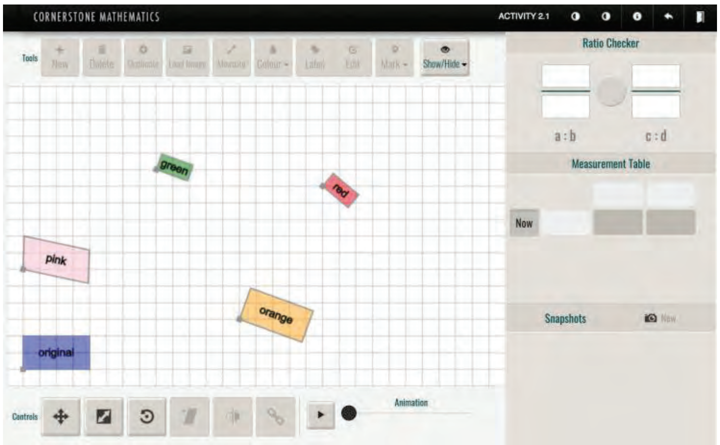

Figure 2: Task 2.1 in the DMT where students play the animation and identify the similar shapes

Jack, however, recognized a misconception as the students had concluded the area scale factor of the orange and original rectangles was the same as the length scale factor (a value of 3). To enable the students to address their misconception, he posed them the question "You see that the perimeter increases by 3 times, does the area increase by 3 times, too?" and then invited them to drag the animation slider such that the lengths of the orange rectangle were twice as large as those of the original. Having drawn the students' attention to that the side lengths of the orange rectangle were now double the side lengths of the original as it had been enlarged by a scale factor of 2, Jack asked them to examine what happened to the area of the orange rectangle in the dynamic learning environment. By looking at the original and orange rectangles on the screen, the students assumed the area of the orange rectangle had doubled. Jack then encouraged them to figure out "How many of them [the original rectangle] could sit into the orange one [rectangle]?" using the grid as a measurement tool available in the DMT, leading them to realise the area of the orange rectangle was 4 times that of the original.

In his post-lesson interview, Jack stressed when the students came up with the mathematical ideas concerning the area and perimeter of similar shapes, which actually went beyond his lesson agenda, he wanted to exploit this learning opportunity to promote students' understanding of the mathematics a stake using the DMT.

> What they [a pair of students] said the perimeter and the area has doubled, so it was a nice teachable moment to say, you know, that was not really part of my learning intention at all, but I felt like it was just a nice opportunity to talk about the behaviour of the area and the behaviour of the side lengths, and the software [the DMT] let them see really nicely what had happened to the area […], so it was just a nice teachable moment where the software gives some nice visual and dynamic pictures that let them notice what was happening.

Conclusion

The focus of this paper is what student misconceptions about the topic of GS teachers predict and/or identify as part of their curriculum scripts and how they exploit the affordances of DMT in the classroom to promote students to confront, reflect upon and address them. The findings suggested all three teachers' curriculum scripts contained some anticipated (and/or identified) misconceptions about GS to be addressed with (and without) the DMT in the classroom. During their post-lesson interviews, all three teachers acknowledged the key role the DMT played in addressing students' misconceptions about GS. However, there were differences in the quantity of misconceptions the teachers anticipated and/or identified and in the ways in which they used the DMT dynamically to help students address their misconceptions. The analysis suggested Jack, the expert teacher, could anticipate several misconceptions with GS and develop alternative approaches to address them using the DMT. He was also, perhaps more importantly, open to employ *ad hoc* strategies to spot and identify misconceptions about GS students encountered in the lessons and use the DMT dynamically to address them. This implies the expert teacher had both confidence and proficient skill in the use of the DMT (even in unplanned use) to respond to perceived students' emerging misconceptions and to develop the underlying mathematics at stake (Ruthven, 2014). However, Lara and Alex, the advanced beginner teachers, showed a limited but growing awareness of their need to anticipate student misconceptions about GS and to consider alternative ways to address them. Lastly, this research was conducted in the context of English secondary schools that limits the generalisability of the findings. Further research is necessary to determine the extent to which the findings of this study might generalise beyond the English context.

Digital tasks with feedback as core of a mathematical learning concept for prospective teachers

Annabelle Speer[1] and Andreas Eichler[2]

[1] University of Kassel, Germany, annabelle.speer@mathematik.uni-kassel.de

[2] University of Kassel, Germany, eichler@mathematik.uni-kassel.de

Due to the increasing importance of digitalization in our society, there are new demands on school, teaching and thus on teachers. Nowadays digital competences belong to the key competences of teachers. The acquisition of digital competences should already be developed in university education of teachers. In this regard, we refer to a university seminar aiming to support professional competences of prospective teachers in digital mathematical teaching and learning contexts. The seminar is based on learning mathematics with the digital assessment system STACK, reflecting the use of STACK, designing learning environments with STACK and, finally, reflecting school students' use of STACK. We collected data of prospective teachers' development of digital competences through interviews. First results show that prospective teachers' competences including knowledge, beliefs and motivation can be developed and differentiated.

Keywords: Electronic learning, computer uses in education, feedback, teacher education.

Introduction

"In a digital world, knowing how to use ICT and having access to such technologies are proving increasingly important for participating effectively in society" (Fraillon et al., 2020, p. 5). For this reason, gaining digital competences is a main issue for school students. However, research showed that in Germany digital competences of school students are partly poorly developed (Fraillon et al., 2020). One reason for the poor development of school student's digital competences seems to be caused by teachers (Hegedus et al., 2017; Misfeldt et al., 2016). In an international comparison, teachers in Germany use digital tools (computer, calculators, mobile devices etc.) less frequently in the classroom and also assess the potential of these less than teachers in other countries (Fraillon et al., 2020). For this reason, a main goal of university education and professional development of prospective teachers is to improve their digital competences as part of mathematics teachers' professional competences including knowledge, beliefs and motivation (Baumert & Kunter, 2013).

A contribution to this line of research will be made by this PhD-project called "Learning, Reflecting and Designing: Digital tasks with feedback as core of a mathematical learning concept", in which we investigate in a qualitative study how prospective teachers' knowledge, beliefs and motivation could be increased in a specific seminar in the teacher education program. In this seminar, the prospective teachers experience the importance of learning mathematics with the digital assessment system STACK by learning with digital tasks themselves. Afterwards they reflect on the potential of STACK such as the opportunity of the STACK system to give individualized feedback to learners and after that, the prospective teachers design their own mathematical tasks with STACK and use them with school students. Finally, there is a renewed reflection on the STACK system, the task, the feedback and the practical application. Our main research question (RQ) is as follows:

RQ: How does learning with and designing and reflecting on one's own digital (STACK) tasks in a university mathematics education seminar affect the knowledge, beliefs and motivation of prospective teachers?

In this paper, we primarily focus on prospective teachers' beliefs referring to the potential of digital tasks with feedback including partly also aspects of knowledge and motivation.

Knowledge, beliefs and motivation

According to Baumert and Kunter (2013), professional competences comprise knowledge, beliefs and motivation. With regard to digital competences Koehler et al. (2013) provide the TPACK-model which differentiates knowledge into three main components (Figure 1): content knowledge (CK), pedagogical knowledge (PK) and technological knowledge (TK). Content knowledge comprises factual knowledge and subject-specific ways of thinking and working (Koehler et al., 2013). The pedagogical knowledge contains the knowledge about different concepts for designing learning environments, such as teaching methods, classroom management but also motivational aspects (Koehler et al., 2013). Knowledge of how to use (digital) technologies, such as hardware and software, is called technological knowledge (Koehler et al., 2013). The three main components of teachers' knowledge are set in relation to each other. Research showed that the positive influence on student performance is greater if the teacher has previously done further training on the use of digital tools and has thus acquired digital competences (Hillmayr et al., 2020). Although an influence of the teacher on the design of lessons with digital tools has already been proven, offers for the acquisition of digital competences in university teacher education in Germany are only available to a small extent (Vogelsang et al., 2019).

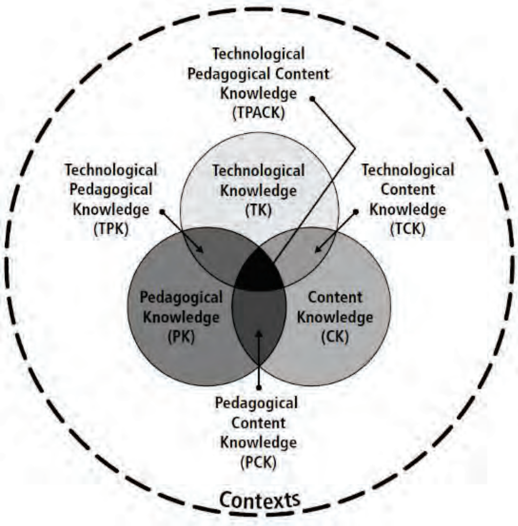

Figure 1: TPACK-model (Koehler et al., 2013)

Another essential competence facet of teachers are beliefs (Baumert & Kunter, 2013). We understand the term beliefs "as an individual's personal conviction concerning a specific subject, which shapes an individual's ways of both receiving information about a subject and acting in a specific situation" (Erens & Eichler, 2015, p. 136). Different dimensions of teachers' beliefs can be identified: beliefs concerning teaching, learning and a specific subject. (Fives & Buehl, 2012). Research showed that beliefs are difficult to change and that a belief change needs a substantial situational impact (Liljedahl et al., 2012). Thus, also to change prospective teachers' beliefs in a university seminar potentially needs to include a strong impact on their beliefs. Beliefs also shape the way, teachers understand teaching with digital tools (Erens & Eichler, 2015; Misfeldt et al., 2016). Specifically for the use of digital tools, Thurm et al. (2017) developed categories for teachers' beliefs about advantages, disadvantages and general issues of digital tools. In the category advantages are those teachers' beliefs that are positively disposed towards the use of digital tools in the classroom, for example, that digital tools can be used to support a change of representation (visual, symbolic). One of the disadvantages of digital tools mentioned by Thurm et al. (2017) is the high amount of time required for the introduction of digital tools in classroom. The general category includes beliefs about the timing and thus the question at what point in the lesson a teacher should use digital tools.

Besides knowledge and beliefs, motivation is another essential competence facet of teachers (Baumert & Kunter, 2013). According to Eccles and Wigfield's (2002) expectancy-value model, motivational orientation is influenced by expectation and value variables. The expectation variable can be defined as individuals' view "about how well they will do on upcoming tasks, either in the immediate or longer-term future" (Eccles & Wigfield, 2002, p. 119). The value variable can be divided into four facets: "attainment value, intrinsic value, utility value and cost" (Eccles & Wigfield, 2002, p. 119). The value variables comprise intrinsic components (intrinsic value), rather extrinsic components (utility value) and any perceived negative aspects (costs) of an action (Eccles & Wigfield, 2002). The motivation to use digital tools in one's own lessons is positively influenced by knowledge about the use of digital tools as well as by corresponding beliefs (Ertmer & Ottenbreit-Leftwich, 2010).

Design and materials

The seminar for improving prospective teachers' digital competences

We developed a seminar concept for prospective high school and vocational school teachers focused on digital tasks with feedback within this PhD-project (Figure 2). The seminar, which is one of the elective modules in the teacher education program, is divided into four parts. In the first part, prospective teachers learn with digital tasks (STACK) themselves. For this purpose, digital tasks are provided for them to deal and to learn with. After learning with the digital tasks, the prospective teachers change their role from learner to teacher and test, evaluate and assess the given digital tasks and feedback included in the digital tasks. They also reflect the potential of the digital assessment system STACK. In the second step, the participants independently design their own digital tasks with feedback in the system STACK. In the third part, school students selected by the prospective teachers work with these tasks and comment on them, the digital format of the task and the feedback given within working on the task. In the fourth part based on students' feedback, the task, the feedback, the system STACK and the practical application are reflected by the prospective teachers. The seminar has already been conducted, evaluated and optimized in three cycles.

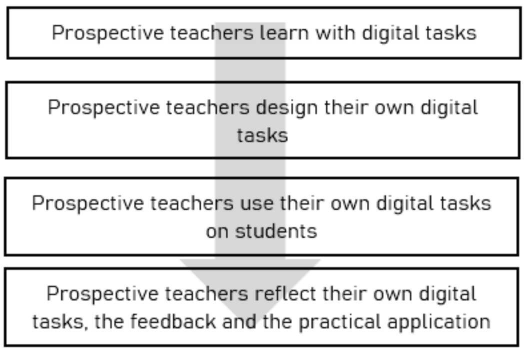

Figure 2: Seminar concept developed within this PhD-project

The digital assessment system STACK

STACK (System for Teaching and Assessment using Computer Algebra Kernel, Sangwin, 2013) is a digital assessment system in which digital mathematical tasks can be designed procedurally and conceptually (Rittle-Johnson & Schneider, 2014) and at different levels of representation (symbolic, graphic, interactive). The STACK system uses the computer algebra system Maxima (Sangwin, 2013), which makes it possible not only matching user input with stored sample solution, but also checking it for mathematical properties. Task developers are able to create a potential response tree (PRT, Sangwin, 2013) in STACK. The potential response trees, in which the input made can be examined for a specific mathematical property at each node, make individualized feedback for each user input possible (Figure 3).

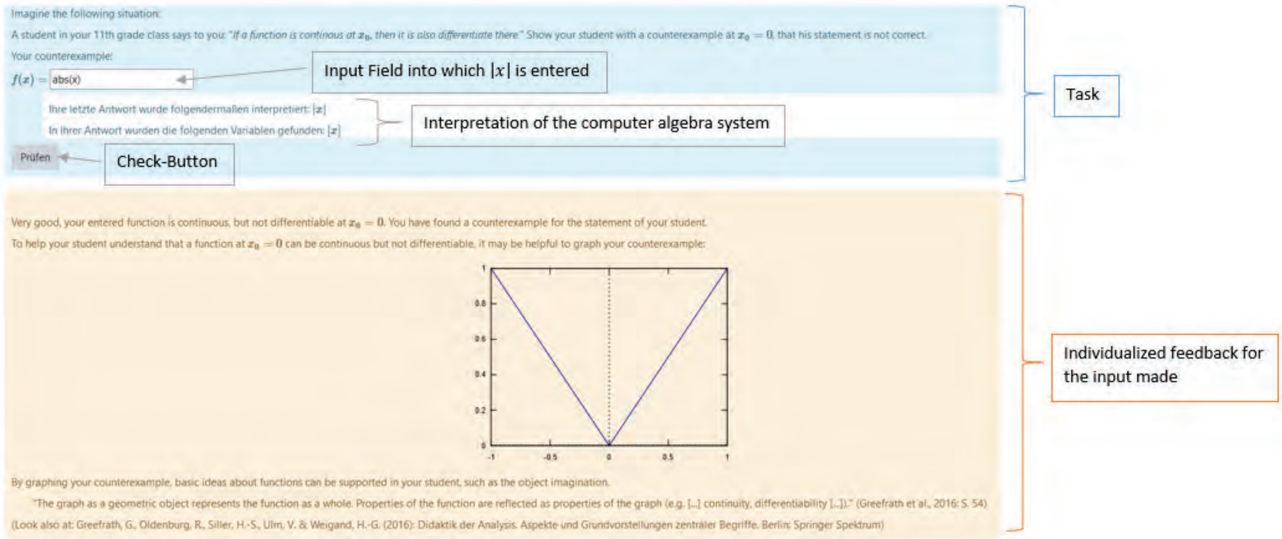

Figure 3: An exemplary STACK task with individualized feedback

Particularly, the possibility of STACK to provide individualized feedback is crucial since feedback is considered information that focuses on aspects of performance and understanding (Hattie & Timperley, 2007). Feedback is an effective intervention to support and optimize learning processes (Goldin et al., 2017). Feedback can increase cognitive performance, motivation and the feedback-recipients' willingness to make an effort. Furthermore, feedback can support learner individually and according to their potential. Within digital learning environments there are numerous possibilities to give feedback on learning processes (Goldin et al., 2017). The individualized, differentiated feedback for each user input seems to be crucial but often there is given rather simple and evaluative feedback (categorization into right or wrong) (Fraillon et al., 2020).

Design of the study

The sample for the data collection consists of three prospective teachers from each of the three seminar cycles. A main method for collecting data of the prospective teachers were semi-structured interviews which took place two times in each seminar. The semi-structured interview guide contains three domains (Figure 4). The first domain refers to beliefs and motivation from the learner's perspective. Therefore, this domain is about the prospective teachers' university education. This contains the use of digital tools in university studies and the attitude towards digital tools. The second and the third domain ask for beliefs and motivation from the teachers' perspective. In the second domain, we ask for the motivation to use digital tools and digital tasks in the classroom in the four facets that Eccles and Wigfield (2002) describe (attainment, intrinsic and utility value as well as cost). The third domain concerns school and teaching in particular. There we ask for beliefs towards digital tools and digital tasks with feedback while teaching and self-efficacy to design lessons with digital tasks. In this context we also collect beliefs about feedback in school context.

Furthermore, we work with written comments from the prospective teachers on different digital tasks. Within the written comments, the prospective teachers should vary the given tasks, design new feedback to different inputs and name advantages and disadvantages of the digital format and the digital feedback. With this method, we want to collect professional knowledge which contains variation of tasks and designing feedback, but also beliefs towards digital tasks and digital feedback.

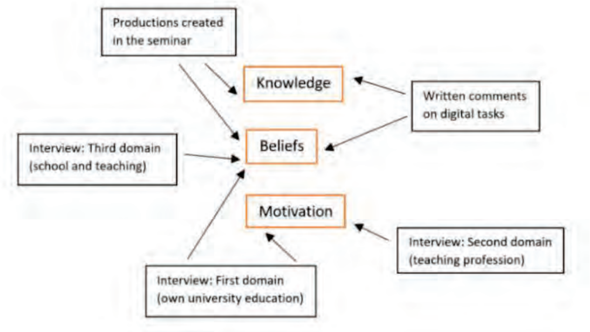

Figure 4: Methods and which competence facets we ask for within these methods

Moreover, we analyze productions from the prospective teachers, which are created in the seminar. This includes their own digital tasks, the written reflection on their own digital task, the designed feedback and their final term paper. With this, we want to survey the professional knowledge as well as the beliefs about the use of digital tasks in lessons (Figure 4).

We analyzed the data using content analysis. For this purpose, the competence facets knowledge, beliefs and motivation are subdivided into different categories, such as learning with digital feedback, advantages of the digital format for teachers and negative aspects concerning the STACK system.

Findings

In this paper we exemplarily show interview excerpts. In the first example, Adrian names the possibility to get feedback directly while working on digital tasks:

Adrian: [The system gives] feedback directly. This means that the student works on a task and during the work he already gets feedback on what is correct, what is wrong and why he does something wrong. This gives a great potential to directly address and counteract the problems a student has while working on the mathematical task.

The expressed belief relates to learning with digital tasks with feedback and applies more to an advantage of feedback than of the digital task itself. Adrian only mentions superficially the structure of feedback and the containing components. He rather focuses on one function of direct feedback which is the early prevention of misconceptions. This is not only a belief, but also concerns the knowledge facet TPACK (technological pedagogical and content knowledge, Koehler et al., 2013). TPACK describes the knowledge about mathematical digital learning environments. In this context, it is necessary for a teacher to know about the functions of the STACK system as well as to recognize misconceptions and problems of students while working on a task and to be able to design individualized feedback.

In the next example, Jacob's statement relates to teaching with digital tasks with feedback from the teacher's perspective and applies to an advantage of the digital format of the task:

Jacob: For me as a teacher it is important that I can see what the students' learning level is. The students' inputs are listed in a table. There I can also see how many attempts [to solve the task] were needed, what misconceptions existed among the students and what feedback the students received.

He explains that the digital format gives the teacher an accurate overview of students' missed attempts and misconceptions. This can form the basis for a better assessment of the students' performance on the one hand and for planning the following lessons on the other hand. This statement also refers to the utility value of motivation (Eccles & Wigfield, 2002). Digital tasks and the associated better overview on the students' learning level are useful for a teacher to plan further lessons. This is a rather extrinsic reason for using digital tasks in one's own lesson. The facet of knowledge addressed here is technological knowledge (TK, Koehler et al., 2013). The teacher needs to know about the function associated with digital tasks and how to handle the STACK system.

Patrick's statement concerns teaching and learning with digital tasks and applies to an advantage of the digital format and the digital task:

Patrick: The digital format of the task gets students motivated to start working. I believe that the students have more fun working digitally than calculating a task from the textbook. Especially students who are not mathematically inclined are more likely to want to work on digital tasks and try them out.

The first part of Patrick's statement is about teaching with digital tasks. He mentions the positive attitude of the students towards digital tools. Therefore, it will be possible to get students into action. The second part of the statement concerns learning with digital tasks. It explicitly refers to students who are not mathematically inclined. The inhibition to deal with mathematical content and to do something wrong can decrease through the digital format of the task. This also concerns the utility value of motivation (Eccles & Wigfield, 2002). The digital format of the tasks is useful to get students motivated to work and therefore the use of digital tasks in one's own lessons is influenced rather extrinsically. This statement also concerns TPACK (Koehler et al., 2013). Patrick focuses on cognitive activation within mathematics teaching which can be supported by digital tasks.

Not all beliefs towards digital tasks with feedback are positive. In addition to the advantage explained above, Jacob also mentions a critical point towards working on digital tasks. He discusses whether the process of working on the task is really digital:

Jacob: In case of a complex digital task that cannot be solved in head but, for example, requires five to ten intermediate steps before solution can be found, these steps must be written on a sheet of paper in analogue form. This means that the process finding a solution is partly not digital, but only the input and evaluation of the solution are digital.

Jacob explains that students need an analogue medium like a sheet of paper to solve a complex digital task. Therefore, the task as well as the evaluation of the input can be described as digital but not the process of solving. This belief concerns learning with digital tasks with feedback and the process of working on a digital task respectively and applies to a disadvantage of digital tasks because not the entire process of working can be considered digital. Jacobs' statement also relates to the facet cost of motivation (Eccles & Wigfield, 2002). Within this facet, all negative aspects of the use of digital tasks with feedback in the classroom are summarized.

Discussion and conclusion

The presented study investigates how prospective teachers' knowledge, beliefs and motivation towards digital tasks with feedback can be changed through a specific seminar in the teacher education program. First results show that prospective teachers' beliefs are varied. Some of the beliefs relate to feedback as a part of a digital task. Other beliefs concern teaching with digital tasks and associated with a better overview of student performance. Beliefs about learning with digital tasks were also expressed such as that students are more motivated to engage with a mathematical topic because of the digital task format. We can thus see that the prospective teachers' beliefs relate either to teaching and learning with digital tasks as well as to the specific subject of feedback, what has already been described by Fives and Buehl (2012). The fact that the prospective teachers adopt multiple perspectives could be due to the seminar concept presented. The prospective teachers first learn with digital tasks themselves, taking the learner's perspective. In the seminar, they then change to the designer's perspective when designing their own digital tasks and finally to the teacher's perspective when using them with school students. Furthermore, the beliefs can be classified into the categories advantages, disadvantages and general issues found by Thurm et al. (2017). It also becomes visible that the competence facets knowledge, beliefs and motivation are not disjoint. Many of the prospective teachers' statements can be assigned to categories of beliefs as well as categories of knowledge and/or motivation.

Preservice teachers' beliefs about mathematical digital competency – a "hidden variable" in teaching mathematics with digital technology?

Daniel Thurm[1], Eirini Geraniou[2] and Uffe Thomas Jankvist[3]

Recently the construct of mathematical digital competency (MDC) was put forward in which mathematical competency and digital competency are seen as a connected whole. This entails that student understanding of mathematical concepts may be almost inseparable from digital tools. We report on a quantitative study with n=238 preservice teachers (PSTs) from Germany that investigates PSTs' beliefs about such a "connected position" of MDC. Results show that a large group of PSTs believe in the potential of digital technology but at the same time opposes the notion of MDC and rather believe that mathematical and digital competency should be separated. Furthermore, PSTs' beliefs about MDC are largely independent from epistemological beliefs. We hypothesize, that beliefs about MDC may be an overlooked variable which may influence how teacher think about and use digital technology in the mathematics classroom.

Keywords: Beliefs, digital technology, teacher education, graphing calculators, self-efficacy

Introduction

Teacher beliefs are an important factor for implementing digital technology (DT) in the mathematics classroom (Thurm & Barzel, 2021). The question arises which facets of teacher beliefs are relevant for teaching mathematics with (DT). In this respect, previous research has shown that teachers' beliefs about the potentials of DT use, teacher epistemological beliefs (i.e., beliefs about the nature of mathematics and teaching and learning mathematics) and self-efficacy are important dimensions of teacher beliefs (Thurm & Barzel, 2020). In this paper we investigate a somewhat novel dimension of teacher beliefs in the context of teaching mathematics with DT. Starting point for this research study was the work of Geraniou and Jankvist (2019) who argue that mathematical competencies and digital competencies are rarely seen as a connected whole even though students will have to simultaneously activate and use these competencies. Therefore, they conceptualize the construct of "mathematical digital competency" (MDC), which describes an amalgam of mathematical and digital competencies. In particular, they use the theories of conceptual fields (Vergnaud, 2009) and instrumental genesis (Guin & Trouche, 1999) to show that such an amalgam entails that a student's understanding of a mathematical concept may almost inseparably be connected to digital tools and the student's instrumented techniques. In this paper we investigate how PSTs think about such an amalgam and how their beliefs are related to other belief facets like epistemological beliefs and beliefs about affordances and risk of DT use. We start by elaborating in more detail on the two main theoretical frameworks for our study, namely MDC and teacher beliefs. Throughout the paper the term "digital technology" (DT) refers to mathematic-specific digital technologies like function plotters, dynamic geometry systems, computer algebra systems and multi-representational tools.

Theoretical background

The notion of competency has gradually gained momentum and is nowadays a key construct in the educational paradigm (Geraniou & Jankvist, 2019). Mathematical competency can be defined as "someone's insightful readiness to act appropriately in response to a specific sort of mathematical challenge in given situations" (Niss & Højgaard, 2019, p.14) while digital competency has been conceptualized as "the set of knowledge, skills and attitudes […] that are required when using ICT and digital media to perform tasks; solve problems; communicate; manage information; collaborate; create and share content; and build knowledge" (Ferrari, 2012, p.43). Geraniou and Jankvist (2019) linked mathematical and digital competencies by using the theory of instrumental genesis (TIG) and the theory of conceptual fields (TCF). TIG (Guin & Trouche, 1999) describes the process of transforming a digital tool (an artefact) into a mathematical instrument which is a psychological construct that combines (parts of) the artefact and cognitive schemes in which technical knowledge about the artefact and the domain-specific mathematical knowledge are intertwined. TCF (Vergnaud, 2009) takes, similar to TIG, a developmental point of view. TCF highlights that a concept is not only referring to explicit objects of thought, but comprises a set of schemes, a set of situations and a set of linguistic and symbolic tools of representation. In particular, Vergnaud (2009) stresses that different concepts and situations are interconnected forming conceptual fields, which he defines as "a set of situations and a set of concepts tied together" (Vergnaud, 2009, p.86). The set of situations gives meaning to the concept and acts as a point of reference.

Geraniou and Jankvist (2019) show that both TIG and TCF can serve as a lens to investigate the simultaneous activation and development of mathematical and digital competency which they call "mathematical digital competency" (MDC). In particular they highlight, that the situations that make up students' conceptual fields "*may be embedded so deeply in a techno-mathematical discourse that, potentially, also their understanding of the mathematical concepts involved is almost inseparable from the digital tools and the students' instrumented techniques*" (p. 42). This could for example mean that the set of situations that students use as points of reference to give meaning to a concept will largely comprise situations involving DT. Moreover, a student may only be able to do (some) mathematically activities within a digital environment. Hence students might only be able to think about, explain and do mathematics with reference to a digital tool. Starting from this notion of a close amalgam of student's mathematical competencies and digital competencies, the question arises what teachers believe about such a potentially close interwovenness.

According to the broadly accepted definition proposed by Philipp (2007), teacher beliefs can be defined as "psychologically held understandings, premises, or propositions about the world that are thought to be true" (p.259). Beliefs are part of teachers' conception - a general notion or mental structure encompassing beliefs, meanings, concepts, propositions, rules, mental images, and preferences (Philipp, 2007). Teacher beliefs are an important factor for teaching mathematics with DT since they act as a bridge between knowledge and action (Thurm & Barzel 2020; 2021). However, teacher beliefs are not an unidimensional construct but can be differentiated into various dimensions (clusters) and sub-dimensions which form a differentiated belief system in which (clusters of) beliefs can be logically connected and some (clusters of) beliefs are more important than others (Philipp, 2007; Leder et al. 2002; Thurm & Barzel, 2020; 2021). With respect to teaching with DT, three dimensions of teacher beliefs have so far been identified as particularly important: (i) beliefs about teaching and learning with DT, (ii) self-efficacy beliefs and (iii) epistemological beliefs (Thurm & Barzel, 2020). These dimensions of teacher beliefs can be further differentiated into various sub-dimensions (Thurm & Barzel, 2020; see figure 1).

However, teacher *beliefs about MDC* have not yet been investigated, which is not surprising given that the notion of MDC has just recently emerged with the work of Geraniou and Jankvist in 2019. Clearly, a teacher can have different belief positions with respect to the relation of mathematical and digital competencies. On one extreme one can fully embrace the "*connected position*" of MDC (e.g., that students understanding of the mathematical concepts involved may be almost inseparable from DT). On the other extreme, someone could strongly favor a "*independent position*" believing that mathematical and digital competencies should not be closely interwoven but rather clearly separated (i.e., a student should be able to think about, explain and do mathematics without a DT). Clearly if teachers oppose a close interwovenness ("*connected position*") as conceptualized by MDC this will be problematic if the goal is to develop students MDC or if students learn mathematical concepts with the support of DT. In the following, we will refer to beliefs about the interwovenness of mathematical competencies and digital competencies simply as "beliefs about MDC".

Research questions and methodology

In our exploratory research study, we investigate two distinct but interconnected research questions:

RQ1: What are preservice teachers' beliefs about MDC? (Belief position)

RQ2: How are preservice teachers' beliefs about MDC related to epistemological beliefs, beliefs about teaching and learning with DT and self-efficacy beliefs? (Belief system)

To answer the research questions, we used quantitative instruments to measure PSTs beliefs about MDC, about the nature of mathematics and mathematical learning, about teaching and learning with DT and PSTs self-efficacy beliefs. The reason why we use questionnaires to catch teacher beliefs is that questionnaires allow to simultaneously measure different belief dimensions and relate them to each other by statistical analysis. Furthermore, questionnaires also provide opportunity to investigate the discriminant validity of the dimensions (Fives & Gill, 2015). In the following we briefly elaborate how the different dimensions were assessed through multi-item-scales (figure 1 gives an overview of all scales).

Since there were no items/scales available to measure PSTs beliefs about MDC, we started to construct a scale following the recommendations for scale and item construction of Simms (2008). The item design was guided by the goal to write items that capture PSTs believe whether or not it is acceptable if a student's understanding of a mathematical concept is almost inseparable from digital tools. If it is inseparable, this would mean for example that a student is only able to think about, explain and do mathematics with reference to a digital tool. We set up an initial pool of eight items (sample items are given in table 1) which were further refined with PSTs and experts. Response format for all items was a 6-point Likert scale ranging from "1=strongly disagree" to "6=strongly agree" (hence higher values indicate a more "independent position"). After administering the scale to the PSTs, we conducted an exploratory factor analysis (EFA). Based on the results four of the eight items were dropped and the final MDC-scale was constructed using the mean of the items MDC1-MDC4 displayed in table 1. Hence high values on the MDC-scale reflect that PSTs oppose the notion of a close link between mathematical competencies and digital competencies (which we call “independent position”) while low values of the MDC-score reflect a more “connected position” in line with the MDC concept. Reliability (Cronbach’s alpha) of the scale was 0.75 indicating an acceptable reliability score.

Table 1: Sample items for the scale to measure PSTs beliefs about MDC

MDC1	A student should be able to explain a mathematical concept or relationship without referring to a digital mathematical tool.
MDC2	A student should be able to solve a mathematical problem without a digital mathematical tool.
MDC3	A student’s understanding of a mathematical concept should be independent from digital mathematical tools.
MDC4	A student should be able to give examples of a mathematical concept or relationship without referring to a digital mathematical tool.

- To measure PSTs’ epistemological beliefs about the nature of mathematics we used three shortened multi-item-scales from the international TEDS-M-Study (Blömeke & Kaiser, 2014). One scale captured to what extend PSTs believe that mathematics is a static collection of rules and procedures (Scale: “Rules and Procedures”, E1). The second scale captured to what extend teachers view mathematics as a dynamic science which consists of problem-solving processes and the discovery of mathematical structures and regularities (Scale: “Inquiry”, E2). The third scale captured to what extend PSTs believe that mathematics is discovered rather than invented (Scale: “platonic conception”, E3).

  Epistemological beliefs about the learning of mathematics were captured with two scales. A shortened scale from the COACTIV-Study (Kunter & Baumert, 2013) measured to what extent students believe that learning mathematics is best achieved by receptive learning (Scale: “Instructivist”, E4). We also asked PSTs to rank the four conceptions of learning mathematics put forward by Kuhs and Ball (1986) by preference (classroom-focused; content-focused with an emphasis on performance; content-focused with an emphasis on conceptual understanding and learner-focused). By taking the mean of the ranks of the two instructivist conceptions (classroom-focus, content-focused with an emphasis on performance) we derived a scale (E5) where higher values indicate a more constructivist approach to teaching.
- To measure PSTs’ beliefs about teaching and learning with DT we used five established multi-item-scales (all items can be found in Thurm (2020)). Beliefs about the potentials of teaching with DT were captured by the scales “Supports discovery learning”" (T1) and “Support of multiple representation” (T2), whereas negative beliefs were captured by the scales “loss of computational / by-hand-skills” (T3) and “Mindless working” (T4). The scale “Prior mastery of mathematics by hand” (T5) captured whether students believe that DT should only be used when the mathematics is thoroughly understood without DT. Response format for all items of the scales was a 6-point Likert scale ranging from “1=strongly disagree” to “6=strongly agree”.
- Self-efficacy was measured using two established multi-item-scales (all items can be found in Thurm (2020) capturing PSTs’ self-efficacy for task design and selection (S1) and lesson design

and implementation (S2). Following Bandura (2006) response was given on a scale ranging from 0 to 100, where higher values indicate higher self-efficacy.

The online-questionnaire which comprised all previous described scales was administered in 2021 to n=238 PSTs from two German universities in the state of North Rhine-Westphalia. Participation was voluntarily and anonymous. To ensure a certain level of basic expertise in mathematics education and a basic exposure to digital mathematical tools during university studies, the questionnaire was only administered to PSTs who had completed at least four semesters of teacher education. 35% of the participants were male while 65% were female. The PSTs indicated that they had used digital mathematical tools for their own learning approximately once a week during their university studies.

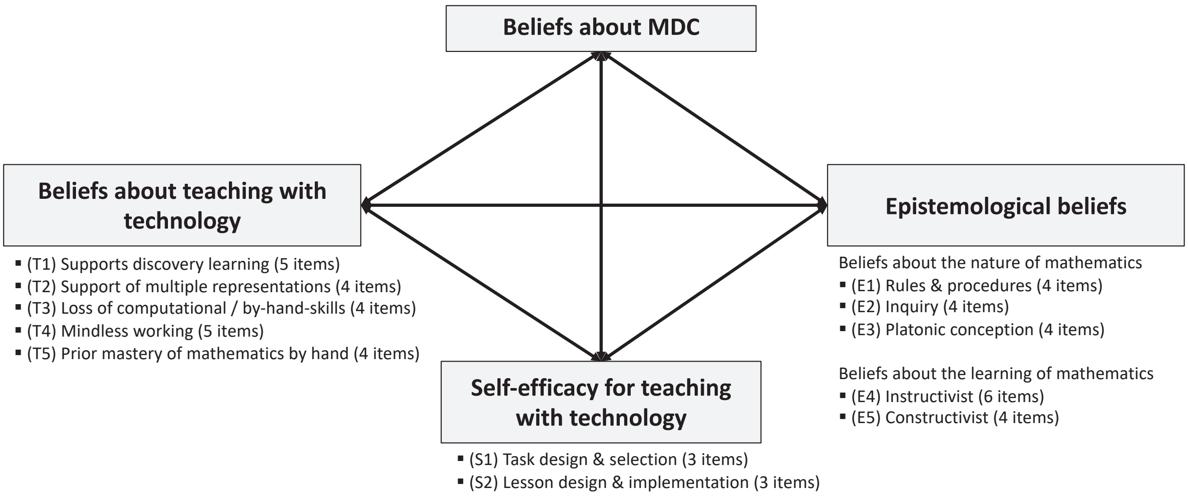

Figure 1: Overview of the different dimensions of teacher beliefs that were investigated

Results

RQ1: What are preservice teachers' beliefs about MDC? (Belief position)

Figure 2 shows the distribution of the MDC-scale (average of the items MDC1-MDC4). The mean of the MDC-scale is 4.51 indicating that PSTs on average clearly agreed more with an "*independent position*". In particular, 55.5% of the PSTs show an MDC-score ≥ 4.5 and thus strongly identified with the "*independent position*". A group of 40.3% of the PSTs was somewhat undecided/moderate (MDC-score between 2.5 and 4.5), while only 4.2% identified strongly with a *"connected position"* (MDC-score ≤2.5).

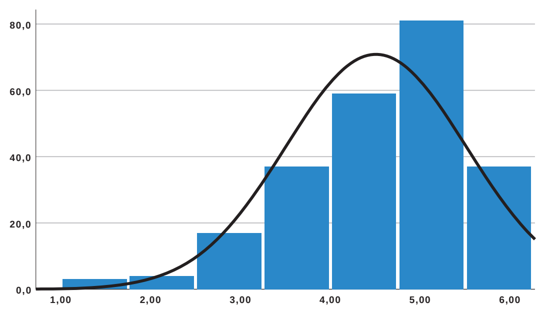

Figure 2: Frequency histogram of the scale measuring PSTs beliefs about MDC (mean of the items MDC1-MDC4)

RQ2: How are preservice teachers' beliefs about MDC related to epistemological beliefs, beliefs about teaching and learning with DT and self-efficacy beliefs? (*Belief system*)

Table 2 shows the means, standard deviation and reliability of all scales used in this study. Table 3 gives the correlation among the different constructs. First, none of the correlations are extremely high which indicates that the MDC-scale is indeed measuring a distinct construct different from the other constructs. The correlations in table 3 also show that a stronger "*independent position*" (higher values on the MDC-scale) is significantly associated with more negative beliefs about teaching and learning with DT (T1-discovery learning: ρ=-0.31**, T3-loss of skills: ρ=0.34**, T4-mindless working: ρ=0.39***). However, a closer look at the subgroup of PSTs that holds a particularly strong "*independent position*" (MDC-score ≥ 4.5, see table 2) reveals that this subgroup has still very positive beliefs about the potentials of DT for teaching and learning (DT supports discovery learning=4.65 on a 6-point scale, DT supports multiple representations=5.36 on a 6-point-scale). Remarkably, there were almost no significant correlations between MDC and epistemological beliefs (E1-E4) or self-efficacy beliefs (S1, S2). Only scales E2 ("Inquiry") and E5 ("Constructivist") were slightly negatively correlated with a more "*independent position*".

Table 2: Mean (M), standard deviation (SD) and reliability (Cronbach's alpha) for the total sample (Mean total) and the subgroup with strong "independent position" (Mean MDC≥4.5)

Scale	α	Mean total (SD)	Mean MDC≥ 4.5	Scale	α	Mean total (SD)	Mean MDC ≥4.5
MDC	.75	4.51 (1.00)	5.23	(S1) Task design & selection	.84	64.63 (20.12)	64.64

Discussion and conclusion

In this study, we took a first step to investigate PSTs' beliefs about the relation between mathematical and digital competency. We found that many PSTs in the sample agreed with an *"independent position"* meaning that they believe that a student should be able to think about, explain and do mathematics independently from digital tools. This clearly opposes a more "*connected position*" as conceptualized in the concept of MDC by Geraniou and Jankvist (2019).

Remarkably, beliefs about MDC were only barely associated with epistemological beliefs by the PSTs. Moreover, we found, that even the PSTs who were very strongly favoring an *"independent position"* at the same time strongly believed in the potentials of teaching and learning with DT (e.g., for discovery and investigation). These are interesting findings since they may point to some contradiction in the PSTs' belief system. If a PST highly values the potential of DT (e.g., to support discovery learning) but at the same time believes that mathematical understanding should be independent from DT, it will not be easy to balance these two views. In fact, if DT is used in a constructivist way for discovery learning of a new concept, the conceptual fields and the set of situations that students use as points of reference to give meaning to a concept will not be independent of the DT. Rather students' conceptual fields will be constructed around and therefore interwoven with DT. Hence, if PSTs hold an *"independent position"* this may limit the use of DT to understand and learn mathematics, or even reduces the use of? DT to "do mathematics". We hypothesize that PSTs may not be aware of this contradiction in their beliefs system. The observation that most PSTs agreed strongly that DT should only be used if the mathematics is thoroughly understood, may be a consequence of managing the tension of using DT (acting in line with their positive beliefs about DT) and at the same time maintaining an independence between mathematical understanding and DT (acting in line with their "*independent position*").

In total, the results of this study indicate that beliefs about MDC might be an overlooked variable—especially if the goal is to support students to develop MDC. In particular, the results of the study point to a discrepancy: If students learn with DT, they may develop some form of MDC (Geraniou & Jankvist, 2019). Yet, teachers expect students' understanding to be independent of DT and to be able to think about, explain and to do mathematics without DT. This discrepancy will be problematic and likely impact how teachers use DT. Consequently, it might be fruitful to engage PSTs in reflection about their beliefs on MDC and how these influence / conflict other beliefs in their beliefs system (e.g., beliefs about the potentials of DT for learning). Finally, we would like to mention one main limitation of the study – namely, that the belief position measured by the MDC-scale was not triangulated with qualitative data. Currently we are conducting qualitative interviews with PSTs after they have answered the MDC-scale to validate whether the MDC-scale is indeed measuring teachers' beliefs about MDC, and to uncover the PSTs' belief argumentation for their position.

An interdisciplinary educational path enhanced with technologies: Cloud Computing in Education

Francesco Saverio Tortoriello[1] and Ilaria Veronesi[2]

[1]University of Salerno, Faculty of Mathematics, Italy; fstortoriello@unisa.it

[2]University of Salerno, Faculty of Mathematics, Italy; iveronesi@unisa.it

Keywords: Interdisciplinarity, cloud computing, education, technology, mathematical language.

This poster describes an interdisciplinary educational path developed in cooperation among different schools participating in Mathematical High School Project (MHS) and implemented thanks to Cloud Computing. The activities lead us to think that Cloud Computing in teaching can enrich curricular activities conducted with a constructivist methodological-didactic approach in a wide vision of knowledge. We present the case study, a laboratorial path of analysis and deepening of mathematical books that led to the production of an educational game.

Modern educational theories subline that students must be the protagonists of all educational activities, playing an active role in all training moments. The sharing of good educational practices allows the enrichment of the whole school communities thanks to the potentials of new technologies that enable remote access to tools, programs and didactic models. Sharing and collaboration become more difficult to manage when institutions are placed in distant locations. In these cases, the technologies are powerful and effective tools for cooperative work and the Cloud is a widespread methodology for sharing in educational activities is much less widespread even if it could become extremely powerful. Generic software, offers online productivity applications such as word processing, spreadsheets and functions that can be used in the classroom. This provides to work and share progresses or results in real time.

The project was implemented in the classroom in the year 2017/18 with the participation of researchers from Department of Mathematics of the University of Salerno, teachers (Italian literature, Math and Computer Science) and four middle classes (about eighty students) from different MHS Schools. In our activity we used the Cloud platform as an enhancement of a teaching-learning practice oriented towards metacognitive teaching that allows the enhancement of higher mental functions. Social interaction between students and teachers is fundamental for cognitive development as a result of interactions between peers and with experts in different contexts (Vygotsky L.S., 1934).

The transformation of mathematical narrative books into a video game required a careful analysis of different languages for different contexts. Students mediated the various communicative languages bringing their analytical and synthetic thinking to a higher level of sophistication. It is consistent with MHS activities oriented to insert mathematics as a transversal language between humanistic and scientific culture (Rogora, E., Tortoriello, F.S. 2021, Tortoriello, F.S., Veronesi 2021-1) to integrate curricular paths by exploiting the tools that technology offers (Tortoriello, F.S., Veronesi 2021-2).

The purpose of the activities carried out in cloud mode was to reconstruct the plot of popular books of mathematical interest in the form of a video game with the Skretch software. One group of students designed the scenes from the books, another group developed the backgrounds and game environments, the last group built the actions on the characters drawn by other groups.

Asset structure of the project:
Step 1: brainstorming - all students read the entire books, some of them are “What is the name of this book?” (Raymond Smullyan), “The Parrot’s theorem” (Denis Guedj), “A tangled tale” (Lewis Carroll). Their teachers solicited the exchange of opinions and suggestions to define the most engaging moments of the books and rewrite them by turning them into videogame scenes.
Step 2: creating scenes - students wrote the storyboard, organized the story sequences and transcribed the selected scenes storing them into a repository on a shared drive.
Step 3: creating the digital story - students organized into groups, used the scenes saved in the shared Drive folder and used the Scratch software to create the scripts with the collaboration of the teachers. Images, videos and sounds have been added to the game in which the protagonist (the player) faces challenges of different skills, logical reasoning, spatial observation, memory skills, speed and dexterity, historical and scientific cultural competences.
Step 4: presentation- a first sharing activity was carried out by each group of participants in their own school. A second dissemination meeting was the National Seminar of Mathematical High Schools that took place at the University of Salerno in a workshop.

The use of a constructivist approach enhanced with technologies has shown that the participation of students, the quality of the video game as the final product of the course were qualitatively excellent and this activity allowed students to learn by doing, enriching the path with active participation

In the analysis of the didactic impact of this laboratory activity, all the students were very interested and involved because each student found the most congenial area among the various ones of the project. The methodological choice of group-works and the active collaboration between different schools and students developed social skills as communication, respect for the other and allowed them to share their knowledge by experimenting the work of a design team. Students interacted with knowledge mediated by an artifact (software Scratch, congenial to them) that lightened the weight of the study of curricular disciplines. The processing of students’ reports to experiential stimuli highlighted the production of skills that are individual cognitive potentials enriched by the exchange in different school contexts and shows the high degree of satisfaction and the willingness to participate in similar activities in the future.

Abstract: This short contribution summarizes the results of TWG16 according to the five themes described in the Call for papers. As an overall conclusion, we notice that the somewhat general theme of good practices in technology-rich mathematics education attracts much attention, whereas the other themes apparently are addressed to a lesser extent in our research community, with the impact of digital technology on research methods as the most striking underrepresented example.

Keywords: Digital technology, embodiment, good practice, mathematics education.

Overview of themes and contributions

The scope of thematic working group TWG16 was to address opportunities and constraints of digital technology and other resources for students' learning of mathematics; a topic that is all the more relevant in times of an immense increase of distant learning and teaching practices. As a targeted outcome, we wanted to establish an overview of the current state of the art. We also aimed to suggest important trends for technology-rich mathematics education in the future, including a research agenda. TWG15 addresses a similar global topic but focuses on teaching rather than on learning.

Table 1: TWG16 themes and contributions

Theme	# accepted papers	# accepted posters
1. Theoretical advances on using digital technology in mathematics education	5	1
2. Embodiment and the use of digital technology in mathematics education	4	0
3. New roles for new tools (e.g., augmented and virtual reality, 3D printers)	5	1
4. Good practices in technology-rich design, learning and assessment in mathematics education	15	5

5. The impact of digital technology on research methods	1	0

The TWG16 call for papers identified five main themes to be addressed. Table 1 provides an overview of these themes and of the number of contributions per theme. Altogether, we had 30 accepted papers, 7 accepted posters. Some 60 participants from many countries within and outside Europe took part in the sessions, and contributed to having a positive and productive atmosphere.

Main results per theme

Theoretical advances on using digital technology in mathematics education

The crucial role of theory was an important issue within various discussions, not only limited to the contributions specifically addressing this theme. To a great extent this is due to the interconnectivity of the different themes. For example, innovative contributions focusing on embodiment or implementing new tools suggest a need for suitable theoretical frameworks to design and reconstruct mathematical learning activities. The contributions specifically addressing theoretical advances took particular aspects into account. On the one hand, some of the contributions addressed the value of theoretical frameworks when working with digital tools. In terms of extending a theoretical framework with regards to the use of digital tools, the potential of Cultural Historical Activity Theory (Engeström, 2000) was discussed in the context of programming activities. In terms of methodological considerations, the use of an instrumental approach in a quantitative study on functional thinking was explored. The role of an epistemological approach to inclusive settings using digital tools provided another theoretical lens. On the other hand, some contributions showed the need to develop new theoretical frameworks in the context of using digital technology. For example, a framework for creating heuristic videos to enhance students' modeling competencies was presented, as well as a model for learning about black boxes. Both the contributions and the discussions show that the key role of theory as well as theoretical advances keeps being a central theme for TWG16.

Embodiment and the use of digital technology in mathematics education

This theme included a range of papers, with some focusing specifically on embodiment—in terms of theorizing it—and others only evoking the role of the body in mathematical meaning-making. In the latter case, one study considered the dynamic animations created by students using geometric transformations. Although the conceptual focus here was on creativity, the analysis of the expressive and aesthetic dimensions of the students' work could certainly relate to theories of embodiment that account for the role of the senses in mathematical thinking. In the former category was a contribution that focused explicitly on embodied design. It explores a possible alignment between Abrahamson's embodied design (Abrahamson et al., 2020) and Sfard's (2008) commognitive approach, proposing the perception-actions that could correspond to saming, encapsulating, and reifying. A second example taking an explicit theoretical stance was on enactivism. The researchers compared the finger gnosis deployed in two digital technology settings, TouchCounts and Rakin, studying the fingers movements of a child as they relate to number sense. Finally, a systematic literature review was presented on the embodied approaches to functional thinking involving the use of digital technology. This paper leverages a particular approach to embodiment arising again from the work of Abrahamson (e.g., see Abrahamson et al., 2020).

Overall, it was remarked that the theories of embodiment used tended to be focused on the individual learner and their intact bodies, conceptualized as ontologically distinct from the environments (including the digital tools). This contrasts with approaches to embodiment that are more distributed, socially situated and politically inflected.

New roles for new tools

The thematic working group discussed the use of innovative digital tools in mathematics classrooms. The participants discussed specifically the use of augmented reality, robots, and 3D printers. The contributions evidence how such digital tools affected students' learning and teachers' instruction. In particular, the researchers presented studies that showed how such tools shape the students' language, formulation of mathematical concepts, and shed light on robust teaching. In addition, participants discussed how these new tools may invite negotiation of the mathematical meanings embedded in the tools and the learning environment. A comparison of physical objects, common-use digital technologies, and new digital tools was also presented. Most of the contributions to this theme were qualitative studies conducted with few participants. This fact required the participants to consider the feasibility of implementing these new digital tools in regular classrooms. Without any doubt, scaling up the use of such digital tools to regular classrooms will bring new opportunities and challenges for the learning and teaching of mathematics, and little is known about them yet. This may open a window toward a new research trend that will include questions on how to implement new tools in teaching practice. How should students engage and interact with such new tools? How will teachers' practices change through using such digital tools? This theme, of course, is far from having final answers, and seems suitable to revisiting during next CERME conferences.

Good practices in technology-rich design, learning and assessment in mathematics education

Developing good teaching practices that foster mathematics learning through technology-rich student activity is a prominent issue, all the more in times of emergency remote teaching due to the pandemic. Contributions describing good practices focused on topics such as the flipped classroom and distance learning environments, more established tools such as GeoGebra, tools for computer programming. Also, more innovative tools were used, such as a digital spirograph and the online application GeoGebra classroom. From the discussions we conclude that new pedagogies and practices have emerged in practices of using various digital tools, such as practices of digital-collaborative learning. It has become clear that the teachers' instrumental genesis of teachers is a prerequisite for good practice. Also, the availability of advanced digital technology used in the learning process questions the regular curricular goals. A main idea that emerged from the discussions is that good practices should use digital technologies to deepen mathematics learning through in-depth meaningful learning trajectories (teaching sequences), rather than through superficial tool use. To do so, new theoretical approaches might be needed. Another important conclusion was that social-media norms may change to enable new pedagogies to be put into practice. Finally, as our experiences with and knowledge of emergency remote learning with digital tools has drastically increased during the pandemic, we wonder how to capitalize on this in the future.

Many contributions in this theme presented examples of well-designed good practices. However, describing and investigating good practices also resulted in raising the issue of design principles. It was pointed out that design is group work, with different types of expertise involved, and that it is usually done in cycles. There is a need to identify overarching design principles, and theories that can underpin them, both for the design of tools and environments and for the design of learning activities. Moreover, the sustainability of such design principles was recognized as a key point, as they need to be still applicable—maybe in adapted form—when new, more advanced digital tools will emerge.

The impact of digital technology on research methods

Many types of digital technology impact on our work as educational researchers. We have eye tracking, video labs, data logging, learning analytics, machine learning, software for qualitative data analysis, and artificial intelligence, to mention just some. Even if the TWG team felt the need to address the question of how these tools affect our research methodologies, we hardly received any contributions to this theme. Apparently, this is not (yet?) a ‘living’ topic in our community. We wonder whether this will change in two years, if the new TWG team takes up this theme once more.

Conclusion

A first goal of this TWG was to provide an overview of the current state of the art in the domain of technology-rich mathematics learning. Based on the contributions and discussions, we conclude that the field is moving quickly, and that much attention is paid to the design, implementation and evaluation of good practices for mathematics learning and teaching using digital technology. The need for further foundations, in terms of theoretical frameworks—being new or adaptations of existing ones—and design heuristics is widely recognized. However, the suggested themes that aim at such foundations received not many contributions. This may be partly caused by the impressions that the TWG attracted many relatively early-career researchers, with seniors being somewhat underrepresented. As a practical feed-forward for CERME-13, particular attention might be paid to ensuring a balanced group of participants in terms of seniority.

A second goal was to identify a research agenda. Even if this was touched upon only implicitly, the above theme reports provide an interesting picture: whereas the need for theoretical foundations is widely acknowledged, the themes on theoretical approaches, new tools, embodiment, and new research methods were not popular in terms of numbers of contributions. One of the challenges for the next edition, therefore, is to reiterate these themes and ensure a more explicit place for them in the call for papers. The number of participants in the CERME-12 group shows that the field is alive and the topic is attracting much attention by researchers. The distribution of contributions over themes shows that there is a clear research agenda: let’s work on these theoretical and innovative foundations to ensure progress in these directions for the next edition.

"Doing well" in the Teaching for Robust Understanding approach revealed by the lens of the semiotic potential of tasks with the GGBot

Anna Baccaglini-Frank[1] and Maria Alessandra Mariotti[2]

[1]University of Pisa, Department of Mathematics, Pisa, Italy; anna.baccaglinifrank@unipi.it

[2]University of Siena, Italy; mariotti21@unisi.it

In this paper we report on experiences we have provided students in a grade-3 classroom with the aim of introducing concepts in plane geometry through interaction with the GGBot, a drawing robot that can be programmed with SNAP! Blocks. We do this to explore the effectiveness of the use of a new theoretical approach that combines the Teaching for Robust Understanding Framework with the Theory of Semiotic Mediation. We claim that the articulation between the two frames is not only feasible but also insightful, providing an a priori analysis of two tasks, and a detailed analysis of a short excerpt from the corresponding Didactic Cycle.

Keywords: Coding, GGBot, geometry, personal meanings, situated signs, STEM education, Theory of Semiotic Mediation (TSM).

A STEM scenario: the position of mathematics when coding with the GGBot.

More attention is being placed on educational experiences in the context of STEM, as shown, for example, by the increasing importance and number of international STEM education journals (Li et al., 2020). However, STEM disciplines are not yet treated in a coherent way in educational settings; moreover, the role of mathematics in this panorama has been problematized by Li and Schoenfeld (2019) who advance an interesting and constructive proposal about the positioning of mathematics within STEM contexts within the Teaching for Robust Understanding (TRU) Framework (Shoenfeld, 2013). Presenting the framework, thew authors exemplify how it can be applied to mathematics, in order to help students "develop into powerful thinkers" (2019, p. 8).

In this paper we are interested in exploring the appropriateness of certain mathematical experiences we have offered primary school students using the GGBot, a drawing robot, in terms of STEM education and of the overarching goal of fostering their development into powerful thinkers. Specifically, we conceptualized the GGBot and students' experiences with it with the aim of fostering sense-making in a STEM perspective. Coherently with the TRU Framework, we followed Schoenfeld's suggestion "to operationalize what was meant by “doing well” in each of the five dimensions, and to see how “doing well” related to student outcomes." (Schoenfeld, p. 492, 2018).

However, given the breadth and generality of such a framework, in order to design and implement experiences with the GGBot, we felt the need of a more specific, though coherent, framework that describes the didactical potential of the GGBot, allowing a reformulation of chosen dimensions of the TRU Framework upon which we will focus our analyses. The specific framework we choose for this description is the Theory of Semiotic Mediation. Now we introduce our conceptual framework.

Teaching for Robust Understanding (TRU) and the Theory of Semiotic Mediation (TSM).

As explained by Li and Schoenfeld (2019), the Teaching for Robust Understanding (TRU) Framework is comprised of the following five dimensions, that can be introduced through guiding questions: 1) *content*: is it conceptualized as something rich and connected that can be experienced and codified in meaningful ways? 2) *cognitive demand*: what opportunities do students have to do that kind of sense-making and codification? 3) *equitable access to content*: who has such opportunities: is there equitable access to the core ideas? 4) *agency, ownership, and identity*: do students encounter the discipline in ways that enable them to see themselves as sense makers, building both agency and positive disciplinary identities? 5) *formative assessment*: does instruction routinely use formative assessment, allowing student thinking to become public so that instruction can be adjusted accordingly?

In presenting the framework as an alternative to viewing mathematics as "given" or "fixed" and arguing how such a framework also applies to STEM education, Li and Schoenfeld propose a conception of mathematics as "empirical". That is, mathematics can be (and should be) seen as products created through experience (as opposed to pre-existing). This perspective focusses on students' experience, in which a shift needs to take place from "instruction conceived as "what should the teacher do" to instruction conceived as "what mathematical experiences should students have in order for them to develop into powerful thinkers?"" (Li & Schoenfeld, 2019, p. 8). For mathematical experiences to accomplish this, the authors argue that they need to provide not only opportunities for making sense of the mathematics at stake, but for *sense-making* processes (McCallum, 2018), highlighting "the importance for students to experience mathematics through creating, designing, developing, and connecting mathematical ideas" (Li & Schoenfeld, 2019, p. 6).

While the TRU seems quite appealing for framing mathematical experiences that strive to find a place and identity in STEM scenarios, we find it too broad and general to actually help gain insight into how specific mathematical experiences are (or not) well-designed and, when carried out, whether they help students become powerful mathematical thinkers. Moreover, the context we are interested in studying – the learning of geometry through coding of a drawing robot – involves an artefact. Therefore, an appropriate framework that seems to compensate for the generality of the TRU Framework and allow for more detailed analyses in this setting is the Theory of Semiotic Mediation (TSM). Indeed, the TSM has its roots in Vygotskian socio-constructivism, according to which students are guided by their teacher to construct mathematical knowledge by solving appropriately designed tasks with the use of appropriately designed and chosen artefacts (Bartolini Bussi & Mariotti, 2008). Students' activity with artefacts allows the unfolding of their *semiotic potential* leading to students to produce personal signs that are closely related to the task and to the artefact, and that gradually, through mathematical discussions orchestrated by the teacher, are transformed into shared signs. The shared signs are generalizations of the situated personal signs, and they are more closely related to the mathematical signs belonging to the concepts being taught.

Focusing especially on three dimensions of the TRU Framework, we need to draw connections between such a broad framework and the TSM. The notion of semiotic potential expresses the relationship between the personal meanings emerging from the experience of acting with the artefact and the mathematical meanings recognizable by the expert in such actions; its strict dependency on the task to be accomplished by the students makes it the key tool for designing appropriate tasks. In doing so, it operationalizes a link between dimension 1 (Mathematical content) and dimension 2 (Cognitive demand) of the TRU Framework.

The structure of the iteration of the Didactic Cycle (work on a task with an artefact, individual production of signs, collective production of signs through mathematical discussion) organizes the implementation of teaching sequence in the classroom, and it is in line with dimension 4 of the TRU: the potential of agency ownership, and identity. For instance, typically the first cycle is characterized by a "discovery task" that foresees guided exploration of the artefact, in which the teacher's intervention is expected in order to prepare students to the following tasks, where their autonomous work is encouraged, with the aim of making personal meanings emerge and the semiotic potential unfold. Students' personal meanings can emerge in their conversation with peers during the solution of the task, providing a base for the following collective discussion (e.g., Mariotti, 2009) during which the semiotic production can (and should) foster the evolution of the expected mathematical meanings.

Objective and Methodology.

The broad objective of our work with robotic toys (e.g., Bartolini & Baccaglini-Frank, 2015; Baccaglini-Frank et al., 2020) is to study their educational potential with respect to specific geometrical concepts and with respect to significant reasoning processes in a STEM educational perspective. As for this paper, we explore the effectiveness of the use of a new theoretical approach that combines the TRU Framework and the TSM both for the design and the analysis of classroom activities. In order to show that the articulation between the two frames is not only feasible but also insightful, we provide an a priori analysis of two tasks to be carried out in a grade-3 classroom, and a detailed analysis of a short excerpt from the corresponding Didactic Cycle.

We will use a fine-grained analysis of a short excerpt, paying particular attention to the unfolding of the semiotic potential and to the teacher's actions, to show how the activity placed the students in a meaningful (to them) situation, in which they felt the need to explore and express mathematical ideas.

Presentation of the GGBot.

The GGBot (short for "GREATGeometryBot") builds on the convergence of physical and digital affordances, combining the well-known strengths and opportunities offered by Papert's original robotic drawing-turtle (more recently developed into robotic toys like the "Bee-bot") and LOGO programming with those of the block-based programming language SNAP!. The GGBot can hold a marker between its wheels (Figure 1a) that draws out its path as it moves on a sheet of paper on the floor, as well as a marker at the front, on its "nose", to highlight its movement when it changes direction (Figure 1b). Such traces provide situated signs that can be elaborated into geometrical notions – such as segment, vertex, angle, rotation, polygon – while still carrying the situatedness given by the real movement of the physical artefact. Commands are given to the GGbot through an SNAP! interface that was customarily designed, and they can be gradually added based on the teacher's needs. Other than the possibility of holding two markers, the way in which commands are given to the GGBot is quite different from other robotic toys like the Bee-bot, because the blocks represent commands (in the machine's language) that can be given to the GGbot by putting them together into sequences or *codes* (figure 2c) that are transmitted to the GGbot via a wifi module. Although these blocks are virtual objects that "live" on a screen (touch-screen of an interactive white board, tablet, or computer screen), they are concrete enough to be accessible to and shared by the whole class, and by each student–consistently with respect to TRU dim. 4, on agency, ownership, and identity–when engaged in tasks such as the following.

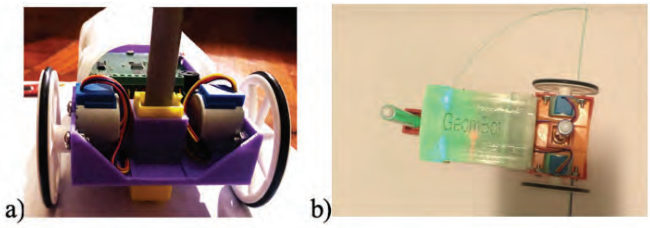

Figure 1*:* a) back view of the GGBot; b) top view of the GGBot

Though the GGBot also has a completely digital version (https://sprintingkiwi.github.io/virtual-geombot-snap), that is more similar to the LOGO turtle (though still in the block-based SNAP! environment), the physical artefact offers (especially younger) students a very different experience.

The semiotic potential of the figure-to-code and code-to-figure tasks.

A *figure-to-code task* consists in giving students the name of a figure and asking them to work in pairs and use the blocks to produce a code, so that when sent, the GGbot draws the required figure. The task we will be considering is: "Make a code so that when it is sent, the GGBot draws a square".

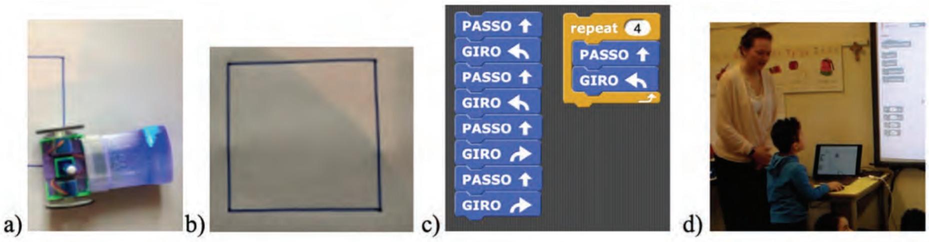

Figure 2: a) GGBot's moves; b) GGBot's trace; c) examples of codes; d) collective discussion of codes

In order to accomplish the task, it is necessary for the students to engage in a process that relates the GGBot's affordances with their conceptualization of "square shape". The shape needs to become an envisioned contour (e.g., figure 2b), a path along its border that corresponds to the GGBot's trace mark as it moves along such a path. Then, through the lens of the available commands (blocks), such a contour/path must be seen as a sequence of steps, leading to the realization of a code (such as those in figure 2c) to be communicated to GGBot. A spontaneous approach (e.g., Clements & Battista, 2001) consists in imagining to walk along the border of the figure and, based on such a simulation, planning the code to send the robot. While it is straightforward to identify the four *segments* constituting the sides of the square, and relate them to the step ↑ commands, it might be more challenging to decide how to connect these four steps. Indeed, it requires mastering the complex meaning of the Turn ↱ command (whether it is to the right or to the left) in order to relate it to the interpretation of each connecting point as "turn on the spot". Such points correspond to the thick dots left by the GGBot as it executes the turn ↱ commands, making the robot change direction before it takes another step forward to continue moving along the path. Moreover, a consistent interpretation, leading to complete the drawing, needs putting these points in relation with one another, as *the vertices of the square*, and as centers of the *rotations of the external angles of that polygon.* So, an essential feature of the semiotic potential of this artefact is its building on the relationship between the global movement and its breaking up into steps and turning points and the geometrical meaning of a polygon at a global and an analytical level. From a cognitive point of view (and this relates to TRU dim. 2, on cognitive demand), the task consists in breaking down a path that is imagined to be generated through physical continuous motion, into geometrical elements (TRU dim. 1) of a different nature: they are static and discrete.

Producing the code involves the use of signs corresponding to the required commands. Such signs refer both to the GGBot's movement and to the trace mark left, and their efficiency depends on the relationship between the drawing produced and the breaking up of the movement into its constituent elements and the corresponding commands. Comparing different codes produced in response to a figure-to-code task opens the way to the dual type of task: *code-to-figure*, that consists in focusing on a given code and asking the students to predict the trace mark that will be left on the paper by the GGbot when it executes such a code. This type of task asks to invert the relationship as the one described above between blocks in a code, the movements of the GGBot and the trace mark left. A potential challenge for students (TRU dim. 2) lies in finding a cognitive harmony between specific movements induced by a single command in the code and the continuous movement leading to the global trace mark imagined.

Design of the experiment and data collection.

We focus on a grade-3 class that worked with the GGBot over 3 sessions of one period (45 min) each. The students had been introduced to the bee-bot in earlier grades, but they had not previously worked with the GGBot. They had learned about plane geometry figures (though not specifically the notion of angle), but not in the context of coding with drawing robots. First, the students discovered and explored the GGBot, through the questions: What is it? What is it for? Why does is do it? How does it do it? The sessions were conducted by the first author in collaboration with the classroom teacher. After the initial discovery of the artefact (first cycle), the first author was prepared to propose both figure-to-code and code-to-figure tasks in the next cycles, based on students' responses. No rigid sequence of tasks (after the first exploration) was decided a priori. This design choice was made to increase the potential of agency, ownership, and identity (dim. 4), because the flow of the experience could better match students' actions, curiosity and involvement by building on the situated signs actually produced. Consistently with this purpose, the tasks proposed were intended to foster the unfolding of the semiotic potential: from the situated signs carrying the students' personal meanings the teacher would foster the development of mathematical signs. In the following section, we present an episode to illustrate a key moment of the unfolding of the semiotic potential, when the teacher changed the task from a figure-to-code to a code-to-figure task. In the analysis presented in the next section, we will consider a code-to-figure task.

"Doing well" in the TRU approach revealed by the lens of the semiotic potential.

After considering some of the codes produced in response to the figure-to-code task "Draw a square", the teacher selected the following: "step, left turn, step, left turn, step, right turn, step, right turn"; the teacher shared it on the main screen (figure 2a) and asked: "What will the GGBot draw if we give it this code?", posing a *code-to-figure task*. She then called on various students, asking them to share their predictions with the class. Below we present an excerpt from a student's response (among the six other ones provided by other students contributing to the discussion) concerning the interpretation of this code. We chose this excerpt because of how it shows the sprouting of an apparent cognitive conflict that triggers the unfolding of the semiotic potential of the GGBot. We use the example to show how the evolution of the semiotic mediation process is consistent with the TRU approach.

Silvia's prediction: the unfolding of the semiotic potential through a cognitive conflict.

Table 1 shows Silvia's prediction, including both words and gestures.

L.	S.'s words	S.'s gestures
1 2	So, he took a step forward (a), no? a rotation (b)	(a)  (b) 3	then another, a ...another step forward, so (without touching the paper with the tip of the marker) the rotation...(c)	 [oscillating over the second segment] (c)
4	yes well, the, the step forward (c)	oscillating the marker over the two segments drawn
5	a rotation [(c) to (d)]	draws over the third short segment
6 7 8	and then after the rotation again a step forward (d) then he put the rotation the opposite way, and so like this (e) and like this (f)	   (d) (e) (f)

Table 1: Silvia's prediction expressed through words, gestures, and drawing

The task appears to be demanding for Silvia: she seems to be struggling as she thinks aloud (TRU dim. 2). Even though she had already envisaged a figure, she still seems hesitant about the "rotation", to which she returns again and again (lines 2, 3, 5). Silvia keeps on moving the marker on the paper as she says "rotation" (it. "rotazione") the first time (line 2), which suggests that she has not yet conceptualized a turn/rotation as a change in direction without continuing the movement in the new direction. Indeed, in real life, one does not rotate without continuing to walk in the new direction! However, there seems to be a seed of conflict (line 5), that might bloom into the mathematical notion of angle as rotation (dim. 1), by engaging in productive struggle (TRU dim. 2). The conflict remains unresolved, as Silvia then continues to draw a longer segment as she mentions again "rotation" and "step forward" (line 6). We interpret this as a global perception that seems to dominate over Silvia's analytic prediction: she starts off looking at each block on the screen and looking for a correspondence with the trace mark, but then her global perception takes over, making her lose control of the analytic relationship between blocks and the parts of the predicted trace mark.

We interpret Silvia's conflict as being (at least in part) due to her relying on personal meanings that are based on a physical everyday experience of "turning" during a walk, that is never accomplished as a rotation without moving along a straight trajectory "before" and "after" the turn". In this sense, the seed of the mathematical concept of *angle* is "empirical" in nature, and full of aspects that gradually will be "weeded out" as this (and other) mathematical discussion(s) move away from situated signs and towards mathematical signs, pointing to more abstract mathematical meanings. On the one hand, designing tasks that foster sense making through the production of personal meanings that live in a sort of "empirical" mathematics, seems to be very much in line with what Li and Schoenfeld (2019) argue for. On the other hand, being aware of the hybrid nature of the personal meanings produced by students like Silvia can help the teacher better exploit the semiotic potential of the tasks accomplished with the GGBot.

In terms of signs produced, we notice that Silvia produces distinct signs (word and gesture) only for the step ↑ block, which is a straight segment of a fixed length. While her drawing shows, in a global way, the "change in direction" in the form of perpendicularity between consecutive segments. However, though her struggle in trying to elaborate a sign for interpreting the Turn ↱ block remains unsolved, she successfully contributes to the conversation about mathematical ideas (dim. 4).

Discussion and conclusions.

The dual set of tasks proposed by the teacher led the students (not only Silvia, but all her classmates, too) to producing a very rich set of situated signs corresponding to personal meanings, that helped the students gain insight into the relationship between the single blocks, the robot's movement and its trace marks. Beyond the opportunity of reconceptualizing the square to be drawn as a contour, many students were led to conceiving such a contour as being made up of segments and points/turns (some spoke of "turning points") where the idea of *rotation* is associated to a specific point around which the robot stops and turns/rotates without moving forward.

The excerpt analyzed certainly shows that tasks such as those described have a high potential for mediating geometrical concepts. However, experiences such as those presented with the GGBot (and more in general with an artefact), may not be purely mathematical. Indeed, the cognitive complexity of tasks with a physical artefact such as the GGBot calls into play personal meanings that are indeed seeds of formal mathematical meanings, but initially they are hybrid, with an important "empirical" component. Such a component can be insightfully woven into the didactical cycle by the teacher, who can elaborate on it helping the students construct more formal mathematical meanings related to certain mathematical notions. Moreover, the way in which such an empirical component contributed to Silvia's cognitive conflict, fuels the notion of semiotic potential at a theoretical level. Indeed, according to its definition the notion of semiotic potential alone describes the possible coherence of the meanings emerging from the use of an artefact with the expected mathematical meanings. However, not always does such a coherence occur, and conflicts may arise; studying connections between the semiotic potential and cognitive conflicts that can emerge as students carry out the tasks, opens new theoretical and practical avenues.

Overall, this contribution shows that the articulation between the TRU Framework and the TSM, combined as we have suggested, is not only feasible but also insightful; and it operationalizes "doing well" in (3 of) the 5 dimensions in the context of coding with the GGBot.

Acknowledgment

The GGBot is an invention of Eric Frank and the first author, with patent n. 102019000018254; it is produced by GREATRobotics Srl. The SNAP! commands are developed by Alessandro Norfo under the collaboration with ASPHI onlus within the PerContare Project, co-funded by the Fondazione per la Scuola della Compagnia di San Paolo di Torino.

How do students describe and understand properties of special quadrilaterals with digital tools? – An epistemological perspective on mathematical interaction in inclusive settings

Ruth Bebernik[1], Christina M. Krause[1,2,3] and Florian Schacht[1]

Both digital learning and inclusive learning become of increasing relevance in mathematics education research and practice. Still, the opportunities the first brings for the latter are underexplored, especially in secondary education. This paper presents a digital learning environment on quadrilaterals as considering design principles for inclusive learning, and its implementation. Through an epistemological analysis of a collaborative activity involving students with different learning abilities, the paper reconstructs how mathematical meaning evolves in signs, focusing in particular on the role of the digital tool in use.

Keywords: digital learning environment, geometry, inclusive settings, epistemological analysis

Introduction and theoretical foundations

Inclusive education and equity play an important role within mathematics education research and practice (e.g., Scherer et al., 2016). One approach addressing the heterogeneity in such settings is geared towards allowing students to work on the same basic mathematical idea in different ways and through different, student-led, approaches, following the idea of natural differentiation (Scherer & Krauthausen, 2010). However, little is known about how a mutual mathematical understanding of the idea actually develops in interaction among students with different learning abilities, especially in secondary mathematics classrooms. This paper presents a case study that adopts an epistemological perspective to better understand such a process of meaning-making between two students with and without special educational support. In particular, the case explores the role of a digital learning opportunity designed to facilitate the exploration and negotiation of concave quadrilaterals and their properties. Hence, it draws attention to the potential of digital learning tools in inclusive settings as they become suggested in this specific case.

We will first elaborate on the notion of inclusive education and present an epistemological perspective for reconstructing students' processes of constructing meaning as developing in interaction through and with signs, together with the epistemological triangle as its analytical tool (Steinbring, 2006). We will then describe the methodological background of the study, including the mathematical content in focus, the design of the digital learning opportunity, its empirical implementation, and methods of data collection and analysis. From the then following case analysis, we will draw tentative conclusions on the two research questions:

1. How can mathematical concepts evolve in interactions among students with different learning abilities through the interpretation and the use of signs?
2. Which role can the digital tool play within such an interaction process?

Inclusive learning

Inclusive learning follows the idea of fostering all students with and without different learning conditions, taking into account the vast spectrum of abilities and needs (e.g., difficulties or special talents) encountered in the mathematics classroom. This understanding follows Article 24 of the Convention on the Rights of Persons with Disabilities, which claims equal opportunities for all people to participate in quality education and to develop their potential, regardless of special learning needs, gender, social and economic conditions (cf. United Nations, 2006). In inclusive learning, children should be supported individually and also learn collectively through collaborations and interactions (cf. Häsel-Weide & Nührenbörger, 2013; Scherer et al., 2016; Swidan & Daher, 2019). All students should get the same learning opportunities, but with individual learning aims. When implementing inclusive learning, enabling social participation and the explicit demand for social involvement should be taken into account. One challenge is to deal with heterogeneity and to develop learning environments accessible to all, while at the same time requiring social participation in collaborative learning phases. There is considerable need for research and development, particularly at secondary level. Didactic concepts suitable for inclusive teaching already exist for the primary level, such as *natural differentiation* through substantial learning environments (Scherer & Krauthausen, 2010). Although there are experiences of using digital tools in special education (Moyer-Packenham & Suh, 2012; Peltenburg et al., 2013), their use is often limited to learning and practice software for targeted training. In contrast, we understand digital tools more broadly as appropriate learning tools in the sense of enabling substantial mathematical experiences (Drijvers et al., 2016), acknowledging their potential for inclusive mathematics education. We therefore adapt the idea of 'natural differentiation' for the design of learning environments at the secondary level, taking into account the opportunities offered by digital tools.

Epistemological perspective

Children's mathematical knowledge is situational and linked to certain learning contexts and experiences. These learning and experiential contexts can be extended through interactions by constantly negotiating and interpreting mathematical understandings (Steinbring, 2006). The epistemological triangle (see Figure 1) can be used for analyzing such processes of meaning-making in interaction as processes of learning mathematics. It is "used for modeling the nature of the (invisible) mathematical knowledge by means of representing relations and structures the learner constructs during the interaction" (p. 136). Central to this model is the interplay between *signs* that are interpreted, the *concept* about which the learner constructs knowledge as understood to be represented in some way in the sign, and the *reference context* corresponding to the meaning of the concept through the interpretation of the signs. Figure 1 shows a pictorial rectangle as a sign, which doesn't have a meaning of its own. The meaning has to be produced by the learner by means of establishing a mediation to suitable reference contexts.

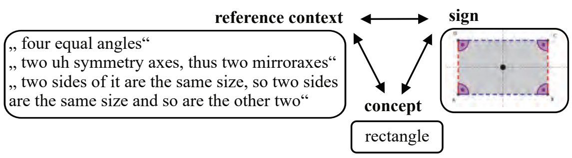

Figure 1: Exemplary epistemological triangle (adapted from Steinbring, 2006, p. 135)

In this case, the student describes the properties of the rectangle that represent the students' reference context, thereby establishing the meaning of the concept. This analytical tool allows a fine-grained reconstruction of evolving mathematical meaning in interaction processes. Therefore, the development of sign-use, the underlying reference contexts and the concepts involved can be analyzed in their synergy (cf. Steinbring, 2006).

Methods and methodology – from design to analysis

Mathematical background and didactical approaches

Quadrilaterals are characterized by their four sides and four angles and can be classified through hierarchy (De Villiers, 1994). Sub-concepts have the characteristics of the general concept and additional differentiating characteristics. A parallelogram has a center of rotational symmetry and opposite sides are parallel to each other, with sub-concepts (rectangle, rhombus, square) sharing these characteristics, thereby being considered special parallelograms. Conceptual understanding of quadrilaterals contains the understanding of a conceptual hierarchy in the sense of realizing ideas and sub-concepts *included* in the same concept (extensional definition of the concept), while also understanding the entirety of properties characterizing the concept and its sub-concepts (intensional definition of the concept) in order to *exclude* hierarchical relationships. Also, ideas like the operational principle consider actions crucial for conceptual development, with these being performed with real, visual and imagined objects, and described verbally. Designing a learning environment then means to offer all learners opportunities to openly approach and manipulate, such that properties can be explored on individually selected quadrilaterals.

The digital learning environment, the activities on it, and underlying design principles

The purpose of the digital learning environment 'dynamic quadrilateral' is to provide opportunities to explore and classify the properties of quadrilaterals (Bebernik & Schacht, 2019; https://www.geogebra.org/m/x7syhqny). It mimics activities manually carried out on GeoBoards, realized digitally through dragging corners or sides with the finger on a touchscreen or with a mouse. In this specific design, properties of the quadrilaterals - such as right angles and axis of reflection - are highlighted by specific markers. It thereby allows students to explore and order quadrilaterals by means of their properties locally through operative manipulations and visual feedback. The tasks focus on convex quadrilaterals, which will appear grey in the digital learning environment. Functioning as an example generator, the digital tool allows for exploring quadrilateral properties, to make discoveries, and to order different types of quadrilaterals (e.g., square and rectangle) locally by identifying similarities and differences. To do this, it is first necessary to ascribe meaning to the markings, such as interpreting equally colored angles as angles of equal size. It is about understanding logical structures of special quadrilaterals rather than naming the quadrilateral. The digital learning environment is first worked on individually, along with prompts to facilitate systematization of what is found out. Later, students work in pairs on a reconstruction task (Wollring, 2012) in which each of them has a specific role. In the setting shown in Figure 2, one person (sender) manipulates a particular quadrilateral with the digital tool and then describes its properties. The partner (receiver) now has the task of reconstructing the quadrilateral with the digital tool. The pair changes roles several times.

• Assemble in pairs so that you can't see each other.

• Person 1: Create with the file 'dynamic quadrilateral' a particularly beautiful quadrilateral and describe ist properties.

• Person 2: Create with the file 'dynamic quadrilateral' the described quadrilateral.

• Compare your quadrilaterals. Which one is it? Was the description good?

• Change the roles!

Figure 2: Reconstruction task (Bebernik & Schacht, 2019; Wollring, 2012)

The design of the digital learning environment and the accompanying tasks is informed by three main design principles specifically aligned to inclusive education. First, the already presented ***principle of natural differentiation:*** In the digital learning environment, the conceptual understanding of individual quadrilaterals can be worked on at different levels – some children are able to interpret specific properties, other children can investigate similarities and differences between individual quadrilaterals. Free exploration and allowing different approaches to deal and engage with the content enable different learning objectives (from pre-formal explorations to formalizations). Second, the ***principle of representation networking:*** In the sense of Duval (2006, p. 125), this involves operational variations in connection with different representations, considering *treatment* as transformation within one register of representation (e.g., within the geometric representation) or *conversion* from one register of representation to another one (e.g., the change from the geometric to the symbolic representation), whereby Duval considers the latter as being crucial for mathematical activity and learning (p. 125). With regard to the designed learning environment, the children should perform both treatment and conversion. For example, through the reconstruction tasks, the transition to symbolic representation or verbal description can be made by describing a quadrilateral. A third design principle concerns the relevance of ***integrating individual and cooperative learning phases:*** Conceptual understanding is built through interactions with others, as interpretations of concepts are negotiated and constructed together. This is realized through the reconstruction task that stimulated exchange about quadrilateral properties, thereby enabling social participation, but also demanding for social involvement.

Data collection and analysis

The data presented in this contribution has been drawn from a larger design research project on developing and researching substantial learning environments for inclusive classrooms. Following individual explorations with the digital learning environment, seven pairs of students (age 13-16) have been videographed while carrying out reconstruction tasks, stimulating the negotiation of mathematical understanding of the quadrilaterals and initiating social learning. The students had different learning conditions (with/without special educational needs) and attended different grades (5 to 8). In each pair, both students attended the same class. The students' interactions and the development of mathematical meaning are reconstructed using the epistemological triangle model (Steinbring, 2006). This paper provides an illustrative case study that allows to explore the research questions, providing rich conditions for reconstructing students' reference contexts through their use of signs while exploiting the affordances of the digital learning environment.

Results: Reconstruction of the learning processes

The results presented in this section especially address the reconstruction of an interaction process emerging while using a digital tool. Here, the students **S**am (sender) and **R**on (receiver) (7th grade, age 13-14) work on the reconstruction task as described above. Ron gets special educational support at school, he has been diagnosed with learning difficulties that encompass both math and written language. Writing and reading are difficult for him. In contrast, Sam has good mathematical and linguistic skills. This combination mirrors a prototypical inclusive learning setting. In the following transcript (translated from German), the two students use the dynamic geometry software GeoGebra to carry out the reconstruction task. Due to space limitations, the transcript only includes verbal interaction without a description of gestures and actions with the DGS.

1	S.:	So, my, my shape has four equal angles. (...) And (...) two uh symmetry axes, thus two mirror axes.
2	R.:	Wait, four large angles, two mirror axes.
3	S.:	But only two sides of it are the same size, so two sides are the same size and so are the other two.
4	R.:	Ah, I think, is it a kite?
5	S.:	No.
6	R.:	(...) Ok. It has two mirror axes and one rotation axis, right? Or doesn't it have a rotation axis?
7	S.:	No, um, just two mirror axes and, well, two symmetry axes and a centre of symmetry.
8	R.:	Ok, so yes. (.) That's what I mean by the rotation axis. Um, that should be the same *(manipulates the quadrilateral)*. Trapezium?
9	S.:	No.
10	R.:	(...) So (...) hmm (14 sec.). Is that a, a (...), a, what's it called? (...) Uh a question, may I please have my two sheets back where I uh, or where the things are on (...). So where here, where you can read the names, of the angles, of the different quadrilateral patterns. (...) I can't remember the name.
11	I.:	That's a rectangle. What you see there.
12	R.:	Oh, ok. Is it a rectangle?
13	S.:	Yes. (...) not like that, but it's also a rectangle.

The following analysis (1) first describes the specific structure of this interaction between the two students. In this context, we especially focus on the role of the digital tool. Secondly (2), an example of the development of reference contexts will be discussed. This will give insights into the conceptual development within a certain learning period based on the activities within the reconstruction tasks. A third analysis (3) will show the important distinction between sign-vehicle (*signifier*) and the underlying concept (*signified*) within a situation, in which a student uses the properties of a certain concept in order to determine the corresponding sign. Hence, the results presented in this section not only give insights into conceptual processes within the interaction, they also describe a process that starts with conceptual geometric activities with digital tools and leads to ways of signifying the underlying concept through verbal description.

(1) Evolvement of meaning during interaction

The following analysis shows how mathematical meaning can evolve during an interaction when working on reconstruction tasks. In a first step, Sam describes (to Ron) certain properties of the quadrilateral he has configured with his DGS (Figure 3 (left), [1] & [3]). For Ron these descriptions are signs to be interpreted first (Figure 3, in the middle is the ep. triangle of Ron being an interpreting agent). He partly repeats the described properties ([2]) and manipulates a quadrilateral with his DGS in order to find a quadrilateral that fits to the given signs by Sam. After a while, he has (supposedly) determined the corresponding configuration (∆, in process) and he asks: “is it a kite?” ([4]). Sam receives this question, which is now his sign, that he has to interpret (Figure 3 (right)). He compares the given sign (kite) with the properties of his initial quadrilateral. Because, for Sam, the underlying concept is the rectangle, he says “No” ([5]).

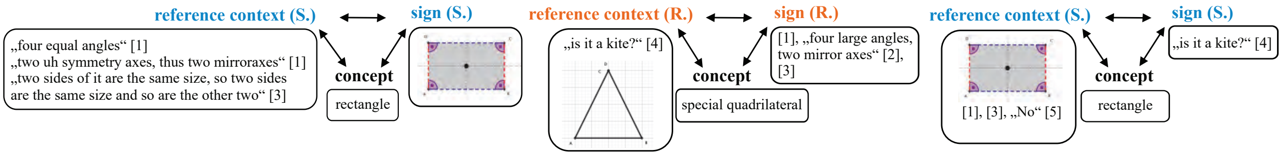

Figure 3: Epistemological triangles - Evolvement of meaning during interaction

The following interaction pattern can be identified here: First, a reference context (the description) is produced by Sam in the light of the sign (the geometric configuration) and the underlying concept. The description formulated by Sam is – in the next step – the sign to be interpreted by Ron. Ron produces a reference context and tries to find the matching quadrilateral with their own geometric configuration by using DGS. In the following reaction by Ron (in this case the question: “Is it a kite?”), Sam compares this sign to his initial situation (the geometric configuration and his properties) and formulates an answer (in this case: “No”). This pattern shows how the reference contexts produced by one of the two partners have to be interpreted by the second partner as a sign. It also shows that within this process of interpreting signs, producing reference context (descriptions) and integrating signs into one’s referential context, conceptual development can be observed in which properties are progressively made explicit by the students in the course of interaction. In this situation, Ron uses the possibilities of the tool in order to produce certain quadrilaterals which relate to the sign being given by Sam and his reference context.

(2) Development of reference contexts

Figure 4 shows the development of Ron’s reference contexts during the interactive situation when working with the reconstruction task with Sam. Note that the first reference context in Figure 4 (left) equals Ron’s first reference context in Figure 3 (middle). The development of Ron’s reference contexts shows that he cumulatively integrates questions to it in order to interpret the underlying signs (the described properties by Sam) ([4], [6], [8]). He uses the information received to manipulate the geometric configuration with his DGS. Note also that “new” reactions in the next step of the interaction are in black font color whereas former reactions are in grey font color.

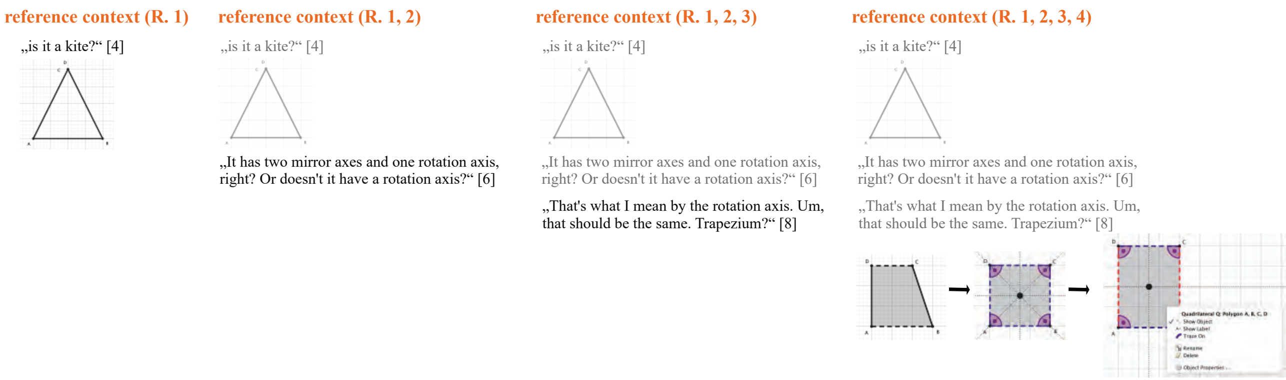

Figure 4: Development of reference contexts from the receiver (Ron)

Through the information Ron received in response to his questions, and the simultaneous tool use, the sign in demand from Sam (rectangle) becomes more and more meaningful. The conceptual development is manifested in this example by excluding properties and thus types of quadrilaterals. In this process the digital tool serves as an aid. Ron uses the digital tool as an example generator.

(3) From conceptual content to the corresponding signifier (sign vehicle)

The last example in Figure 5 shows Ron's epistemological triangle at the end of this episode. Ron and Sam have exchanged a variety of properties, questions and assumptions. Ron has found a geometric configuration with the DGS that seems not to contradict the received information. Indeed, the picture in Figure 5 shows that he constructed a rectangle as Sam did in the first step (Figure 3 (left)). In this situation, Ron asks if he can get back a previously edited sheet with different quadrilaterals and their properties to determine the signifier ([10]). He doesn't know what the correct mathematical term is of this specific quadrilateral with the properties exchanged. The interviewer provides the conventional terminology ([11]). This example shows a process of the evolvement of mathematical meaning by working on a reconstruction task. Signs are interpreted through reference contexts and thus the meaning of the concept evolves. The students determine and use the properties of the concepts before and with the aim of determining the corresponding signifier (rectangle).

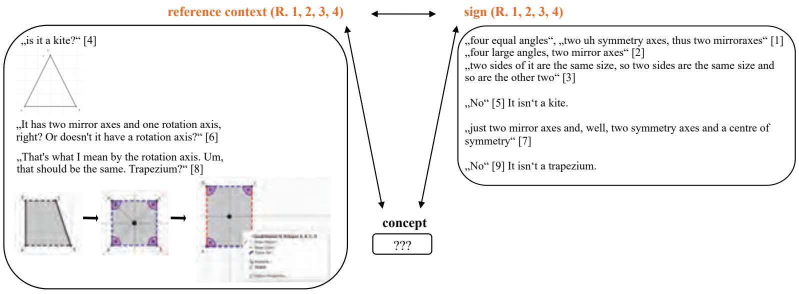

Figure 5: From conceptual content to the corresponding signifier

Conclusion and outlook

The analyses provide first insights into how mathematical concepts – here specifically quadrilaterals – can evolve in interactions among students with different learning abilities through the interpretation and the use of signs. In this process, the evolvement of mathematical concepts is enhanced by the use of digital learning environments. Related to our example, a mutual mathematical idea develops through negotiation of quadrilateral properties during interaction. The analysis of the interaction processes of the students engaging with the reconstruction task shows how mathematical concepts develop by focusing on sign, reference context, and concept. Patterns of interaction emerge that reveal the interplay between signs and reference contexts. A crucial characteristic of the specific type of the reconstruction task is that given signs (information/description) have to be interpreted by producing reference contexts. Within this cascade-like process, a conceptual network is established by sending and receiving information based on the interpretation of given information. The digital tool plays important roles in this context: On the one hand, it highlights certain properties of the quadrilaterals, thereby inviting the students to interpret and communicate these properties represented in signs in the course of interaction and by doing so, extends their conceptual network. On the other hand, it serves as an example generator that has potential to constantly check and re-evaluate information and interpretations. Future work might also explore design-modifications against an embodiment framework to integrate how conceptual understanding can be fostered through the development of sensorimotor schemes (Abrahamson et al., 2020). Together with the epistemic analyses of the interaction processes, this might further enlighten the role of digital tools for conceptual development as encompassing the individual and the social, also in inclusive settings.

Students with special needs solve word problems in their mother tongue with an app

Christina Bierbrauer

Saarland University, Faculty of Mathematics and Computer Science, Germany

bierbrauer@math.uni-sb.de

Keywords: Special needs learning, word problem, mother tongue, digital media.

Description of the research topic

How can digital media support students with special needs by understanding word problems? One focus of the project presented here are word problems which are presented to students with a non-German mother tongue in their mother tongue. First, a tablet app was designed. Second, the app was tested in interviews with pupils with special needs learning.

Theoretical framework

Solving word problems is a complex process that is especially challenging for students with special needs learning (Häsel-Weide, 2016; Scherer & Moser Opitz, 2010; Verschaffel et al., 2000). Understanding the word problem is often a hurdle which affects subsequent processes of the process of modeling. The wording of a word problem is important, especially for non-native speaking students. Digital media can support mathematical teaching and learning processes (e.g. Krauthausen, 2012; Ladel, 2009; Walter, 2018). There are different possibilities to simplify the understanding of a word problem with digital media (Bierbrauer, 2021), e.g. the problem can be presented simply in different mother tongues. Based on the cognitive load theory, digital media offer possibilities to reduce cognitive loads when working on word problems (Paas & Sweller, 2014).

App Design

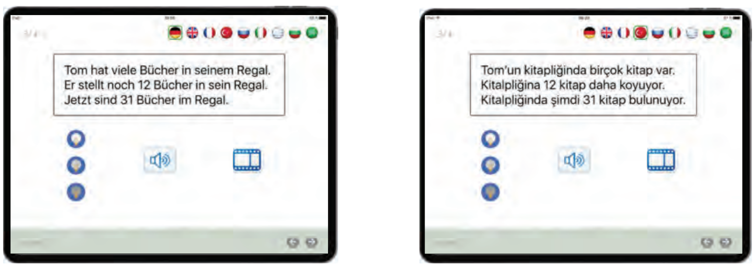

Figure 1: App "Understanding Word Problems"

Within the course of this research project, a tablet app was designed which is intended to facilitate the understanding of word problems. The design of the app is based on a theoretical background of mathematics, special education and multimedia learning. The app offers tools which reduce the cognitive load when trying to understand the problem, so that students can focus on dealing with the mathematical model. One feature is that students with a non-German mother tongue can chose simply their mother tongue. The word problem and other informations are then presented in this language. In Figure 1, the screen of the app is presented. The same problem is presented in German and in Turkish. The app offers further tools: hints for text interpretation, a speech recording and a video.

Testing the app by students

The app was tested in guided individual interviews with pupils with special needs learning who are taught in German schools and who are 9 to 12 years. Altogether 76 word problems are solved with the app, 28 word problems are solved by students with a non-German mother tongue. The collected data was evaluated using qualitative content analysis (Mayring, 2015) with the software MAXQDA.

Results and implications

The poster presents selected results of the project. No student whose mother tongue was not German selected the whole time their mother tongue during solving a word problem. The problems were mostly solved in German even if the knowledge of languages of the mother tongue was better. This result could be due to different reasons, e.g. German is the language of teaching. When the text was presented in a non-German mother tongue the word problem was not solved better. The students reported that a text in their mother tongue does not support them in solving the problem because they cannot read and write the language. Two design principles for the conception and evaluation of digital applications which intend to facilitate the understanding of word problems could be formulated by the findings: Information that is presented in the mother tongue is always accessible in the language of teaching. Text that is presented in a non-German mother tongue is always accessible audibly.

Action-property duality in embodied design

Rogier Bos

Action-property duality in embodied design

Rogier Bos

Utrecht University, Freudenthal Institute, Utrecht, the Netherlands; r.d.bos@uu.nl

For those working on embodied design it is a challenge to create tasks that enable students to develop abstract mathematical concepts. We approach this issue from the perspective of Sfard's notions of saming, encapsulation, and reification. We discuss a duality of properties and actions, and use this duality to review saming, encapsulation and reification from an action- and perception-based perspective. To illustrate the power of this theoretical contribution we discuss one new embodied task design and two from literature: MIT-P for proportion and a design for the gradient of a plane using the Augmented Reality Sandbox.

Keywords: Embodied design, Operational-structural duality, Action-property duality.

Introduction

In her 1991 paper on operational and structural conceptions in the formation of mathematical concepts Sfard writes that "we have good reasons to expect that in the process of concept formation, operational conceptions would precede the structural" (1991, p.10). Research into action-based embodied design seems to support and exploit this view that operations – in the form of goal-oriented actions that develop in the context of motor problems – form a ground for developing mathematical concepts (Abrahamson et al., 2020). Operational-structural theory and Abrahamson's embodied design theories share a central role for the transitions from process to object, and the aim of this paper is to study in more depth how a further application of ideas of operational-structural theory can inform embodied design. In particular, we are interested to see how the terminology of object formation—saming, encapsulation, and reification—as it evolved in Sfard's later work (2008), apply to the context of embodied design. To this purpose we write about *action-property duality*, a duality we believe to be at the heart of students' discovery and development of new mathematics in embodied designs. Whereas in Sfard's later work emphasis lies on how the development of saming, encapsulation, and reification take place in communication—in the introduction of new discourse, through signifiers, like nouns—we would like to draw attention to how these developments take place and are observable in students' non-communicative *actions* in embodied learning environments, in particular their interaction with artifacts (Shvarts et al., 2021).

In the next section we present a theoretical perspective on operational-structural theory and embodied design, immediately adding our view on action-property duality. In this section these theoretical ideas are illustrated a new embodied design for studying quadrilaterals. The next section illustrates how the theory applies to embodied designs in two studies, a well-known example from design for the concept of *proportion*, the MIT-P (Abrahamson & Bakker, 2016), and a more recent embodied design, using augmented reality, for the equation of a plane in a three-dimensional coordinate system and its relation to the gradient vector (Bos et al., 2022).

Theoretical contribution and background

Action-property duality

Let us postulate what we mean by a property in relation to actions:

A property is an invariant under constrained actions

The invariance means a property is perceived to be the same before and after (and possibly during) the constrained action. Trivial but crucial to us, a property is only invariant under actions that maintain the invariance. For example, an angle is only invariant under angle-preserving actions. There is an interesting duality in this formulation: properties and invariant-preserving actions cannot exist without each other. A naïve perception of sameness underlies the ability to discern a property. Our main claim is that such a naïve sense of sameness co-develops with an ability to maintain the property. To be able to compare the sameness across instances of the property in different objects, transformations of one object to the other need to be performed or imagined. In short, action-property duality refers to the phenomenon that the sameness with respect to a property across objects can only be perceived by transforming those objects into each other while maintaining the property either physically or in the mind's eye.

To make sense of this, let us look at the example of the angles of polygons. Suppose a student is invited to manipulate a polygon by dragging the corners. A naïve perception of *angle* depends on a naïve perception of the *sameness* of angles, since different instances of, e.g., straight angles need to be recognized as the same. As a consequence, a naïve perception of the sameness of angles must co-develop with a naïve ability to maintain an angle while transforming one polygon into another.

Operational-structural development

A theory of operational-structural development within mathematics education developed in the 90s within the framework of traditional cognitive psychology. Sfard argues that operational understanding precedes structural understanding of mathematical concepts (1991). She describes three stages in object/concept development: interiorization, condensation, and reification. Later, Sfard elaborated her perspective on operational-structural issues within the commognitive framework (2008). In the first two columns of Table 1 we present this later view on object formation (cf. Sfard, 2008, p.170). We do not intend to embrace or study the whole theory of commognition here, but find its description of saming, encapsulation and reification most suited to apply in the embodied design context.

Table 1: Operational-structural development from a commognitive and an embodied/action-based perspective

	Commognitive (Sfard, 2008)	Embodied: Perception-Action
Saming	Creating a subsuming discourse on hitherto unrelated objects with the help of a single signifier. Example: "This is a square and	Hitherto unrelated objects are perceived as similar and acted upon in similar ways. Example: two different squares are manipulated

	that is a square too".	with similar dragging schemes.
Encapsulation	Assigning a signifier to a set of objects and using this signifier in the singular when talking about a property of all objects together. Example: "A square has right angles."	A set of objects is perceived and/or acted upon as instances of a more abstract object. Objects in the set can be transformed into each other, if one perceives the defining properties to stay invariant. Example: dragging one square top of a congruent one, while maintaining equal sides and right angles.
Reification	Introducing a noun or pronoun with the help of which narratives about processes on objects can now be told as 'timeless' stories about relations between objects. Example: "These squares are similar through *rotation* and *translation*."	A series of actions on objects is perceived and performed as part of a single process. Example: rotating a square 90 degrees clockwise and then rotating it back to the original position.

A role of the operational-structural perspective in embodied design

Over the last 20 years, ideas from the psychological theory of embodied cognition have gained currency in mathematics education research, see (Abrahamson & Lindgren, 2014) and references therein. Embodied designs allow students to develop mathematical concepts from naïve perceptions (perception-based designs) or actions (action-based designs) in embodied learning environments (Abrahamson et al., 2020). In perception-based design students are challenged to use their innate perceptive qualities to observe certain events with potential mathematical meaning. Similarly, in action-based designs students are challenged to solve a problem of motor control with potential mathematical meaning. These naïve perceptions and actions are then developed into more robust mathematical concepts with the guidance of a tutor, thus grounding the meaning of the concepts in embodied (perceptive and motoric) experiences (Flood et al., 2020).

Returning to operational-structural development, as presented in the second column of Table 1, we argue, firstly, that saming, encapsulation, and reification are not exclusively revealed through communicative acts, but additionally through non-communicative actions: the way artifacts are handled in an embodied learning environment. This point of view is elaborated in the third column in Table 1. Below we present support for the idea that students' actions evidence stages of saming, encapsulation, and reification, before those stages are communicated through speech or gesture.

Secondly, from an action-property duality perspective, we argue that saming, encapsulation, and reification can be interwoven in embodied design. Motoric fluency in action-based design indicates that the series of necessary actions to solve the motor problem is perceived as part of a single process. These transformations contribute to the discovery of a property (of a new object) and hence contribute to a process of saming and encapsulation. As a consequence, development towards saming/encapsulation and reification are made simultaneously; this rephrases the idea of action-property duality within operational-structural perspective. This way action-based design offers an opportunity for the simultaneous development of a new object and the associated constrained actions (transformations).

To illustrate this let us look again at quadrilaterals. We developed a task series in which a student is invited to move similar quadrilaterals on a multi-touch screen on top of each other by dragging the corners with their fingers (see Figure 2). The corners must be moved independently but simultaneously by four fingers. Moreover, the similarity of the quadrilaterals must be maintained while moving – this is supported by color feedback as in MIT-P. Recognizing similarity of types of quadrilaterals relies on recognizing the similarity of angles and proportions of side lengths. This, in turn, co-develops with the ability to mentally or physically transform one quadrilateral onto/into the other while maintaining those properties. Movements that maintain similarity are turning, dragging, and mirroring. While students try to "same" similar quadrilaterals, they inevitably stumble upon those transformations as naïve actions. Naturally adaptive motor control might lead students to develop distinguishable fluent transformations that could be developed into more rigorously mathematical concepts of rotation, translation, and reflection. This illustrates the main point of how new objects and the associated transformations potentially codevelop in a saming-task.

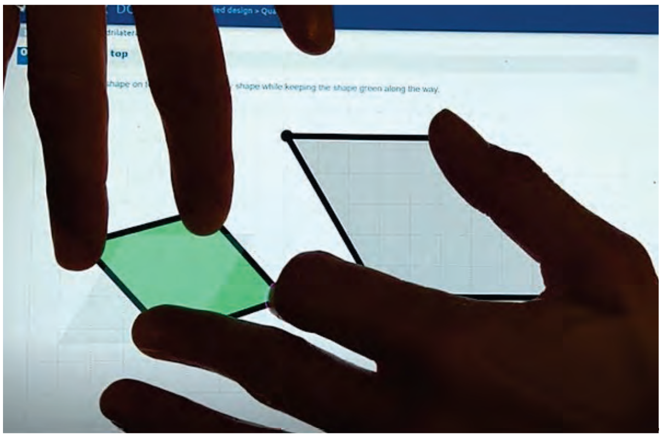

Figure 2. Action-based task: saming flexible quadrilateral by dragging four corners

Examples of embodied designs: the role of transformations

In this section we present two examples of the role of the action-property duality and the operational-structural development in embodied design. We emphasize how fluent motor-action could be reified into mathematical transformations (seen as objects).

Example 1: embodied design for proportion

A well-studied example of embodied design is the action-based task for proportion based on dragging two vertical bars (Abrahamson & Bakker, 2016). The student is encouraged to find positions where the heights of the bars are in a fixed proportion (e.g. $2:3$) by receiving green feedback when such a position is achieved, changing to red if the heights are not according to this proportion. Once a position has been achieved the student is invited to move the bars in a way that maintains the green feedback. In our interpretation from a procedural-structural perspective the student is hence invited to perform constrained transformations on the system of two vertical bars. The outcome is not only a naïve conception of proportion, but also a naïve conception of those transformations that leave a proportion invariant. Flood et al. (2020) report on a student, Ben, who arrived at a solution where the bars move with constant, but different speeds. We infer that Ben not only explored the invariant proportion, but also the actions that maintain the invariant. The latter could be reified into the notion of geometric vertical multiplication, i.e. the transformation that leaves the proportion of height invariant (see Figure 3). In particular, Ben established how (what we call) vertical multiplication has properties different from vertical translation, a transformation that does not leave the proportion of heights invariant. This transformation alludes to the property of proportional variables that, increasing one variable with a factor, the other must increase with the same factor. In general, this again illustrates how the process of saming situations of two bars' heights, the defining property of proportion codevelops with an ability to perform fluent vertical transformation, which could be reified into a mathematical notion of vertical multiplication.

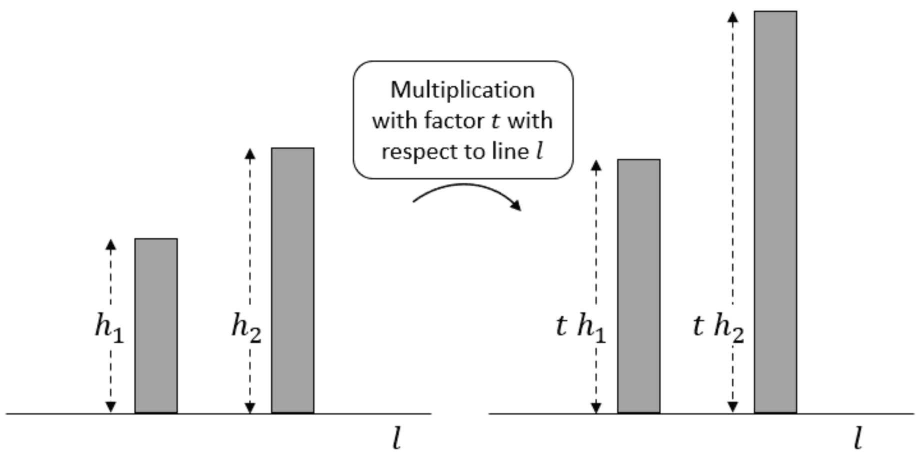

Figure 3. Vertical multiplication as a transformation that leaves the proportion of heights invariant

A transformation can also be associated with the eye movements from one bar to the other. For the task to make any sense the bars need to be considered 'the same' by the student: There must be reason to compare the heights. Some students tend to focus on an imaginary diagonal line between the tips of their two hand dragging the tops of the bars, a so-called attentional anchor (Abrahamson & Bakker, 2016). We argue that this diagonal line is a naïve conception that could (or even should) be reified into a more formal mathematical notion: the transformation of one bar into the other through enlargement with respect to a point (see Figure 4). The diagonal line is the essential ingredient for this transformation. This transformation alludes to the property of proportional variables $H_1 \sim H_2$ that one is a multiple of the other: $H_1 = c\ H_2$. So, yet another process of saming leads to a potential transformation to be reified.

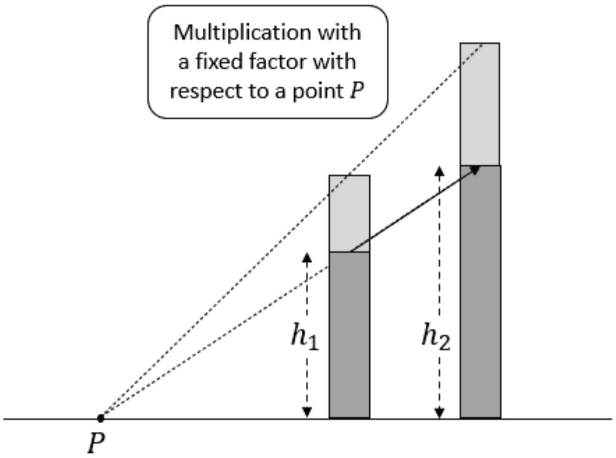

Figure 4. The diagonal line (attentional anchor) can be extended to form an essential ingredient for multiplication with respect to point P: a transformation from bar to the other (ignoring the width).

Example 2: embodied design for the gradient of a plane

In a recent study the author and collaborators investigated embodied design tasks for plane equations ($z = a\,x + b\,y + c$) and the relation to the gradient vector (a, b) (Bos et al., 2022). The embodied learning environment consisted of an Augmented Reality Sandbox (ARSB) – cf. https://web.cs.ucdavis.edu/~okreylos/ResDev/SARndbox/ – together with some plastic planes and bamboo sticks (see Figure 5). The ARSB consists of a box of sand of area roughly 0,6m^2, a stereo camera and a projector. The stereo camera captures images of the height of the sand and objects in the box, and the projector projects height lines and color feedback onto the sand and objects accordingly.

The first few tasks of the teaching sequence aim for students to discover the relations between the parameters a, b and c in the equation $z = a\,x + b\,y + c$ and the transformations rotation parallel to the y-axis, rotation parallel to the x-axis, and translations. In this paper we would like to highlight the next task in the sequence. This task aims to support development of the meaning of the gradient vector in a qualitative way. A vector is defined by its two properties: direction and length. In the case of the gradient vector these properties correspond to direction of the steepest ascent, and to the steepness, respectively. Applying the action-property perspective, each property has associated transformations that leave the property invariant. In the case of direction these are translations and rotations around an axis perpendicular to the direction; in case of steepness these are translations and rotations around a vertical axis. The task is divided into two sub-tasks accordingly: (1) move a circular plane in a way that the direction of the height lines stays the same, but the distance varies; meanwhile, roll a marble down the plane in several positions and try to explain the rolling direction; (2) do the same, but keep the distance between the height lines the same, and explain the speed of the marble. Observing the marble adds a perception-based element to these action-based tasks. Below is an excerpt from a dialogue between tutor Rogier and student Tiago, the case student in the study presented in (Bos et al., in press). The fragment begins while Tiago is working on sub-task 2.

1	Tiago	Like this you get [it] too, and then you can make all those movements again” [Tiago refers to horizontal and vertical translations] but then, in any

		case, it will remain just as steep. [Then Tiago begins to rotate the plane round the place where it touches the sand (see Figure 3)]
2	Tiago	Whether you hold it like this or this.
3	Rogier	Ah.. What movement are you making?
4	Tiago	I rotate it. I rotate it round an axis. That is actually what I'm doing. [Tiago keeps rotating the plane. He chooses a correct position, then waits for the feedback to update, thus clearly using the affordance of the ARSB for establishing a new action.]
5	Rogier	Do you pay attention to anything in particular while rotating?
6	Tiago	No, nothing special. Yes, that I keep it equally steep. Otherwise, it doesn't matter whether you rotate around the point at the bottom [where it touches the sand] or at the top [where Tiago holds it]

Tiago fluently performs a series of actions he calls rotation (line 4), "saming" the plane positions with equal steepness. In line 1 Tiago mentions that during his actions the plane "remain just as steep". This is the first time he associates this adjective "steep" to the plane as a property: one of the two which define the gradient vector. Moreover, Tiago's explanation in line 6 and remarks earlier in course of the experiment suggest he perceives an imagined triangle as depicted in Figure 4 as an attentional anchor, where the angle between the diagonal on plane and the horizontal line on the sand is a measure of steepness. In the light of Table 1 it is important to stress how the introduction of the noun "steep" (commognition perspective, column 2) is preceded and accompanied by the development of fluent action to solve the motor problem and a perception (attentional anchor) that facilitates this action (action-based perspective, column 3).

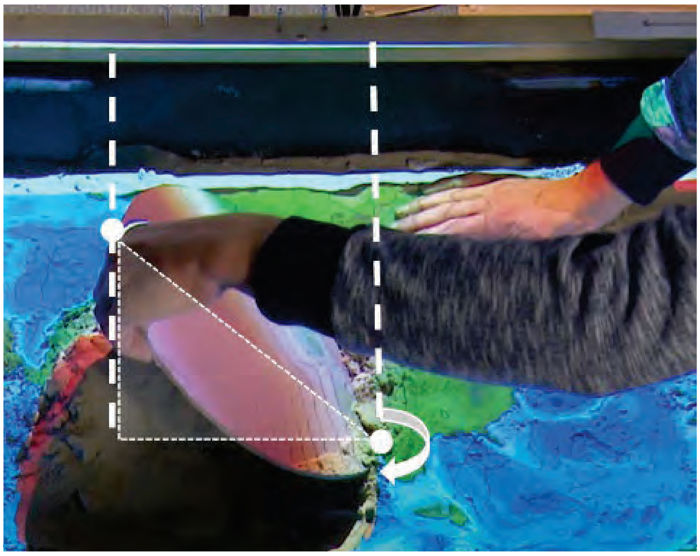

Figure 5. Tiago manipulating a plane while keeping the distance between height lines invariant

Table 2 summarizes the action-property duality for the two properties that constitute the gradient vector. The table highlights how each property is closely connected to an action that can be reified into a transformation as an object. We observed how the actions described in the first column are performed as single process with a clear goal, e.g. in line 6 during rotation "I keep it equally steep". The reification of the object "gradient vector" goes hand in hand with the reification of rotation round a vertical axis as a "keeping equally steep"-action and rotating round a horizontal axis as a "keeping same direction"-action.

Acknowledgment

I would like to thank Anna Shvarts for many discussions and the organization of the Embodied Instrumentation Group meetings at the Freudenthal Institute. The ideas in this paper originate from the inspiring conversations on embodiment with all participants.

Table 2. Action-property duality for two properties that constitute the gradient vector qualitatively

Action	Invariant (property)	Property gradient	Changing
Rotation round vertical axis	Steepness, angle of imagined triangle	Length	Direction of steepest ascent, direction of rolling marble
Rotation round horizontal axis	Direction of steepest ascent, direction of rolling marble	Direction	Steepness, angle of imagined triangle, speed of marble

This paper illustrates the current status of the design and research of a digital, case-based learning platform (FALEDIA), which is being iteratively (re-)designed and researched to increase the diagnostic skills of pre-service teachers. In an interdisciplinary design team consisting of researchers from mathematics education and computer science, digital learning modules on central topics of arithmetic in primary school are designed and implemented in university courses. The learning modules are characterized in particular by the consideration of potentials of digital media from the mathematics education's point of view, such as multiple external linked representations and informative subject-related feedback systems. In this article, the design approach of FALEDIA learning platform is presented by outlining selected learning modules and insights into first results are given.

Keywords: Digital learning platform, case-based, diagnostic skills, place value understanding, understanding of operations.

Introduction

International assessment studies such as TIMSS (Mullis et al., 2020) indicate that pupils are not sufficiently supported in many countries. This particularly holds true for pupils with difficulties in learning arithmetic. Following these recurring empirical findings, it can be assumed that teaching should be consciously oriented towards the learners' individual learning levels and that diagnosis-based support for children should be practiced (Phelps-Gregory & Spitzer, 2018). Therefore, teachers necessarily need diagnostic skills. In order to support pre-service teachers in increasing their diagnostic skills, digital learning platforms can offer new learning opportunities by including multiple representations and intelligent feedback systems.

First, the theoretical background relevant to the design and research of the learning platform is outlined by addressing diagnostic skills, working with cases, and learning with digital learning platforms. The following two sections address the design of the FALEDIA learning platform and the design of the research study. Finally, the research questions and first results are presented.

Theoretical background

Diagnostic skills

‘Diagnostic skills’ are considered a key skill which all teachers should have in order to be able to provide individual support in (mathematics) lessons (Schulz, 2014). Although there is consensus that diagnostic skills are central to any teaching-learning process, the construct is often conceptualized in different ways. On the one hand, diagnostic skills are understood as adequately assessing pupil characteristics and learning as well as task requirements (*accuracy of assessment*, Karing et al., 2011). On the other hand, they are also understood as validly recording the learning status, difficulties and possible backgrounds on the basis of learners' statements (*diagnostic depth of focus*, Prediger et al., 2013). The latter conceptualization of diagnostic skills is followed in the FALEDIA study, since accuracy of judgement has a focus on performance assessments, whereas diagnostic depth of focus also takes potential causal factors of observable performance into account.

FALEDIA aims at contributing to raising diagnostic skills in central arithmetic topics such as *understanding basic arithmetic operations* (UO) and *place value understanding* (PVU).

Case-based learning

In order to prepare pre-service teachers to diagnose the learning levels of children and, based on this, to take appropriate support measures, case-based learning is of decisive importance (Syring et al., 2016). Cases can be in the form of vignettes – as a video, transcript or teaching/learning related document – and can be an occasion for linking theory and practice by establishing relationships between the general and the specific (Markowitz & Smith, 2008). When analyzing the cases, the pre-service teachers – unlike in classroom practice – are not exposed to any immediate pressure to act. Accordingly, it is possible to repeatedly work through a case and, thus, adopt different perspectives (Krammer et al., 2012). Furthermore, the analysis of cases can help to better cope with the diversity of individual cases without getting lost in the multitude of individual approaches.

Based on the promising experiences with the use of cases outlined above, the FALEDIA learning platform is characterized by a consistent integration of school practice cases.

Learning with digital platforms

Web-based, subject-specific learning with digital learning platforms has become increasingly important. With regard to the degree of student activity within learning systems, two approaches can be distinguished:

- *Worked-examples* (Renkl, 2017): Well-structured examples are presented, largely without learners' self-activity.
- *Problem-based learning* (Koedinger et al., 1997): The learners' own activity is encouraged and accompanied, for example, by intelligent tutorial systems.

Design of the FALEDIA learning platform

To emphasize this distinction, the first FALEDIA learning platform version includes two separate variants of the same content. One variant presents the content with informative elements (*worked-*

examples) only, while the other one includes elements to stimulate exploration (*problem-based learning)*. Each one of these will be briefly presented in the following.

FALEDIA conceptional design

Currently, the FALEDIA platform offers learning opportunities for two different topics – *UO* and *PVU*. The website content for each topic consists of three parts. It is considered fundamental for the pre-service teachers to gain (1) the necessary background knowledge. This forms the sound basis for (2) diagnosis on the one hand and (3) accordingly fostering pupils' learning on the other.

FALEDIA provides the necessary content concerning the three most prominent aspects of each topic at first. For *UO* the three aspects of basic mental model, linking representations and using numerical relations have been identified as the most prominent to know. Examples of competency expectations pre-service teachers should be able to acquire are given in Table 1.

Table 1: Competency expectations towards pre-service teachers

Basic mental models	Linking representations	Using numerical relations
Background knowledge – Pre-service teachers …		
can explain which basic image is addressed by given everyday situations or subjects.	can change and describe representation forms – even in more complex contexts.	can describe which task patterns do (not) suggest usage of a specific mathematical law.
Diagnosis – Pre-service teachers …		
can state in how far a basic image is shown in pupils' documents and name difficulties.	can state in how far a child is able to link representation forms and name difficulties.	can state in how far a child uses task relations und mathematical laws and name difficulties.

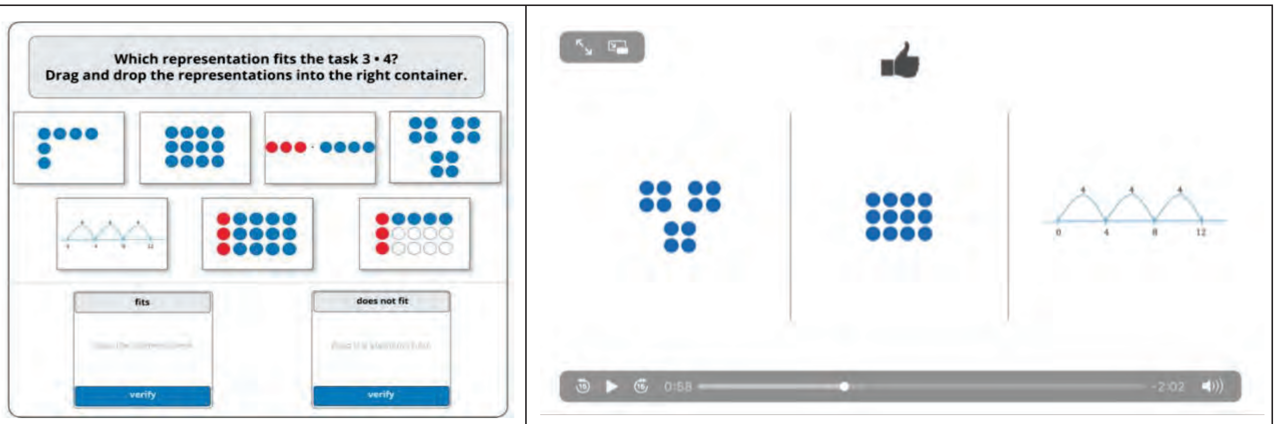
Based on these competencies FALEDIA focusses on background knowledge for pre-service teachers and exemplarily diagnosis of primary school pupils' documents. The two different variants are described in the next section.

Current FALEDIA variants

The current FALEDIA learning platform includes two variants – one with informative elements only and another one mainly with explorative elements. In order to make a comparison between the two variants, either worked-examples or elements of problem-based learning are offered at the same location of the learning content. The way the learning content is offered should contain the same information and be equally attractive to users. The accompanying text, in both variants, is the same.

In the following figures, an example of the implementation of the same content from the two different design perspectives is given. Figure 1a shows a problem-based learning element, where users actively group elements by ordering visual representations according to whether or not they fit the multiplication task 3 x 4. The German conventions dictate that multiplicator x multiplicand = product; the multiplicator expresses how many groups there are while the multiplicand defines the quantity of these groups. A figurative representation shows the quantity of the groups in rows. Users can drag and drop the representations into "fits" and "does not fit" containers. They can click "verify" at any time and receive solution-based feedback.

Figure 1b shows an excerpt from the implementation of the work-example. In this case, the user *is informed* by a video – not as in the example above actively interacting with the platform – about whether or not a representation resembles the task 3 x 4. In each case, a short explanation is given why the respective element was grouped accordingly. This comparison of the examples of the two variants demonstrates that both variants present the same content, but the access to the information differs.



(a) Problem-based learning element

(b) Worked-example

Figure 1: FALEDIA learning modules

The FALEDIA variant with elements of problem-based learning contains various so-called "learning modules"; one of which is the module for "grouping" shown in Figure 1a. To give only a few examples, there is the "slider" in which sequential processes are worked on. At certain important decision points, the pre-service teachers are supposed to choose between three different possible sequels, only one of which is correct. Another activity is "sorting", which is about linear ordering of elements.

The variant with solely worked-examples contains textual and tabular elements; informative videos and audios are integrated. All modules and informative elements are used for various content-related activities and information, both in the background and in the diagnosis.

The following Table 2 illustrates how some contents are realized differently, depending on which variant of the platform they are presented on. Each realization offers learning opportunities – depending on the specific content and its complexity, different accesses might be considered more supportive.

Table 2: Included learning and work-examples only models in comparison

Including interactive modules	Worked examples only

Sorting into groups whether the representation matches a certain task	Explanatory video concerning the connection of different representations
Sorting different contexts to the multiplicative basic mental model which were unknown before	Tabular presentation of the multiplicative basic mental model giving exemplary contexts
Linkage of single-choice tasks concerning an audio file of a pupil explaining her train of thoughts while using mathematical laws	Explanatory audio file including an audio file of a pupil explaining her train of thoughts while using mathematical laws

Design of the FALEDIA research study

The project is designed in a mixed methods design. In the current state, users are offered access to only one of the two pages for each of two topics (PVU and OU). Hence, the pre-service teachers once get access to the variant with worked-examples and once to the one with the problem-based learning, so both variants of access, based on a different topic, are offered. For example, if you see the variant with worked-examples for understanding place value, you see the problem-based variant for operation understanding.

In a next step, the alternative form of access is released for all users in each case, so that access to the information can be chosen freely as required. These multiple representations of the FALEDIA platform are used to gain insights into the perception of the participating pre-service teachers as well as their change in diagnostic tasks.

Research questions

The two following research questions will be addressed in what follows below:

1. Which diagnostic skills do pre-service teachers show before and after using the FALEDIA platform?
2. Which conceptional features and design elements prove to be conductive to learning and in how far are they applicable to other concepts and/or platforms?

Design of the study

To gain insights into the diagnostic skills of pre-service teachers all participating students of a course (N = 188) in their third or fifth semester of studying to become a primary school teacher are obligated to participate in two written surveys and use one of the FALEDIA platform versions for self-study purposes to complete another written task. The students were divided into two groups. One group had the variant with the problem-based learning elements and the other group had the worked-examples to PVU. For the OU, access to the other variant was later enabled for the respective group. The two surveys are designed in a pre-post design. The first test was performed. Then the background knowledge of PVU as well as exemplary diagnosis and fostering was elaborated with the help of the FALEDIA platform. Finally, the posttest was conducted. Among other tasks, the pre-service teachers are given a child’s solution which reveals weaknesses in understanding basic arithmetic operations, and are supposed to describe the errors and specify possible causes. Additionally, guideline-based interviews with randomly chosen pre-service teachers (N = 21) were conducted while they used the FALEDIA platform to provide more detailed information which elements of the two different variants pre-service teachers prefer over the other.

Data evaluation

A system of categories – based on a quantitative study by Brandt (in press) – has been developed to quantify the results of the written survey and get an overview of possible differences in results depending on which variant of FALEDIA was used by the participants. In the evaluation, the diagnostic subskills of describing mistakes, analyzing the causes of mistakes, and assessing diagnostic tasks are looked at. In each case, the three central content aspects of the respective topic are included in the evaluation. The correlations and significances were calculated using Anovas (RQ 1).

As important as that, these results are used to merge the current two variants of the FALEDIA platform into one variant that is tailored to the needs of pre-service teachers. For this purpose, the qualitative content analysis according to Mayring (2019) is applied (RQ 2).

Empirical findings

The first results of the surveys are available for both the diagnostic skills and the design elements. In this paper, a subset of the results on understanding basic arithmetic operations, looking at analysis causes of mistakes is focused on. Amongst others, a before-and-after comparison is used to examine whether the pre-service teachers were able to improve their score after working with FALEDIA and whether there are differences depending on which variant of the learning platform they worked with – the one with the worked-examples or the one with the problem-based learning elements.

Diagnostic skills (RQ 1)

For the average value of the scores achieved in the pre- and post-tests, it can be observed that the pre-service teachers improved both in the worked-examples variant and in the problem-based learning variant (Table 3).

Table 3: achieved scores (UO) averages out of max. 6 points

	score before FALEDIA	score after FALEDIA	score difference
worked-examples (N = 94)	1.33	1.60	+ 0,27
problem-based learning (N = 94)	1.32	1.64	+ 0,32

The increase of points for the analysis of causes of mistakes in the *UO* is statistically significant. Which variant of the learning platform the pre-service teachers had, however, is not significant. This means that the FALEDIA learning platform could help pre-service teachers to increase their diagnostic skills in the field of analyzing the causes of mistakes. However, there is no evidence that one variant of the platform can increase the learning success significantly better than the other variant in this area. As noted previously, prior research has found that a learning platform that includes both – work-examples or problem-based learning elements – proved particularly conducive to learning

(Saatz & Kienle, 2013). Qualitative interviews were conducted to determine which criteria should be used to decide whether a learning situation is better served with a worked-example or a problem-based learning element.

Design elements (RQ 2)

The qualitative interviews offer a more detailed insight into the subjectively perceived learning opportunities. In the interviews, various statements could be clustered into categories. Two particularly conclusive categories for the use of worked-examples and problem-based learning, which can be proven on the basis of the students' statements, are listed below.

Worked examples are preferred if…

… the mathematical content is considered rather difficult or new. ("For the videos the increase in value is when it explains an aspect that I've never noticed before." (Student 1))

… knowledge should be refreshed or presented in an overview. ("If there's something, where you have some kind of 'supercategories' and then you have examples in a comparison, where it's not about diagnosing something, but that you get a feeling for what it's based on, I think the table is more appealing." (Student 1))

Problem-based learning elements are preferred if…

… already acquired knowledge should be verified or deepened. ("This is a good exercise to get more confidence, because you also have to do something yourself […] because you simply have to think more yourself." (Student 2))

… practical diagnostic skills are to be fostered. ("It was good to work practically, like you'll do later as a teacher at school. You do it on your own, you can see how to implement [a diagnostic instrument] – not only theoretically." (Student 3))

These identified categorical differences will be used in the next step to elaborate on the merged site with elements of worked-examples and problem-based learning.

Conclusions

Looking at the insight into the initial survey results provided here, the following can be summarized: for RQ1, there is evidence that pre-service teachers increased their ability to analyze causes of mistakes through the FALEDIA platform. A correlation to the delivery method, i.e. which variant of the platform was used, could not be found significantly. Previous research has demonstrated learning effects for both approaches. However, learning platforms which combine elements of worked-examples and problem-based learning have proven to be particularly beneficial for learning (Saatz & Kienle, 2013). Students' comments from the interviews indicate that both variants are perceived as helpful in certain requirements (e. g. depending on the subject matter and phase in the learning process). Because of this, the final version of the FALEDIA learning platform should not and will not be strictly dedicated to one of the two approaches, but will contain elements of both. For this, with reference to RQ2, categories were worked out in interviews that serve as a basis for decision-making in order to determine which learning opportunity is offered in which variant on the merged platform. Research on the now emerging merged platform based on the initial results of the surveys will be established across sites in the same study design in the coming semester.

Distance learning versus face-to-face classroom learning: student achievement in conditional probability when using a digital textbook with integrated digital tools

Maxim Brnic[1] and Gilbert Greefrath[2]

[1]University of Münster, Germany; m.brnic@uni-muenster.de

[2]University of Münster, Germany; greefrath@uni-muenster.de

The COVID-19 pandemic has had an impact on learning and teaching mathematics in many countries. In Germany, as in other countries, the measure of distance learning was taken. We consider the use of digital mathematics textbooks with integrated digital tools to be particularly suitable for remote or distance learning. The potentials of digital mathematics textbooks, such as assessment, interactivity or collaboration possibilities address the challenges teachers faced in distance learning. Whether mathematical learning processes can also be initiated among students during distance learning is investigated in this study using achievement tests. For this purpose, students in distance and classroom learning who have completed the same series of lessons on conditional probability and authentic contexts are compared. Results from the pretest-posttest design are presented.

Keywords: Achievement, digital textbook, digital tools, distance learning, influence of technology.

Introduction

In the project KomNetMath, teachers and their upper secondary mathematics courses in Germany are provided with a digital textbook with integrated digital tools for one school year. The use of the digital textbook is being empirically investigated. One of the main goals of the accompanying study is to investigate the influence on learning and achievement (Brnic & Greefrath, 2021). Of particular interest is the comparison of the use of the digital textbook to the use of analogue printed materials. This is done in the context of a series of lessons on conditional probability in a face-to-face classroom setting. As a result of the COVID-19 pandemic, a study was conducted in which students in a distance classroom setting performed the same series of lessons. Therefore, students who used the same digital materials in the face-to-face and distance classroom settings and received the same tasks and teacher instructions in synchronous learning can be compared. Using a pretest-posttest design, it is possible to measure the extent to which achievement differences occur depending on whether the students completed the series at school or at home using a digital textbook.

The COVID-19 pandemic and its impact on mathematics education

The COVID-19 pandemic has had a major impact on everyday life in many countries, as well as on educational institutions. Lockdowns and social distancing regulations have changed teaching and learning during this period (Engelbrecht et al., 2020). In Germany, for example, parts of the school year in 2020/21 took place in remote or distance learning. In such a teaching setting, the use of technology was crucial (Bakker et al., 2021). Technology could be used, among other purposes, to connect with students via videoconferencing or to work with digital materials, such as a digital textbook. At the same time, the school closures and the different access to technology are seen as possible causes for a deepening of social gaps (Engelbrecht et al., 2020). The long-term consequences for teaching mathematics and mathematical education are currently being discussed in particular in the editorials of various mathematics education journals (e.g., Cai et al., 2020; Engelbrecht et al., 2020).

First studies on the impact of the COVID-19 pandemic on mathematics teaching focus especially on the teachers' perspective (Aldon et al., 2021; Drijvers et al., 2021). In particular, interaction, communication, and opportunities for in-person feedback are reported to have changed in distance education compared to face-to-face instruction and are associated with greater hurdles (Aldon et al., 2021; Cai et al., 2020). Additionally, for some teachers in Germany, Flanders and the Netherlands the belief was found that distance teaching is more suitable for teaching procedures and algorithms than for teaching authentic and complex mathematical activities (Drijvers et al., 2021). Aldon et al. (2021) identified four challenges for teachers in particular:

> (a) managing distance learning to support students' learning through specific methodologies; (b) managing distance learning to develop assessment; (c) managing distance learning to support those students that face difficulties and/or are living a difficult situation/developing inclusive teaching; and (d) managing distance learning to exploit its potentialities for fostering typical mathematical processes. (Aldon et al., 2021, pp. 1, 6)

To what extent these challenges can be overcome in distance learning and how teaching-learning processes can be successfully implemented from the students' point of view, remains to be clarified.

The potential of digital mathematics textbooks

For many teachers, the textbook is the most important resource in the mathematics classroom (Fan et al., 2013; Rezat et al., 2021). Thus, the textbook has a significant influence on classroom instruction (Fan et al., 2013). Due to the importance of the textbook, it can be assumed that this resource was also relied upon in times of the COVID-19 pandemic. The use of digital textbooks exemplifies the use of technology in distance learning. Digital mathematics textbooks may differ significantly from analogue printed mathematics textbooks. The potential of digital mathematics textbooks is visible in various dimensions. Modern digital textbook offers opportunities to interact with the book and with individual tasks (*Interactivity*), but also with other people (*Socialization*). In addition, new adaptation and design options are available (*Customizing the Learning Experience*) and assessment is an integral part of a digital textbook (*Ongoing Assessment and Reporting of Student Progress)*. Furthermore, a digital textbook can be updated quicker and continuously (*Potential Economic Benefits of Digital Content)* (Choppin et al., 2014).

Pepin et al. (2015) distinguish three different types of digital mathematics textbooks, which differ in their design or structure as well as in their creation. The "integrative e-textbook" is a digitised version of a traditional, printed textbook. It therefore largely corresponds to the characteristics of analogue printed textbooks. The content is enriched by add-ons and links. In contrast to the integrative e-textbook, the "evolving or 'living' textbook" is not written by a classical authorship, but is continuously developed by a community. The third type corresponds to an "interactive e-textbook". This is a variant that mainly consists of learning objects. These learning objects include tasks and interactive elements. These objects can be linked and connected to each other (Pepin et al., 2015).

However, other types of digital textbooks or learning tools that do not fit into this categorisation are also conceivable (Pepin et al., 2017).

Learning with digital textbooks and its integrated digital tools

The structure and content of a (digital) mathematics textbook have an impact on the learning opportunities a textbook offers, and this can eventually result in an impact on learner performance (Pepin et al., 2015; Sievert et al., 2021). The textbook, as an artefact, is a mediator between the intended curriculum and the teachers' final actions (Fan et al., 2013; Valverde et al., 2002). According to the *didactic tetrahedron model*, the textbook influences the interactions between mathematics, students and teachers (Rezat & Sträßer, 2012).

So far, the use of textbooks and the influence on learners' achievement has only rarely been investigated (Fan et al., 2013). Research comparing digital and analogue materials has shown an initial positive effect of digital materials (Brnic & Greefrath, 2021; Reinhold et al., 2020). It became apparent that certain groups of people could particularly benefit from digital materials, specifically low-achieving students (Reinhold et al., 2020) or – in comparison of gender – female students (Brnic & Greefrath, 2021). With regard to the use of digital tools, meta-studies also found a positive effect on learning outcomes (Hillmayr et al., 2020).

Research Question

Initial study results indicate that digital mathematics textbooks with integrated tools have positive effects on learning compared to analogue materials (Brnic & Greefrath, 2021; Hillmayr et al., 2020; Reinhold et al., 2020). Digital textbooks are particularly characterised by their potentials and interactive features (Choppin et al., 2014; Pepin et al., 2015). These technological potentials precisely address the challenges that teachers face in mathematics lessons in distance learning, e.g. communicating with students or giving feedback (Aldon et al., 2021; Engelbrecht et al., 2020). However, the extent to which learning processes can actually be successfully initiated in a lesson with a digital textbook that also takes up authentic contexts is still a research desideratum. This results in the following research question:

What influence does the use of a digital textbook with integrated tools have on the students' achievement in the context of a series of lessons on conditional probability in distance learning?

This question will be investigated in a comparison with students who have completed the same series of lessons in a face-to-face classroom setting.

Method

The digital mathematics textbook Net-Mathebuch

The digital mathematics textbook Net-Mathebuch (www.m2.net-schulbuch.de) was used for this study. This interactive textbook was designed as a *digital* textbook and is not based on a printed textbook. The book can be used in the sixth form of the Gymnasium in Germany and covers the content relevant for the German Abitur. It is continuously revised and further developed by a group of mathematics teachers. Feedback from other teachers or students is incorporated. It therefore has the characteristics of an "evolving or `living` textbook" (Pepin et al., 2017). Besides, digital tools are constantly provided with integrated GeoGebra features, thus fulfilling the characteristics of an "interactive textbook" (Pepin et al., 2017). It takes up several of the theoretical potentials of a digital textbook (Choppin et al., 2014):

Potentials of digital textbooks	Examples from the Net-Mathebuch
Use of Multimedia	Learning videos; animations; simulations; pop-up windows and tool tips: gap texts; slide shows; …
Interactivity	Interactive tasks, e.g., through GeoGebra apps; tasks with selection options through checkboxes or radio buttons; drag and drop tasks; …
Socialization	Upload function for own materials; chat; …

Potential Economic Benefits of Digital Content	Quick revision possibility of the content and features of a digital textbook by the editors; integration of current contexts; …

Figure 1: Potentials of digital textbooks with examples from the Net-Mathebuch

Sample and data collection

As part of the KomNetMath project, teachers and their students are provided with the digital mathematics textbook Net-Mathebuch free of charge for one school year. Teachers participating in the project receive regular in-service training to support the use of the textbook in the classroom. By participating in the project, the teachers agree that they and their students will take part in an accompanying study. In the study, different mathematics didactic questions are investigated, e.g. the influence of the use of a digital textbook on computer-specific self-efficacy expectations and the comparison between the use of a digital textbook and analogue printed materials (Brnic & Greefrath, 2021).

In the study presented here, 12 upper secondary mathematics courses (year 10 and 11) participated. The average age of the students was $M = 15.62$ ($SD = .69$). The five-hour series of lessons on conditional probability was conducted by 87 (39 female) students in September/October 2020 in face-to-face classroom settings and in April/May 2021 63 (28 female) students in distance learning. The distance learning students were home-schooled at this time due to the pandemic and a nationwide lockdown. The lessons were taught using the Microsoft Teams video conferencing system. The mathematics lessons took place regularly according to the timetable. In the video conferences, the students and teachers were online for the entire time. In the distance and face-to-face lessons, the pre- and posttest as well as the series of lessons were conducted synchronously in the respective courses. In both research groups the students always received the same instructions so that they worked on the same tasks in the same order in the series of lessons.

Design of the intervention and test instrument

A lesson series on conditional probability was developed for the KomNetMath project. In this five-hour lesson series students work on tasks from the Net-Mathebuch. Most of the tasks deal with authentic contexts, for example a home HIV test and DNA analysis. The lesson series is to be carried out according to predefined course plans for the individual lessons. In order to minimise the influence of the teacher, the students should mainly work on their own. The students can check their own solutions for some tasks with feedback options in the digital textbook independently (see Figure 2).

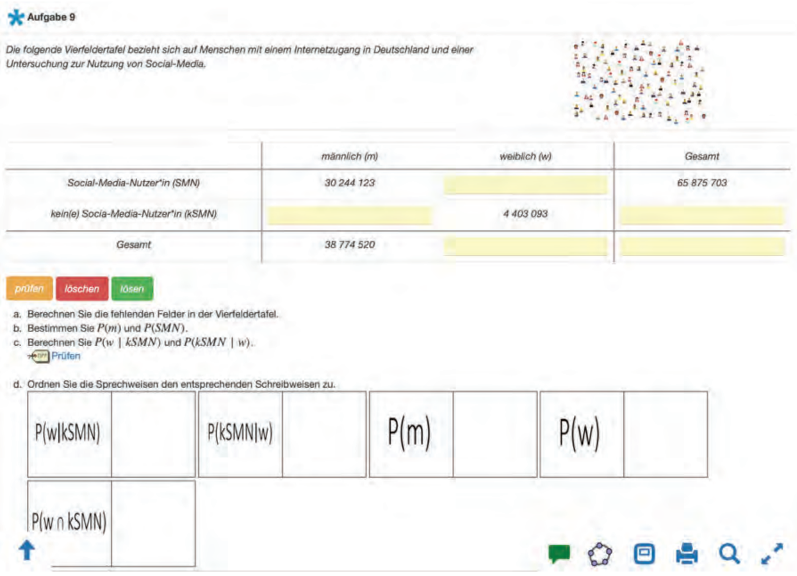

Figure 2: Sample task with feedback option for the solution

Before and after the lesson series, the students take a test on conditional probabilities. The test contains a total of 21 items. The pre- and posttest are linked with 5 anchor items so that the students also solve different tasks in both tests and no repetition effects occur. The test is originally designed as a paper-pencil test for face-to-face instruction so that students can draw their own tree diagrams or fourfold tables. For distance learning, the test format was slightly adapted and partially digitised so that the pre- and posttest could be conducted via video conference. In distance learning, the items were made available to the students digitally using the SociSurvey software. The answer options in multiple-choice format and semi-open response format could also be entered directly by the students digitally. Necessary calculations were carried out on a piece of paper as in a paper-pencil test and uploaded. Since the items were only coded dichotomously, a comparable evaluation of the tests was possible between the classroom and digital setting.

The data are scaled using the Conquest software and a Rasch model. Subsequently, person parameters are analysed with evaluation procedures of the classical test theory. A one-parameter and one-dimensional Rasch Model is used for the pretest and posttest (Rasch, 1960; Wu et al., 2007). Two items were excluded from the analysis because they had a discriminatory power of less than 0.2, which is too poor (OECD, 2012). To check the fit of item and model, the weighted mean square fit (WMNSQ) for each item is also considered. The values for the remaining items range between 0.89 and 1.07 and are thus in a suitable range for the discriminatory power (OECD, 2012). The EAP/PV reliability is 0.51, which is a sufficient value for group comparisons (Lienert & Raatz, 1998).

Results

Figure 3 shows the results from the pretest and posttest from both groups. A higher score corresponds to a better result in the pretest or posttest.

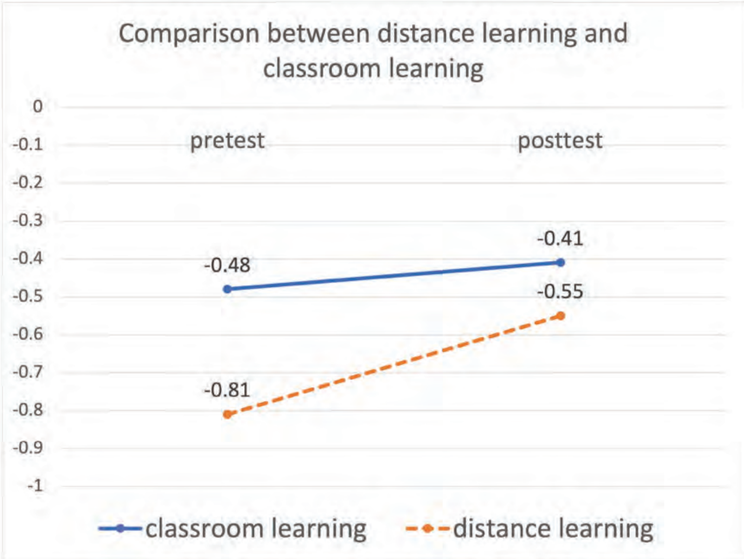

Figure 3: Results of the pretest and posttest on conditional probability

The pretest already portrays that both groups differ significantly with $t(147) = 2.23$, $p = .027$. The effect size of Cohen`s d = .37 corresponds to a small effect. A two-way repeated measures ANOVA shows a significant result for the main effect between the measurement time point with $F(1, 147) = 3.96$, $p = .048$, partial $\eta^2 = .03$. This is a small effect. The interaction between the measurement time points and the group reveals no significant effect ($F(1, 147) = 3.96$, $p = .254$, partial $\eta^2 = .01$). The within-subject factor group is not significant with $F(1,147) = 2.785$, $p = .097$, partial $\eta^2 = .02$. Analyses in both groups show that the face-to-face classroom setting group does not significantly increase with $t(85) = -.73$, $p = .229$. In contrast, the distance learning group increases significantly from pretest to posttest with $t(62) = -1.82$, $p = .038$ and a small effect of Cohen's d = .23.

Discussion

Although the groups already differ significantly at the first measurement point before the treatment, no interaction between the measurement points and the group can be found. Nor are differences in achievement attributable to the group membership.

The assumption that the students show a gap in distance learning to the students in face-to-face classroom learning seems to be confirmed by this sample. Although they manage to improve significantly, they are still at the level below the face-to-face group after the intervention. Whether these differences can be attributed to the challenges for teachers mentioned above (Aldon et al., 2021; Cai et al., 2020) cannot be answered by this study design. Differences between the groups can also be attributed to the fact that both reference groups were taught by different teachers.

The results give indications that the students in distance learning were even able to benefit comparatively more from the digital textbooks and its integrated tools than in face-to-face learning. The digital textbook seems to have particular potential in distance learning and the results indicate that especially low-achieving students from the pre-test benefit particularly from interactive materials (Reinhold et al., 2020). Which potentials and digital tools or in which areas of the tests the respective groups could particularly benefit from requires additional in-depth analyses. Further analyses can also examine whether multidimensional Rasch models can be used or whether a more differentiated analysis of student solutions is possible. Nevertheless, the study shows that students can also learn to deal with complex mathematical content in distance learning. A prerequisite in this study was that the lessons take place synchronously and all students have access to the technology. Nevertheless, it was also observed during the course of the lessons that technical problems can occur occasionally, making communication, for example, more difficult.

The results show that across the entire sample, students were able to improve their performance. This is consistent with other studies that have also found positive effects of digital tools (Hillmayr et al., 2020). In this project, we will further investigate to what extent achievement differs from the use of analogue materials and to what extent students benefit from the potentials of digital mathematics textbooks.

Why introductory experiments on functional relationships should be qualitative to foster covariation

Susanne Digel[1] and Juergen Roth[2]

[1]University of Koblenz-Landau, Institute for Mathematics, Landau, Germany; digel@uni-landau.de

[2]University of Koblenz-Landau, Institute for Mathematics, Landau, Germany; roth@uni-landau.de

The covariation aspect of functional thinking (FT) is difficult for students but at the same time central for the development of a concept of function. Looking at high school mathematics, covariation is not in focus. Prevalent approaches put the well accessible correspondence aspect in foreground and support this imbalance with numeric processing. Although student experiments have proven to be a beneficial introduction to functional relationships, the measurements collection could contribute to this problem. In our pre-post-test intervention study, we contrast a numerical and a qualitative introductory learning environment to functional relationships with a combination of hands-on and digital experiments. Results (N = 332) show significant increases in functional thinking in both settings, but significantly higher gains in the qualitative setting. Effects of the constraints cooperation level and school form indicate possibly relevant influential factors on this lead in line with theory.

Keywords: covariation, digital technology, student experiments, concept of function.

Developing a concept of function

The concept of functions is a major concept and at the same time a major hurdle in mathematics at school. Hence a considerable amount of research has been dedicated to the teaching and learning of functions. This study tries to bring together several branches of evidence to a coherent approach to the concept of functions. Breidenbach et al. (1992) used the Action-Process-Object-Scheme (APOS) theory for a developmental perspective on students' conceptualization of functions. The action concept on the lowest level is limited to the assignment of single output values to an input. With the more generalized process concept students consider a functional relationship over a continuum, enabling the reflection on output variation corresponding to input variation. Finally, functions conceptualized as objects can be transformed and operated on. Students with an elaborate concept of functions are supposed to be able to use the action, process or object conception depending on the mathematical situation (Dubinsky & Wilson, 2013).

Aspects of functional thinking

The developmental stages of APOS are in line with key elements of a function concept, that are described as aspects of functional thinking (FT) by Vollrath (1989) as follows: the *correspondence* of an element of the definition set to exactly one element of the set of values; the *covariation* of the dependent variable when the independent variable is varied and the final aspect, in which the function is considered as an *object*. Although with the APOS perspective one might deduce a teaching sequence with an initial focus on correspondence, then covariation and finally object, current research advocates for a major role of covariation. Thompson and Carlson (2017) argue that the correspondence aspect alone does not evoke an intellectual need for the new concept function and difficulties with functional relationships are mainly rooted in lacking ability and opportunity to reason covariationally. Johnson (2015) points out that correspondence induces a static view on a functional relationship, while a dynamic perspective is a prerequisite for covariation and a process concept. These arguments lead to the call for a qualitative approach to functional relationships in school.

Experimenting fosters functional thinking

Learning environments with experimentation activities have proven to be beneficial for functional thinking (Lichti & Roth, 2018). One possible explanation could be the proximity of functional thinking to scientific experiments as illustrated by Doorman et al. (2012): with a given variable as starting point, a dependent variable is generated in an experiment. Relating the output to the input clearly addresses the correspondence aspect and the action concept. Following manipulations of the input and concurrent observation of the output make the covariation of both variables tangible and enables a process view. Another benefit of student experiment is the inherit constructivist learning approach that leads to higher learning gains in combination with digital technologies (Drijvers, 2019).

Lichti and Roth (2018) implement the scientific experimentation process – preparation (generate hypotheses), experimentation (test the hypotheses) and post-process (reflect results) – in a comparative intervention study to foster functional thinking of sixth graders with either hands-on material or simulations and report learning gains for both approaches (ibid.), but a closer look reveals disparities that can be explained with the instrumental genesis.

Hands-on experiments and simulations in the light of instrumental genesis

The instrumental approach (Rabardel, 2002) and its distinction between artefact and instrument can be useful when interpreting these results: while the artefact is the object used as a tool, the instrument consists of the artefact and a corresponding utilization scheme that must be developed. This developmental process - the so-called instrumental genesis - depends on the subject, the artefact and the task in which the instrument is used. Hence, different artefacts lead to different schemes. Artefacts that are more suitable for the intended mathematical practice of a task appear to be more productive for the instrumental genesis and facilitate the learning process (Drijvers, 2019). When using simulations, schemes that develop are dynamic and concerned with variation as well as transition and hence support the covariation aspect (Lichti, 2019). Measurement procedures of the hands-on material induce static schemes for values and conditions, fostering the correspondence aspect (ibid.). While hands-on material stimulates basic modelling schemes, relating the situation to mathematical description, a simulation already contains a model of the situation. When used as multi-representational systems, the simulation illustrates connections between model and mathematical representations (e.g. graph and table) that evoke schemes for these representations and their transfer. The study presented here attempts to make use of both beneficial influences on the instrumental genesis through an appropriate combination of hands-on material and simulations in experimental activities to foster functional thinking.

Fostering the conceptual development

The measurement procedure is laborious, giving it a dominant role, which sets a focus on correspondence and induces static view on the relationship. As stated above, it would be desirable to shift to a dynamic view, a process concept and covariation. Thus, we explicitly developed a non-numerical approach for experimenting with immediate examination of covariation and compared this qualitative setting to a numerical one, following the implementation from Lichti and Roth (2018).

The learning environments

Both settings use a story of two friends preparing to build a treehouse and contain identical overarching tasks. The contexts are implemented with the same hands-on material and simulations (see Figure 1 and 2), but different components of the simulations are visible in the settings. The student activities are structured in six contexts (see below for details), each one laid out like a scientific experimentation process with preparation, experimentation and post-processing phase. The students work in pairs (A and B), each working on three contexts (see Figure 1). The contexts are chosen to represent a linear and a quadratic relationship and one with varying change rate.

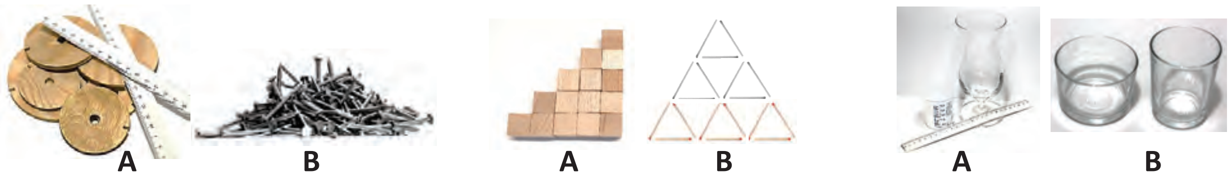

Figure 1: Hands-on material of the contexts for partner A and B

For partner A these are: the perimeter of a circular disc determined by its diameter, the number of cubes needed for a "staircase" determined by the number of steps and the fill height of a vessel determined by the volume of water filled into. Partner B examines the weight of a package of nails determined by the number of nails, the number of beams needed for a woodwork determined by the number of floors and the fill height of cylindric vessels with different diameters determined by the volume of water filled into. A bonus context for quick learning teams depicts the diameter of an unrolling tape determined by the length of tape that has been unrolled.

The **numerical setting** follows the scientific experimentation process: after initial hypotheses in the preparation phase, inspect hands-on material and estimate value pairs, students take a series of measurements and record their data in a table within a simulation (GeoGebra), which creates a graph from the data. The simulation also contains a model of the hands-on material, enabling systematic variation and parallel observation of the altering quantities in model and graph. In the post-processing phase the students verify their measurements, analyze the graph (interpreting and interpolating) and get back to the real material to check their estimations from preparation phase. The learners go through these phases for three contexts subsequently (see above), share their insight after each context with a partner and solve overarching tasks for each context as team.

In the **qualitative setting** the students also start off with hands-on material to activate modelling schemes and enable embodied experience. They are asked to make assumptions about a pattern and on that basis estimate subsequent values. With the aid of a simulation, where they can manipulate a model of the hands-on material, the students get a dynamic view of the relationship and are asked to identify the related quantities, which concludes the preparation phase. In the following experimentation phase students observe the variation and covariation of the quantities in the simulations and verbally describe the relationships discovered. Subsequently graphs are generated within the simulations to enable observing the covariation in multiple representations and in the post-processing phase students are asked to analyze the form of the graphs and connect their insights with the relationship described in the previous phase. The students then team up with their partner, compare both contexts and identify similarities in the relations. In an additional experimentation phase, they take measurements in the context of their partner, represent the covariation in the measurement table and compare this to the results reported by their partner. As a final task the partners are asked to group the contexts by the kind of covariation, i.e. build pairs of similar contexts based on their findings. Both settings can be accessed in digital classrooms[1].

Study Design

A comparative intervention study (pre-post design) is implemented both as in-classroom and as home schooling with seventh and eighth graders at grammar and comprehensive schools. It contrasts the qualitative and numerical settings and includes an additional control group with the simulation only implementation of Lichti and Roth (see above). In a subsample the settings are laid out as individual learning paths, i.e. without team phases. The intervention is designed for six lessons (split into three sessions). It is preceded and followed by a short test on functional thinking (FT-short[2]), to compare the learning outcomes in both settings. Students work in teams of two pairs (except the individual work subsample). A pilot study (ibid.) verified the comparability of the two settings in terms of processing time and difficulty. With this layout we aim to answer the following research questions:

RQ 1: Which setting is more beneficial for FT?

RQ 2: Is the combination of hands-on material and simulations more effective regarding FT than the setting with simulations only?

RQ 3: Do the systematic constraints cooperation level (individual/team) and school form (grammar/comprehensive) have an impact on the learning gains in the compared settings?

Method

Data analysis was conducted according to Item Response Theory. The dichotomous one-dimensional Rasch model and the virtual persons approach were used to estimate an item difficulty for every item of FT-short. The person ability was then estimated with fixed item difficulties. We applied mixed ANOVAs (between factors: setting, school form, teaching mode, cooperation level; within factor: time) after controlling data for normal distribution and homogeneity of variance. Pairwise t-tests were used to investigate differences of the settings. Due to the corona restrictions the distribution of the sample on the different constraints is somewhat imbalanced. For the mixed ANOVA of cooperation level, a subsample was selected out of the team sample and parallelized by pre-test (see values in brackets in Table 1 for team sample sizes).

A statistical power analysis (3 groups, 2 measurements, power .9, α =.05) for a medium effect (η_p^2 = .06) in a mixed ANOVA gave a desired sample size of 204.

---

[1] www.geogebra.org/classroom numerical Setting: HQX7 UZRQ and covariational Setting: D3XM DDSB

[2] Rasch-scalable, 27 items, see Digel & Roth, 2020, online version of FT-short: www.geogebra.org/m/undht8rb

Results

Here we present quantitative results of the main study (N = 332, 121 female, 187 male, age M = 13.0, SD = 4.8). The distribution of the sample over the settings and constraints is shown in table 1.

Table 1: Data sample sizes of subgroups

	Numerical Setting	Qualitative Setting	Control Group
Total	125	114	93
Comprehensive / Grammar	52 / 73	39 / 75	27 / 66
Individual work / Team	20 / 20 (105)	18 / 18 (96)	16 / 16 (77)

The estimation of the Rasch-model, used to determine the person abilities for the total sample, showed good reliabilities in the pre- and post-test: $EAP\text{-}Rel_{pre}$ = .86 and $EAP\text{-}Rel_{post}$ = .80 as well as $WLE\text{-}Rel_{pre}$ = .85 and $WLE\text{-}Rel_{post}$ =.80.

Comparison of the settings in total

The mixed ANOVA (see Figure 2) resulted in two significant and one minor significant effects: first, there was a significant main effect for time $F(1, 329) = 188.17$, $p <.001$, $\eta_p^2 = .36$. The results in FT-short for the total sample (numerical, qualitative and control setting together) increased significantly with a large effect from $M = -.46$ logits (SD = 1.37) up to M = .26 logits (SD = 1.01). Second, there was a minor significant main effect for setting $F(1, 329) = 256.34$, $p <.01$, $\eta_p^2 = .04$. The subsamples of both treatment groups (numeric/qualitative) did not differ before the intervention ($t(198) = -.18$, p =.571), but they did afterwards ($t(198) = .26$, $p <.001$, d = .32) and both together did not differ from the control group before the intervention ($t(134) = -.78$, p =.219).

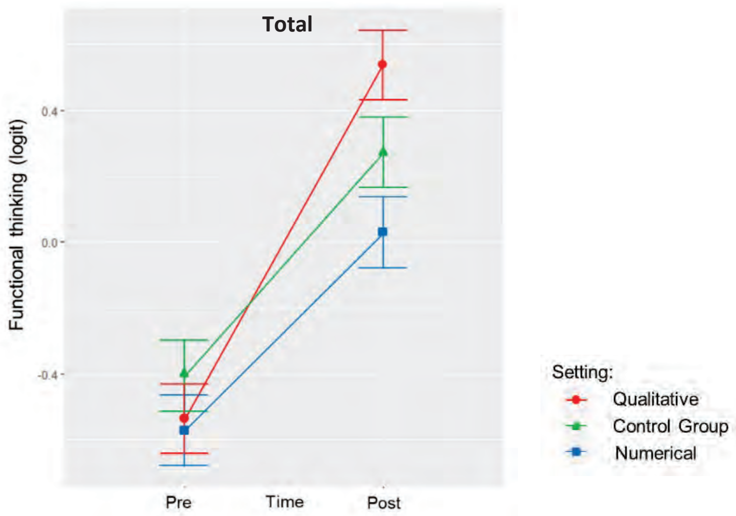

Figure 2: Increase in FT pre to post by setting

Results in all three settings increased significantly from pre- to post-test (see Table 2). The mixed ANOVA also showed a significant interaction between time and setting ($F(2, 329) = 5.33$, p =.005, η_p^2 =.03) with a small effect. Due to limited space, the results of the following ANOVAs are only reported briefly. If not stated otherwise, the remaining main and interaction effects were not significant.

Table 2: Learning Gains pre to post in subgroups per setting

Reported are effect sizes (Cohens' d) with significance level *** (p < .001) if not stated otherwise

	Numerical Setting	Qualitative Setting	Control Group
Total	.25	.51	.27
Grammar / Comprehensive	.27 / .32	.48 / .63	.28 / .34
Individual work / Team	.37** / .25*	.37** / .76	.26* / .23*

Comparisons of the settings under constraints

Regarding the **school form** (see Figure 3 left) the mixed ANOVA showed a significant main effect for time ($F(1, 326) = 197.34$, $p < .001$, $\eta_p^2 = .38$) and a significant effect of school form ($F(1, 326) = 87.82$, $p < .001$, $\eta_p^2 = .21$). Above, there are two significant interaction effects: between time and setting ($F(2, 326) = 5.92$, $p < .005$, $\eta_p^2 = .018$) and between time and school form ($F(2, 326) = 9.57$, $p < .005$, $\eta_p^2 = .029$). The grammar school students outperformed the comprehensive school students in the pretest significantly ($t(174) = 8.09$, $p < .001$, $d = .61$), but for both school forms students' ability increased significantly with a small to medium effect (grammar: $t(425) = 7.08$, $p < .001$, $d = .34$; comprehensive: $t(216) = 5.84$, $p < .001$, $d = .40$). In both school forms students in the qualitative settings showed the highest learning gains (see Table 2).

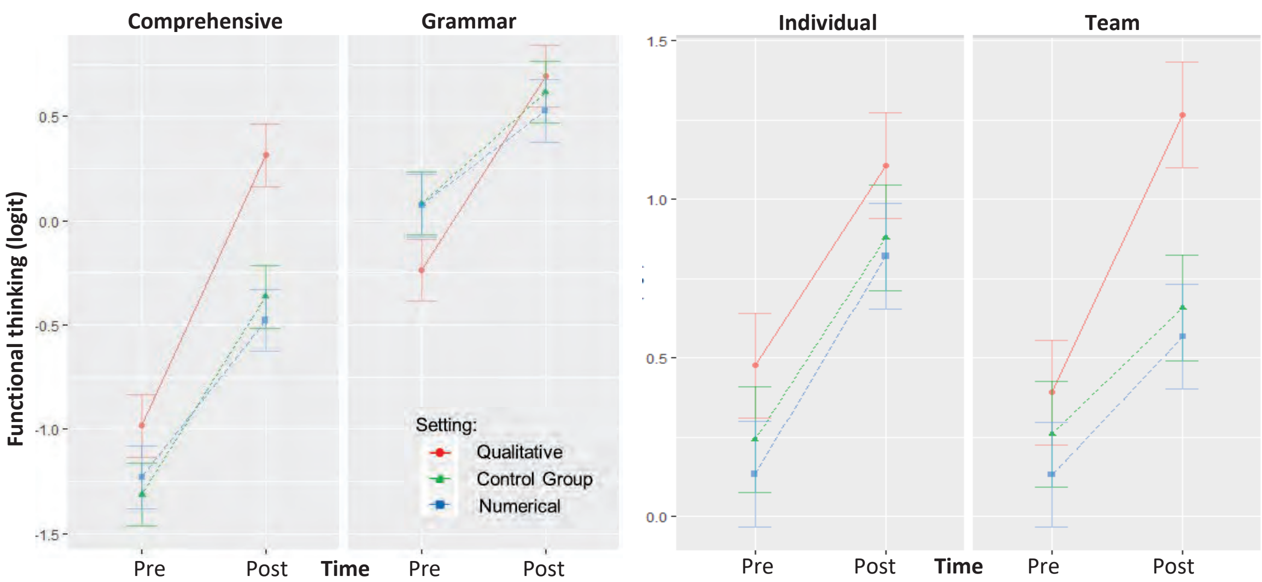

Figure 3: Increase in FT pre/post by setting & school form (left) / by setting & cooperation level (right)

The mixed ANOVA for **cooperation level** (see Figure 3 right) resulted in a significant main effect for time ($F(1, 102) = 79.38$, $p < .001$, $\eta_p^2 = .44$) only and no significant interaction effects. This subsample is part of the grammar school sample (high abilities in the pretest with $M = .36$ logits and $SD = .87$). The effect sizes of the learning gains are reported in Table 2.

Discussion

One of the major restrictions are the unbalanced subgroups, caused by requested flexibility towards the participating schools due to the pandemic restrictions. Above the results are not generalizable without reservation, since they depend on the concrete settings developed in the study. Nonetheless, the results show a significant increase of FT in the numerical (small effect d = .25) and the qualitative settings (medium effect d = .51), as well as the control group (small effect d = .27), from pre- to post-test. Hence all three approaches are suitable to foster functional thinking of seventh and eighth graders. The learning effect for FT in the qualitative setting is significantly higher (small interaction effect of time and setting η_p^2 =.03). Thus, we can conclude that the qualitative approach with a focus on covariation seems to be more beneficial for functional thinking than the other two (RQ1).

Since all three approaches in this study use identical (in case of the control group similar) simulations and contexts, it seems that the specific sequence and focusing of the tasks are decisive. Referring to our theoretical background, we consider two characteristics of the qualitative setting as influential aspects: first, the early focus on the dynamics of the observed variables in the qualitative approach provide opportunities to reason variationally and to develop a dynamic view on functions. Second, the shift of the measurement procedure to a very late step might also contribute to this view. We can assume that replacing early measurement with investigation and observation of the relationship initiates practice in covariational reasoning.

The learning effects in the numerical setting and the control group do not differ significantly as opposed to the qualitative setting. Regarding RQ2 we assert that the combination of hands-on material and simulations, as laid out in the qualitative and numerical setting, only lead to higher learning gains for FT (compared to the control group with simulations only), when the combination is embedded in a qualitative approach. From the perspective of instrumental genesis, we might conclude that the utilization schemes developed with hands-on material could have conflicting influences on FT. For instance, modelling schemes could be beneficial by facilitating the identification of independent and dependent variables, while schemes developed when investigating values and conditions of the hands-on material could hinder a dynamic view.

Regarding RQ3 the significantly different FT results of grammar and comprehensive school students in the pretest (d = 0.61) are in line with PISA results reported by Reinhold et al. (2019). But the medium learning effect in the qualitative setting for comprehensive school students indicate that the covariational focus is also accessible to lower levels of FT and not restricted to high achievers. Since the sample size does not match the power analysis, especially the results regarding the cooperation level must be handled with caution and need to be verified. The contrast of comparable learning gains for all three settings in the subgroup “Individual” and higher learning gains in the subgroup “Team” for the qualitative setting might allude to the importance of the team discussion phases, only present in the “Team” subgroup. They might represent the opportunities for co-/variational reasoning, Thompson and Carlson (2017) call for.

To sum up, a qualitative approach to the concept of function with experiments (1) attains higher learning gains across competence levels, (2) makes the covariational aspect accessible for high and low achievers and (3) benefits from the combination of hands-on material and simulations, when (4) opportunities to reason covariationally are included. In classroom practice, an approach to functions accommodating these aspects has the potential to enhance learning gains.

Orchestrating the discovery of the Greatest Common Divisor and the Least Common Multiple hidden in a digital spirograph

Eleonora Faggiano, Federica Mennuni and Silvia Rizzi

University of Bari Aldo Moro, Italy; federica.mennuni@uniba.it

This paper focuses on good practices in technology-rich mathematics education, and in particular, on the principles and heuristics that may guide the teacher's orchestration of fruitful activities. We present a teaching activity, framed by the Method of Varied Inquiry (MVI), which involved a small group of 10th grade students, with the aim to let them discover the Greatest Common Divisor (GCD) and the Least Common Multiple (LCM) as objects that mathematize a digital spirograph. Results are analysed and discussed to show how students' learning can be supported by the teacher's orchestration of the activity.

Keywords: Digital spirograph, Greatest Common Divisor and Least Common Multiple, Instrumental Orchestration, Method of Varied Inquiry.

Introduction

Addressing opportunities and constraints of learning mathematics in a technology-rich environment has happened to be even more relevant in times of an immense increase of distance learning and of unexpected changes in teaching practices. In this paper we focus on the principles and heuristics that may guide the design and implementation of a didactic activity developed during the pandemic. More precisely, we are interested in reflecting on the way students' learning can be supported through appropriate design of the activity and teacher's behaviour. For this reason, we refer to the notion of teacher's orchestration developed within the research field of mathematics education, particularly in the case of the use of technological resources in classroom (Trouche, 2004; Drijvers et al., 2010).

The idea of the teaching activity we present in this paper comes from a study in which Ferrara, Ferrari and Savioli (2020) focussed on the mathematics "in movement" that can be addressed using a spirograph (a drawing tool used to create curves for recreational purposes): the movement is the key aspect used to give meaning to the mathematical relationships embedded in the spirograph, such as the concept of the Greatest Common Divisor (GCD) and the Least Common Multiple (LCM). In their work, Ferrara and colleagues suggest some reflections on the mathematical modelling of the spirograph, showing and analysing a teaching experiment developed with 5th grade students. Our attention was attracted by the idea that the characteristics of the spirograph fit with the purpose to offer students a situation in which variation gives power to the development of mathematical thinking, especially in terms of conjectures and argumentations. With this respect, the potential of the spirograph can be exploited not only at the 5th grade, but also at high school level. For this reason, we chose to use the spirograph as a didactical instrument with 10th grade students. The free online availability of a digital spirograph (https://nathanfriend.io/inspiral-web/) contributed then to design a teaching activity, to be developed in the distance context due to the pandemic. We wanted to exploit the opportunity given by the spirograph, in its digital version, to foster students' investigation of hidden mathematics. The functioning of the spirograph, with its related schemes of use, and the characteristics of the obtained curves do not depend on the version of the instrument (digital or not).

The reason why we have used the digital spirograph was due to the constraints of the pandemic. A comparison between the two versions of the spirograph was not an aim of this study but could be investigated in the future. According to this, our assumption was that, throughout the use of the spirograph, students can behave like researchers collecting data, formulating hypotheses and conjectures, and feeling the need to argue their own ideas and to discuss them with their peers. This requires, however, effective teacher orchestration in terms of task design and classroom interventions. To design and implement the teaching activity discussed in this paper we refer to the Methods of Varied Inquiry (MVI) (Arzarello, 2016). Results of this activity are analysed to answer the following research question: how can the students' discovery of the GCD and LCM hidden in a digital spirograph be supported by the teacher's orchestration of the activity? To answer to the research question, we describe and analyse the teacher's orchestration of the teaching activity, referring to the theory of variation developed by Marton and colleagues (2004).

Theoretical framework

Through the metaphor of the Instrumental Orchestration, Trouche (2004) offered a theoretical perspective to describe how the teacher can compose coherent sets of instruments within the classroom in order to guide students' instrumental genesis (Artigue, 2002) and its possible benefits for learning. In the teacher's intentional and systematic organisation and use of the various artefacts available in a learning environment in a given mathematical task situation, Drijvers and colleagues (2010) then distinguished three main elements: a didactical configuration, an exploitation mode and a didactical performance. In terms of the metaphor of the musical orchestrations: setting up the didactical configuration can be compared with choosing musical instruments to be included in the band, and arranging them in space so that the different sounds result in polyphonic music; setting up the exploitation mode can be compared with determining the partition for each of the musical instruments involved, bearing in mind the anticipated harmonies that will emerge; the didactical performance can be compared to a musical performance, in which the actual interplay between conductor and musicians reveals the feasibility of the intentions and the success of their realisation. In the next sections we will present the teacher's orchestration of the teaching activity describing the didactical configuration, the exploitation mode and the didactical performance.

This paper focuses on a teaching activity that was framed by the MVI method. It was introduced by Arzarello (2016) as a method to help students to consider a topic from different points of view and to understand it in a deeper way, fostering the transition from forms of "natural" argumentation to forms of mathematical reasoning. Its approach is near to that of a controlled experiment in science, in which the scientist can vary one variable and observe how another variable changes accordingly. Assuming that teaching with variations, in a controlled and systematic way, helps students to construct mathematical concepts, the MVI is based on the theory of variation, according to which in varying the didactical situations four schemes should be taken into account: to experience something, we must experience something else to compare with it (contrast); to fully understand what "three" is, we must also experience varying appearance of three (generalization); to experience a certain aspect of something, and to separate this aspect from other aspects, it must vary while other aspects remain invariant (separation); if there are several aspects that the learner has to take into consideration at the same time, they must all be experienced simultaneously (fusion) (Marton et al., 2004, p.16).

Methods

As said before, to identify the principles and heuristics that may guide the teachers to orchestrate the students' discovery of the GCD and LCM hidden in a digital spirograph, we analysed the development of the teaching activity in terms of didactical configuration, exploitation mode and didactical performance. In our study, the didactical configuration, characterised by the teaching setting and the artefacts involved in it, is defined by the digital spirograph and by the MVI. The exploitation mode, determined by the role of the spirograph, is described by the design of the teaching activity with its stages and its tasks. Finally, the didactical performance, in which the actual interplay between the teacher, the students and the spirograph reveals the students' discovery of the GCD and LCM, is the basis for the results' discussion.

The teaching activity, carried out in a distance context, was entirely video-recorded and transcribed. The transcripts were analysed according to the Marton's theory of variation, with the attempt to identify the variation schemes as they emerge in the students' intervention.

In this paper we briefly show and discuss results coming from the final collective discussion conducted by the teacher. They are representative of how the teacher's orchestration can guide the students' development and evolution of the variation schemes, thus fostering the discovery of the GCD and LCM hidden in the spirograph.

Orchestration of the teaching activity

In this section we describe the teaching activity focusing on the first two elements of the teacher's orchestration: the didactical configuration and the exploitation mode. The last element, the didactical performance, will be described in the results section.

Didactical configuration

As already underlined, in our study the didactical configuration is defined by the digital spirograph and by the MVI. The artefact, as it is explained below, was chosen for its potential to mediate the mathematical meanings of GCD and LCM. The MVI is used to design the tasks, because it well exploits the characteristics of the spirograph as an artefact in which everything is played on varying wheels and rings.

The spirograph is an artefact that can be used to draw a particular kind of geometrical curves (roulette) called hypotrochoids and epitrochoids. It is composed of a set of gear rings and wheels of different sizes which, by their combination, allow to create aesthetically fascinating curves. On each wheel there are some small holes positioned on a spiral at a different distance from their centre. To use this artefact, you must first choose a ring and a wheel, fix the ring on a sheet and position the wheel internally or externally to it. In our case the wheel was always put inside the ring and so the obtained curves are hypotrochoids. By inserting a pen inside one of the small holes in the wheel, the wheel is rotated around the ring and the curve begins to be drawn. After a complete rotation of the wheel inside the ring, a portion of the curve is traced, which could have cusps, or small roundings similar to flower petals. After a certain number of revolutions, the wheel returns to the starting position and then the curve closes, regardless of the choice of the hole on the wheel and the combination of the gears chosen (Figure 1).

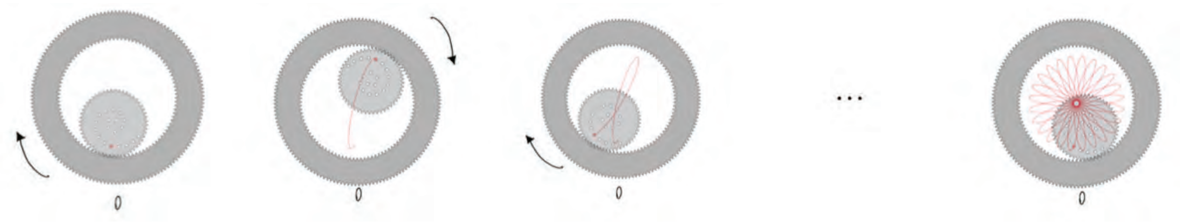

Figure 1: The drawing of the curve with the spirograph

Each curve that is drawn with the spirograph always has the following characteristics: a certain number of petals, a fixed distance between the petals (the number of ring teeth between two petals), a number of complete revolutions of the wheel inside the ring (up to the point where the wheel touches again the tooth of the ring from which it was started) necessary to complete the curve. Of these three characteristic elements, once the spirograph is removed, only the number of petals can be detected by the drawing.

What can be observed, using the spirograph, is that the number of petals, as well as the other characteristics, remains invariant if you change the hole, but instead varies if you change the choice of the ring-wheel combination. This is due to the mathematical relationships (involving the concepts of GCD and LCM) among the characteristics of the geometric curves and the numbers of teeth of the gears. Indeed, if R is the number of teeth of the ring, W is the number of teeth of the wheel, p is the number of petals, d is the distance between the petals and r is the number of revolutions of the wheel inside the ring, it can be seen that: $p \cdot d = R, r \cdot d = W, R \cdot r = W \cdot p$. Moreover, the number of petals corresponds to the number of times the wheel rotates around itself before returning to the starting point, while the curve closes when the repeated sum of the wheel teeth becomes a multiple of the number of the ring teeth. Hence, $R \cdot r = LCM(R, W)$. On the other hand, as $R \cdot r = W \cdot p$, it follows that $W \cdot p = LCM(R, W)$. So, $p = \frac{LCM(R,W)}{W}$ and $r = \frac{LCM(R,W)}{R}$. As a consequence, due to the relationship between GCD and LCM, it can be found that $d = GCD(R, W)$.

These considerations, which connect GCD and LCM to the hypotrochoids obtained with the spirograph, allow students to understand that the characteristics of the curves can be foreseen if the numbers of teeth of the chosen ring-wheel combination are known.

Exploitation mode

The goal of the activity is to use the digital spirograph as an instrument that allows students to untie the mathematical objects GCD and LCM from the idea of being useful objects only for the decomposition into prime numbers, but to see them as objects that mathematise the situation presented with the spirograph. The activity is divided into two phases, guided by appropriate tasks given to the students through an online word document to be filled and discussed: an initial phase of exploration of the instrument and a phase of discovery of the mathematics embedded in the spirograph. At the end of the two phases, to be done in small groups, a collective discussion is expected to be orchestrated by the teacher.

In the exploratory phase students are expected to answer to the questions "how is it done?" and "how does it work?" with the aim of making them familiar with the spirograph and discovering how it draws curves. The second phase of the activity can be divided into four sub-phases (described below), which takes into account the opportunity given by the spirograph to make variations and observe their consequences. To discover the mathematics of the spirograph, indeed, the tasks are designed to let students use different gears, observe and describe what was happening.

Variation of the small hole on the wheel - Students can be asked to choose a ring, a wheel and a small hole and to save the image obtained. Then keeping the same combination of the ring-wheel gears, students can be asked to choose another hole, to save the new image obtained and to compare the two images to describe what was happening. In this way, it is expected that the separation will emerge as a possible variation scheme of Marton's theory. Observing the two images, the students can also be pushed towards a first generalization: by changing the hole in the wheel, the characteristics of the curve obtained do not change, but that what changes is only its "size".

Variation of the wheel, keeping the ring fixed - Students can be asked to take the ring with 96 teeth, to choose a different wheel each, to draw the curve and to save the image. After completing the various drawings, students can fill a table in which, in addition to entering the choice of the wheel and the hole, they can also enter information relating to the characteristics of the curves obtained (the number of petals, the number of teeth between two petals and the number of complete revolutions of the wheel inside the ring) and to observe what happens. Varying the wheel while the ring is kept fixed can, again, boost the separation scheme to emerge. Moreover, as the characteristics of the curve vary when the wheel is changed, in this case, the students can experiment with the scheme of the contrast. The number of teeth of the wheel, in this way, can be seen as affecting the characteristics of the curve.

Variation of the ring, keeping the wheel fixed - Students can be asked to take the ring with 105 teeth and use the same wheels of the previous task. Again, students can fill a table entering the choice of the ring and the hole and the information relating to the characteristics of the curves. The comparison with the previous variation could allow the separation scheme to emerge again: the characteristics of the curve vary when the ring is changed while the wheel is keeping fixed, hence also the number of teeth of the ring affects the characteristic of the curve. This implies that the number of petals, the number of teeth between two petals and the number of complete revolutions of the wheel inside the ring, all depend on the number of the teeth of both the ring and the wheel.

Table 1: Summarising table of the characteristics of the curve according to the R-W choice

Ring (R)	Wheel (W)	Petals (p)	Distance (d)	Revolution (r)
96	36	8	12	3
105	36	35	3	12
96	52	24	4	13
105	52	105	1	52
96	63	32	3	21
105	63	5	21	3

Search for regularities - Students can be asked to take the rings with 96 and 105 teeth, use three wheels (such as those with 36, 52 and 63 teeth) and fill in a table to summarise the characteristics of the curves (see Table 1). With the questions, such as "Is it possible to find relationships between the numbers on each row? If so, which ones? Try to justify your answer", students can be helped to reflect and progress in the searching of regularities and in particular to find the dependence of the curve by both the ring and the wheel. The last sub-phase, thus, is meant to foster the fusion scheme to emerge, through the simultaneous experience with the critical and relevant aspects at stake.

The teacher, aware of the mathematics of the spirograph, can lead the collective discussion in order to guide the students in achieving their learning objective. Attention must be paid to the data shown in the table and the possibility of describing the regularities using mathematical formulas. For the collective discussion it is expected that the possible scheme of variation that can be reached is that of generalisation. From the discussion of experience, it will be possible to deduce: the independence of the characteristics of the curve from the choice of the hole; the dependence on both the number of teeth of the wheel and on the number of teeth of the ring; the mathematisation of the functioning of the spirograph, through the formulas that bring into play the GCD and LCM.

Results: the didactical performance

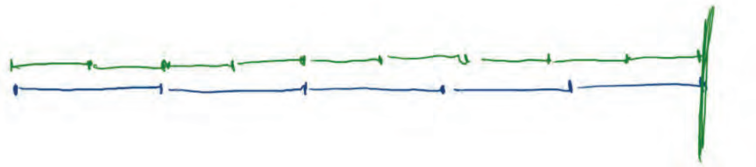
The teaching activity required three hours and involved 12 students. At the beginning of the lesson the teacher explained to the students that they would have been required to be divided into 3 sub-groups and accomplish two different tasks (related to the two phases described above) to be collectively discussed at end. The group work was conducted using the same online platform and sharing a unique document for each sub-group of students. Students were given 30 minutes to accomplish the first explorative phase and 60 minutes for the tasks of the second phase. We do not have enough space here to report the exact tasks given to the students, but the requests were made by the teacher according to what is described in the exploitation mode section. After a small break, the students were invited to leave the breakout rooms and to join the collective discussion guided by the teacher. In this section we focus on the final discussion concerning the second phase. In the first part of the discussion the teacher, showing and discussing a prepared picture, brought the students to share their considerations on what changes and what does not change if the combination of the ring-wheel gears remains fixed while the hole is changed. To guide the students to the shared conclusion that the petals size changes, but the number of the petals does not change, she did not re-voice those answers that are considered not pertinent to her aim. Afterwards, the discussion moved to the variation of the wheel and of the ring. The teacher boosted the students to experience the variation of one aspect at a time, keeping fixed the other, and the students arrived at the conclusion that the characteristics of the curves depend on both the ring and the wheel.

The excerpt below refers to the observations done when considering the obtained table (Table 1).

Teacher:	What observations did you make? Can you see any relationships between these numbers on each line?
Mattia:	8 times 12 gives 96, likewise 24 times 4 and 32 times 3 give 96
Teacher:	So, you are saying that: Petals ∗ Distance = Ring. Now we haven’t embedded the wheel in any relation yet. Do you see any other relations in which the wheel appears?
Michele:	Distance * Revolutions = Wheel, in fact 12∗3,4∗13...
Giulia:	I did something a little different: Ring/Wheel ∗ Revolutions = Petals
Teacher:	We could also write it as: Ring ∗ Revolutions = Petals ∗ Wheel. Indeed, we see that 96 ∗ 3 = 288; and if I do Wheel ∗ Petals, so 36 ∗ 8...
Michele:	I always get 288
Teacher:	What does 288 have to do with the wheel and the ring?

At this point, given the difficulty of the students, the teacher brought their attention to the fact that it is the revolution of the wheel around itself that draws the petals. In particular, in this case the curve is completed after 8 revolution of the wheel around itself and, at the end, the wheel has made 3 revolutions around the ring. The following excerpt starts with Michele's intervention after this last observation of the teacher.

Michele:	The Least Common Multiple! 288 is the LCM between 96 and 36
Teacher:	Why do you think it is the Least Common Multiple?
Michele:	Because we have to fill the same number of wheels and rings, i.e. we have to occupy with a certain number of revolutions the wheel and the ring and then return to the same tooth […] we put in sequence all the teeth of the wheel and of the ring, and we see that… it is the same segment. We must then get to a certain point where the two segments formed by all the ring teeth and all the wheel teeth are equal
Teacher:	That's like I have this kind of thing:



Michele:	Yes, we have to fill the same quantity with 2 different segments. And so that's 288
Teacher:	Now, the distance between one petal and another, if you were to read inside the ring, what will it represent?
Michele:	Perhaps the Greatest Common Divisor. […] Basically, it is the same reasoning, but we have to divide, not to multiply. That is... in this case we have to find a segment that divides both the ring and the wheel equally. And that segment is the distance.

Discussion and conclusion

Results were analysed using the lens of the Marton's theory. At the beginning of the final discussion, the students focussed on the effect of the change of the hole on the obtained curves. Thanks to the teacher's decisions (to show and discuss a prepared picture and to ignore students' answers that are not pertinent to her aim) the students moved from the separation scheme, fostered by the task itself, to the generalisation given by the recognition that the choice of the hole does not affect the number of petals. In the following part of the discussion, the students' focus moved from the observation of particular drawings to the understanding that the ring-wheel choice affects the characteristics of the curve. Also in this case, the students' development of the separation scheme was fostered by the teacher's orchestration, and especially her decision to let students experience the variation of one aspect at a time, keeping fixed the others. Students' awareness of the meanings of the variations among the aspects in the table is evident in the first excerpt: the teacher's questions, aimed at fostering the reading of the table with a researcher lens, allowed students to develop the fusion scheme and to recognise the complex relationships among the various aspects. However, the intervention of the teacher was fundamental to give meaning to those relationships. In the last excerpt, indeed, it can be seen how Michele, thanks to the teacher's suggestion, succeeded in connecting the spirograph movement to the numbers in the table, thus endowing the LCM with both the products $R \cdot r$ and $W \cdot p$, and the GCD with the distance between two consecutive petals.

To conclude we can say that the analysis of the teacher's orchestration showed how students can be supported in the discovery of the mathematics hidden in the digital spirograph, thus answering our research question. Indeed, the students' learning was supported through an appropriate task design of the activity and an aware teacher's behaviour during the classroom intervention. In our case study, the teacher's orchestration was based on her willingness to exploit the opportunity given by the digital spirograph to offer students a situation in which variation gives power to the development of mathematical thinking. Results showed how students behaved like researchers, feeling the need to argue their own ideas and to discuss them with their peers. This was fostered by the teacher's decision to use the MVI as a method to help students to consider a topic from different points of view and to understand it in a deeper way.

Although this study was developed by taking into consideration only one case, its results can give a contribution to the discussion on good practices in technology-rich mathematics education. Moreover, they can be considered as a starting point to develop further investigations focusing on the principles and heuristics that may guide the teacher's orchestration of fruitful activities.

Acknowledgment

Authors are grateful to the teachers and the 10th grade students of the Liceo Scientifico "E. Amaldi", Bitetto (BA), involved in the activities of the project Liceo Matematico.

Perspectives and challenges on programming as a tool to learn mathematics

Martyna K. Fojcik[1,2]

[1]Volda University College, Norway; martyna.fojcik@hivolda.no

[2]University of Agder, Kristiansand, Norway

This paper focuses on the terminology of computer programming as a tool for learning mathematics and the intersection between teaching programming and teaching mathematics. It shows different perspectives and challenges that might arise when combining these two disciplines. The foundation is the newly introduced Norwegian curriculum, where programming has been integrated into four school subjects in primary and secondary education, including mathematics. The aim is to take a closer look at the concept of 'computer programming' and 'computational thinking' and discuss in what ways programming as a tool in mathematics teaching and learning may be theorized.

Keywords: Programming, computational thinking, mathematics education.

Introduction

The development of digital tools in education used both inside and outside the classroom has increased in recent years. Digital tools have introduced new methods of communication, increased access to information, and streamlined daily tasks. The Ministry of Education and Research in Norway (Kunnskapsdepartementet, 2012) points out that in a digital society, it is important that pupils are given good opportunities to develop digital skills, skills that "involve being able to use digital tools, media, and resources efficiently and responsibly, to solve practical tasks, find and process information, design digital products and communicate content" (p.12).

To prepare pupils for this digital reality, many countries have changed the compulsory curriculum to facilitate the development of digital skills and programming to create a potential learning environment for future skills. The way programming was integrated to the curriculum differs from country to country. The United Kingdom had introduced a separate information technology subject called 'Computing', while the Nordic countries introduced programming and computational thinking as a separate subject or a part within the mathematics subject in primary and secondary education. In Sweden, programming is a part of 'algebra' in mathematics, while in Norway, programming has been introduced in subject's mathematics, science, music, and art and crafts (Bocconi et al., 2018).

In Norway, the new curriculum in mathematics states that: "Digital skills in mathematics refers to the ability to use graphing tools, spreadsheets, CAS, dynamic geometry software, and programming to explore and solve mathematical problems" (Utdanningsdirektoratet, 2019, p.5). This definition indicates that (1) children learning mathematics should also learn to use different digital tools in mathematics to develop their digital skills, and (2) the tools should provide opportunities to make deeper connections and understand mathematical processes when using the tool. By enlisting programming with tools like spreadsheets, graphic tools, or computer algebra systems (CAS), the curriculum indicates that programming can be a *tool* for teaching and learning mathematics. This definition states that programming should be used to *solve* mathematical problems and *explore* these problems as well. However, may programming be a tool to teach and learn mathematics? Is programming not a field in itself? May programming be used in a proper way to support mathematical thinking? This study aims to look at the concept of ‘programming’ and ‘computational thinking’ and discuss in what ways programming as a tool in mathematics teaching and learning may be theorized.

Digital skills and tools in mathematics

Fuglestad (2007) analyzed the use of digital tools by lower secondary pupils in Norway and argued that many tools can support pupils’ mathematical thinking if they are used through inquiry, exploration, experimentation and if the visual and dynamic properties of software are taken advantage of, allowing the pupils to be active and to investigate mathematical patterns. The research of Smeets (2005) also showed that digital tools give new possibilities and perspectives that can emphasize parts of mathematics that can be difficult to visualize. He concluded that the potential in digital tools lies with the pedagogical approach, and to maximize the pupils’ learning outcomes, the learning activity should highlight things that would otherwise be challenging. Thus, using digital tools as if they were not digital would eliminate any potential that the technology might bring, like visualization, dynamic interaction, or active participation that would differ from using pen and paper (Kim et al., 2013).

Trouche (2004) pointed the definition between the use of a digital tool. He commented that a tool can be used for many different purposes, while an *artifact* is a “tool before considering its users and its uses” (p.282), and an *instrument* can be considered when there is a meaningful relation between an artifact component and psychological component. This means that the instrument “involves the techniques and mental schemes that the user develops and applies while using the artifact” (Drijvers, 2010, p.108). This approach, the instrumental approach, emphasizes that the critical part is how “the user's conception of the instrument is formed through use” (Trouche, 2004, p.295). This suggests that not every use of a digital tool can benefit learning because it depends on how the instrument is used and how the users' thinking is changed through using the instrument.

Drijvers (2015) argued that there are factors that can influence the integration between mathematics and digital tools. He mentioned (1) the design of the lesson, the activity, and the digital tool, where the activity or the task could determine if the tool would become an instrument or not; (2) the role of the teacher and teacher's competencies, where the teacher's professional development of both digital and didactical understanding is crucial; and (3) the educational context, where he argued that mathematical practices need to be related to pedagogical opportunities. This can be interpreted as creating an environment for learning and using the potential of digital tools (Smeets, 2005).

Programming and computational thinking

Programming has been defined in different ways. When creating a stepwise description of an algorithm for solving mathematical problems in 1843, Ada Lovelace was called “the first programmer” (Computer History Museum, s.a.), but a precise description of what it does to ‘program’ was not given. A technical definition of the term ‘programming’ separated two working methods while writing a program. The first was the process of drawing up a plan of the sequences of decomposed problems and algorithms that the program would consist of (‘the programming’), and the second was to write the code in a programming language and implement the program (‘the coding’) (Hartree, 1950). Since then, there have been many new developments in programming, changing the programming process. Blackwell (2002) presented the development through a concept that started with “describing calculations”, then went on to “defining functions”, and finally developed further into “defining and treating objects” (p.205). The methods of programming have changed when new digital developments have been integrated into the structure of programming. Duncan et al. (2014) argued that programming has “changed and developed over time as software, hardware and usage of computers has changed” (p.62) and therefore, they suggest to “use the term ‘programming’ for the broader activity of analysing a problem and implementing a program that solves it” (p.62, emphasis in original).

This development has made programming and coding more available, creating new easy-to-use programming languages and environments that can both write and execute the code. In recent years there has been a development of programming/coding environments for children which are based on the idea of visual programming where a program “is a set of linear sequences of ‘jigsaw pizzle’ pieces representing commands” (Klassner & Anderson, 2003, p.15, quotes in original). As Duncan et al. (2014) stated, “Drag-and-drop environments on the other hand do not require users to manually enter programming expressions; instead they provide the user with a selection of ‘blocs’ that represent programming expressions (…) This prevents novices from encountering confusing error messages, which can be very discouraging to learners” (p.65).

The access to free software prepared to start to code without previous knowledge has made the terms ‘programming’ and ‘coding’ blurred, and there are people that present these terms as synonyms (Balanskat & Engelhardt, 2015; Resnick and Siegel, 2015). Duncan et al. (2014) explained that “[*c*]*ode* is a popular buzz word in today's technology driven world, and it also provides an element of mystery (there are hints of a secret code), and achievement (cracking the code)” (p.62, emphasis in original). This is clearly the opposite of Hartree's (1950) division of these two terms. Duncan et al. (2014) stated that “[i]n the context of programming, traditionally *coding* would only refer to the last stage of the process of programming, translating a designed program into programming expressions and typing/entering these into a computer” (p.62). Computer scientists still lean up to the technical definition and consider programming to be more than coding, but people from outside computer science often do not divide between the process of scheduling the sequences and writing the code in a certain programming language.

Papert (1980) argued that programming should be associated with the process of thinking when he wrote that by “teaching the computer how to think, children embark on an exploration about how they themselves think” (p.19), and then the children can use programming to construct their knowledge. He saw the possibilities of using programming as a way of thinking when solving problems. Wing (2006) built on this idea by reintroducing the concept of *computational thinking*, CT (first used by Papert in a different context in 1980). She defines it as: “an approach to solving problems, designing systems and understanding human behaviour that draws on concepts fundamental to computing” (Wing, 2008, p.3717). In her explanation, there is a clear link between the thought processes associated with processes of abstraction and decomposition and computing.

According to Wing's definition, computational thinking is a fundamental skill, which “means more than being able to program a computer” (2006, p.33). Computational thinking is dependent neither on technology nor programming languages (Bocconi et al., 2016). Denning and Tedre (2019) defined it as "(…) computational thinking, or CT– is not a set of concepts for programming. Instead, CT comprises ways of thinking and practicing that are sharpened and honed through practice" (p.6). The idea is to teach pupils how to think in structures so that they can gain knowledge about specifying and breaking a problem into several subproblems to find a systematic solution to the subproblems and evaluate whether the solution was useful and effective to solve the problem.

Lie et al. (2020) stated that Wing presented terminology and concepts as a computer scientist, and they argue that someone "outside that community might be prone to narrowly construe the idea of CT to direct connections with *number computation* or *computer*" (p.2, emphasis in original). Denning and Tedre (2019), also computer scientists, defined computational thinking as "the mental skills and practices for (i) *designing* computations that get computers to do jobs for us, and (ii) *explaining* and interpreting the world as a complex of information processes" (p.4, emphasis in original). Curzon et al. (2014) got into more detailed concepts of computational thinking (logic, algorithms, decomposition, patterns, abstraction, evaluation) and approaches (tinkering, creating, debugging, persevering, collaboration). Weintrop et al. (2016) presented a model of computational thinking that has four main categories: (i) Data practices, (ii) Modeling & simulation practices, (iii) Computational problem-solving practices, and (iv) Systems thinking practices (p.135). The interesting part of this model is relevant for this argumentation is that one of the sub-categories in the group (iii) is named 'Programming', which could mean that programming is considered a narrower approach than computational thinking. This is contradictory to the technical definition of Hartree (1950) and maybe has more in common with the perception of Resnick & Siegel (2015) and Balanskat & Engelhardt (2015).

The modern concept of computational thinking has in some way replaced the dual term of programming as presented by Hartree (1950), making the definition of the term 'programming' different than before. In addition, the programming environment that Hartree (1950), Papert (1980), and Blackwell (2002) considered were not the ones that are used in schools today. These scholars described a version of text-based programming languages. The languages of BASIC or LOGO were simplified and adapted for children, but they were still based on detailed syntax. Today's programming environments for children (for example, Scratch, Micro:bit, LEGO, Minecraft, etc.) are designed for the purpose of being easy to use, and many children meet programming through block-based programming languages, where the children are free to construct, modify and change codes with a simple push. Today, someone learning programming does not need to have a scheduled algorithm figured out before (s)he starts to code. One can code by trials and errors and continuously modify the program without stopping the software or creating bugs, but it is unclear if this can be considering 'programming'?

Challenges in introducing programming in mathematics teaching

Kilhamn and Bråting (2019) reminded that programming is a field with its own structures, rules, goals, processes, methods, and notations. The same symbol can be used both in mathematics and programming, but it does not necessarily have the same meaning. For example, '=' means equality in mathematics, but in most programming languages, it assigns a variable. This can be confusing when writing a variable like x=x+1. A common code for adding one to a variable in programming is mathematically wrong because there does not exist a value of x that could make this equation valid.

A few more challenges arise from teaching programming in mathematics. Firstly, the syntax in programming differs from one programming language to another, and mathematical symbols can have different meanings. How does it affect pupils learn to use the equal sign differently in programming and mathematics, and then change the programming language and use ‘:’ as equality. This would be confusing for the pupils that would need to be specified and clear in the syntax they use, as well as the terms and structures that each programming language represents. In Norway, there are not any national criteria for choosing a programming language, and each school, teacher or subject could use different software.

Secondly, programming, as mentioned before, is a field with its own rules and structures. The definition of programming differs between computer science and other disciplines, and many concepts are used to describe different approaches and actions. The terminology from computer science is not easy to translate to other situations and contexts, and much of the argumentation consists of explaining approaches from computer science used in other contexts. There are differences in syntax and in structure, different approaches in solving a mathematical problem with 'pen and paper' or solving it through the creation of new software. However, programming was implemented in four school subjects in Norway without explanation on how these disciplines could be combined. Currently, it is up to each teacher to choose how they want to implement programming in their subjects. It could be a part of computer science, or as simplified coding and gaming to motivate pupils in cases in different subjects, or as a tool for learning the subjects more in-depth. There is a lack of research on what would be most beneficial for the pupils, at their grade and in certain subjects, and how programming could be helping them to learn and develop skills.

Finally, the challenges lie within the teachers' competencies. The teachers need not only to learn how to program themselves but how to explain the program and support pupils in creating their programs as well. This could be solved by inviting computer scientists to teach programming parts at certain subjects. However, that may not give the educational and didactical results desired in the school curriculum. There could be some advantages if the pupils were taught to program by experts in their profession. Then the misunderstanding of structures, methods, terms, and syntax would not be problematic. The disadvantage of such an approach would be that the programming would be connected to computer science and used for the same purpose to create effective, friendly, and structural programs, but then there might be a lack of pedagogical or didactical approaches that children in primary and secondary school might need in their development.

Teachers' role in introducing programming in mathematics

Kaup (2019) has done a research review describing how in-service teachers and pre-service teachers understand the term computational thinking and what attitude they have towards that concept. Her results showed that many participants were not familiar with computational thinking, and even if they had noticed that concept before, their understanding of what it is was superficial and simplified. Also, the study of Misfeldt et al. (2019) showed that some teachers do not feel prepared to teach programming. Only 4,5% of the teachers participating in the survey answered that they feel ready “to a great extent”, even though almost 70% said that these disciplines are connected and can be combined within the same subject.

Bocconi et al. recognize the teacher's role when they admit that: “Evidence shows that the transfer of programming skills is more likely to happen when (i) transfer is addressed in the upskilling of all teachers involved and (ii) forms an integral part of the pedagogical approach adopted in the classroom” (2018, p.6). This claim emphasizes that upgrading mathematics teachers’ skills with programming may not give the wanted results if the knowledge is not adapted in a pedagogical approach. As Drijvers (2015) previously stated, teachers' development is crucial for integrating digital tools as instruments in mathematics teaching and learning. Yet, in many cases, the teachers today are confused about correct terms and methods (Kaup, 2019).

Conclusion

Can programming be a tool in mathematics? There are different definitions of 'programming', 'coding' and 'computational thinking', and these concepts are used in a variety of ways. The concepts themselves have changed in time, both because of further digital development (Blackwell, 2002; Duncan et al., 2014) and the need for more interdisciplinary connections (Wing, 2006; Weintrop et al., 2016). The integration of programming into mathematics education in Norway creates new possibilities for the pupils (Utdanningsdirektoratet, 2020), and the implementation of digital tools can support mathematical thinking (Fuglestad, 2007, Drijvers, 2015). Especially when the tool is used in a way that forms and influences the users' conception and becomes an instrument (Trouche, 2004). The remaining question is if programming can be such a tool?

The role of the teacher is significant in introducing programming with understanding and relevance (Drijvers, 2015, Bocconi et al., 2018), but the competence of today's in-service and pre-service teachers do not give them much confidence to teach programming in mathematics (Kaup, 2019, Misfeldt et al., 2019). Programming has some similar elements with mathematics (Papert, 1980, Kilham & Bråting, 2019), and studies of teachers' attitudes towards programming in mathematics show some connections between these two disciplinaries (Misfeldt et al., 2019, Kaup, 2019). Yet, there are many challenges that could arise when programming is introduced to pupils in teaching and learning mathematics, and the practical approaches of implementing and using programming as an instrument in mathematics have not been researched. There is a need for more knowledge in how programming can be used to solve and explore mathematical problems.

Digital technology in mathematics education – more than a tool

Sanna Forsström[1] and Rune Herheim[2]

[1]University of Stavanger, Norway; sanna.e.forsstrom@uis.no

[2]Western Norway University of Applied Sciences, Norway; rune.herheim@hvl.no

Digital technology in the mathematics classroom is often seen only as a tool. The purpose of this paper is to expand the discussion about the kind of roles digital technology can play by using programming activities as examples. We apply components from Engeström's Cultural Historical Activity Theory to discuss programming as the object of the activity; the tool in use; part of the division of labor; and as a part of a classroom community. Digital technology as a part of division labor and classroom community has the potential to provide rich classroom communications and learning processes in which the students, the teacher, and digital technology interact with each other.

Keywords: Digital technology, programming, roles, CHAT, mathematics education

Introduction

Digital technology has become an increasingly more important part of education in the last decades. In mathematics education, we see a development of concepts like ICT literacy (e.g. Dede, 2010) and digital competence, and research titles like Clark-Wilson et al.'s (2014) *The mathematics teacher in the digital era*. During the last decade, programming has been introduced as an important 21st-century skill. It is included in mathematics curriculums (and other subjects) in many countries (Balanskat & Engelhardt, 2015) and national policy documents (Bocconi et al., 2018).

Hoyles (2018) stated that the dominating view on mathematics is that "mathematics is simply a set of disparate rules for calculation and students attempt to master this 'mathematical machinery' without seeing its purpose" (p. 209). Teaching based on this view is dominated by students being given premade tasks to be solved with predefined mathematical tools and students have difficulties seeing the purpose of doing the tasks. Hoyles argued that the digital technology in such classrooms is used to speed up procedures, and calculations are largely only replicating doing mathematics with paper and pencil.

According to reviews by Batiibwe (2019) and Bray and Tangney (2017), digital technologies are often integrated into non-transformative ways in mathematics classrooms, and they are often regarded as tools only. Batiibwe (2019) reviewed articles on the mediating role of digital technology in mathematics education from a Cultural Historical Activity Theory (CHAT) perspective. All of the reviewed articles discussed the role of digital technology in classroom activities only as a mediating tool. Other roles, such as digital technology as an object, as the driving force in the activity, were not discussed. Bray and Tangney (2017) found that digital technology is primarily used traditionally in mathematics classrooms. Task assignments are not adapted to the integration of digital technology, and digital technology is used as a substitute for the teacher or to save time in calculations (e.g. Åberg-Bengtsson, 2006). Digital technology is often used because it simplifies things and releases students from tiresome calculations. Such use of technology generates to a little extent changes for the teaching and learning of mathematics.

However, digital technology can be used to explore mathematics in diverse ways. The integration of digital technology has the potential to transform activities in mathematics classrooms by engaging students and providing them possibilities to take ownership of their learning (Hoyles, 2018). According to Bray and Tangney (2017), programming activities were more transformative than the activities with other digital technologies used in mathematics classrooms. In most of the studies that discussed programming integration, the task assignments in programming activities were often collective, freer, and more student-centric. The teacher was often acting as a guide instead of just being a lecturer, and the students were able to use their ideas in the task design by negotiating with each other and the teacher and by interacting with digital technology.

To investigate the transformative possibilities of including programming in mathematics education, *the focus in this paper is on programming's potential to play roles that go beyond the role of being a tool*. We use examples from two earlier studies on mathematics and programming presented in Forsström and Afdal (2020) and Herheim and Johnsen-Høines (2020). In both studies, the students worked collectively with their programming activities. By taking a CHAT perspective, we exemplify and discuss programming's potential to be an object, to become part of the division of labor and community, as well as being a tool in the students' collective activities. The analysis is based on a micro-level approach of the activity system analysis in Engeström's (1987) version of CHAT, where social, multi-voiced interactions are part of the knowledge creation processes. Focusing on collective classroom activities instead of individual actions gives the possibility to get information about relational processes in the classroom. An activity system analysis enables a discussion of the potential roles of programming as a part of mathematics classroom activities in addition to being a tool. The different roles can be discussed in relation to other components in the activity system during the activity development. Taking a CHAT perspective makes it possible to see teaching and learning as dialectically intertwined processes (Engeström & Sannino, 2012).

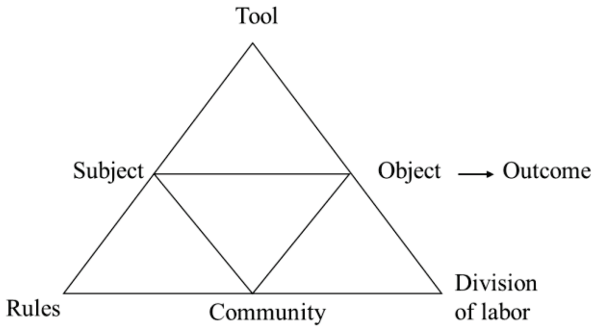

Figure 1: The activity system model from CHAT (Engeström, 1987, p. 78)

Cultural-Historical Activity Theory

The analytical approach is based on an activity system analysis, where the seven components: subject, object, tool, rules, community, division of labor, and outcome (see Figure 1 and Table 1) include the potential roles we argue that programming can play. According to Engeström (2005), the components are interrelated. For instance, in the uppermost sub-triangle, the tool mediates the subject's activity towards the object. With the help of tools, subjects interact with the object of the activity, which is the driving force in the activity. The activity is framed by collective components of rules, community, and division of labor, and the relationships between the components influence the activity development. Due to the interactions between subjects and dynamic relationships between the components, the collective activities are constantly transforming and developing. Knowledge is distributed between the different participants and components in the activity system, and learning is seen as a change in the components of collective activities; as an expansion of a collective object.

Table 1: Components in the activity systems analysis

Component	Definition/meaning	Examples from these studies
Subject	The individual/group of people who engage in the activity (Yamagata-Lynch, 2010)	The students and the teacher
Object	The driving force of the activity (motive and goal) (Engeström, 1987)	Fulfil a task by using programming
Tool	Instrument that mediates the activity (Engeström, 1987)	A robot, app, computer, and mathematical tools
Rules	The regulations that are relevant to the activity (Yamagata-Lynch, 2010)	Task assignment, the rules of the mathematics classroom
Community	The group the subject belongs to during the activity (Yamagata-Lynch, 2010)	The whole class of students and the teacher (or teachers)
Division of labor	How the tasks are shared during the activity (Yamagata-Lynch, 2010)	Collaboration between students, the role of the teacher and the programming
Outcome	The result of the activity (Yamagata-Lynch, 2010)	A robot drives a track, a shape is drawn etc. as they are programmed

When applying this theoretical perspective, we understand mathematics and digital technology such as programming, as components in an activity system. They can play different kinds of roles depending on the activity, the other components and the relationships between them, and how the activity develops. To understand the role of programming in relation to the role of mathematics, the activities described in Forsström and Afdal (2020) and Herheim and Johnsen-Høines (2020) were analyzed from a CHAT perspective, with a particular emphasis on the components object and tool, and on community and division of labor. To identify the object of the activities, we focused on the collective aim of the subjects (the students). We identified, for instance, what the students and the teacher were aiming to do, what the driving force in the activities was, such as to make a robot drive a track. The tools in the activity were determined by identifying what kind of tools the subjects used to achieve their object. The tools were distinguished from the objects by identifying the focus of the subjects. According to Engeström (2005), the focus can only temporarily be on tools. The activity components are dynamical and multilayered and the activities constantly transforming. The role of programming and mathematics developed in relation to other components in the activity system.

Expanding the discussion about the roles programming can play

In the following, we discuss how programming can play the role of an object and tool, be part of the division of labor and community, and how programming, when being more than a tool, can act as a resource in students' collective learning processes in mathematics.

Programming as an object and tool

In the programming activities discussed in this paper, the students are challenged to program a robot to drive a certain path (Forsström & Afdal, 2020) and to draw a particular geometrical shape with programming in Scratch (Herheim & Johnsen-Høines, 2020).

In Forsström and Afdal (2020), students aged 12–13 years old programmed Lego Mindstorm robots. The students were challenged to make the robot drive a circle, and the programming elements became their main object at the beginning. The students then used a trial-and-error strategy to achieve their object, but the mathematical tools were not used systematically (see Figure 2). The teacher negotiated with the students and suggested that they could program the robot to drive a circle with a radius of one meter. In that way, the teacher helped the students to mathematize their programming object and it developed a need for mathematical tools in the activity. The students focused on mathematics when they did the calculations. They used, for instance, the circle perimeter formula to find out the length of the route the robot had to drive, as well as proportions to uncover how much the robot had to turn. After the students obtained the needed results from their calculations, they used them in their programming to reach their object (see a more detailed discussion about the activity development in Forsström and Afdal (2020)). From a mathematics education perspective, such transformation of an object, from a programming object to a mathematical object, is often the intended purpose of including digital technologies in the teaching and learning of mathematics.

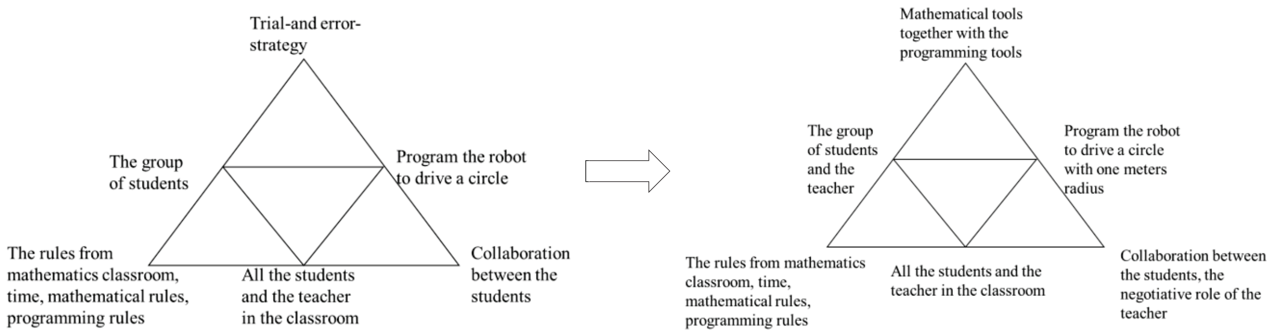

Figure 2: The activity development in Forsström and Afdal (2020)

Programming tools were in use together with mathematical tools. The students revised their codes according to their mathematical calculations to improve the programming of the robot. The programming tools provided an opportunity and a need to test mathematical tools. When the students did not remember the circle perimeter formula and used radius instead of diameter, they got immediate feedback because the robot only drove one half of a circle. Because of the visual feedback of an error, the students were able to return to their code and do corrections. Based on the feedback, the students successfully concluded that to get the robot to drive a whole circle, they needed to double their answer. The teacher encouraged, with his questions, the students to find out why they needed to double their answer. The students accepted the challenge and mathematics became the object of the activity.

Herheim and Johnsen-Høines (2020) investigated screen-based programming with Scratch where two 12–13 years old students collaborated to program a pentagon. This programming required both mathematical and programming considerations from the students. The students were unfamiliar with the geometrical properties of a pentagon, about the number of sides and the size of the interior angles. They also faced programming challenges such as how the turn block does not give the anticipated interior angle but the turning angle. The students struggled with both mathematical and programming aspects, but they used a systematic trial-and-error strategy to get closer and closer to programming a pentagon. The properties of the programming software allowed them to find out more about pentagons. They could test different angle sizes in their code and after each attempt, they received immediate feedback through the shapes drawn by the program: a hexagon shape that lacked one side; a pentagon where the first and last side intersected; and a pentagon with a tiny gap between the first and last side. This Scratch programming activity can be regarded as an example of how programming and mathematics can become an intertwined object of the activity – not only as of the overall object but for sub-objects during the process as well.

Being able to successfully program something can be the main driving force for students, and that makes programming an overarching object. However, during such work processes, students need not only to figure out what mathematics is needed and how to use it. They also need to figure out how a path or a shape can be programmed, what code blocks to include in the code and how to include them, and then they often need to try out different versions of a code. In several phases of their work, there are programming aspects that play the role of intermediate aims in the students' activities. This gives ground for saying that students can have several programming sub-objects as well.

Based on our discussion of the examples from Forsström and Afdal (2020) and Herheim and Johnsen-Høines (2020), we argue that programming can be an object as well as a tool. This can take place through a transformation between being a tool and an object, or as an intertwined object together with mathematics. Programming as an object in activities can enable the use of mathematics as a tool in students' activities. The programming tools enabled the testing of mathematical tools and by that, the programming tools brought a new dimension to the use of mathematical tools. As the activities unfolded, the programming provided feedback to the students about the mathematical tools they were using. When the students tested the codes, the robot and the visualizations on the computer screen gave them immediate feedback on the mathematical tools in use. The robot and the Scratch program acted as a part of the division of labor in students' activities. That will be discussed in more detail in the following.

Programming and robots as a part of the division of labor and as a part of the community

In some studies on digital technologies in mathematics education (e.g. Monaghan, 2005; Lavy & Leron, 2004), the technology is considered by students as a participant or quasi-human agent. The classroom activities can be seen as networks, which constitutes both human and non-human actors, such as the students, the teacher, and the robot. Students use screen images to express themselves and the other students use the same images to interpret the utterances – the technology provides language. Digital technologies can prompt, respond, and frame communication, but they have, unlike teachers and peers, infinite patience and do not have expectations and are not judgmental (Monaghan, 2005). Technologies can appear to act like subjects when they respond to inputs so that students get the feeling they must justify their responses, without feelings or expectations. Wegerif (2004) pointed out that this dual role of digital technologies can make them able to play a part in students' activities.

In the studies presented by Forsström and Afdal (2020) and Herheim and Johnsen-Høines (2020), knowledge was embedded in processes between robots and students and between computer screens and students. Students got information about their mathematical tools by getting feedback from nonhuman actors – the robots and the computer screens. With this feedback, the students got the opportunity to interact and negotiate with their mathematical object. The nonhuman actors worked as resources for students' understanding of their mathematical object and mathematical tools in use. The students interacted with their mathematical object through the mediation of tools but also through the mediation of division of labor. The programming, together with the students and the teacher, took part in the division of labor and mediated by that the relationship between the community and the object of the activity. In that way, programming did not act as a substitute for the teacher, but it acted to some extent as a participant together with the students and the teacher.

In Forsström and Afdal (2020), the development of the activity was constituted by the negotiations between the students and the teacher. The teacher encouraged the students to use mathematical tools with his questions. However, the teacher's questions would have been of little value without the participatory role of the robot. He referred to the robot's movements when discussing with the students, for instance when the robot drove only a half of a circle and he challenged them to find out why they needed to double their answer.

In Herheim and Johnsen-Høines (2020), the students discussed the geometrical properties of a pentagon. They based their discussions and revisions for the next attempt on the feedback from the Scratch program, on how the mathematics was represented by the code and in particular the drawings of the shapes. Through the collaboration with each other and with the programming, the students found out more about pentagons and programming. During this process, the programming played a role in the division of labor (see Figure 3).

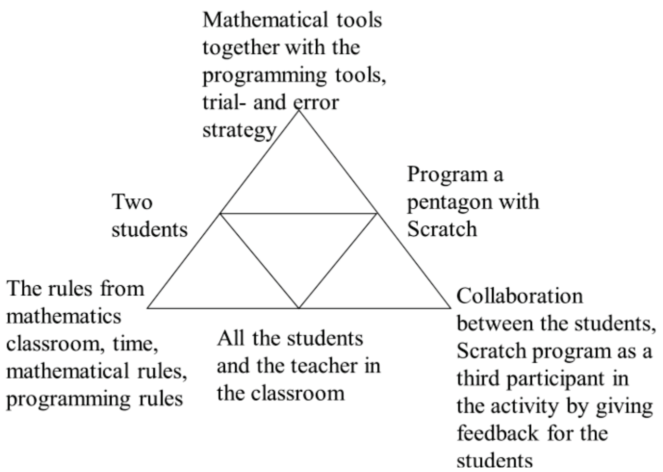

Figure 3: The activity system in Herheim and Johnsen-Høines (2020)

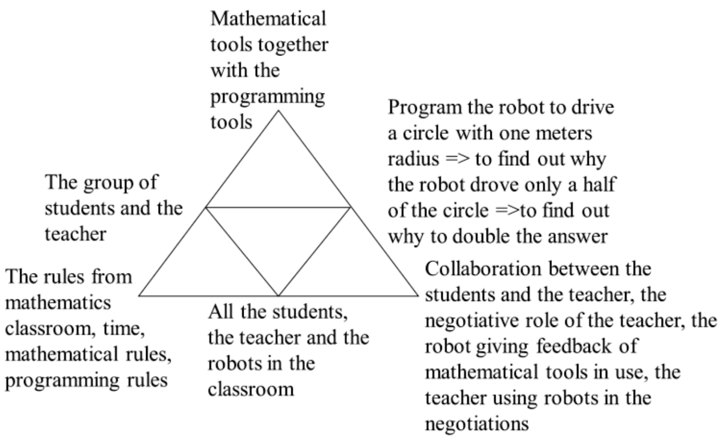

Figure 4: Robot as a part of the division of labor and community in Forsström and Afdal (2020)

When programming becomes a part of the division of labor and interacts with the students and the teacher by giving feedback, it also becomes part of the collective activities. The programming can be seen as a part of the social classroom group, as a part of the community in students' activity systems. Such communities can be regarded as digitalized classroom communities. In digitalized classroom communities, students and teachers interact with digital technology, and digital technology can be seen as a kind of a digital participant in the collective classroom activities (see Figure 4).

Concluding comments

As discussed in the introduction, digital technology is often regarded as a tool. Based on Bray and Tangney (2017), digital technology is mostly integrated into mathematics classrooms in non-transformative ways, used as a tool to save time in calculations, and as a substitute for the teacher or paper and pencil. We have discussed how digital technology can play more than the role of being a tool, how it can take different kinds of roles in classroom activities by introducing programming activities from earlier studies. The different roles discussed are programming as a tool, an object of the activity, a part of a division of labor in students' classroom activities, and as part of the community.

From a mathematics education perspective, the students' use of mathematics in programming activities is a priority, and the different roles of programming are discussed in connection to the role of mathematics in students' collective activities. We have argued that programming acted as part of the division of labor and as a part of the digital classroom communities in both the robot and the Scratch example and contributed to fruitful learning processes in mathematics. We called the classroom communities, where digital technology acts as a part of the community as digitalized classroom communities.

In the digitalized classroom community, digital technology can take different kinds of roles in students' collective learning processes in mathematics. The students, the teacher, and the digital technology can interact with each other, and programming and mathematics can have an active and transformative role. Digital technology can act as a resource for students' understanding of their mathematical object by giving students feedback and in that way play a participative role. In the examples described in this paper, it might appear as if the programming acted just like a paper and pencil by drawing a circle or a pentagon, but the programming acted more diverse than paper and pencil. The programming brought an extra dimension to the students' activities by acting together with them, the teacher, and mathematics. It gave confirmations of the use of mathematical tools by correcting students' mistakes and providing visualizations of key properties in mathematics and showed by that a potential to trigger and facilitate students' mathematical activity.

Furthermore, the teacher can use digital technology as a teaching partner. As in the examples discussed in this paper, the programming gave information to the teacher about students' understanding as well as their struggles and mistakes. The teacher and the students can base their comments, suggestions, and revisions on the movements of a robot or drawing of shapes on a screen. Digital technology as a part of the classroom community can play a valuable role in the collective activity with students and the teacher. In the digitalized classroom community, the students can work towards their object, together with the teacher, the digital technology, and the mathematics.

This paper presents a graduate student's reflections on the design of learning opportunities using the Desmos tool for carrying out mathematical activities and the online Zoom platform for facilitating mathematical learning. Using the theory of instrumental orchestration as our interpretative framework, we discuss the different types of orchestrations when a digital tool is used to support mathematical learning not in the familiar face-to-face classroom-based environment, but online instead. The contribution of this paper lies in the discussion of the design considerations and orchestrations to overcome the challenges of online learning and at the same time to capitalise on the opportunities it offers for mathematical learning.

Keywords: Online mathematical learning, distance learning environment, instrumental orchestration.

Introduction

There is a vast range of digital technologies (DTs), designed for and used in mathematics education, serving different purposes. Such technologies offer affordances for and constraints on students' learning, but also on teaching practices. DTs refer to digital tools and applications used "(a) as a support for the organisation of the teacher's work (producing worksheets, keeping grades) and (b) as a support for new ways of doing and representing mathematics" (Sinclair & Robutti, 2014, p. 598).

Using DTs for teaching mathematics at a distance has also been progressively researched, with many authors discussing the great opportunities of such a mode of teaching and learning, as well as the challenges teachers and students face (e.g., Silverman & Hoyos, 2018; Drijvers et al., 2021). Classroom-based strategies and activities, such as think-pair-share, role playing, group discussion, gesturing, modelling, assessing, etc., that are known to be engaging and effective for students' learning in the face-to-face classroom environment, and therefore widely used, present new challenges for teachers and students in online learning environments (Collison et al., 2000). During online synchronous teaching, the teacher-students interactions are certainly limited and the opportunities to observe individual students' work and intervene when necessary decrease (e.g. Silverman & Hoyos, 2018). In such online settings, assessing individual students' learning is challenged and the tools for doing mathematics need to be carefully chosen. In face-to-face classroom-based lessons, learning takes place in a social context, in which students and teachers use various strategies to communicate with one another, including verbal and non-verbal strategies. In online remote learning, certain aspects of such communications are more challenging to achieve, such as writing and sharing each other's written mathematical work, pointing at notations and symbols written on the board, and other gesturing used by students to support their explanations. In fact, while verbal communications are possible online (via video/audio/chat features), supporting such conversation with written notes is more challenging online, since such online spaces allow limited mathematical learning input (Aldon et al., 2021; Drijvers et al., 2021; Leventhall, 2004).

In this paper, we share how a graduate student on our MA in Mathematics Education master's course, Tania, capitalised on the opportunities DTs offer for remotely supporting the learning of mathematics. She designed learning opportunities to be used via the online Zoom platform that replaced the usual face-to-face classroom environment. Aware of the constraints of the online Zoom platform with regards to mathematical input and notation, she also planned for using Desmos, a digital tool that would 'make up' for constraints with respect to writing mathematics and sharing mathematical work in real time. The data presented in this paper is based on Tania's written assignment, which was submitted in September 2020 as part of the master's module on 'Digital Technologies for Mathematical Learning' (DTML). In her assignment, Tania shared her reflections on how best to support learners make links between different representations of quadratic functions using Desmos, and how face-to-face classroom-based activities were adapted to online learning via Zoom. We start by introducing the Theory of Instrumental Orchestration (TIO), which we used as our interpretative framework to present and analyse Tania's pedagogical considerations (or in other words orchestrations) when planning for mathematical learning with Desmos, and where the face-to-face classroom environment was replaced by the Zoom online learning space. We then give an overview of Tania's design considerations for online learning, followed by an analysis of Tania's reflections on how best to support online mathematical learning applying the TIO framework. We conclude with some reflections on broadening the TIO framework's orchestrations, as a result of overcoming the constraints, while capitalising on the opportunities when facilitating online mathematical learning.

Theoretical Background

The integration of DT into mathematics education has been an ongoing and non-trivial issue, mainly due to the complexity of the use of DTs. In order to describe how a teacher manages the use of DTs, steers students' instrumental genesis and orchestrates mathematical situations, the TIO was developed by Trouche (2004). Trouche (2004) introduced TIO by arguing that an instrumental orchestration describes the teacher's organisation and use of the different artefacts within a learning environment in a mathematical situation, so as to guide students' instrumental genesis (as cited in Drijvers et al., 2010, pp. 214–215). Trouche (2004) argued that an instrumental orchestration is defined by "didactical configurations (i.e. the layout of the artifact available in the environment) and by "exploitation modes of these configurations" (p. 296). A *didactical configuration* involves the teaching set-up and the artefacts available in the teaching environment and set-up. An *exploitation mode* involves the approach a teacher decides to take when exploiting a didactical configuration, aiming at supporting their didactical intentions (ibid). For example, how tasks are introduced to students and how they are solved, what roles the artefacts might play, or what schemes and techniques students may develop, are a teacher's decisions (ibid). Drijvers et al. (2010) added to Trouche's (2004) two elements: 'didactical configuration' and 'exploitation mode', a third element that of 'didactical performance'. *Didactical performance* involves the decisions a teacher takes while teaching, considering their chosen 'didactical configuration' and 'exploitation mode' (Drijvers et al., 2010). As Drijvers et al. (2014) add "what question to pose now, how to do justice to […] any particular student input, how to deal with an unexpected aspect of the mathematical task or the technological tool, or other emerging goals" (p. 191). Six orchestration types have been identified in the literature regarding whole class teaching and the seventh one involves students working on their own or in pairs with technology (Drijvers et al., 2014). These are:

> Technical-demo orchestration concerns the demonstration of tool techniques by the teacher […]. Explain-the-screen orchestration concerns whole-class explanation by the teacher, guided by what happens on the computer screen […]. In the Link-screen-board orchestration, the teacher stresses the relationship between what happens in the technological environment and how this is represented in conventional mathematics of paper, book, and blackboard […]. The Discuss-the-screen orchestration concerns a whole-class discussion about what happens on the computer screen […]. In the Spot-and-show orchestration, student reasoning is brought to the fore through the identification of interesting DME student work during preparation of the lesson, and its deliberate use in a classroom discussion […]. In the Sherpa-at-work orchestration, a so-called Sherpa-student uses the technology to present his or her work, or to carry out actions the teacher requests. (Trouche & Drijvers, 2010, pp. 219–220).
>
> In the Work-and-walk-by orchestration, the didactical configuration and the corresponding resources consist of the students sitting at their technological devices, and the teacher walking by in the classroom (Drijvers et al., 2014, p. 192).

Design Considerations for Online Learning

In this section, we present data from one graduate student's (Tania) reflections on designing activities to support eighteen 15-16 years old students' making links between different representations of quadratics functions using Desmos via Zoom. Tania was a student on the DTML masters' module and therefore a *learner* herself, who gained knowledge about technology-enriched practices in mathematics education. In this module, students learn about the affordances of various digital tools and critically discuss their value for mathematical learning. For their assignment they are expected to trial a digital tool with learners and critically reflect on the mathematical learning. Tania's assignment stood out, as she offered a particularly detailed account of and reflections on not just the mathematical learning with a DT, but also of doing so online. For this reason, we selected Tania's case study to illuminate how TIO can be applied to analyse orchestrations for online mathematical learning and how her design decisions showcase good practice in technology-rich learning.

The mathematics topic and choice of a tool

In her reflective writing, Tania justified her choice of a digital tool (Desmos – the technological artefact) for supporting eighteen Year 11 (15-16 years old) students' learning about 'quadratics'. In preparation for their mathematics examination (iGCSE), the students learned how to plot and recognise quadratic graphs; how to factorise, expand, complete the square of quadratic expressions; how to solve quadratic equations in various formats; and how to apply the 'rules' for graph transformations. By engaging with relevant mathematics education research (e.g. van der Meij & de Jong, 2006) as part of her the DTML module, Tania was aware that students master all of the above as separate knowledge and skills about quadratics, but may not necessarily develop a fuller, more holistic understanding of 'quadratics'. Inspired by her recent experience with graphware digital tools and knowledge of their potential for mathematics learning she gained in DTML, Tania thus planned for activities where Desmos would be used to support students to engage with the multiple representations of quadratics.

Planning for Online Learning

Tania trialed these activities with students via Zoom. In her written reflections, Tania was explicit about how much she learned from studying on the DTML and how it influenced her design decisions for mathematical activities which she ended up carrying out online. She became aware of the affordances and constraints of Zoom and Desmos, and there is evidence in her written reflections that such awareness affected how she orchestrated the learning of the students, as will be discussed next.

Tania's Instrumental Orchestrations

In this section we apply the TIO to describe and analyse Tania's own re-count of and reflection on her own practices to support online learning, where Desmos was used with the learning objective of supporting students make connections between different representations of quadratics. More precisely, we will be using Drijvers et al.'s (2014) interpretation of an instrumental orchestration consisting of three elements: a didactical configuration, an exploitation mode and a didactical performance. We will be using quotes from Tania's assignment, which we will indicate using single quotation marks '_'.

Tania wanted to find out about students' prior knowledge about the mathematics topic under scrutiny. She set a pre-task for the students to carry out on paper. Students then emailed her their scanned work in advance of trialing the online activities.

The *didactical configuration* for carrying out the online activity included the online platform (Zoom) as the online learning space which replaced the usual face-to-face classroom-based learning environment. Tania had to quickly become familiar with Zoom's functionalities, i.e. video camera (to make herself visible to the students), audio and chat features (to 'see' and talk with the students), breakout rooms for group activities, sharing screens and files (to share the resources she prepared for the online activities), Whiteboard, and certain functionalities that Zoom offered and which she referred to as the 'Pace', 'Pause' and 'Response' features; the Desmos tool; the mouse; and her computer. She referred to a 'Pace' feature of the Zoom platform to restrict students' access to specific screens. Tania also mentioned how she used the 'Pause' feature to remove students' ability to interact with the screen to capture everybody's attention and focus on the next activity; asking a student to provide an oral explanation; discuss a screen, etc. According to Tania, the 'Response' feature (how she referred to the chat box) allowed students to offer an answer for any questions or tasks that were posed.

Tania carefully thought about her *exploitation mode* regarding the online activity. For example, aware of the need for students to have plenty of time to explore the mathematics with the DT, Tania facilitated many such opportunities by organising students to work in pairs in breakout rooms. To better capture Tania's design considerations for the online activity, she created for the 18 students, we present these in Figure 1 below. In this figure, we exemplify the elements of mathematical learning Tania planned for (left column), the challenges she faced due to carrying out the activities online (middle column), and how Tania decided to exploit the artefacts mentioned above in her *didactical configuration orchestration* for the online activities (right column). Afterwards, we present her reflections on the elements involved with the *exploitation mode* regarding online learning and how she was able to overcome the challenges she was faced with, based on the affordances of the DTs she used.

Planning for…	Challenges for online teaching and learning	Tania's *Exploitation Mode* for online teaching and learning
Assessing prior knowledge	Writing mathematics in real time	Setting work for students to carry out on paper and then email their scanned work
Sharing work in lesson	Hand writing equations Hand sketching graphs	Using new symbolic representation x^2; Using Desmos for writing equations and sketching graphs; Treating computer screen like paper Sharing screens
Sketching graphs	Hand drawing graphs	Using Desmos to write equations and draw graphs, in parallel with verbal and written explanations
Managing the lesson	Presence and gesturing	Using the 'Pause class' Zoom feature
Monitoring and assessing students' progress	Walking through the classroom and checking on students' work	Joining break out rooms; Monitoring chats of break out rooms; Asking students to type explanations in the chat
Supporting collaboration - pair work; whole class	Students sharing working out in their books or on the board	Use of breakout groups; Students sharing screens
Gesturing	Using hand gestures to point at written work, to explain mathematics, to show own work on paper	Mouse used like a finger/pen to point to parts of the screen, while offering verbal explanation; 'Pause Class' for focus and joint attention
Sharing oral explanations	Facilitating rich conversations between teacher&students and among students	Teacher monitoring students' work by visiting breakout rooms, then asking the students to share their screens and explain their solutions.

Figure 1: Tania's design considerations for online learning

Tania's *didactical performance* involved the use of the 'Pause' and 'Pace' Zoom features in order to allow all students to see or work on the same screen together or have whole-group conversations and be provided with further support or introductions to new tasks, without many distractions. In her assignment, she referred to Godwin and Beswetherick (2003) by stating that 'teachers can be reluctant to use technology in the classroom if they are concerned that their students will lose focus and misbehave', and while she did not provide evidence that this did not happen online, she certainly hinted that she spent little time on managing students' transition to new activities. By asking the students to type their reasoning in the chat, Tania was pleased to be able to assess students' understanding, as she was able to quickly see their answers in the chat box. *Work-and-walk-by orchestration* and *Sherpa-at-work orchestration* were carried out with much ease, moving from one breakout room to another, checking on students' work, and hence monitoring students' work in less time than in a face-to-face classroom-based learning environment for example.

At the start of the online activities, Tania ensured that the students themselves had access to the Desmos application on their own devices, and they knew how to share screens. Her *technical-demo orchestration* included modeling to students how to input mathematics superscripts so that Desmos would recognise quadratic functions by using the '^' symbol for powers. Tania commented on how using Desmos to test out and modify their answers without judgement encouraged students to hypothesise about what would happen if variables changed. Tania noted that that was the case for all students, as she was able to quicky monitor their responses in the chat boxes, therefore gaining a window to every student's mathematical thinking. After sending the students to work in pairs in breakout rooms for the set activities, Tania would bring them back together and would always seek explanations from randomly selected students about how they (in pairs) found the solution to the mathematics question posed. *Spot-and-show orchestration* was used often in these online activities, due to the ease of sharing screens (hence students' work) and inviting students to explain their reasoning, followed by the *discuss-the-screen orchestration*, where their peers were invited to reflect and discuss the volunteer-student's contribution. Tania wrote explicitly about how she was able to check on students' progress through the 'Response' mode, being able to offer individual support, or lead a group discussion by *explaining-the-screen*, all of which were also highlighted by Tania as benefits of online learning. Tania's *didactical performance* was visible in her actions: 'In the 'Response' mode I could see students were happy to try out different equations. Only one pair were not inputting anything so I joined their breakout room' and while this aspect was clearly an advantage of online learning, Tania appreciated that it could be a limitation, as the rich mathematical conversations she had with pairs of students in breakout rooms were missed out by the rest of the students. She admitted '[All] students would also benefit from being able to listen in to each other's conversations' in a face-to-face learning situation.

For one of the activities, she designed (presented in Figure 2), Tania sent the students in breakout rooms for another opportunity to work with and consolidate their understanding of links between different representations. She particularly liked this activity as it asked the students to 'explain their thinking'. The justification box completed by students in the breakout rooms would instantly be visible to her, meaning that she was able to monitor students' understanding and support them when and if needed. At one point in the online activity, she noticed that one pair of students provided the answer as a quadratic expression in the expanded form, and not in the form that would evidence their understanding of the links between graphs as horizontal translations. She joined their breakout room to praise the students for finding the answer and asked them if their equation could be written in any other format. One student proceeded to re-write the equation of the parabola passing through the purple points on the graph as $y = (x + 4)^2$, while the other student immediately then said 'oh, because it's moved to the left four' having made the link to their knowledge of transformations of graphs. Tania brought everyone back together and asked this pair of students to explain what they had discovered by sharing screenshots and pictures of their graphs, their written work, and by actively interacting with Desmos while explaining their work. Using Drijvers et al.'s (2014) framework, there is evidence in Tania's reflections that the *link-screen-board orchestration* happened often in this online activity. In fact, throughout the activity, Desmos screens were shared via Zoom, which together with the written and verbal justifications, and pointing-at-screen by students and Tania, facilitated the *link-screenS* (Desmos and Zoom)-*board* orchestrations, supporting thus transitioning and making connections between the two DTs and conventional mathematical work.

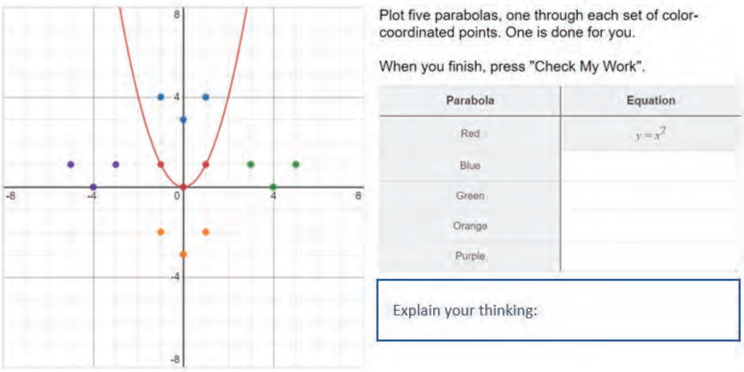

Figure 2: Mathematical Investigation with Desmos

Conclusion

The application of TIO to the data (graduate student's written reflections on her design considerations for online mathematical learning with a DT) we presented above indicates that the three elements of the TIO framework, namely *didactical configuration, exploitation mode* and *didactical performance*, which were developed for face-to-face classroom teaching and learning, provided us with a useful framework for describing the orchestrations necessary for designing and carrying out online learning activities. We investigated the reflections of a graduate student on practices involved when technology-rich learning activities take place online instead of a face-to-face learning situation. The nature of social interaction normally observed in face-to-face classroom-based mathematical learning activities, such as pair-work, students' and teachers' non-verbal gesturing, instant assessment of and feedback to students' learning, needed to be orchestrated for carrying out a mathematical activity online to ensure students' learning did take place. Breakout rooms, contributions to chat, freezing screens, pacing the learning, ease of use of mathematics specific DTs, were used to promote the same learning outcomes for students.

In many respects, such orchestrations facilitated learning in more productive ways according to Tania, as the ease of instant or timely access to each student's work and their contributions in the chat tool at the click of a button were pointed out as advantages of online learning. The ease of monitoring the students' work led to offering instant and timely individual support, and Tania reflected on these aspects as being more productive in an online environment. In other cases, Tania's orchestrations hindered certain pedagogical practices. For example, Tania had rich mathematical conversations with some pairs of students in the breakout rooms, but then the rest of the students missed these conversations as they were not in the 'same room'. This of course would not have necessarily been the case if Tania and the students were all in the same 'physical' room, where she could have easily initiated a whole group discussion.

Online input of mathematical writing is a well-known challenge (Leventhall, 2004), and Tania found a way to 'make up' for this limitation by designing the online activities around students' mathematical investigations using Desmos. Her pedagogical decision for this DT was taken in order to address both the learning objective of the mathematical activity (linking different representations of quadratics), but also to support students to do and share mathematical work through Desmos (graph drawings), and chat boxes (typing explanations). We argue that there are ways around such issues (e.g., Tania would take notes of the key messages in the breakout conversations she had and mention these to all students when they are back in the same virtual room), but this strategy, and the many others that Tania shared with us in her reflections, clearly indicate the need for careful considerations and investment of time in designing activities for online mathematical learning.

This paper's contribution lies in exemplifying how the TIO framework's orchestrations can be broadened as a result of overcoming the challenges and tapping into the opportunities of online learning, as supported by careful design considerations for technology enriched practices based on certain affordances of DTs. We discussed how a graduate student addressed the challenges of online learning and capitalized on the opportunities offered by DTs, while developing her own knowledge of and expertise with technology enriched mathematical learning. Tania had to quickly broaden her field of pedagogical expertise, by identifying how best learners interact online with their peers (in breakout rooms and the main Zoom room), and with technology (Desmos) to do mathematics and therefore accommodating their needs. These considerations should be central to any design decisions when orchestrating students' mathematical learning online.

Learning about black-boxes: A mathematical-technological model

André Greubel[1] and Hans-Stefan Siller[1]

[1]University of Wuerzburg, Germany, andre.greubel@uni-wuerzburg.de

Technology fastly becomes more relevant, both in real life and within mathematical and technological education. In everyday life, this technology frequently comes in form of a black-box, a system whose inner-workings are (partly) unknown to the user. In this paper, we argue that we should emphasize teachings about black-boxes in technological and mathematical education. This is because a black-box conception of technology is neglected by current teachings, but crucial for everyday life. To bridge this gap, we present a model that can be used as a basis for such teachings. We argue why the containing conception and analysis techniques are useful for mathematical and technological education. More precisely, we argue that such a model can be used as meta-informational knowledge to reflect upon technology, especially in cases with incomplete information.

Keywords: black-box conception, black-box analysis methods, mathematical-technological education, curriculum development, teaching models

Introduction

With the progression of the 21st century, technology becomes more relevant, both in real life and within mathematical and technological education. This is primarily because "[d]igital technology has the potential to open up new routes for students to construct […] new approaches to problem-solving" (Bray & Tangney, 2017). As such, technology is included more and more frequently in education.

This inclusion of technology can manifest itself in different ways. Firstly, one can differentiate between *tools* (used to automatically solve generic inner-mathematical problems) and *applications* (used to solve a specific real-world problem). Secondly, one can teach *with* and *about* technology. Teaching *with* technology focuses on teaching regular subject areas, but in a better way (whereas "better" can be understood in a huge variety of ways). Contrary to that, teaching *about* technology corresponds to an epistemic mediation of technology and focuses on goals internal to the user, e.g., his familiarity with or conception about technology (Rabardel & Bourmaud, 2003; Trouche, 2005).

Thus, teaching about technology can foster a reflective approach to the usage of technology (*critical reflection*). Notably, this critical reflection requires (some) insights into that technology. However, the mathematics of complex applications (like search engines, product recommendation, or self-driving cars) frequently exceeds the scope of typical school education. Additionally, many of these technologies hide their inner-workings from the user. Hence, at least parts of these applications must be treated as a black-box. Because of this, it is worth asking: "*What conceptions and techniques should be taught to students to foster their critical reflection of complex black-box applications?*"

In this paper, we contribute to this question with a normative approach. We first propose a theoretical model consisting of a black-box conception of technology and five analyzation techniques. Afterwards, we describe why we should teach this model to students. More precisely, we show how this model can be used as meta-informational knowledge to reflect about complex applications.

State of the Art of Teaching about Technology

Teachings about technology can be done both explicitly and implicitly: Students might get explicit instructions of how they should view and use technology, or they build their own model by their experience about their interaction with technology and its inclusion in their education.

Current Curricula Often Implicitly Build a White-Box Conception

As of right now, explicit teaching *about* technology is not part of most curricula. For example, in Germany, the central document guiding the creation of the state-local mathematics curricula states:

> "The inclusion of digital tools should foster the development of mathematical skills. The potential of such tools should support the exploration and understanding of mathematical relationships, the use of individual approaches to problem-solving, and reduce the focus of schematic activities in problem-solving." (KMK, 2015, p. 13, translated from German)

Thus, mathematical education focuses on mathematical *tools* and on teaching *with* technology; no explicit conception for technology is introduced. Hence, it is likely that students learn their conception implicitly, based on their learning and everyday experiences. Currently, the most prevalent theoretical model used to describe the inclusion of technology during learning is the technology enhanced modelling cycle (Greefrath et al., 2011). In this cycle, a mathematical model is translated into a technological model and the technological results are interpreted as mathematical results.

Thus, this model focuses on a white-box conception of technology: Students have full understanding of what the system does, how it is defined, why it is doing it, and know about all inputs and outputs.

Additionally, German computer science education complements this approach by teaching about how a system is doing something. This also includes lessons on how to implement such systems, e.g., using object-oriented programming. Notably, these courses also use a white-box conception where technology directly corresponds to a known model. Teaching about these models (e.g., a computer, the internet, databases, or an UML diagram) is an important part of the teaching (c.f. Röhner, 2016).

Strengths of the White-Box Conception of Technology

With this (implicit) white-box conception, students are able to understand a fundamental property of technology: In order to build or use it, explicit and correct translation between these representations is necessary. Using technology in this way can increase the scope of solvable problems with automaton. This might be because a single approach is executed faster, or multiple approaches can be executed simultaneously. However, it is not possible that technology solves problems a human (with infinite time) cannot solve, since technology is seen as a mere extension of a mathematical model. As such, technology can only be as valid as the models used to create it. More precisely: any output is an inherent property of the used model or algorithm, and not of the method of execution.

This coherence to a mathematical model can motivate the discussions of various concepts like determinism (the output of the model is defined only by its behavior and input values) and edge-cases (situations that defy the assumptions of the model). It can also be used to introduce the important difference between verification (the technology accurately represents the mathematical model) and validity (the model accurately represents the real-world).

Limitations of the White-Box Conception of Technology

While this current, implicit white-box conception accounts for many important properties of technology, it fails to account for black-boxes, in which (at least important parts of) the inner-workings of the technology are unknown to the user. Notably, this limitation is not the fault of the current teaching methods like the technology-enhanced modelling cycle: They were never meant to build a full conception of technology. Regardless of fault, the lack of an explicit black-box conception is undesirable.

Firstly, while technological white-boxes are prevalent in education, black-boxes are far more prevalent in everyday life. This is primarily because every technology not created by the user is, at least initially, a black-box. While it might be common that (in education) all applications or models within a tool are created by students, this is not true for the majority of applications used in everyday life.

Secondly, the impact of these black-box applications on our everyday life is significant. They might affect the information we see (Google), the peer group we interact with (Facebook), dates we arrange (Tinder), the safety of our commute (self-driving cars or trains), our fitness (smart watch and fitness apps), and even our health (medical technology like automatic insulin pumps).

And lastly, black-boxes are often used in the workplace to hide mathematics (Williams & Wake, 2007). As such, designing or working with these black-boxes is a necessity in many jobs. Hence, there is an additional incentive to teach about black-boxes as vocational preparation.

Overall, black-box applications are very prevalent both in everyday life, and in the workplace. As they might have a significant impact on both, a reflective approach to their usage is desirable. However, as the conception of a black-box is currently not taught, there is little students can actually do to pursue such a reflective approach.

Proposition: A Model for Teaching about Black-Boxes and their Analysis

As such, we propose to bridge this gap by explicitly teaching about black-box technology in mathematical and technological education. We describe a conception of black-boxes and five techniques that can be used as basis for such teachings. These techniques differentiate in the amount of resources necessary (from low to high) and the amount of insight gained by utilizing them (from high to low).

Proposed Conception: Black-Boxes

Firstly, we denote the proposed conception students should have about black-boxes:

> Frequently, (parts of) the inner-workings of a given application are unknown to the user. This occurs naturally if the creator and user are not the same person. In this case, a user typically has no influence on the quality of the software if applied in a given situation. Similarly, the creator typically has no influence on the situations a software is applied.

The most important aspect a user must know about a technological black-box is, that it still has all of the properties of a white-box. Most importantly, its behavior and results are deterministic. Notably, this includes the output of pseudo random number generators, as they solely rely on their input value (the seed). This is also true if the user (or, in the case of neuronal networks, even the creator) cannot explain the exact functionality. This also highlights the most important limitation of any technology:

It cannot (magically) adjust to the requirements of a situation and evaluating the quality of the result requires (some) knowledge about the (mathematical) models used to acquire that result.

Nevertheless, it importantly is often still possible to use the technology, even with this lack of understanding from the user or the lacking intention of the creator for this use-case. Because of this, it is crucial that the quality of the software and its applicability to a given situation were thoroughly evaluated. Otherwise, wrong or misleading results might follow, whose consequences can be dire.

Proposed Technique 1: Accepting the Black-Box

The first approach is *accepting* the black-box. In this case, the technology is used without examination and evaluation. We will call such a technology a *true* black-box.

When using a true black-box, one has knowledge about the most important input and output of that black-box: The most important output corresponds to why we use the black-box (e.g., for a self-driving car: “moving towards a destination”) and the most important input corresponds to how we use the black-box (“by inserting a destination into the user panel”). However, even this knowledge about the inputs and outputs might be incomplete or wrong.

At this point, it is important to note that true black-boxes both exist and have educational legitimacy.

On the one hand, accepting a black-box and using it as a true black-box is the default (and natural) behavior of many people. However, it is hard to discuss how desirable this is or to evaluate the consequences of that approach without explicit acknowledgement of the conception of a true black-box.

On the other hand, accepting a black-box can sometimes be the most reasonable choice: It might just be unfeasible or impossible to analyze a black-box at all. For example, many users will (likely) never have the ability (or feel the need) to analyze the algorithms used in self-driving cars themselves.

Proposed Technique 2: Testing the Black-Box

The first evaluation approach including interaction with the black-box is *testing* it, leading to a *tested* black-box. In this case, the technology is executed in a safe environment using specific inputs. If the observed output matches some expected output (to some precision), the technology is then applied to the real problem. Thus, if something fails, the resulting problems are limited to the safe environment.

For this technique, learners need to understand that it only works if the same inputs are used during testing and usage and if all relevant outputs are observed. It is important to fight the misconception “if all observed outputs are correct using one input, then all outputs are correct using any input”. Notably, this can be difficult, as the user does not necessarily know about all inputs and outputs.

However, a tested black-box already offers some amount of information to the user: If the test was successful and seems to represent the future use cases, we can infer that the most important inputs and outputs are likely recognized at this point and that the future outputs will suit the future use-cases.

Proposed Technique 3: Integrating the Black Box

A more comprehensive approach is *integrating* the black-box: First, the black-box is modeled as an unknown function from some inputs to some outputs. Notably, “some inputs and outputs” does not necessarily mean “all relevant inputs and outputs”. Then, outputs to selected inputs can be collected.

This systematic collection of inputs and outputs (rather than unsystematically collected tests), leads to more information as some generalizations can be made. For example, a user might notice that all outputs fall into some magnitude, regardless of input variation. Additionally, if we assume that the inputs are representative for any future use-case, we can infer that the product is likely safe to use.

Proposed Technique 4: Inferring the Black-Box

An even more comprehensive approach is *inferring* the behavior of the black-box. In this case, a re-modelling approach is taken: A mental model of the system is build, which is then verified by comparing coherence between this mental model and the actual behavior. As such, this techniques does not rely solely on some inputs and outputs of the black-box, but also takes the behavior into account.

The model-building process itself might use the observed dependency between inputs and outputs as basis for such a model and follow the steps of a modelling cycle. Regardless of approach, the resulting model can be represented in a variety of ways. This includes mathematical formulas ("speed of car = maximum allowed speed - 10"), verbal statements on different levels of abstraction ("The motor only starts if the battery is not empty", "The car follows the traffic laws"), algorithms ("if the cars sees a red light, then it breaks until standstill"), and meta-information ("This process takes 5s.").

The depth of both the mental model and the verification can vary significantly: The model can be a simple approximation (e.g., using a linear function) or be identical to the actual model. The verification can reach from a single execution in a common scenario to complex statistical tests using several carefully-constructed edge-cases (e.g., "how often does the motor starts if the battery is at 1%?").

Depending on the depths of the models and verification used, it is now *possible* to gain accurate knowledge about the exact lists of inputs and outputs, and the inner-workings of the technology. But this is no necessity: The model is only inferred and relies solely on a finite cutout of the observable behavior of the technology – contrary to any secured or proven knowledge of its inputs, inner-workings, or outputs. As Rice's theorem states that it is impossible to determine the exact functionality of a system without knowledge of its inner-working, this imples that this approach cannot lead to secured knowledge – even if the mental model used is actually the same as the real model (c.f. Rice, 1953).

Proposed Technique 5: Opening the Black Box

The fifth approach relies in *opening* the black-box. In this case, students not only examine its observable behavior, but also its inner-workings (*reverse engineering*). This approach can transform the black-box into a white-box. However, for comprehensive technology, accessing and understanding the implementation of a system is frequently outside the scope of education. For very comprehensive technologies, it might also be out of scope for any single person.

While it is frequently unpractical or impossible to open a black-box, understanding the limitation of the prior approaches only becomes possible if they are explicitly contrasted with this technique.

Additionally, some seemingly arbitrary aspects (like calling things that are treated as secured knowledge a "theory" in science, or arguing why mathematics can be seen as part of the humanities) only becomes comprehensible after understanding the epistemological difference between inferring and opening black-boxes.

Reasons for Teaching our Model

In this section, we show how the proposed model can be helpful and why to include them in curricula.

Reason 1: Intermediate Stages of Black-Boxes as Meaningful Conceptions

First and foremost, our model introduces "intermediate stages" of black-boxes (e.g., tested or integrated black-boxes) as meaningful conceptions. Without such an explicit conception, one might think about black-boxes as "incomplete white-boxes", i.e., a white-box that is left to be opened or inferred. Indeed, this conception was dominant in initial black-box research (e.g., Glanville, 1982) and remains relevant in many recent research projects. See (Krell & Hergert, 2019) for an overview of approaches.

However, this conception is not useful in practice: It is not always desirable to open or infer a black-box. Instead, depending on the time, skill, and jurisdiction of the student, the complexity of the technology under consideration and its available implementation, documentation, explanation, and licenses, it might be impossible, unfeasible, illegal, or uneconomic to apply some of these techniques.

This is quite apparent for self-driving cars or search engines: Access to their source code is limited because of intellectual property rights. Additionally, the complexity of their source code likely exceeds the capability for analysis for most (even trained) single individuals. Similarly, building and verifying an accurate mental model for such a technology also is both very hard and time-consuming.

As such, it is naïve to argue "one should always open or at least infer a black-box". In reality, opening or inferring certain black-boxes is not something most individuals will opt to do. But notably, this does not imply that one should not analyze a system at all. Instead, the intermediate stages show alternative and frequently valid courses of action or analysis one can take.

Reason 2: Stages of Black Boxes as Meta-Informational Knowledge

Secondly, our model highlights aspects of the trade-off between invested resources and gained insights. Thus, the techniques and their potential insights and requirements act as meta-informational knowledge: It can help to build an informed opinion on "whether one knowns enough about a black-box for a specific use-case, given the resources one is able or willing to invest".

As such, these stages can help to assess ones knowledge and identify limitations. Notably, this includes assessing ones knowledge about aspects where one has incomplete or uncertain information. Notably, the assessment of such information is an important step while "deciding what do believe or do", a phrase often used as definition of critical thinking (Ennis, 1987).

This is especially important for political participation: If one assesses that it not possible or feasible to analyze a black-box oneself, one has to ask about the implications. Most importantly, it might be desirable that somebody else analyses the black box. How to design such systems of evaluation can be an important part of a political debate, because different legitimate interests of stakeholders might collide: For example, a user has the desire to use a safe product even if he cannot verify its safety for himself. However, a company in a free market wants to keep certain implementation details as a company secret to keep their advantage over competitors and a government might try to reduce public expenses for institutional verification. Thus, a compromise between these legitimate interests has to be designed and evaluated. This requires insights into the technical aspects of potential solutions.

Illustration of the Benefits: Application of our Model in a Thought Process

To illustrate the prior benefits, we want to come back to the example of self-driving cars. More precisely, we want to exemplarily show how our model can guide the thought process of coming to a meaningful conclusion for the question “How likely is an emergency to occur while using this car?”

With our explicit model, we can first structure our knowledge: We can list available techniques for analysis and consider how they could be applied to the current application (the self-driving car):

True Black Box: Initially, one does not know anything about a self-driving car, expect for its basic functionality. It takes a destination and afterwards drives to this destination. Treating a self-driving car as a true black-box is easy, but reveals nothing about its safety.

Tested Black Box: A self-driving car can be tested in a specifically designed training course. If the course requires some representative situations (like interacting with different car or reading traffic signs), we can conclude that the car is safe to drive at least in some common situations.

Integrated Black-Box: To integrate the self-driving car, we can observe whether the car produces correct output (i.e., drives correctly and according to the traffic laws) for most anticipated inputs. If we chose a comprehensive set of inputs (e.g., a representative selection of all roads of the corresponding country and in a variety of different weather and traffic situations) and observe no (or few) invalid outputs, we can infer that the car is probably safe to use for most everyday cases we want to use it for

Inferred Black-Box: To infer more information about the self-driving car, we could build a set of models based on its behavior. For example, one can build the sub-model “If the car sees a red light, it breaks until standstill” and verify its correctness by building a representative amount of situations (including different distractors like weather and traffic). Afterwards, one can combine several sub-models (and verify this combination) to acquire an accurate mental model of the self-driving car. With this method, we can infer the safety of the car if the mental model indicates safe behavior.

As a second step, we can use this knowledge about the techniques to decide what to do: Using the system as a true black-box does not provide sufficient information about its safety. Since vehicle malfunction can be fatal, testing in a single environment also seems inadequate. However, both integration and inferring can give valuable information about its safety. Nevertheless, they require detailed knowledge and many resources (like verifying the behavior of the car in multiple real-world situations). As such, one might opt to not do this oneself, but rather vote for an obligation (by the producing company or by government regulators) to verify its safety using integration or inferring.

Overall, we used this model to progress from a simple “we don´t have any idea about its safety” to a more sophisticated “There should be an external entity that verifies its safety. An important aspect of this verification is the amount of hours driven in representative situations (rather than test scenarios)”.

Notably, this assessment benefits from knowledge about the techniques in the model. On the one hand, this is because they highlight the difference between behavior in a test vs. a representative environments (test vs. integration). On the other hand, the metric “amount of hours driven in representative situations” is a consequence following from the application of integration or inferring. Hence, it might be overlooked if only thinking in conceptions of “true” and “opened” black-boxes.

Summary and Conclusion

In this paper, we proposed a model of black-boxes in STEM education and argued why it accounts more for the special requirement of mathematical and technological education. This is primarily because technological system relevant for everyday life (especially those based on complex mathematical models like neuronal networks) are frequently too complex to open with typical school education.

Then, we argued why we should include teachings about black-boxes in mathematical and technological education. This is because, firstly, the conception of intermediate stages of black-boxes (rather than "incomplete white-boxes") are useful constructs if opening a black-box is impossible or unfeasible. As discussed before, this is often the case with complex mathematical technology. Secondly, our model can act as meta-informational knowledge to assess ones reflection about a system that is too complex for a full analysis. This also enables the generation of new knowledge. Thirdly, our models highlights that one does not necessarily know about all inputs and outputs of a black-box.

However, the proposition of this model can only be seen as a first step: How to design curricula and lessons based on this model is an important question for future research. Furthermore, it would be desirable to unite our technology-focused model with existing models in science education to achieve a more general "STEM approach to black-boxes" usable in interdisciplinary teaching.

Communication of technology as a productive element in learning Mathematics in remote settings

Paul Gudladt[1] and Simeon Schwob[2]

[1]Carl von Ossietzky University of Oldenburg, Germany; paul.gudladt1@uol.de

[2]Westfälische Wilhelms-Universität Münster, Germany; simeon.schwob@wwu.de

During the COVID-19 lockdowns, mathematics classes took place in distance learning settings in large parts with help of digital technology. Our research interest is to enhance digital face-to-face learning environments to stimulate and support mathematical interaction among learners with the help of digital media. In this article, we address the research question to what extent the consideration of the concepts of multiple external representations and communication of technology enable learning opportunities in online meeting tools. For this purpose, we present the learning environment developed based on these concepts and analyze a transcribed meeting with the help of an interpretative approach. By means of the analysis, identified potentials are presented.

Keywords: Communication of technology, Multiple external representations, Distance education

Introduction

During the school lockdowns caused by the worldwide COVID-19 pandemic, the way mathematic was taught and learned has changed. The traditional face-to-face interaction in classroom cannot take place. In Germany synchronous mathematics classes are held using online meeting tools like Zoom (https://zoom.us) or Big Blue Button (BBB; https://bigbluebutton.org). In our research project, we focus on diagnostic and support meetings held via online meeting tools. Various learning environments for online meeting tools have been constructed and implemented in our teaching-learning lab.

This article focusses on one developed learning environment: Interactive comparison of proportions using the rectangle model. In the theoretical background, the concepts of multiple external representations and communication of technology considered in the construction of the presented learning environments are introduced. Next, the developed learning environment is presented. In our empirical study we address the research question to what extent the consideration of the concepts of multiple external representations and communication of technology enable learning opportunities in online meeting tools. After presenting the selection of data as well as the method of analysis, empirical results from the implementation of the learning environment are presented and discussed.

Theoretical Background

Communication through and communication of technology

When learning with technology, communication is distinguished into two aspects: *Communication through technology* refers to the simple use of technology in mathematics classrooms (e.g., data projectors, displays, document cameras, tablets can be used to display and share the generated learning products). *Communication of technology* refers to the interaction evoked by the output of the technology (e.g., the discussion about the underlying mathematical concept while using a dynamic geometry software) (Drijvers et al, 2016). To realize a communication of technology via online meetings, for example GeoGebra worksheets can be used, which are programmed to show the learners a corresponding output. Depending on the conception of the task or the worksheet there is a potential that learners can generate numerous mathematical phenomena themselves with the help of digital technology (such as a GeoGebra applet or worksheet) to come to mathematical reasoning by observing them (Eichler, 2019). This can initiate fundamental learning processes (Nührenbörger & Schwarzkopf, 2016), which should be the overarching goal when creating a learning environment.

Multiple external representations

The concept of multiple external representations goes back to Bruner's remarks:

> Any domain of knowledge (or any problem within that domain of knowledge) can be represented in three ways: by a set of actions appropriate for achieving a certain result (enactive representation); by a set of summary images or graphics that stand for a concept without defining it fully (iconic representation); and by a set of symbolic or logical propositions drawn form a symbolic system that is governed by rules or laws for forming and transforming propositions (symbolic representation). (Bruner, 1966, pp. 44-45)

In (mathematics) learning environments, intermodal as well as intramodal transfers between and in these representation levels should be explicitly addressed so that learners link their knowledge from the respective areas (Bruner, 1966). One potential in the use of digital media is the synchronous and interconnected presentation of the different forms of representation via multiple external representations (MERs) (Ainsworth, 1999). When manipulating one level of representation, e.g., symbolic representation, the iconic representation changes at the same time. The use of MERs in learning environments can support learners in internalizing the interconnectedness of the levels of representation and in intermodal transfer between them (Moyer-Packenham & Bolyard, 2016).

The developed learning environment

Based on theoretical considerations above, the following learning environment was specifically designed for students attending the Teaching and Learning Lab to support their competencies in the area of numbers and operations, especially in fractions. To tap the potentials presented above as much as possible, tasks were designed with the help of a GeoGebra worksheet. The goal of the first task is to compare different fractions (see Fig. 1).

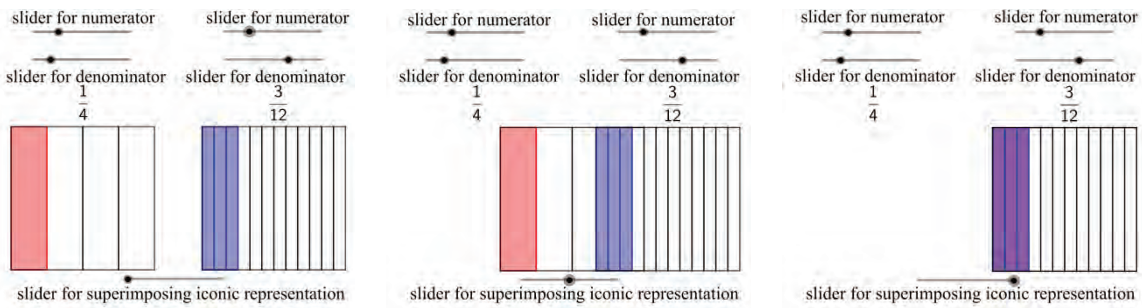

Figure 1: Designed tasks – numerator and denominator are manipulable via sliders

Besides symbolic representation, iconic and enactive approaches are offered. Digital enactivity is limited to the use of sliders to manipulate the iconic or symbolic representation. For example, the numerator and denominator of a fraction can be adjusted while changing the subdivision of the iconic representation. As an additional level of assistance, students can unlock another slider that allows them to superimpose the iconic representations of fractions.

The preliminary theoretical considerations have been taken up in the conception of the learning environment. Since the (enactive) change of the symbolic representation also adapts the iconic representation, the developed GeoGebra worksheet can be classified as MER (Ainsworth, 1999). The students can create different phenomena themselves (Eichler, 2019) by setting and comparing fractions and their iconic representation in quick succession using the sliders. Thereby, a Communication of Technology is initiated (Drijvers et al., 2016), as manipulation of the sliders produces an output in the form of change in the iconic representation, and the iconic representations can be manipulated so that they can be slid over each other to verify equality.

Methods

The collected data was gained in our virtual teaching and learning lab in Summer 2021. The learning environment presented here was conducted with three pairs of sixth graders attending a middle school in northwestern Germany. Partner schools were offered participation in the teaching and learning lab and teachers selected the participating students. The diagnostic and support meetings were held and recorded via the online meeting tool BBB.

In the following, the qualitative analysis of one of the three sessions is presented. The focus is on the pair of students that showed the greatest difficulties in the symbolic handling of fractions at the beginning of the session. Based on the interpretative analysis of the transcripts, the research question to what extent enables the consideration of the concepts of multiple external representations and communication of technology learning opportunities in online meeting tools will be addressed.

With the help of the interactionist approach (cf. Schreiber, 2004; Voigt, 1995), the interpretations of the participants are reconstructed in a turn-by-turn analysis of the transcript. Participants in interviews or classroom discussions interpret the actions of other participants themselves in these situations. These interpretations influence the further course of the social interaction. A detailed understanding of the course of interaction in a learning environment allows conclusions to be drawn about possible adaptations of the learning environment. These can be implemented in terms of the design research approach (van den Akker et al., 2006).

For the sake of clarity, this article only presents the results of the interpretations that have proven themselves within the framework (Krummheuer & Brand 2001). Starting from an observed phenomenon, an attempt is made to translate the cause into a general case with the help of a law. The resulting laws are always based on a hypothetical conclusion, so there is only the possibility of a plausible but not certain hypothesis (Meyer, 2009). The point is not putting the methodological background of the analyzes up for discussion. For the methodological discussion, the translation process of the original transcript would already be a strong interpretative intervention that is worth a discussion. Rather, exemplary episodes are presented that represent different ways of communication with the help of digital technologies.

In the following, the interpretative analysis of a scene from an online meeting with Angela and Susan is presented. Here, the empirical realization of the potentials is examined and, in particular, the question is pursued whether Angela and Susan can transfer the acquired knowledge in the digital-active and digital-iconic areas to the symbolic level with the help of the prepared environment.

Empirical Results

Before the present excerpt starts, the students were asked to use the sliders (Figure 1) to create the fractions $\frac{1}{4}$ and $\frac{3}{12}$. Andrea and Susan successfully solved this task. Simultaneously, the corresponding iconic representations were displayed to the students in the GeoGebra worksheet. The two students further used the possibility to superimpose the two representations with the help of the lower slider (Figure 1 and Figure 2).

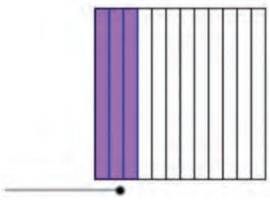

Figure 2: Superimposing the iconic representations with the help of the slider

The transcript (translated by the authors) starts at the moment when the students are asked by the worksheet to describe their observation:

12 S (Reads the task:) Tell what you have observed.. ehm well we have twelve parts three of them are marked and ehm on the quarter we had four parts but one was marked.. If you put them on top of each other three ehm three twelfths ehm the three are exactly as large as the ehm quarter

13 I Can you confirm your guess'

14 A Yes they belong to each other

The students describe the different subdivision of the two rectangles and emphasize that in one rectangle three of twelve parts were marked and in the other on of four. The equality of the given fraction representation assumed at the beginning is confirmed and justified by the students by taking advantage of the possibility to superimpose the two iconic representations with the help of the slider.

Afterwards, the interviewees are given the next task:

16 S (Reads the task:) Ohh interesting do you think that there are other fractions that belong to a quarter and three twelfths' enter your solution in the empty fields on the right side of the page

17 S Ehm (5 sec)

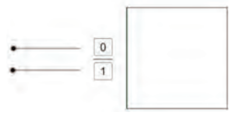
18 A I know ehm no (5 sec)

19 S There are only three twelfth ehm a quarter is slightly larger it therefore fits into the other one..

20 A So the marked part has to.. I don't know how to explain (5 sec.) ehm.. I don't know

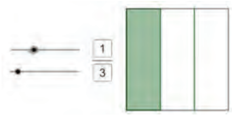
At the beginning of the task, the students can only enter their solutions using the symbolic notation. The task of specifying further fractions that are suitable for $\frac{1}{4}$ and $\frac{3}{12}$ cannot be processed by the students on the symbolic level. Susan focuses on the given iconic representation from the previous task without relating it to the new task in an explicit way. Angela seems to relate the given iconic representation to the task – unfortunately, she does not finish her thoughts.

21 I You can click on the help button (by clicking two sliders appear next to the upper rectangle)

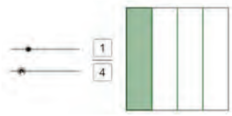


22 A Okay (starts to use the slider on the upper rectangle) ah okay

23 S Ahh one third



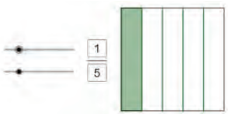
24 A But this is one more it has to fit in to the other one. We had a quarter



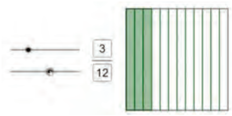
25 S This also does not work

26 A It does

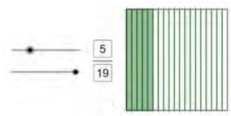
27 S (Keeps trying on the slider so that the rectangle is divided further) One fifth is too small yes that really does not work but I make it smaller.. wait three twelfth fit into three twelfth



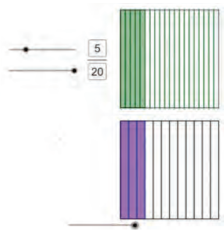
28 A That's right but now go on



29 S Wait five nineteenth no that does not fit



30 A What about five twentieth'.. that does fit



31 S We are ready

As soon as the sliders are provided as a support, Angela and Susan can take action. They try out different settings. Once the sliders are set, the corresponding symbolic notation and iconic representation is provided in the worksheet. The students compare the generated iconic representation with the permanently available representation of $\frac{3}{12}$ of the previous task (e.g. Turn 16). A mathematical systematic is not recognized, rather Angela and Susan persist on the comparison of the iconic representations. Nevertheless, Angela and Susan use the slider to make an increasing finer division and also verbalize this (Turn 27). Furthermore, it is noticeable that when the number of subdivisions is increased by the slider that influences the denominator, Angela and Susan also set the slider for the numerator to a larger setting to make the marked area of the rectangle as fitting as possible in relation to the given iconic representation of $\frac{3}{12}$. The central criterion for the two students is that the marked areas in the iconic representations take up the same proportion of the rectangle, so that they would fit on top of each other (Turns 29, 30). After finding the iconic solution, Susan formulates that they have finished working on the task.

32	I	Okay can you briefly explain how you arrived at your solution
33	A	We looked at how much ehm we needed and ehm how small the parts had to be so that they would fit into the three twelfths
34	S	So we have made the lower number always larger and thus made the lines shorter so that it fits

When asked by the interviewer to describe their solution procedure, Angela and Susan explicitly formulate the procedure interpretatively reconstructed above. By adjusting the sliders, the generated iconic representations were manipulated in such a way that a representation appearing congruent to the already given subdivision was produced. In Turn 34, Susan explicitly speaks of larger numbers without verbally associating them with the fraction representation as numerator and denominator.

35	I	Can you explain how you can get to the solution without using the sliders
36	S	Ehm
37	A	I can't do this
38	S	Five twentieths must have something to do with this.. I don't know

Explicitly asked for a possible solution without referencing the sliders, Angela and Susan are evasive. Susan names the generated fraction $\frac{5}{20}$ for the first time but does not relate it to $\frac{1}{4}$ or $\frac{3}{12}$.

Discussion

Angela and Susan generate a variety of mathematical phenomena (Eichler, 2019) in the form of iconic representations of fractions through the different settings of the sliders (Turns 21-30). They compare the generated fractions to the given iconic representation to find a solution to the task. By using the opportunity of the setting options via the sliders, Angela and Susan are enabled to indicate a solution using the technology. Through the settings of the sliders, the symbolic representation of the fraction is automatically specified, and the corresponding iconic representation is displayed. Angela and Susan argue with the help of the iconic representation via the offered GeoGebra worksheet and generate a solution for the task. However, although Susan and Angela develop findings on the iconic level, they are not sufficiently stimulated to transfer them independently to the symbolic level. An intermodal transfer does not take place. This might be explained by the interpretive hypothesis that from Angela's and Susan's point of view the argumentation on the iconic level is completely sufficient. There is no need for symbolic argumentation or backup of the iconically confirmed results. The apparent fit of the subdivision found through trial and error is seen as a complete solution. Reconstructively, there seems to be no need to give a symbolic argumentation for the iconically gained knowledge. Even though the digital medium offered a synchronicity of the presentation of iconic and symbolic levels, this does not necessarily mean the retrieval of the potential by the learners in form of a realization of an intermodal transfer.

Overall, it can be stated that Susan and Angela are enabled to solve the task on an iconic level through the tools offered by the worksheet which was constructed under consideration of the concepts of MERs and communication of technology. However, a transfer of the iconically obtained solution to the symbolic level does not take place and obviously requires a further impulse in the form of an authentic and precise anchoring in the given task. This adaptation of the learning environment with a view to forcing an authentic intermodal transfer stimulated by the worksheet will be focused on in the continuation of our Teaching and Learning Lab.

Based on the results presented and the discussions, the following possible adaptations of the learning environment emerge: The multiplicative link between numerator and denominator (for equivalent fractions), for example, could be focused more by corresponding buttons to double, triple or half the numerator and denominator. This highlights a more systematic change between numerator and denominator. In the presented form, the given rectangle for iconic representation is divided only horizontally. In a revision of the learning environment, both horizontal and vertical subdivision could be offered. Students might then experience a productive irritation (Nührenbörger & Schwarzkopf, 2016) since you get more examples with different structures for the same fraction. Likewise, the colored part is always the part to the left. In future, other parts might be colored to make clear that, for example, any three out of twelve parts (of equal size) form one quarter. Building on these constructive changes, learners should also be asked to make more arguments about whether the proportions presented are equivalent and why.

By considering the presented points, the potential arises to initiate the intended linking of iconic and symbolic levels and thus to take up the problems that could be reconstructed in the interpretative evaluation of the learners' use of the learning environment. Thereby, the given *model of fractions* could become *model for fractions* for the learners (e.g. Gravemeijer, 1999).

In addition to the reconstructed potentials regarding the argumentations, an organizational potential can also be identified: Due to the principal possibility of successfully conducting pure online teaching-learning arrangements via online meeting tools, the circle of learners who can be enabled to participate in our Teaching and Learning Lab can be enlarged insofar as learners from the entire catchment area in the northwest of Lower Saxony can be reached without hurdles of distance and travel.

Characteristics of students’ covariational reasoning in an augmented reality environment: a language-oriented analysis

Otman Jaber[1,2] and Osama Swidan[1]

[1]Ben-Gurion University of the Negev, Program for science and technology education, Beer-Sheva, Israel; jaberot@post.bgu.ac.il, osamas@bgu.ac.il,

[2]Al-Qasemi Academic College of Education, Baqa El-Garbiyeh, Israel; Jaberot@qsm.ac.il

This study reports preliminary results on the characteristics of covariational reasoning in an augmented reality-rich environment. In contrast to the research literature that has hitherto focused on levels of covariational reasoning, this study addresses its linguistic characteristics. Two groups of three 15 and 17-year-old students participated in this study. Each group carried out two activities (Hooke's law & Galileo) using AR headsets. The students' interactions were video-recorded. Based on inductive analysis of the students' covariational reasoning language, we identified five linguistic categories of covariational reasoning: direct-covariation, mediated-covariation, conditional covariation, multi-variable covariation, and second-order covariation.

Keywords: Augmented reality, covariational reasoning, linguistics, characteristics of covariational reasoning.

Introduction

Covariational reasoning is a central concept in mathematics and science education, which has drawn the attention of many researchers in these fields (Johnson et al., 2017). The research literature mainly focuses on the levels of covariational reasoning, as suggested by Thompson et al. (1994), Carlson (2002), and Thompson and Carlson (2017). In this context, several studies have focused on students' covariational reasonings as they learn in several learning environments, (e.g., Doorman et al., 2012). Among these studies, Swidan et al. (2019) is one of the few that focused on using AR technology to foster covariational reasoning. Swidan et al. (2019), like many others, focused on learners' covariational reasoning levels (see also e.g., Kertil, 2020; Sokolowski, 2020; Thompson and Carlson, 2017). However, little is known about linguistic aspects of students' engagement in covariational reasoning. By linguistic aspects, we mean the structure and the meanings of students' discourse about covariation.

The socio-cultural theoretical framework argues that language plays a central role in the development of human thinking. This suggests that identifying the linguistic characteristics of students’ covariational reasoning may shed light on that reasoning, and its development. Identifying these linguistic characteristics is therefore this study’s goal.

Theoretical framework

Covariational reasoning

Thompson and Carlson (2017) described understanding covariation as holding a sustained image in the mind of two quantities' values (magnitudes), which change simultaneously. In their study, they characterized six levels of covariational reasoning (1) No-coordination; (2) Pre-coordination of values; (3) Gross coordination of values; (4) Coordination of values; (5) Chunky continuous covariation; (6) Smooth continuous covariation. In the first level, the person has no image of variables varying together. In the second, the person can predict the change of each variable value separately but does not create pairs of values . In the third, the person perceives a loose link between the overall changes in the values of the two quantities. In the fourth, the person can match the values of one variable (x) to the values of another variable (y), thus creating a discrete set of pairs (x, y). In the fifth, the person may perceive that those changes in the two variables co-occur and vary smoothly, but only at separate domains. In the sixth and final level, the person can perceive an increase or decrease in the value of one variable as coinciding with changes in another variable value in its entire domain and see both variables as a smooth and continuous change.

Thompson and Carlson (2017) suggested descriptions and examples that illustrate each covariational reasoning level. We adopted their descriptions to identify the level of covariational reasoning and the linguistic structure of the utterances. Such identification of covariation reasoning may assist us in addressing the linguistic characteristics of each statement.

Augmented reality

Augmented reality (AR) is an innovative technology that combines layers of virtual objects or information about physical objects from the real world, such as texts, images, graphs, etc. This creates a kind of augmented reality, in which virtual objects and a real environment coexist to increase the learning experience (Arvanitis et al., 2009; Dunleavy et al., 2009). These virtual layers are created in real-time and layered on the physical objects in the real environment in 3D. Insofar as it augments mathematical representation with the real phenomenon, we assume that AR technology may play an essential role in engaging students in covariational reasoning, due to its ability to visually present information that is naturally invisible. It also simplifies objects' visual appearance and helps students think about their symbolic representations.

Fig.1 Students with AR headsets

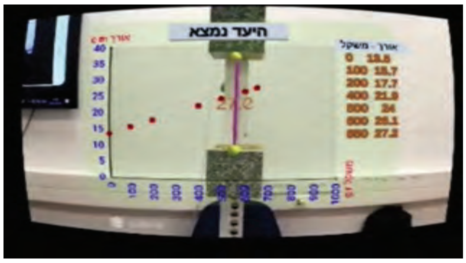

Fig.2 Virtual and physical objects as seen through AR headset

Methods

Research context and participants

Since this study seeks to understand the linguistic characteristics of covariational reasoning, it is based on the qualitative research method. Learning experiments were conducted with two groups of three 9th- and 11th-grade students. The students had already learned linear and quadratic functions. The learning experiments were held at Ben-Gurion University of the Negev. Each session lasted about

180 minutes, during which each group carried out two experiments: (1) the Hooke's law experiment, which examines the relationship between mass and the elongation of a spring (Figures 1 and 2), and (2) the Galileo experiment, which examines the relationship between time and distance that a cube travels as it slides down along an inclined plane. Each group worked on a task sheet corresponding to both physical experiments. The tasks were based on the inquiry-based learning approach. Each task included three inquiry phases: conjecturing, experimenting, and reflecting.

For this study, we designed a new AR prototype that utilizes augmented reality in an educational setting using a special headset, presenting a dynamic object in a real environment with virtual representations provided simultaneously. The prototype is designed to juxtapose mathematical representations (numbers, tables, graphs) with the dynamic real-world object to evoke engagement in covariational reasoning (Figure 2).

Research question

What are the linguistic characteristics of students' covariational reasoning when they learn in an AR environment?

Data collection and analysis

All the learning experiments were video recorded. Students' interactions and materials (written notes, files) were collected. Thus, a solid set of data was obtained. We used Thompson and Carlson's (2017) framework to identify covariational reasoning and determine covariational reasoning levels. We also used the inductive approach (Patton, 2002) to linguistically analyze (structurally and semantically) utterances that indicate covariational reasoning. Finally, we grouped the data into categories of linguistic characterization.

The semantic aspect of our analysis refers to the context in which covariational reasoning utterances emerge, while in the syntactic aspect we address the structure of the covariational reasoning utterances.

The inductive approach we adopted is based on the following phases:

- Looking for utterances indicating covariational reasoning.
- Identifying linguistic characteristics of each phrase.
- Identifying categories of characteristics (linguistic and content) in the statements.

Table 1 illustrates the ways we analyzed the covariation utterances:

Table 1: Illustrative analysis-table of covariational reasoning utterances

Utterance	Thompson-Carlson level lens	Linguistic lens	Category
Dennis: As time passes on, then the sliding cube gains acceleration, and so travels greater distance	**L3**: Dennis seems to perceive a loose link between the overall changes in the two quantities' values (time, distance)	Covariation between time and distance is ***mediated*** by another variable *(acceleration).* The linguistic structure is: As A, then B and so C	Mediated covariation

Alex: If the elasticity is weak, then, the more mass is added, the longer the spring length is.	**L3**: Alex seems to perceive a loose link between the overall changes in the two quantities values (mass, length)	Covariation is ***conditioned*** on a specific situation. The linguistic structure is: "If A then, the more B, the more C.	Conditional covariation
Shahar: At a weight of 200 grams, the length of the spring is 11.8 cm, and at 400 grams, it increased to 14.3cm.	**L4**: Shahar can match values of one variable (weight) to values of another one (length), creating a discrete set of pairs (weight, length).	Covariation is ***directly*** achieved between the variables' quantities (weight, length). The Linguistic structure is: at A=x, B=y.	Direct covariation

Results

Our data analysis produced five categories of linguistic characteristics that characterize students' engagement in covariational reasoning in an AR environment: Direct-covariation (n=130), mediated-covariation (n=12), conditional-covariation (n=7), multivariable-covariation (n=13), and second-order covariation - Cov2 (n=45).

Below, we present a series of excerpts that illustrate the linguistic characteristics of each category.

Direct covariation: In this excerpt, the students' coordination between variables, or variables' quantities, is achieved directly, without any mediation of other variables

Ex1. Lior: As *time* passes, then the cube travels a longer *distance*

Ex2. Shahar: At a *weight of 200* grams, the *length* of the spring is *11.8 cm*, and at 400 grams, it increased to 14.3cm.

In Ex1, Lior covaries time with the distance the cube travels. In Ex2, Shahar covaries the weight of the cube with the spring length. This kind of covariation is usually characterized as Level 3 of covariation. Here, the linguistic structure that the students use is: "as A then B" & "at A=x, B=y."

Mediated covariation: In this category, the covariation between two variables is mediated by another variables.

Ex3. Nir: As the plane's slope is greater, the cube gains more *acceleration* and the *distance* increases.

Ex4. Sagi: As the *elasticity* of the spring changes, so its <u>*length*</u> becomes greater and ..., so... The *graph slope* becomes sharper.

In Ex3., Nir covaries the plane's slope with the distance the cube passes; here, the covariation was mediated by the cube acceleration. In Ex4., Sagi covaries the elasticity of the spring with the graph slope. Also, here, the covariation was achieved through the mediation of the length of the spring.

The following images illustrate the students' engagement in the covariational reasoning that corresponds to Ex 4. As Sagi and Alex interact with the physical model and add mass to the spring (Fig 2a and 3b), they observe the mathematical representations through their AR headsets. They interact with virtual objects observed through the AR headsets (Fig3c). First, Sagi covaries the elasticity of the spring, which is a physical quantity, with the length of the spring, which is displayed on the AR headset; then, he varies the graph of the function shown in front of them via the headset. Hence, the covariation between the spring's elasticity and the function graph was mediated by the length of the spring (Fig 3c).

(a) (b) (c) (d)

Fig 2. (a)&(b) Alex and Sagi interact with the model by adding mass on the elastic spring. (c) Students interact with the virtual objects observed through the AR headsets. (d) The graph and spring's length as seen from the AR headset.

In these excerpts, students use the structure: “as A then B and so C” &, “As A so B and so C”

Conditional Covariation: In this category, the covariation is accompanied by the condition of a specific situation.

Ex5. Alex: *If the elasticity is weak*, then the more *mass* is added, the longer the spring's *length* is.

Ex6. Noam: *If the slope (of plane) is down*, then *as time* passes, so the cube travels a greater *distance*.

In these excerpts, the students use the structures: “If A, then: the more B, the more C” & “if A, then: as B, so C.”

Multi-variable covariation: In this category, the students' covariational reasoning is characterized by using a multiplicity of variables.

Ex 7. Sagi: In the graph, we simply see the change…that the distance increases ...That is, as *time* passes, then the *distance* increases, then you see that the *slope* (graph) simply increases from one second to another and ... and we also see this in the table of values in large jumps …that is the *acceleration* increased.

In this excerpt, Sagey covaries four variables: time, distance, the slope of the graph, and the acceleration of the cube. Here, students use the linguistic structure: “As A, then B, then C and D, so E.”

Second-order covariation: In this category, the students covary quantity and object, or two objects, but not two quantities as anticipated in covariation as defined in the literature.

Ex 8. Shaked: as the *spring* goes down, the *graph* grows up.

Ex 9. Shaked: The *graph shape* rises diagonally because the cube gains *acceleration* and time passes.

Ex 8. shows how Shaked covaries between two objects, spring and graph, while Ex 9. illustrates how she covaries between a quantity (cube acceleration) and an object (graph shape).

The following images illustrate the students' interaction and engagement in covariational reasoning corresponding to Ex 9. As Dennis slides down the cube, Shaked and Nir observe the phenomenon and mathematical representations through their AR headsets (Fig 3a). Shaked connects physical and virtual objects. She describes the graph (virtual) (Fig 3b) as growing diagonally because the cube (physical) is accelerating, and time is passing. Then, Shaked and Nir share their insights with Dennis (Fig3c).

(a) (b) (c)

Fig 3. (a) Dennis slides down the cube while Shaked and Nir observe the phenomenon through their AR headsets. (b)The graph as it seen through Shaked's AR headset. (c) Shaked and Nir share their insights with Dennis.

Final Remarks

We found five categories of linguistic characteristics that characterize students' engagement in covariational reasoning in AR environment: direct-covariation, mediated-covariation, conditional-covariation, multivariable-covariation, and second-order covariation.

With *direct covariation*, students find it easy to reveal the relationship between the two variables. Hence, they address the changes in variables' quantities directly. The AR environment, with its sensory and visual resources, seems to facilitate engagement in direct covariation. For example, in the Hooke's law experiment, the mass and length are visible in the real world and through the AR headset. Furthermore, AR provides numerical measurements augmented and juxtaposed to the observed phenomenon, facilitating students' direct engagement.

Mediated covariation may reveal the quantities or objects that relate to the phenomenon the students observed. The emergence of the mediated covariation might be attributed to the learners' need for such mediations to organize their reasoning, which may support their exploration. Such mediation seems to be an essential part of their deductive reasoning when exploring the relationships among variables.

Conditional covariation seems to be attributed to two factors: the task and the nature of the experiment. The students' utterances reveal that some of their conditional covariation statements seem to be inspired by the task questions. Since the task requested the students to explore the effect of the spring's elasticity on the mass-length relationship, the conditional covariation emerged as an answer to the task's question: "If the elasticity is weak, then the more mass is added, the longer the spring's length is."

The rest of the conditional covariation utterances arose in the context of task 1 of the Galileo experiment. In this task, the students were required to explore the time-distance relationship as a cube slides down along an inclined plane. Changing the plane inclination is not determined in the task questions. However, the students manipulated the plane inclination during their exploration. The features of the Galileo experiment evoke sensory interaction and invite available manipulations: adjusting inclination, sliding objects, free manipulations on the sliding object. Furthermore, this manipulation invites students to address other variables, such as inclination, even though the first task is not explicitly managed to require this.

During students' engagement in covariational reasoning, they resorted to other multiple variables. It seems that addressing such variables assists them in better understanding the observed phenomena and connecting with the variables determined in the task. This phenomenon of multi-variable covariation may be induced by the features of AR technology, which invites the interaction between the users and the real and virtual objects (Azuma et al., 2001). Utterances on multi-variable covariation mainly emerged in advanced levels of covariational reasoning. This may be attributed to students' attempts to utilize and organize the rich available variables' data resources to achieve deep insights into the observed phenomenon.

Although the students covaried between quantities along the learning process, we also identified situations in which students coordinate between a quantity and an object, or even two objects. This phenomenon, covarying two objects rather than two quantities, also appeared in Arzarello (2019), who investigated students' engagement in covariational reasoning when performing the Galileo experiment using computer simulation. This suggests that this type of covariation emerged due to the characteristics of the tasks, independently from the digital tools used in the experiments.

The linguistic characteristics provided in this study may shed light on the students' covariational reasoning processes. Furthermore, this categorization may help teachers foster the students' covariational reasoning and help them design dynamic technological environments. The findings of this study refer to a small sample of 10^{th} and 11^{th}-grade students. Therefore, additional research is required to further explore the linguistic characteristics of students' covariational reasoning as they learn in a dynamic and computer simulation technological environment, considering larger samples of high school and junior high school students.

Swedish students' exploration of trigonometrical relationships: GeoGebra and protractors yield qualitatively different insights

Trigonometry, an important pre-requisite for many advanced topics of school mathematics, links geometric, algebraic and graphical reasoning, but remains a difficult topic to teach and learn. The dynamic nature of many trigonometric functions is amenable to dynamic geometry software, which, in the form of GeoGebra, is the focus of this paper. However, both generally and in respect of trigonometry, research on GeoGebra's efficacy seems ambivalent. In this paper, we offer a case study of two groups of Swedish upper secondary students' solutions to the same tasks. One group was instructed to use GeoGebra and the other a protractor to investigate the sine and cosine functions in in the interval $0° \leq v \leq 180°$*. Analyses yielded qualitatively different outcomes; students using the protractor typically identified a geometrical relationship based on symmetry around the protractor's 90° line, while those using GeoGebra tended to identify only numerical relationships.*

Keywords: Trigonometry, GeoGebra, Protractor, Sweden, Upper secondary school.

Introduction

For at least half a century, technophiles have asserted the transformative impact of various forms of computer software on the teaching and learning of mathematics. An early example can be seen in Papert's (1972) enthusiastic promotion of Turtle Geometry as a way of engaging young children with mathematics in ways that generate rather than replicate mathematics. Later, spreadsheets were presented as a means of introducing various aspects of both school mathematics (Healy & Sutherland, 1990) and university mathematics (Steward, 1994). More recently, attention has been focused on, inter alia, dynamic geometry software (DGS), particularly GeoGebra, the focus of this paper. Unfortunately, despite the undoubted quality and availability of the software, much GeoGebra-related research seems to have been underpinned by the technophiles' desire to 'prove' its educational efficacy and is often little more than instructions or tips for teachers to develop their own applets for teaching purposes (e.g., Little, 2011; Phan-Yamada & Yamada, 2012). Even when attempts have been made to establish a baseline understanding of its impact on learning, research has typically been equivocal in its outcomes, methodologically problematic or both. In the following, before introducing our study, we summarise these methodological problems.

GeoGebra and the teaching and learning mathematics

Our reading of the literature indicates an important distinction between the use of preprepared applets, designed to facilitate the exploration of the mathematics under scrutiny, and expectations that students construct their own applets. In respect of the former, which is more frequently reported than the latter, studies have reported on, for example, undergraduates' investigations of the definite integral (Tatar

& Zengin, 2016), circle theorems (Sigler et al., 2017) and Fermat and Steiner points (Flores & Park, 2018). Such studies, while supportive of the software's potential efficacy, seem not only to lack details of the ways in which such applets support learning but assume that such learning could not be achieved via other means. When control groups have been employed, as with studies of high school students' learning of functions (Zulnaidi et al., 2020) and exponential functions (Birgin & Yazici, 2020), researchers typically report higher achievement and deeper learning in the groups exposed to GeoGebra applets than the control groups. However, these studies seem not to be without problems, particularly with respect to details pertaining to the students' experiences. For example, Zulnaidi et al. (2020p. 54) wrote only that "students in the control group were taught using the traditional method whilst their counterparts in the treatment group utilised GeoGebra", while Birgin and Yazici (2020, p.5) wrote only that "the control group was taught by using textbook-based direct instruction". In other words, such studies seem problematic in their unarticulated assumptions about traditional teaching and the experiences of control group students.

GeoGebra and trigonometry

Understanding trigonometric functions is a pre-requisite for understanding many other topics in science and engineering, and as "one of the earliest mathematics topics that links algebraic, geometric, and graphical reasoning, it can serve as an important precursor towards understanding pre-calculus and calculus" (Weber, 2005, p.91). However, it is a difficult topic to teach, with approaches based on the right-angled triangle stressing procedural skills at the expense of any conceptual understanding of either sine or cosine as functions (Kendal & Stacey, 1997). In attempts to address such matters, a number of studies have exploited GeoGebra in the teaching of different aspects of trigonometry.

Unfortunately, much of this research is prone to the problems as discussed above. For example, Kepceoğlu and Yavuz (2016) investigated the teaching of periodicity of trigonometric functions with grade ten students. In one classroom, the teacher demonstrated by means of an applet, while in the other, the same teacher adopted a traditional exposition. The post-test found the experimental group performing better than the control, although no tests of statistical significance were used, and little detail was offered with respect to what students were invited to do in either classroom. In similar vein, Zengin et al. (2012) developed a five-week trigonometry course for high school students. A post-test found greater improvements in the experimental group than the control. However, beyond the implied use of applets, nothing was said with respect to the interventions, other than to assert that "GeoGebra prepared activities aimed to make the subject more dynamic, concrete and visual" (p. 185). By way of contrast, Mosese, and Ogbonnaya (2021) undertook a controlled experiment in which one group experienced GeoGebra-based applet led instruction, while the control group experienced, inter alia, a model of a rotating arm to underpin a series of lessons focused on basic trigonometric functions. In both instances, some detail was offered with respect to what students experienced, with the experimental group performing better on a post-test than the control. Finally, Nordlander's (2021) study drew on observations of upper secondary students working on the limit of $\sin\theta/\theta$. Her hope was that students would "explore, compare, and connect items leading to discovering relationships and learning through their own reflections and self-explaining" (p. 3). She found students' conceptual and procedural knowledge to be enhanced by the visualisations afforded by the software.

In conclusion, much GeoGebra-related research seems problematic, mainly because the tasks students receive are rarely adequately described. Even the authors of review papers seem unaware of such problems. For example, Chan and Leung's (2014) meta-analysis, despite identifying 428 articles, evaluated just nine that satisfied their selection criteria and, while acknowledging factors like length of intervention, student age and teacher role, concluded that DGS-based instruction had a significant impact on achievement in relation to traditional instruction. However, no attention was paid to the tasks students received or, importantly, what is meant by traditional instruction.

This study and its methods

Acknowledging what seems to be a significant gap in the literature, this paper presents an investigation of the impact of different 'technologies' on students' learning of trigonometry. It is conceptualised as an exploratory instrumental case study in which two student groups, one working with GeoGebra and the other with protractors, solve the same tasks. Exploratory case studies aim to identify hypotheses for further inquiry (Woodside & Wilson, 2010), while instrumental case studies aim to advance knowledge of the issue under scrutiny (Garner & Kaplan, 2019). The study is framed by the question

> What differences emerge in upper secondary students' solutions to the same trigonometrical tasks when some students work with GeoGebra and others work with protractors?

The study involved 22 students in the second year of the Swedish upper secondary school's (17-18 years) natural science programme. Participants, who had previously encountered trigonometry only in relation to right-angled triangles, were randomly assigned to two groups, each split into pairs. Twelve students (6 pairs) worked with GeoGebra (G) and 10 (5 pairs) with the protractor (P). Each group completed the same tasks in, effectively, identical lessons of 60 minutes duration.

During the first part of each lesson, (ca 25-40 minutes), students undertook an investigative activity aimed at extending earlier trigonometric relationships beyond acute angles to arbitrary angles. During this time, both groups were allowed pocket calculators, paper and pencil, while group G uniquely used GeoGebra and group P uniquely used protractors and a unit circle drawn on paper. Next, participants in both groups worked through identical textbook-based tasks (ca 10-25 minutes), using whatever tools they preferred. Finally (ca 10 minutes), students solved a trigonometric equation, during which time they were allowed only a unit circle drawn on a paper, paper and pencil. At the beginning of the lesson, written instructions were distributed and afterwards the teacher clarified any misunderstandings for individual pairs. Throughout, students were asked to discuss their thinking, with each conversation being audio-recorded and every GeoGebra activity being digitally recorded.

In this paper, due to limitations of space, we focus on the results of students' work from the first and final phases of the lesson, which were structured by two tasks, presented in ways that would be amenable to either protractor or GeoGebra approaches.

Task 1, the introductory investigations, comprised several parts

- Draw a circle with radius 1 and its centre in the origin.
- Working from the centre of the circle O and the positive *x*-axis, draw an angle 125° and its corresponding radius OP.

- Note the coordinates for the point where the radius intersects the circle: the *x*-coordinate is the cosine value, the *y*-coordinate is the sine value.
- Find an angle for which $\sin v = 0.8$ in the interval

  a) $0° \leq v \leq 90°$ b) $90° \leq v \leq 180°$
- Find all angles in the interval $0° \leq v \leq 180°$ for which $\sin v = 0.5$.
- Examine the results of the previous tasks and make a note of the relationship between them.

The solutions to the first part are a) $v \approx 53°$ and b) $v \approx 127°$, while those of the second are 30° and 150°. Finally, it was hoped that students would have noticed that the angles are symmetrically placed either side of 90° and that the sum of the angles is 180°.

Task 2 comprised one part, namely, determine, without using a calculator or digital tool, which angles in the interval $0° \leq v \leq 180°$ are solutions to $\sin v = \sin 56°$. Its solutions are $v = 56°$ and $v = 124°$. During this time, it was hoped that students would exploit the relationship discovered during Task 1.

Data analysis

Analyses of qualitative data are typically either theory- or data-driven (Boyatzis, 1998). Our view is that the exploratory nature of this study is best served by the latter, as it privileges emergent insights that may be masked by the former (Andrews & Sayers, 2013). Consequently, participants´ utterances and actions, including the GeoGebra digital recordings, were interpreted, and coded in ways that would expose similarities and differences in how students approached their tasks. For example, during their work on the investigative task, Epsilon pair (P), offered the following:

Epsilon (P): But it is 90 degrees. Or is it 180 minus that angle, is the same … Look, it should be the same distance … 90 degrees plus ... or … Ok, check, ok, now, now I came up with it, check, if you have the angle here, you should add 90 degrees minus the angle you have here, because then you come here on the other side. So, if you have 90 degrees … So, it's 0 plus the angle ... is the same sine value as 180 eh ... minus ... yes ... 0 minus the angle *v*.

In this excerpt, the various utterances indicate that the two students had identified a symmetrical relationship around the protractor's 90° line and were attempting to articulate a geometrical relationship. By way of contrast, during their work on the same task, one of the GeoGebra pairs, Gamma, suggested:

Gamma (G): So, 53 divided by 127 might be the same thing as… 30 divided by 180.

Such an utterance, focused on division, indicates little, if any, awareness of symmetry and, we infer, reflects a loosely formed interpretation of a proportional relationship. Later, continuing to work with numerical values, the same pair identified a relationship, although there remained no explicit evidence that they had noticed the symmetry embedded in the situation:

Gamma (G): Now I have found another connection, 53 degrees plus 127 degrees is 180 degrees and 150 plus 30 is 180. It is also a small connection.

Interestingly, their description of the relationship as 'small' indicates a view that they thought an additive relationship of such a form was, possibly, too trivial to be correct.

Results

In the following, we summarise the results for each of the two tasks respectively, highlighting important similarities and differences.

Task 1

Overall, ten of the 11 pairs identified a connection between the angles in Task 1. Five of these, four protractor pairs and one GeoGebra pair, discovered the expected symmetrical relationship. The protractor groups typically drew on expressions like 'equally far' or 'mirror image' to highlight the physical location of the angles in relation to the vertical associated with the 90° line of the protractor. With respect to the former, in addition to the comments made by Epsilon (P) above, another of the protractor pairs, Lambda, was heard to say:

Lambda (P): They are on each side of... both are equally as far away from 90 degrees... the line. If you take 90 minus those in the ... 90 ... 0 to 90 range. Yes. Then it will be as much as if you take... 90 plus …Yes exactly. Between 180 and the 90 range. Yes... that is the connection. It is the same distance on both sides as well. Yes? The degrees are equally far from 90 degrees.

With respect to the latter, another protractor pair, Iota, seemed more explicit in their articulation of a symmetrical relationship. They said:

Iota (P): It looks like as if ... like a mirror image… Yes exactly. It's not plus 90 but ... but it is mirror-inverted, mirror-inverted ...Yes. Yes. So that it (the 90° line) is the line of symmetry.

In short, four of the five protractor pairs, drawing the physical characteristics of their given tool, were able to identify the expected symmetrical relationship.

By way of contrast, and in addition to the comments made by the Gamma pair discussed above, one of the Sigma (G), identified a numerical rather than geometrical relationship, was heard to say:

Sigma (G): Just that, if we add them, yes? Yes. Mm then it will be ... These, added to each other should always be 180. Yes. Is that the connection they want? I think that's the connection, it sounds like a nice connection.

Indeed, the utterance, "added to each other should always be 180", seems to confirm that this pair was thinking numerically rather than geometrically. Moreover, the closing comment that "it sounds like a nice connection" indicates that they were not only content with their conclusion but that they were not expecting to think in anything but numerical terms.

Finally, in this section, one of the GeoGebra pairs, Omega, initially struggled to make sense of their results, as seen in their initially confused and confusing comment that:

Omega (G): Is it the same, em, number of degrees between here it is 120 degrees between this … and this … and what were the angles? Ok, no it is not, because then it is … about 54 something, I think. And here it is ... no it is nothing, there is no connection, it seems…

The utterances "no it is not because then it is … about 54 something" and "no it is nothing, there is no connection, it seems" indicate that the students of this pair were struggling to identify any form of connection between the angles under scrutiny. However, after further thought, they shifted attention from the purely numerical to notice that:

Omega (G): I don't know if it's a connection but that they are just as far … from here to there and from there, em, from the *x*-axis, yes. Yes exactly, it's true. And from the *y*-axis.

In such an utterance, despite their obvious hesitancy, this pair had come close to identifying and articulating the expected symmetrical result.

Task 2

Overall, nine of the 11 pairs, four protractor and five GeoGebra, were able to solve Task 2 and find the values $v = 56^{\circ}$ and $v = 124^{\circ}$ respectively. In most cases, the successful pairs exploited the result they had identified earlier. For example, drawing on the symmetrical relationship they had found previously, Iota were heard to say:

Iota (P): Do we have *v* at all?... Can't we just do our ninety tactics?... If we have… like one answer, we take the other. Yes? …90 minus 56 is equal to 34. Yes? So, 34 plus 90, 124. Boom.

The somewhat rhetorical question, "Can't we just do our ninety tactics?" confirmed the pair's connection to their solution to Task 1. Afterwards, by performing "90 minus 56, is equal to 34... So, 34 plus 90, 124. Boom.", their task is solved efficiently and, it seems, with understanding.

However, not all protractor pairs made such an explicit connection between the two tasks. For example, uniquely among their colleagues, the protractor pair Epsilon solved Task 2 by drawing on a numerical interpretation of the symmetrical relationship they had discovered during Task 1. They began by repeating the task:

Epsilon (P): Determine without calculator which angles in the range are solutions to … Ok. This one we know already; it is 180 minus 56. Yeah!

The utterance, "This one we know already, it is 180 minus 56", came shortly after they had read the task and shows how they connected the two tasks swiftly. Interestingly, their conversation, due to its brevity, indicates that they transformed the relationship they found in Task 1 to the process used here.

GeoGebra pairs using numerical approaches that had not found the symmetrical relationship at Task 1, solved Task 2 by working once again with purely numerical values, and, as expected, did not used symmetry when solving it. For example, the Gamma pair noted that:

Gamma (G): … when it was sine, and it was 180 degrees, it was positive all the time…. So, sine 56 degrees … must be the same as … 180 minus 56 degrees what is … Yes, 130, 124 … it will be, because then the value is the same? Because it is always positive.

Finally, the Alfa pair connected the expectations of the task to their understanding that sine values were read-off the *y*-axis, before performing their calculation and commenting, with a degree of irony, that any connection had been obscured by the number of decimal places returned by the software.

Alfa (G): It's equal to 56 degrees? Yeah? Sine was the *y*-axis, right? Sine what *x*-axis ... *y*-axis. So, it should be 56 degrees.... Now, I do not understand anything. Wait, it's... So, first of all 180 minus 56. I was so confused, I just … how are we going to do this? … The connection is that there are unsatisfyingly many decimals.

Discussion

In this paper, acknowledging that trigonometry is a difficult topic to teach, we have examined the impact of two qualitatively different approaches, involving the same tasks, to the teaching of trigonometry to Swedish upper secondary students. The outcomes were unexpectedly different with, on the one hand, students using the protractor tending towards an awareness of a symmetrical relationship that allowed them to understand and exploit the sine of angles in the range 90-180 degrees, while, on the other hand, students using GeoGebra tending towards an awareness of a numerical relationship between such angles. Significantly, in contrast to Nordlander's (2021) study, there was little evidence of the G group's conceptual and procedural knowledge being enhanced by the visualisations afforded by the software. While further research would be necessary to establish the reasons for these differences, it is not improbable that the protractor scaffolds students' awareness of symmetry in ways that GeoGebra does not. Also, as noted by the Alfa pair of students, the decimal places offered by GeoGebra may interfere with students' interpretation and subsequent generalisation of their results, highlighting a need for teachers to ensure that the appropriate number of places is set.

In sum, the results indicate a need not only for further comparative studies but also for teachers to understand how different technologies may enable or hinder learning. If there are any generalisation to be inferred from a limited study such as this, they are, firstly, that teachers have a role in facilitating students' awareness of any teacher-expected outcomes and, secondly, if students are to make sense of their experiences with DGS, then the role of paper and pencil seems crucial (Komatsu & Jones, 2020); working without such tools may create unnecessary barriers.

Mathematical creativity in coding dancing animations: a fallibilistic view

Myrto Karavakou[1] and Chronis Kynigos[2]

[1]Educational Technology Lab, National Kapodistrian University of Athens, Greece; karavak@ppp.uoa.gr

[2] Educational Technology Lab, National Kapodistrian University of Athens, Greece; kynigos@eds.uoa.gr

In this paper we investigate student's creative mathematical activity, while engaging in coding digital animations. A logo-programming authoring system which integrates Turtle Geometry, 3D space and dynamic manipulation of figural models was used. Three students of 8th and 10th grade engaged in creating figural dancing animations and synchronizing them to the rhythm of a song, by constructing an artefact and manipulating its geometric transformations in space. We adjusted the Creative Mathematical Action Framework, that is based on a fallibilistic view on creativity, into a constructionist technological context. The results indicate that artistic values such as synchronicity, symmetry and periodicity were conceived and applied within the digital resource and acted as motivators for persistently tinkering with the artefact. This context provided fruitful ground for creative mathematical activity of forming, expressing, exploring and expanding mathematical ideas.

Keywords: Creative mathematical actions, fallibilism, programming, mathematics, art.

Introduction

During the last decades, creativity has been constantly revisited with research attempts for understanding, analyzing and cultivating it in mathematics education. Thus, a diversity of theoretical perspectives on mathematical creativity has been developed, mainly addressing it by means of inborn trait and giftedness (Mann, 2006; Sriraman, 2005) or problem solving-posing processes (Silver, 1997). However, Riling (2020, 2021) has recently made a critical review on the existing approaches, pointing out their limitations over how creativity takes place in mathematics classroom and who can be seen as mathematically creative. Riling proposed an alternative view where mathematical creativity is discussed in terms of students' actions and is open to cultural and social influences – in a parallel manner as in artistic domains such as painting or choreography. She developed a framework in which mathematical creative actions are defined in a concrete way, that enables their investigation in students' activity. In this context, creativity emerges as free, independent expression of mathematical ideas, that can be nurtured in all students. This kind of creativity dissociates mathematical meaning-making from taken-as-established mathematics and fixed curriculum structures (Kynigos & Diamantidis, 2021). In this study, we adopted this challenging view towards mathematical creativity within the context of middle school students using a digital resource called MaLT2, which provides means for developing, expressing and investigating mathematical ideas while modeling 3D figural objects (Kynigos, 2015). Our aim was to investigate how this kind of creativity can be cultivated in the context of open artistic creation. We employed Riling's framework as lens to identify and look into instances of student's creative actions while engaging in creating a digital animation in MaLT2.

Theoretical Framing

Fallibilism in Mathematics Education

The view of creativity we are examining has its epistemological roots into the fallibilist approach on mathematics nature, as opposed to the formalist one (Davis & Hersh, 1980; Ernest, 2003; Kynigos, 2015). Formalism is an epistemological paradigm that conceives mathematics as 'an objective, absolute, certain and incorrigible body of knowledge, which rests on the firm foundations of deductive logic' (Ernest, 2003, p. 2). Thus, mathematical systems are discharged from any human influence and are served as pure isolated knowledge that humans can only approach through discovery. On the contrary, fallibilism relies on the assumption that mathematics is originally created by human thought. Fallibilist mathematics is open to be modified or disproven according to a person's use of it. A main difference between these two paradigms is their educational purposes. Formalism aims at understanding the abstract products of the served mathematical knowledge through practice. On the other hand, fallibilism focuses on the activity of doing mathematics, rather than mathematics itself, aiming at enriching students' meaning-making process (Kynigos, 2015; Kynigos & Diamantidis, 2021). Traditional schooling consist of formalist practices, which are based on the assumption that every task has a unique right answer and any mistake is accompanied with disapproval and criticism. This approach leaves limited space for students to experience creative engagement in mathematics. Fallibilism, in contrast, is connected with constructionist practices in education (Kynigos, 2015). According to Constructionism, students' learning of mathematics occurs naturally while creating and sharing tangible artefacts (Papert & Harel, 1991). The design of constructionist activities within expressive digital media aims at providing fertile ground for powerful mathematical ideas to be constructed. Constructionist learning environments play a two-way role; that is an interplay of reinforcement between mathematics and artefacts. On one side, mathematics is used as tool for constructing or tinkering an artefact, taking a fallibilistic form. Conversely, creating an artefact provides dense opportunity for students to formulate and explore mathematical possibilities. Students are encouraged to engage in both directions and externalize their ideas by adopting the role of a designer, an engineer or an artist. The tangible outcome then becomes a public entity, accessible for reflection by its creator or others. In this fallibilist context, creativity becomes an integral part of mathematics learning in a direct way: mathematics is used for actual creation of personally meaningful content.

Creative Mathematical Action Framework

For our study, we adopted the Creative Mathematical Action Framework (CMAF) proposed by Riling (2020, 2021), which views creativity from a fallibilist perspective and places it into its community of action. We adjust this framework into a constructionist technological context. The CMAF offers a model for identifying creativity in mathematical contexts, such as a mathematics classroom providing a specific technological resource (Kynigos & Diamantidis, 2021). It puts emphasis on the process of *how* creativity takes place, instead of *what* final product is created. Creativity is conceived as a type of action connected to the emergence of new mathematical possibilities as experienced by oneself. Thus, CMAF links creativity to personal meaning-making process. We further connect new mathematical possibilities to the way they are communicated and represented through changes in a digital artefact. According to Riling, a creative mathematical action is defined “as one that transitions a given mathematical context into a new version of mathematics by creating ways of doing or thinking about mathematics that were previously not possible for a particular community of mathematicians” (2020, p. 17). We expand this consideration by adding the component of the way a technological resource can influence this transition in a constructionist learning context. Thus, we conceive a creative action within a technological resource as one that transitions a given mathematical context into a new or expanded form of mathematical meaning by using technological tools to generate, express or explore novel mathematical ideas for creating and tinkering digital artefacts. Two main criteria for an action to have creative potential are: a) to origin from students’ own account instead of others’ (i.e. their teacher) guidance and b) to refrain from the standard ways of doing mathematics in school, where actions are traditionally manipulated by superior established curriculum practices (Riling, 2020). She also emphasizes the importance of aesthetic experiences, such as fruitfulness, visual appeal, mystery and surprise, in activating creative actions. Riling (2021) listed six types of creative actions derived from her data analysis. These types were adjusted to our constructionist view as follows: 1. *setting out*: generating initial ideas and goals intuitively by using the digital tools spontaneously as means to explore unknown aspects of an artefact; 2. *imagining:* using the digital tools more systematically in order to imagine a plan of implementation of an idea and set more clear goals; 3. *manifesting*: taking concrete intended actions to make changes to the artefact by altering the existing mathematical context; 4. *familiarizing*: taking time to survey the current status of the artefact in a comprehensive or reflective way; 5. *recognizing*: reconsidering an aspect of the artefact or interpreting it in a new way; 6. *naming*: distinguishing an action pattern in the medium for a specific object or idea as a distinct entity. In this study, we consider creativity inside the CMAF and investigate students’ creative actions within the digital medium MaLT2 for the creation of a “dancing animation”.

Design of the research

The task in MaLT2

The digital medium used for this study was an online dynamic mathematical programming tool to tinker with 3D figural models called MaLT2 (http://etl.ppp.uoa.gr/malt2/), which is recognized by the Greek Ministry of Education. MaLT2 integrates a UCB-inspired Logo procedural language with affordances for dynamic manipulation of procedure variable values (Kynigos & Grizioti, 2018). Thus, MaLT2 provides three interconnected representations: programming, figural representations and dynamic manipulation of generalized values through their sliders. This last feature enables the dynamic behavior of a figural model that is constructed by a parametric procedure. Therefore, it provides a mathematical way to create an animation through geometrical transformations of figures. Dynamic change of figural models by manipulating variable values also enriches the opportunity for exploring mathematical properties, posing questions, formulating assumptions and getting instant feedback. In this way students can engage in a loop of interaction with the artefact. The task designed for this study was titled as “Dancing Animations”. We designed an artefact in MaLT2 that would be given to students to begin with, in order to make their own animation (Figure 1). The task was described in a worksheet as open as possible. The aim was to make an animation by manipulating only one variable (instead of six variables in the case of the given artefact) in the same rhythm as a song selected from a specific list. The final product would be a video of the animation (the middle representation in Figure 1) added by the song audio.

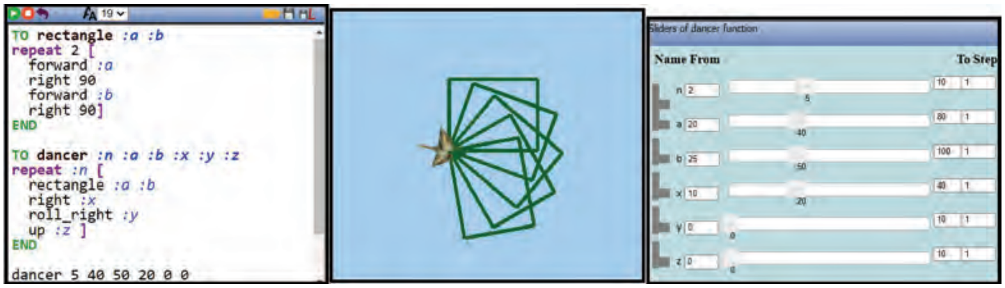

Figure 1. The initial artefact, in the three interconnected representations of MaLT2

Research Method

This study was implemented in a pilot level to three students; one girl of the 8th (Maria) and one boy and one girl of the 10th grade (Dimitris and Anna) of secondary school. They voluntarily participated all together in this two-hour-activity in an atypical after-school setting. They all had already participated in an introductory to MaLT2 activity. Each student had a laptop, a set of headphones and a notebook. A teacher-researcher was facilitating the activity by encouraging students to express their thoughts and ideas out loud. Data was gathered from screen-video, audio and voice recordings as well as students' notes. We analyzed data from students' discourse, notes and activity in MaLT2, following a grounded approach. We identified and analyzed instances of students' actions that demonstrated mathematical creativity in terms of the CMAF. We categorized them into actions of *setting out*, *imagining, manifesting, familiarizing, recognizing* and *naming*.

Results

We identified instances of creative actions for each student that led to the creation of three distinct "dancing animations" synchronized to the rhythm of a song. In Table 1 we briefly describe the sequence of eleven creative actions made by Dimitris and Anna, who collaborated during the process. The merged shells of the Table indicate a common, shared creative action.

Table 1: Description of Dimitris' and Anna's creative actions

Type of action	Description of Dimitri's action	Description of Anna's action
1. Setting out	They expressed the goal to create a dancing movement while dragging the sliders spontaneously and observing the changes on the artefact.	
2. Imagining	While focusing on dragging one slider, they set the goal of finding a way to create a complete rotation that simulates the spinning around oneself, in order to "create the sense of dancing".	
3. Manifesting	They selected the variable x that stands for the turn-command 'right' and tried different values for its upper limit.	
4. Familiari-zing	They ended up setting the limits from 0 to 360 and realized that 360 is the value for the whole rotating dancing move.	
5. Naming	They connected this value to the notions of "full angle", "full turn" and "full circle". Dimitris also referred to it as "the period of the animation".	

6. Recogni-zing	By dragging the slider of the variable x using the right arrow from the keyboard and simultaneously listening to the song each one selected, the expressed that their animation was "out of rhythm" and "too slow".	
7. Imagining	They set the aim to fix the period of dancing move to the period of the song and "find a way to make it move faster and fit".	
8. Manifesting	He considered the period of the song (Iggy Pop - The Passenger) to be 2 seconds and calculated that it corresponds to 60 units of the variable slider range. He used a multiplier to the command "right :x", which could control the speed of the animation. After trying different values, he ended up changing the command to "right 6*:x". He mentioned that "after I tried different values I realized 6 was the right one since 6 times 60 equals 360".	She considered the period of the song (Milky Chace – Stolen Dance) to be 9 seconds and calculated that it corresponds to 270 units of the variable slider range. She used a multiplier to the command "right :x", which could control the speed of the animation. After trying different values, she ended up changing the command to "up 1.3*:x". She mentioned that she found it "almost empirically".
9. Familiari-zing	They observed their animation and realized it was doing "a complete dancing rotation perfectly fitting to the period of the song".	
10. Recogni-zing	They realized their dancing move only lasts for a part of the song rather than its whole duration. They set the goal to make it last as long as the song extract.	
11. Manifesting	The song extract lasted 50 seconds. He calculated the right value of the upper limit of the variable slider for the animation to last 50 seconds, too. He counted the repetitive patterns (=25) and multiplied 25 by 60 (=1500), that is the number of degrees of each period of the animation.	The song extract lasted 34 seconds. She tried empirically values of the upper limit of the slider of the variable. She approached the exact value (=1020) by saying "I realized that each 3 beats it's almost 100 degrees so I was adding 100 each time to reach it.".

Dimitris and Anna followed a common sequence of creative actions, as a result of their collaboration and sharing of ideas. For example, they began with a shared instance of *setting out* and *imagining*, by manipulating the dynamic variation tools (sliders) of the procedure "dancer" (Figure 1). A dialog between them demonstrates their first instances of creative actions:

Dimitris: How can we make the shape dancing?

Anna: I imagine something like that... (She got up and made a complete rotation around herself.)

Dimitris: We need to find a way to make the shape spin. This (dragging the slider of the variable x) creates the sense of dancing. (...) As the variable x values change, the shapes turn continuously.

Anna: Yes, but we have to increase the limit value. Right? Because we want a whole rotation.

This investigation was the starting point of these two students' activity as a quest for answer to their own questions on how to create the sense of dancing. They posed the problem of "what value is suitable for the figure to complete a whole rotation" in order to simulate the dancing move of "spinning", formulating an example of creative mathematical action of *imagining*. During this action, they used the concept of variable and made sense on it. Afterwards, two shared instances of creative actions of *manifesting* and *familiarizing* took place, as the following dialog indicates:

Anna:	I tried changing the right limit of the variable x. I think 360 is the value for the whole rotation.
Researcher:	Why did you choose variable x instead of a or b?
Dimitris:	I thought that these variables (showing x, y and z) are for the turns. A turn means something that changes its angle. 360 is a whole angle. This is why it works for 360. It's 360 degrees, so it's a circle. I realized it right before it reached 360. A circle means a complete angle, so a full rotation.
Anna:	If you put more than 360, it starts repeating the same move again. We could use that to make it keep rotating for the whole song.
Dimitris:	Yes, you are right. (...) It makes another whole rotation when it reaches 720. And then 1080. So 360 is the period of the animation.

Dimitris connected the turn of 360 degrees to the concepts of a complete angle and a circle, noting that this realization was not possible before. In addition, Anna pointed out that values higher than 360 degrees make the animation repeat in the same way. After testing it, Dimitris realized that in every multiple of 360 the movement was making a whole rotation. They both imagined a choreography of repeated rotations fitting at the period of the song. The rest of their creative activity is captured at Table 1. They worked cooperatively, with actions of *imagining* and *recognizing* shared and discussed, but their actions of *manifesting* and *familiarizing* were independent, leading to two uniquely different animations.

Table 2: Description of Maria's creative actions

Type of action	Description of Maria's action
1. Setting out	While dragging the sliders freely, she set the goal to create a dancing movement by using them.
2. Imagining	While dragging back and forth the slider of some variables, she expressed the idea of finding a way to create the sense of moving "up and down around the horizontal state continuously".
3. Manife-sting	She selected the slider of the variable z that stands for the turn-command 'up' to move forth and back. She tried different values for both lower and upper limits. She ended up putting values that range equably from 360 which was the horizontal state: from 340 to 380; from 300 to 420; etc.
4. Familiari-zing and Naming	She observed it and expressed that "360 is the center of the move and I need to keep the same distance right and left". She called the value of 360^o as "the center of the animation" combining it to the notion of the center of symmetry.
5. Recogni-zing	She realized that her dancing movement "takes too long" and that she wants "to make it move faster" but "into the rhythm".
6. Imagining	She set the goal to find a way for the animation to "repeat the complete up and down move several times during the period of the song".
7. Manife-sting	She considered the period of the song (Milky Chace – Stolen Dance) to be 14 seconds. She selected the time period of 2 seconds for her dancing motion, in order to be repeated 7 times during the song period. She noted that "2 sec = 22 forth and 22 back". She ended up setting the value range from (360-11=) 349 to (360+11=) 371.
8. Recogni-zing	While observing the animation by dragging the slider of the variable z, she expressed that the motion was very slow and didn't fit in the 2-second-song period.
9. Manife-sting	She used a multiplier to the command "up :z", which could control the speed of the animation. She ended up changing the command to "up 1.5*:z".
10. Recogni-zing	She expressed that the speed of the animation seemed ok, but the shape does a different, less interesting movement. She said she needed to change the limits of the

	slider in order to make the previous symmetrical move in the selected speed.
11. Mani-festing	While trying different values she said: “when :z becomes 360, the shape is not horizontal like before. The new middle state is at 360/1,5=240. So the proper values are from (240-11=) 229 to (240+11=)251.
12. Familia-rizing	She observed the dancing animation and said that “Now it is even nicer, since the movement is faster and as a result its movement is longer, more extensive and even nicer!” (Figure 2).

Maria on the other hand followed a different path of actions. She did not participate to the discussion with the others and chose to work on her own. Her creative actions are shown at Table 2. Firstly, her idea of dancing animation included a periodic rising and falling motion and the problem of synchronization with the song emerged naturally:

Maria: Maybe I can create this dancing move. (She started moving her hands up and down periodically.)

Researcher: Great idea! Can you think of a way?

Maria: I would try moving the shape up and down by dragging it back and forth. I will write down the limits I like the most (referring to the right and left limit values for the slider of variable z). But, first I need to find the value for which the shape is horizontal and put it in the middle. (...) Well, it is 360. 360 is the center of the move and I need to keep the same distance right and left (...) But when I listen to the song, the movement is too slow. I need to make it move faster up and down.

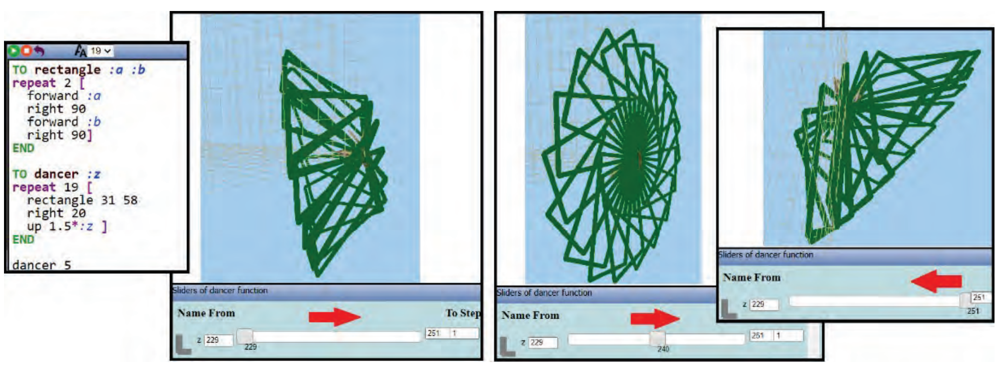

Figure 2. Maria’s final “dancing animation”

After Maria posed the question “how to create the dancing motion of moving up and down”, she generated answers through *imagining*, *manifesting* and *familiarizing* actions. As revealed by her words, she considered the value of 360 degrees to be the “center” of the dancing move, connecting it to the concept of the center of symmetry. Afterwards, she set the goal to synchronize the motion to the music rhythm. In order to achieve it, she listened to the song carefully and noted down its rhythmic period (14 seconds). She went back to her animation and tried various values for the variable z limits, all of them symmetrical to the value of 360. She timed the duration of her artefact’s period and noted that it takes 2 seconds for the slider to be dragged forth and then back when the value range is 22. Then she simulated the “up and down” motion by fixing the variable limits from 349(=360-11) to 371(=360+11). As it is shown in Table 2 (from 5th to 12th action) she went through three more circles of forming an idea, expressing it in the medium and reflecting on it, that led her to the creation of her final dancing animation (Figure 2).

Discussion

All three students participated in this study generated ideas while seeking ways for creating a dancing move and synchronizing it to the rhythm of a song. The CMAF provided an insightful scope for identifying and exploring their actions within MaLT2. We detected a sequence of creative mathematical actions, which formed circles of *imagining*, *manifesting*, *familiarizing* and *recognizing* actions, composing three unique paths of mathematical meaning-making processes. They approached mathematics in a fallibilist way, as it became the basic tool for applying their artistic ideas which were freely open for investigation and reformation. Conversely, their artistic ideas constituted of motivators for their creative way of thinking and doing mathematics. In the instances described above, they used and made meanings on the mathematical concepts of angle, variable, parameter, linear function, periodicity and central symmetry. MaLT2 was used as means for posing both mathematical and artistic questions and investigating their answers through testing and instant feedback. We conclude that both MaLT2 and the artistic context fostered naturally generated creative mathematical actions of all six types described in CMAF.

SMART – online formative assessment: Professionalising teachers & enhancing students' understanding

Katrin Klingbeil[1], Fabian Rösken[1], Bärbel Barzel[1], Daniel Thurm[2] and Florian Schacht[1]

[1]University of Duisburg-Essen, Germany; katrin.klingbeil@uni-due.de, fabian.roesken@uni-due.de

Keywords: Online formative assessment, student thinking, teacher professionalisation

This project of German Center for Teacher Education in Mathematics (DZLM) sets out to investigate the effects of SMART, an online formative assessment tool, on the professionalisation of teachers and on the development of students' understanding. Formative assessment can be conceptualised as "all those activities undertaken by teachers, and or by their students, which provide information to be used as feedback to modify the teaching and learning activities in which they are engaged" (Black & Wiliam, 1998, pp. 7–8). Core elements of formative assessment include eliciting evidence for student learning and understanding, for example, through appropriate tasks, as well as adapting classroom teaching based on the diagnostic information (Black & Wiliam, 1998). In this respect, it is important that diagnoses of students' learning do not remain on a superficial level such as the correctness of a task. Rather, diagnoses should focus on concept images and possible misconceptions of learners. Such deep diagnosis is the basis for teachers adapting their teaching in meaningful ways in order to foster their students' concept development. However, accurate and deep diagnoses usually require a considerable amount of time and effort on the side of teachers which might be the reason why formative assessment with a focus on understanding is often rarely implemented into classrooms. An expedient solution to this problem can be certain online tools such as the Australian SMART-tests ("**s**pecific **m**athematics **a**ssessments that **r**eveal **t**hinking"), which were specifically designed for this purpose by a group of researchers at the University of Melbourne (Stacey et al., 2018). SMART-tests provide not only understanding-oriented diagnoses within a few minutes, but also further teaching recommendations and information on common misconceptions. Hence, on the one hand, SMART delivers quick, directly usable results that can be used by teachers to enhance their students' understanding. However, its developers demand further research to scientifically investigate whether the system does improve student learning outcomes in general (Stacey et al., 2018). On the other hand, SMART can implicitly foster teachers' pedagogical content knowledge and thus their diagnostic skills. Nevertheless, "it also seems important to have professional development showing its advantages and distinctive features, and to provide teachers with advice on implementation." (Stacey et al., 2018, p. 20). Without such support, teachers may use the diagnosis from formative assessment environments more in the sense of a summative assessment instead of developing their teaching in an understanding-oriented way (Stacey et al., 2018).

Therefore, in addition to SMART-tests being adapted and translated for use in German-speaking countries, this project includes the design of an accompanying professional development (PD) programme to scale up the effects on teachers' diagnostic competencies and thereby students' understanding. The study will investigate to what extent teacher competencies, practices and students' understanding in the field of algebra develop through the use of the SMART system depending on whether teachers take part in an accompanying PD programme:

1.	How do teachers' diagnostic and support skills and teachers' self-efficacy beliefs about digital formative assessment develop through the use of the SMART tests?
2.	What kind of support do teachers implement in their lessons depending on the type of support teachers receive?
3.	How do teachers integrate SMART test results into their teaching?
4.	How do students' conceptual understanding and misconceptions develop through the use of SMART?

Figure 1: Research questions

These research questions are investigated by comparing three groups of teachers and their students (see Figure 2). While both first and second group will receive SMART diagnoses and teaching suggestions, only teachers from group 1 will be supported by an accompanying PD programme. Teachers in group 3 (control group) will only receive the corrected results of their students but neither a diagnosis in the form of stages of understanding and misconceptions nor any teaching suggestions.

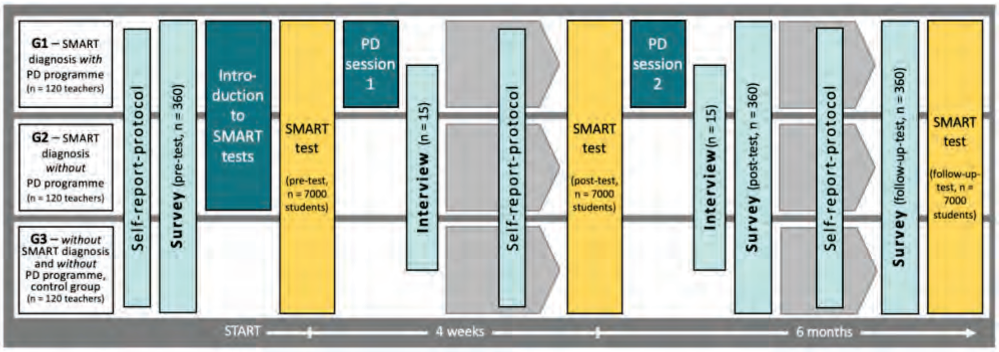

Figure 2: Research design

To answer the research questions, different types of data will be gathered: On the teacher level we assess teachers' diagnostic competencies and beliefs with questionnaires. Additionally, teachers' formative assessment practices in the classroom will be captured by pre-structured self-report-protocol. Furthermore, we conduct qualitative interviews with a subset of teachers from each group. On the student level, we gather data on student understanding by using the SMART-tests.

A first small pilot has shown, firstly, that German students indeed exhibit the misconceptions that were intended to be tested by the Australian developers. Secondly, although teachers acknowledge that knowledge gaps were filled by SMART information, their understanding and conclusions from the information differ considerably. This supports our presumption that additional PD might be helpful to further enhance teachers' formative assessment competencies.

In this article, we investigated differences in the effects of student-owned smartphones (BYOD) and provided smartphones (pool) on mathematics modeling competence development and cognitive load. Therefore, we conducted an intervention study, used a Rasch model and applied a mixed model ANOVA to investigate the competence development (n = 176) as well as a Mann-Whitney U test to investigate the cognitive load (n = 186). We showed that there is no significant difference between the two treatment groups in terms of their competence development (p = .876). For cognitive load, we showed for one task that learners in the BYOD group were significantly less cognitively loaded than learners in the pool group (p = .047) and no significant differences for four other tasks (.08 ≤ p ≤ .579).

Keywords: Handheld devices, technology planning, influence of technology.

Introduction

An essential question when using digital media and tools in the classroom is with which device the students should access the digital materials. In addition to the question of the device type (e.g., desktop computer, laptop, tablet, smartphone, ...), it is also relevant whether students' own devices or school devices should be used—although it does not seem logistically sensible for all device types (e.g., desktop computers) to have students bring them to school. The question does not become clearer if one takes into account that different variants of the two possibilities mentioned exist, which differ, for example, in terms of the concrete design of the variables ownership, device management and device availability. Furthermore, differences arise from the device provisioning concepts, for example in the distraction potential of the devices or in the student motivation. In addition to the great uncertainty, this question also has great significance for school learning. In the study presented here, the two provisioning concepts BYOD ("bring your own device") and pool are compared with each other in terms of competence development and the directly connected cognitive load perceived by students when working either with their own devices or with provided devices.

Theoretical Background

Device Provisioning Concepts

Any use of digital media requires access to a suitable digital device. There is a wide range of concepts for the provision of mobile devices such as laptops, tablets or smartphones. In the school context, most commonly the concepts of *BYOD*, *GYOD*, *COPE* and *pool* are used (see Table 1). Under the

BYOD ("bring your own device") concept, students' private devices are used at school. Also, under the GYOD ("get your own device") concept, private devices are used at school, but the school limits more or less precisely which devices may be purchased by the students, thus reducing or eliminating device heterogeneity in the classroom. Under the COPE ("corporate owned, personally enabled") concept, learners are given school-owned devices to use on a long-term basis. Whereas in the concepts mentioned so far the devices are available to the students outside of class time and can thus also be used, for example, when working on homework, this is generally not possible under the pool concept. Within this concept, the school acquires a pool of devices—often several class sets—and usually only issues them to the students for short-term use during class time.

Table 1: Characteristics of Different Device Provisioning Concepts

Device provisioning concept	Device owner and cost bearer	Device selection	Device management	Device availability
BYOD [a]	Student	Student	Student	In and out of class
GYOD [b]	Student	Preselection or full selection by school	Student	In and out of class
COPE [c]	School	School	Student and school	In and out of class
Pool [d]	School	School	School	In class

Note. The most common realizations of the four device provisioning concepts are given. Some of the stated realizations are not unambiguous, but may vary slightly.

[a] Acronym for "bring your own device". [b] Acronym for "get your own device". [c] Acronym for "corporate owned, personally enabled". [d] Short for *device pool*.

The differing characteristics result in further potentially learning-relevant consequences between the concepts. On the one hand, digital devices have a certain potential for distraction (Karsenti & Fievez, 2013), which may also increase with greater possibilities for individualization and inhibits the growth of competencies. In contrast, however, students are more motivated when digital devices are used for learning (Burden et al., 2012). This motivation may vary depending on ownership or individualization opportunities.

Cognitive Load

According to the multi-store model of memory, a limiting factor for learning is the finite capacity of working memory (Atkinson & Shiffrin, 1968). However, this memory is stressed by different types of cognitive load during learning. Specifically, three types of cognitive load can be distinguished that affect learners: intrinsic cognitive load, extraneous cognitive load and germane cognitive load (Sweller, 1988). While intrinsic load is dependent on the complexity of the learning object, extraneous load is influenced by the external learning conditions. Whereas germane load is considered as positive cognitive load and is defined by the actual learning processes. Successful learning is achieved when the total cognitive load does not exceed the capacity of the working memory.

In a study of 520 smartphone users, Ward et al. (2017) showed that the mere presence of one's own smartphone causes cognitive load. Study participants who had their smartphone on the table during a corresponding test showed significantly worse results in the area of available cognitive capacity than participants who stored their smartphone outside the test room. Whether provided smartphones cause similar effects was not investigated in this study. In contrast, however, students' familiarity with their own device can be assumed to reduce the cognitive load in the BYOD concept (cf. Welsh et al., 2018).

Mathematical Modeling

Mathematical modeling is one of six general mathematical competencies of the German educational standards (see Sekretariat der Ständigen Konferenz der Kultusminister der Länder in der Bundesrepublik Deutschland, 2004) and allows for a diverse use of digital tools (Greefrath et al., 2018).

Research Questions and Hypotheses

Since in school currently different concepts for the provision of digital devices are practiced, the question arises whether these concepts have different effects on the competence development of the students. In view of the shown effects of the presence of one's own smartphone on cognitive load, a further question arises as to what extent the smartphone-caused cognitive load differs between different provisioning concepts when the smartphones are actively used. Specifically, the following questions are investigated and the related hypotheses are tested:

RQ1	Is there a difference in effects on mathematical modeling competence development between the BYOD and pool concept?
RQ2	To what extent does the cognitive load of a task differ between the BYOD and pool concept?
H1	The mathematical modeling competence develops differently between students taught under application of the BYOD concept and those taught under application of the pool concept.
H2	The cognitive load of a task differs between students taught under application of the BYOD concept and those taught under application of the pool concept.

Method

The comparison of the two device-type-independent provisioning concepts BYOD and pool has been carried out in this study using smartphones as an exemplarily device. The main reason for this is that the BYOD concept requires that students already have their own devices of the corresponding type. In order to not make the schools' participation in the study dependent on whether or not they have a device pool (of smartphones), the students in the pool group received university smartphones that were configured in a school-like manner. For example, students were not able to install apps on their own. Since it can be assumed that an established pool concept tends to cause fewer operating difficulties for the students than using an unfamiliar operating system, pool devices with the Android and iOS operating systems have been purchased and handed out according to the operating system used by the students privately.

The Project *smart for science*

This study is part of the research project *smart for science*, which investigates how student-owned smartphones (BYOD) can be successfully integrated into school classes. For this, the project offers workshops in the subjects of mathematics, physics and chemistry on the topic of electromobility for lower secondary school classes. During these workshops, qualitative data, namely videos from students' perspective, is recorded as well as a variety of variables is collected quantitatively. This data is complemented by further general data, collected at an additional date prior to the workshops.

Sample and Data Collection

In total, 234 students participated in the mathematics workshops between November 2020 and October 2021. The study sample is a convenience sample at the class level. The sample was formed through requests for participation made to school teachers or through self-selection by teachers. However, individual students were able to opt out of data collection and thus participation in the workshop. The assignment of the students to one of the two experimental groups was randomized at the individual level.

As for two classes the workshop realization differed from the manual, these classes had to be excluded from the analysis. Furthermore, some single students had to be excluded as well, as they showed up late, had to leave early or had to leave inbetween. Moreover, for analysis of the modeling competence development 10 further students had to be excluded from the analysis, as they did not participate in the posttest or swapped their assigned posttest with their seatmate. This leads to a sample size of 186 students ($M_{\text{age}} = 13.98$, $SD_{\text{age}} = 0.69$; 88 female, 70 male, 4 non-binary) for cognitive load analysis and 176 students ($M_{\text{age}} = 13.97$, $SD_{\text{age}} = 0.69$; 83 female, 67 male, 3 non-binary) for modeling competence development analysis. The students are distributed among nine classes of grades 8 and 9 in four secondary schools from North Rhine-Westphalia, Germany.

Quantitative Study Design

Prior to attending the workshops, students completed two general quantitative questionnaires once at a preceding meeting to collect background data. Study participants were then randomly assigned at the person level to one of the two study groups, BYOD or pool. The students then attended one, two or all three of the aforementioned workshops. The two study groups were each taught in parallel by a trained project staff member.

The data collection during the mathematics workshop days have been roughly structured as follows: First, a 15-minute organizational phase, a 10-minute questionnaire and a 15-minute competence-based performance test have taken place. Then, the intervention of approximately 3:00 hours has been conducted. During this intervention, students have completed a short questionnaire after completing tasks 1, 2, 3, 5 and 8 that measured, among other things, cognitive load. Further, during task 8, students have participated in a concentration test. Finally, again a 15-minute competence-based performance test has been conducted.

The restriction and selection of the tasks to measure cognitive load took place in order not to overload the students and at the same time to get an impression of possible differences between diverse tasks. For an insight in the tasks see the following section.

Intervention

During the learning time of the mathematics workshop, students completed eight mandatory and two optional tasks (no. 9 and 10) in the area of mathematical models describing the relationship between the mileage of an electric car and the emissions of climate-changing greenhouse gases it causes.

As an introduction to the workshop, in task 1 the students watched and worked through an interactive explanatory video with quiz questions embedded using H5P. These were multiple-choice questions or a drag-and-drop cloze. In task 2, students used a CO_{2eq} calculator to determine the related CO_{2eq} emissions caused in eight life domains based on a given person description. Then, in task 3, students used a bar chart applet to visualize the determined values, created a screenshot, and shared it with the class on a digital collaborative bulletin board. In task 4, only minimal smartphone use took place when writing down the determined values of the mobility life domain (cf. task 2) analogously. In task 5, the students first used the familiar CO_{2eq} calculator as a simulator to generate data pairs of distance driven and CO_{2eq} emissions caused, and then a multi-representation system to visualize the previously obtained table of values in a coordinate system and to determine a regression line using two sliders (one each for slope and y-axis intercept). In task 6, students interpreted the regression line in the factual context; little or no smartphone use occured here. In task 7, students used the smartphone as a function plotter to graphically determine intersections and potentially as a calculator beforehand. Task 8 allowed the students to use the smartphone in a variety of ways, especially for research on the World Wide Web and also as a calculator or function plotter.

Modeling Competence Instrument

To record the students' modeling competence before and after the workshop, a competence-based performance test was used. In total, there is a pool of 16 items, which are based on items of the Institut zur Qualitätsentwicklung im Bildungswesen (n.d.), developed for the German comparative test in grade 8 (VERA-8) and were used in prior years. All 16 items measure the competence *mathematical modeling* within the core theme *functional relations*. From these, four test versions with 8 items each were created. Since the data collected will be used to explore a possible effect of the digital device, the pre- and posttest were paper-based without the use of the smartphone.

Cognitive Load Instrument

To measure task-related cognitive load, the learners rated the item "How easy or difficult was it for you to complete the task?" on a 9-point Likert scale ranging from "very very easy" to "very very difficult" after completing the respective task. This instrument is adopted from Kalyuga et al. (1999).

Data Analysis

To answer research question RQ1, the underlying competence in mathematical modeling had to be determined for each student both before and after the intervention based on the responses in the pre- and posttest. Following Item Response Theory, a one-dimensional dichotomous Rasch model (1-PL model) was used for this purpose. Any tasks that were not answered were treated as if they had been solved incorrectly. Afterwards, a mixed model ANOVA was conducted to investigate differences within time between the two groups.

To answer research question RQ2, for each of the tasks 1, 2, 3, 5 and 8 a two-sided Mann-Whitney U test was applied to the data optained by the cognitive load instrument.

Results

Mathematical Modeling Competence

The Rasch model for the investigated data showed an EAP reliability of .723 for the pretest and .701 for the posttest. Thus, it can be stated that the data met the requirements for a Rasch model. The estimation of the Rasch model was run with the R package *TAM* version 3.7.16.

The mixed model ANOVA of the mathematical modeling competence development within time between the two device provisioning concepts BYOD and pool revealed no significant difference ($p = .876$). The R package used to run the ANOVA was *ez* version 4.4.0. Figure 1 presents the mean and standard deviation as well as the distribution of the students' mathematical modeling competence of the two groups BYOD and pool at both time points. This part of the study has already been presented in Krause (in press).

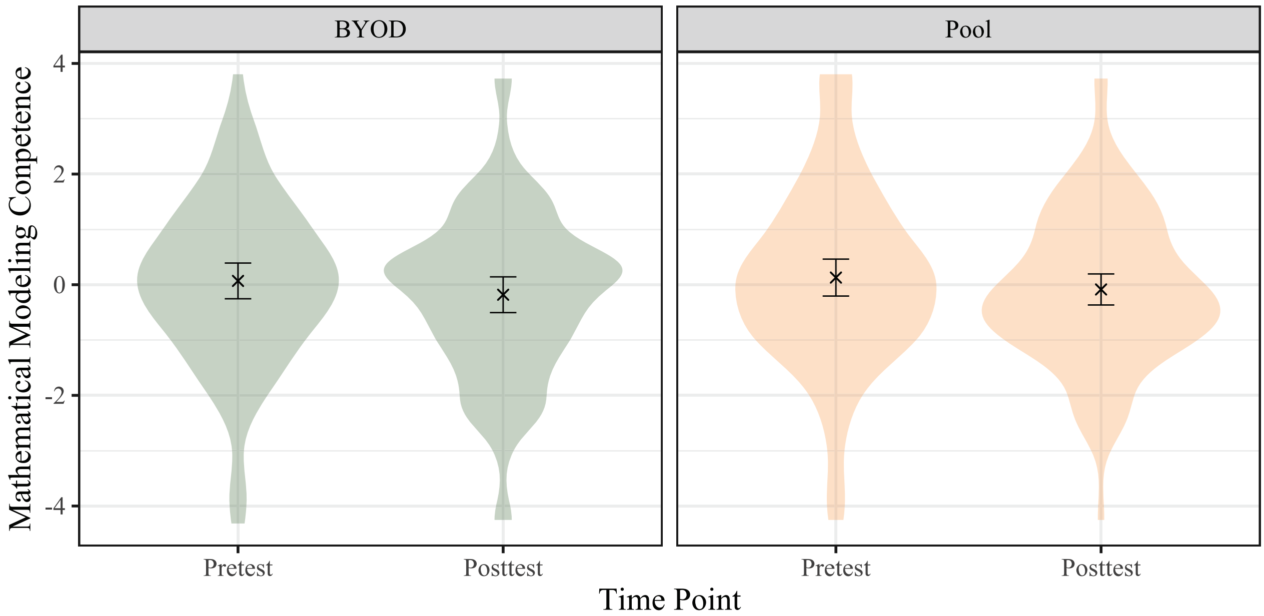

Figure 1: Mean With 95% Confidence Interval and Distribution of Students' Mathematical Modeling Competence

Cognitive Load

For task 8, students who used their own device to complete the task ($Mdn_{\text{BYOD}} = 7$, $M_{\text{BYOD}} = 6.64$) rated this task to be easier than students using a provided device ($Mdn_{\text{Pool}} = 7$, $M_{\text{Pool}} = 7.23$). A Mann-Whitney test indicated that this difference was statistically significant with small effect size, $W(N_{\text{BYOD}} = 83, N_{\text{Pool}} = 66) = 2228.5$, $z = -1.98$, $p = .047$, $r = .16$.

No significant differences were found between the two provisioning concepts for the remaining tasks 1, 2, 3 and 5 ($p = .423$; $p = .08$; $p = .579$; $p = .117$). The R package used to run the Mann-Whitney U test was *stats* version 3.6.2. Figure 2 presents the cognitive load distribution of the two study groups as box plots with whiskers with maximum 1.5 IQR for all five tasks.

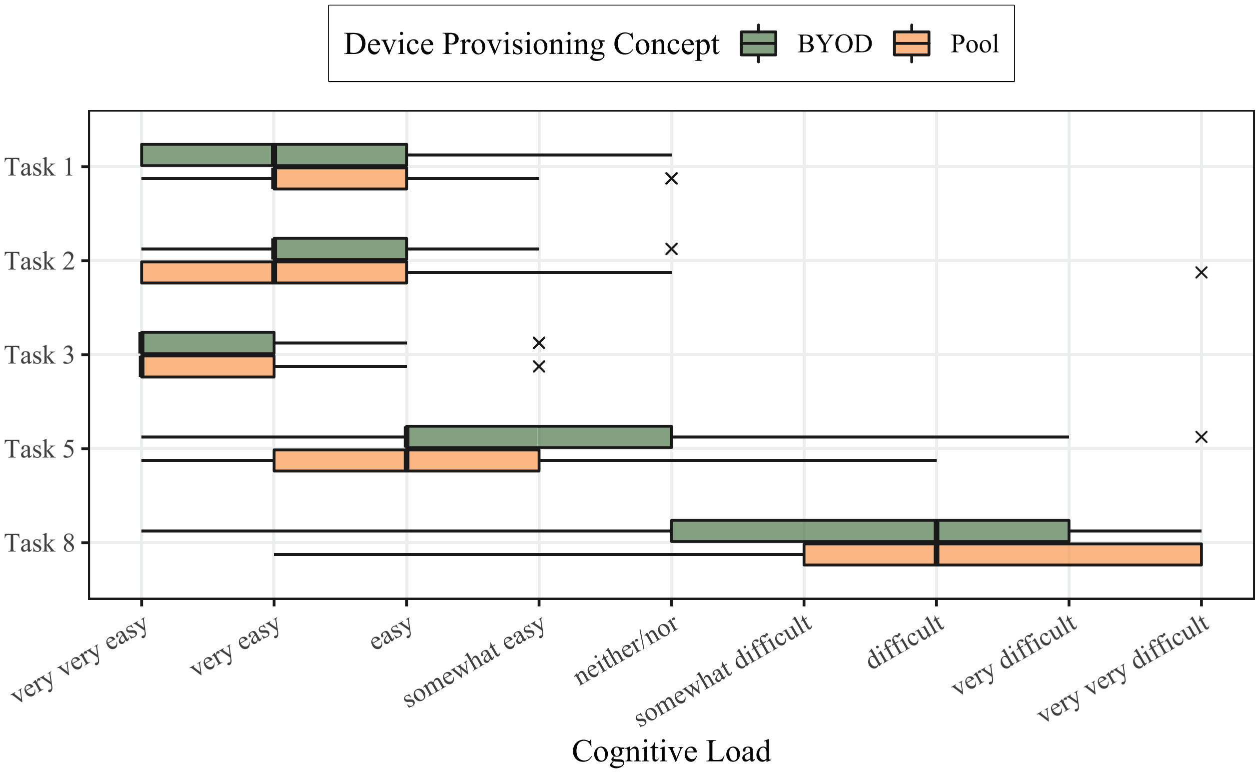

Figure 2: Cognitive Load of the Students Regarding Different Tasks

Discussion

As can be seen in Figure 1, there are only slight and non-significant differences in the students' mathematical modeling competence development within time and between the groups for this sample using the current analysis. To further investigate the research question, it is planned to repeat the analysis with a larger sample and also to consider other IRT models.

As can be seen in Figure 2, task 8 is rated as more difficult by the learners than the other tasks (in terms of 0.25-, 0.5- and 0.75-quantiles). In both experimental groups, only 25 percent of the students rated the cognitive load of task 8 as *neither/nor* or easier; whereas for all four other tasks, 75 percent of the students rated these tasks as *neither/nor* or easier. This raises the question of the extent to which the difference in cognitive load between the two groups depends on the task's cognitive load itself, possibly in particular on the cognitive load caused by the performed digital activities. Further, it is noticeable that exactly the last surveyed task shows a significant difference in cognitive load. This raises the question of the extent to which the duration of digital device use influences the observed effect. It is possible that the benefits of the BYOD concept will take effect after a (short) period of getting used to using one's own digital device at school.

Overall, we take the reported effects as indications that the advantages of using student-owned devices in the classroom may offset or exceed the disadvantages. Nevertheless, further analysis is needed to corroborate this interpretation. So far, it remains open what impact the single characteristics of the two device provisioning concepts (cf. Table 1) have on the results and thus also to what extent the results can be applied to other provisioning concepts (e.g., GYOD or COPE).

Keywords: Cognitive activation, interactive videos, H5P.

Cognitive activation in mathematics learning videos

Cognitive activation and individual learning support are key factors that explain students' learning in traditional classrooms (Baumert et al., 2010). Learning videos seem to hardly support both factors. However, activation does not mean a physical activity; instead, active participation includes active thinking. In mathematics, cognitive activation needs to be focused on mental activities that fit to the learning goals (see Leuders & Holzäpfel, 2011). Cognitive activation further means that learners engage with the subject matter at a cognitive level that is as high as possible and appropriate to their learning requirements. Cognitive activation can thus especially occur when videos are combined with tasks or interrupted for the learner's own activities. Even basic interactive elements like playback control, segmentation and table of contents improve both learning and learner satisfaction. As technology develops, there is an increasing number of possibilities to design videos in a cognitively activating way and to support individual ways of using them.

We aim to make mathematics learning videos more cognitively activating. In our poster, we present didactic scenarios taking account of the type of content during activation and individual use.

Technical background: the H5P software

The free and open-source software H5P is based on HTML5 and allows to create interactive learning content (https://h5p.org/). In particular, videos can be embedded in a container that offers predefined question formats, among others multiple-choice, drag-and-drop, and free text questions. In addition, a table of contents with navigation can be added to the video.

Didactic scenarios

Like in classroom settings, questions can serve different purposes in video: they can assess prior knowledge, support comprehension of the presented ideas, underline cognitive conflicts or stimulate further engagement with the subject (Lim & Wilson, 2018). The question formats mentioned above can be used to activate both prior knowledge and newly acquired knowledge while watching the video. The force to respond to the pop-up questions or to fill in the blanks may underline students' cognitive conflict.

Self-explanations have been found to improve both conceptual and procedural knowledge in the context of learning from worked-out examples (e.g., Berthold & Renkl, 2009). They can be supported with cloze texts. Renkl (1997) identified two types of successful self-explanations, anticipative and principle-based explanations. Implementing questions and cloze texts according to these types, we can encourage students to think ahead and establish links (anticipative explanations) as well as to reflect on the central principles underlying the presented content (principle-based explanations).

Practical Examples

In the project studiVEMINTvideos (Biehler et al., 2020), we develop videos embedded in digital learning material. The materials shall help students to autonomously review their mathematics knowledge when they transition to university.

To implement interactions in videos, we identify appropriate positions and question formats based on central problems and cognitive conflicts in the video. In the beginning of a video, we often opt for anticipative questions. In the end, we consider principle-based questions summarizing the main ideas. We adapt the number of interactions to the length of the video and try to vary the question formats within one video. In a video on the fundamental theorem of calculus, for example, we embedded three interactive questions. At the beginning, prior knowledge is activated by asking for the definition of the antiderivative with the help of a drag-and-drop question. After having explained the theorem, we explained how to generate an antiderivative. To consolidate this newly acquired knowledge and to transfer it to other functions, we embedded two single-choice questions to identify antiderivatives of given functions. Our poster will illustrate such examples. Further research will focus on students' learning with these enhanced videos.

Affordances and constraints of the Dragonbox School teaching material

[1]Andreas Lorange, [2]Jørgen Sjaastad and [2,3]Martin Carlsen

The aim of this paper is to analyze the affordances and constraints of the way dynamic representations are used in the digital learning lab 'The set line' from the Dragonbox School teaching material. The learning lab is designed for second graders. The starting point of our analysis is the task 18 + 6. Our analysis shows that 'The set line' offers affordances for the users' learning of addition and other aspects of the number concept because the regrouping involved in the addition of 18 and 6 is explicitly displayed by the dynamic representations in the learning lab. 'The set line' may also cause constraints for students' opportunities to learn the inherent mathematical concepts and relations because several operations are carried out automatically by the learning lab.

Keywords: Addition, affordances, constraints, digital tool, dynamic representation.

Introduction

Digital tools may provide dynamic representations (Ainsworth & VanLabeke, 2004; Günster, 2019) which offer visualizations of mathematical concepts and relations. The digital tool under scrutiny here, is the Dragonbox School teaching material. When users, i.e., second grade students, interact with this tool, the dynamic representations are changed according to the input of the users. Such changes may make essential features of the mathematical structures more apparent, and this may facilitate understanding of the mathematical concepts and relations involved. If the students had been working with static representations, like concrete materials, these structures would in many cases not have been made apparent in the same way. For example, students may separate a digital rod representing the number 7 into a two rod and a five rod. This process demonstrates a decomposition of the number 7 not facilitated by physical rods in the same manner.

The reason for choosing the Dragonbox School teaching material, from now on called 'Dragonbox School', is that it contains digital learning labs which facilitate open-ended explorations and visualizations of mathematical concepts and relations using dynamic representations. These learning labs are designed in a way that enables the students to use them with little or no support from the teacher. The students are invited to explore on their own how the learning labs work and use these labs to explore mathematical concepts and relations. This approach to designing mathematical teaching material is rather novel. Because Dragonbox School was launched in 2018, very little research is carried out concerning this teaching material. Therefore, it is interesting to know more about the affordances offered by the learning labs, and the constraints they may cause in the learning process.

Dragonbox School is made by the company Kahoot Dragonbox AS and is used in Norway, Finland, and France. It consists of digital resources, textbooks, and concrete manipulatives for 1st to 4th grade. The digital resources consist of learning labs and quizzes developed for use on tablets or laptops with touchscreens. The quizzes are learning labs combined with mathematical tasks. The textbooks mainly consist of different types of tasks the students may work with. The concrete manipulatives, called *nooms*, are a development of the Cuisenaire rods (March, 1977). These concrete manipulatives also appear digitally in the learning labs and quizzes. Each of these manipulatives corresponds to a natural number between 1 and 10, see Figure 1.

Figure 1: The nooms in Dragonbox School

Dragonbox School is supposed to be used according to 'The Dragonbox method'. In the teacher manual (Dragonbox Kahoot, 2021), every lesson is structured according to this method. Each lesson consists of four phases: 1) exploration; 2) discussion; 3) practice; and 4) recapitulation. In the exploration phase, the students explore a digital learning lab individually, with a fellow student, or with the teacher in a whole class discussion. In the discussion phase, the students are given time to think, discuss with a learning partner, and share their reasoning with the teacher and the rest of the class. In the practice phase, it is recommended that the students start to work with the quizzes and then solve tasks in the textbook. In the recapitulation phase, the teacher facilitates a whole class discussion about the learning goal of the lesson and how the activities of the students are linked to this goal.

Theoretical framework

The work of Brissiaud (2016) has been central in the development of Dragonbox School (Uggerud, 2021). Brissiaud argues that solid understanding of a number means having access to its decompositions. This claim is supported by other researchers (Anghileri, 2000; Ma, 2010). With a developed conceptualization of the cardinality of number, e.g., the number eight, a student can easily think of different decompositions of this number: 8 = 7 + 1, 8 = 5 + 3, 8 = 4 + 4, etc. The idea of decomposition and composition led to the construction of the nooms, which play important roles in Dragonbox School. Using a tablet, one can split (decompose) one noom into two smaller nooms by 'slicing' it with the finger, and one can join two nooms (compose) by moving one on the top of the other. Then the bottom noom will 'eat' the upper noom and grow accordingly.

Duval’s (2006) theory of representations is central in our analysis of Dragonbox School. He defined the concept of representation as “something that stands for something else” (p. 103). He stressed that “the ability to change from one representation to another is very often the critical threshold for progress in learning and for problem solving” (Duval, 2006, p. 107). Dragonbox School offers several activities where students have to change from one representation to another. The concepts of treatments and conversions are core elements in Duval’s theory of representations. Treatments are “transformations of representations that happen within the same register” (Duval, 2006, p. 111), e.g., decomposing a 6-noom into a 2-noom and a 4-noom and composing a 5-noom by concatenating a 3-noom and a 2-noom. Conversions are “transformations of representations that consist of changing a register without changing the objects being denoted” (Duval, 2006, p. 112), e.g., transforming the number 6 into the 6-noom. When the students manipulate the dynamic representations in the learning labs and quizzes of Dragonbox School, both conversions and treatments are carried out. Skemp’s (1976) terminology of ‘relational understanding’ and ‘instrumental understanding’ of mathematics will also play an important role in our analysis of Dragonbox School. ‘Relational understanding’ refers to “knowing both what to do and why” (Skemp, 1976, p. 20), and ‘instrumental understanding’ refers to “rules without reason” (Skemp, 1976, p. 20). Relational understanding should, according to Skemp, be the goal of mathematical learning.

Affordances and constraints are two terms often used in mathematics education research in evaluation of teaching materials and learning activities (e.g., Carlsen et al., 2016; David & Watson, 2008). Gibson (1979) launched these terms. He defines *affordances* as relationships between the environment and the animal, in our case the digital environment of Dragonbox School and students. Gibson argues that these affordances exist independently of the user, but the user has to perceive these in order for them to be realized. Additionally, Norman (1988) emphasizes that affordances are linked to cultural conventions. We thus argue that in a digital environment, affordances denote action possibilities offered by a digital tool with respect to the capabilities of the user of that tool. The goals of actions and interactions with a digital tool, the user’s mathematical experience, and the mathematics classroom culture fundamentally informs the user’s perception of affordances. *Constraints* is a term that denotes factors delimiting the user’s actions and interactions with the environment. Such delimitations may support the user to focus at intended mathematical content.

In our study, inspired by Gibson (1979) and Norman (1988), we draw on these constructs and situate them to fit our purpose of analyzing Dragonbox School. Therefore, we use affordances to denote possibilities offered for the user’s actions and interactions with a digital tool that, if perceived, may nurture the development of relational understanding. We use constraints, despite the term’s denotations as to also support users’ attention, to denote the inherently emerging restrictions for the user’s actions and interactions with a digital tool that may delimit opportunities for developing relational understanding.

Based on these ideas and considerations, we will analyze a specific learning lab called ‘The set line’, which will be described below. We have thus formulated the following research question:

> Which affordances and constraints can be identified in ‘The set line’ with respect to how it facilitates treatments and conversions in addition of single- and two-digit numbers?

Presentation and analysis of the learning lab ‘The set line’

We immersed ourselves with the Dragonbox School teaching material and familiarized ourselves with its various resources. Particularly, we became interested in the learning labs due to their visualizations of natural numbers. In this study we analyze a learning lab called ‘The set line’ because it explicitly displays both treatments and conversions (cf. Duval, 2006). We inspected actions made possible by this learning lab, and further analyzed these actions’ affordances and constraints with respect to the task “Compute 18 + 6”. We have chosen this task because it involves the decomposition of 6 into 2 and 4. Such decompositions are a central theme both in the Norwegian curriculum (Utdanningsdirektoratet, 2020) and in Dragonbox School. Moreover, decompositions are fundamental to understanding addition and numbers in general (Brissiaud, 2016).

The insertion of 18 into the two first containers[1]

To carry out the calculation 18 + 6, the student must start by producing the number 18. To do this, the student has to press the grey area on the tube in the upper left corner of the tablet surface, causing three empty fields to appear (see Figure 2). Then, in the last two of these, the student must write 18 using a finger on the tablet surface. Then a 10-noom (black) and an 8-noom (pink) emerge from the tube displayed on top of each other (to the left in Figure 2). Using the terminology of Duval (2006), the digital tool conducts a hidden treatment of the number 18 into the numbers 10 and 8. Then, a conversion of the numbers 10 and 8 into the 10-noom and 8-noom is carried out and visualized. Therefore, this treatment-conversion may nurture the development of relational understanding of the number 18. This treatment-conversion may thus constitute an affordance in the student’s learning process.

To proceed with the calculation, the student has to press the 10-noom and the 8-noom using a finger. When this is done, a funnel appears at the left side of the first container, see Figure 2:

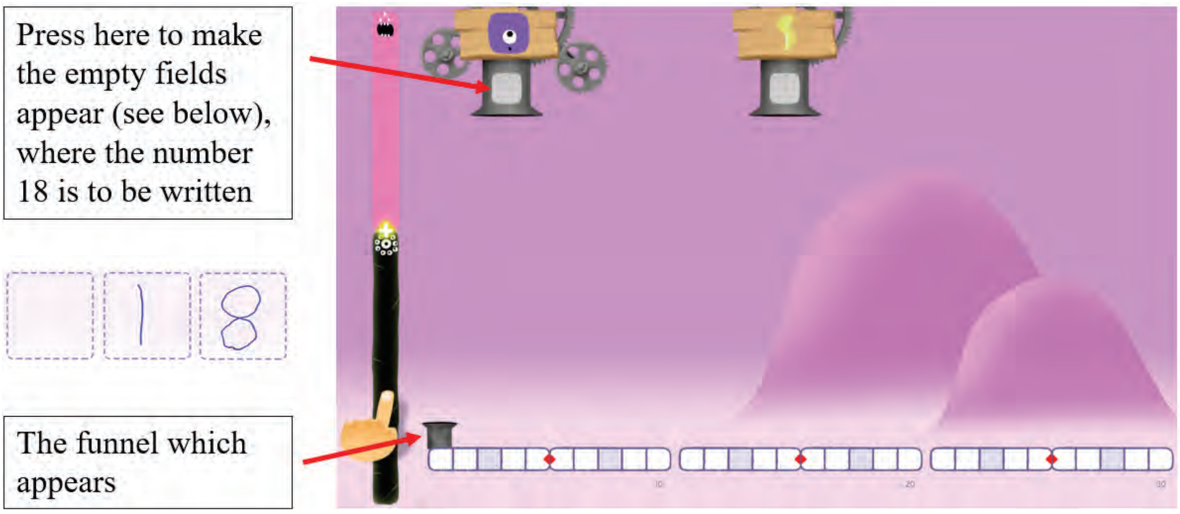

Figure 2: The funnel appears when the 10-noom and 8-noom are pressed. Text boxes and arrows are added by the authors

[1] By “container” we mean one tube with space for ten 1-nooms, as displayed at the bottom of the tool screen in Figure 2.

The funnel is automatically positioned at the correct place, namely at the first vacant cell in the first container. This informs the student about what to do next, that is, to insert the 10-noom and the 8-noom into the first container through the funnel. When the 10-noom and the 8-noom are inserted into the funnel, ten 1-nooms are fed one by one into the container, and a 'thumping' sound is heard as each 1-noom is fed into the container, see Figure 3. Then the feeding-process stops, and the remaining 8-noom is automatically moved to the second container. Using the terminology of Duval (2006), a treatment from one 10-noom to ten 1-nooms is carried out and explicitly displayed by the learning lab. This may nurture the development of relational understanding of this treatment and may thus constitute an affordance in the student's learning process.

When the remaining 8-noom is moved to the second container, a funnel automatically appears at the first empty cell in the second container, see Figure 3. In this way the student is informed about what to do next, namely, to insert the 8-noom into the first vacant cell in the second container. When pressing the appeared funnel, the 8-noom is fed into this container in a similar way as the 10-noom was fed into the first container. Nevertheless, the two automatic actions may constitute a constraint in the student's learning process. The only thing the student needs to do, is to insert the 10-noom and the 8-noom into the funnels. This may be mastered without relational understanding of the composition of the number 18. These two automatic actions may thus delimit the development of relational understanding.

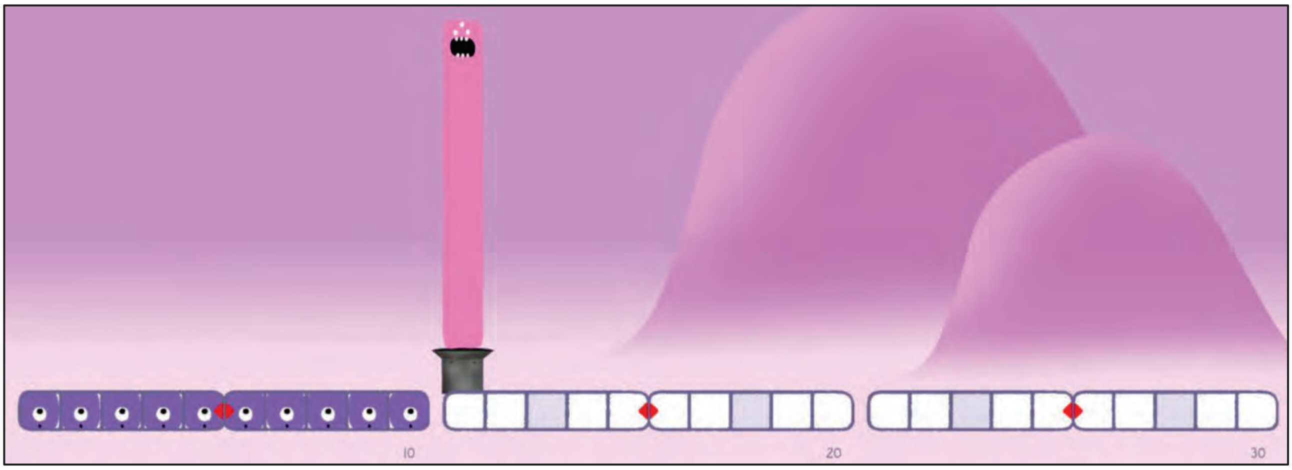

Figure 3: The remaining 8-noom is moved to the second container and a funnel appears

The insertion of 6 into the second and the third containers

To proceed with the calculation 18 + 6, the student needs to press the grey area on the tube once more, as when producing the number 18, and write 6 in the empty fields that appear to produce a 6-noom (orange). To complete the calculation, the 6-noom has to be decomposed into a 2-noom and a 4-noom. This decomposition can be carried out either automatically or manually. We begin with explaining how this can be done automatically. First, the student has to press the 6-noom. When this is done, a funnel with an addition sign automatically appears at the first vacant cell in the second container, see Figure 4.

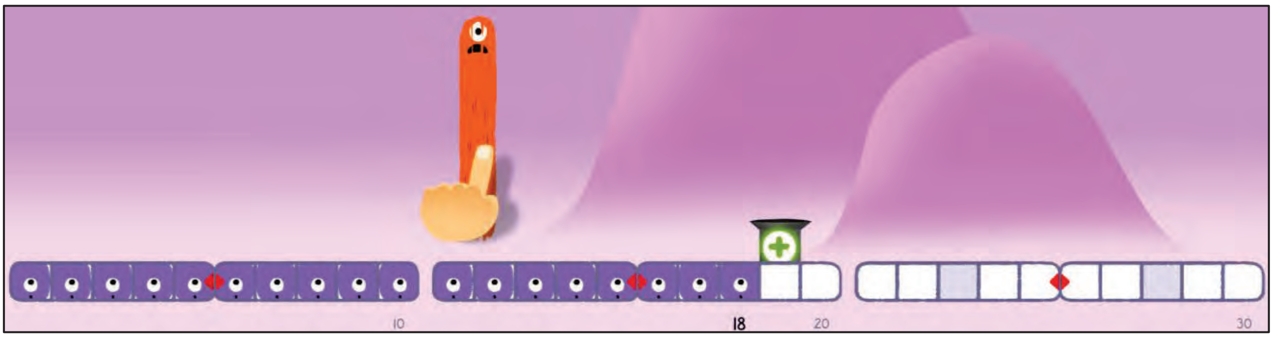

Figure 4: A funnel appears in the first vacant cell in the second container

The positioning of this funnel informs the student to insert the 6-noom into the funnel at the correct place, namely, the first vacant cell in the second container. This is indicating that the second container should be filled first. When the student moves the 6-noom to the funnel and presses the funnel, the 6-noom is starting to be fed into the container, but the process stops after the two first 1-nooms are fed into the container. Then the second container is full, and the remaining 4-noom (green) and the funnel are automatically moved to the first vacant cell in the third container, see Figure 5. Then the student has to press this funnel to insert the 4-noom into the third container.

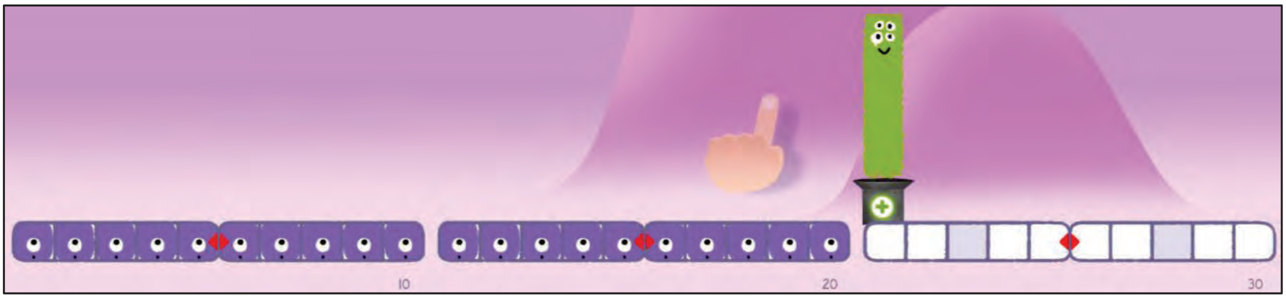

Figure 5: A funnel appears in the first vacant cell in the third container

In this way the student may notice the decomposition of the 6-noom into one 2-noom and one 4-noom. According to a Duvalian (2006) stance, this corresponds to a treatment from one 6-noom to one 2-noom and one 4-noom. This treatment is explicitly displayed, and this may nurture the development of relational understanding of the decomposition of 6 into 2 and 4. This treatment may thus constitute an affordance in the student's learning process. However, the automatic appearances of the two funnels at the correct places, may constitute constraints in the student's learning process. The only thing the student needs to do to proceed with the calculation is to feed the nooms into the funnels. This may be mastered without relational understanding of the decomposition of 6 into 2 and 4. The automatic appearances of the two funnels at the correct places may thus delimit the development of relational understanding.

When the student presses the funnel to insert the 4-noom into the third container, the number 24 automatically appears below the last 1-noom in the third container, see Figure 6. The appearance of this number corresponds to a hidden conversion from twenty-four 1-nooms into twenty-four 1s, which through a treatment become the number 24. This visualizes that the number 24 consists of two containers filled with ten 1-nooms each, and a container filled with four 1-nooms. This visualization may nurture the development of relational understanding of the number 24. Thus, the automatic conversion-treatment from twenty-four 1-nooms to the number 24, may constitute an affordance in the student's learning process.

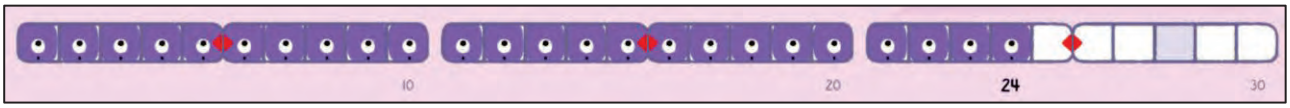

Figure 6: The conversion from twenty-four 1-nooms to the number 24

The decomposition of the 6-noom into the 2-noom and the 4-noom can also be carried out manually by 'slicing' the 6-noom with the finger. If this 'slicing' is done correctly, that is a bit above or below the middle of the 6-noom, the 6-noom will be decomposed into a 2-noom and a 4-noom. Then the 2-noom can be inserted in the second container, and the 4-noom in the third container. This manual decomposition may constitute an affordance in the students' learning process because it may nurture the development of relational understanding of the decomposition of 6 into 2 and 4.

Discussion and conclusion

Our analyses show that 'The set line' may constitute both affordances and constraints with respect to students' learning process. Firstly, we will address the affordances. These relate to how the learning lab may nurture the development of relational understanding by utilizing the dynamic potential of visualizing the addition process. With respect to conversions (Duval, 2006), the learning lab for instance transforms the numbers 10 and 8 into a 10-noom and an 8-noom. With respect to treatments (Duval, 2006), the learning lab visualizes transformations within the noom-setting: how the 10-noom is made up of ten 1-nooms, and how the 6-noom strategically can be decomposed into a 2-noom and a 4-noom in order to utilize the grouping of tens in our number system. Moreover, the learning lab visualizes how addition is executed by adding the second addend from where the first addend ends at the set line and then reading off the final endpoint. Thus, we claim that 'The set line' offers substantial affordances when it comes to visualizing basic number concepts and relations.

In our analyses, we have described operations that are automatically carried out by 'The set line'. These operations may facilitate the learning process because the students are guided regarding what to do next. Therefore, it is likely that the students may be able to operate this learning lab with little or no support from the teacher. This is an important point because one purpose of the learning labs is to enable users to explore mathematical concepts and relations on their own. However, the operations that are carried out automatically, may constrain students that would benefit from conducting these operations themselves. Moreover, these automatic operations may enable students to solve the tasks at hand without having relationally understood these operations. The students may write the numbers provided by the tasks without reflecting on the meaning of the numbers, and they may move the available noom(s) to the nearby funnel without reflecting on why this should be done and without paying attention to the ongoing visualizations. Furthermore, if the decomposition of the 6-noom into the 2-noom and 4-noom is carried out automatically, the students may be constrained from deciding on how the decomposition of the second addend is to be carried out. The operations that are automatically carried out may thus deprive the students of opportunities for learning.

We want to point out that if 'The set line' is used according to the Dragonbox method, the impact of the constraints we have described, may be significantly reduced. This method strongly recommends teachers to nurture student reasoning concerning the inherent mathematical content of the learning labs and quizzes. The Dragonbox method is explained in the teacher manual, and it is also taught in courses for the teachers who use Dragonbox School. Nevertheless, to inform and teach about the Dragonbox method do not necessarily prevent students from using the learning labs and quizzes without achieving relational understanding.

Our conclusion is that 'The set line' may offer both affordances and constraints in the users' learning process. The students' outcome is to a great extent dependent on teachers facilitating student reasoning about the dynamic representations and the inherent compositions and decompositions (cf. Brissiaud, 2016) of the learning lab. Further, empirical research is needed that investigate whether the identified affordances and constraints are experienced as such by students who engage with the learning labs.

Instrumental orchestrations by a university teacher in an online linear algebra course

José Orozco-Santiago[1], Armando Cuevas-Vallejo[2] and Luc Trouche[3]

In this article, we present an instrumental orchestration for online math education. The case study is of a university teacher in a linear algebra course with engineering students in a remote learning setting. We used the instrumental orchestration approach as a theoretical framework for planning and organizing the artifacts involved in the environment (didactic configuration) and the modalities of their implementation (mode of exploitation). The activities were designed using virtual manipulators, guided exploration sheets, and video recordings of individual or paired work by the students. The results of the observation of five sessions are presented and the orchestrations of a pedagogical sequence to introduce the concepts of value and eigenvector are briefly discussed. This work suggests new instrumental orchestrations for the teaching of mathematics online.

Keywords: Instrumental orchestration, linear algebra teaching and learning, university mathematics, online course.

Introduction.

In March 2020, the World Health Organization declared a global pandemic due to COVID-19 and recommended lockdowns and mobility restrictions, forcing educational institutions to migrate from their face-to-face teaching model to online education (Engelbrecht et al., 2020). Most institutions had to improvise online courses using various digital devices and internet platforms. Although remote education has been developing for years in various forms –distance learning, e-learning, and hybrid learning– to reach more students (Silverman & Hoyos, 2018), it had not fully permeated most educational institutions. Oktaç (2004) reports the implementation of a remote introductory linear algebra course in an asynchronous learning environment. Teaching linear algebra online is a challenge, as it is one of the first abstract math courses students encounter during their early years in college. At ICME13, there was a discussion group on teaching and learning linear algebra, which considered the ways a linear algebra course could be adapted to meet the needs of students from other disciplines, such as engineering, physics, and computer science. It also reflected on how technology should be used in teaching linear algebra (Stewart et al., 2018, p. ix). Gol-Tabaghi and Sinclair (2013) studied the geometry of eigenvalues and real eigenvectors of a 2×2 matrix using dynamic geometry software (DGS), in which by dragging the vector x onto the screen, the vector Ax moves accordingly. They concluded that dynamic geometric representations in the sketch enabled students to understand the concepts of eigenvector and eigenvalue by identifying their invariant geometric properties and helped them develop dynamic-synthetic-geometric thinking.

On the other hand, and perhaps in anticipation of the current circumstances, Trouche (2004) introduced the notion of *instrumental orchestration* for planning a lesson, defined as the didactic management of the different artifacts available in the classroom, the organization of space and time, and the way the artifacts are connected.

Theoretical background

An instrumental orchestration is “the intentional and systematic organization of the various artifacts available in a computerized learning environment by the teacher for a given mathematical situation, in order to guide students’ instrumental genesis” (Drijvers & Trouche, 2008, p. 377). An instrumental orchestration is defined by a didactical configuration and the way in which this configuration is exploited. The Sherpa-student orchestration, which involves a student whose computer or calculator is displayed to the rest of the class on a projector, was for several years an emblematic didactic configuration. For a given configuration, there are several possible operating modes. As an instrumental orchestration is partly prepared in advance and partly created "on the spot" during teaching, Drijvers and colleagues (2010) add a third level called *didactical performance* to account for the multiple adjustments that the teacher and students may make. Drijvers and colleagues (2010) suggest considering the triplets model, a sort of jazz ensemble composed of beginners, advanced musicians, and the teacher as a conductor who prepares joint participation, but who is open to the pupil’s improvisation and interpretation, on order to recognize the contributions of each of these levels. This metaphor became a reality in our experience because there was no precedent for online teaching of linear algebra, so we had to "improvise" ways and methods to teach both the mathematical task and the technological tool, for example, the forms of student-student and student-teacher through communication through the platform. Drijvers and his colleagues have extended the repertoire of instrumental orchestrations to include technical-demo, explain-the-screen, link-screen-board, discuss-the-screen, spot-and-show, Sherpa-at-work (Drijvers et al., 2010), board-instruction and guide-and-explain (Drijvers et al., 2013). In the first three orchestrations is it mainly the teacher leading the communication, while in next three students have more opportunities for participation. In the technical-demo orchestration, the teacher explains the basic techniques of a tool in order to familiarize students with it.

In the explain-the-screen orchestration the teacher explains what is happening on the computer screen, but unlike the previous one, this orchestration involves mathematical content. Technical-support orchestration refers to the process of helping the learner with technical issues with the tool, such as software and/or hardware issues. Discuss-the-screen orchestration involves a group discussion about what is happening on the computer screen. In the link-screen-board orchestration, the teacher refers to the relationship between what the tool displays and the mathematical concept. In spot-and-show orchestration, the teacher chooses a student's work before class, either for the student to explain in class or for discussion with the whole class. For the Sherpa-at-work orchestration, the teacher asks a student (referred to as the Sherpa) to demonstrate or perform a certain process in the technological environment (for details, see Drijvers et al., 2013). Thus, our research question is: What instrumental orchestrations are applied by a university professor using technology to teach the concept of eigenvalue and eigenvector in a distance education setting?

Method

The study was developed under a design-based research methodology, which consists of three research phases: preparation and design, teaching experiment and, retrospective analysis (Bakker, 2018). A first research cycle (Orozco-Santiago, 2020) was carried out in face-to-face teaching. For the design of our task sequence, we used a hypothetical learning trajectory (Simon, 1995) but, due to the global public health emergency caused by COVID-19, circumstances compelled them to use the Zoom platform for the first time for online teaching. However, the teacher has extensive experience in the use of digital resources. The trajectory consists of seven activities. During the second cycle of research, the teaching experiment was carried out with a small group of ten students (6 women and 4 men) in their second year of engineering studies at a Mexican public university, over a period of two weeks. When designing the didactic path of our work, we were able to detect a priori the use of the following orchestrations for the teacher (Figure 1), and each activity for the pupils was accompanied by a didactic interactive virtual environment (DIVE) and a guided exploration sheet.

Figure 1: Orchestration suggestions for teachers

The design of a configuration depends on the technological environment (Figure 2), and in this case the students had laptops or mobile devices (smartphones, tablets). However, the hardware and conditions available to them for remote study were less than ideal. Internet connections were quite weak, there was noise at home and outside, and due to pandemic conditions, students were prone to stress. Most students could not use their cameras or microphones during courses because these require more bandwidth, which many did not have. In the course, the following topics had already been taught: matrices, systems of linear equations, vector spaces, linear combination, linear independence, and linear transformations. The participants had not previously studied the concept of eigenvalue and eigenvector.

Throughout the course, activity data was collected by the following: a) e-mail; b) WhatsApp; c) Google Drive; d) the Zoom platform; e) free software for video recording OBS Studio; d) digital capture of students' notebooks; e) video recordings of the researcher's classroom activities on Zoom; and f) video recording of student work and teamwork, in the DIVE and guided exploration sheets. Five of the lectures on the concepts of eigenvalues and eigenvectors were recorded on video. To answer the research question, after the end of the teaching experiment, the five video recordings of the class were observed and the data analysis presented in this article focused on the identification of the orchestrations proposed by Drijvers and colleagues (2013), in the first three video recordings. In the video recording of session 1 (S1), 12 different episodes were identified. In S2 19 and in S3, 21.

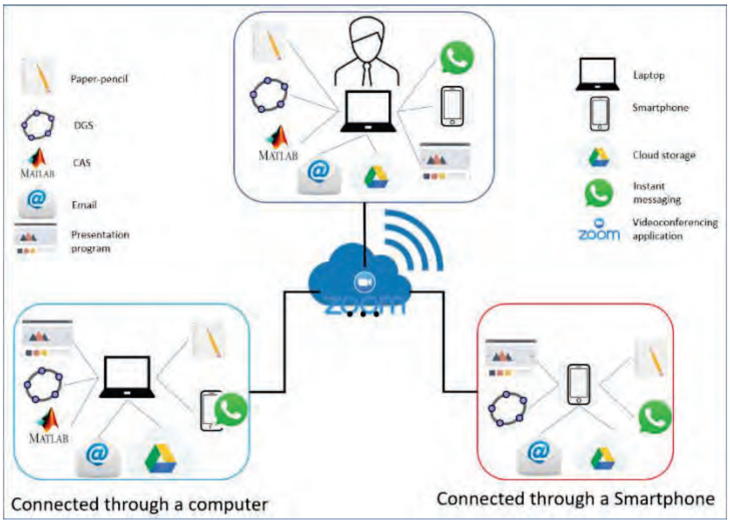

Figure 2: A remote configuration

Results

The instrumental orchestrations reported by Trouche (2004) and Drijvers et al. (2010, 2013), were developed within the framework of face-to-face teaching where the teacher and the students are in a classroom. But because of lockdown requirements during the pandemic, this teaching experience was developed synchronously online, which allowed for the use of some orchestrations and required the improvisation of others. For example, the technical-demo orchestration was used for the students to familiarize themselves with the Zoom software, offering instructions on how to use meeting control.

Since in the virtual model, the Work-and-walk-by orchestration was not possible, and we wanted to observe the individual instrumental genesis developed by the students and at the same time discuss as a group the correctness or not of the answers and the work of each student, the modality that we called *Student-shared-screen* appeared, which allowed the teacher to accomplish the task, it should be noted that the name, the peculiarity, and the characteristic of this orchestration are made in the analysis after the experiment with the data obtained described in Figures 1 and 2. As this orchestration was improvised, when we analyzed the data and using the taxonomy defined by Drijvers and colleagues, they mention that the didactic configuration for the Spot-and-show orchestration "includes access to the students' work in the technological environment during lesson preparation" and for Sherpa-at-work orchestration, "includes access to the technology and projecting facilities, preferably access to student work" (2013, p. 999), but to implement access to the pupil's screen, it is necessary to ask the student's permission. Not having found an orchestration for this type of activity which we believe is important in online education, we call it the new Student-shared-screen orchestration, which consists of a didactic configuration in which the student allows the whole class to access his work on his computer screen. As an exploitation mode, the teacher asks the student to share his screen and discuss his work with the whole group. As can be seen, this is an orchestration prior to Sherpa-at-work and spot-and-show.

To simulate chalk, the teacher chose to use the Zoom Annotation tool and use a blank PowerPoint slide or a DIVE as a whiteboard, on which the teacher and students could write in order to present, explain and solve the exercises. We will call this the *Share-board* orchestration, and it is a recurring didactical configuration very similar to traditional classroom teaching (see Figure 3).

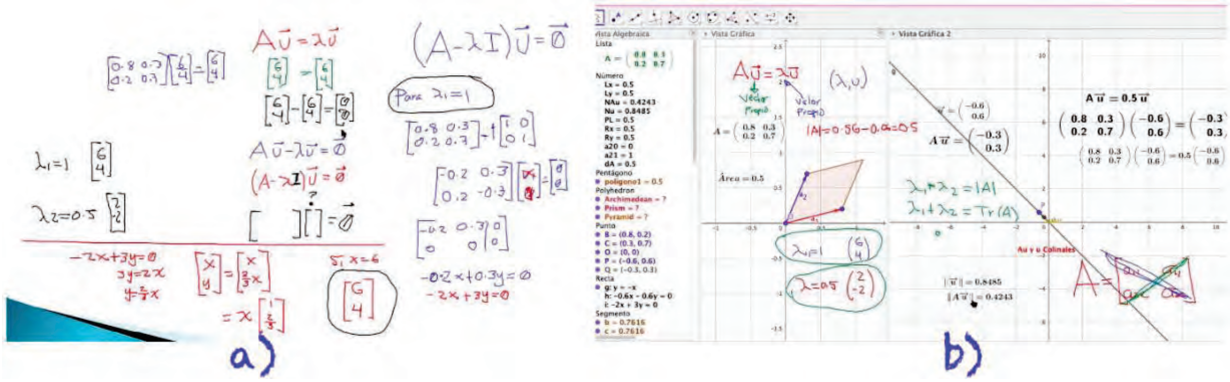

Figure 3: a) PowerPoint and b) DGE, both used as a whiteboard

In the third task, students had to drag two vectors onto $\mathbb{R}^2$ in the DGS and observe their relationship to the columns of a 2×2 matrix. The teacher identified an inappropriate response from the video recordings: some students did not drag the vectors, but directly changed the values of the matrix in the algebraic view. Through to the student-share-screen and spot-and-show orchestration, the teacher decides to ask the student to explain to the whole class how he modified the matrix,

Teacher:	The coordinates of the vector a: what relation does it have with the matrix A?
Student1:	None.
Teacher:	When you drag vector a1, what happens to matrix A?
Student1:	Nothing happens to it.
Student2:	Changes the values a11 and a22 of the matrix [this answer is provided by the chat].
Student3:	The values in the first column change.

Students who did not drag the vectors and directly modified the values of the matrix failed to identify the relationship between the vectors and the columns of matrix A. This didactical performance was observed thanks to the design of the DGS.

For the fourth task, the teacher used the explain-the-screen and share-board orchestration, using the work of one of the students as a mode of exploitation. The selected student's work was the criteria for the first work to be uploaded to Google Drive (see Figure 4).

For the next activity, construct matrix A.
Drag the point **P** (vector $\vec{u}$) and position (if possible) the vector $\vec{u}$ collinear with the vector $A\vec{u}$ and note its coordinates.

$\vec{u}$	$A\vec{u}$	λ Proportionality ratio between $A\vec{u}$ and $\vec{u}$
(6,4)	(6,4)	1
(−2,2)	(−1,1)	0.5
(−2.5122, −1.6682)	(−2.5102, −1.6702)	1
(4,−4)	(2,−2)	0.5
(2,−2)	(1,−1)	0.5
(−4,4)	(−2,2)	0.5

Figure 4: Search for collinearity of the u-vectors and the Au-vector

Thomas and Stewart (2011) point out that textbooks show $A\vec{x} = \lambda\vec{x}$, then $A\vec{x} = \lambda I\vec{x}$, but do not explain that it is $\lambda I\vec{x} - I$ is a matrix and not a scalar. Using the *board-instruction-tech* orchestration, the teacher explains how the equation $A\vec{x} = \lambda\vec{x}$ is transformed into $(A - \lambda I)\vec{x} = \vec{0}$ with student participation (see Figure 3a). In another activity, the teacher began with explain-the-screen orchestration, providing students with a DIVE that was not considered in the learning trajectory. After having carried out the calculation of the eigenvalues and the eigenvectors on the screen, the teacher explained to the students that in the CAS view of the DGS, they could observe step by step the calculation of the characteristic polynomial, of the roots of the characteristic polynomial (eigenvalues), and the solution of the equation $(A - \lambda I)\vec{x} = \vec{0}$ for each of the eigenvalues (if they exist). After each line of the CAS was explained, a didactical performance was presented. Here the students commented that on their computers, the IME given did not work like the one the teacher presented, and the CAS did not recognize the same commands as those of the teacher (see Figure 5a). Using student-shared-screen orchestration, a student split his screen to perform and follow the teacher's instructions, and the student's computer screen froze. The teacher had to ask another student to share his screen. To solve the command problem, the teacher was able to use his technological knowledge to search the GeoGebra Wiki and find another command which made the DIVE work correctly on the students' computers (see Figure 5b).

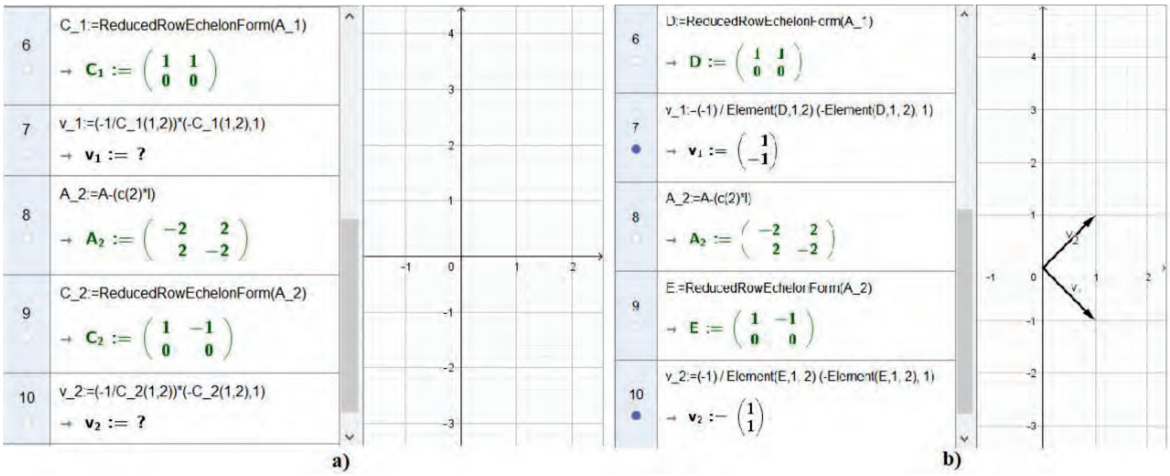

Figure 5: Calculation of eigenvalues and eigenvectors in the CAS view of the DGE

Discussion

For the student-share-screen orchestration, a didactical configuration for this orchestration is the sharing of the videoconference screen by a student, which allows the students to follow the discussion, using Sherpa-at-work or spot-and-show. As an exploitation mode, the teacher can ask the Sherpa-student to explain her work, or he can ask questions and ask the student-Sherpa to perform specific actions. In our case, when a student wanted to share their paper-and-pencil work, there were several exploitation modes. 1) A student with a weak internet connection could take a photo of their notebook using their smartphone, upload it to the WhatsApp group, their cloud folder, or conference chat, so that the teacher or another classmate could download and project their work while they explained it. This way we can define this orchestration as *Shared-resource*. But because of the weak internet connection, the gestures of the teacher and the students were overlooked.

The videoconferencing platform used allows for the creation of small work teams (Breakout Rooms) assigned either randomly using the app, or by the teacher. It also allows the teacher to move among the teams to observe their work and, on the same platform, the students in each teams can ask for help from the teacher (Ask for Help). A downside to this option is that if multiple teams ask for help with the same issue, only members of the team visited by the teacher will be able to hear and see the discussion.

Conclusion

Supporting mathematics teachers in their efforts to integrate technology into their teaching practice remains a challenge for the mathematics education community (Trouche, 2018). We believe that teachers need basic skills and knowledge in the use of technologies so that they can support their students' learning in these online environments.

Returning to our research question: What instrumental orchestrations are applied by a university professor using technology to teach the concept of eigenvalue and eigenvector in a distance education setting? As technology evolves, existing types of instrumental orchestrations (Drijvers et al., 2010, 2013; Trouche, 2004) need to be re-examined to determine how they might be modified and expanded. We examine the teaching practice of a university engineering professor during the onset of the COVID-19 pandemic through online education, using the theoretical framework of instrumental orchestration. Students contributed through video recordings of their work and ideas, which allowed the teacher to access this work and decide between Sherpa-student or spot-and-show orchestrations from this work. Some orchestrations from traditional education were also observed. In this observation, we identified four new types of instrumental orchestration: student-share-screen, share-board, board-instruction-tech and shared-resource.

In this course, being able to observe the personal development on paper-and-pencil by the whole class made the students more willing to share their incomplete attempts at problem-solving. Videoconferencing technologies offer means of communication that raise new questions regarding the organization of lessons. The pandemic has raised new questions about synchronous teaching: the use of computer screens and webcams instead of blackboards, the ability to carry out multiple activities such as Chat watching, student participation by raising their hand, muting and unmuting the microphone, solving technical problems on the fly. The activities developed in this study can be implemented in face-to-face classes, encouraging autonomous and collaborative work, and installed on a freely accessible server where students can learn at their own pace.

The role of the smartphone as a computer has changed the way we can experience mathematics (Borba, 2021). We believe that the impact of the pandemic has changed the traditional way of teaching and learning, which, together with the ever-increasing demand for study and the limitations of institutions, makes hybrid distance learning a necessity. It is, therefore, necessary to carry out studies on the design and implementation of educational software on digital devices and, of course, new orchestrations.

The use of auditory media as mathematical language support in elementary classroom practice

Franziska Peters

Justus-Liebig-University of Giessen, Germany; franziska.peters@math.uni-giessen.de

This paper focuses on the use of auditory learning material as specialized language support in elementary classroom practice. Radio features, with their relevance in everyday life, can serve as a natural auditory learning material for children. Thus, we investigated various applications of radio resources in teaching practice. The aim of this research is not only to investigate what a profitable use of auditory material would look like, but also to investigate the effects of such practice on the learning procedure in general and specifically on the development of the school register. First results show that auditory media can indeed be effectively implemented in teaching practice as a provided linguistic model and reveal just how these effects look like.

Educational media, aural learning, radio, language acquisition, visualization.

Cooperation with a Radio Station

In 2015, the Department of Mathematics Education at the University of Giessen started a project in cooperation with a regional radio station *hr2 – Hessen Radio for Culture*. Within this project, a series of radio broadcasts on mathematical topics for the primary school level was developed – calles *Kinderfunkkolleg Mathematik*[1], as well as accompanying material for use in elementary classrooms. More information about this can be found in the proceedings of CERME11 (Peters, 2019). Based on this project, research on innovative classroom practices was started that integrate auditory learning material as a central element to find out what a profitable use of such material could look like. Furthermore, the effects of auditory media as a specialized language support in mathematics education were investigated. In particular, the question was asked how auditory material can stimulate the development of the school register as a linguistic model.

The Potentials of Auditory Media in Mathematics Education

According to Mayer's memory model (2009; see also Baddley, 2007), visual and auditory information are processed in two different sensory channels. Using auditory media as learning material reduces the sensory impressions on the visual channel and focuses the sensory impressions on the auditory channel. Hence, the auditory channel becomes more tasked and can be trained more. Purposive use of auditory media can supply the listener with repeated and specific auditory input and thus foster the processing of information in the auditory channel. Based on this, the Purposive use of such media can furthermore foster the development of language (Niehbuhr-Siebert & Ritterfeld, 2012). Building up on the memory model, the Cognitive Load Theory by Sweller (1994) says that the capacities of the working memory are limited and should not be exhausted by extrinsic factors like too many animations or reading. Reading difficulties can exhaust the working memory and lead

[1] www.kinderfunkkolleg-mathematik.de

to not understanding mathematical content as well as not being able to solve mathematical tasks. Keeping mathematical concerns in the center of learning processes while reducing extrinsic factors is one important principle of auditory learning. For this reason, Rink and Walter (2019) are using text-to-speech technology (TTS) to support learners with difficulties in the written language while solving written tasks. Thus, it can be stated that auditory support can aid children with reading difficulties to understand mathematical contents and tasks without the need of having to read coherently and extract the meaning. The absence of a visual representation of the subject can be a learning potential as well. Children are cognitively challenged to develop their own visual representation of what they heard. When working with auditory media of mathematical content, students have to develop visual representations of e.g. mathematical concepts, geometrical shapes or figures (Peters, 2021).

In pandemic times, we also made first experiences of using auditory media in distance learning and developed accompanying material for homeschooling parents as well as for teachers that needed educational material suitable for distance teaching and learning.[2] There are a lot of good radio resources that can be found online and be used as educational material. So, good auditory learning material is very easy-to-access and all it takes for a teacher to get it to his students in distant learning is to send them a link. A very easy and useful tool - if implemented intently and well-thought-out i.e. if criteria for choosing and using auditory media are considered. Those criteria will be explained below.

Potentials of Auditory Media Concerning Language

One of the most obvious potentials of auditory media is the development of active listening skills. Such competence is a primary requirement for education, but it is seldom supported or even trained (Pimm, 1987). Another potential can be described by looking at the *Model of Orality and Writtenness* (Koch & Oesterreicher ,1985). In this model, auditory learning materials can foremost be categorized as being medial-oral. If they are designed for children, they are also more likely conceptual-oral because they utilize everyday language and explain in a child-orientated and situational manner. Still, they use mathematical terms and phrases of educational language. Thus, they are also characterized through conceptual-textual elements and – in the right learning environment – can be able to lead children from orality into writtenness. At best, this can possibly guide listeners to use mathematical terminology in orality as well as in writtenness. This makes them act in a more conceptual-textual way.

Prediger and Krägeloh (2016) are referring to a model of three registers relevant for mathematical learning (everyday register, school register and technical register). School register is an important factor for successful learning in mathematics, as it is a shared language basis and helps with explaining, describing and justifying (Götze, 2015). However, children do not bring this type of language to school with them. It must be learned. Thus, linguistic models are needed to develop educational language and to fill terms with representations. These linguistic models are scaffoldings

[2] https://www.kinderfunkkolleg-mathematik.de/unterrichtsmaterial

onto which children can lean (Gibbons, 2002). Here, auditory educational material could be a profitable addition.

Criteria for Choosing and Using Auditory Media

Exploiting the potentials of any media starts with choosing “good” media. Considering auditory media, conditions of success are necessary in order to support an active processing of what has been heard and then to achieve an output that is correct in terms of content and language. Thus, criteria for student-friendly audio offers must be established as well as methodological notes for good embedment in classroom practice. For example, listening to auditory resources should be combined with (listening) tasks to support selective and comprehensive listening. Also, opportunities to document results should be given. In accordance with the segmenting principle (Mayer, 2009), important sequences should be cut and listened to in segments. Those segments can then be repeated and talked about to make sure the brief acoustic representations are understood by every student. By these means, not only an effective use of auditory media in general but also specialized language support can be ensured.

As there is no visual representation of the subject given by auditory media, verbal explanations in such media need to be very accurate. While working with the production team of the radio station, the importance of a deep reflection and good structuring of the mathematical content became very clear. Verbal explanations in auditory media must also counter the fugacity of spoken language through e.g. linear representation, reputation or sound effects. With those criteria kept in mind, teachers will firstly be able to choose good auditory media for use in mathematics education. And secondly, they will be able to develop teaching concepts in which auditory media serves as transfer of mathematical knowledge, as stimulus in the sense of educational reduction and as language support for developing the academic register.

Methodological Approach

Following these concepts, my research can be focused on the evaluation of the use of auditory media for mathematics education in various settings – particularly regarding possible learning effects. Thus, my research issues can be stated as follows:

> RQ 1: How can auditory material support mathematical understanding as well as the development of school and technical register?
>
> RQ 2: What could a profitable use of such teaching concepts look like?

Building on the knowledge base described above, two teaching units consisting of four lessons on the topics *The House of Quadrilaterals* and *Probability and Random Experiments* were examined. In both units, auditory media was used as the central knowledge-imparting medium - the radio features *Wann ist ein Spiel fair?* (When is a game fair?)[3] and the radio feature *Wer wohnt im Haus der Vierecke?* (Who lives in the House of Quadrilaterals?)[4]. The teaching units were carried out in two

[3] https://www.kinderfunkkolleg-mathematik.de/themen/wann-ist-ein-spiel-fair

[4] https://www.kinderfunkkolleg-mathematik.de/themen/wer-wohnt-im-haus-der-vierecke

fourth-grade classrooms. The lessons were videographed, transcribed and categorized using the qualitative content analysis according to Mayring (2015). To develop the aspects of interpretation, the categories, as near as possible to the material, the procedure of inductive category development (Mayring 2015) was used to analyze the data with the software MAXQDA. After formulating a criterion of definition based on the theoretical background and the research questions, categories could be developed which determined the excerpts of the textual material considered for more detailed analysis. In this study those categories are the aspects of mathematical learning as well as the aspects of register development (RQ 1). All of the collected data was worked through and categories were deduced as well as revised in various steps. The detected categories were reduced to main categories and categories relevant to the research issues described above were determined. Subsequently, a selection of scenes for the detailed analysis was made from those relevant categories. Those scenes were interpreted in detail in the sense of interaction analysis (Krummheuer/ Naujok, 1999) to examine the specific research subject and to interpret not only the research itself, but also the specific situation of investigation – between the interaction partners and within their interaction.

All of the radio features from the *Kinderfunkkolleg Mathematik* are of 10-12 minutes length. The features are often built around a story line which includes a mathematical problem or situation and involve speakers as well as protagonists that use school register and mathematical terms to confront children with new terms in a playful way. The overall aim of the units is the development of concepts like *fairness* or *the house of the quadrilaterals,* while the linguistic aim is the understanding and the use of important terms that are presented by the radio feature. Those aims work together: language development can help to develop the concept. Working with the auditory media, the classes begin to listen to the first parts of the radio features. In class conversation, students repeat the content of what was heard and discuss the respective mathematical problem. Then, they imitate experiments or work on tasks and problems they heard about in the radio feature. In between those steps, the teachers present more parts of the radio feature and a lexical storage (posters with sentence phrases and guidelines for formulations as well as the necessary vocabulary) (Erath et al., 2021) is collectively developed based on the content of the radio feature. The units also involve tasks in which the students have to transfer their acquired knowledge whilst using the structures of language and reasoning they had been offered and trained while working with the radio feature.

Mathematics Register Acquisition (MRA)

To evaluate the teaching quality and the effectiveness of the use of radio resources in those teaching units, the *Model of Mathematics Register Acquisition* will be of help (Meaney et al., 2012, p.199). The MRA-model is divided into four stages: The first stage is *Noticing*. In this stage, teachers introduce new terms or expressions, use them frequently and then encourage students to using them as well. The second stage, *Intake*, describes the process of understanding. Students start to explore and work with the new terms. In the next stage titled *Integration*, testing, feedback and modification takes place. Students have a good understanding of the new term and are responsible for using it, but might be supported or reminded of their knowledge by the teacher. In the last stage, *Output*, there is a fluent use of the new terms. Teachers do not need to support, but should provide activities where the use of these terms would arise naturally. Auditory media can be of use in the first two stages. It can be used to introduce new terms and to repeat them frequently in the stage *Notice* and can serve as a linguistic model in the stage *Intake.*

First Findings

Initial observations of those interactions showed that students were highly concentrated while listening to the radio features. It can also be stated that nearly every student was able to correctly repeat the things that have been heard. If anything was unclear, it was easy for the teacher to repeat a certain part of the radio feature. This way, auditory material can counteract transitory learning and be a relief to the teacher as instructions and knowledge are proportioned between him and the auditory learning material.

The qualitative content analysis led to the identification of twelve categories which could be subsumed into three main categories:

- Mathematical-conceptual aspects
- Aspects of language acquisition
- Aspects of media didactics

Exanimating the relative frequency of occurrence of these categories showed that the aspects of language acquisition make up a significant proportion of the collected data. Thus, further in-depth examination of this area should be of main interest. On the basis of the quantified data and with a view to the research issues, a well-founded selection of transcript excerpts – mostly from this main category – was made for a subsequent detailed analysis in order to examine the influence of audio media more closely. The interaction analysis (Krummheuer & Naujok, 1999) then enabled a deeper insight into individual processes of technical language acquisition. Detailed analysis of interactions showed e.g. that the combination of listening, repetition of specific sequences as well as conversations and discussions of what was heard were of great support for teachers – especially whilst introducing new terms and developing the lexical storage. In terms of scaffolding, auditory materials served as linguistic models on which students were able to lean on. Furthermore, it has become evident that students demanded the visual level of what is heard (for detailed analysis see Peters, 2020). Although sometimes the teacher asked for something written, students developed a visual representation (e.g. by drawing) to support the visual work they were already doing in their head. Even if they didn't draw something (for example a geometric shape) they developed a mental representation without the help of a given image. This can be illustrated by the following example from the data:

01	Teacher:	So who remembers what they said in the audio about those special quadrilaterals?
02	Max:	Well, there was the convex quadrilateral where all the corners show to the outside… and then concave quadrilaterals…
03	Teacher:	Can someone help? What about the concave quadrilaterals?
04	Lea:	There the corners show to the inside… they are like inside the quadrilateral.
05	Teacher:	Okay… and how can you picture this?
06	Lea:	They said something like it's punched inside…
07	Teacher:	Yes.. Silas?
08	Silas:	Like an navigation arrow or boomerang.
09	Teacher:	Great that's correct. Can someone sketch how a concave quadrilateral could look like? Joella?

10 Joella:		Well… Maybe like the roof of a house but a roof that is a little bit thicker than normal.
11 Teacher.		Can you make a sketch on the blackboard?

After this Joella goes to the blackboard and draws the following sketch:

Figure 1: Joella's sketch of a concave quadrilateral

So even without ever having been confronted with the concept of convex and concave quadrilaterals and even with just the auditory (i.e. verbal) information and no image of such quadrilaterals, Joella was able to develop a visual representation of what she heard in the auditory resource. She was confronted with only the auditory information and therefore challenged to listen carefully, understand the explanation of the geometric shape – in form of technical register – and furthermore to make up here own visual representation. This cognitive challenge was clearly initiated by the need of visualization which emerged from the absence of visualization in the learning material. Thus, it can be stated that listening to auditory media without the direct provision of visual support led to a development of representations that was initiated by the learner himself.

Considering the language aspect, detailed analysis of interactions show that in the beginning of the teaching units most explanations of the students could be considered as a form of everyday register. However, during and after working with auditory media there was a visible change towards more school and technical register. At the end of both units (e.g. during the final presentations of their experiments, work or tasks), students did in fact use new mathematical terms and phrases that were introduced by the auditory material. Thus, referring to the MRA model (Meaney et al., 2012), it can be stated that there is a development from the first introductory stage *Noticing* to the second stage *Intake* (the process of understanding) in many of the analyzed sequences. Even the third stage *Integration* (testing and modification through feedback) is reached by many students.

Discussion

Despite those positive aspects of mathematical language development there are some limitations that need to be stated. To reach the stage of fluent *Output* students would still need more support and a longer period of use and training. Here a long-term study would be useful. However, the development from stage one to three – from *Noticing* to *Integration* – indicates an apparent improvement in the students' mathematical expression and understanding over the course of the units. The offer of professional language in (educational) auditory media combined with the absence of visuals, gestures and deictics (unlike YouTube videos etc.) might be a challenge – but a positive challenge – and represents an interesting opportunity for the development of mathematical language and thinking. In the next step of this study, the use and effects of auditory learning material is to be examined in grades two and six to get a broader view on the various aspects of mathematical learning and language development in different age groups.

Fair games – A case study on a negotiation of meaning on the concept of fairness in probability in mathematics classes

Felicitas Pielsticker

University of Siegen, Germany; pielsticker@mathematik.uni-siegen.de

This paper describes a student's negotiation of meaning about the concept of fairness in a 10th grade mathematics class. Using the case study approach and the approach of empirical theories, key scenes in a learning unit about gambling are examined and knowledge structures are analyzed. A 3D printed dice tower plays a special role and is used to reflect on fairness in probability calculation.

Keywords: Empirical theories, knowledge development process, case study, empirical-oriented mathematics classes

Introduction and motivation.

Fairness is a much-discussed concept in various contexts. It often seems as if everyone has clear beliefs of fairness and "whether something is fair". Fairness for us people have quite different facets (Möbius, 2018). So we can say we want everyone to be rewarded equally. Or we can say that the person who has done more gets more. But we can also say we want those who have higher needs to get more (Möbius, 2018). A frequently made statement is "That is unfair!" and not "That is fair!" But how can we decide whether something is fair? Questions of fairness and justice (used synonymously in most contexts, e.g. Duden online, 2021) are dealt with by different disciplines. The concept of fairness thus has many facets, even beyond a simple mathematical distribution model (Möbius, 2018). In mathematics, the concept of fairness plays a crucial role. Looking at the work "An Introduction to Probability Theory and Its Applications" by Feller (1968), we can see that a "theory of 'fair' games" (Feller, 1968, p. 248) is treated here. Textbooks also address fairness for mathematics education. Often we can read: A game is said to be fair if the expected value for winning is 0. The expected value seems to be important in connection with fairness. A fair game is often discussed in connection with probability calculation. The Common Core for High School: Statistics & Probability. Using Probability to Make Decisions also states: "Use probabilities to make fair decisions (e.g., drawing by lots, using a random number generator)" (Common Core State Standards Initiative, 2021). This paper describes what beliefs of fairness can be analyzed in a student (10th grade of a high school) of our case study and what discussion impulses on "fair" and "unfair" can be gained from it. For this goal, the teaching unit "A fair game of chance?!" was developed (section: Material and data collection).[1]

Theoretical background – empirical-oriented mathematics classes.

If students acquire mathematical concepts by dealing with empirical objects (visual materials and physical objects, e.g., folded and drawn figures) in the constructivist sense, we assume according to the approach of empirical theories (Burscheid & Struve, 2020a; 2020b) that they develop a so-called empirical belief system (Schoenfeld, 1985). We describe the knowledge of students in empirical

[1] We note that parts of the results of this paper have also been published in the German-language volume "Neue Perspektiven auf mathematische Lehr-Lernprozesse mit digitalen Medien" by Springer.

theories which are constituted by dealing with these empirical. According to studies of Burscheid and Struve (2020a) and Witzke (2019), this "'non-abstract' point of view [...] is a reasonable one for the developing of mathematical knowledge" (Witzke, 2019, p. 199). Students construct their mathematical knowledge by themselves in interaction with their environment. With Hefendehl-Hebeker (2016) we can state that the concepts and contents of school mathematics have their phenomenological sources predominantly in our surrounding reality. For our analysis of the cognitive aspects in students' knowledge development processes, the concept of empirical-oriented mathematics class is crucial. An empirical-oriented mathematics class builds on, on the approach of empirical theories. Empirical-oriented mathematics classes are classes in which the teacher intendedly makes decisions to work with empirical objects as the mathematical objects of math classes. In mathematics classes, the empirical objects (e.g. dice or drawn figures) do not intend to illustrate mathematical concepts that are abstract in nature, but they are rather the subject of the lesson, where students acquire their knowledge on (Pielsticker, 2020). Empirical objects that play a role in this paper are 3D printed dice towers (Figure 1 and 6) and commercially available dice. Studies have shown that the use of 3D printing seems particularly useful for probability. For example, Pielsticker and Witzke (2022) argue that with a creation and use of 3D printed manipulated dice, profitable negotiation processes on the theoretical concept of probability can be initiated among learners. An empirical object such as the 3D printed dice tower described in this article (Figure 1 and 6) then serves in the classroom as an object of instruction (Pielsticker, 2020). 3D printing as a digital tool in a teaching conception of an empirical-oriented mathematics class creates student-oriented occasions to exchange ideas about mathematics. Students negotiate mathematics, which means that the digital tool 3D printing can be seen as a motor for the further development of student knowledge in the classroom. A self-construction of the dice tower in the CAD program in mathematics lessons is quite desirable and a crucial part also of the teaching unit "A fair game of chance?!" considered here. In this process, the learners negotiate the construction and thus also the functioning of the 3D printed dice tower. In the following, a teaching-learning process from a mathematics class that takes this conception into account is described.

Design and methodological decisions.

Research questions.

In this paper, we describe the beliefs of fairness that can be analyzed in a student in a 10th grade class at a high school. The research of Burscheid and Struve (2020a; 2020b) on questions of fairness of games of chance (Burscheid & Struve, 2020b) in historical reference is also guiding for this. There are many different games of chance. Often there was agreement on what the ratio of stake to winnings had to be in order for the game to be fair. In the "force majoure" problem, however, mathematicians pursued different solutions with respect to the question: How is the stake to be distributed fairly? Pascal and Fermat propose a solution to this in 1654, which corresponds to the modern probabilistic view (Burscheid & Struve, 2020b). Leibniz, knowing the solution of Fermat and Pascal, makes a different proposal for division in 1678. For normative problems there are just no right or wrong solutions, but only more or less appropriate proposed solutions (Burscheid & Struve, 2020a). In this context, probability theory nowadays plays an authoritative role for an assessment of the fairness of games of chance. This was not the case before, because probability theory has a root in the theory of the fairness of games of chance (Burscheid & Struve, 2020b). Thus, it is interesting to note that the concept of probability, which is fundamental to probability theory, has historically been developed within an application-related context: precisely the question of the fairness of games of chance (Burscheid & Struve, 2020a). For us, it is interesting to see how the student in our case study deals with the concept of fairness in the instructional context of probability. We pursue two research questions in this paper: 1. Which beliefs does the student of our case study develop about the concept of fairness? 2. To what extent can (students') theories about the concept of fairness be (further) developed when dealing with the 3D printed dice tower?

Material and data collection.

Data collection for the analysis of knowledge structures was based on student documents created before, during and after the implementation of the lesson "A fair game of chance?!". These include worksheets and a questionnaire. Both tasks of the worksheets and the questionnaire are part of the data collection and will be analyzed in this paper. The topic was introduced by the students' report about their experiences with gambling. Afterwards, there was a worksheet where cheating and fraud were discussed. This was intended to create a deeper awareness of the problem. In ancient times, for example, the use of a dice tower was considered a guarantee of fairness in dice games. The task of constructing a dice tower using 3D printing technology was intended to create an action-oriented approach in relation to a game situation. 3D printing is a quite new tool for mathematics education. It is an additive manufacturing method which allows digital models constructed with CAD-software to be transformed layer by layer into a real model (e.g. out of liquid plastic) (Gibson et al., 2014). This technology makes the development as well as the production of empirical objects in a variety of mathematical contexts quite easy and thus may facilitate embodied (Tall, 2013) approaches to mathematical content. In ancient times, a dice tower was seen as a way to prevent cheating. In the learning unit the students designed their dice towers on their own using the CAD software Tinkercad™ and 3D printed them out of plastic (Figure 4). To ensure that the tower had the conditions required for fair play, common criteria had to be defined within the student groups. In partner work, the students discussed the criteria. Subsequently, the students conducted test series with their dice towers and calculated the absolute and relative frequencies of their throws. In the worksheet with the sentence beginning "For me, fairness is ...", the students of the class summarized their view of the concept of fairness once again.

Methods.

In our instrumental case study (Stake, 1995), we describe the student Ardelin (a 10th grade student, 16 years old, name changed) in relation to our two research questions (see section: Research questions). „Case studies are undertaken to make the case understandable" (Stake, 1995, p. 85). With our case study we need to understand the case in order to understand our two research questions (Stake, 1995). We use the case study approach to identify our key scenes in terms of the research questions and to process the data material. We use the approach of empirical theories according to Burscheid and Struve (2020a) for informal description of the student's knowledge structures. We use the following terms (Table 1) as the basis for our analysis in terms of our research questions.

Terms	Explanation
intended applications	The phenomena of reality described and explained by an empirical theory.
empirical objects	In this study, empirical objects are understood as items and objects of reality that are immediately accessible to students, especially in a tactile or visual way.
theoretical concepts	Terms whose meaning can only be clarified by setting up or within a theory and which do not have an empirical reference object.

Table 1: Terms of empirical theories for analysis (Pielsticker, 2020; Burscheid & Struve, 2020a)

We use the terms from Table 1 as an analysis tool. In terms of our research concern, this is an informal description using the terminology of the empirical theories approach according to Burscheid and Struve (2020a).

Analysis and Results.

In order to achieve a deeper understanding of the case, key scenes have been selected, which we describe below. In the learning unit, the game of chance – dice game – was considered and knowledge about fairness was acquired. The question of when a game is fair should be addressed. In the learning unit, a link between ancient and digital tools – the dice tower – was used for this purpose. With reference to the construction of an (ancient) 3D printed dice tower (section: Material and data collection), the aim was to reflect on fairness. For the case of fair play, we will first discuss the results of the student Ardelin. To do this, we will start by looking at the student's answers in the questionnaire and then describe her answers on the worksheets. In the questionnaire, Ardelin is asked: "What does 'fairness' mean to you?". The student states, "That everyone is treated or valued equally, so that everyone is equal and no one is favored" (Figure 1).

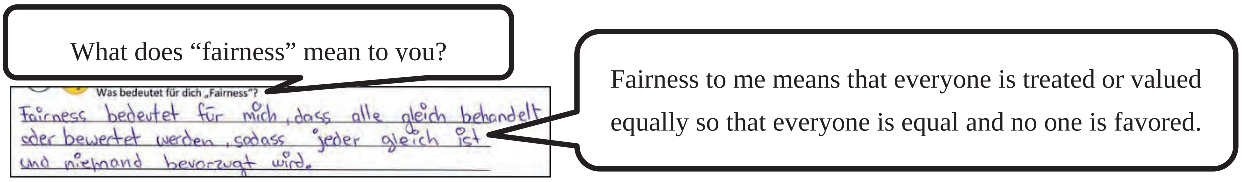

Figure 1: Answer to 2) from Ardelin in the questionnaire

The student bases her concept of fairness on dealing with people ("everyone" and "no one"). She thus refers to (her) fellow players. Ardelin is now asked to relate her concept of fairness to a game. She is asked, "When is a game fair for you?". The student states, "when everyone is treated equally and everyone gets the same chances and everyone gets the same rules" (Figure 2).

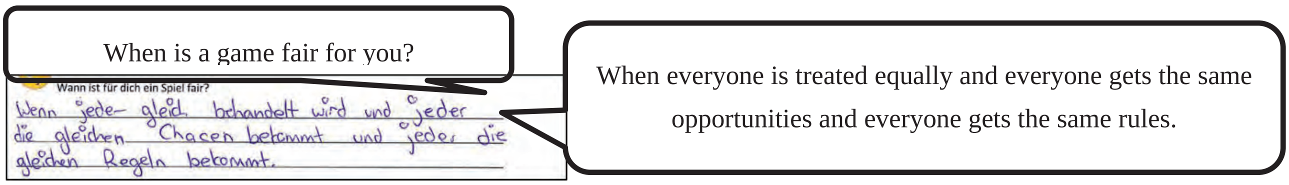

Figure 2: Answer to 3) from Ardelin in the questionnaire

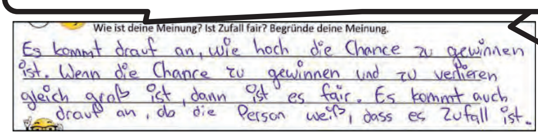
Ardelin sticks to the reference ("everyone"), emphasizing that "everyone gets the same chances" and "everyone gets the same rules" (Figure 3). The student thus makes a fair game once to a game context in which "the same rules" apply, also she connects a fair game with "equal chances" and finally she names the players, "everyone", who should be "treated equally". When Ardelin is asked for her opinion in the 4th question of the questionnaire, "Is chance fair? Give reasons for your opinion.", the student first makes this point, about the chance of winning a game. "If the chance of winning and losing is the same, then it is fair" (Figure 3). At the same time, Ardelin also refers back to the players by noting, "It also depends on whether the person knows it's chance."

What is your opinion? Is coincidence fair? Give reasons for your opinion.



It depends on how high the chance of winning is. If the chance to win and to lose is equal then it is fair. It also depends on whether the person knows that it is chance.

Figure 3: Answer to 4) from Ardelin in the questionnaire

In her answers, the student thus distinguishes between the game, the people involved (players), and the chance of winning the game. At this point, we would like to discuss the results of the student's worksheets. Ardelin created a 3D printed dice tower and tried it out in the further course of the learning unit (Figure 4). Figure 4 shows the 3D printed cube tower. Ardelin has constructed some inclined levels (the student herself writes "steps") inside the cube tower and further a cube tower wall to be attached to the rest of the cube tower with tape afterwards. The student explained in the classroom situation that she only wanted to tape the cube tower wall because she wanted to control how the cube rolled along the inclined planes.

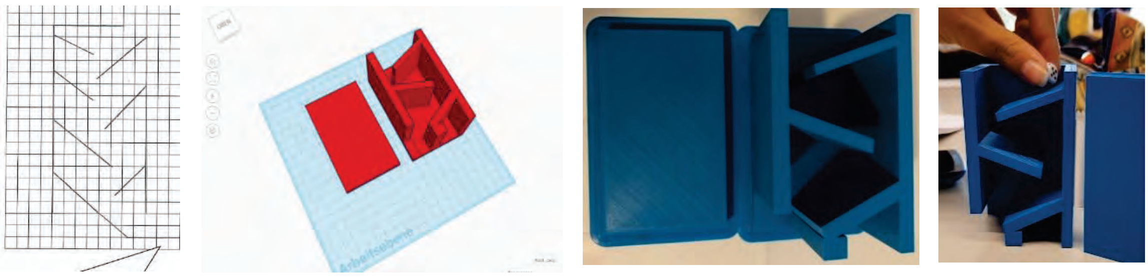


Figure 4: Adrelin's 3D printed dice tower

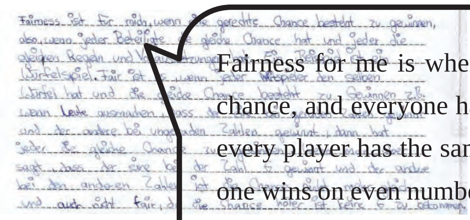
On her worksheet, the student describes regarding the criteria that should apply to her dice tower, "It must be fair" and "It must always be dropped with the “1” from the top and give more of these steps." The empirical object to which Ardelin refers at this point is the 3D printed dice tower. For the game with the dice tower, special rules should continue to be recorded, such as, "It [the dice] must always be dropped with the 1 from the top [into the dice tower]," there must be "more of these steps," which should be placed "at even intervals," and ultimately, "nothing should fall out of the sides." Using the example of the 3D printed dice tower, as an empirical object, Ardelin argues how it must be designed for fair play. To do this, she first states that the game must be fair, and then simultaneously formulates what rules must apply. Ardelin also describes her view once again on her worksheet (Figure 5). Here, Ardelin describes a "fair chance [...], that is, [...] equal chance" - she probably uses the two expressions synonymously - with "equal rules and conditions." She argues this with the help of the intentional applications "dice game" and "game of chance: even - odd" - as intentional applications of the student theory about games of chance. The dice can be regarded as the empirical object for the intended application dice game. Ardelin emphasizes here that "every player should have the same die" (Figure 5).



Fairness for me is when there is a fair chance to win. That is, when every player has the same chance, and everyone has the same rules and conditions. An example is a dice game. Fair is when every player has the same dice and the same chance to win. For example, if the players agree that one wins on even numbers and the other wins on odd numbers. Then everyone has the same chance to win. But if you say that one wins on the number 6 and the other wins on all other numbers, the chance is no longer equal. This is not fair, because the chance is higher not to get a 6.

Figure 5: Adrelin's 3D printed dice tower

In relation to the theory of the fairness of games of chance, the "game of chance: even - odd" is an intended application with even and odd numbers as failures of a random experiment. At this point, the student gives a counterexample, which she relates either to the intended application of the dice game or to another game of chance: "But if you say that one wins with the number 6 and the other with the other numbers, the chance is no longer equal and also not fair, because the chance is higher not to get a 6". If we assume the intended application of the dice game (where "one wins on the number 6 and the other on the other numbers"), the dice can be seen as an empirical object on which Ardelin explains her counterexample to "equal chance". It is also clear that she is oriented to the game context in her negotiation of meaning regarding the concept of fairness. The intended applications in relation to the student's theory of fairness of games of chance are games of chance such as "dice game" (with or without 3D printed dice tower) or "even - odd". In this context, Ardelin gives meaning to the concept of fairness in the context of gambling. Whether a game is fair is decided for the student by this game context, with the associated rules and "prerequisite" (Figure 5), such as, for example, that "every player has the same dice" (Figure 5). It should also be mentioned that Ardelin's examples probably tacitly assume that each player pays the same stake.

Discussion

1. Which beliefs does the student of our case study develop about the concept of fairness?

We can describe for Ardelin that she behaves as if she developed an empirical beliefs system, an empirical theory about the fairness of gambling. In doing so, the student repeatedly uses words like "chance" and "equal chance" (Figure 2 & Figure 5), with which a connection to probability theory can be assumed. This would not be surprising, because until today (not from the beginning!), however, probability theory has remained the authoritative theory for assessing the fairness of games of chance (Burscheid & Struve, 2020a). In relation to a fair game, the student – in relation to her theory on the fairness of games of chance – can describe the intended applications "dice game" and "game of chance: even - odd". Ardelin makes the "same rules and preconditions" (Figure 5), which apply to a fair game in the student's sense of the word, on empirical objects such as the 3D printed dice tower or dice. For a fair game, Ardelin emphasizes that "every player should have the same dice" (Figure 5). In her negotiation of the meaning of the concept of fairness, the student orients herself to the game context, and she gives her concept of fairness a meaning in this application-related game context. Whether a game is fair is determined for the student by this game context, with the associated rules and "prerequisite" (Figure 5), such as that "every player has the same dice" (Figure 5). The notion of fairness is seen in connection with the expectation value, as for example in Christian Huygens, who defines the notion of expectation in terms of fairness as equal expectation prevails in a fair game (Gigerenzer & Krüger, 1999). Burscheid and Struve (2020a) also make it clear with historical reference that the concept of expected value, which is fundamental for probability theory, did not develop within a formal theory, but within an application-related context (Burscheid & Struve, 2020a). In this context, expected value can be identified and described as a theoretical concept. Ardelin decides whether a game is fair along the chance of winning (and the expectation of winning) of the players in the game situation. In doing so, the concept of fairness takes on meaning for her in this context.

2. To what extent can (students') theories about the concept of fairness be (further) developed when dealing with the 3D printed dice tower?

Ardelin seems to add the dice tower as a (further) possibility of throwing the dice in her student theory about the fairness of gambling. The 3D printed dice tower is not crucial for the student to decide whether fair game prevails in a gambling situation (such as the "dice game"). The 3D printed dice tower is integrated by the student into her empirical theory as a further dice-rolling possibility and thus expands her knowledge of dice-rolling possibilities. The notion of fairness can be identified as an epistemological obstacle (Sierpinska, 1992) in probability theory and in connection with expected value (in relation to our case study). Here, parallels to the historical development of probability theory can also be identified on an epistemological level, in line with the remarks of Burscheid and Struve (2020b). With a development of meaning of the concept of fairness, as a theoretical concept in relation to a (school) theory of probability, special challenges are therefore associated in mathematics education. In the practical application (of probability theory in schools), time should not only be given for the development of the meaning of the concept of fairness, but it should also be addressed in game situations, e.g. in the sense of fair play and fair game. This impulse should also be followed up in further research and it should be considered whether and how both theories of fair game and fair behavior of persons in gambling are related.

Digital support for proving arithmetic relationships - insights from the DigiMal.nrw project

Annika Raßbach[1], Kira Karras[2], Daniel Walter[2], Marcus Nührenbörger[1] and Karina Höveler[2]

[1]TU Dortmund University, Faculty of Mathematics, Dortmund, Germany; annika.rassbach@tu-dortmund.de; marcus.nuehrenboerger@tu-dortmund.de

[2]University of Münster, Faculty of Mathematics and Computer Science, Germany; kira.karras@uni-muenster.de; daniel.walter@uni-muenster.de; hoeveler@uni-muenster.de

Keywords: Digital support, self-checks, explanatory videos, proof, pre-service teacher training.

Theoretical Background

The proof of arithmetical relationships is a mathematical content that causes difficulties especially for pre-service primary school teachers (Kempen & Biehler, 2019). They often encounter typical difficulties when carrying out proofs, formal transformation errors in terms as one example (Moore, 2016). In addition, pre-service teachers have problems when changing representations and showing completeness or generality (Kempen & Biehler, 2019).

To counter these difficulties targeted measures are needed to support pre-service teachers in constructing proofs. Besides analogue support, digital support may be helpful since it offers further specific potentials: For example, automated product-oriented feedback, as well as informative feedback, are possible (Hattie & Timperley, 2007). Furthermore, the synchronicity of presentations offers a high subject-specific didactic potential (Ainsworth, 1999). The production of explanatory videos may positively affect knowledge acquisition (Fiorella & Mayer, 2014), since they offer pre-service teachers to try out their future teacher role as an 'explainer', and their digital competencies can be promoted (Feurstein, 2017). As digital support in the context of proving is currently not widespread (Stylianides & Stylianides, 2017), this development project aims at creating and evaluating digital support materials for proving elementary statements on number theory. The findings are taken into account in the development of support options.

The project DigiMal.nrw and its subproject 'Arithmetics'

The project DigiMal.nrw (eng.: digital mathematics teacher training) aims at improving the quality of leading mathematics courses in pre-service teacher training (focus on primary schools and special education) with the help of digitally supported measures. In addition to teaching-related challenges, the project addresses the core contents of elementary school mathematics. As part of the DigiMal.nrw sub-project 'Arithmetics', corresponding teaching-learning opportunities in digital self-checks, and video-based learning environments for developing and working with explanatory videos are being developed and evaluated at the University of Münster and the TU Dortmund University.

The poster focuses on the following two questions: (1) How do pre-service teachers develop their mathematical and didactical knowledge of proof when working with video-based learning environments? (2) How do they perceive the subject-related feedback in the digital self-checks on the topic of proof?

Two first prototypes and their evaluation

On one hand, a video-based learning environment is being developed. Pre-service teachers prove the statement 'The sum of two consecutive square numbers is always odd' and deal with fictitious incomplete proofs. To deepen their knowledge, they create explanatory videos for 'fictitious pre-service teachers of the first semester'. The pre-service teachers analyse and reflect on their videos produced. They receive feedback from fellow students and lecturers. On the other hand, digital self-checks are being developed. They address the typical difficulties in proving. With the help of drag-and-drop tools, pre-service teachers deal with term transformations and their legitimation. Besides, pre-service teachers are given the task of deciding which formal and iconic representations fit a verbally given expression in different task formats. After completing the interactive elements, they receive automated feedback and have the opportunity to get further explanations via videos and texts.

The prototypes of the first survey cycle were evaluated with questionnaires due to their suitability for a large number of participants (Bortz & Döring, 2016). The evaluation of the video-based learning environment showed that pre-service teachers engaged more intensively with proofs and their explanations (RQ1). The evaluation data for the self-checks point to the effectiveness of the digital learning opportunities, especially since the majority of students rated their learning gains as 'high' or 'rather high' and indicated that the informative feedback supported their understanding of the content (RQ2). Based on the evaluation, the prototypes will be further developed.

Students Undertaking an Elective Programming Course: Their Views on the Connection Between Programming and Mathematics

Kim André Stavenæs Refvik[1], Annette Hessen Bjerke[2] and Morten Misfeldt[3]

[1]Volda University College, Norway; refvikki@hivolda.no, [2]Oslo Metropolitan University, Norway; annette.hessen@oslomet.no, [3]University of Copenhagen; Denmark, misfeldt@ind.ku.dk

In this study, we investigate how students undertaking an elective programming course experience the connection between programming and mathematics. Based on stimulated recall interviews with six Grade 8 students who have solved test items from PISA 2003, we identify various experiences among the students regarding how they draw on programming skills in mathematics and vice versa. We propose that three findings, in particular, are worthy of further discussion and investigation: the way some experience programming as a context for mathematics and mathematics as a context for programming; the challenges that follow from how some students assert that programming and mathematics complement each other while others struggle to see a connection; and, perhaps the most important, the way in which the students report that experiences from programming have equipped them with skills such as being systematic and exact, which they find they need in mathematics.

Keywords: mathematics education, problem solving, computational thinking, programming

Introduction

After recognising computational thinking (CT) as a vital 21st century skill (Bocconi et al., 2018), several countries have recently introduced CT to their curricula, either as a separate programming subject or as part of existing subjects. In Norway, CT is introduced in mathematics across grades (Directorate of Education, 2020), adding to being an elective programming subject in lower secondary school (Grades 8–10, ages 12–16). In the new Norwegian curricula, after Grade 4 in primary school, CT is exclusively addressed and talked about as *programming*. In programming, CT entails the ability to develop programmes to perform different algorithms and is considered a systematic description of how to solve a problem using a specific approach (Kaufmann & Stenseth, 2021, p. 1030).

As several studies have asserted that programming can induce improved understanding in mathematics (Moreno León et al., 2016), and even more precise – improved problem-solving skills in mathematics (Husain et al., 2017; Sinclair & Patterson, 2018) – it is easy to understand why many European countries introduce programming in mathematics (Balanskat & Engelhardt, 2015). However, Kaufmann and Stenseth (2021) warned against assuming that the programming's effect on problem solving is automatic. Exploring these findings while considering Kaufmann and Stenseth's (2021) warning, we seek to better understand whether those students undertaking an elective programming course in lower secondary school can communicate how mathematics and programming are interrelated. Hence, we give students a voice in the matter. It is imperative that the students themselves experience this connection. Hence, we ask the following research question: *How and to what extent do students undertaking an elective programming course experience a connection between programming and mathematics?*

Theoretical Framework

To investigate the interplay between programming and mathematics, we turned to Kilhamn et al. (2021) and Elicer and Tamborg (2021). Kilhamn et al. (2021) investigated the relationship between mathematics and programming in 32 mathematics lessons and found four 'categories' of relationships: *only programming* (lessons only focusing on programming); *mathematics as context for programming* (lessons where no new mathematical concepts are used, but programming can be used to repeat or confirm mathematical knowledge); *programming as a computational tool in mathematics* (lessons that clearly have mathematical content, and programming is used to carry out calculations efficiently); and *programming as a tool for exploring mathematical concepts* (lessons where programming is used to explore mathematical concepts and relations, where programming adds new insights and develops one's mathematical competence). Similarly, Elicer and Tamborg (2021) analysed activities from the Danish 'Texforsøget' and described the role of mathematics and what they refer to as programming and computational thinking (PCT) in different activities. They found six categories, where the first two are *no mathematics involved* and *no PCT involved*, implying either no mathematics or no PCT involved in the tasks, and that the focus of the task is either purely mathematical or purely programming. The two following categories, *mathematics as a context* and *PCT as a context*, are categories where mathematical concepts are explored using PCT operations or where PCT concepts are explored using mathematical operations. The next category is *conceptual integration*, which are tasks that are "not solved with mathematical or PCT actions but involve concepts in both math and PCT" (Elicer & Tamborg, 2021, p. 5). The last category is *operational integration*, where "mathematical and PCT competencies are interdependent" (Elicer & Tamborg, 2021, p. 6).

While exploring what these two studies revealed on the relationship between programming and mathematics, both at the level of a lesson and at the level of the tasks given, we sought to see how a discussion around some problem-solving tasks can work as a starting point for investigating how students see the relationship between programming and mathematics. Problem-solving tasks were a natural point of departure, as research seems to unanimously assert that problem solving is the most obvious overlap between mathematics and programming. For instance, in pursuing the definition of CT for mathematics and science classrooms, Weintrop et al. (2016) proposed a taxonomy comprising four practices, one of which focuses on computational problem-solving practices. In this practice, Weintrop et al. (2016) identified problem solving as a central practice for developing CT in mathematics (and science), which sometimes takes the form of conventional programming (p. 138). This made us take a set of mathematics problem-solving tasks as our point of departure when interviewing students on how and if they see a connection between programming and mathematics.

Methods

In Norway, students choose one elective subject in each of their three years in lower secondary school. This study used data collected from a larger project, where all participants (N = 247) completed a test comprising five different problem-solving tasks from the PISA 2003 test (these were the tasks on the library system, course design, transit system, irrigation and energy needs; see Faculty of Educational

Sciences UiO [2003] for details). Due to how the library system task was mentioned and discussed in most interviews, we give a brief account of it here to inform the reader:

> The task starts by giving a flowchart that shows a library lending system: If you are a teacher (yes), you are allowed to lend books for 28 days; if you are not (no), you are allowed to lend books for 7 days. Based on this system, the students are asked to build more complicated flowcharts.

Participants selected for this subproject are six Grade 8 students (ages 13–14) who chose programming as their elective subject (hereafter referred to as the *elective programming course*). The participants (five girls, one boy) came from four different schools (a mix of city-centre and rural schools) in four different counties in the western and southern parts of Norway and were chosen for interviews based on a) their choice of elective, b) their answers on the initial test, and c) how their methods on the initial test stand out from the rest of the students. Also, they were selected to ensure distribution across schools. The names presented later in the Results section are fictional.

Each of the six participants was interviewed by the first author of this paper on the same day as they had completed the initial PISA-2003-based test. The semi-structured interviews lasted for about 15 minutes (between 11–28 minutes) and were recorded. The overall intention of the semi-structured interviews was to explore the students' accounts of their solutions and to see if there were any cross-references between their experiences in mathematics and the elective programming course. The first author used stimulated recall when asking questions about what knowledge they drew on when solving the five selected problems. Additionally, the participants were asked if they had examples of when they had drawn on knowledge learned in their elective programming course in their mathematics class and vice versa.

The interviews were transcribed in full in their original language (Norwegian) and analysed in two steps. Step one involved a process of consistent coding (Mason, 2017) that entailed reading and re-reading the transcript to identify if and how the interviewees related programming and mathematics and their accounts of how they drew on their programming knowledge in mathematics and vice versa. Step two was to identify the central experiences and understanding of the students, which led to two main categories in the results: programming in mathematics and mathematics in programming. These two categories also build on the categories where mathematics is the context for programming and programming is the context for mathematics from Kilhamn et al. (2021) and Elicer and Tamborg (2021).

Results

This results section comprises two parts. In the first part, we will consider how the 8th grade students saw the possibility of using methods, knowledge and skills from their elective programming course when solving problems in mathematics, while in the second part, we will focus on how students used methods, knowledge and skills from mathematics in their elective programming course.

Drawing on Elective Programming Skills in Mathematics

When talking about the library system task, three of the students explained how they recognised the need to use a flowchart, which they had been introduced to in their programming elective course.

Peter immediately recognised the flowchart and explained how he had used it as part of his programming process:

> I recognised this one immediately [points at the flowchart] because we have had many flowcharts in the elective programming course when making programmes in different programming languages. The first thing we have to do is make pseudocodes and flowcharts.

We see how Peter drew on knowledge from his programming elective course when solving the Library system task. This also applies to two other students, Andy and Nick, who recognised the flowcharts as a method from the elective programming course.

While the section above provides examples of how students draw on methods from their programming elective course when solving problems in mathematics, we also found that the programming elective course provided the students with a new vocabulary that came in handy in their mathematical problem solving. During interviews, the students revealed how they tended to use programming concepts to solve and explain *how* they solved the library system task. Nick and Michael used TRUE/FALSE statements or IF-ELSE statements to explain how they solved the library system task and related this problem to earlier experiences:

> (…) is it a magazine? If yes, seven days. If no, go to the next step. If you do not return books or magazines, then you are not eligible to borrow (…) (Nick)

Peter, however, described how he solved other problems during regular mathematics classes using the programming concept variable and loops:

> One time, I developed a programme in Trinket or Python. Then I used a counting variable. I got a task where I could use the counting variable to solve it. This is a formula I can use in the programme because I have learnt to calculate this way using variables and 'x in range' [a command for loops in Python].

The third finding is connected to how the students identified whether or how the elective programming course changed their mathematics problem-solving approach. Due to how they had learnt to work in the elective programming course, Robbie revealed that he made more use of diverse strategies and focused more on finding multiple solutions to mathematical problems, and both Nick and Peter said they saw themselves as working more systematically when solving mathematical problems. Adding to this, Nick talked about how he felt more accurate in solving mathematical problems since this is vital in the elective programming course:

> My mathematical view has become slightly more systematic. (…) In programming, one must be more exact to make a programme work.

Overall, these findings indicate that students acquire general skills through the elective programming course that they see as positive for their mathematical problem solving. Andy even highlighted that he sees a clear connection between programming and mathematics – he sees that both subjects are about solving problems:

> Programming is much about solving different problems in a code, and some of the tasks in mathematics are about the same: solving a problem.

However, some students did not see a connection between the elective programming course and mathematics. Nora, like Michael, claimed that there is no connection between programming and mathematics, adding that there is much she has not understood in the elective programming course. As she finds the elective programming course challenging, kind of softenings her statement on the disconnect. When asked if the elective programming course had affected him in mathematics, Michael put it like this:

> That is a good question; I do not think so since programming does not involve, or it involves numbers, of course, but I am not sure if it is under [has to do with] mathematics. (…) It is not addition or subtraction (…)

Adding to this and despite his vague idea that the elective programming course might have changed his mathematical competency, Robbie revealed that he had never experienced any programming in mathematics and therefore saw no apparent connection. However, he said that one must know mathematics to programme, which we will return to in the second part of the results, which we turn to now.

Drawing on Mathematics Skills in the Elective Programming Course

Our data revealed three ways in which the students reported how they drew on mathematics skills in their elective programming course. The first entails how they report on the use of mathematical concepts in programming tasks, such as figure numbers and geometry. Five of the students had experience with mathematics in programming, one of which is Nora. She explained that she had experienced using rotation and angles when programming how to make different figures move. Likewise, Peter connected experiences from algebra to the concept of variables in the elective programming course:

> There is much mathematics in programming because there is much algebra in programming. One uses many variables to make calculations, and that is almost the same as in algebra.

The second entails that students report on how they find their experiences of using different digital tools in mathematics to better understand what is going on in the elective programming course. Andy described an experience with GeoGebra, where he talked about making and using different functions to solve problems in mathematics. Similarly, Nick drew on an experience of using Excel and claimed this to be programming when he was asked if he used programming to solve mathematical problems: "Excel is technically programming". Both Andy's and Nick's experiences come from well-known computational tools in mathematics, and they reported that their experiences with those tools can help them in the elective programming course.

Third, our analysis shows that all the students, in one way or another, agreed that one needs to understand mathematics to programme. For example, Robbie, who mentioned the four arithmetic operations earlier, used arithmetic to argue that one needs to know them to develop a programme. Nick adds to this, saying "… one has to know much mathematics to programme properly". From this, we can see that Nick sees how mathematics plays a role in the elective programming course.

Discussion

In answering the research question – How and to what extent do students undertaking an elective programming course experience a connection between programming and mathematics? – we decided to investigate how students tend to draw on programming in mathematics, and vice versa. Due to how, for instance, Weintrop et al. (2016) identified problem solving as a central practice for developing CT (and conventional programming) in mathematics, we decided to use the students' solutions on a set of five PISA 2003 problem-solving tasks for knowing their thoughts on the connection between programming and mathematics.

Our analysis resulted in three main findings, where the first two confirm, and considerably elaborate on, the findings of Kilhamn et al. (2021) and Elicer and Tamborg (2021). First, we saw that our students reported programming as a context for mathematics and mathematics as a context for programming. This became apparent in how some students argued that one needs to know mathematics to programme, and conversely, in how they revealed that they had experienced programming in mathematics. Andy, for instance, saw problem solving as a potential connection between programming and mathematics. We believe that this result argues for a potentially fruitful integration between mathematics and programming.

Second, we found differences in how the students talked about and experienced the relationship between mathematics and programming. If we lend the vocabulary of Kilhamn et al. (2021), we can say that some students tended to talk about how programming can work as a computational tool in mathematics. Peter, for instance, explained how he uses concepts from programming to solve problems in mathematics. Moreover, he asserted that programming tools made him approach and view mathematics differently. Robie added to this picture when revealing how he saw programming helping him find multiple solutions to a given problem. This adds insight into Kilhamn et al.'s (2021) category of "programming as a tool for exploring mathematical concepts", where they propose that programming can be used to explore mathematical concepts and add new insights. However, there are students, Nora and Michael in particular, who experienced the elective programming course and mathematics as two different subjects. We see how this adds insight into the categories of Elicer and Tamborg (2021) in the way Nora and Michael's experiences seem to reflect an understanding of "no PCT in mathematics" and "no mathematics in PCT". Hence, we see how some students enhance their understanding of mathematics when engaging in programming activities, while others struggle to see how they can leverage programming in mathematics and vice versa.

Our third finding adds to the "categories of interplay" between programming and mathematics set forward by Kilhamn et al. (2021) and Elicer and Tamborg (2021). Both Nick and Peter stated that the elective programming course provided them with new skills. They emphasised that their experiences with programming had made them see the added value of being *systematic* and *accurate* in mathematics. We propose that this is a new category, and more research is needed to elaborate on it.

Concluding Remarks

This paper contributes to the ongoing discussion on how (and if?) programming and mathematics should be integrated in an educational context. We report on the experiences and views of the students, which, in sum, speak for an integration of the two. In addition, we assert, that by comparing our results with those of Kilhamn et al. (2021) and Elicer and Tamborg (2021), we strengthen their findings regarding how we see that the students' utterances confirm most of their categories of interplay.

Enriching learning of analytic geometry by augmented reality – development of an AR smartphone app

Xenia-Rosemarie Reit

University of Education Karlsruhe, Germany; xenia.reit@ph-karlsruhe.de

Keywords: Augmented reality, digital tools, mathematics education, design-based research

Augmented reality (AR) combines reality with computer-generated representations in real time (Milgram & Kishino, 1994). Both are simultaneously present or continuously merged (Azuma, et al., 2001). Instead of replacing a real situation, e.g. by modelling with dynamic geometry software, AR supplements the real situation with objects or information (Avanitis et al., 2007; Martin-Gutierrez et al., 2010). Therefore, merging reality with additional objects is a unique way to make things tangible without switching to an artificial environment.

From a technical point of view, AR enables the mathematical situation to be represented in the familiar 3-dimensional environment around us and allows the user to navigate within this familiar situation in order to explore it. On a cognitive level, the theory of embodied cognition plays a role, which describes the mutual influence of physical interaction and human thinking (Tran et al., 2017). Through AR, learners can physically explore a mathematical situation given by a task instead of having to imagine it. Thus, it can be assumed that physical exploration reduces the "cognitive load", a measure of cognitive capacity, so that greater cognitive capacities are available to solve the task.

The AR smartphone app "MalAR"

The aim of the project MalAR (transl.: AR-supported mathematics learning) is to research the potential of AR-supported instruction on learning analytic geometry. In a first phase of the project, an AR smartphone app was developed, which is based on the needs of the learners and on the content of analytical geometry.

Due to the complex three-dimensional representations in analytic geometry, physical representations play a subordinate role. This favours a technical and not very descriptive view of these contents (Borneleitet al., 2001). In order to overcome this bias, Filler (2007) suggests a more experiential approach that involves visual perception. The developed AR smartphone app allows learners to place mathematical notions of analytic geometry such as planes (in parameter, coordinate and normal form), straight lines and points into a coordinate system that is embedded in their surrounding reality. The latter is a real novelty compared to other visualisation possibilities with e.g. dynamic geometry software. The input of mathematical objects can be done following the notation learners know from school, so that the barrier of input language, which is a problem with many current AR applications, is overcome. With the AR smartphone app MalAR, learners are able to physically explore the given mathematical situation as well as to evaluate their result in the context of the given situation.

Figure 1 (left) shows the AR implementation of the following task in the app. A plane $E_1: 2x - y - z = -1$ is given. A plane E_2 is sought, which contains point $A(3|1|2)$ and is orthogonal to E_1.

The learners have the possibility to explore the given situation with the help of the AR app by entering the coordinate shape of the plane and the point A in the app and placing them together with a coordinate system in their environment (Figure 1, left). In addition, learners can enter their calculated solution for plane E_2 (correct solution $E_2: x + 2y = 5$, purple plane in Figure 1, right). The required orthogonality as well as the position to point A can then be visually verified through changing the perspective by walking around the situation, i.e. by moving one's own body in the room.

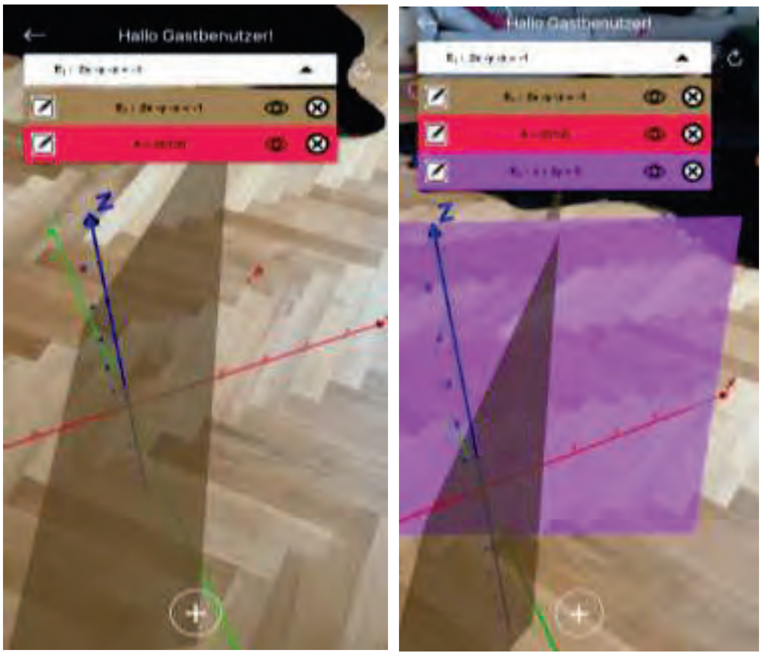

Figure 1: Implementation of the task in the AR app (left) together with the solution (right)

This representation of hitherto only 2-dimensionally represented 3-dimensional mathematical objects as part of the surrounding reality offers the potential to have a decisive influence on spatial perception and the fundamental understanding of those mathematical concepts.

Near and far transfer in the flipped mathematics classroom: student's evaluation of learning activities

Jennifer Rothe[1] and Silvia Schöneburg-Lehnert[2]

[1]University of Leipzig, Germany; rothe@math.uni-leipzig.de

[2]University of Leipzig, Germany; schoeneburg@math.uni-leipzig.de

In contrast to traditional forms of instruction, flipped learning enables students and teachers to focus on consolidating knowledge and fostering a deeper understanding of new mathematical content during class time. Both near-transfer problems and far-transfer problems can be the focus of such consolidation during a face-to-face lesson. In this study, we examine how students evaluate different learning activities in a flipped classroom setting when class time is dedicated to near transfer and far transfer, respectively. Results indicate, for example, a general preference for collaborative work, especially during face-to-face lessons that focus on far-transfer. To contextualize the results, we took the teacher's perspective into account. It adds a valuable point of view but is not always compatible with the students' perspective.

Keywords: Flipped classroom, Learning activities, Transfer of Learning.

Introduction

Flipping the classroom divides students' learning into two phases: the homework phase taking place before class and the face-to-face in-class phase. During the homework phase, students study new content at home, usually with the help of a video (Bishop & Verleger, 2013). Often, such videos focus on different forms of direct instruction (Bergmann & Sams, 2012), such as introductory videos, that explain new mathematical concepts, or illustrative videos, that present worked examples (Voigt et al., 2020). During the in-class phase, face-to-face time can then be used to focus on applying the content studied during the homework phase (Love et al., 2013). This can include various tasks and activities differing in their cognitive demand and the underlying educational objectives. One criterion to characterize different ways of content application in mathematics is the transfer of learning (Tüker, 2013). More specifically, near transfer and far transfer can be distinguished. Near transfer occurs between very similar contexts, whereas far transfer occurs between contexts that seem more remote to each other (Perkins & Salomon, 1994).

Near and far transfer in the flipped classroom

In a flipped learning environment, near transfer during the in-class phase can refer to tasks and activities in this phase being similar to the content of the video, especially worked examples previously presented in the video. For instance, in the context of teaching the Pythagorean theorem, near transfer occurs when students are given the task to calculate the length of the hypotenuse in a right-angled triangle in class after watching a video at home demonstrating such a calculation based on a different numerical example. Students can apply the algorithm displayed in the video directly in the context of the new task. In contrast, activities and tasks of far transfer in class go beyond the context presented in the video. For instance, far transfer occurs when students watch a video demonstrating how to apply the Pythagorean theorem to calculate lengths for one type of polyhedron, such as a pyramid, by looking for auxiliary right-angled triangles. In class, they are then asked to transfer this more general strategy to new types of polyhedrons, like cuboids, for example. While near transfer and far transfer are discussed in theory for designing activities for the in-class phase of a flipped classroom (Enfield, 2016), previous research on these forms of transfer in the flipped classroom is scarce or focusses on students' performance, e.g., Harrison et al. (2017). Hence, it has been suggested by Lo and Hwang (2018) that future research on course activities for flipped learning should also take into account near and far transfer as well as student perceptions of such activities. Therefore, we examine student perceptions of flipped learning activities in the context of near transfer and far transfer in this study.

Research Questions

The study aims to compare students' evaluations of learning activities in a flipped classroom for lessons that focus on near transfer and far transfer of the video content during the in-class time (hereafter referred to as near-transfer lessons and far-transfer lessons), respectively. To guide this comparison, we pose the following research questions:

1. How do students evaluate learning activities in the flipped classroom for near-transfer lessons?
2. How do students evaluate learning activities in the flipped classroom for far-transfer lessons?
3. How do students' evaluations of activities in the flipped classroom differ between near-transfer lessons and far-transfer lessons?

Methods

Participants

This study was conducted with students of four classes of the 9th grade of two German academic-track secondary schools (Gymnasium) in June 2021 (N = 79). These are schools granting the highest possible secondary school qualification in Germany. Convenience sampling was used to select the participants. The classes were taught by two different teachers. Their experiences in teaching mathematics in general as well as teaching the classes participating in the study were similar. Neither teacher had used the flipped classroom method regularly before this study. However, the teachers implemented flipped learning for several individual lessons before the start of the main study under the authors' guidance to accustom the students to the changed requirements in the flipped classroom (Lo et al., 2017). According to the teachers, students in all classes were familiar with cooperative forms of work, such as working with a partner or in small groups, before the study.

Design and Procedure

The students were taught two back-to-back flipped lessons on the Pythagorean theorem. The flipped lessons were conducted within a longer lesson sequence on the Pythagorean theorem, i.e., the students had prior knowledge of some aspects of the subject matter. However, each flipped lesson introduced new learning contents that had not been taught in previous lessons. The instructional material was designed and provided by the first author of this paper. During the homework phase of each lesson, students worked with an instructional video of nine to twelve minutes. These videos can be classified as illustrative videos (Voigt et al., 2020) since they contained worked examples or solutions for different problems related to the Pythagorean theorem, e.g., calculating the missing length of a side in a right-angled triangle or calculating the edge lengths of pyramids. Each video was accompanied by a short task relating to its content as an incentive for students to prepare for class (Kim et al., 2014). Completing these tasks, including watching the video, takes an estimated time of 30 minutes. The following in-class phase consisted of a face-to-face lesson of 90 minutes. It started with comparing students' solutions to the task related to the video and clarifying problems or questions. The remaining time of the lesson was devoted to exercising and consolidation. Here the two flipped lessons differed. Students' tasks for consolidation focused on near-transfer problems in one lesson and far-transfer problems in the other lesson. However, both lessons provided differentiated tasks according to students' level of prior knowledge and the opportunity for students to determine the pace of working through those tasks themselves. Furthermore, students could decide to work collaboratively with a partner or in small groups. For most tasks, students could also opt for working on their own if they preferred. During this phase, the teacher acted as a "guide on the side" (King, 1993), answering questions and providing scaffolding if necessary. At the end of each flipped lesson, students completed a survey evaluating the learning activities of the lesson. One teacher taught the near-transfer lesson before the far-transfer lesson. In classes of the other teacher, it was vice versa.

Instruments and Data Analysis

For the post-class survey, an adapted version of the Student Assessment of their Learning Gains (SALG) instrument (Seymour et al., 2000) was used after the near-transfer lesson and again after the far-transfer lesson. Students' evaluations of how much the learning activities in the flipped classroom helped their learning were gathered on a 5-point Likert scale ranging from 1 (no help) to 5 (great help). Since this does not constitute an interval scale, non-parametric tests were used for data analysis (Rasch et al., 2010). For students who did not engage in certain activities during a lesson, e.g., individual work, the option 'not applicable' was given in the questionnaire. In total, 75 students completed the survey after both flipped lessons. Four students, who only completed one of the two surveys, were excluded from the study. To determine whether students' evaluations for the individual activities during the near-transfer lesson and far-transfer lesson themselves differed, we applied the Friedman test for comparing multiple dependent samples (Janssen & Laatz, 2017). Since a comparison of all evaluated activities would not allow a meaningful interpretation, multiple Friedman tests were conducted for groups of related activities, e.g., comparing types of collaborative work. For the Friedman test, a post hoc analysis is necessary (Janssen & Laatz, 2017). Therefore, pairwise comparisons were conducted within each group using the Bonferroni correction. For further separate analysis of activities during the near-transfer lesson and the far-transfer lesson, the correlation between students' evaluation of the individual activities and their level of prior knowledge was examined through Spearman's rank correlation coefficient r_s for ordinal data (Janssen & Laatz, 2017). For this purpose, students were ranked into three groups according to their level of prior knowledge (low, average, and high) based on grade point average. Since students could choose not to do certain activities, missing data had to be taken into account. Therefore, a χ^2-test for the independence of nominal data (Rasch et al., 2010) was conducted to determine whether the decision against a specific type of activity depends on the students' level of prior knowledge for each form of transfer. Another χ^2-test was conducted to examine whether the decision against a specific type of activity during the near-transfer lesson coincides with such a decision in the far-transfer lesson. Finally, differences in students' evaluations of activities during the near-transfer and the far-transfer lesson were analyzed using the Wilcoxon signed-rank test for comparing two dependent samples (Rasch et al., 2010). All tests were applied at a significance level of 0.05 using SPSS. To contextualize the results of the SALG, we added an open-ended question to the surveys asking students to elaborate and explain their assessment. Furthermore, an interview with the teachers was conducted to gather an assessment on student learning from an observer perspective. The students' answers to the open-ended survey question and the teachers' statements were analyzed by the authors applying a thematic coding strategy (Kuckartz, 2010). When differences in the analysis occurred, the corresponding segments were discussed further until consensus was reached.

Results

Evaluation of learning activities for near-transfer lessons

Table 1 displays the evaluation results of the near-transfer lesson for all activities. The Friedman test for the different types of collaborative work, i.e., individual work, partner work, and group work, indicates significant differences (χ^2 (2, n = 47) = 38.38, p < .001). Post hoc analysis demonstrates that individual work was rated as significantly less helpful compared to partner work (z = -4.95, p < .001) and group work (z = -3.89, p < .001), respectively. However, the difference between partner work and group work evaluations was not statistically significant (z = 1.08, p = .836). Students' statements in the open-ended survey question yielded the same results with students describing both partner and group work mainly as a possibility to exchange ideas and thus to reach the goal faster.

Table 1: Evaluation results of individual learning activities for the near- and far-transfer lesson

	near-transfer lesson			**far-transfer lesson**		
Learning activity	n	M (SD)	Mdn	n	M (SD)	Mdn
Video-related activities						
Watching the instructional video at home	70	4.00 (0.87)	4.00	71	4.01 (0.80)	4.00
Completing tasks related to video at home	73	3.41 (1.05)	3.00	66	3.42 (0.96)	3.00
Comparing results of video-related tasks in class	62	4.02 (0.98)	4.00	71	4.13 (0.97)	4.00
Types of explanation						
Hearing explanations by the teacher in class	73	4.23 (0.84)	4.00	73	4.22 (0.97)	4.00
Participating in discussions in class	48	3.40 (1.22)	3.50	60	3.77 (1.06)	3.50
Hearing other students explain their work in class	51	3.49 (1.07)	4.00	65	3.23 (1.09)	4.00
Interacting with the teacher in class	65	4.34 (0.76)	4.00	65	4.63 (0.65)	4.00
Explaining my work to other students in class	47	3.19 (1.23)	3.00	64	3.13 (1.15)	3.00
Collaborative work						
Participating in group work in class	50	4.04 (0.95)	4.00	72	4.26 (0.89)	4.00
Participating in partner work in class	67	4.18 (0.82)	4.00	69	4.12 (1.02)	4.00
Studying on my own	69	3.32 (1.08)	3.00	65	3.08 (1.16)	3.00
Other						
Working at my own pace	75	4.32 (0.83)	5.00	75	4.39 (0.80)	5.00
The overall approach to teaching and learning	75	4.15 (0.73)	4.00	74	4.12 (0.78)	4.00

For the five different types of explanation (see table 1), the Friedman test also indicates significant differences (χ^2 (4, n = 37) = 45.59, p < .001). In this case, post-hoc pairwise comparisons revealed that interaction with the teacher was evaluated as significantly more helpful than participating in discussions (z = -3.01, p = .026), hearing other students explain their work (z = -3.57, p = .004) or explaining one's own work (z = -4.96, p < .001), respectively. Furthermore, hearing explanations from the teacher was rated significantly higher than hearing other students explain their work (z = 2.98, p = .029) or explaining one's own work (z = 4.38, p < .001). Between other pairings no significant differences were found. Using χ^2-tests for further examination of missing data, i.e., occurrences of the evaluation 'not applicable', did not reveal any significant relationships between the choice not to partake in a specific learning activity and the students' level of prior knowledge. Furthermore, the application of Spearman's rank correlation coefficient did not indicate a significant correlation of the students' level of prior knowledge and their evaluation of any learning activities during the near-transfer lesson.

Evaluation of learning activities for far-transfer lessons

The evaluation results of the far-transfer lesson for all activities are also displayed in table 1. Similar to the results for the near-transfer lesson, the Friedman test for the different types of collaborative work suggests significant differences (χ^2 (2, n = 60) = 49.69, p < .001). Again, post hoc pairwise comparisons indicate that individual work was rated significantly lower compared to partner work (z = -5.02, p < .001) and group work (z = -5.39, p < .001), whereas the difference between partner work and group work was not statistically significant (z = -0.37, p = 1.000). The explanations for this rating given in the open-ended survey question do not differ from those for the near-transfer lesson. The Friedman test for the five different types of explanation indicates significant differences (χ^2 (4, n = 50) = 84.79, p < .001) during the far-transfer lesson, too. Post hoc analysis is comparable to the near-transfer lesson revealing that interaction with the teacher was again evaluated significantly higher than participating in discussions (z = -3.92, p = .001), hearing other students explain their work (z = -6.19, p < .001) or explaining one's own work (z = -7.18, p < .001), respectively. Once again, hearing explanations from the teacher was rated as significantly more helpful than hearing other students explain their work (z = 4.05, p = .001) or explaining one's own work (z = 5.03, p < .001). However, unlike during the near-transfer lesson, the activity of participating in discussions was rated as significantly more helpful than explaining one's own work to others (z = 3.26, p = .011). No other significant differences were found. As was also the case for the near-transfer lesson, no significant relationships were found between students' level of prior knowledge and their evaluation of any of the learning activities of the far-transfer lesson or their choice not to partake in any specific activities during this lesson. This result is not consistent with the results gathered during the teacher interview. One teacher voiced the opinion that flipped learning as an overall approach is not as suitable for students with a low level of prior knowledge. The other teacher expressed the opposite view that activities of the homework phase are especially suitable for such students if they exhibit a certain level of diligence.

Comparison of the near-transfer lesson and the far-transfer lesson

The Wilcoxon signed-rank tests indicate significant differences in students' evaluations between both lessons only for some of the learning activities. Students' evaluations rated individual work ('Studying on my own') during the near-transfer lesson statistically significantly higher than during the far-transfer lesson ($z = -2.21$, $p = .027$, $n = 61$). In contrast, group work was rated significantly less helpful during the near-transfer lesson than during the far-transfer lesson ($z = -3.00$, $p = .003$, $n = 49$). A similar result was found for (individual) interaction with the teacher, which was also rated significantly less helpful during near-transfer lessons than during far-transfer lessons ($z = -3.05$, $p = .002$, $n = 62$). For certain types of explanations, one-sided hypotheses were formulated. In the case of the activity of 'hearing other students explain their work', it was assumed that during far-transfer lessons, students would be able to produce fewer mathematically correct explanations than during near-transfer lessons. Thus, it was expected that the helpfulness of this learning activity would be ranked higher during the near-transfer lesson than during the far-transfer lesson. This was confirmed by the Wilcoxon signed-rank test ($z = -1.83$, $p = .067$, $n = 48$). Since rank differences occurred in the predicted direction, this result can be interpreted as statistically significant in accordance with the one-sided hypothesis. For the other learning activities evaluated with the SALG, no significant differences between the near-transfer and far-transfer lessons were found. Comparing the occurrence of the evaluation 'not applicable' for the learning activities during both lessons, the χ^2-test revealed a significant relationship for the activities of explaining one's own work to others (χ^2 (1, n = 71) = 10.81, p = 0.001), hearing other students explain their work (χ^2 (1, n = 70) = 8.89, p = 0.003) as well as interaction with the teacher (χ^2 (1, n = 74) = 36.21, p < 0.001) during class. Students who did not partake in one of those activities during the near-transfer lesson were also unlikely to partake in the same activity during the far-transfer lesson.

Discussion

In the previous section, we have examined how students evaluate different learning activities in a flipped classroom setting when class time is dedicated to near transfer and far transfer, respectively. Most of the results were to be expected, and student comments and teacher interviews largely confirm the statistical results. However, the comments and interviews cast an interesting eye on the following aspects. As generally expected, partner and group work were both rated significantly more helpful than individual work. Also, the significantly higher evaluation of individual work in near-transfer lessons in contrast to far-transfer lessons is in line with our expectations, since here tasks and activities are similar to the content of the video. In contrast, this is hardly evident from the student comments, which focus almost exclusively on the partner and group work. However, this omission can be explained by observations of one of the teachers: the students frequently opted for partner or group work during the near-transfer lesson, but observing them, one got the impression that everyone completed the tasks on their own without any exchange in between them. During the far-transfer lesson, the teacher observed a much more vivid exchange during the group work. This comparison suggests creating opportunities for individual work phases in near-transfer lessons and offering more possibilities for group work in far-transfer lessons, a concept that needs further investigation. Nevertheless, the role of the teacher should not be underestimated during individual and collaborative work. In both the near-transfer lesson and the far-transfer lesson, students find explanations by their peers to be less helpful than explanations by the teacher. Especially interacting with the teacher, which can provide the opportunity to clarify individual problems, seems to be more important during far-transfer lessons than during near-transfer lessons. This was reflected in students‘ comments in the open-ended survey question which consistently emphasized the importance of interacting with others during group work, including the teacher. Another aspect worthy of discussion concerns the level of prior knowledge. The teachers assessed the suitability of flipped learning activities differently depending on students' level of prior knowledge. In contrast, the survey results suggest that students' preferences for any of the given types of activities do not correlate with their level of prior knowledge neither for near-transfer lessons nor for far-transfer lessons. This can also be seen from analyzing the occurrences of the answer 'not applicable' in the survey. A students' choice to not engage in certain types of activities at all (like interacting with a teacher) during a lesson cannot be explained by their level of prior knowledge in our study. Instead, a comparison of the near- and far-transfer lesson suggests that the more likely explanation for not choosing certain activities is that there are students who generally communicate less on an individual level with a teacher or other students during lessons. This effect seems to be independent of the teaching design.

Conclusion

In summary, our results show that students appreciate the possibility to work in groups during the in-class phase of a flipped classroom, both in near- and far-transfer lessons. The qualitative part of the study suggests focusing on individual work during near-transfer and group work during far-transfer lessons. A correlation between students' preference for certain types of activities and their level of prior knowledge could not be detected. This could be superimposed by other variables, especially aspects of behavioral engagement (Cevikbas & Kaiser, 2021). Traditionally, research on engagement in the flipped classroom focuses on the influence of flipped learning on student engagement (Bond, 2020). We suggest that further research also investigates the reversed case, i.e., the influence of student engagement on learning activities in a flipped classroom, particularly video-related activities.

Fingers or rods? Using AI block play recognition to endorse children's mathematical re-worldings

Michael Rumbelow

University of Bristol, UK; cc18401@bristol.ac.uk

Keywords: Artificial intelligence, manipulative materials, mathematics education.

Research topic

What is a wooden cube? In the Kindergarten pedagogy of Friedrich Froebel (1782-1852), children and caregivers or teachers are encouraged to playfully transform a cube through storying and actions:

> for example, the cube can be now a table on which something is placed for the child. Again, it can be a stool on which the mother places her feet; again, a chair on which she sits with the child; again, the hearth on which something is to be cooked. (Froebel, 1895, p.99)

Similarly in mathematics classrooms children may be encouraged to transform wooden and plastic manipulatives, such as interlocking cubes and Cuisenaire rods, into 'real world' objects through storying and actions. For example, in enacting a word problem, cubes may become oranges or cupcakes etc, which are physically gathered by the child. In 'bar modelling' these cubes (aka 'oranges' etc) may be lined up in a row to facilitate acoustic counting, and eventually this row may be storied as having a 'length', then drawn as a rectangular 'bar' and labelled with a symbolic number.

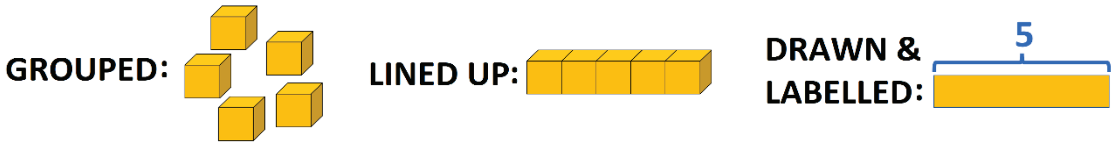

Figure 1: Typical bar modelling stages eg 5 oranges as cubes grouped, lined up and drawn as a length

In my doctoral study I am interested in studying these mathematical transformations, or 're-worldings', of wooden blocks, through children's storying and actions, often modelled and endorsed by teachers or caregivers, books, videos or apps. To support this research I was keen to explore technological tools, such as AI object detection to recognise and record children's positioning of blocks. In collaboration with a software developer, PySource, with seedcorn funding from the Bristol Digital Futures Institute, we developed an app in Python which uses artificial neural network (ANN) algorithms to recognise the placements of Cuisenaire rods on a tabletop, from a webcam, in near real time, and records the data in a spreadsheet for analysis. The rod recognition is triggered when the webcam detects no movement, ie when children take their hands away from the tabletop. In addition, the app can be programmed to respond to the placing of rods with sound files, such as speaking the colour, or length of the rod. It can also tell when two rods are placed end to end, or in parallel, and generate simple audible mathematical sentences accordingly, such as "two plus three equals five".

The app is still at a prototype stage, the ANN has only been trained on a small sample set of images so far, and requires further training and user-testing before it can be used as a reliable experimental research tool in the field. We hope as a tool it may eventually support a variety of experiments and methodologies. However, for the purposes of testing the app technically with users in a 'realistic' experimental scenario, we developed a theoretically ‘light’ methodology to inform task design, based on analysis of observed discourse as a highly reductive artificial Wittgensteinian ‘language game’, consisting of actions and interwoven language, where the actions are restricted to a child’s placements of Cuisenaire rods on a table, and the language is restricted to the app’s utterances, and questions, or ‘challenges’, posed spontaneously by the researcher, in the form of ‘Can you make it say…?’

Method

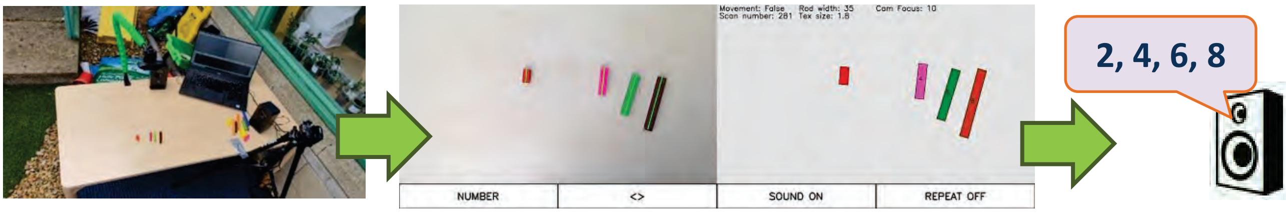

Figure 2: The app processes a webcam feed of rods placed on a tabletop and ‘speaks’ the lengths

In a local primary school in southwest England, Year 1 children (aged 5-6), who were not familiar with Cuisenaire rods, were invited individually to play a ‘game’ with rods, the app and a researcher, where the researcher challenged the children to ‘make it say’ certain numbers or sequences, such as the number five, or the two times table, or a sum, by placing rods on the tabletop. The children have to infer by experiment the ‘rules’ of which utterance is triggered by the placement of which rod. The tabletop block play was video recorded and the dialogue, and images grabbed by the app, analysed.

Results

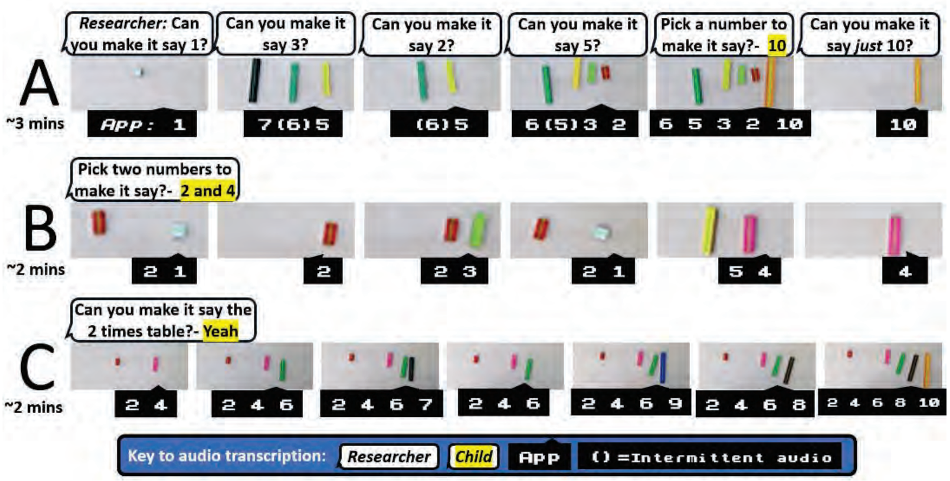

Figure 3: At first rods are placed as if ‘fingers’ eg 3 rods for ‘3’, then after experimenting , as lengths

As an early technical test we do not claim the tool was yet reliable enough for a rigorous experiment, with occasionally intermittent detection of some rods. However, on analysis of one 7-minute clip we observed an interesting shift in actions – of rod placements – consistent with a shift in inferred ‘rules’ from rods as ‘counters’ or ‘fingers’, eg placing 3 rods to (unsuccessfully) ‘make it say 3’, to rods as proportional ‘lengths’ eg placing 2, 4, 6, 8, 10 rods to (successfully) ‘make it say the 2 times table’.

Design of digital teaching and learning materials for mathematics teacher education at the university level

Florian Schacht, Petra Scherer, Julia Marie Stechemesser, Karolina Hasebrink and Jessica Bau

University of Duisburg-Essen, Faculty of Mathematics, Germany; florian.schacht@uni-due.de; petra.scherer@uni-due.de; julia.stechemesser@uni-due.de; karolina.hasebrink@uni-due.de; jessica.bau@uni-due.de

Keywords: Digital tools, OER, university mathematics education.

Motivation

In recent years there is a growing body of research concerning the use of digital tools at the university level. Whereas many studies focus mathematical programs like geometry or functional reasoning (cf. Albano et al., 2021), there has been less research concerning the use of digital tools in the context of mathematics teacher education, which addresses both, content-related as well as educational-related topics in mathematics and mathematics education. School-related research suggests, that digital technologies offer the possibility to help students autonomously acquiring mathematical knowledge (Drijvers et al., 2016), which is relevant for teacher training programs, too. Another advantage of digital learning materials is that they are not limited to one institution, as they can be distributed as Open Educational Resource (OER). Hence, OER has the potential to reshape and improve teaching in higher education (Camilleri et al., 2014). Not only the implementation of technological innovations but also their design is of great importance (OECD, 2015).

Goals and objectives of the explorative project 'DigiMal.nrw'

The development of digital learning materials for mathematics teacher education at the university level, and research on students' learning processes is the main purpose of the project DigiMal.nrw. The research activities in this project are oriented towards a design-based research approach. Developed materials address both, mathematical content and more didactical, practice-oriented content for learning situations (e.g. in seminars and lectures) and exam situations. The development and use of digital learning materials (e.g. interactive videos) and diagnostic tools (e.g. digital self-checks) shall enhance the individual student teacher's learning process to understand, reflect and use the content for learning independently of time and location. All digital materials developed will be available as Open Educational Resources (OER) on the (federal) state portal ORCA.nrw (Open Resources Campus NRW), a platform for exchange, communication and the use of digital materials.

Project group and sub-projects

DigiMal.nrw consists of five thematic sub-projects: The sub-projects 'arithmetic', 'geometry' and 'stochastics' refer to mathematical core contents. The sub-projects 'heterogeneity in mathematics classrooms' and 'subject-related language education' address didactical challenges. The project involves all eight universities in North Rhine-Westphalia (Germany) that provide teacher training for elementary school and special education. In this constellation, the project realizes a core idea of OER already in the process of the development: The material is developed and used in teams of different universities, and the material is exchanged within the project group. Hence, when distributing the material as OER on the platform, it is already exchanged and widely used in different locations so that the potential of further distribution will be increased.

First results

The developed digital learning materials vary in terms of their application and technical realization. The following types of materials have been created so far (most of them designed with the software H5P): 13 self-checks, 3 video based learning environments, in which students create videos, 27 interactive books, 1 digital introductory course, 1 digital learning environment, and several explanatory videos. Figure 1 gives an insight into different excerpts of an interactive book out of the sub-project 'geometry'. An interactive book consists of different pages. Every book page is a combination of e.g. interactive videos, GeoGebra-applets, tips, multiple choice questions, and drag and drop tasks, helping students to learn lecture contents autonomously.

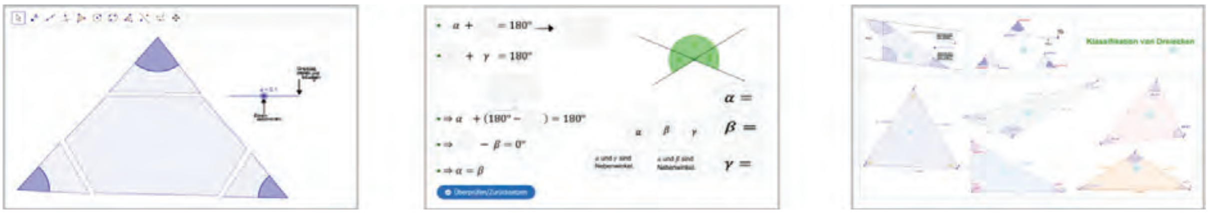

Figure 1: Extracts from interactive books (sub-project 'geometry')

The associated research projects especially address questions like the use of the digital resources. In the case of geometry, for example, first analyses of interviews and questionnaires suggest that the combination of videos, digital tasks and tips in an interactive book supports students investigating geometric proofs on their own and reflecting their work profoundly. Further evaluations will give hints for revising the material and derive implications for the design of digital learning materials.

An impact of 3D computer and 3D printed models on the students' success in spatial ability and geometry testing

Petra Surynková

Charles University, Faculty of Mathematics and Physics, Charles University, Prague, Czech Republic; surynkov@karlin.mff.cuni.cz

The aim of the presented study was to measure whether 3D computer and 3D printed models could improve students' performance in testing their spatial ability and what brings the greater benefits. This study employed a quasi-experimental approach with a total of 25 secondary school students. A pre-test was employed to determine each student's level of spatial ability, namely the Mental Rotations Test. All students were taught the topic of three-dimensional geometry using 3D physical printed models, 3D virtual computer models or 2D drawings of 3D objects. A newly designed 3D geometry post-test was used in two groups of students - the first group was allowed to manipulate 3D printed models, the second group was allowed to use 3D computer models during the test. The group with 3D computer models outperformed peers with 3D printed models but a statistically significant difference was not found. Afterwards, the same students were tested again using the identical 3D geometry test without any visual aids. It was concluded that the 3D computer models provided statistically significant higher scores in comparison to the absence of any visual aid.

Keywords: Spatial ability, 3D printed models, 3D virtual models, geometry.

Introduction

Secondary school geometry is traditionally focused on studying geometric relationships in the two-dimensional space, i.e. planar geometry, and on studying solid geometry, i.e. spatial geometry. To study geometry is a big challenge and even if we live in the three-dimensional world it is difficult to work with three-dimensional objects especially when they are depicted on two-dimensional display. To be successful in the solving geometry problems spatial ability plays the main role. According to Lean and Clements (1981), *spatial ability* is the ability to formulate mental images and to manipulate these images in the mind. Very similar definition is provided by Linn & Petersen (1985) that is spatial ability generally refers to skill in representing, transforming, generating, and recalling symbolic, nonlinguistic information. Sorby (1999) distinguished *spatial ability* and *spatial skills*. Spatial ability is considered as the innate ability to visualize, whereas spatial skills are learned and acquired through training. Anyway, the both terms are very closely related and it is very difficult to distinguish them. In compliance with the literature, I will uniformly use the term spatial ability and will not examine the way in which the ability was acquired.

Spatial ability is a very essential part of intelligence and it is proved that continuous training has a great effect on its enhancement (Maresch & Posamentier, 2019, p. xv). Many studies undoubtedly proved that spatial ability of persons of different age can be trained (Maier, 1998). According to Sorby & Baartmans (2000) spatial ability can be improved through the targeted engineering graphics courses where diverse spatial activities are used ranging from manipulation of concrete models to computer visualization activities. Alias et al. (2002) state that spatial ability can be fostered trough activities predominantly consisting of free-hand sketching and object manipulation. Spatial ability is important for engineering, design, or other technology disciplines. It has been found to be very useful to a students' success in engineering related subjects as mathematics, engineering drawing, or computer-aided design (Alias et al., 2002). Moreover, spatial ability involves our mathematical, verbal, and logical capabilities and it is even crucial for our everyday life. We need the spatial ability to be able to orient ourselves in the environment, to understand the spatial relations among objects, to solve everyday tasks such as packing, moving, and many more.

The extensive research on spatial ability mainly based on factor analysis studies has resulted in the detailed categorization of spatial ability and its factors (Lohman, 1979). However, there was not a clear consistent model of different subcomponents of spatial ability. To illustrate this fact, let us mention that based on mental processes which are used for solving certain tasks McGee (1979) described two major components (factors) of spatial ability – *spatial visualization* and *spatial orientation*. On the other hand, the classification proposed by Lohman (1979) consists of three basic spatial ability factors – *spatial relation*, *spatial orientation*, and *visualization*. Five major factors of spatial ability – *visualization*, *spatial relations*, *closure speed*, *flexibility of closure*, *perceptual speed* were detected by Caroll (1993). Yilmaz (2009) provides a picture of a comprehensive model also with some another components of spatial ability. It seems that the number of underlying factors of spatial ability varies from study to study. However, *visualization*, *spatial relation*, *mental rotation*, and *spatial orientation* are subcomponents of spatial ability which are nowadays often designated as the relevant (Maresch & Posamentier, 2019). I will consider these subcomponents also in my research.

If we need to move or to alter in our mind some parts or the whole mentally presented objects, then it is considered as a spatial visualization task. Spatial visualization is the ability to imagine manipulating, moving, rotating, twisting, or inverting objects without reference to one's self. It means that the imagined object or its parts are moved or changed in our minds. Spatial relation works with the mental comparing of objects and with the identification of object parts which fits together. This subcomponent is not completely independent from the visualization subcomponent. The subcomponent mental rotation is the ability to imagine rotating a two and three-dimensional object or figure. Finally, the factor spatial orientation requires one's ability to imagine the appearance of an object from different perspectives. In other words, the imagined object does not mentally move, it remains the same and we mentally move ourselves to different viewpoints. Nowadays, the identification and description of the strategies for solving spatial problems emerge as a very interesting topic and it is brought into focus of the researchers. The classic research methods on factors of spatial ability assume that the spatial ability tasks of some category are solved using the same intended strategy. From the literature (Maresch & Posamentier, 2019) and also according to my own experiences with students, we know that geometric tasks are solved differently by different individuals.

In my research, I focus on the measurement and improvement of spatial ability of secondary school students. On the ground of the study, I include the optimal training and teaching methods into mathematics instructions to improve students' spatial ability. The objective of my research is to measure whether the 3D computer models and 3D printed models could improve students' performance in testing their spatial ability.

Spatial ability and the use of dynamic geometry and 3D printed models in mathematics education

In the presented research, let us focus on secondary school mathematics, namely on the topic of solid geometry. This traditional geometric topic covers the study of two-dimensional and three-dimensional Euclidean space. It includes the study of properties of and relationships between geometrical objects in the plane and in the three-dimensional space. It includes the measurements of volumes of various solid figures such as pyramids, prisms, polyhedrons, cylinders, cones, truncated cones, or spheres, cross-section of solids, transformations of two- and three-dimensional shapes in the plane and the three-dimensional space. Students determine the relative positions between two geometrical figures – lines and planes. Very typical tasks of solid geometry are to determine the size of an angle formed by two rays, to find the size of a dihedral angle, i.e. the angle between two intersecting plane, or to compute the size of an angle between a plane and intersecting straight line. Usually students solve such tasks depicted in two dimensional situations; so the proper visualization and its correct interpretation are crucial here. In the Czech mathematics textbook, usually the oblique projections are used. An oblique projection is a simple type of parallel projection which produces two-dimensional images with the specific properties (Carlbom & Paciorek, 1978). It holds that parallel lines are projected into parallel lines. If a polyhedron is projected, usually some its face or faces are parallel to the image plane (then these faces are projected in true shapes and sizes and are not distorted). I insist on working with an arbitrary position of projected solids, i.e. solids can be viewed from above from the right, from above from the left, from below from the left, and from below from the right. This is usually neglected in mathematics textbooks and only one position of the viewpoint is used.

I use dynamic software GeoGebra in my mathematics instructions. Indisputably, GeoGebra belongs among DGS (dynamic geometry systems) which are the most widespread all over the world among teachers and students. It is open-source software which is easy to use and understandable even for the absolute beginners. According to my experiences, GeoGebra software can be used with a potentially positive impact in teaching and learning process especially in such cases where its dynamic features can be used. It offers basic functions to model solid figures or more complex three-dimensional situations. Moreover, the modeled situation can be arbitrary rotated so it is viewed from different viewpoints; so it can substitute the real physical model to a certain extent.

Although, the computer-aided education is very modern and popular and brings indisputably advantages to the process of education, physical object manipulation plays the important role in the learning geometry and enhancing spatial ability. Especially action oriented training methods that work with real models have always shown good results in the improvement of spatial ability (Maier, 1998). This can be based on the approach of embodied cognition which emphasizes that cognition involves a motor behavior (Schneegans & Schöner, 2008).

In my mathematics instructions related to geometry, I use 3D computer models together with physical 3D printed models of solid figures and of three-dimensional situations as a visual aid. The properties of geometrical objects are demonstrated in my instructions using 3D virtual models and physical 3D printed models or students can use these models as a visual aid when they are solving the geometric tasks.

Methodology

As has been already pointed out, my aim is to measure students' success rate in geometric tasks; specifically whether and how much the 3D computer models and 3D printed models could improve their performance in testing their spatial ability. In order to explicate the effectiveness of visual aids, a quasi-experimental approach was chosen. 25 students (one class) in the third grade (17-18 years old) of a secondary school (grammar school) in the Czech Republic were involved in the experiment. The topic of solid geometry was taught for two months at the end of the school year 2020/2021. Partially it was a distance learning (3 weeks) which was caused by the worldwide pandemic situation; the rest was standard face-to-face education. All students were taught the topic of three-dimensional geometry (solid geometry) using 3D virtual computer models, 3D physical printed models (this visual aid was used only at school), or 2D drawings of 3D objects. The teaching method was the same for all students in the experiment realized by one teacher.

Firstly, the students took the *Mental Rotations Test* as a pre-test to determine their level of spatial ability. The students received the test approximately in the middle of the period when the teaching of solid geometry was realizing. The Mental Rotations Test is one of the most common instruments for measuring spatial ability. The original test was developed by Vandenberg & Kuse (1978) and it contains 20 items in five sets of four items. Each item consists of a criterion figure, two correct alternatives and two incorrect ones. The alternatives are always shown in a rotated position. Each item in the test is counted as correctly answered if both choices are correctly chosen. This eliminates the need to correct for guessing. The reliability of the test has been found satisfactory. In a sample of 3,268 adults and adolescents of age 14 year or older, was .88; in a similar sample of 336 subjects, the test-retest correlation was .83 after an interval of one year or more, and in an age corrected sample of 456 the test-retest reliability after a year or more was .70 (Vandenberg & Kuse, 1978). For the purposes of the research, I used a redrawn modified version of the Mental Rotations Test called MRT-A (Peters et al., 1995) with the official permission from the author Michael Peters. This modified version of the test consists of 24 items and the nature of the test is completely the same. The maximum score of the test was then 24 points.

Secondly, the students divided into two coherent groups took a newly designed post-test on solid geometry at the end of that two month period. According to the results from the Mental Rotations Test, it was shown that the both groups of students were close to equal. The first group of students (Group 1, n_1=13) was allowed to manipulate 3D printed models during the test as the visual aids; the second group of students (Group 2, n_2=12) was allowed to use 3D computer models during the test as the visual aids. Students of Group 1 are denoted by G1, students of Group 2 are denoted by G2. The 3D geometry post-test consists of five types of geometric problems in the three-dimensional space – the relative positions between two lines (12 individual tasks), the relative positions between a line and a plane (6 individual tasks), the size of an angle between two lines (3 individual tasks), the size of an angle between a line and a plane (3 individual tasks), and the size of an angle between two planes (3 individual tasks). All the geometric problems were depicted in two dimensional situations, i.e. projected to the plane; the oblique projection was used in all cases and different positions of the viewpoint were considered. In Figure 1 you can see three concrete tasks of the relative positions of two lines. Students were asked whether the depicted lines (drawn in the auxiliary cube) are parallel, intersecting, or skew. In Figure 2 you can see three concrete tasks of the size of an angle between a line and a plane (again drawn in the auxiliary cube). Students were asked to determine the size of an angle without any algebraic calculation. Every single task was for one point, so the maximum score of the test was then 27 points.

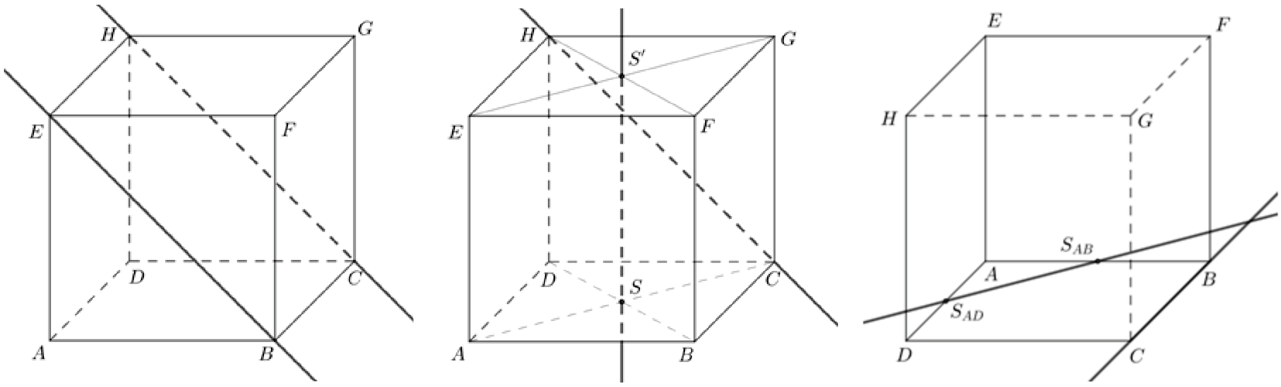

Figure 1: The relative positions of two lines – parallel, skew, intersecting, respectively

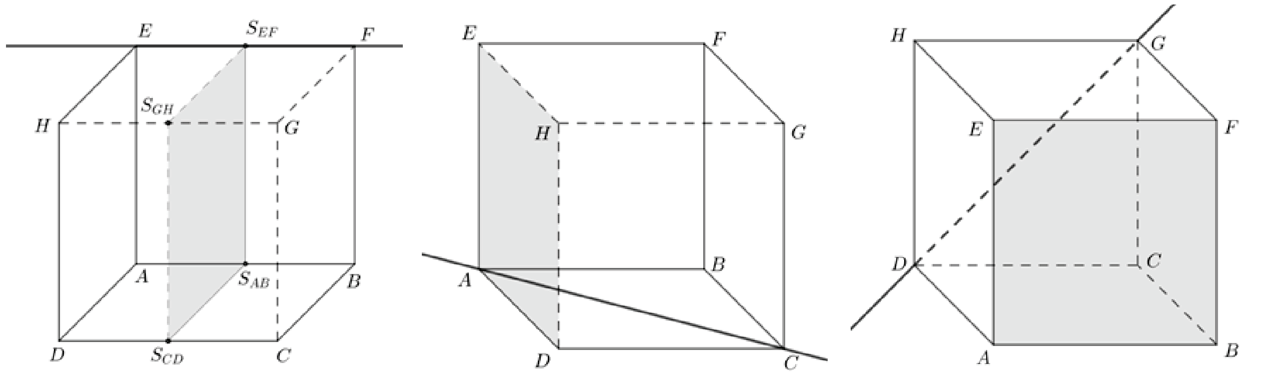

Figure 2: The size of an angle between a line and a plane – 90°, 45°, 0°, respectively

3D virtual computer models were created in GeoGebra software and 3D printed models were made on the 3D printer (Felix 3.0); the both by the author. The 3D virtual computer model is shown in Figure 3, on the left. Students were allowed to draw arbitrary lines into the prepared cube and they could rotate with the three-dimensional situation in GeoGebra software. 3D printed models are shown in Figure 3, on the right. Students were allowed to use them together with the sticks to model lines.

Thirdly, the same students were tested again using the identical 3D geometry test without any visual aids at the beginning of a new school year 2021/2022. For this final testing and for the interpretation of the results, the G1 is newly designated G1' and the G2 is newly designated G2'.

The relationship between the use of 3D computer models and 3D printed models and students' spatial ability was investigated in this research by focusing on the following research questions: What visual aid brings greater benefit to students when they solve geometric problems? Can 3D computer models and 3D printed models improve the students' performance in testing their spatial ability?

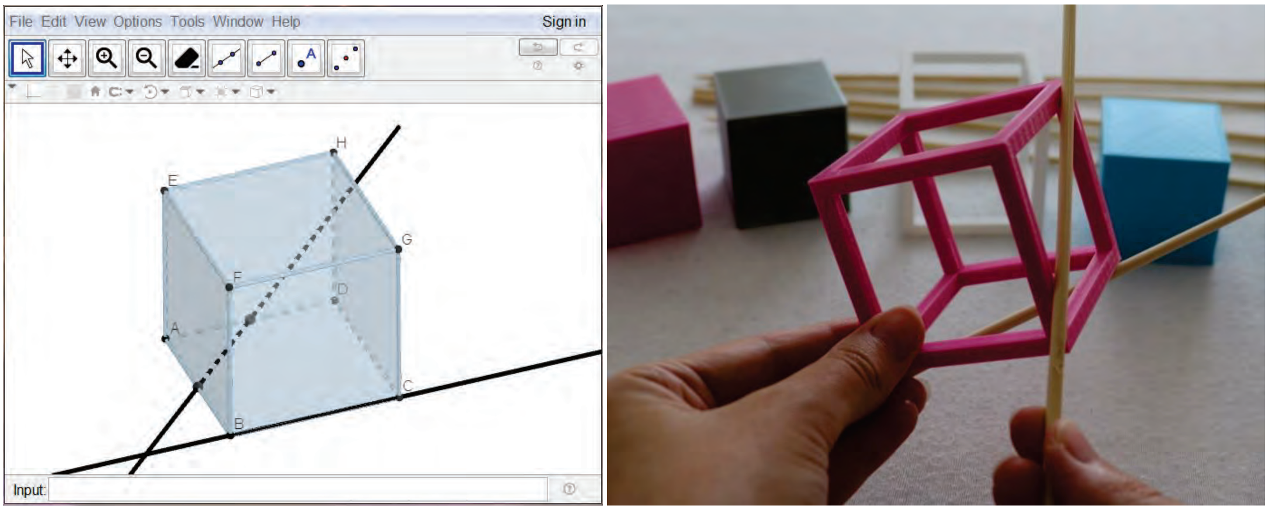

Figure 3: 3D virtual computer model in GeoGebra with allowed functions for drawing an object (a point, a line, a segment line, a midpoint) and functions for control (move graphics view, zoom in, zoom out, delete) on the left, 3D printed models with auxiliary sticks on the right

Students' scores in the Mental Rotations Test and in 3D geometry test were interpreted using the Mann Whitney U or the dependent *t*-test for paired samples. The significance level was chosen 0.05 in each test.

Results

There were no significant differences between the two groups (G1, n_1=13 and G2, n_2=12) of students as measured by the Mental Rotations Test. The G1 had a mean score of 16.92 and the G2 had a mean score of 16.25. The second method of data collection involved students' scores in 3D geometry test. The G1 that was allowed to manipulate 3D printed models during the test had a mean score of 21 and the G2 that was allowed to use 3D computer models during the test had a mean score of 22.92. The Mann-Whitney U test was used to compare differences in students' scores between the groups. The critical value of U at $p < 0.05$ is 41 which is lower than the test criterion of 52.5. Therefore, the result is not significant at $p < 0.05$. Students' performance can be observed in Table 1. Students are sorted according to their score (S) in the test and are assigned ranks (R). It can be visually observed that the group (G2) with 3D computer models outperformed peers (G1) with 3D printed models but a statistically significant difference between these two groups was not found.

Table 1: Students performance scores in 3D geometry test – Group 1 and Group 2

	G2	G1	G1	G1	G1	G1	G2	G2	G1	G2	G1	G1	G1	G2	G1	G1	G2	G2	G1	G2	G2	G1	G2	G2	G2
S	13	16	16	17	19	20	20	20	21	21	22	22	22	22	23	23	23	23	25	26	26	27	27	27	27
R	1	2,5	2,5	4	5	7	7	7	9,5	9,5	12,5	12,5	12,5	12,5	16,5	16,5	16,5	16,5	19	20,5	20,5	23,5	23,5	23,5	23,5

The third method of data collection involved students' scores in 3D geometry test again. This time any visual aid was not allowed. The first group (G1', n_1=13) had a mean score of 19.08, the second group (G2', n_2=12) had a mean score of 20.25. The dependent *t*-test for paired samples was used to compare the means between groups G1 and G1', and G2 and G2'. In the first comparison of groups G1 and G1', the p-value is 0.00043. The result of the test is significant at $p < 0.05$. In the second comparison of groups G2 and G2’, the p-value is 0.00185. The result of the test is significant at $p < 0.05$. So the both tests showed that there are statistically significant differences between G1 and G1’, and between G2 and G2’ too.

Discussion

I analyzed the effects of using 3D computer models and 3D printed models on students’ success rate in testing their spatial ability. Surprisingly, the group with 3D computer models performed better than the group with 3D printed models but a statistically significant difference between these two groups was not found. According to Katsioloudis et al. (2014), 3D printed models have greater positive effect on spatial ability than 3D computer models. This inconsistency could be probably caused by a small sample but still the difference was not significant. Using of 3D physical models is also supported from other researchers (Maier, 1998; Alias et al., 2002). The positive effects of using 3D virtual computer models on spatial ability over not using of any visual aid are consistent with earlier studies (Katsioloudis et al., 2014). Not to mention students’ reactions on visual aids; based on my observations students were much more motivated to solve geometric tasks if they were allowed to use some visual aid. Moreover, final testing showed that students’ results in the same 3D geometry test without any visual aids were worse even though they were solving the same geometric tasks.

Conclusion and future plans

This small quasi-experimental research showed that the use of 3D visual aids has a great potential in the process of mathematics education, namely in the topic of solid geometry. The study resulted in favor of 3D virtual computer models. It was demonstrated that 3D computer models can help students to better understand three-dimensional geometry. On the ground of this study, I include the optimal training and teaching methods into my mathematics instructions to improve students’ spatial ability. I plan to continue using the both types of visual aids. I also plan to repeat these experiments with bigger samples and with modified versions of the 3D geometry tests. The reliability and the validity of newly designed tests is also planned to be measured.

Acknowledgment

The paper was supported by the project PROGRES Q17 Teacher preparation and teaching profession in the context of science and research and by Charles University Research Centre No. UNCE/HUM/024.

Developing digital scaffolding modules to support oral description skills – Results of a teacher survey

Sophie Tittel[1], Karina Höveler[2] and Franziska Tilke[3]

University of Muenster, Faculty of Mathematics and Computer Science, Germany; [1]sophie.tittel@uni-muenster.de; [2]hoeveler@uni-muenster.de; [3]f.tilke@uni-muenster.de

Oral descriptions of mathematic phenomena are indispensable for mathematic conversations in primary school but pose challenges for learners on a conceptual and linguistical level. Digital media offers potential to foster the oral descriptive skills, but the application of digital language scaffolding in mathematics has not been researched yet. Therefore, a digital scaffolding tool addressing primary school learners' oral descriptions of mathematical patterns and structures using the app 'Book Creator' is being developed in a design research project following the Integrative Learning Design Framework. This paper reports on teachers' evaluation of a prototype and its already implemented design principles, in order to identify implications and suggestions for the development in further micro-cycles. Results show that the current version is considered to be fruitful for primary school learners already but should be revised concerning the linguistic level and the cognitive activation.

Keywords: Digital scaffolding, Language in mathematics education, Design research.

Introduction

Oral descriptions are a very important part of communication in primary school mathematics as they lay the foundation for sharing different approaches to solve problems, explanatory statements and lines of reasoning, however, the necessary linguistic and conceptual requirements are challenging for many learners (Maisano, 2019). One possibility to promote language – including oral descriptions – in the mathematic classroom is by providing scaffolds according to the learners' needs. It has been shown that digital scaffolding that focusses on both the language and the mathematical content has positive effects on the students' math test scores and their math self-efficacy (Freeman, 2012). However, there are no findings yet whether digital scaffolding also has a positive impact on the students' language use in the mathematic classroom as seen from a commognitive perspective (Sfard, 2008). To fill this research gap, our design research project 'DeScriBe', following the Integrative Learning Design Framework (Bannan, 2013), aims at micro-cyclically developing and researching a digital scaffolding tool to promote the learners' descriptive skills with the app 'Book Creator' (https://bookcreator.com). This paper presents the development process of prototypical digital language supportive modules as well as results of a Local Impact Evaluation (Bannan, 2013) by teachers to assess the language supportive modules' technology-specific design principles' (DPs) fruitfulness for the learners' learning processes as well as the usability of the digital scaffolding tool.

Implications of oral descriptive skills for mathematical learning

Oral descriptions in the primary mathematics classroom can verbalize observable patterns and structures and therefore promote the children's understanding of the mathematic contents while simultaneously promoting the language skills themselves (cf. Lüken & Tiedemann, 2019). According to Sfard's (2008) commognition framework both thinking and talking about mathematics are communication processes, the former on an intrapersonal level, the latter on an interpersonal level.

This fusion of cognitive and communicative processes shows that language is required to both think and talk about mathematics and that communication is an integral part of doing mathematics. As such, communication is subject to determined routines in the process of mathematizing between the interlocutors (Sfard, 2008). A long-term-goal of mathematics education is to enable learners to explain mathematical patterns and structures. These explanations are based on the description of a mathematic phenomenon, the procedure of describing a phenomenon therefore needs to be established as a routine in the classroom. Since there exists a relation between the proficiency in the academic language and the access to knowledge and a successful education respectively, there is a mathematic educational interest in fostering the school or technical register (Tiedemann, 2015). Functional and generalized descriptions cannot be expressed in an everyday register (cf. Prediger & Wessel, 2013). The necessity to use a school or technical register to express these descriptions can however be challenging, especially for primary school learners. A promotion of oral descriptions is therefore necessary to lay the foundations for future explanations and argumentations. Teachers should make their context-specific linguistic norms explicit (Tiedemann, 2015) and include the student's progress related to the educational code in self-evaluations and feedback (Hammond & Gibbons, 2005). Besides the linguistic demands, oral descriptions also require a conceptual understanding of the phenomenon that is to be described, therefore language promotion should always go hand in hand with the mathematic content (Prediger & Wessel, 2013).

Fostering oral descriptive skills - analogue and digital

Scaffolding consists of specific support measures provided by more experienced persons that help learners reach their zone of proximal development (Hammond & Gibbons, 2005). Successful analogue measures that can also serve as the basis for digital language supportive modules in an adapted form are – among others – the inclusion of the learners' progress related to the educational code in self-evaluations and feedback, provision of transparency of the expectations as well as the use of different representational means that help the learners to structure their learning process (Erath et al., 2021). A checklist allows an integration of these facets as it is both a tool to work with for the learners as well as a synopsis of important aspects of a good oral description. In relation to specific tasks, it has been proven to be useful to offer sentence phrases and guidelines for formulations as well as posters with the necessary vocabulary and thus provide linguistic models (Erath et al., 2021). However, the limit of the analogue fostering of the oral descriptive skills is reached when learners cannot use a written linguistic support due to an uncompleted acquisition of the written language or insufficient reading comprehension. This problem is pervasive in primary schools (Mullis et al., 2017).

Digital scaffolding generally uses the same strategies as analogue scaffolding but offers additional opportunities by using text-to-speech technology (TTS) or linked scaffolds in hypertexts. Both features support learners with difficulties in the written language (Dalton & Strangman, 2006). Referring to Mayer's (2007) cognitive theory of multimedia learning, the use of digital media, which enables the combination of different media, such as pictures, videos, texts, TTS and audio samples can help students to engage in meaningful cognitive processes. Audio recordings with the voice memo function of a tablet can be played back multiple times and therefore avoid that the volatileness of oral utterances might hinder teachers and learners from precisely evaluating the descriptions.

The project ‘DeScriBe’

For the reasons given above, the project ‘DeScriBe – **D**igital**e** **S**pra**c**hfö**r**derbauste**i**ne für das mündliche **Be**schreiben mathematischer Strukturen’ (digital language supportive modules for oral descriptions of mathematical structures) aims at developing and researching a digital scaffolding tool to foster oral descriptions of mathematic structures. To develop the ‘digital scaffolding’, the project follows the design research approach of the Integrative Learning Design Framework (Bannan, 2013). This framework encompasses the four phases of Informed Exploration, Enactment, Local Impact Evaluation and Broad Impact Evaluation that are conducted in iterative micro-cycles to cover “the entire scope of research from initial conceptualization to diffusion and adoption” (Bannan, 2013, p.116). While the Informed Exploration phase built the theoretical base for the development, in the Enactment phase design principles and a first prototype of the language supportive modules were developed. The current Local Impact Evaluation phase puts to test, whether the developed design is usable, accessible, efficient and supports learning, by having different stakeholders rate the design which may then lead to the next micro-cyle for improvement (Bannan, 2013). This paper presents the theory-based development of prototypical digital language supportive modules as well as results of a Local Impact Evaluation by four teachers. As experts and stakeholders for the future adoption of the digital language supportive modules in the classroom, they test and review the digital scaffolding tool as well as the potential and challenges of the already implemented DPs.

The analysed potential of digital tools for scaffolding oral descriptions led to the formulation of the following language supportive modules and corresponding technology-specific DPs (Table 1):

Table 1: Language Supportive Modules and Design Principles

Language Supportive Modules	Design Principles (DPs)
Digitalisation of a Checklist for a Good Oral Description (Module 1)	• Interactive Feedback (DP 1.1) • Linking of Supportive Means (DP 1.1)
Digital Support for the Development of Meaning-Related Language (Module 2)	• Multimedia-Based Relation of Different Representations (DP 2.1) • Digitalisation of Task-Specific Scaffolding Means (DP 2.2) • Digital Differentiation (DP 2.3)

Enactment phase – Functionality of the digital scaffolding and implemented design principles

The digital language supportive modules are realised in the app ‘Book Creator’, a tool for effortlessly creating and sharing digital books. ‘Book Creator’ has been chosen due to its degree of popularity in German primary schools and its features (https://bookcreator.com/features/) that offer opportunities to overcome the limits of analogue scaffolding by integrating different media, TTS, linking pages to avoid difficult orientation to find the desired scaffolds and sending scaffolds via Airdrop or a QR-Code which allows a use in the classrooms as well as in distance learning settings or for homework. In the current version of the scaffolding tool, two DPs have already been implemented: **‘**Linking of Supportive Means**’** (DP 1.2) and ‘Multimedia-Based Relation of Different Representations’ (DP 2.1). In the following we will outline the central features of the prototypical tool and how it can be used to support learners’ competencies in orally describing mathematic patterns and structures.

The DP ‘Linking of supportive means’ has got the subject-specific aim of providing scaffolding elements according to the learners’ personal needs to allow content- and language-integrated mathematical learning (Prediger & Wessel, 2013). This aim should be reached by using the digital potential of hyperlinks as well as dialoguing and controlling interactivity (Hillmayr et al., 2020). It is implemented in the language supportive module ‘digital checklist’ and realised through the button “Tips” that leads to specific scaffolds of the respective aspect of the checklist (Figure 1).

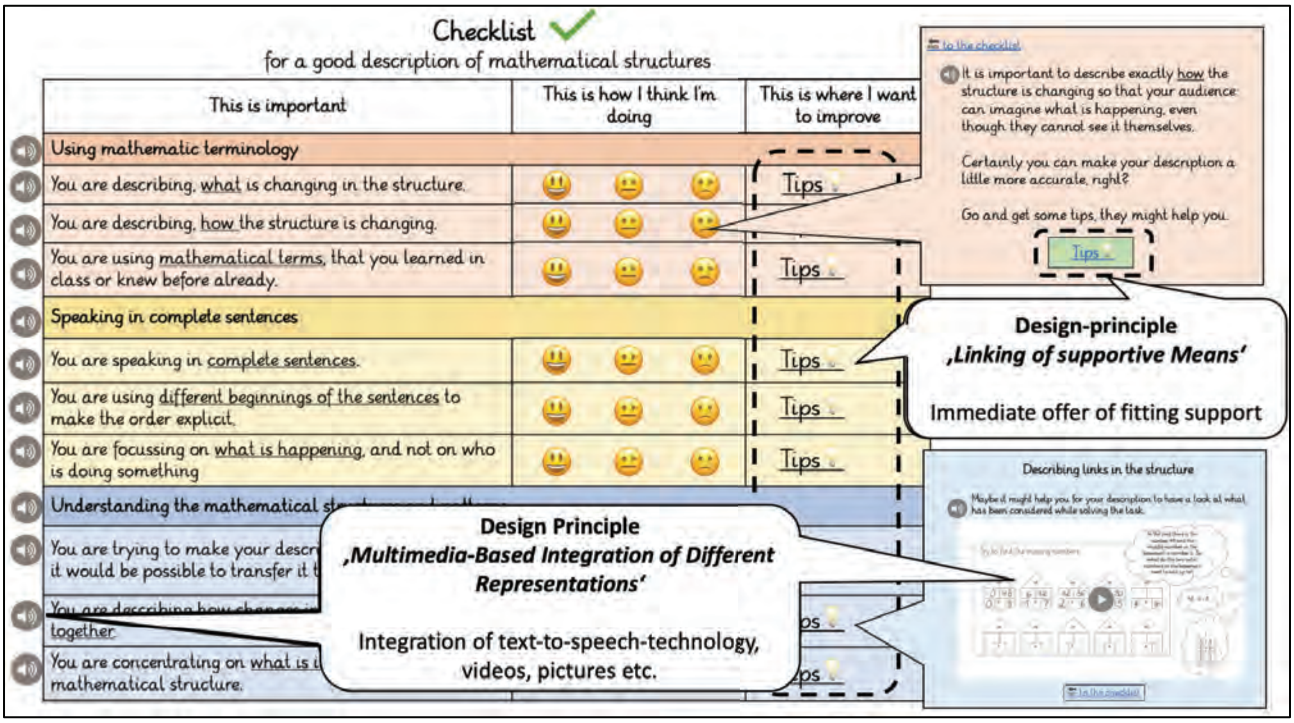

Figure 1: Implementation of DPs in the Digital Scaffolding Tool (translated screenshots)

The DP ‘Multimedia-Based Relation of Different Representations’ aims at the subject-specific goal of changing and relating registers (Prediger & Wessel, 2013). This aim should be reached by using the digital potential of the TTS (Dalton & Strangman, 2006), multiple external and linked representations (Walter, 2018) and by shifting learning processes to allow more capacities to focus on the mathematical content (cf. “cognitive load theory” in Chandler & Sweller, 1991). This DP is realised by enriching the digital checklist and scaffolds (that could generally also be used in an analogue form) via different related media, like audio samples, videos, TTS etc. (Figure 1).

Research questions and methods of the Local Impact Evaluation

The main goals of this Local Impact Evaluation were to assess the fruitfulness of the implemented DPs as well as to check the usability of the basic functions already available in the language supportive modules to compile aspects that should be considered when developing digital language scaffolds and to improve the design of the digital tool in the following micro-cycles. Teachers were interviewed as experts since they are competent in rating the helpfulness of (digital) scaffolding measures according to their learners’ needs. In addition, it was expected that as stakeholders they could think about possible extensions of the scaffolding tool on a meta level and therefore provide useful ideas for the future development. The following questions were leading: (1) What potential and challenges do teachers see in the implemented DPs? (2) How do teachers rate the usability of the basic functions in regards to their learners' experiences with digital tools? (3) Which additional functions are desired and suggested by teachers with regard to the support of oral descriptive skills?

The data collection was based on semi-structured guided interviews (Galletta, 2013) with a total of four teachers in which the teachers first used the scaffolding tool themselves and then answered open questions that asked whether the teachers would rate aspects of a respective DP, like TTS, videos or links as supportive for their learners and explain their assessment. Their answers were then analysed with a qualitative content analysis (Kuckartz, 2019). The resulting categories of the content analysis have been subdivided into positively and negatively connotated categories, named 'potential' and 'challenges'.

Results

(1) Potential and challenges of the digital scaffolding tool

The four teachers were asked to evaluate the usability and practicability of the digital language supportive modules in the scaffolding tool. A synopsis of the categories generated via qualitative content analysis, complemented with some exemplifications, can be found in the following Table 2.

Table 2: Assessment of the Digital Scaffolding Tool

Potential	Challenges
• Informative with regard to the aspects of an oral description • Intuitive handling • Very well arranged due to the use of different colours, underlined important words and the use of smileys for self-evaluation • Well suitable for primary school learners • Allows a versatile use in the mathematics classroom • Linguistic level well suitable for children with good knowledge of German	• Linguistic level might be too high for learners with little knowledge of German • Very extensive – might lead to an overload of weaker learners • Requires the skill to self-assess one's description • Requires previous experience with checklists • Some buttons do not function properly yet • 'Book Creator's' function to turn over pages might lead to difficulties in the classroom when learners accidently use this function

These categories indicate that in general, the teachers see opportunities for the use of the digital scaffolding tool in the primary mathematics classroom since they assess it to expatiate on the context-specific linguistic norms as claimed by (Tiedemann, 2015). While they rate the checklist as being well arranged and the digital aspects as being intuitive, it also has to be summarized that the teachers see challenges in including the student's progress related to the educational code in this form of self-evaluations that is based on Hammond and Gibbons (2005) claims, since self-evaluation requires additional skills of self-reflection that need to be acquired before working with this tool. However, all teachers claimed that this challenge can only be solved by a change of the socio- and sociomathematical norms and not by the digital language supportive modules themselves. When applying Sfard's (2008) idea of discursive routines on the 'rules' that are being set in the checklist, it might be concluded from the teachers' assessment that the routine that is supposed to be established with this tool might be not accessible for all learners yet due to the high linguistic level and the extent of the language supportive module. The technical issues reported as challenges will be revised.

(2) Potential and challenges of the implemented design principles

In addition to the assessment of the digital scaffolding tool, the teachers were also asked to evaluate the language supportive modules with a focus on the respective DPs' estimated fruitfulness for their students. The consolidated results of their assessment can be found in the following Table 3.

Table 3: Assessment of Potential and Challenges of the Implemented DPs

Design Principle	Potential	Challenges
Linking of supportive means	• Immediate reaction to the self-evaluation • Does not require posters and/or tip cards • Helps the learners to decide where support is needed • Use of links in the checklist before evaluation can help to get a better idea of the statement	• Risk of students' unfocussed use of all the linked elements due to easy accessibility
Multimedia-Based Relation of Different Representations	• Video that relates verbal, symbolic and (animated) iconic representations is very helpful for both the linguistic and conceptual understanding • TTS is particularly useful for weaker readers • Relation of different media caters for different types of learners • Related verbal and non-animated iconic representations in audio samples can be supportive for the learning process (mixed review)	• Related verbal and non-animated iconic representations in audio samples can be hard to follow (mixed review) • Headphones need to be used to make full use of the media • Risk of students' unfocussed use of TTS due to easy accessibility

The teachers' assessment of the DPs' current realization supports Dalton and Strangman's (2006) statement that TTS and linked scaffolds support learners with difficulties in the written language. Their positive evaluation of the implementation of different media second Erath et al.'s (2021) suggested support measure to use different representational means that help the learners to structure their learning process of language for mathematics. However, the mixed review of the relation between audio samples and non-animated representations points out that the use of different representations is not perceived as helpful in general, but only when fitted exactly to the different learners' needs. The teachers' ideas to improve this relation of representations are presented in the section 'Suggested additional functions'. The perceived challenges mostly consider the practical use of digital media in the classroom and can be traced back to the reported insufficient equipment of and experiences with digital media in primary schools.

(3) Suggested additional functions

To collect input for the future development in the next micro cycle of the integrative learning design, the teachers were asked to propose additional functions on both the level of the DP 'Multimedia-Based Relation of Different Representations' and the practicability for using the digital language supportive modules in their classrooms. Concerning the first aspect, they propose a stronger inclusion of the typical non-verbal illustrative and representational means like arrows, colours or magnifying glasses to help the students develop a conceptual understanding. Even though they already appreciated the video as a relation of different representations, they suggest to make even more use of the digital potential by linking the spoken text in the video and the visual stimuli closer together – e.g. while saying "the sum in the roof" the respective number should simultaneously be enlarged and accentuated. They also propose an interactive design of the video to include the students more and avoid passive watching. All these features could be summarized under the quality criteria of cognitive activation that is supported by the media design (Korntreff & Prediger, 2021).

Conclusion and Outlook

In this paper we discussed the Enactment and Local Impact Evaluation of a learning design's development addressing digital scaffolding using the app 'Book Creator'. The outcome of the Enactment phase is a prototype of the digital language supportive modules which can be used in order to support oral descriptions of mathematical structures. Given that language promotion is always supposed to go hand in hand with the mathematic content (Prediger & Wessel, 2013), it needs to be considered that this digital scaffolding tool can only be used to accompany the mathematics lessons and not to promote the mathematical content on its own. The results of the Local Impact Evaluation indicate that the general idea of a digital language scaffolding tool is well accepted by the teachers and their list of perceived potential (Tables 1 and 2) is long. In the following micro-cycles revisions of the current language supportive modules will be necessary to better align their linguistic standards with the primary school learners' competencies. To allow a digital differentiation that helps learners reach their zone of proximal development, it is necessary to analyse the competencies learners need in order to perform good descriptions of mathematic structures. This analysis will be undertaken in the PhD-project of Sophie Tittel. The teachers' suggestions for improving the videos by stronger linking the visual and auditive stimuli will be implemented in the future and may also be applied in other projects and explanatory videos. In addition, it is planned to further implement the DPs 'Interactive Feedback', 'Digitalisation of Task-Specific Scaffolding Means' and 'Digital Differentiation' on the basis of teachers' feedback in the next iterative micro cycle and evaluate their local and broader impact.

Construction of Mathematical knowledge in digital-collaborative settings

Stephan Tomaszewski[1]

[1]TU Dortmund University, Institute for Development and Research in Mathematics Education (IEEM), Germany; stephan.tomaszewski@math.tu-dortmund.de

There are many different ways in which technology can enhance learning and teaching of mathematics. Therefore, a specific research focus is needed. One of the foci is to look at the role technology plays in learning mathematics through the lens of communication – especially the way in which it influences the construction of mathematical knowledge in interaction. To do this, student teachers were filmed while using Padlet to collaboratively summarise and discuss characteristics of different mathematical functions. First results hint at Padlet being a useful tool to induce and support meaningful mathematical discourse and mathematical thinking.

Keywords: Communication, technology, digital media, collaboration, knowledge building.

Introduction

Although the use of digital media for educational purposes has become an omnipresent topic – whether it is in research, politics or every-day-conversation – teaching with technology is often based on best-practice approaches or personal preference (Rink & Walter, 2020). Research also shows that while students use technology on a daily basis, they do not use it for academic purposes as often (Zawacki-Richter, 2021; Dolch & Zawacki-Richter, 2018). Although the academic use of technology in schools and universities has significantly increased over the last year, it often remains on a 'consuming' level (e.g. reading documents or watching videos) and rarely leads to subject-rich learning processes (Zawacki-Richter 2021; Biermann & Kommer, 2012). Considering that communication is fundamental for learning in general (e.g. Miller, 2002) and developing mathematical knowledge in particular (Steinbring, 2015), this problem is addressed by making communication the key focus when looking at digital media used in education (Ball & Barzel, 2018).

In this paper, we focus on the question of how technology influences communication and, thus, the construction of mathematical knowledge in collaborative settings. In what follows below, a brief theoretical background is given on *Construction of Mathematical Knowledge in Communication* and *Technology in Mathematics Education*. Afterwards the *Methodology* as well as some initial *Results* are presented.

Theoretical Background

Studies by Sung, Yang and Lee (2017) show evidence that digital-collaborative learning may lead to an increased learning performance and a more positive attitude towards learning in general. However, one should not assume that using technology will always be beneficial as "all [digital tools][…] come with affordances and limitations, with opportunities and constraints" (Drijvers, 2019, p. 9). With a view to university levels, research indicates that technology is in fact used a lot to share documents or to collect data (e.g. in online courses), but is only infrequently used to encourage collaborative learning (Zawacki-Richter 2021; Dolch &

Zawacki-Richter, 2018; Biermann & Kommer, 2012). This is problematic since working on tasks collaboratively in small groups is one of the best ways to induct productive mathematical thinking (Nührenbörger & Steinbring, 2009). Students working and learning together are forced to communicate and interact with each other. "Statements and suggestions are offered for joint consideration. These may be challenged and counterchallenged, but challenges are justified and alternative hypotheses are offered" (Howe & Mercer, 2007, p. 6). These situations are of uttermost importance, because – following enactivism – learning itself is manifested in communication (e.g. Miller, 2002).

Learning mathematics is somewhat unique since it is not accessible by senses (Ball & Barzel, 2018). In fact, *mathematical knowledge* is not a given set of definitions and theorems, but is only accessible "using signs, words or symbols, expressions or drawings" (Duval, 2000, p. 61). The meaning of those signs, symbols or expressions has to be constructed by the learners themselves during the act of communication (Steinbring, 2006). Therefore, communication is at the center of constructing any mathematical knowledge. Based on this underlying interpretation of learning, the construction of mathematical knowledge can be modeled using Steinbring's *epistemological triangle*:

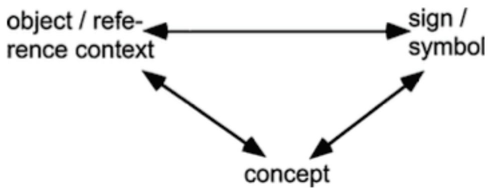

Figure 1: Epistemological Triangle

"Mathematics requires *certain sign or symbol systems* in order to keep a record of and code the knowledge. […] [The meaning of those signs] has to be produced by the learner by means of establishing a mediation to suitable *reference contexts*" (Steinbring, 2006, p. 135). A sequence of such triangles can be used to cover the whole learning process (Ball & Barzel, 2018) and to examine the impact of technology on those processes. "To use technology for effective collaboration and communication in mathematics classrooms it is necessary to consider the role of technology in the epistemological process" (Ball & Barzel, 2018, p. 229).

There is a great variety of digital tools that can be used in education. To gain some orientation it seems appropriate to characterise these tools with regards to how they are used in communication. Ball and Barzel (2018) distinguish between *communication through technology*, *communication with technology* and *communication of technology displays*. The first one involves use of technology to directly support online synchronous communication between people (e.g. Skype, Zoom). Communication *with* technology "considers the entry of syntax, selection of menu items, programming or any command that drives the technology to produce a display" (ibid.) (e.g. Apps like "digital-twenty-frame"). The third one describes a situation in which the technology display is a stimulus for discussion. "This discussion could occur in a range of contexts, for example, through two students' consideration of one shared screen or through public display of student work via technology such as an interactive whiteboard or data projector" (ibid.) (e.g. Padlet). While those categories are useful to distinguish and analyse the use of technology in communication, they may overlap and do not occur in isolation (ibid.). For example, students may discuss a technology display while at the same time interacting with the display itself. Thus, they may be even interacting with each other through the input itself. This shows how complex the connection between communication and technology is. Naujok (2012) and Knopf & Abraham (2016) mention that those discussions and interactions evolving while working with technology may be especially important and fruitful for deep learning processes.

Combining those three ideas – *constructing mathematical knowledge in communication*, *technology* and *collaboration* – it becomes evident that there are specific affordances and opportunities in teaching and learning mathematics in *digital-collaborative* settings. One such setting and initial results are presented on the following pages.

Methods

The research presented in this paper is part of a research project called K4D ('Collaboration for Digitisation'), funded by the German Federal Ministry of Education and Research. The project started in early 2020 at TU Dortmund University and aims at a better understanding of teaching and learning with technology in higher education.

During their first year at TU Dortmund University, students of mathematics education are obliged to attend the lectures '*Arithmetic and its Didactics I*' and '*Arithmetic, Functions and its Didactics II*'. Those lectures are accompanied by a mandatory seminar once a week in which students tackle mathematical tasks in small groups. Due to the Covid-situation, students worked remotely from home using Zoom. During some of those exercises, students were given tasks they had to collaboratively work on, while using Padlet, which is a tool considered a 'digital pinboard' enabling users to share, connect and sort documents (e.g. videos, recordings, pictures, text). Users can comment and react on those documents in real-time. Padlet can be categorized as a general educational technology and – in contrast to subject-specific technology – could be used for many different activities. The usage of Padlet to foster collaboration was planned before the pandemic, but within the usual seminar settings. Data was collected by screen-capturing and voice-recording those situations. The sessions were 30 to 60 minutes long and about 20 groups have been recorded. Additionally, questionnaires were given to the students to better understand how they themselves experienced the collaborative work with Padlet. Research is intended to continue in 2021 and 2022 to gain more data. At this stage of the research process, only exemplary insight into the data and findings can be given.

Tasks for working with Padlet

The topic of the recorded session is basic functions (linear, proportional, reciprocal) and the tasks (listed below) are supposed to engage the students in discussions about their specific content knowledge.

(1) Find a context/situation to those functions (linear function, proportional function, reciprocal function) and upload it to Padlet. Don't name the function in your context/situation.

[Additional information: (1) done by each student on their own the day before the group exercises took place. In each group, about 25 students uploaded their contexts in one Padlet.]

(2) Cluster the different contexts/situations and discuss which situation belongs to which type of function.

[Additional information: (2) done in small groups (3-5 students) during the exercises. The original Padlets were copied so that all groups could create and discuss their own cluster.]

(3) Name characteristics for each type of function and upload them to Padlet.

[Additional information: (3) done in small groups (3-5 students) during the exercises. One Padlet was created for each type of function. The students kept working in small groups (3-5 students), but those Padlets were not copied for each group, but filled by different groups of students simultaneously.]

Questionnaires

In order to gain additional insights into the processes, questionnaires were conducted to better understand how the students themselves experienced the collaborative work using Padlet. Items were given to the students (n = 220) which they could agree or disagree with on a 1 to 5 scaling. Some exemplary examples of those items are as follows: “Working with Padlet was very intuitive.”; “Other students’ postings confronted me with new ideas/approaches/ representations.”; “Other students’ postings led to more intense discussions within our group.”

Selected Results

The following transcript shows four students working on task (2) and (3). At the beginning, they discuss which type of function is represented in a given context-situation.
(Transcripts are translated)

1	Student 3:	[…] I don’t really get (…) get the difference. Between a reciprocal function (..) and the others.
2	Student 2:	[…] There is that mnemonic (*for reciprocal functions*): “the more, the less”, so#
3	Student 3:	#so it’s decreasing?
4	Student 2:	Exactly. Exactly.
5	Student 3:	[…] Okay, that makes sense.

The students proceed to cluster the given context-situations and decide – using the mnemonic: “the more, the less” – that the following is a reciprocal function:

“Peter spends a fixed amount of money each month. […] He got 3000€.
He withdraws 100€ each month.”

Later during the group-exercise, the students start working on task number (3). While doing so, they are confronted with other groups’ posts in Padlet. Two of those posts and the unfolding discussions can be summarised as below:

Post I:	Post II:
“a reciprocal function has no zero point and no intercept.”	“x * y is always the same for each coordinate.”

Confronted with those posts, a discussion emerges:

6	Student 3:	[…] But they wrote “it (*a reciprocal function*) has no zero point and no intercept” (..) but it could (..) it could start with an intercept, couldn’t it? (…) Or what do they mean?”
7	Student 1:	Yes.

8	Student 2:	Yes.
		…
9	Student 1:	[…] It's like with that money. If it starts at 3500€ (*3000€*), then that is on the y-axis."
10	Student 3:	Sure.
		…
11	Student 3:	[…] It's the same with those workers (*Referring to another context-situation: "For the construction of a new [building] a single worker needs 120 days. Two workers need 60 days. […]"*)
12	Student 1:	Sure.
13	Student 3:	Yes, and then you would still start with one, two, three, four workers on the y-axis.
14	Student 1:	But you have no zero point, like, like the intercept means that there is something like (..) zero, three thousand (*(0|3000))*. So x is always zero. And I think in that worker-context, that is not (..) it is not possible, because (..) one (..) zero workers, you can't say that, that they need twice as long as one worker. Because that makes no sense. Because if no worker is working, nothing ever happens.
15	Student 3:	Mhm.
16	Student 1:	So maybe the other context is wrong.
17	Student 3:	Maybe (*laughing*). But I don't get what they mean with "x * y is always the same for each coordinate".
		…
18	Student 3:	Especially "for each coordinate" (..) "for each coordinate". What does that even mean? (…) Maybe something like it's linear (..) so that (..) like it's (the function) increasing all the time (..) But#
19	Student 1:	#Ah, I think I know what they mean. They mean (..) like what you said before. That if one worker needs 120 days and two workers need 60 days, then it's still 120 days in total.
20	Student 3:	Ah okay, that's possible.
21	Student 1:	So for example one worker is your x and 120 is your y.
22	Student 3:	Yes, yes.
23	Student 1:	And 60 times two equals 120.
24	Student 3:	Mhm, okay. Nice.

The group decides that the first context (the one with the "money") does not represent a reciprocal function, but the latter (the one with the "workers") does.

Interpretation and discussion

The scene summarised above is analysed using an epistemological perspective. Since that analysis is open for discussion, we will try to re-construct the underlying knowledge and ideas, using Steinbrings epistemological triangle and focusing on how the process is shaped by the use of technology.

Clustering the different context-situations in Padlet proves to be a solid way to force students to interact. They engage in meaningful discussions about whether or not a given situation can be linked to a specific type of function. By doing so, they create a common ground for different *concepts* – for example, what they understand of a reciprocal function (1-5). The students link the situation ('*Peter and his money*') to a reciprocal function. This link acts as the *sign/symbol* the students try to interpret, using their *reference context*. In this specific case, the reference context is the mnemonic ("the more, the less" – meaning: for an increasing x value, the y value is decreasing) which S2 mentions to legitimate the situation describing a reciprocal relation (2) (Fig. 2).

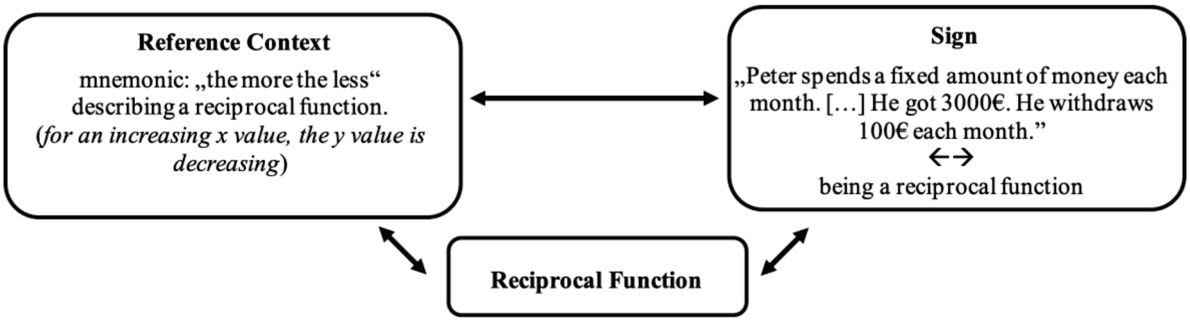

Figure 2: Mechanic significance with a mnemonic

Since no group member protests against the above interpretation, it appears to be a shared one within the group. Now, the use of Padlet comes into play: the posts by other groups inflict a conflict to the formerly shared interpretation – a "productive irritation" (Nührenbörger & Schwarzkopf, 2019).

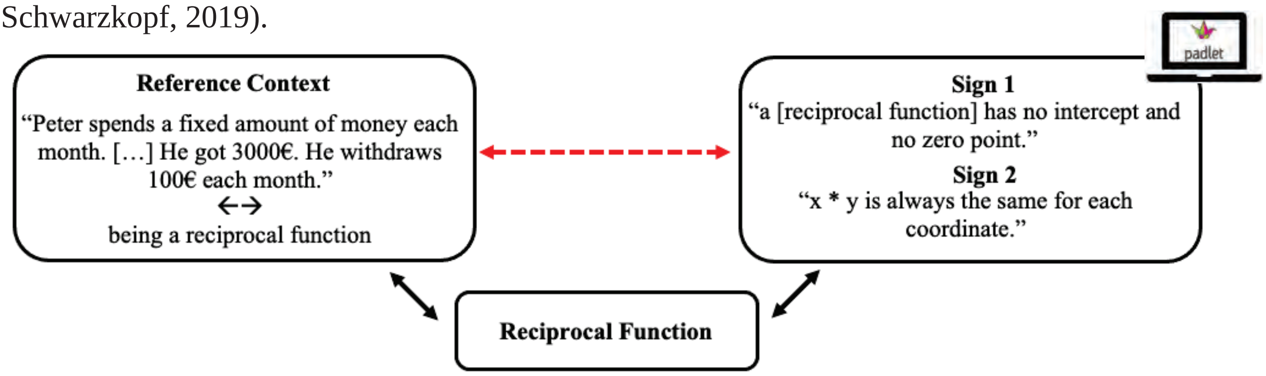

Figure 3: Productive irritation through the confrontation with a content post

The new sign is the statement ("a [reciprocal function] has no intercept and no zero point") in Padlet. The group tries to understand that statement by mediating it to a reference context. In this case, the reference context is the former sign. However, the group is irritated in a twofold mode. On the one hand, the mediation cannot be done successfully (6). On the other hand, they have to interpret the meaning of the second statement ("x * y is always the same for each coordinate") (17) (Fig. 3). When the group fails to interpret the new signs in relation to their reference context, they question their original assumption (16). Therefore, the group looks at another one of the given context-situations: The one with the "*workers*". During their discussion, they realise that both of the statements made in Padlet can be explained using this context (14 & 19). The connection between the "new" context situation and those "new" statements acts as the new signs (Fig. 4). Finally, the students successfully mediate them to fitting reference contexts (Fig 4). The epistemological analysis of these sequences clearly shows a shift from a vague understanding and interpretation of functions to a more sophisticated one – for example by (unknowingly) referring to the anti-proportionality factor (Heiderich & Hußmann, 2013). Padlet seems to induce these mathematical learning processes by confronting students with different ideas and interpretations.

An evaluation of the questionnaires (n = 220) supports those findings: 88% of students said that when using Padlet "they were confronted with new ideas, approaches and representations" and 75% said it led to "more intense discussions".

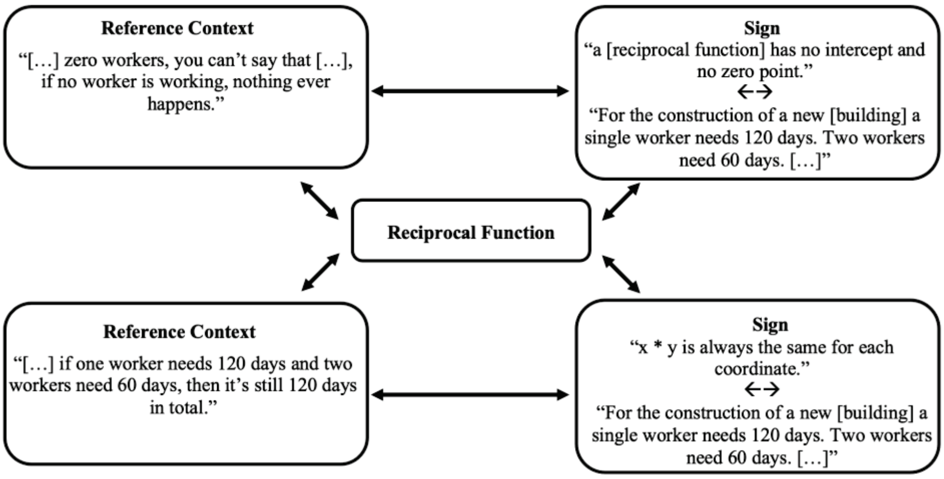

Figure 4: Structural significance on reciprocal functions

Conclusion

This paper highlights specific potentials of the use of technology (by using Padlet) in mathematics education. The first results hint at Padlet being a useful tool to induce and to support mathematical discourse and mathematical thinking. With Padlet, students can be confronted with multiple different ideas and approaches, while at the same time communicating and discussing in a small group. This combines aspects of collaborative learning in smaller groups and class-wide discussions at the same time, resulting in manifold occasions for productive irritations and mathematical discourse. As with every other media or technology, it has to be carefully considered when and how to use them in order to do so most efficiently. Therefore, more research will be done to identify specific design elements and to deepen the understanding of how the use of interactive pinboards, like Padlet, affects mathematical knowledge building.

Evaluating digital student work through model backtracking

Gerben van der Hoek
Utrecht University, The Netherlands; g.vanderhoek@uu.nl

Designing a digital assessment system for mathematics brings along a number of challenges, such as creating an intuitive interface or providing the right feedback. We investigate how these challenges are met in different methods for evaluating digital student work. After done so, we formulate an idea for a new approach: model backtracking. That is, retracing students' calculations through their final or intermediate answers. We explain the mathematical principle behind model backtracking and conclude that the method is promising, despite its limitations. Finally, we hypothesize about possible ways of meeting design challenges using model backtracking and provide recommendations for further research.

Keywords: Digital assessment, Intelligent Tutoring System, Model tracing

Introduction

Digitally assessing mathematics has become increasingly important in the field, since there are many different applications that can lead to increased potential for student learning and summative assessment as well as didactical insight in students' problem-solving behavior. When designing a digital assessment system, a number of challenges needs to be overcome. In this paper we formulate a new approach for evaluating digital mathematical student work, that may help to overcome such challenges: model backtracking (MBT). With this technique, the model the student employs is derived from the final or intermediate answers. The aim of this paper is to explain the idea behind MBT and hypothesize about possible applications, this paper is therefore purely theoretical.

Although MBT could be used in summative settings, in this paper we mainly focus on the applications of MBT in formative settings. We single out intelligent tutoring systems (ITSs) to discuss in detail and outline the general structure of ITSs. We then proceed to investigate feedback and relate specific feedback to the granularity of the student input. We elaborate on various challenges that arise when designing ITSs. The principles behind MBT are explained and we proceed to hypothesize on how MBT may help to overcome design challenges. After done so we discuss the limitations of MBT and give suggestions for further research. Since MBT is still very much in a developmental stage, the results in this paper are of a hypothetical nature, indicating which design difficulties could be overcome using MBT.

Intelligent tutoring systems

ITS can guide the learning process by providing students with feedback. There are essentially two types of feedback: inner loop feedback which focusses on in-task guidance, and outer loop feedback which guides the learning process over several tasks (Santos & Jorge, 2013; VanLehn, 2006). Inner loop feedback can provide appropriate hints if a student fails to make a correct step or is unable to successfully complete the task (Heeren & Jeuring, 2014). Outer loop feedback can include an indication of the degree of mastery of different learning goals, based on a student model covering the domain. From such a model a suggestion on the next task to be completed by the student can be provided adaptively (Heeren et al., 2018).

Generally, ITSs consist of four modules (Nwana, 1990), as Figure 1 illustrates.

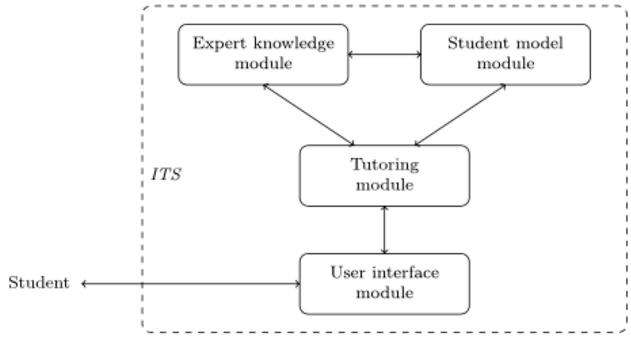

Figure 1: structure of ITSs from Heeren & Jeuring, 2014, p.112, with permission

The *user interface module* is used for communication between the system and the student. It is an important part of the ITS since the way in which information is displayed can affect, for instance, the willingness of the student to work with the ITS. The user interface module communicates directly with the *tutoring module*; this module is also known as the pedagogical module, it can make educational decisions such as suggesting the next tasks best suited for the student or how much and what type of feedback to provide. The tutoring module draws on the *student model* module which contains information about the knowledge of the student. This knowledge is often represented as a subset of the expert knowledge in the expert knowledge module (Brusilovsky & Millán, 2007). The expert knowledge module contains rules governing the way objects in a domain may be manipulated. It also contains so-called buggy rules. These rules model well known student errors within the domain. Currently, there are two approaches to evaluating student input: model tracing (Anderson et al., 1995) and constraint-based modelling (Mitrovic et al., 2007). In a model tracing approach, a step in the user input is compared to an expert solution for the problem. If a step deviates from the expert model, a buggy rule can be applied to check which specific error occurred. In constraint-based modelling the input is evaluated using two conditions: a relevance condition and a satisfaction condition. If a relevance condition of the error applies, then the satisfaction condition also needs to be satisfied to flag the error.

Feedback

Both Shute (2008) and Narciss (2008) studied literature on feedback, in this section we compare both studies with regard to specific errors. In both papers we find evidence that specific student errors need to be known in order to provide meaningful feedback. Both authors give a definition of feedback:

Formative feedback is information communicated to the learner that is intended to modify his or her thinking or behavior for the purpose of improving learning. (Shute)

Feedback in instructional contexts is all the post response information that is provided to a learner to inform the learner on his or her actual state of learning. (Narciss)

In both definitions feedback is information provided with the intent of informing the learner on the state of learning. Where Shute takes it one step further by demanding that the purpose of feedback is to modify behavior to improve learning. How may learning be improved by communicating information on the actual state of learning? Shute argues that a factor inhibiting learning is uncertainty. Since uncertainty is an unpleasant state that needs to be reduced it induces a cognitive load that could distract attention from actual task completion. Feedback could reduce this uncertainty; however, feedback can also serve the function of informing the learner on possible solving strategies or mistakes. To accomplish this, the feedback needs to be specific (Shute, 2008) or equivalently: elaborate (Narciss, 2008), although, the feedback should not contain the actual solution. Both Shute and Narciss support the claim that specific feedback leads to better learning outcome than feedback only on the correctness of answers. Narciss formulates five cognitive functions for feedback four of which require the specific error to be known. According to Narciss, a key issue is: how well a learning medium (i.e. teacher or ITS) is able to transform a discrepancy between the current state of learning and the required state into feedback that contains relevant information to mastering the requirements. The performance of a learning medium in this respect increases if it is more able to identify specific errors.

Granularity (VanLehn, 2006) of the student input plays an important role in digitally assessing students reasoning. The granularity can range from students inputting every aspect of their reasoning to inputting only the final answer. When there is less information available the difficulty of correctly assessing student reasoning increases. Typically, ITSs require that students input every step of their calculation in order to detect specific errors and provide specific feedback in the sense of Shute (2008) and Narciss (2008). Drijvers (2019) stipulates that a task shouldn't be essentially altered to accommodate a digital environment. However, inputting every step, in comparison to just calculating steps using pencil and paper, forms an additional requirement for completing a task. Furthermore, inputting every step could be cumbersome and might discourage students from working with ITSs.

Challenges

When designing ITSs there are certain factors that need to be considered.

Interface

One needs to avoid that proficiency in editing mathematical text digitally is required (Drijvers, 2019). Heeren et al. (2018) deal with this problem by allowing all kinds of input, even textual or mathematically nonsensical. The drawback however is that it is very difficult to evaluate such input to a high degree of accuracy.

Stepwise evaluation

When dealing with tasks concerning equivalent expressions, such as solving equations and simplifying algebraic expressions, often assessment systems require stepwise input. For example, Heeren and Jeuring (2014) describe such a system. Through such a system the required feedback can be provided with a high level of expediency if all the steps are inputted. Although inputting each step separately in the environment can be quite time consuming. Additionally, step by step input isn't feasible on devices with small screens such as smartphones, making this technology less accessible.

Granularity

The granularity of the expected student input concerns the step size of the input by the student. If the student skips a few steps the assessment system was expecting, the efficiency of diagnosing possible errors drops. In the ASSISTment system (Feng et al., 2009) this problem is solved by asking additional questions to the student. However, in a summative setting there is a risk that these questions give away part of the solution.

Non-stepwise evaluation

Some tasks consist of the calculation of several different non-equivalent components such as for instance, linear extrapolation where first the average change is computed before computing a future value. Since stepwise evaluation generally evaluates equivalency of steps it is not applicable here. One way to deal with this problem is to ask the student to input each of the different components of the calculation. The drawback however, is that this gives away part of the structure of the calculation. Tacoma et al. (2019) solve this problem by letting the student select the next step from a dropdown menu before performing the actual calculation. However, this only partly solves the problem since the menu only contains steps necessary to perform the required computation.

The general idea of model backtracking

We propose to retrace the students' computation from the final answer. There will be obvious limitations to this method, however many of the problems mentioned above could be solved for certain classes of digital assessment environments.

Consider the task of computing the derivative of $f(x) = (3x + 2)^3$, if the student arrives at the answer $f'(x) = 3 \cdot (3x + 2)^2$ it is unclear if the student forgot to multiply with the exponent 3, or if the student forgot to apply the chain rule. In this example these two errors are indistinguishable. However, when computing the derivative of $f(x) = (3x + 2)^5$ these errors are in fact distinguishable since they lead to different answers. So, when implementing a task for computing derivatives of functions of the type: $f(x) = (p_1x + p_2)^{p_3}$ one should choose the parameters such that $p_1 \neq p_3$.

The idea behind model backtracking is to design tasks in ITSs with parameters that make it possible to distinguish different errors. Along with a structure in the expert model module as a tree containing all possible paths of errors through the steps of the task given the predetermined buggy rules. When certain conditions are satisfied one can retrace a student error by means of just the final answer. Of course, model backtracking can also be used for evaluating intermediate steps in a computation.

One immediately notices that not all tasks can be designed using MBT (since there are restrictions on the initial values of the task), for instance not all real-world tasks can be modelled using MBT. However, MBT works well on tasks that draw on random parameters, these parameters can simply be restricted to a domain that makes backtracking possible.

The mathematics of MBT: an example

In this section we will describe how model backtracking works, doing so we will formulate certain definitions that can be extended to more general settings. We start out by defining what we mean by a computational task. We proceed to show how, in this setting, buggy rules can be represented by functions and that various errors are comprised of compositions of these functions. We then find sufficient conditions for determining the path, that is, which composition of functions, the student used to arrive at a certain answer. When the path is known, appropriate feedback can be given to the student.

A computational task is the pair (Ω, F) where $\Omega \subseteq \mathbb{R}^n$ is called the parameter space and $F: \Omega \longrightarrow \mathbb{R}^m$ is called the computation. An element $(p_1, p_2, \cdots, p_n) \in \Omega$ represents the given parameters in the task.

Given the table

t	…	t_1	…	t_2	…
N	…	N_1	…	N_2	…

Assume N depends on t exponentially.

Compute the growth factor per unit of t.

Figure 2: computational task on computing a growth factor from a table

This task is a computational task with $\Omega = \{(t_1, t_2, N_1, N_2) \in \mathbb{R}^4 \mid t_1 < t_2, N_1 \neq N_2\}$ and $F(t_1, t_2, N_1, N_2) = \left(\frac{N_2}{N_1}\right)^{\frac{1}{t_2 - t_1}}$

On didactical bases we can distinguish between two steps in this calculation:

Step 1: Computing the growth factor for $[t_1, t_2]$: $f_1(t_1, t_2, N_1, N_2) := \left(t_1, t_2, \frac{N_2}{N_1}\right)$

Step 2: Computing the growth factor per unit of time: $f_2(t_1, t_2, x) := x^{\frac{1}{t_2 - t_1}}$

We see that:

$$F = f_2 \circ f_1$$

In each of the two steps we can now introduce buggy rules for errors in the steps, the compositions of these rules represent different calculations by the student:

$E_1 := \{e_1^1, e_2^1, e_3^1\}$ denotes the set of rules for the first step where: $e_1^1 := f_1$ and e_2^1 and e_3^1 are buggy rules defined by:

Wrong time direction: $e_2^1(t_1, t_2, N_1, N_2) := \left(t_1, t_2, \frac{N_1}{N_2}\right)$

Calculating the difference: $e_3^1(t_1, t_2, N_1, N_2) := (t_1, t_2, N_2 - N_1)$

$E_2 := \{e_1^2, e_2^2, e_3^2\}$ denotes the set of rules for the second step where: $e_1^2 := f_2$ and e_2^2 and e_3^2 are buggy rules defined by:

Dividing by elapsed time: $e_2^2(t_1, t_2, x) := \frac{x}{t_2 - t_1}$

Forgetting to recalculate for time: $e_3^1(t_1, t_2, x) := x$

Now for fixed $p \in \Omega$ we look at the 3×3 matrix $\bar{M}(p)$ with entries: $\bar{M}_{i,j} := e_j^2 \circ e_i^1(p)$. We can compare the input from the user to the entries in this matrix. For instance, if the input matches the entry $\bar{M}_{3,2}(p)$, we know the growth factor was calculated as a slope.

Two examples of $\bar{M}(p)$:

$$\bar{M}(22, 27, 29, 329) = \begin{pmatrix} 1.63 & 2.3 & 11.34 \\ 0.62 & 0.02 & 0.09 \\ 3.12 & 60 & 300 \end{pmatrix}$$

$$\bar{M}(24, 28, 8, 16) = \begin{pmatrix} 1.19 & 0.5 & 2 \\ 0.84 & 0.13 & 0.5 \\ 1.68 & 2 & 8 \end{pmatrix}$$

Above we see all the entries of $\bar{M}$ are different, which means the steps through the various errors are uniquely determined by the outcome; whereas below we see that various entries of $\bar{M}$ have the same value. So, for $p = (24, 28, 8, 16)$ backtracking the student error isn't possible. We wish to avoid this. Having the entries in $\bar{M}$ differ can be characterized by the following equivalent statement:

For fixed $p \in \Omega$ we define the function:

$$M_p: \{1,2,3\} \times \{1,2,3\} \longrightarrow \mathbb{R}$$
$$M_p(i,j) := \bar{M}_{i,j}(p)$$

Then M_p needs to be injective.

For the computational task, we only select parameters from: $RS \coloneqq \{p \in \Omega | M_p \text{ is injective}\}$. This ensures that we will be able to backtrack the students' computation. These definitions can be generalized to tasks with more than two steps. And depending on the structure of the ITS[1] one can find relaxations on the injectivity condition allowing for a wider selection of possible parameters.

The definition of a computational task as the pair (Ω, F) where $\Omega \subseteq \mathbb{R}^n$ and $F: \Omega \longrightarrow \mathbb{R}^m$ seems to exclude tasks involving computations done on functions. However, when the class of functions is known, these functions may often be expressed in terms of their parameters. Therefore, MBT can also be used to develop ITSs involving functions and algebraic expressions. Arguably MBT can even be used for evaluating formulae derived from geometrical representations.

[1] For examples of ITS with MBT see:
Linear interpolation: https://www.geogebra.org/m/e5ewfude
Linear equations: https://www.geogebra.org/m/rqa4w5wb

Possible applications of MBT

In this section we conjecture how MBT could contribute to overcome design challenges. However, currently these conjectures remain to be proven.

Interface

When working in an ITS for the first time, students often start by inputting only their final answer. Therefore, just demanding the final answer is very intuitive. With the use of MBT, feedback can be provided on the basis of just this input. A student can make a calculation using pen and paper and input only the final answer, thereby staying very close to the way mathematics is normally practiced (Drijvers, 2019). As very little input is needed ITSs can be created for small screen devices, which make ITS technology more accessible. Of course, major drawbacks are that sloppy notation isn't detected nor corrected.

Stepwise evaluation and Granularity

By adding the identity function to the set of rules at each step, MBT could also be used to inspect intermediate steps in a calculation. Where, if steps are skipped or haven't been inputted, MBT could still provide feedback. This could constitute an addition to existing systems improving error detection. MBT could be used in combination with constraint-based modelling and model tracing. This way expert knowledge modules that already exist can be employed. When a student for instance inputs step i and then inputs step j $(> i + 1)$ without inputting the intermediate steps, the parameters at step i can be seen as starting parameters p for a computational task. The corresponding function M_p generally won't be injective however a list of possible paths can still be produced.

Non-stepwise evaluation

If the task consists of the calculation of several different non-equivalent components it is possible to let students work in a digital environment without adding any structure: an empty page. After which the computations are scanned for intermediate answers (Heeren et al., 2018). By construction the intermediate (wrong) answers differ. Therefore, it may be possible to recognize intermediate steps by just the values they produce and provide specific feedback.

Limitations and suggestions for further research

A clear drawback is that MBT can only be implemented for certain tasks since the possible parameters will be subject to constraints. Furthermore, the class of computational tasks does not contain many higher order tasks, aside from deriving expressions from geometrical representations. Further research might extend the possibilities of ITS beyond computational tasks. One of the drawbacks of the design principle of MBT is that it is very specific for the computational task. Usually ITSs make use of expert knowledge modules which contain rules for an entire mathematical domain. This way different tasks can be designed using the same set of rules (Heeren & Jeuring, 2014). Perhaps MBT could also be used over entire domains, possibly in combination with existing expert knowledge modules. Currently it is unclear what the performance of error detection trough MBT is, nor is it clear if specific feedback on the final answer enhances learning. Empirical experiments will be necessary to indicate if MBT can contribute to a positive learning outcome.

Numerical cognition with Touchcounts or Rakin? An enactive and ecological approach to finger gnosis

Ronnie Videla Reyes[1] and Claudio Aguayo[2]

[1]Universidad de La Serena, Departamento de Educación, La Serena, Chile; rvidela@userena.cl

[2]Auckland University of Technology, Auckland, New Zealand; claudio.aguayo@aut.ac.nz

Our paper aims to provide a proof of concept about the theoretical framework of enactive and ecological approaches to the field of perceptual learning of mathematics with digital technology. We reporst on the finger gnosis or finger knowledge that school children deploy when engaging with digital technologies such as Touchcounts and Rakin. From our theoretical lens we contrast both applications and conclude that they offer rich possibilities for number learning, however, Touchcounts adheres better with enactive and ecological foundations by prompting finger gnosis in different ways, while the Rakin technology application restricts actions and gestures, leaning toward representationalist cognitivism.

Introduction

In this article we emphasize how digital technology promotes new ways of learning by doing within the framework of new contemporary approaches to enactive and ecological cognition. The evidence on technology and mathematics education from an embodied, intersubjective and instrumental approach is auspicious, see Sinclair and Freitas (2014) and Drijvers (2019). In the framework of these studies, we place special attention to the understanding of cognition and digital learning from a dynamic sensorimotor theory based on the progressive structural coupling between the agent and the sociotechnological environment (Videla et al., 2021). We highlight and share the contribution of Shvarts (2021) on the importance of instrumented action constituted by a body-artefact dynamic functional system that regulates the actions of the agent and the sociomaterial environment. As a complement and from our enactive and ecological theoretical lens, we argue that digital technologies should be presented as ecological niches of skilled sensorimotor expansion, that is to say, they enhance the ecological control of actions for the achievement of learning goals. We highlight the movement of hands and fingers in the framework of perceptual and gestural exploration with tactile technology for the understanding of number. Particularly, we emphasize "finger gnosis", which consists in the knowledge of numbers through finger movements on touch screens. The aim of our study is to contrast the use of Jackiw and Sinclair's TouchCounts (2014) and CEDETI's Rakin (2021) applications for number comprehension, in light of our theoretical approach that highlights the specialization and expansion of actions and gestures that make it possible to bring a world of numbers and motion.

Theoretical framework

Enactivism: cognitive agency

In this section we provide brief clarifications of the role of perception in enactivism in order to illustrate the sub-personal dimension of agency. In face of the persistence of the traditional cognitivist approach based on representationalism, computationalism and internalism, enactivism emphasizes the role of action for perception by pointing out that: "(1) perception consists of perceptually guided action and (2) cognitive structures emerge from recurrent sensorimotor patterns that allow action to be perceptually guided" (Varela et al., 1991). This implies that cognition does not require mental representations to cause skilled bodily activity, since enactivism is framed within the circular dynamics of the perception-action loop in which cognition is action. When the enactive approach is alluded to, it refutes the idea of cognitive processing and emphasizes the notion of a decentralized cognitive system based on autonomy, sense-making, embodiment, emergence and experience (Di Paolo, 2020). Embodiment refers to movements, gestures and multimodal perception intertwined and constitutive of cognition through experience. Also, enactivism embraces the principles of the biology of knowledge, in which living beings are considered adaptive, autonomous agents and creators of their own worlds as a result of their history of coupling with the environment (Maturana and Varela, 1980). A cognitive system means that interchange with the world are inherently meaningful for the knower, given that movements are at the center of mental activity.

Ecological psychology: skillful expansion

Next, the role of perception from ecological psychology is presented in order to understand the interpersonal relationship between agent and sociomaterial environment. Gibson's (1979) ecological psychology proposes that cognition is enacted, shaped and structured by reciprocal interactions between the organism and the environment. Gibson (1979) argues that the environment is hierarchical in ecological information available to support everyday activities, think of; roads, rocks, slopes, forests, buildings, technology, and actions among others (Heft, 2020). Ecological psychology proposes a relevant epistemological debate by promoting an understanding of the world that overcomes dichotomies: perception/action; organism/environment; subjective/objective and mind/body. These dichotomies are at the basis of the theoretical assumptions of behaviorist and cognitivist psychology, which adscribe to the poverty of the stimulus, the passiveness of perception and the processing of information. Hence the importance of ecological information for Gibson, since it depends on the specification of the relationship established by the legal covariation between energy-optical, mechanical and chemical patterns, when actively participating in the environment (Chemero, 2009). This mode of participation, highlights affordances that are conceived as a relationship between an aspect of the sociomaterial environment and an ability available in a life form (Kiverstein and Rietveld 2015).

Brief Overview Tactile Technology and Numerical Cognition

In this article, we ascribe to the radically enactive approaches of numerical cognition developed by Zahidi and Myin (2016) on the importance of the body in the understanding of numbers and counting: correspondence, ordinality, and cardinality.

Rakin

Rakin is an inclusive Chilean application that seeks to promote the learning of mathematics in preschool children through a virtual desktop interface where skills such as seriation, classification, conservation of quantities, numbers, counting, cardinality and ordinality can be stimulated. In addition to being aligned with many of Chile's preschool mathematics learning objectives (CEDETI, 2021).

Touchcounts

TouchCounts (Jackiw & Sinclair, 2014) is an app that allows young learners to simultaneously coordinate various forms of numbers: number names such as 'three', number touches on the screen, number of records on the screen, and number symbols such as 3. It represents a multimodal correspondence between touching with fingers, seeing numbers, and hearing number words (a one-to-one correspondence of touch, sight, and sound). The application has two worlds: enumeration and performance.

Our enactive-ecological proposal: learning number with Touchcounts or Rakin?

Our proposal consists of a dynamic approach to sensorimotor agency for understanding the enactive-ecological approach to numerical cognition, see Videla et al (2021). The unification of these approaches seen as a continuum relieves the human cognitive-technological tool assemblage beyond the subpersonal dimension of enactivism and the interpersonal dimension of ecological psychology (Heras-Escribano, 2018). In the case of number learning with digital technology, we propose that a form of human-tool assembly is only possible from the ecological niche. This meta-relationship is flexible, dynamic and expansive, therefore, the technological niche grows in relation to the cognitive agent's experience. For example, in the case we address here is corresponding to finger gnosis, we assume that changes in the position and movements of the fingers make it possible to bring a world of numbers and not to have or objectively grasp a world of numbers as is characteristic of representationalist cognitivism. Below we present a brief description of the key concepts that nourish our proposal and that we have borrowed from other articles:

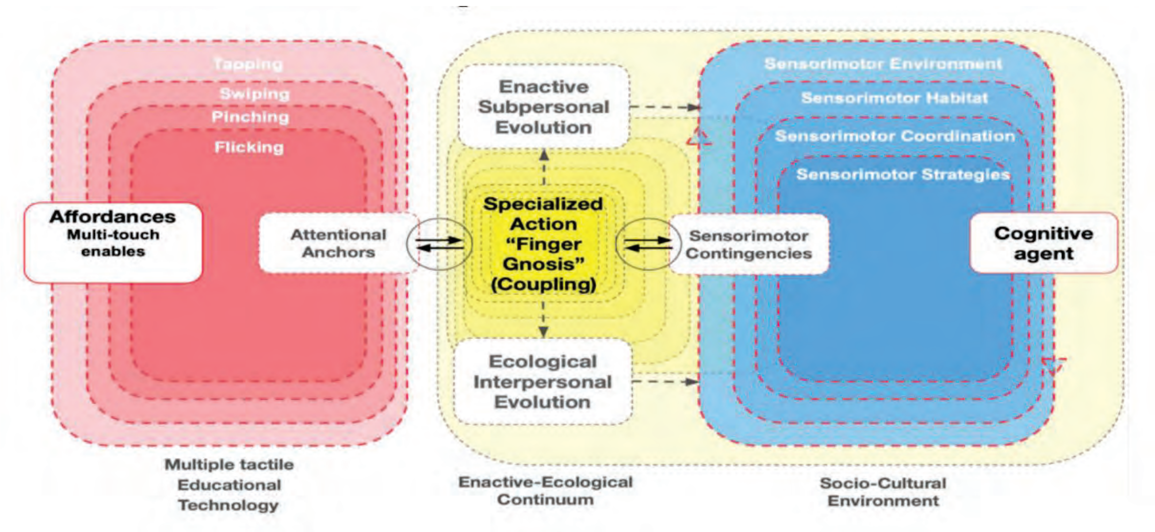
(i) Attentional anchors: during the flow of sensorimotor contingencies of cognitive activity, dynamic equilibrium is instantiated from the attentional anchors that interpolate between the internal dynamics of the agent and the environment in which it participates facilitating emergent understanding (Hutto et al., 2015).

(ii) Sensorimotor contingencies: distinguish four types of (SMC) that contribute to specialization of action: (a) sensorimotor environment: intuitive movements of perceptual exploration, without considering sensory feedback (b) sensorimotor habitat: sensory feedback movements between sensory and motor activity as a function of the agent's internal dynamics (c) sensorimotor coordination: specific action patterns that tend to dynamic control according to task goals (d) sensorimotor strategies: optimal balance of the cognitive agent within a normative framework that solves specialized actions (Buhrmann et al., 2013).

(iii) Finger gnosis: Butterworth (1999) proposed that fingers are important for representing numerosity. Sinclair and Pimm (2015) have evidenced in their studies that number sense in general is dependent on finger knowledge. Finger knowledge involves a performative gestural act such as (tapping, swiping, pinching and flicking) to produce numbered objects on a multi-touch screen.

In what follows we present Figure 1 as a representation of our proposal. Here we show how the evolution of the performative gesture of finger gnosis (tapping, swiping, pinching and flicking) is linked to the sensorimotor contingencies (sensorimotor environment, sensorimotor habitat, sensorimotor coordination and sensorimotor strategies), as can be seen in the red and blue figures. The segmented lines indicate the dynamic coupling between the cognitive agent and the environment reaffirming the co-dependence or mutualism of reciprocal constitution. The bidirectional arrows related to finger gnosis indicate that the specialization of the finger action is co-dependent on the attentional anchors and the sensorimotor contingencies. As the anchors interpolate between the cognitive agent and the touch screen, the sensory variety decreases as a result of the digital affordances that engage the cognitive agent with increasingly specialized actions that transduce number and its operations.

Figure 1. The enactive-ecological continuum model of finger gnosis in numerical cognition with multitouch technology



Empirical findings

To assert our theoretical proposition, we present the excerpt in which author Videla participated in a clinical interview with a 4-year-old kindergarten student named Andy, who interacts for the first time with TouchCounts and Rakin. We chose this excerpt from a larger investigation, as it illustrates a variety of gestures co-dependent on their coupling with the material affordances of the touchscreen. We illustrate that hand and finger movements are becoming specialized in Touchcounts, whereas in Rakin the movements to enact numerical comprehension are restricted. The resulting finger movements have not been explicitly taught, but have emerged in the sensorimotor flow of contingencies in the tactile ecological niche.

Table 1. Specialization of the action of the finger's gnosis in the understanding of the number

Technological ecological niche (Digital affordances)	**Finger Gnosis** **Specialization of tactile action (enacting-ecological numerical comprehension)**			
Multiple Tactile	**Tapping (sensoriomotor environment)**	**Swipping** **(sensoriomotor habitat)**	**Pinching** **(sensoriomotor coordination)**	**Flicking** **(sensoriomotor strategies)**

Touchcounts				Dialogue	**Andy:** I touch and 1 comes out. **Research:** Yes, try again. **Andy**: I play again and it comes out 1, you can also hear 1. **Research:** What else can you do? What appears on the screen? **Andy:** tap and move, numbers come up.	**Andy:** oooh! tap twice and it comes up 2. If I tap three times it comes up 3? **Research:** Yes, and if you tap 4 times how much comes out? **Andy:** 4. Also, you can put the balls together. **Researcher:** Yes, show me. **Andy:** Look, I put two little balls together that say 1 and I get 2.	**Andy:** Now I can form different circles of balls. **Researcher:** How do you do it? **Andy:** I do the little fingers like this (shows the pinching motion by putting thumb and forefinger together on the screen). **Researcher:** When you do those movements, what do you get? Andy: The sum.	**Andy:** You can also separate the balls from the big circle. **Researcher:**Yes, how? Show me. **Andy:** Look, with my two hands I can do it. With one I squeeze and with the other I pull. **Researcher:** What happens to the number in the big circle? Does it increase or decrease? **Andy:** It decreases. **Research:** Why? **Andy:** Because we remove balls.
Rakin				
Dialogue	**Andy:** up come the numbers, I touch 1 and it sounds 1, I touch 2 and it sounds 2. **Research:** Do you know the numbers 1 to 10? **Andy**: Yes. **Research:** What else can you do? What appears on the screen? **Andy**: On the side there are different things that I touch and they sound.	**Andy:** I can touch things and move them here (indicating the central screen divided in two parts). **Research:** Do you see that it changes in the first quadrant? **Andy:** Yes, it changes the amount. **Researcher:** How do you know? What appears on the screen? **Andy:** I move an object and it appears and it sounds 1. I move another one and it sounds 2. **Researcher:** What else can you do with your		

		fingers? Andy: Just move objects to the center.		

Table 1 illustrates the specialization of the action of the knowledge of the fingers for the understanding of the number with the Touchcounts and Rakin applications. This specialization of the action can be seen in the changes presented by the movements of the fingers on the touch screen, of which we have selected (tapping, swiping, pinching and flicking) reported by Sinclair and Pimm (2015) as finger gnosis. In relation to the contrast presented in table 1, we can identify that Andy when participating with Touchcounts begins tapping the multi-touch screen and makes a disc with the number one visually appear and an audio that says one. Later, after several tapping where other discs 1, 2 and 3 appear, he reconfigures this movement for swiping, and where the possibility emerges of making collections of discs that represent new numbers. These two movements correspond to changes in the structural couplings with the touch screen, of which the first are more exploratory and ingenuous where a touch is enough, to move to another sliding movement that makes it possible to join different discs and configure new numbers from the numbers of objects in the popup collection. The reorganization of these actions is due to the emergence of attentional anchors that interpolate in Andy's internal dynamics and the emerging content of the touch screen. From a numerical understanding, these movements promulgate the notions of ordinality, correspondence, and cardinality. In turn, within the framework of sensorimotor contingencies, it can be established that the tapping and swiping movements in Andy are gestated from the sensorimotor reconfiguration of the environment to the sensorimotor habitat.

This occurs within the framework of changes in the movement of the fingers, the first ingenious and without contact with Andy's internal dynamics (environment) to one with sensory feedback that triggers the sense of agency (habitat). At a phenomenological level of qualitative changes in what we call “finger gnosis”, it is possible to observe the alternation of the ring finger with the thumb. Subsequently and in relation to pinching, it can be seen that the movement of the index finger in tapping and the thumb or index finger in swiping, ceases to be one or the other, but transforms into a specialized gesture that encompasses both fingers simultaneously of one hand to respond to emerging objectives. This is relevant, since the effective movement requested by the touch screen is precisely the click to form collections of discs. Andy finds himself moving in some way to bring out new collections in a specialized way. This is what is known from the flow of contingencies in the performative gesture as sensorimotor coordination. Once this movement is coupled to his experience with the pop-up content on the touch screen, he realizes that the collections of discs formed by the pinching movement can also be separated or removed from the collection through a more specialized movement that requires not only sensorimotor coordination of one hand, but it is strategically discovered that you must use both hands to respond effectively to the emerging target. This is known from contingencies as sensorimotor strategies and it is where attentional anchors contribute to sensorimotor ecological control in the understanding of the number: ordinality, correspondence and cardinality.

Regarding the Rakin application, Andy exhibits only the tapping and swiping movements, as evidenced in Table 1. This is not to say that Andy fails to engage in a sustained manner by integrating broader sensorimotor contingencies that contribute to dynamic equilibrium such as sensorimotor coordination and sensorimotor strategies. Rakin offers an environment rich in digital affordances in relation to ordinality, correspondence and cardinality as evidenced by tapping and swiping in which Andy can tap the ordinal sequence of numbers on top and can select from a set of available objects (animals, plants and toys) to establish correspondence and cardinality. Nevertheless, the movements that Rakin requests as digital affordances, do not allow the tactile specialization of the action that does justice to the finger gnosis that leads to enacting numerical comprehension. In this area, we consider that Andy is deployed in a restricted environment of actions that the fingers only lead to tapping and swiping to understand and learn the number. Finally, we consider that Rakin is an important application for the development of the fundamental notions of numerical cognition such as ordinality, correspondence and cardinality, however, it is more framed in a representationalist perspective in which cognition is more linked with representing pre-existing contents that make the contents emerge in the specialization of the action.

Conclusion

In this paper we have considered a proof of concept for enactive and ecological unification in the framework of finger gnosis of number learning with multi-touch technologies such as Touchcounts and Rakin. If our proposal is correct, we contribute to the field of research in embodied perspectives of mathematical cognition that allow to favor instances of learning with technology that resonate with basic forms of actions and gestures.

How the students chased perpendicular lines in GeoGebra Classroom

Lukáš Vízek[1] and Libuše Samková[2]

[1]University of Hradec Králové, Czech Republic; lukas.vizek@uhk.cz

[2]University of South Bohemia in České Budějovice, Czech Republic; lsamkova@pf.jcu.cz

This paper focuses on the issue of what solution strategies do secondary school students provide while performing non-standard geometric constructions. For this purpose, we developed an interactive electronic environment in GeoGebra Classroom and, in that environment, we let students construct perpendicular lines in multiple ways. We formulated the task for students so that it corresponded with their school geometry curriculum but in a non-standard open-ended way. Then we analyzed students' constructions qualitatively. Findings showed that the students were usually able to solve the task but just a few of them were able to generate multiple strategies. However, creative constructional approach appeared in data indicating the significance of the assignment or instruction where a variety of mathematical approaches are possible.

Keywords: Dynamic geometry environments; multiple solution strategies; plane geometry; secondary school students.

Introduction

Recently, school geometry has got a rather dual role: it seeks to reflect ongoing technological progress but at the same time still arises from fundamental concepts described in ancient Euclid's *Elements*. One of the significant aspects of the *Elements* consists in stressing on acknowledging the definitions and proving the theorems, while one of the goals of school geometry is developing students' justification skills or, in general, students' conceptual knowledge in the domain. In the past decades, educational researchers have been naturally concerned with the impact of the use of modern electronics technologies on learners' mathematical reasoning. They have explored how dynamic geometry environments (DGE) such as Cabri Geometry or GeoGebra could assist students to improve their understanding of proof in geometry (e.g. Marrades & Gutiérrez, 2000). In this context, an important characteristic of DGE lies in the ability to modify geometrical objects and to observe their features during the modifications. It has become clear that this feature of DGE provides students with opportunities for deep explorations and heuristics on their way to argue the properties of geometrical objects (Lawson & Chinnappan, 2000; Sträßer, 2001). Through the dynamic process of observing modifications of geometrical objects, DGE does not only facilitate students' justification skills but can also provide visual information that a particular property does not apply in general (Prusak et al., 2012). Altogether, the research has revealed the importance of DGE for stimulation of formulating conjectures and creating proofs (Komatsu & Jones, 2017).

Along with the use of DGE, other activities in school geometry could contribute to formulating geometrical conjectures, namely geometric constructions (Herbst et al., 2017: see p. 106). However, there is a lack of investigations that would deeply focus on the relation between constructional problems and reasoning in geometry, or, in general, on explaining how performing geometric constructions can contribute to improving students' conceptual and procedural knowledge and flexibility in the domain. In this contribution, we present an introductory exploratory study on the topic. We proceed from a construction of perpendicular lines, formulate a task that is not standard compared to common activities in school geometry in our country, and analyze students' solutions of such a task. The task is not standard for three reasons:

(i) we let students construct two perpendicular lines on tablets in an online application GeoGebra Classroom whereas it is standard for them to perform geometric constructions on paper;
(ii) we ask students to solve the problem in multiple different ways;
(iii) we allow students to use only two tools: one that creates a line through two points, and another one that creates a circle from a center and point or a center and radius – despite the fact that the standard approach to school geometry also allows them to use a tool that creates a perpendicular line to a given line.

Our explorations correspond with the theoretical framework of flexibility which is defined as the knowledge of multiple solution methods and the ability to generate and perform them appropriately and effectively (Rittle-Johnson et al., 2012). With respect to notes on learning and teaching geometry mentioned above, it becomes clear that developing students' capability to solve mathematical problems in different ways has a significant potential for increasing their conceptual and procedural knowledge (e.g. Star et al., 2015). Since including the facet of multiple solution procedures required from students, we follow up the studies on so-called multiple solution tasks (MSTs) that might be used as a means of developing students' creativity and flexibility in geometry (Levav-Waynberg & Leikin, 2012; Gridos et al., 2019). From the general perspective of research on incorporating an artefact of ICT into the teaching/learning system, we focus on an online application, learners, and knowledge, i.e., on all three edges of the face "ALK" of the corresponding didactic tetrahedron (Donevska-Todorova & Trgalova, 2017).

Within this context, we introduce an exploratory qualitative empirical study with the following research question: "What solution strategies do secondary school students provide when asked for multiple constructions of perpendicular lines while using only circles and lines within the GeoGebra Classroom environment?"

Theoretical background

Geometric constructions

Geometric constructions are understood as a specific category of mathematical problems that ask solvers to draw a geometrical object in a precise and exact way. According to the given circumstances, it requires choosing an appropriate construction method that would correspond to geometrical characteristics of the desired object (Kuřina, 1996). Therefore, geometric constructions are considered a form of mathematical activity combining the process of manipulating objects with the processes of visualization and reasoning (Duval, 2006). What remains to be discussed, is the way how performing geometric constructions could stimulate doing proofs in geometry and, in particular, how it could provide students with significant ideas that would be helpful during the proving process (Herbst & Brach, 2006).

In the Czech Republic, where our research study took place, geometric constructions as a part of school geometry are commonly performed on paper while using a pencil, straightedge, compass, and a special ruler called *a triangle with a guideline*. This special ruler has a form of a transparent piece of plastic in a shape of an isosceles right-angled triangle with a guideline (an impressed line segment) connecting the center of the hypotenuse with the opposite vertex. The tool is frequently used in school geometry from early elementary school grades, where it provides students with an easy way of drawing a line that is perpendicular to a given line – the solver just has to match the guideline with the given line, and then outline the longest side of the ruler with a pencil. From the perspective of the GeoGebra environment, a triangle with a guideline corresponds to the tool *Perpendicular line*.

As mentioned above, we do not allow the use of the tool *Perpendicular line* in our study. It means an obstacle for the students but, on the other hand, it challenges them to come up with an original solution and opens a rich space for multiple correct ways of constructing the object. This arrangement provides us with an opportunity to explore various students' ideas on a problem that is unfamiliar for them but still fully corresponds with the content of school geometry that is appropriate to their age. This way, our approach shifts the issue of geometric constructions into the frame of open-ended problems in mathematics education (Pehkonen, 1997), and thus mediates a suitable environment for investigating students' knowledge.

GeoGebra Classroom

The use of DGE in our research follows the above-mentioned studies that focus on the benefits of the modern technologies for teaching and learning geometry. We work in an online application GeoGebra Classroom provided by GeoGebra software. This software was originally created by Markus Hohenwarter (2002) and has been under continuous development and addition of new elements in the past two decades. These days, GeoGebra has the form of a rich open-source application covering the topics of geometry, algebra, calculus and statistics, in the range from primary school to university levels (GeoGebra, 2021).

GeoGebra Classroom is one of the latest features of GeoGebra software which was introduced to public in May 2020. It allows teachers (or researchers) to assign various tasks to students, then ask them to join the environment via entering a code and solve the tasks individually. Teachers or researchers can observe updated students' advances in the solving process live, and record the step-by-step course of all the constructions contributed by individual students. Such interactive features provide us with complex data on students' work. In this contribution, we show how these features might be used in research focusing on student knowledge.

Design of the study

Participants

Participants of our research study were 19 students from the same ninth-grade class (age 15 to 16 years) at a suburban school. At the time of the study, they had already discussed whole mathematical curriculum belonging to the lower-secondary school level (grades 6 to 9), including prescribed parts of Euclidean planar geometry and geometric constructions such as copying a line segment, an angle, or a triangle, constructing circles, triangles and quadrilaterals on the basis of certain requirements, or constructing an image of an object in particular symmetry. During some of their previous mathematics lessons, they had also gotten to experience exercises in the GeoGebra environment. Nevertheless, they had not been asked to perform geometric constructions in GeoGebra Classroom before.

Data collection

As indicated above, we prepared GeoGebra Classroom based on three activities with GeoGebra applet where we let the students construct perpendicular lines. The first activity was named “Right angle for the first time” and its assignment was formulated as “Make a right angle! I.e., construct two lines, about which you can safely say that they are perpendicular to each other.” The second activity was named “Right angle differently” and it requested to “Make a right angle again, but now construct two perpendicular lines in a different way than in the previous task.” The third activity was named “Right angle still differently?” and it asked “Can you do it again? Construct a right angle by a different method than in the two previous tasks.”

For the purpose of our research, the GeoGebra toolbar was customized in all three activities. Solvers were able to use only the tools *Move*, *Point*, *Intersection*, *Line segment*, *Ray*, *Line*, *Circle with center through point*, *Compass* and *Delete*. They could also go through the steps of their construction using *Navigation bar*, return to the previous step pressing *Undo*, redone an undone action by pressing *Redo*, or start again with the button *Reset construction*.

Data collection was conducted during a mathematics lesson, while working face-to-face with the participants in the classroom. At the beginning of the lesson, each participant has got its own school tablet, i.e., a device with touchscreen and internet connection. They were used to working with this equipment. We gave them the code of the arranged GeoGebra Classroom to type in the box and join the environment. The participants had 20 minutes to complete all three assignments. They worked individually and independently; we provided them only with technical support.

Task analysis

As a preparation for data analysis, we investigated the assigned problem from the geometrical point of view. We looked for different construction strategies that would lead to creating perpendicular lines using only the given tools. We identified eight basic strategies; others might be derived from them by minor changes (e.g. in the order of steps) or by combining various basic strategies together. In their background, they all have a construction of a geometrical object that contains a right angle as a general property of its basic attributes (e.g. between a line segment and its axis, between diagonals in a rhombus, between a side and its median in an equilateral triangle, between a base and its median in an isosceles triangle) or as a consequence of a general principle used to construct the object (the Thales’s or Pythagorean theorem – Proposition 31 in Book 3 or Proposition 47 in Book 1 of Euclid's *Elements*). We ordered the strategies according to the interrelations between them. In the next paragraph, we illustrate the issue by introducing three of the identified strategies and their interrelations.

The strategy that can be considered as the simplest one is based on the construction of the perpendicular bisector of a line segment consisting of creating two circles with the centers at the end points of the line segment, the circles having the same radii greater than half of the line segment length. This construction had been well-known to the participants as a method of finding the axis (perpendicular bisector) of a line segment. Such an approach leads to obtaining two points (the intersections of the circles) that are at the same distance from the end points of the line segment. The set of all such points is exactly the same as the line that divides the given line segment into two halves forming right angles at the intersection point. This, in its substance, is a geometrical theorem that can be proven on the basis of the congruence of triangles or the properties of the diagonals of a rhombus. When the radii of the circles are equal to the length of the line segment, the circles go through the end points; we labeled this strategy as PL1. The general case when the radii are arbitrary but same and not equal to the length of the line segment, we labeled as PL2. The modification of the general strategy, where the radii are not the same, we labeled as PL3. The PL3 case leads to properties of diagonals of a kite (a quadrilateral with two pairs of adjacent sides of the same length has its diagonals perpendicular).

Data analysis

We analyzed collected data qualitatively, using open coding and constant comparison (Miles, Huberman & Saldaña, 2014). We carefully observed all students' solutions from the perspective of correctness and relevance of (i) individual construction steps, (ii) the figure presented as final in the construction, (iii) the sequence of the GeoGebra tools used during the construction. The latter information was available through the GeoGebra functionality *Construction protocol*. We were also comparing the ongoing findings with our list of basic strategies.

Findings

Strategies provided by participants – an overview

During data analysis, we identified three different basic strategies used by the respondents: PL1 mentioned above, a strategy based on the Thales's theorem (an angle inscribed across a circle's diameter is a right angle) that had also been stated in our list of strategies, and a new strategy that had not been stated in the list. The new strategy consists of the construction of three circles with collinear centers and the same radii, and two rays passing the intersections of the circles and forming the equilateral triangle. Generally speaking, the method is based on the properties of triangular lattice. We added this new strategy to our list, and reordered the list of basic strategies to still follow the sequence of relations between them. After the reordering, PL1 stayed PL1, the new strategy became the fifth one, i.e. PL5, and the strategy based on the Thales's theorem became PL9.

For details on the three strategies see Fig. 1: for each of the strategies, we present the number of respondents that provided the strategy (in square brackets), the list of GeoGebra icons that were available for the respondents during the task, the final figure, the sequence of the construction steps expressed through the GeoGebra tools icons, an explanatory drawing proving the perpendicularity, and a note on the geometrical background of the method.

In all of the assigned activities together (i.e., among the $3 \cdot 19 = 57$ attempts to create perpendicular lines), 16 students completed the strategy PL1 (one of them twice, with two different orders of construction steps), one student completed PL5, and four students completed PL9. All other attempts were unsuccessful: the participants either did not present any perpendicular lines, or presented just a freehand sketch (they drew two lines that looked like they were perpendicular but, in reality, they were not).

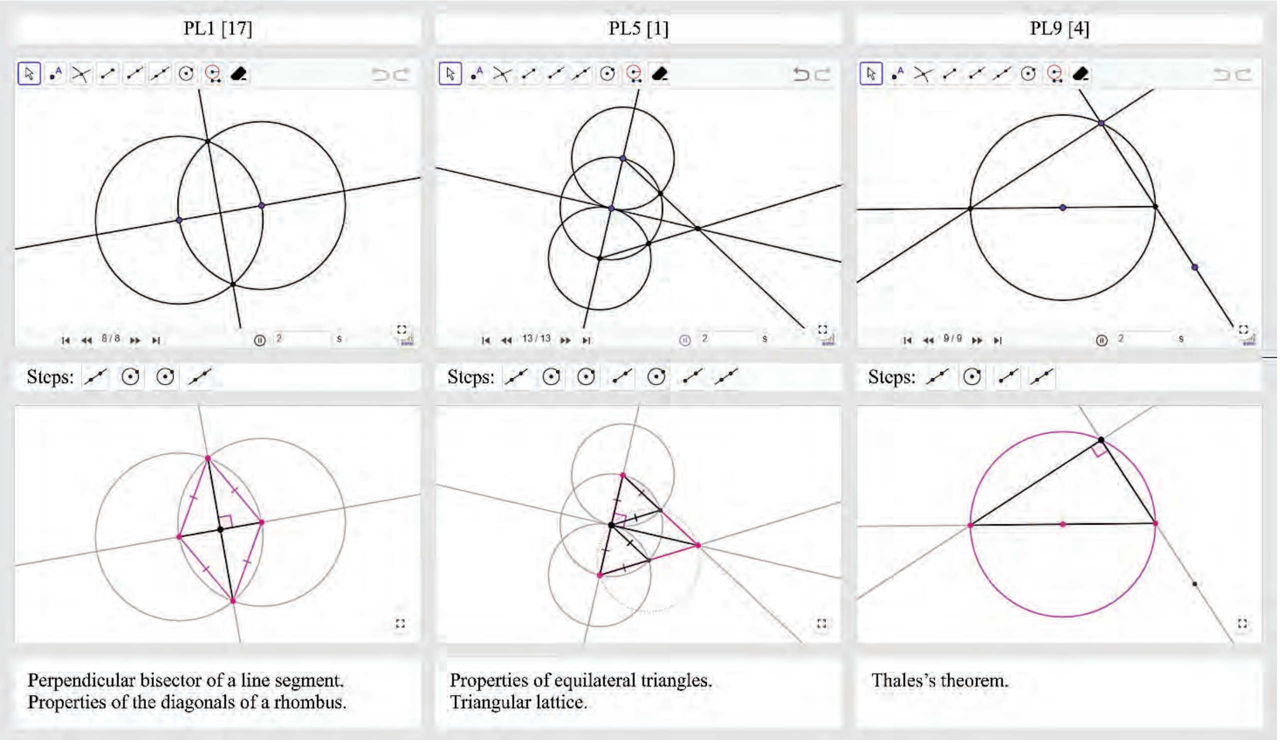

Figure 1: Three constructional strategies that appeared in data with, in square brackets, the number of respondents that provided the strategy

Individual participants

From the perspective of individual participants across the three activities, nobody was able to provide three different strategies. One student provided three different constructions that were based on two different strategies (one of the strategies was presented twice, with two different orders of steps), three students provided two different strategies, 12 students provided one strategy (all of them PL1), and three students did not manage to provide any strategy. The diagram of individual strategies within individual assigned activities that also captures individual participants' shifts in strategies across the three activities is shown in Fig. 2.

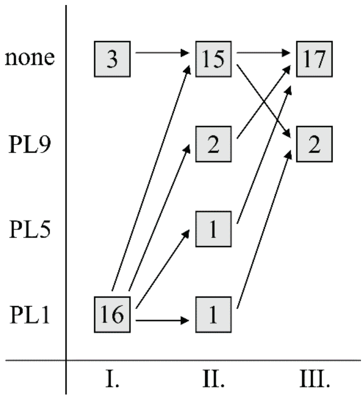

Figure 2: The number of students using individual strategies (PL1, PL5, PL9, none) within individual activities (I., II., III.), the arrows indicate participants' shifts in strategies

Discussion and conclusion

In this study, we focused on the variety of solution strategies that secondary school students provided while performing non-standard geometric constructions. For this purpose, we developed an interactive electronic environment in GeoGebra Classroom, and asked the students to construct perpendicular lines in multiple ways. To accomplish the non-standard nature of the task, we allowed just lines and circles to be used as tools during the construction. Using the GeoGebra Classroom environment, we obtained detailed complex data on students' work which confirmed the potential of DGE in rendering students the opportunities for deep explorations and heuristics (Lawson & Chinnappan, 2000). On the other hand, most of the students provided just one construction strategy, although we asked them to come up with three different ways of constructing perpendicular lines. The variability of the strategies was also low, we detected only three different students' approaches whereas we found at least eight solving methods available and appropriate for the given students. Therefore, as a plan for the future, we see the need to investigate further the relationship between students' performance in non-standard geometric constructions and multiple solution tasks, their conceptual understanding and their justification skills.

Among the construction strategies provided by students, two were based on a fundamental feature of a basic geometric figure or a basic construction – a perpendicular bisector of a line segment (PL1), Thales's theorem (PL9). These methods could be considered mere applications of a known geometrical shape property or construction procedure. However, the approach PL5 that emerged from data represents a shift from the use of the known individual object or construction procedure to a creative synthesis of various geometrical objects and constructions. We could perceive this method as a construct that arises from an enhanced connectedness of student's knowledge in the domain (Levav-Waynberg & Leikin, 2012) or from student's ability to use concepts and procedures in a flexible way (Rittle-Johnson et al., 2012).

The strategy PL5 also highlights the significance of open-ended approach in mathematics teaching and learning (Pehkonen, 1997) that goes hand in hand with the need for stimulation of using various construction strategies as in our assignment. It can be concluded that, without this request, the strategy PL5 would not have been explored, contemplated and developed by the student. For the future, it would be helpful to investigate which other impulses can lead students to such innovative and original solutions of geometric problems.

Embodied approaches to functional thinking using digital technology: A bibliometrics-guided review

Hang Wei, Rogier Bos and Paul Drijvers

Freudenthal Institute, Utrecht University, Utrecht, The Netherlands; h.wei@uu.nl

Digital technology offers many opportunities for embodied approaches to mathematics education. To investigate what is known from literature about such approaches for the case of Functional Thinking, we carried out a systematic literature review, followed by a bibliometric and an expert content analysis. We included 36 peer-reviewed articles from 1986 to 2020 in the study. As a result, we identified five research themes in the field, which are further merged into three categories labelled Embodiment not central, Pseudo embodiment and Embodiment.

Keywords: Bibliometric analysis, digital technology, embodied cognition, functional thinking.

Introduction

In cognitive science, it is emphasised that cognition originates or is grounded in bodily motions and perceptual experience (Barsalou, 1999; Barsalou, 2008; Lakoff & Johnson, 1999; Lakoff & Núñez, 2001). In this context, recently developed digital technology, including motion detectors and augmented reality, seems to offer opportunities for an embodied approach to mathematics education (Bos et al., 2021; Drijvers, 2019; Nemirovsky et al., 2013). A bibliometric approach, which is an objective method that provides an overview of the knowledge structure of the domain (Li et al., 2019), was applied to explore these opportunities for the case of Functional Thinking (FT), a fundamental learning goal in mathematics education (Thompson, 1994; Vollrath,1989). The research question addressed is as follows: *What is known about the use of digital technology for an embodied approach to the teaching and learning of FT?*

Theoretical underpinnings

We draw on theoretical notions from embodied cognition and design research, digital technology research, and research on functional thinking.

Embodied cognition and embodied design

Several theories concern the role of the body in cognition and learning. Based on Conceptual Metaphor Theory in cognitive linguistics (Lakoff & Johnson, 1980), Lakoff and Núñez (2001) analysed the cognitive structure of mathematics and argued that the kinds of everyday conceptual mechanisms, image schemas, aspectual schemas, conceptual metaphor, and conceptual blends are central to mathematics. Some studies carry a similar idea about mathematics cognition concerning embodied design in function learning (e.g., Font et al., 2010; Oehrtman et al., 2019; Paz & Leron, 2009). From a perceptual perspective, Barsalou frames embodiment through grounding experiences, which is also advocated by Schwartz (1999) and Abrahamson et al. (2016) and employed in their own research. In addition, Shvarts et al. (2021) emphasise that knowledge emerges as part of a complex dynamic behavioural system that is constituted through multiple perception-action loops.

For educational materials, Abrahamson (2009) defined embodied design, which was first proposed by Rompay and Hekkert (2001), as a systematic and procedural design method, helpful in guiding the student's construction of meaning. At first, embodied design was classified into two categories: perception-based design and action-based design (Abrahamson, 2009, 2014; Abrahamson & Lindgren, 2014). Action-based designs aim to ground mathematical concepts in students' natural capacity to adaptively solve sensorimotor problems. Perception-based designs aim to ground mathematical concepts in students' natural perceptual ability in their naive views relating to a situation. Similar to the action-based genre, it is followed by a phase of reflection in which these views are developed. Concerning the role of artefact in learning design, Bos et al. (2021) propose a new type of embodied design, incorporation-based design, which is in a sense the opposite of outsourcing a task to an artefact instead of a person.

Digital technology in mathematics education

A major consideration in designing and using technology in mathematics classrooms is how to identify and use the different didactical functionalities. According to task-based interviews, Günster and Weigand (2020) set up a category system. We followed some of the categories for our study: (1) Feedback through the learning arrangement, (2) Use of sliders, (3) Creating objects, and (4) Adjusting existing objects to analyse the digital technology dimension. These four usages are related to doing mathematics and developing conceptual understanding with possible embodied elements. What's more, an embodied instrumentation approach, which can offer a design heuristic for ICT activities, was proposed by Drijvers (2019). This integrated approach, in which digital technology, mathematical cognition and sensorimotor schemes co-emerge, helps us better understand the relationship between embodied approaches, digital technology, and FT.

Functional thinking

Since the beginning of the twentieth century, functional thinking has been a central aspect of mathematical education throughout primary, secondary, and tertiary education (Vollrath, 1986). Although there is no widely adopted definition of FT, we propose that FT encompasses the process of building, describing, and reasoning with and about functions (Pittalis et al., 2020; Stephens et al., 2017). In a broader interpretation, FT connects to the four main aspects of function distinguished in literature (Confrey & Smith,1995; Doorman et al., 2012; Thompson, 1994; Vinner and Dreyfus, 1989; Vollrath, 1989): a) Function as an input-output assignment; b) Function as a dynamic process of covariation; c) Function as a correspondence relation; d) Function as a mathematical object.

Methods

To address the research question, we carried out a systematic literature search, followed by a bibliometric clustering (BC) and expert content analysis (Drijvers, Grauwin, & Trouche, 2020). The first step was part of the FunThink Erasmus+ project, a European research project.

Systematic literature search

The literature search was conducted in four databases: ERIC, PsycINFO, Scopus, and Web of Science. We searched for relevant studies published in peer-reviewed journals and written in English without restricting the publication date. Qualitative studies, quantitative studies and mixed-method studies were included. The query focused on Functional Thinking × (Embodiment OR Digital Technology). Our initial search yielded 278 journal articles. After deduplication, 257 unique publications remained. Next, we carried out two rounds of screening. The first round concerned a scan of title, abstract and keywords, to judge each article's relevance to each of the three aspects: Functional Thinking (FT), Embodiment (EM), and Digital Technology (DT). This led to 93 papers – empirical as well as theoretical papers - being selected with the help of ten coders from FunThink project. In the second round, eleven coders participated in the literature appraisal round, during which each coder read full texts and filled in a spreadsheet with the core ideas of each article. We removed the articles coded 0 to 2 as they are perceived as less helpful to our project. As a result, thirty-six articles were included in the final corpus.

Bibliometric clustering and expert content analysis

The studies in the final selection were classified with the help of BC techniques (Drijvers, Grauwin, & Trouche, 2020), which provides a sense-making sketch of the 'landscape' of our topic. We did not regard the bibliometric results as strict, exclusive categories; rather, we saw them as analytic tools that help us make sense of the rich diversity in this research field and to locate the main areas of embodied elements. Triangulating the bibliometric findings with expert content analysis helped us to find out a new taxonomy of the studies in relation to the different embodied approaches / embodied elements, which formed a basis for the study's results.

Results

Results from BC techniques include clusters that gather thematically close (based on the references) publications of the studied corpus; overall descriptions of the clusters, including an analysis of publication year, numbers involved, reference, and global meaning (see Table 1); and categories of embodied approaches to the use of digital technology for FT (see Table 2).

The bibliometric clustering leads to five clusters, containing 31 thematically close publications. The quality measure Q=0.429 suggests a meaningful partition. In each cluster, the most frequent references, the most frequent subjects, and the most cited authors are analysed. Table 1 presents some of these features.

Table 1 Description of the five clusters

	Cluster 1 (n=3)	Cluster 2 (n=5)	Cluster 3 (n=6)	Cluster 4 (n=6)	Cluster 5 (n=11)
Time distribution						between 2009 and 2015	mainly written after 2020	mainly after 2013	since 2007	since 1990
Top three cited	O' Callaghan (1998) Kennewell(2001) Keong (2005)	Drijvers(2015) Dubinsky (2013) Ellis (2011)	Artigue (2002) Zbiek (2007) Lagrange (2008)	Falcade (2007) Tall (1996) Vollrath (1989)	Nemirovsky (1998) Lakoff (2000) Mariotti (2002)

Our global analysis of tasks	based on computer algebra systems (CAS) but without explicit embodiment	based on animation and dynamic geometry software (DGS) but without explicit embodiment	based on TI-Nspire software/ calculator but without explicit embodiment	involving mouse movements (dragging, sliders, etc.)	based on embodied design

In light of the research question, our main goal is to explore how an embodied approach in learning design can affect developing functional thinking. We merged Cluster 1, Cluster 2 and Cluster 3 into one category labelled as *Embodiment not central*. This category focuses on digital technology-enhanced function learning and teaching without elaborate embodied designs, but has different types of technology. Next, we labelled Cluster 4 *Pseudo embodiment* category, which describes technology-enhanced designs with sort of embodied elements (like dragging). Finally, we labelled Cluster 5 *Embodiment* category, including eleven articles focus on embodied designs for function learning. Figure 1 depicts the results of the BC method, where the node size is proportional to the number of publications contained therein and the line thickness is proportional to the average similarity between the publications of the two linked clusters (in terms of shared references).

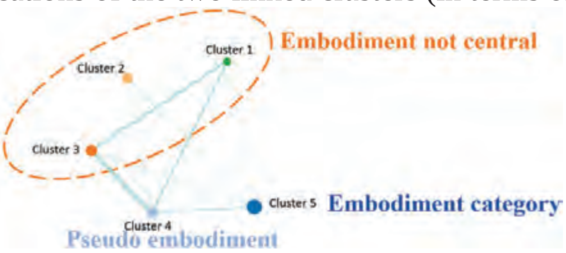

Figure 1 The network of clusters

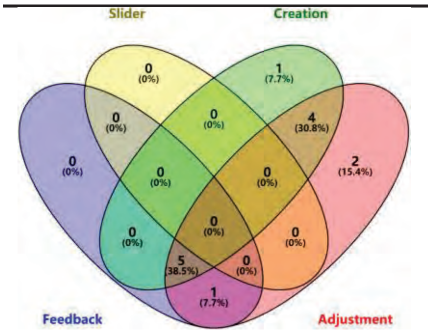
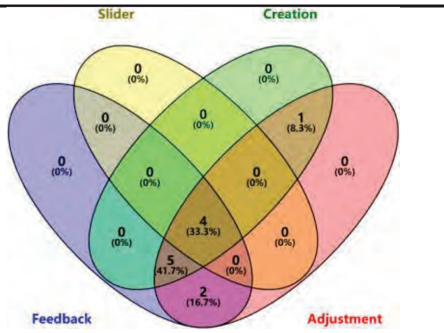
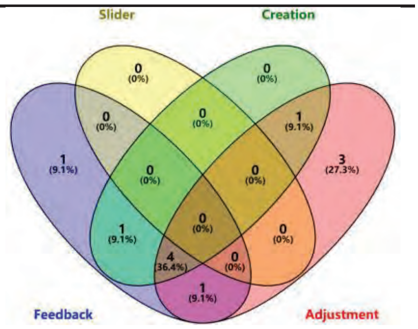
Following the labelled categories, Table 2 illustrates how the possible embodied elements (the use of slider, create object, feedback through the learning arrangement and adjust object) are involved in the three types of embodiments. First, the use of sliders only appears in the Pseudo embodiment, that is, most designs only allow students to control sliders in the digital environment by mouse. Second, students are given many opportunities to create and adjust functional objects, mainly digital geometric objects, in the designs from Embodiment not central and Pseudo embodiment. But in the Embodiment category, about half of the designs offer the existing, elaborate objects that students only need to adjust. Finally, feedback from the digital environment appears more frequently in the Pseudo embodiment category.

Table 2 Categories of Articles Based on the Use of Digital Technology and Embodiment

Embodiment not central (n=13)	Pseudo embodiment (n=12)	Embodiment (n=11)
		






As a final result, given the theoretical underpinnings and bibliometric results described above, our content analysis led to the identification of three categories of embodied approaches: Embodiment not central, Pseudo embodiment and Embodiment.

Embodiment not central

In the Embodiment not central category, the most common configuration of the designs is creating and adjusting objects with/without feedback. And in these designs, students are allowed to adjust objects by inputting different values or pressing buttons on the calculators. Considering the mathematical object aspect of FT, especially the aspect graphing, GeoGebra, Graphmatica and TI-Nspire software/calculator are used to help students detect the effects of changing parameters in function on its graphical representation through supporting the modelling of different scenarios that allow students to study the effect of changes in the value of one variable on the other (Duijzer et al., 2019; Jon, 2013; Ogbonnaya, 2010). Along with the adjusting functionality, feedback from digital technology was also emphasised in the studies. For example, Asli Özgün-Koca (2016) pointed out that the feedback from the representations on the screen might help students recognise their misconceptions and overcome them through additional interactions with the digital tool. In addition, digital technology has the potential to motivate students and instil a curiosity that enables them to learn more when receiving real-time feedback from the tool (Ogbonnaya, 2010).

Pseudo embodied approach

Compared to the first category, embodied elements in this second category are more visible in the learning design, such as slider using and mouse dragging tasks. Mouse movements play an important role in using DGS (e.g., Cabri and GeoGebra) or in other digital environments (e.g., the Digital Mathematics Environment DME). There are two different settings of sliders: a) continuously slider (free movement on a bar without restriction), b) discrete slider (static selection of particular values). In Liang and Moore's case (2020), students could drag the endpoint (without restriction) to vary the length of the bar, which leads to the dynamic point on the circle moving correspondingly. Students can recognise amounts of change (covariation aspect of FT) when the perceptual material was given, but can not anticipate, represent or regenerate the changes when the perceptual material is absent.

Apart from using sliders, this category includes diverse mouse movements that provide more opportunities for students to create or explore relationships between entities and variables. The Arrow Chain module in DME, for example, is designed to foster conceptual understanding of the notion of function, where the main aspects of function in this design are input-output assignment, dynamic process of covariation, and mathematical object with different representations (Doorman et al., 2012). Students are able to drag and connect machines into function chains. In doing so, the idea of embodying the functional level to compose as well as the input-output assignment is clear. This design could offer educators and researchers some informed directions or ideas for using the technologies to achieve specific learning goals.

In addition to the different mouse movements of embodied elements, the type of feedback from digital technology can also differ among designs. The abovementioned design shows that the movement of connecting embodies the input-output process essential for the function notion, but there is no feedback on the movement itself. Falcade et al. (2007) designed two tasks with real-time feedback on the screen that allows the user to feel functional dependency in the domain of space and time. Students can find the effect of moving one of these points at a time and observe the traces they make through the Trace tool. The traces of points on the screen provide real-time feedback and serve as a cognitive anchor for learning about and understanding abstract concepts (Cox, 1999; Reiner, 2009).

Embodied approach through digital technology

This category of embodied studies in our corpus includes physical motions with the help of digital technology, especially registering movement digitally, processing, and providing feedback. A main similarity between the papers is the presence of (adaptive) motor tasks. In accordance with the three types of embodied task designs, action-based, perception-based, and incorporation-based (Bos et al., 2021), the following analyses provide insight into the possible embodied instrumentation approach (Drijvers, 2019) used in the studies of the third category.

Most studies used function-related tasks from an action-based perspective (8 out of 11). The embodiment of actions can supplement the input received from other modalities (e.g., vision), enabling students to construct richer multimodal representations to support more complex understanding (Drijvers, 2019). Distinctive regarding the understanding of functions, Nemirovsky et al. (2013) designed a mathematical instrument called Drawing in Motion, which is a prototype exhibit that requires physical engagement and collaboration between two people who jointly produce a graph on a displayed Cartesian coordinate plane through a large LCD screen. It did provide a new perspective of understanding function using the embodied instrumentation approach, compared to the conventional ways of thinking about functions (e.g., dynamic/process and static/structural conceptions). The authors claim that, given suitable mathematical instruments and practices, even young learners can engage in the learning of functions with the emphasis on the parameterisation of time.

Studies in the genres of perception-based and incorporation-based designs concerning FT so far are rare. Ferrara & Ferrari (2020) used WiiGraph software to engage pairs of students with functions through graphing motion, and one of their tasks, named *Line option for a+b*, showed the perception features. They even drew a conclusion that aspects of coordination and imagination push the mathematical activity further no matter whether the tool is in use or not. Again, the significance of perceptual experiences in the learning of function has been proved. The graphing motion technology, which allows working with couples of positions over time graphs, provides students with the opportunity to observe in real-time the graph of the sum of two functions on the screen, and then gain perceptual experiences supporting a concrete understanding of function.

Conclusion

With the aim of exploring how an embodied approach in learning design can affect students' FT with the support of digital technology, this study performed an expert content analysis using the BC approach. The literature analysis based on the selected corpus revealed three categories: (1) Embodiment not central; (2) Pseudo embodiment; and (3) Embodiment. All three categories have distinctive features in characterising the embodied elements of technology-enhanced learning designs. In the Embodiment not central category, embodiment remains implicit with keyboard strokes tasks and mouse-clicking tasks occupying the most learning designs. In the Pseudo embodiment category, mouse movements, as a distal movement, play an important role that can be made more proximal through touch screen technology and gestures that more closely correspond to the actual movements intended in using sliders or adjusting geometric objects. In the Embodiment category, digital technology allows for an embodied approach to register movement, process, provide feedback. From a methodological point of view, the bibliometric clustering technique did not offer new insights but did confirm our impression on how embodied approaches are involved in the domain of function.

Developing a framework for creating heuristic worked example videos to enhance students' modeling competencies

Laura Wirth

University of Muenster, Germany; laura.wirth@uni-muenster.de

As a large number of instructional videos can be found online, the question arises to what extent videos can be used in mathematics classroom practice. While many videos address algorithmic domains, this theoretically informed paper focusses on the possibilities of using videos to enhance heuristic skills in the domain of modeling. It introduces a framework for developing heuristic worked example videos based on multimedia learning principles, (heuristic) worked example research and criteria for creating instructional videos. In addition, the framework and directions for future research are discussed.

Keywords: Interactive video, instructional design, cognitive load theory, mathematical modeling, secondary education.

Objective and rationale

Videos are gaining importance in the educational setting. The production of videos has become easier in recent years and many videos are available online (Kay, 2012; Kay & Edwards, 2012). Studies have shown that videos can have a positive effect on learning performance (for an overview, see Kay (2012)). Video formats that contain an instructional method, which is considered particularly beneficial for novices, are so-called worked example videos (Kay & Edwards, 2012). Worked examples present a problem and a step-by-step solution. In mathematics, the efficiency of (text-based) worked examples has been shown in several studies (e.g., Sweller & Cooper, 1985; Renkl et al., 1998). The efficiency is not only observable in algorithmic domains but also in less-structured domains such as proving or modeling using heuristic worked examples (Reiss et al., 2008; Zöttl et al., 2010; Tropper, 2019). First indications of the effectiveness of worked example videos in an algorithmic domain are provided by the study of Kay and Edwards (2012). The question arises, to what extent videos can be used to enhance heuristic skills in mathematics as videos offer new possibilities opposed to the medium "text", such as dynamic visualization. A domain that requires heuristic skills is mathematical modeling because it involves the whole process of mapping a real-world problem to a mathematical model by structuring information, searching for data that is not given, working mathematically and translating the results back to the real world (Niss et al., 2007). The process can be demanding for students because they face many obstacles along the way (Niss et al., 2007). This is why research on teaching through heuristic worked examples to enhance modeling competencies should be continued (Renkl, 2017) and a video provides a new approach. A video can not only explain a step-by-step solution of a modeling problem but it can also establish reality references by presenting scenes from the real world. On the contrary, one main criticism regarding videos is the frequent lack of interactivity and the correspondingly low level of student activation (Brame, 2016). Hence, this paper aims at developing a framework for effective heuristic worked example videos which are interactive and student-activating. To achieve this, principles derived from the cognitive theory of multimedia learning (Mayer, 2020) are considered as well as principles from (heuristic) worked example research. Both are closely related to cognitive load theory (Sweller et al., 1998), which makes this a key component when developing the framework. Moreover, existing frameworks for creating worked example videos (Kay, 2014), educational videos (Brame, 2016) and effective science explanation videos (Kulgemeyer, 2018) are analyzed for the specific demands of developing heuristic worked example videos. The goal is to provide a framework that can be used as an orientation for teachers, educational researchers or anyone who wants to produce interactive videos addressing heuristic domains in mathematics.

Cognitive load theory

When developing a framework for heuristic worked example videos (see Figure 1), criteria for creating educational video/multimedia and (heuristic) worked examples should be taken into account. The effectiveness of both is largely explained by cognitive load theory and design criteria are aiming at minimizing cognitive load. Three different kinds of cognitive load can be distinguished: intrinsic, extraneous and germane cognitive load (Sweller et al., 1998). While intrinsic cognitive load is caused by the intrinsic nature of the material and thus cannot be reduced by the instructor, extraneous cognitive load is imposed by poorly designed material. Germane cognitive load is necessary to construct schemas and is, thereby, an important requirement for storing knowledge in long-term memory (Sweller et al., 1998). Instructors should seek to increase germane cognitive load (e.g., consider suitable cognitive activities), decrease extraneous cognitive load (e.g., avoid confusing instructions, design material carefully) while keeping in mind that each subject imposes an intrinsic cognitive load on learners.

Criteria for developing heuristic worked example videos

In the following, each category for developing heuristic worked example videos (see Figure 1) is described and explained by video/multimedia research and research on (heuristic) worked examples.

Segmentation of the video based on a solution plan

One possibility to enhance germane cognitive load is following the *segmenting principle* by splitting a video into meaningful segments with a break in between two segments (Mayer, 2020, p. 247 ff.). When presenting videos as a continuous unit, learners might have problems processing preceding steps resulting in difficulties connecting them to following steps (Mayer, 2020, p. 252). In a study conducted by Biard et al. (2018), breaks after each main segment of a video and continuing the video by manually pressing the “play-button” led to a reduction of cognitive load. This did not apply when learners could pause a continuous video at self-determined points which might be due to the fact that learners made very little use of the pause-button (Biard et al., 2018). The *segmenting principle* has also been shown as advantageous for (text-based) worked examples (“modular worked examples”) in the domain of probability problems as it resulted in less study time, more correctly solved problems, less cognitive load and a higher feeling of success (Gerjets et al., 2006). If the instructor assigns labels to subgoals and makes the sense of each solution step salient, it can help learners to encode the structure of a problem (Renkl, 2014). This is also included in Kay’s (2014) framework for creating worked example videos as “meaningful steps”. Considering the heuristic worked example literature, it is advised to display a heuristic worked example by following a solution plan (Reiss & Renkl, 2002). Solution plans have been shown as a promising method to scaffold the modeling process of students (Schukajlow et al., 2015; Beckschulte, 2020). Thus, a solution plan provides guidance on how to segment a video into meaningful steps. Furthermore, pauses in between two steps offer the opportunity to prompt for self-explanations (see below).

Implementation of self-explanation prompts

When teaching mathematics, self-explanation prompts can help students build up procedural knowledge, conceptual knowledge and procedural transfer (Rittle-Johnson et al., 2017). Writing an explanation after each section of a video is considered as a *generative activity* and enhanced learning from video (especially for low-knowledge learners) (Mayer et al., 2020). This technique has been superior to rewatching the video or generating a drawing (Fiorella et al., 2020). Other options for prompting during videos are having the learners compare the content observed to prior knowledge or other material (Chi & Wylie, 2014). This corresponds to the *self-explanation and comparison principle* in worked example research (Renkl, 2014). In the case of novices or learners being unable to produce self-explanations, instructors should offer scaffolds such as structuring self-explanation responses (Renkl, 2017; Rittle-Johnson et al., 2017). When implemented into heuristic worked examples in modeling, principle-based prompts helped students elaborate the underlying procedures of an example (Tropper, 2019, p. 235).

Category	Indication from video and multimedia research	Indication from (heuristic) worked example research
Segmentation	segmenting principle (Mayer, 2020) meaningful steps (Kay, 2014)	usage of modular examples (Gerjets et al., 2006) following a solution plan (Reiss & Renkl, 2002)
Self-explanation prompts	generative activity principle (Fiorella et al., 2020; Mayer et al., 2020)	self-explanation and comparison principle (Renkl, 2014, 2017) elaboration of underlying procedures (Tropper, 2019)
Larger concept	follow-up learning tasks (Kulgemeyer, 2018) larger homework assignment (Brame, 2016)	example-set principle (Renkl, 2014) fade worked steps (Renkl, 2017)
Heuristic strategies	clear problem label (Kay, 2014) explain key elements (Kay, 2014)	make used heuristics explicit (Reiss & Renkl, 2002)
Layout decisions	weeding (Ibrahim et al., 2012) / seductive details principle (Mayer et al., 2020) / length shorter than 6 minutes (Guo et al., 2014) dynamic drawing principle (Mayer et al., 2020) / video style: preferably showing instructor's hand (Mayer et al., 2020) signaling (Brame, 2016) / highlighting, write down key information (Kay, 2014) / signaling principle (Mayer, 2020) match modality (Brame, 2016) / modality principle (Mayer, 2020) / use visuals (Kay, 2014)	
Conversational language	conversational language (Brame, 2016) / direct addressing (Kulgemeyer, 2018) / personalization principle (Mayer, 2020) engaging voice (Kay, 2014) / voice principle (Mayer, 2020) pace: 185-254 word per minute (Guo et al., 2014)	

Figure 1: Framework for developing heuristic worked example videos

Integration of the video into a larger concept

Rather than presenting standalone videos, videos should be integrated into a larger learning concept. Especially when learning complex skills, presenting only one (video) example might not be sufficient. Brame (2016) suggests to embed videos into a larger homework assignment. Moreover, Kulgemeyer (2018) recommends supplying learners with follow-up learning tasks, so that they have an opportunity to use the explained information for problem-solving. Considering worked example research, there may be limitations when presenting example-problem pairs, as they do not necessarily lead to a greater learning outcome than presenting worked examples only (van Gog et al., 2011). The *interleaving by fading principle* (Renkl, 2014) suggests to rather design a fading procedure with a complete example presented first before gradually fading solution steps. Atkinson et al. (2003) found that this is especially fruitful when combined with self-explanation prompts as it fostered near- and far-transfer performance in the domain of probability calculation. The integration of the video into a larger concept does not only suggest to fade worked steps and to integrate self-explanation prompts on the level of the video, but also implies different usage scenarios: Students could watch a heuristic worked example video at home in order to initiate in-class (group-)work. Moreover, a heuristic worked example video with its integrated prompts and faded worked steps could be used to support group work in class by stimulating discussion and structuring the solution process.

Explication of heuristic strategies

When solving problems, experts in mathematics usually employ heuristic strategies (Collins et al., 1987, p. 12). In order to present an approach to solve a problem, a video should at first clearly label the problem addressed (Kay, 2014). Subsequently, structuring the video on the basis of a solution plan not only offers guidance for the video segmentation as described above, but it can also be used to depict an experts' approach by outlining applied heuristics explicitly along the way (Reiss & Renkl, 2002). This opens up the possibility of explaining key elements in a way that learners understand the problem structure and the essential elements required to solve the problem (Kay, 2014). Transferred to a video aiming at the enhancement of students' modeling competencies, explaining key elements could involve visually displaying how to search for a comparison value. Depending on the example demonstrated, many other modeling-specific heuristic strategies are imaginable. Presenting those in a video compared to explaining them in a text-based heuristic worked example might be promising because a video supports the modality principle as described below.

Minimizing cognitive load through layout decisions

The underlying principle of the following design recommendations is the reduction of extraneous cognitive load through layout decisions. Since the medium "video" largely differs in the layout possibilities from the medium "text", the criteria are solely based on video/multimedia research. A video containing additional interesting but irrelevant features might increase the precepted learning difficulty and decrease the focus on essential content of the video (Ibrahim et al., 2012). This is called the *seductive details principle* (Mayer et al., 2020) and *weeding* (Ibrahim et al., 2012) describes the process of excluding interesting but irrelevant word or graphics from a video. *Weeding* might also help reducing the length of a video, which has been shown to be an important factor considering student engagement (Guo et al., 2014). Based on the analysis of 6.9 million MOOC videos, Guo et al. (2014) advise that video chunks should not exceed 6 minutes. A video dealing with a complex example probably outranges this recommendation. Nevertheless, it provides orientation when planning the video segmentation as described above, arranging less than six-minute-long segments. Another design feature which should be considered is the display style of the video. Different kinds of videos such as voice-over slide presentations, drawing on a paper and filming from above or drawing on a digital tablet are possible. Mayer et al. (2020) outline that learning outcome increases when an instructor draws graphics on a board rather than adding a voice-over to already drawn graphics (*dynamic drawing principle*), with the instructor's hand visible being an important factor. However, a video containing dynamic drawing without the hand visible still outrated the voice-over to the same already drawn graphics (Fiorella et al., 2019). Altogether, the decision of the video style might be significantly influenced by the content and task presented. When presenting a modeling task through a video including realistic film scenes, the video material may become an essential part to solve the task, if information can only be retrieved from the video (Greefrath & Vos, 2021). In this case, a video including drawings on a digital tablet might be a suitable format. Frames can be used to highlight important information even though the dynamic drawing principle might not unfold its complete potential. Nevertheless, it still offers possibilities for signaling through color codes or arrows. This is seen as an important feature in videos (Brame, 2016; Kay, 2014) explained by the *signaling principle* (Mayer, 2020, p. 166 ff.) because signals provide guidance for learners' attention. Finally, this style allows to address both the audio and visual channel, taking advantage of the *modality principle* (Mayer, 2020, p. 281 ff.), which states that people learn better from pictures and spoken word than from pictures and printed words.

Usage of conversational and engaging language

Other than a text, a video usually relies on visuals and narrated words. This means that the language can have an impact on learning. In videos, a conversational language is preferred over a formal language (Brame, 2016) and using direct addressing is preferred over a passive voice (Kulgemeyer, 2018). The underlying principle is called the *personalization principle* (Mayer, 2020, p. 305 ff.) and its efficiency is explained by learners trying harder to understand the content when the feeling arises that the instructor is talking to them. This is the same reason why speaking in an appealing human voice fosters learning (*voice principle*) (Mayer, 2020, p. 322 ff.) and is considered as an important component of worked example videos (Kay, 2014). It might also be essential to speak relatively quickly (Brame, 2016), with 185-254 words per minute recommended (Guo et al., 2014).

Discussion

The developed framework offers theoretical considerations about how to support student learning from heuristic worked example videos in the domain of modeling by considering the impact of design features on cognitive load.

Even though a comprehensive review of educational video design criteria was conducted and principles of generative learning were taken into account, the criticism that videos frequently lack interactivity cannot be denied completely. The approach of (heuristic) worked examples more or less implies direct instruction. This tension cannot – and should not – be completely resolved in the case of heuristic worked example videos. Providing learners with solution steps is one (if not the) key component of (heuristic) worked examples. It results in a possible limitation of the proposed framework though: Videos based on this framework are probably more suitable for novice learners and may not be a promising approach for advanced learners. The fact that knowledgeable learners might profit more from a minimal instructional approach has been reported as the *expertise reversal effect* in worked example research (for an overview, see Kalyuga (2007)).

Since this theoretical framework has not been tested yet, the next step should be to put it into practice by developing videos based on this approach. Observing students' behavior while working with those videos can allow drawing conclusions about which categories achieve the desired impact. Moreover, the usage of heuristic strategies while working with the videos (especially with the self-explanation prompts and the faded solution steps) should be examined in order to understand to what extent videos can be used to enhance modeling competencies. This may contribute to the proposed further research on worked examples in the domain of modeling (Renkl, 2017) and to the little research done on worked example videos in mathematics (Kay & Edwards, 2012). It is also conceivable to use this framework to produce videos that target other heuristic domains such as problem solving or proving. For this purpose, an adapted solution plan can be used and problem solving or proving strategies can be made explicit analogously to the modeling-specific strategies.

Starting from previous lines of thought

Theories are essential parts of each scientific discipline; they can be used to solve problems, to answer research questions, to capture phenomena, to predict what can be expected or prescribe what can be done in practice (Prediger, 2019). However, in the field of mathematics education, there is no consensus of the notion of 'theory' (Assude et al., 2008). What is agreed upon in most communities in our field is that theories are "… individual or social constructions which serve to understand and describe a part of reality in a consistent manner" (see. Maier & Beck, 2001, p. 45, own translation). They provide a language and a lens "…. to understand what are taken to be the things that can be questioned and what counts as an answer to that questioning.'' (Mason & Waywood, 1996, p. 1056). Theories afford the coherence of a research framework and provide the space for consistent argumentation. As Bishop (1992) summarizes, a theory "is the way in which we represent the knowledge and understanding that comes from any particular research study. Theory is the essential product of the research activities, and theorizing, therefore, its essential goal." (p. 711)

Radford (2008, 2012) has conceptualized theory as a way of understanding based on a collection of principles (P), methods connected to those principles (M), and paradigmatic research questions (Q). When researchers draw on a theory for research to produce results (R), those results can contribute to further theory development. Hence theories are dynamic, rather than static, and they continue to evolve via researchers' engagement with them.

Previous TWG17s have addressed the question of how researchers and designers work with theories in the field of mathematics education (Kidron et al., 2018), taking tasks and tools into consideration. Two key, interrelated issues have been (1) how to grasp the complexity of teaching and learning of mathematics and (2) how to deal with the diversity of theories in the field. Working with theories is embedded in the culture of educational systems, and we witness a broad diversity of educational systems worldwide. Accordingly, our working group acknowledges diversity of theories as a kind of richness in mathematics education, through which learning from and with each other provides the potential of advancing the field of mathematics education as a whole.

Coherence of a research framework and consistency of argumentation are guiding principles in the use of theories. This allows researchers to advance knowledge, which may be relevant even beyond mathematics education contexts. In its final discussion at CERME11, the TWG17 has agreed upon the dynamic, evolving nature of theories in research, as Bikner-Ahsbahs et al. (2019) summarize:

> … scholars should neither demand that theories be used with absolute rigor nor allow arbitrarily applications of theory. To form coherent research frameworks, scholars engage in reconsidering, reinterpreting and reusing theories to investigate new phenomena, solve new problems and serve new purposes. Thus, theories develop and evolve through research. Working on coherence and consistency is an ongoing research task, particularly necessary for the Networking of Theories, in which reconsidering the compatibility of the theories or theoretical approaches is an additional epistemological necessity. Achieving generativity, generalizability, and generality affords the potential of the research results to be useful for answering new questions. (p. 3026)

The networking of theories approach (Bikner-Ahsbahs & Prediger, 2014) has been intensively discussed in previous TWG17s (Kidron et al., 2018). It has supported researchers' navigation of a variety of epistemological stances that may underlie the different theories involved in research and their exploration of how various theories can be used to investigate complex situations of teaching and learning. Yet, further elaboration of the networking of theories is needed to expand its research potential. A landscape of networking strategies has proven fruitful for guiding such efforts (Prediger et al., 2008). Specifically, the networking strategies of coordinating and locally integrating theoretical approaches have led to advancing our knowledge (Bikner-Ahsbahs & Prediger, 2014).

The TWG17 of CERME 11 identified the important role of certain sensitivities in theoretical work (e.g., the theory's ecology, its grain size, the nature of the mathematical content it considers, the research objects, etc.), and distinguished between generalizability, generality, and generativity in research methodologies: generalizability in empirical, generality in theoretical and generativity in design research. Chan and Clarke (2019) elaborated how our choices in research are based on mutual affordances between these theoretical sensitivities and the methodologies and methods to be used. Thus, researchers should be aware that theoretical, methodological, and methodical work are intermingled and related to the cultural context in which research is conducted.

Issues addressed in the call: connection to previous TWG17s

Design research has been prevalent in discussions of previous TWG17s. This pointed to various ways that researchers' decision-making could influence their theoretical approaches, specifically with respect to transforming versus depicting in mathematics education research processes. In this TWG17, we addressed this distinction by asking for contributions on theories related to design research, technology use and conditions for a productive dialogue between theorists.

What has been implicit in previous TWG17s were basic commitments underlying theoretical work. For this TWG17 we called for more explicit discussion of ethical commitments in theorizing and theory networking. We also called for attention to ontological, epistemological and axiological presumptions of theories. Adapted from Patterson and Williams (1998), Daene (2018, n.p.) distinguished and described four such commitments. These were “the nature of reality and what really exists (ontology); the relationship between the knower and what is known (epistemology), what we value and how we determine that value (axiology), the strategy and justifications in constructing a specific type of knowledge (methodology), as linked to individual techniques (method/s).” In theories on teaching and learning we–sometimes implicitly–could make ontological assumptions about the piece of reality addressed (e.g., whether teaching-learning is an irreducible entity or consists of two different processes). In epistemology we could build on this assumption to ask how we can know something about the ontological entity and how this knowledge must be so designed. In methodology we could address the question of how knowledge can be produced (and by what means). Ethics, being part of axiology, could enable us “to rethink and re-evaluate some of the taken-for-granted commonplaces of our practices” (Ernest, 2012, as cited in Stinson, 2017, p. 2), “which opens up new possibilities for theorizing and researching mathematics teaching and learning.” (Stinson, 2017, p. 2)

Main contributions achieved

Fifteen papers and four posters were presented in this working group. In sum, 52 authors from 17 countries worldwide were involved. This indicated that doing research happens in communities rather than individually. Fifteen out of 19 contributions followed a networking of theories approach, indicating that networking of theories is being normalized in research although it still needs to be further developed. Design research became more prominent, with many papers involving this approach. In line with previous TWG17s many theory elements were addressed. There were 22 theories and 27 theoretical concepts or ideas addressed across the contributions. The awareness of our own achievements in our home field of mathematics education seemed to be growing. This was not so obvious in the papers but more so in our ways of talking about theories. Scholars became more often named as originators of the theories together with the theories, for example when talking about Duval’s cognitive theory of representation or Schoenfeld’s Resources-Orientations-Goals theory.

A key outcome of our discussion is a new characterization of theorizing, in terms of two dimensions: *horizontal* and *vertical* theorizing, which we illustrate in Figure 1. Horizontal theorizing happens when researchers draw on a theory (or theories) to make sense of problems or phenomena. With horizontal theorizing, researchers focus on the *how* of theory use, for the purpose of illuminating new aspects of complex phenomena. For example, researchers may network different theories to further the investigation of empirical phenomena, such as students’ reasoning in engineering education. In contrast, vertical theorizing happens in the semiosphere, the cultural semiotic space of theory cultures (Radford, 2008; Lotman, 1990). With vertical theorizing, researchers focus on meta-issues of theory use for the purpose of *understanding theories as entities in and of themselves.* For example, researchers may weigh the epistemological ramifications of networking different theories, and argue for the viability of doing so. Researchers’ theorizing may address horizontal or vertical theorizing, or both. As suggested by our examples, the networking of theories entails both. The rule of *keeping our feet on the empirical ground* (Figure 1) takes seriously the purpose of a theory to act as a tool for understanding the empirical world. It means that vertical theorizing can only increase our understanding of theories when it is grounded in horizontal theorizing.

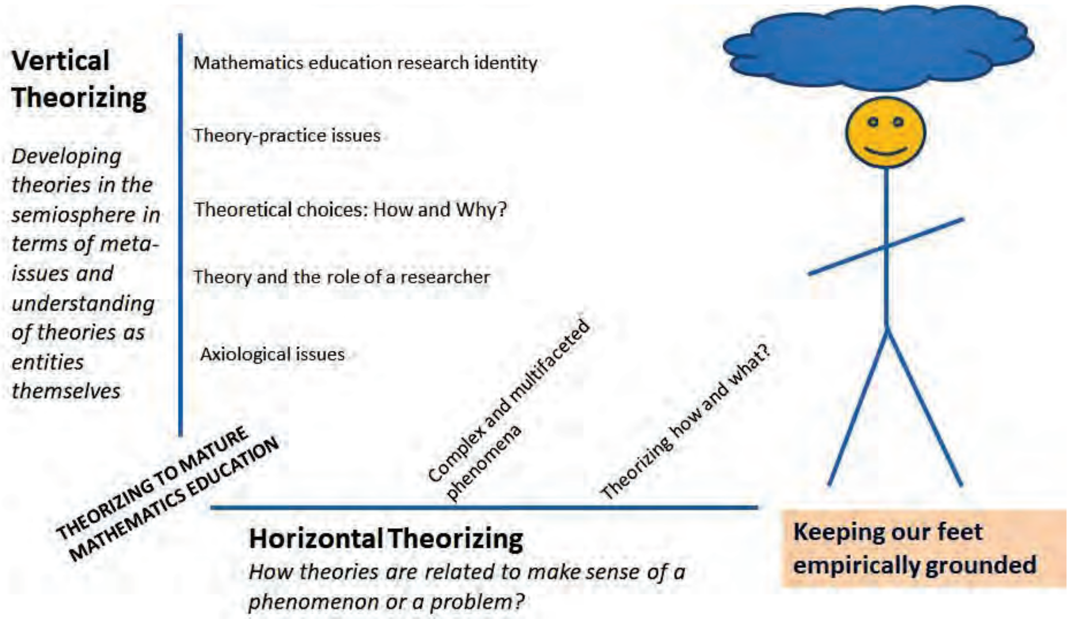

Figure 1: two dimensions of theorizing

Contributions of horizontal theorizing

Some papers addressed complex and multifaceted phenomena as a unity, a balance or tension between theoretical parts. Fosse et al. used Cultural Historical Activity Theory (CHAT) to investigate expansive learning when students crossed institutional cultures in their career. They explored masters students' transitions from university to school to identify if contradictions spark their learning and how and what teacher educators can learn from it for their own teaching. Herbst et al. proposed to use networking of theories to investigate teacher decision making and the role of structure and agency in these processes. Kuzniak and Nechache presented the Mathematical Working Space as a framework to be linked with other theories (e.g., Abstraction in Context) to describe how cognitive actions start from the epistemological level and how it develops with respect to semiotic, discursive and instrumental genesis. They posited that actions may link mathematical work with other theories.

Several contributions theorized the use of artifacts or tools and considered their role for progressing. Shvarts et al. analysed Freudenthal's and Davydov's work disclosing their common understanding of mathematical perception in learning to advance the embodied design framework. Starting with concrete actions, *ascending from the abstract to the concrete* entailed viewing the concrete in a completely new way through the lens of acquired artifacts. Thus, one's perception of the concrete would change as learning proceeds. Salinas-Hernandez et al. linked a cultural-historical approach with a semiotic view. They explored the "Imaging Teaching Scheme" of a physics teacher who used various artifact representations for the production of signs to guide learning. Santi et al. networked the theory of objectification with a differentiation approach for design research. Open Activity Theory Lesson Plan is an artifact they developed to guide designing stations to foster inclusive instruction by processes of objectification and subjectification of all learners. Kanwal networked a CHAT frame with the concept of creative and imitative reasoning to investigate teaching mathematics in engineering education at university. Computer software provided the artifact that shaped the conditions for the students' operating that constrained their reasoning actions.

In some contributions, horizontal theorizing pursued specific purposes. This way, researchers could clarify why networking was needed and helpful. Bach et al. networked Duval's (2017) cognitive theory of representation and the Instrumental Approach in a design research approach for learning functions to foster the representation competency defined in the Danish KOM framework. In their paper, they showed how the networking strategy of coordinating helped them to structure developing design principles. Petersen networked concept image and concept definition also with the cognitive theory of representation to enlighten mathematical thinking related to the KOM framework with a focus on differentiability. Kanwal's theoretical approach allowed for the consideration of students within the activity system as a wider entity. Researchers also could use theories to make new aspects visible. Tuktamyshov offered a "picture of the world." Mali et al. drew on the concept of "perezhivanie" to expose learners' life-changing experiences, and Zagorianakos linked perezhivanie with phenomenology to explore what this might add to previous insights.

Another purpose of horizontal theorizing was to take up and explore new challenges. Bikner-Ahsbahs et al. met the challenge of the pandemic and shifted the summer school YESS10 to an online conference format. This new situation allowed them to conceptualize the rhythmic orchestration of the research pentagon (Bikner-Ahsbahs, 2019). Gardesten coordinated the Knowledge Quartet and the Pedagogical Relational Teachership to build a methodological tool to explore teachers' pedagogical content knowledge and relational abilities when teaching mathematics in inclusive settings. Barquero et al. identified points of contact between the Antropological Theory of the Didactic and the Theory of Didactic Situations to explore constraints of a new paradigm of instruction, the Study and Research Path.

Contributions to vertical theorizing

Vertical theorizing can happen in many ways. Lensing has provided an example of vertical theorizing as he looked at the three essential systems in mathematics education, the social, the individual and the body, and the problem of the impossibility to theorize them jointly. His solution of this complexity problem was to look at regularities the systems share and, thus, build theories on a more formal level. Other ways of vertical theorizing ask for how we understand and practice theorizing, and what kind of ethical, ontological, epistemological, and methodological commitments are present in theorizing. Critical for the ethical dimension are the aspects to which a theory attends while leaving others left aside, which means that some aspects are valued over others. For example, the theory of objectification (TO) addresses the dialectic between objectification and subjectification in teaching and learning mediated by tools (Radford, 2021), but it does not tell Santi et al. how to differentiate tasks for an inclusive setting. Thus, differentiation is invisible in the TO. Santi et al.'s networking theories approach is a way to display differentiation and simultaneously adhering to the TO.

To date it is not so clear what, specifically, theorizing entails when the aim is not to apply a theory to an empirical situation but rather to create new theoretical steps. Valdés-Zorrilla et al. have proposed to consider theorizing as a kind of *metaphorizing*, starting from the source domain of a metaphor to theorize the target domain with the help of the metaphor. In such a process, the role of the researcher as a user, borrower, adaptor, developer, or creator of theories comes into play. This necessitates being explicit about how, why, and for what theoretical steps are made. In this context, two purposes of theory use become relevant: using a theory to depict versus using a theory to transform a teaching-learning situation. The former requires quite different kinds of reasoning than the latter. This has consequences for methodological choices as Chan and Clarke (2019) have pointed out. They have explored the reciprocity of theory and methodology showing the mutual affordance between theoretical and methodical choices. It requires vertical theorizing to describe particularities of how mutual affordance is involved in research. Following this path of vertical theorizing, Johnson et al. have elaborated what mutual affordance might mean for the networking of theories. They have proposed to use the metaphor of a multifocal lens to guide mutual affordances between theory networking and methodical choices.

Vertical theorizing is also present in the researchers' sensitivity to decide how, why, and for what purpose a theoretical step is needed and where to start with theoretical choices. Researchers are not free in their choices, as these are constrained by theory traditions. Theory development is only possible within certain limitations of a theory culture. When a transformative step goes beyond the realm of the theory culture, it can create epistemological obstacles. However, some theories such as CHAT may inform quite different research directions. Fosse et al. offer contradiction as a starting point to explore expansive learning. Kanwal also draws on CHAT to relate students' reasoning to the software the students used and to embed both into a wider activity system. When a new challenge such as the pandemic situation emerges, it may constrain research. However, it also may provide opportunities to see calls for new theorizing steps, such as Bikner-Ahsbahs et al.'s description of rhythm to extend the concept of instrumental orchestration.

Vertical theorizing also may address the relation between theory and practice and contribute to shape a disciplinary identity. In the practice of research, a theory needs an appropriate methodology to be put to work and lead to relevant insights. However, theory and methodology do not transform teaching and learning by itself. The practice of teaching and learning can be transformed by design research, which may in turn also transform research and gain new insights for theories. Design research may even be considered a research genre that is specific for mathematics education, thus contributing to form a mathematics education research identity. This can allow researchers to line up and navigate the power-filled landscape of disciplines and institutions. Theoretical work, including further developing the networking of theories approach and design-based research, may help the field of mathematics education to become aware of its strengths and of what it has to offer to other disciplines. In turn, this can strengthen mathematics education's status as a research discipline.

Lessons learned and future directions

Did we proceed with respect to consider the dimensions of ontology, epistemology, and axiology in processes of theorizing more explicitly? Three contributions point to progress in this area. Gardesten and Santi et al. are aiming at establishing inclusive mathematics education research. The dimension of ethics, and hence, axiology, is very explicit in their contributions. Santi et al. appeal to Radford's (2021) theory of objectification (TO) to position students and teachers as "reflective and ethical subjects" who engage in "joint labour" to develop new knowledge. In the analysis of Shvarts et al., we may consider the relationship between the works from Freudenthal and Davydov as being based on the common epistemological assumption that abstraction leads to a new vision of reality.

Ontologically, this means that reality is structured in a new way when it is perceived through using a mathematical artifact. In future TWG17s, there needs to be continued and more explicit attention to ontological, epistemological and axiological dimensions grounding our research.

The distinction between horizontal and vertical theorizing is an insightful step this TWG17 has made because it accredits us as researchers with the sensitivity of what theorizing means and in what kind of theorizing we are involved. Horizontal theorizing on concrete phenomena or problems is a necessary step in research, and we also need to strengthen our practice of vertical theorizing in order to be able to clarify basic assumptions in our research. Through vertical theorizing we can decide whether and how networking of theories is a consistent approach to reveal a coherent body of results. Whereas the objects of horizontal theorizing are phenomena in mathematics education, the objects of vertical theorizing are the theories or theory elements themselves (i.e., abstract entities in the semiosphere). Vertical theorizing is therefore more difficult to communicate, much more difficult than communicating how theories frame our research. Reflecting on concrete work may strengthen our theoretical understanding of a piece of reality allowing us to advance vertical theorizing.

Networking practices in design research: refining design principles

Cecilie Carlsen Bach[1], Rikke Maagaard Gregersen[2], Mathilde Kjær Pedersen[3] and Uffe Thomas Jankvist[4]

Danish School of Education, Aarhus University, Denmark; [1]ccb@edu.au.dk, [2]rmg@edu.au.dk, [3]mkp@edu.au.dk and [4]utj@edu.au.dk

In a design research (DR) study concerning how students exercise their representation competency when using digital tools, we aim to investigate the potential of networking practices to support the purpose of developing theoretically grounded design principles in DR. We provide and discuss an empirical example of how design principles for students' activation of representation competency, when using GeoGebra, are adjusted through retrospective analysis in DR. We further show how such analyses may be structured through the coordinating strategy of networking of theories.

Keywords: Design research, networking of theories, predictive theory elements, design principles.

Introduction

DR aims to develop both theory and practice in an intertwined manner. An important part of DR is to develop principles for designing tasks through careful analyses using theoretical perspectives (Prediger, 2019). However, the development of theory only appears to a limited extent in some DR studies (diSessa & Cobb, 2004). Networking of theories offers strategies for understanding and relating theoretical constructs, while at the same time aiming to connect the many unrelated theoretical perspectives in mathematics education (Prediger et al., 2008). In this paper, we aim to investigate how practices from networking of theories may strengthen theory development in DR. To achieve this, we use an illustrative case involving task design aiming to exercise students' mathematical representation competency when using digital tools, such as dynamic geometry environments (DGE)). The Danish competency framework (KOM) defines eight competencies, among them is the *representation competency*, which involves the capability to make use of, reflectively choose, interpret, translate between mathematical representations and understanding the scope, limitations, and strengths of representations being used (Niss & Højgaard, 2019). For instance, students exercise representation competency when choosing the most appropriate representation for given phenomena or understanding relations between representations (e.g., graphs and equations). KOM does not address the use of digital tools at large, why coordination of two fine-grained theoretical perspectives is relevant. For the use of digital tools, we apply the instrumental approach (e.g., Trouche, 2005), and for further insight on the mathematical representations, we utilise Duval's (2017) perspectives on semiotic registers. Our research question is *Applying practices from networking of theories, how may design principles about students' exercise of representation competency when using digital tools be refined*? We present our DR process focusing on humble design elements. Then, we present perspectives on networking of theories and our theoretical perspectives, followed by our illustrative case of which we carry out parallel analyses conducted to define our design principles for exercising representation competency while using digital tools based on the humble design elements. Finally, we refine the design principles using a networked analysis in a discussion and networking practices in DR.

Design research and importance of design principles for task design

DR includes different phases: 1) *preparation of design*, involving the development of design principles; 2) *testing design* by gathering data in classrooms; and 3) *retrospective analyses*, which serve to analyse the design and refine the design principles (diSessa & Cobb, 2004). Theorising exits in all steps of DR. Different theory elements in DR may be characterised as categorical, normative, explanatory, descriptive and predictive theory elements. In particular, *predictive theory elements* are key for this paper, as it involves the development of *design principles* (Prediger, 2019). Design principles may have the following structure:

> If you want to design intervention X [for the purpose/function Y in context Z], then you are best advised to give that intervention the characteristics A, B, and C […], and to do that via procedures K, L, and M […], because of arguments P, Q, and R (van den Akker, 1999, p. 9)

Based on a previous literature review (Pedersen et al., 2021), involving the representation competency of KOM (Niss & Højgaard, 2019) and the perspective of semiotic registers (Duval, 2017), we present the *humble predictive heuristics*, meaning the design principles that have not yet been tested. The review revealed that students could engage in processes of dealing with different representations and their reciprocal relations in a multi-representational digital tool. Yet, there is a risk that the digital tools outsource essential aspects of mathematical activities by automatically generating translations between representations. As part of the literature review, we proposed five recommendations for task design aiming to have students exercise their representation competency in interplay with digital tools (Pedersen et al., 2021). Three out of the five recommendations are relevant for this study. According to van den Akker's (1999) definition, we regard them as *humble design characteristics* (HDC):

- HDC 1. Including the linguistic register by formulating the task in natural language and asking for answers in natural language.
- HDC 2. Breaking objects and windows of the tool into smaller units by introducing them gradually.
- HDC 3. Using sliders, dragging and tracing for explorations of different representation and representation forms' reciprocal relations.

Networking of theories and presentation of selected theoretical perspectives

Networking of theories provides strategies for connecting theories at different levels: From 'understanding others'/'making understandable' to 'integrating locally'/'synthesising'. We focus on the strategies 'combining' and 'coordinating', both focus on understanding an empirical phenomenon. Often, more than one theory is necessary to understand an empirical problem. When 'coordinating', the involved theories must be *compatible*, meaning that their *background theories outside mathematics education* (Bach et al., 2021) are not in conflict (Prediger et al., 2008).

We aim to network theoretical perspectives to understand the interplay of students' representation competency and their use of digital tools, which are compatible with KOM. KOM plays the role of what Bach et al. (2021) term as a 'framing theory', meaning a background theory inside mathematics education research. Although, it may rather be a framing framework. KOM is of a cognitive nature focussing on an individual's expression of cognition in particular mathematical situations (Niss &

Højgaard, 2019). Semiotic registers and the Instrumental Approach are in line with KOM as both address cognition. As the theoretical perspectives look at different objects and phenomena (mathematical representations and use of digital tools, respectively), they may complement each other. Hence, their backgrounds appear not to conflict indicating that 'coordination' may be possible.

Transformations between semiotic representations are essential in mathematical activity. In their nature, mathematical objects and processes are abstract and only accessible and transformable through their representations. Consequently, the process of mathematical activity involves transforming representations within or between registers. Four registers are distinguished depending on if a register is multi- or monofunctional and discursive or non-discursive (Duval, 2017). Discursive registers (the *symbolic* and the *linguistic* registers, named as such in Pedersen et al., 2021) involve written and spoken languages expressing meaning units of thoughts. Non-discursive registers (the *graphic* and the *figurative* register named as such in Pedersen et al., 2021), only display one (or more) static, visual object(s). Mono-functional registers (the *sy*mbolic and the *graphic* registers) involve algorithmic processes. Multifunctional registers (the *linguistic* and the *figurative* registers) then involve non-algorithmic processes, such as communication and imagination. Each register may contain more representation systems with their own rules. A transformation between representations within the same register is called *treatment.* A transformation between representations from one register to another is called *conversion* (Duval, 2017).

The instrumental approach to mathematics education concerns the cognitive process of turning an artefact (e.g., a ruler, calculator, or dragging in GeoGebra) into an instrument for the activity of solving any kind of task. When distinguishing between artefact and instrument, it is inherent that the artefact in itself is just a material object, and only becomes an instrument when an individual can appropriate parts of the artefact for a certain task. This process is called *instrumental genesis* and is developed over time and shaped through the two-way processes of instrumentation and instrumentalisation. *Instrumentation* is directed from the artefact towards a user, as its constraints and possibilities shape how an individual uses the artefact. Instrumentation can go from a phase of exploiting different possibilities of using the artefact to solve the task relying on prior knowledge to a more stable phase, where the same usage is applied for similar tasks (Trouche, 2005). *Instrumentalisation* is directed from the user towards the artefact, as the user uses and manipulates the artefact (based on the user's knowledge), which can be different from the original intent of the designer of the artefact and can both lead to enrichment of an artefact, or its impoverishment. Within this two-way process of instrumental genesis, an instrument involves an artefact (a material thing) and schemes concerning the mathematical content and its relation to the use of the artefact (Trouche, 2005).

Presentation of the case: Ivy and Aya

The data excerpt and task presented in this paper were chosen because the task represents humble design characteristics. The task (inspired by Johnson & McClintock, 2018) was originally developed to activate the communication competency, which often also involves one or more mathematical representations (Niss & Højgaard, 2019). The task relates different representations and different mathematical contents (geometry and functions) in a GeoGebra template. Further, in this paper, we relate the task to the representation competency. In the graphic view (i.e., the graphic environment in GeoGebra), a rectangle is constructed to the left of a coordinate system (first quadrant) with a point *P*. Point *A* of the rectangle can only be dragged vertically, such that the height changes and point *B* and C are fixed. Point P's *x*-coordinate corresponds to the rectangle's height and the *y*-coordinate to the area of the rectangle. When dragging point *A*, point *P* moves on the line $y=3x$. Unintentionally in the task design, it is also possible to drag point D on the rectangle horizontally. When dragging point *D*, point *P* moves on the vertical line, $x=|AB|$. The algebra view is also accessible in the template. The task and the transcript are translated from Danish. The task has four phases: 1) Investigate the rectangle and features related to it without dragging; 2) investigate the relationship between the rectangle and point *P* by dragging point *A*; 3) fill a table for related values; and 4) represent the functional relationship (to be $y=3x$), by its formula and a graph. The following excerpt presents two students' dialogue about the relationship between point *P* and the rectangle in phase 2, see Figure 1.

Investigate the construction on your computers by dragging point A in the figure. Describe the relationship between point P and the shown figure. For point P, describe what characterises the x-coordinate and the y-coordinate. Explain why the relationship exists.	
Figure 1: Task and illustration of the template with traces (Johnson & McClintock, 2018)

Before discussing the task, the students investigated the template individually. Prior to this excerpt, the students explored the dragging possibilities, e.g., dragging points *A* and *D*. Dragging point *D* was neither intended nor part of the task description. The students began to discuss, dragging point *A*:

1	Ivy	The area moves *P*. Okay, the area moves *P* up.
2	Aya	No, it is not the area. You mean the width.
3	Ivy	Yes, but the width changes the area
4	Aya	So does the height…
5	Ivy	Yes, yes.
6	Aya	But both factors move the area
7	Ivy	No, but, no… Try to see… try to see. If you move this one here, it changes both the area and the height, then it [point *P*.] moves askew. [Ivy drags point *D* back and forth, slowly. The figure is no longer a rectangle.].
8	Aya	Yes, yes, but Ivy… I know that both elements depend on the area. The area is the height times the width.
		[...]
9	Aya	What have you written?
10	Ivy	I have written that if you change the rectangle's height to 0, the intersection *P* ends at (0,0). I think that the intersection is determined by the rectangle's height and area. The area moves *P* up, up by the *y*-axis, and the height moves it by the *x*-axis. When you change the height, you also change the area and *P* therefore moves askew away from (0,0).

Line 10 shows that Ivy concludes on the relationship when dragging point *A* (not *D*), as point *P* moves "askew" and not vertically.

Analyses of the case

To ‘coordinate’, we analyse data in parallel, meaning that we analyse using (1) semiotic registers (Duval, 2017), and (2) the instrumental approach (Trouche, 2005). Then, we ‘coordinate’ the analyses (Prediger et al., 2008). We have regarded the students’ meanings and productions as collective, hence, considering them as a pair rather than individuals.

Analysis through semiotic representations: Ivy and Aya orally discuss the relationship between point *P* and the rectangle. First, they characterise what defines the area, that is the width (line 3) and the height (line 4). Secondly, Ivy drags point *D*, performing treatments on the quadrilateral, while the students do conversions between height and area of the rectangle to point *P* (line 7). Thirdly, they connect the height with *P*’s *x*-coordinate and the area with *P*’s *y*-coordinate, which is specified at the end (line 10). Finally, the students use the word “intersection” in their natural languages in line 10 in connection with point *P*. It is unclear how the students interpret/understand “intersection”, but it appears to stem from the description of point *P* in the algebra view. Possibly, they use it as a description of point *P* as they say “the intersection *P*”, meaning where the height of *AB* and the area intersect.

Analysis through instrumental genesis: Prior to the excerpt and at the beginning of the transcript (lines 1–6), both Ivy and Aya explore the GeoGebra template using their previous knowledge of rectangles. As they drag point *D*, point *P* does not follow the intended line (line 7). The possibility of dragging point *D* is a constraint of the task related to the process of instrumental genesis, particularly for the instrumentation process, when the students explore the tool. This is reflected in their actions (see line 7). As part of their instrumentalisation, they use GeoGebra for what they believe was the intention of the task and realise (see line 10) that they should drag point *A*, which is the intent of the task. The term “intersection” appears in the algebra view, and may consequently be regarded as a constraint of the tool: it leads the students to use a term that stems from the tool but is inappropriate in the given situation. This may even lead to an incorrect understanding of point *P*. To use dragging as an instrument for this particular situation, Ivy and Aya should be able to find the relation between the rectangle and point P while dragging. Hence, the instrument of dragging for Ivy and Aya is developed for answering the task and the instrument relates both dragging (i.e., the artefact) and schemes relate the content of linear functions and geometrical knowledge on rectangles with the specific actions of dragging.

Summary of analyses: ‘Coordinated’ analysis of Ivy and Aya working with the task

When Ivy and Aya explored the template using prior knowledge on rectangles (lines 1-6), it involved understanding and making conversions between and treatments within the involved registers (i.e., the linguistic, the graphical and the figurative) by relating and expressing what defines the area. Dragging point *D* created constant treatments of ‘rectangle’ *DABC* to be a quadrilateral. For the instrumentation, dragging point *D* (line 7) provided the impression of changing the relationship since point P then moved on a vertical line, and for the instrumentalisation process, dragging point *D* was not in line with the intentions of the task. It was necessary for the evolution of the instrumentation and instrumentalisation processes that the students understood the constraint of dragging point *D* indicating another relationship than the intended one. Ivy and Aya did not continue with the attempt to investigate the conversions between point *P* and the area of the rectangle by dragging point *D*. Thus, for dragging to be an instrument, the students develop schemes that relate treatments within the individual representations and conversions between the point *P* and the area of rectangle *DABC* as results of their dragging. For example, they expressed this relationship between point *P* and the rectangle by making conversions to the symbolic or linguistic registers (line 10).

The term “intersection” is a word adopted from its appearance together with point *P* in the algebra view. This is a constraint of using GeoGebra as a recourse for natural language along with the symbolic register. Ivy’s and Aya’s use of intersection is a result of their instrumentation process, which led to inappropriate language in the situation and, potentially, to an incorrect understanding of point *P*.

Refining the design principles based on the ‘coordinated’ analysis

Based on our analyses, we refine the design principles and discuss how the networked theoretical perspectives have influenced the development of refined design principles using networking practices.

For HDC 1, the students use natural language throughout the task. At the beginning of the students’ instrumentation, they express their interpretations of the representations and the properties of the rectangle. Through their communication, their interpretations develop. As they are expected to give a written answer, they express the discovered relationship using the natural language that appears in the algebra view. In this case, this is unfortunate. However, if the tool’s expression is in line with the task, it can support the students’ use of natural language.

For HDC 2, the students only investigate the rectangle at the beginning of the task sequence. In the transcript, Ivy and Aya also investigate the rectangle on their individual computers, when dragging and discussing that both the width and height of the rectangle influence the area (lines 2-6). Hence, the treatments in the rectangle are related to point *P* (lines 1, 7, 10). About the word “intersection”, it is also important to be aware of the vast information provided in the algebra view. Hiding the algebra view could cause less confusion for the students to only focus on the graphical view.

For HDC 3, Ivy and Aya explore the template by dragging both points *A* and *D* at the beginning of their instrumentation process. When they drag, they can test their conjectures, e.g., regarding what happens to the rectangle when dragging either point *A* or point *D*. Through dragging, the students explore and investigate the relationships between the representations.

Applying the analyses to van den Akker’s (1999) structure, the design principle may be defined as: If you want to design teaching with a digital tool for exercising and developing the representation competency in schools, then you are best advised to *gradually relate all four registers (linguistic, symbolic, figurative and graphic) in a task sequence when using digital tools*. Collaboration between students is essential for all three characteristics and procedures. This may be realised by:

1. including the linguistic register (both written and oral) throughout the task (i.e., when formulating the task, exploring the environment and representations, and writing answers), and being aware of how natural language appearing in the environment relates to the intentions of the task, as the linguistic register is often neglected in a digital tool, although it

is an important register expressing the relations between representations, formulating interpretations of different representations and for developing an artefact into an instrument.

2. breaking objects and tool windows into smaller units by introducing different representational registers and components of the artefact gradually (e.g., hiding the algebra view), because gradually introducing representations makes it possible to identify the specific characteristics of a representation and to help the students' processes of instrumental genesis by limiting their explorations to specific parts of the tool.
3. using sliders, dragging and tracing for explorations about different representations and the treatments and conversions caused by the dynamic features since these features make it possible to quickly move and translate between representations, and for developing conjectures about the representations' reciprocal relations.

Discussion of the potentials for networking of theories in DR

Reflecting on our work as networking of theories, the empirical case guided our work. Concerning the eight networking strategies (Prediger et al., 2008), and the compatibility of the theoretical perspectives, the two theoretical perspectives' backgrounds will be discussed. The background for the semiotics register approach may be defined as "Understanding mathematics is a cognitive process, which involves 'coordination of at least two registers'" (Duval, 2017, p. 110). The background for the instrumental approach we define as 'Using digital tools in mathematics is a cognitive process of developing suitable schemes for using the artefact'. Both theoretical perspectives are cognitive in a similar way as KOM. Hence, the perspectives are not too far apart and the networking process is identified as 'coordinating'. The theoretical perspectives have different objects, i.e., semiotic representations (Duval, 2017) and using digital tools for instrumental genesis (Trouche, 2005). Yet, the perspectives are possible to network as the process of instrumental genesis takes place through the representations present in the involved digital tool, and the students' understanding of conversion and treatments of the involved representations. The instrumental approach is informed by the semiotic register approach concerning how students understand and relate mathematical representations, related to mathematical understanding and activity (Duval, 2017). The semiotic register approach is enlightened by the use of digital tools and students' instrumental genesis (Trouche, 2005). The understanding of the students' use of the tool, while working with several mathematical representations, thus becomes deeper by coordinating the theoretical perspectives. The design principles reflect both theoretical perspectives. Yet, the design is only illustrated for one case.

In this paper, we have aimed to investigate how practices from networking of theories could strengthen the development of theory in DR. The implementation of networking practices in DR helps when having a situation involving two perspectives, which for our study is the use of digital tools and mathematical representations. The strategies of 'coordinating' and 'combining' fit the aims of DR with regard to understanding an empirical case and developing theories (Prediger et al., 2008; Prediger, 2019). Both in DR and networking of theories, the processes of analysis are determined by the objects of research. It is of course possible to conduct DR without the implementation of networking practices. Still, for a case such as ours, the relationships between the involved theories are not necessarily taken deeply into account related to each other. However, if aiming at using networking practices, such as 'coordinating' or 'combining', parallel analyses and investigation of the compatibility of the theoretical perspectives involved are important. Implementing networking practices into DR, thus appear to strengthen the development of theories and theoretical perspectives.

The Anthropological Theory of the Didactic (ATD) aims to capture the complexity of real inquiries by using a type of instructional proposal called study and research path (SRP). Experimental research shows that certain notions of the Theory of Didactic Situations (TDS) appear specially adapted to analyse implementations of SRPs and point at some didactic phenomena related to the conditions needed for their implementation and management. We report this experience by first identifying some contact points between the ATD and the TDS and then describing the borrowings done. The analysis of the commonalities and specificities of both approaches helps to question the framework of the ATD and to point at some needed theoretical and methodological developments.

Keywords: Anthropological Theory of the Didactic, Theory of Didactic Situations, study and research paths, didactic contract, didactic situation, adidacticity, networking.

Introduction: ATD, TDS and networking

In this paper, we are considering two of the main theoretical frameworks of what is known as the French tradition in didactics of mathematics (Artigue et al., 2019), namely the Theory of Didactic Situations (TDS, Brousseau, 1997) and the Anthropological Theory of the Didactic (ATD, Chevallard, 2015). We present a networking activity that emerged when using notions from the TDS within ATD analyses and continues by considering their differences and commonalities about the kind of tools they propose to problematise, model and develop teaching and learning processes.

In 2007, in an invited lecture at the First International Conference of the Anthropological Theory of the Didactic, Guy Brousseau established some connections between key notions of the TDS and what could be considered the analogous ones in the ATD. He analysed the differences in how both theories model human activities in their collective and dynamic dimensions, including doing mathematics and teaching and learning mathematics. His comparison involved the notions of situation, milieu, situated knowledges (*connaissances*) and didactic processes, in contrast with some elements of the praxeologies (types of tasks and techniques) and the moments of the study. Brousseau considered these notions "more as points of contact, points of articulation that allow moving from one [theory] to the other, rather than as borders" (Brousseau, 2007, p. 3, our translation). He concluded:

> The ATD and the TDS complement each other. But in my opinion, it would be absurd to juxtapose them simply. In many issues, they are intertwined; they must be considered together. What

problems do they pose for each other? What answers do they offer each other? What advances do they promise together? (Brousseau, 2007, p. 22, our translation)

The relationships between the TDS and the ATD have been the object of previous research in the project of networking of theories initiated by Angelika Bikner-Ahsbahs in 2005 at CERME4 (Bikner-Ahsbahs & Prediger, 2014). For instance, Artigue et al. (2010) show how a teaching episode can be described from both approaches and relates the TDS analysis about the limitations of an *adidactic milieu* with the ATD one in terms of the functioning of the *media-milieu dialectic*. Ghemansi and Lecorre (2019) propose combining some TDS and ATD methods in design-based research related to the university teaching of calculus. These works and our experience as researchers are in tune with Brousseau's proposal of considering notions as contact points to question one theory from the other's perspective. This paper presents a bottom-up networking strategy that arose during the analysis of some empirical work carried out within the ATD, where the resource to some TDS notions appeared in a rather spontaneous way. This research practice nourished a reflection about the contact points between both theories, together with some specificities and differences.

Contact points between the TDS and the ATD

Since 2005, our ATD-research team has been implementing and analysing a new type of instructional proposal named *study and research paths* (SRP) based on the continued inquiry of problematic questions. In a way, SRPs include aspects of project-based and inquiry-based learning (IBL). However, they also provide new perspectives and methodologies currently not elaborated in the IBL literature (Markulin et al., 2021). Barquero et al. (2020) summarised that the implementation of SRPs faces several challenges related to the coexistence of two pedagogical paradigms in the school institutions in a very explicit way. Historically, the one that prevails is the *paradigm of visiting works* (Chevallard, 2015) and is based on the proposal of a set of bodies of knowledge – the *works* – for students to study under the teacher's guidance. The new paradigm that is struggling to emerge is the *paradigm of questioning the world*, in which the bodies of knowledge are replaced by open questions to address (or inquire). Between both extremes, some compromise situations can exist. In any case, our research shows how the conditions needed to implement a study process framed in the paradigm of questioning the world are diverse and fragile. We then identify many constraints coming from the prevailing paradigm of visiting works. In our analysis of such conditions and constraints, four points of contact between the TDS and the ATD appeared, as we said, very naturally. We first present these four points before examining each one in more detail in the following two sections.

First point of contact: new epistemological demands. One of the conditions for the normalised running of SPRs is the availability of tools to describe and manage the different types of knowledge mobilised during an inquiry. The existence of new study processes based on the paradigm of questioning the world highlights the need to deal with knowledge-related aspects, such as uncertainty, temporariness, and validation, that often remain implicit in visiting-works instructional proposals, where knowledge is conceived as static and crystallised. Brousseau was one of the first to point out the necessity for researchers in didactics to question and rebuild school mathematics organisations to avoid assuming the prevailing school epistemology as the only and appropriate one. The TDS proposal is to model mathematical knowledge in terms of *fundamental situations*, defined as games against a *milieu*, that is, an environment without any didactic intention towards the student and providing feedback to the actions received (Brousseau, 1997). The ATD, which is part of the TDS project of building didactics of mathematics as a science, joins its epistemological background about the need to question mathematical practices. It, however, differs in the models chosen and introduces a clearer institutional perspective by pointing at the existence of different conceptions and knowledge constructions connected through didactic transposition processes (Chevallard & Bosch, 2020).

Second point of contact: dealing with the curriculum constraint. Even if competency-based curriculums are on the agenda, to a large extent, curricular content is still described in terms of labelled pieces of preestablished knowledge. In this conception, inquiry-based proposals are often seen as means or methodologies to acquire the specific labelled content. In contrast to this conception, SRPs do not oppose inquiry and transmission but subordinate the learning of contents to the advance of the inquiry, and the elaboration of a final answer to the question initially addressed. This change in the knowledge conception is particularly challenging in a setting where the two paradigms coexist and meets what we call the *curriculum constraint* (Barquero et al., 2020). The TDS' proposal of modelling knowledge as the answers to problematic *situations* appears as a first move towards the paradigm of questioning the world while remaining in the frontier of the paradigm of visiting works because situations are always supposed to model a given piece of knowledge.

Third point of contact: the evolution of the didactic contract. A third and more evident contact relies on the changes produced by SRPs in the traditional sharing of responsibilities among the teachers and the students, which we interpret as an evolution of the *didactic contract* (Brousseau, 1997) that prevails in the paradigm of visiting works. Implementing an SRP requires students to assume different roles in the inquiry process, such as seeking available answers, validating or rejecting them, raising new questions, deciding which ones to follow or discard, planning the work to do, etc. Teachers also experience essential changes in their tasks: they are no longer the "knowledge holders" nor the sole person bringing new knowledge into the classroom. The coexistence of paradigms in the same school institution – and even in the same course – makes this contract negotiation complicated.

Fourth point of contact: didactic and adidactic situations. The students' assumption of new responsibilities in the inquiry process depends on how they engage in the SRP's generating question and the importance they attribute to developing an answer. In the paradigm of questioning the world, the study of works is essential as far as it helps to progress in elaborating a response to the initial question. The SRP generating question needs to remain at stake during the entire process for this to happen. In the analysis of the implemented SRPs, to identify the episodes where students seemed to be engaged in the inquiry for the sake of the considered generating question, we find it helpful to use the TDS distinction between *didactic* and *adidactic* situations.

The four contact points correspond to assumptions and modelling strategies that are common to both approaches. They need to be complemented with some comments about their differences and specificities. We will now approach them in two blocks by first addressing the question of the modelling of mathematical knowledge (points 1 and 2) and then the role played by the notions of didactic contract and adidactic situations in the ATD analysis (points 3 and 4).

The ATD inherits the epistemological programme initiated by the TDS

The first and second contact points correspond to a solid and fundamental connection between the TDS and the ATD. As explained by Artigue and Trouche (2021), Brousseau's project aimed "to find a genuine experimental epistemology of mathematics based on the construction of situations able to make mathematical knowledge emerge from autonomous students' interactions with their environment in the social context of classrooms" (p.3). Moreover, the TDS experimental epistemology relies on the observation and analysis of classroom implementations. Therefore, the central object here is not the cognitive subject, i.e., the pupil or student, but the situations organising the relationship of such subjects with mathematical knowledge and its raisons d'être. The ATD participates in this *epistemological research programme* in mathematics education (Gascón, 2003), which locates the description, modelling and reconstruction of the knowledge to be taught at the core of didactics research. An important difference between the TDS and the ATD is in the type of reference epistemological models (Bosch & Gascón, 2006) they elaborate to model mathematics, as knowledge and as a human activity. The TDS models are formulated as *fundamental situations*, defined as games against a *milieu*, with different dialectics or phases (Brousseau, 1997). Brousseau clarifies the scope he gives to this concept:

> One of the approaches of didactics of mathematics consists in modelling not only the knowledge to teach or learn, but also the conditions in which it manifests itself. Situations are minimal models that "explain" how such knowledge intervenes in the particular relationships a subject establishes with a milieu to exert a determined influence on it. (Brousseau, 2000, p. 4)

When we look at the types of epistemological models proposed by TDS, we can distinguish between a general model in terms of fundamental situations (or games against a milieu) and specific models in terms of sequences of situations. Without going into detail here, it is worth noting that in most of the work developed in TDS, the division of the modelled knowledge does not follow the classic school cartography of knowledge. It corresponds to rather vast domains of the mathematics to be taught, as shown by the work on numeration, measurement, and decimal numbers, which go far beyond what their name indicates. These models also make it possible to identify elements that do not exist in the dominant school epistemological models, a well-known example being that of "enumeration" (Briand, 1993; Rivière, 2017). The international diffusion of the TDS has been often limited by the confusion between epistemological and didactic models. Fundamental situations indeed play a double role in this respect because they define knowledge not by what it is but by the processes that allow it to be constructed. This fusion between didactic and epistemological proposals – or between didactic and mathematical situations – is at the heart of the TDS (Brousseau, 2007).

As said before, the ATD emerged within the scientific project of the TDS. According to Artigue and Trouche (2021, p.4): "ATD then broadened the perspective by placing at the centre of the analysis the diverse institutions, institutional positions, and institutional relationships with the knowledge at stake, and how they condition and constrain what is taught and, therefore, what students ultimately have the possibility to learn or not. To this end, new concepts were introduced, notably the concept of praxeology and the scale of didactic codeterminacy." The notion of *praxeology* is introduced as the basic unit to analyse human action in general and mathematical knowledge in particular. The dissemination of praxeologies takes place through what we call didactic systems. A didactic system is a triplet $S(X; Y; \mathscr{P})$ formed by a person or a group of persons Y (the teachers) who do something to help another group of persons X (the students) to learn a given body of knowledge or praxeology $\mathscr{P}$.

In the paradigm of questioning the world, didactic systems are not formed around a given praxeology to be studied, but rather around a question Q, to which X, with the help of Y, has to provide an answer $A^\heartsuit$. One tool used to analyse inquiry processes is the Herbartian schema: $[S(X; Y; Q) \rightarrow M] \hookrightarrow A^\heartsuit$. The schema considers that the study of Q generates an *inquiry* process involving a *didactic milieu M* including questions Q_i derived from the initial one, "ready-made" answers $A_j^\lozenge$ one can find in the literature or by consulting works and experts (the *media*), together with empirical data D_k and other material and knowledge works W_l: $[S(X; Y; Q) \rightarrow \{Q_i; A_j^\lozenge; D_k; W_l\}] \hookrightarrow A^\heartsuit$. Obviously, an alteration in the available *media* or aspects related to the *milieu* can lead to completely different constructions of $A^\heartsuit$. The schema is helpful to design and carry out *a priori analyses* about potential paths to follow when approaching Q, and also *in vivo* and *a posteriori* analyses about the path actually taken and the means used to do so. The Herbartian schema identifies some critical elements of the inquiry, namely $\{Q_i; A_j^\lozenge; D_k; W_l\}$, which can be detailed in terms of praxeologies. As we will see below, the inquiry dynamics are described in terms of dialectics, like those of *questions and answers* (Bosch & Winslow, 2014) and *media and milieus* (Kidron et al., 2014).

A first important difference between the TDS and the ATD proposals to model mathematical knowledge and activities is terminological (and, consequently, also conceptual). The use of situations enables one to model knowledge in an implicit way, not by pointing at its elements (for what a specific language is required) but by describing the situations it allows to solve. In the ATD, the notions of praxeology and Herbartian schema do propose descriptions of the knowledge elements and therefore require a specific language, which cannot be neutral. It is sometimes provided by the scholarly knowledge complemented with ad hoc elaborations. A second difference is the role given to the *media* in both approaches, which is often reduced to the teacher in the TDS and accessed through *didactic situations* – that is, situations where the teacher intervenes in the students' knowledge construction.

Developing TDS notions in the ATD analysis

The generating question(s) of an SRP and the notion of situation

In the implemented SRPs (Barquero et al., 2020), the generating question Q always plays a critical role. It should lead the inquiry and be always prominent, appearing as an end in itself – instead of an excuse to visit some preestablished works. And it should also conduct to a final answer $A^\heartsuit$ that is of a particular value for somebody, not only for X and Y. The experiences carried out in university engineering degrees showed a visible change in the students' involvement in an SRP depending on the conditions under which Q is formulated and $A^\heartsuit$ has to be received: an imaginary client, a fictitious client or a team of students taking part of a car race from the same university. We find here one of the main raison d'être of the TDS notion of *situation*. It includes the question raised but also the conditions under which it arises – the initial *milieu* – and the requirements for its reception and validation – the rules of the game and the winning strategy. In a way, when we talk about a question Q in the ATD, we are also implicitly including the institution and corresponding contract that ensures the reception of Q as such a question, together with the type of acceptable answers A_i and $A^\heartsuit$. Also, the importance of Q depends on the destiny of the potential final answer $A^{♥}$. Therefore, in the design of an SRP, it is essential to require not only some general interest for Q, but also a kind of external contract with an instance Z about Q, the type of expected answer $A^{♥}$ and how it will be valued or validated.

The notion of milieu

The concept of *milieu* proposed by the TDS corresponds to the environment with which students interact and provides them with objective feedback. It can comprise material objects, informative texts, digital tools, and other collaborating or competing students (Artigue & Trouche, 2021). In an SRP, the *milieu* is built along the inquiry process and can be analysed through the elements previously described in the Herbartian schema: $\{Q_i; A_j^{\lozenge}; D_k; W_l\}$. Its dynamics is then explained through the development of some dialectics. In particular, a central one is the *media-milieus* dialectic. This dialectic includes access to already available answers (or pieces of works found in the media) and their integration into the inquirers' milieu. During this integration, answers need to be validated to become useful for the inquiry progress and appear as potential works to be used by others.

Didactic contract and "adidacticity"

The management of an inquiry process in a "question-driven way" requires a new sharing of responsibilities between teachers and students and can be interpreted as the evolution of the didactic contract (Brousseau, 1997). For instance, students must assume new responsibilities, like planning the work to do, proposing the questions to address and those to discard, deciding what media to consult, validating the answers they find or propose, etc. In a way, in the didactic contract of the paradigm of visiting works, teachers are expected to boost the media-milieu dialectics students will then follow, as if the "question-driven" inquiry was only driven by the teacher, not by the students.

Analysing the changes in the didactic contract led us to use the distinction between *didactic* and *adidactic situations*, two key notions of the TDS. However, in our use of these notions, we do not include its functioning as *fundamental situations*, that is, as reconstructions and epistemological models of the mathematical knowledge to be taught. We only include in this notion the assumption that any question or problem is never raised in the vacuum but always appears to X (and Y) under specific circumstances or conditions and with some available resources (and other unavailable ones), a certain *milieu*. In this context, we use the term *adidacticity* to refer to the very moments when students make decisions primarily considering the generating question Q and the targeted final answer $A^{♥}$, without prioritising the instructional process that supposedly envelops the inquiry, that is, the didactic situation in which the SRP takes place. Looking for these adidactic moments can help measure to what extent an SRP is overcoming the constraints of the paradigm of visiting works.

Open questions in the dialogue between TDS and ATD

This paper presents several contact points between the TDS and the ATD, showing many ways, in which the latter is an heir of the former. But there are also aspects in which they seem to differ sufficiently to make it unavoidable to try to refine the formulation of the ingredients that mark the differences. A work that is still in progress.

The paradigm of questioning the world is the paradigm par excellence in research. Accordingly, the choice of theories when addressing research questions should always be subordinated to the question's sake. In other words, theories are good, helpful, valid, or interesting as far as they help researchers elaborate good, helpful, valid, or interesting answers to the questions addressed. In this context, the bottom-up strategy of networking theories is not a big deal. What specific relevance can we find in the networking experience here presented? First, it illustrates the do-it-yourself character of didactics research, and the freedom researchers should adopt in problematising, experiencing and analysing teaching and learning processes. Second, it provides a new perspective of each considered approach when viewed from the other side, establishing a *dialogue between theories* as proposed by Bosch et al. (2017). In this sense, our paper responds to Brousseau's analysis of ATD notions from the TDS perspective, by proposing some analysis of TDS notions from an ATD perspective. Finally, pointing at their complementary aspects is a way to question the scope of the ATD methodology by pointing at some needs in the proposed analyses, and contributes to its evolution.

We believe that such a bottom-up networking strategy is possible because of the robust commonalities shared by the TDS and the ATD. The most important one is the questioning of the mathematical activities to be taught and the need to elaborate scientific models to reproduce these activities without assuming the prevailing visions of school and scholarly institutions. And we should also add the inclusion of new instructional practices that intent to approach the teaching of mathematics to a questioning the world perspective. These are the critical points of contact that enable researchers to easily switch from one approach to the other without distorting any of them.

Due to the pandemic situation in 2020 the ERME summer school (YESS10) was designed for an online format using a conference system. Our design choices were based on previous experiences with YESS and the use of the research pentagon as a tool to think about research. This paper elaborates theoretically and empirically the specification of the concept of instrumental orchestration of the pentagon use through its rhythmic implementation into the summer school. Research results indicate that this specification had two main effects: The students described their instrumentation of the pentagon as a structuring tool in various ways. The most relevant pentagon use for the students' experience of growing expertise was listening to and observing how the others used the pentagon.

Keywords: Design-based research, instrumental genesis, rhythm, online learning, summer school

Introduction and background

Due to the pandemic in spring 2020 the Young ERME Summer School (YESS) of the European Society for Research in Mathematics Education (ERME) switched to using a synchronic online conference system. Two out of seven thematic working groups (TWG7, TWG5) run in a virtual environment. As neither clear conceptions nor research were available for the design of the school with respect to distance learning of PhD-students via a conference system, the two experts and two brokers (previous PhD-students of YESS) decided to conduct a design-based research study involving the conference system Adobe Connect. Planning jointly these TWGs led the brokers to decide to act as assistances and to provide several Adobe tools to be shared in the TWGs. The leading experts made common design choices based on their experiences in the previous YESS-TWGs. As each student had to submit a short description of their research project, all the students were asked to read all the papers before the school and prepare a presentation of their project to be discussed during the school. Prior to the school, pairs of critical friends were built within both TWGs to make them engage deeper into the friend's paper and present their critical feedback in an explicit presentation. The main design choice concerned the research pentagon (Bikner-Ahsbahs, 2019) as a tool to think and reflect about research in terms of research aims, questions, objects, methods, and situations involving the situation of the project in the field and creating a specific situation for the research in the project (Figure 1, left). The design of how to use the pentagon took into account previous experiences with the pentagon as well as the fact that the students coming from different time zones, and simultaneously being involved in their families during the school, required a clear timetable so that they would be able to manage their pandemic situation and attend YESS10. This resulted in a sequence of five situations of using the pentagon (Figure 1, middle). This sequence was repeated in all the ten sessions in the same order in both TWGs, however with some variations (Figure 1, middle & right).

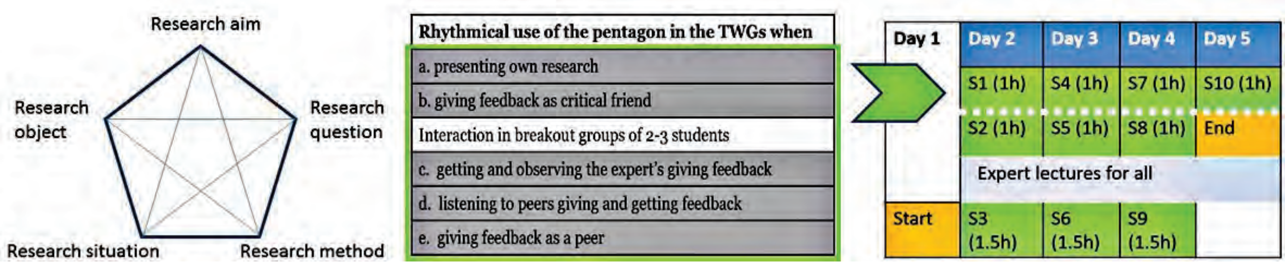

Figure 1: The research pentagon (left), sequence of pentagon use in a session (middle) and the sequence of sessions S1-S10 (right)

Based on these design choices, we ask: How did the students experience the rhythmic orchestration of the pentagon use and the pentagon use itself as contributing to their learning about research?

Theoretical framework

Instrumental approach and instrumental orchestration

Considering the pentagon as a tool that participants need to appropriate in order to use it efficiently, *instrumental approach* (Vérillon & Rabardel, 1995; Rabardel, 2002) is one of two theoretical approaches in our research framework. The key idea is the distinction between an *artefact* – material or symbolic object available to a subject, and an *instrument* – a merging construct that consists of the artefact and the related mental schemes coming from the use of the artefact by the subject in a given context. The process of transformation of an artefact into an instrument, called *instrumental genesis*, consists of two interrelated processes: *instrumentation* leading to the constitution and the evolution of schemes of using the artefact in the subject, and *instrumentalisation* during which the subject adapts and personalizes the artefact according to her knowledge and beliefs. The development of schemes of use manifests itself in the subject's invariant organization of behavior in a given class of situations (Vergnaud, 1990). Trouche (2020) suggests seeing instrumentation both as "an action (by which someone acquires an instrument)" and as "the influence of this action on a subject's activity and knowledge" (p. 307). Thus, using an artefact yields both pragmatic and epistemic outcomes.

In the context of students' learning, students' instrumental geneses need to be accompanied by a teacher. Trouche (2004) introduced the notion of *instrumental orchestration* to describe how a teacher can plan and organize students' interactions with available artefacts in order to enhance individual and collective instrumental geneses. Referring to Trouche (2004), Drijvers et al. (2010, p. 214) define an instrumental orchestration as "the teacher's intentional and systematic organization and use of the various artefacts available in a […] learning environment in a given […] task situation, in order to guide students' instrumental geneses". It consists of three elements:

1. A *didactical configuration*, which is "a configuration of the teaching setting and the artefacts involved in it" (Drijvers et al., 2010, p. 215);

2. An *exploitation mode*, which is “the way the teacher decides to exploit a didactical configuration for the benefit of his or her didactical intentions” and includes in particular the teacher’s decisions “on the possible roles of the artefacts to be played” (p. 215);
3. A *didactical performance*, which involves “the ad hoc decisions taken while teaching on how to actually perform in the chosen didactic configuration and exploitation mode” (p. 215).

Design approach to orchestrate the pentagon use

The pentagon was implemented in the design of the sessions as a tool to structure and reflect on research (Bikner-Ahsbahs, 2019) individually and in interaction with others. Pairs of critical friends provided mutually more in-depth feedback in their presentation in addition to the spontaneous feedback coming from all the other peers. Whereas TWG7 introduced an article about the research pentagon before the school to be used for the preparation of the presentations, the expert of TWG5 introduced this tool in the first session. Besides this distinction, both experts used the tool permanently during the school as a reference object in their feedback and the discussion. We organized each of the 10 sessions in the TWGs by five situations of pentagon use (Figure 1, left) so that, in the course of these sessions, the students’ roles as presenter, critical friend, observer and listener, feedback provider and receiver of peer and expert feedback varied regularly in time and space of the virtual environment. This organization aimed at enhancing participants’ instrumental geneses to improve their research expertise.

The change from a face-to-face summer school to an online format required to theorize the meeting space. According to Lefebvre (1991), any space is established with respect to three dimensions: (1) A space is represented materially (also technologically), (2) it is representational in that it represents some idea (here: switching YESS to an online school), and (3) it is (re-)produced as a social space by the people involved. All the three dimension apply to YESS10. The digital conference system Adobe Connect used as a technological space linked to the individual material home computer spaces, constituted a representation of the virtual space. It provided tools for sharing and distributing information among the students, hence, for creating the social space of acting and interacting of the participants supported by these tools, e.g. the breakout rooms, chat, and note taking possibilities were included into the didactic configuration. This notion of space developed structured in time with a frequency of three sessions per day and breaks of different lengths (session–short break–session–lecture break–session–night break) repeated day after day.

In the summer school, the collective nature of teaching and learning is essential and this depends on the possibility of creating joint attention on the research presented. In face-to-face situations, this is established by building a reference space through deictic expressions, shown e.g., by linguistic means, through a projector, by gestures, gaze, body posture, moving (Balantani & Lázaro, 2021; Stukenbrock, 2015). However, most of these deictic expressions could not be shared in our virtual space. So, we designed the pentagon use in a way that it could facilitate creating a reference space because all the students could refer to this diagram sharing its structure, such as the vertices and their relations, with their peers, and simultaneously talking about their own research.

An implicit key idea in this design was rhythm as a way to structure time. Rhythm emerged as a critical design element when analyzing the data.

Rhythm as a design element

Lefebvre (2004) stressed that space, time, and energy are interrelated by rhythm, the latter being bodily grounded and thus always active. Rhythm as a structure of time is created in the course of sessions by an "ordered variation of changes" (Dewey, 1934, p. 160). Figure 1 (right) shows the *linear* rhythm as a repetition of sessions (three per day) with pentagon use and breaks. Within each session, the order of five situations of pentagon use is *cyclically* repeated involving regular and spontaneous variations by providing all students the opportunity to act in their way in all the roles and addressing various research topics and foci. This rhythmic characteristic of the *didactical configuration* was enriched by a rhythmic *exploitation mode* in which the experts regularly referred to the pentagon explaining while pointing to vertices and connections in varying research projects, and hence, inviting the students to use the pentagon as a reference space, too. Thus, the group could create joint attention on the research presented and discussed. As the experts have used the pentagon in previous summer schools, they related their feedback (*didactical performance*) to students' actual needs, highlighting blind spots, missing aspects, or a change of view, in using the pentagon as an organizing tool for research. So there is constructive interaction of various rhythms, so-called "eurhythmia" (Lefebvre, 2004, p. 16). Lefebvre emphasizes that rhythm allows measuring changes: "No rhythm without repetition in time and in space, without *reprises*, without returns, in short without measure [*measure*]" (p. 6). As the same situations of pentagon use are repeated the students had the opportunity to experience and compare these uses within eurhythmia, thus measure changes of own and others' pentagon uses related to research and hence, measure their own development of expertise on research.

Methodology

We use *rhythmanalysis* (Lefebvre, 2004) to answer the research question focusing on how the students experienced the rhythmic instrumental orchestration, which instrumentation processes they reflect and how the instrumental geneses of the pentagon may have contributed to their learning about research. As we could not observe these processes in time, we shaped this research similar to action research. We drew on our experience of conducting the TWGs, our design choices and note taking. An external expert interviewed 11 volunteers of the 20 participants about the efforts they invested into the school, their experience of the pentagon use and of our design to develop their learning about research. These interviews were video recorded and transcribed verbatim (names were replaced with pseudonyms). Thus, we did not observe the rhythmic processes directly, but rather approached them through the students' individual experience of the (eu)rhythmic orchestration in their interviews. This experience begins with a first contact with the pentagon and ends with reflections on own research. Related to this frame, we conduct our analyses in three steps considering the five different roles (Figure 1, middle) in which each student acted and interacted. First, we identified quotes in the interviews that refer to these roles, and described how each student experienced his/her individual instrumental genesis of the pentagon distinguishing between instances of instrumentation and instrumentalisation within the orchestration (Figure 2, vertical analyses expressed as vertical arrows).

For each role, we secondly compared these descriptions across all the interviews to situate the individual experience into the collective (Figure 2, horizontal analyses expressed by horizontal arrows). In the third step, we identified the students' individual reflections addressing their individual experience on learning about research in the interviews, interpreted them related to their instrumental genesis and through the lens of rhythmanalysis, and compared these across all the students.

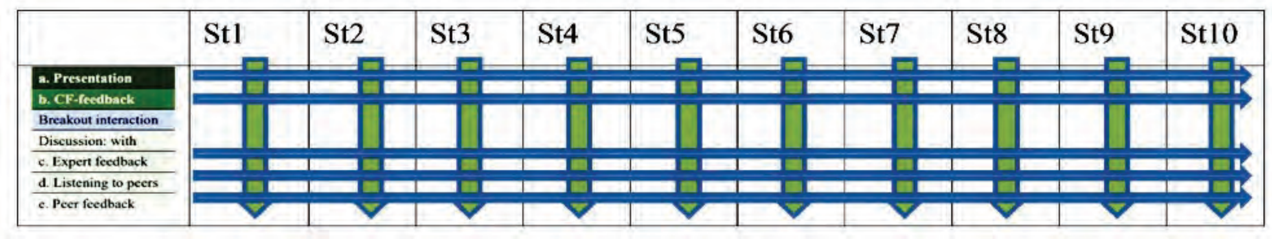

Figure 2: Rhythmanalysis (Stn: Student No. n)

Results

Based on our framework, we extracted quotes from the interview data, which express the students' experience in their reflections immediately after the summer school. Therefore, these results indicate what the students declare to have taken from the summer school rather than the learning processes themselves. The experiences of expertise are regarded as relevant outcomes for the PhD students who after the summer school may then continue their research with a refreshed expertise.

Step 1: The pentagon becoming an individual instrument

From the *case of Emma* we learned that some students' instrumental geneses started before YESS as Emma had read the paper and used the pentagon before the school already. The rhythmic organization of the situations in which she used the pentagon enhanced it. In the interview, she expresses a variety of instrumentation processes developed in different situations. She developed an *instrument for analyzing own research and checking its coherence* ("Also, just to see that you are making progress or making your project more coherent because I think it's very useful to talk about; if there's some parts of your research project that is not coherent.") and for *analyzing other's research projects* **("**I used the pentagon when I read the papers, for instance when I read through my critical friend's paper and whether I found some indications of the research aim and the research object, research questions, the method and…"). She also developed instruments related to feedback, for example for *structuring feedback for a critical friend* ("when I did the presentation for my critical friend **…** I could give feedback on that so what I thought was making a lot of sense") and for *structuring the feedback presentation* ("it can also be quite hard to understand where they [the peers] are exactly in the process and what they would need the feedback on to make them come further because. I think the research pentagon helped in that matter because I could use it to structure my presentation of my feedback"). We identified similar instrumentation processes in other interviews, too.

The *case of Nordy* made us aware that students in TWG5 came to know the pentagon use in the first session when the expert introduced it for the first time. As Nordy was the first presenter, he did not have time ("I need some more time to read the whole text and to incorporate it, to think about this research pentagon") for appropriating the pentagon although he perceived its potential ("I really think that it could be a great thing to organize your work [with the pentagon]"). Compared with the case of Emma, this shows the *lack of and need for instrumentation.* However, his instrumental genesis was about to start. Other students from TWG5 showed similar experiences.

Nordy's *beginning instrumentation process* was based on the expert's didactical performance, when listening to the expert's systematically and repeatedly referring to the pentagon. Nordy says: "as long as our research topic group was going on, then her [the expert's] feedback was more and more referred to it". He relates his individual to the collective instrumental genesis, when stressing "we should do our feedback depending on the research pentagon to our critical friend, I try to do that, I think we handled it quite good".

Through the *case of Kira* we learned that the first parts the students grasp are *vertices* of the pentagon as an instrumentalisation in the sense that students select the artefact features they are going to use. The links between the vertices are more complex to make sense of and need perhaps a specific orchestration (e.g. a 'technical demo' by the expert). For example, Kira used the pentagon as a feedback-structuring instrument identifying missing vertices in a peer's paper ("I could more clearly identify what was missing for me and what was also good"). Then she points to the need to fill the links between two vertices, the research question, and the methods ("filling the link to the research question would mean to ask myself, or for him to ask himself the question 'How can I measure this?' What method can I use? …"). Kira also expresses another instance of instrumentalisation in the idea to take the pentagon home for her peers: "I will take the research pentagon into a small group discussion at the university." Thus, within one week, the instrumental genesis entailed instrumentation as well as instances of instrumentalisation for Kira as well as other students.

Our vertical analyses show that the individual processes of instrumental genesis led to various instruments where the vertices are the primary foci while the links between them are more difficult to understand. Instances of instrumentalisation appeared already as the students decided which vertices they take up. Thus, the pentagon provides instrumentation and instrumentalisation possibilities from the beginning.

Step 2: Rhythm and listening as essential parts for contributing to learning

Kira connected the individual and the common use of the pentagon when she pointed to it as a diagram expressing a common reference space and resource in the didactical configuration of the virtual space ("what appeared were the edges and also a definition of what can be found, what can be identified as a research aim … the research pentagon in the middle on the whiteboard and then it was easy to just point somewhere"). The configuration of the virtual space where the pentagon was used as a diagram in screen sharing allowed sharing different research projects in the group ("This [the vertices] is very very different concerning what kind of research your project is about."). The repeated use of the pentagon emerged as a rhythmic exploitation mode. It helped the students to develop their expertise by listening to and observing others as well as practicing themselves to use the pentagon repeatedly. For example, Peter points to listening to and observing its repeated use by others ("I had the ability to see the pentagon in *action for ten times*.**"**). Dan highlights practicing its repeated use themselves **(**"doing it like *a few times to other colleagues,* each one in a different subject area, and *hearing the other teammates,* how they raise questions, was really really valuable. I mean, I learnt from it a lot."). Therefore, the rhythmic configuration and exploitation mode seem to have the potential to support developing expertise on research. Mirka is a bit more precise as she expressed *how* the repeated use of the pentagon supports growing in expertise. It can happen during one session in the *rhythm of* *different situations* ("I think there were some students who couldn't find… who couldn't use it in a specific way, but during the discussions of their feedback, they realized that they have to be more specific. […]"), as well as through the repetition of the *same situational use* in the course of the school *during the cyclic rhythm* ("once you see how other students used it, I think it's a very nice way to use it [the pentagon] your own way, personally, everyone used it; they didn't use it the same way.")

Step 3: Summarizing students' reflections on learning about research

The students highlighted the relevant role of rhythm, linear as well as cyclic, for the different uses of the pentagon and their learning about research. The most important use, as shown in our *horizontal analysis*, is observing and listening to how others use the pentagon, hence, they benefit from the rhythm in the didactical performance of the experts as well as from observing and listening to the processes of instrumental genesis of peers to learn how to improve their own research. Lefebvre elaborates on rhythm related to measure change with respect to a reference and hence, enables to explain the phenomenon of experience of change in learning. For example, a student may identify that the research object is still a blind spot in the own research project. Through repeatedly listening to others talking about their research objects, he or she can compare and thus measure the change of view on the own object and the experience of learning on own research. For example, Surgeryfish reflects: "what I see from others and fit into my work. … A kind of learning, becoming aware."

Discussion on the theoretical specification of instrumental orchestration

The YESS10-study is deeply rooted in the common experience of an ontological change in the pandemic situation. This change raised the necessity to enable the participants of YESS10 to align their home situations with the summer school in space and time via a conference system. As this study shows, we have achieved this by a rhythmic synchronizing (cf. Akkerman et al., 2021) of the students' instrumental geneses of the research pentagon in our virtual space and time with the goal to advance the students' projects and by that improve their expertise on research. As a result, a *rhythmic instrumental orchestration* emerged as a specification of instrumental orchestration, theorized with the help of rhythmanalysis of the implemented rhythmic structure. This rhythmic instrumental orchestration involves a didactical configuration that provides a rhythmic organization of the various situations and kinds of tool use. Within this configuration, a rhythmic exploitation mode emerged, which involves the expert as well as the students allowing them to use the tool in various ways as well as listening to and observing how their peers use the tool. Within this mode, the expert synchronizes her didactical performance on the tool with the students' needs. In sum, the design choices in the rhythmic orchestration led to eurhythmia, which allowed the students to develop their expertise in a communal way by learning from their peers, particularly through listening.

Issues with using Activity Theory to understand how master's students view their research skills as contributing to their future teaching

Trude Fosse, Troels Lange and Tamsin Meaney

Western Norway University of Applied Sciences, Norway; tfo@hvl.no, trl@hvl.no, tme@hvl.no

Using Engeström's third generation of activity theory, we explore three master's students' views of their completed research projects on children's argumentation in number stories as potentially contributing to their forthcoming teaching of Grade 1 students. Activity theory was chosen because it provided opportunities to consider how two different activity systems, research as part of teacher education and mathematics teaching in Grade 1, might overlap around the shared artefact of mathematical argumentation through number stories. The three interviews are analysed using Engeström's description of four levels of contradictions identified in a matrix of principles and questions. The analysis raised some issues with the use of Activity Theory to understand the master's students' learning from the contradictions between the two activity systems they were in-between.

Keywords: Master's students, research skills, number stories, third generation of activity theory.

Tensions from looking back, looking forward

From 2017, all preservice teachers for the compulsory years of school (Grades 1-10) in Norway are required to complete a five-year master's degree, but this has raised some concerns about the value to teachers of learning to do research (Smith, 2021; Aam et al., 2017). As Rørnes (2017) stated, "a research-based education must … be built on R&D work related to real-world issues connected to being a teacher" (p. 8). Yet, there has been little research on how teacher educators could improve their practices by understanding master's students' (MSs) learning of research skills. Learning about research could contribute to expansive learning activity. For Engeström (2001), "expansive learning activity produces culturally new patterns of activity. Expansive learning at work produces new forms of work activity" (p. 139), but this sort of learning may not be able to be predicted beforehand. Non-explicit learning is common, in that "people and organizations are all the time learning something that is not stable, not even defined or understood ahead of time" (Engeström, 2001, p. 137). In this paper, we explore Engeström's (2001) third generation activity theory (3GAT) to determine its suitability for identifying the kinds of learning activity, that could occur from MSs undertaking research. We chose 3GAT because we anticipated that contradictions would appear in the interviews when the MSs discussed the two activity systems of teacher education and school mathematics teaching in relationship to their research projects.

In research, which focused on contradictions in mathematics education, Engeström's (2001) 3GAT has been used to provide insights into when and how learning can occur, when different activity systems are juxtaposed. For example, Engeström's (2014) contradictions has been used to identify the difficulties that students had transitioning from school to university mathematics (Anastasakis et al., 2020). Solomon et al. (2014) identified the contradictions raised by university students and mathematics lecturers in how they viewed the teaching of university mathematics as a way of identifying expansive learning. Whereas in the Solomon et al. (2014) paper, contradictions were between participants in two overlapping activity systems, Anastasakis et al. (2020) focused on survey responses where students looked backwards at both their school education and their university education. Psycharis and Potari (2017) investigated the contradictions that teachers identified as they worked to develop modelling tasks that used workplace contexts. Although the teachers involved were participating in master's courses, their reflections on the role of research in their teaching practices were not in focus.

As part of a wider research project, we wanted to investigate the contradictions identified by three MSs when reflecting on what they had learnt from doing research both before they began as Grade 1 teachers and after a year of doing their teaching. It was important to understand not just the benefits the MSs saw from doing research on students' mathematical argumentation, but also the difficulties that might hinder them when they were the teacher. Part of our aim for the project was to see what we could learn as teacher educators to improve our practices. In this paper, we explore 3GAT (Engeström, 2001) as a theoretical framework for analysing interviews with the MSs before they began teaching and after they submitted their master's theses. We recognised that we were using activity theory differently to earlier mathematics education research, as we were investigating the contradictions raised, when the MSs looked forward and looked backward regarding doing research about teaching. In particular, we wanted to see whether analysing what the MSs told us would help us to identify and articulate contradictions with the teacher education activity system in which we operated. In his discussion of the Finnish health system around frequently ill children, Engeström (2001) described how difficult it can be for professions to articulate contradictions. Therefore, it was important to determine if 3GAT would provide us with relevant insights about expansive learning.

Theoretical Framework

In elaborating on his theory of expansive learning, Engeström (2001) outlined four questions and five principles. The four questions were described as being essential for any learning theory: 1. Who were the subjects of learning? 2. Why do they learn? 3. What do they learn? 4. How do they learn? The five principles were: the activity system as the unit of analysis; multi-voicedness; historicity; contradictions; and transformations. An activity system involves individual and group actions that operate together. The object of the actions is a cultural entity, formed through mediating artefacts. In the teacher education activity system, the object for the MSs was to complete a master's thesis appropriately, using number stories and research skills as mediating artefacts. In the school mathematics teaching activity system, the object was to teach mathematics appropriately, in our case mathematical argumentation using number stories and potentially research skills.

As "the object of activity is a moving target, not reducible to conscious short-term goals" (Engeström, 2001, p. 136), it is always being reformed both within an activity system and when activity systems meet. As a result, "object-oriented actions are always, explicitly or implicitly, characterized by ambiguity, surprise, interpretation, sense making, and potential for change" (Engeström, 2001, p. 134). This contributes to a multitude of views about the actions within each system, which contribute to its multivoicedness. Multivoicedness can illustrate the similarities and differences between activity systems, because there may be a cross-over in participants. Historicity, or the historical development and the circumstances of that development, of the activity systems determines the actions available. Contradictions are part of each activity system and occur when activity systems come in close contact with each other. Acting upon the contradictions could lead to transforming the activity systems or creating a new one.

Engeström (2014) described four levels of contradictions. At the primary level, contradictions occur within one constituent component of an activity system, such as when a new value system is connected to that component, but other components are not affected. The secondary level is where one constituent component is altered, requiring adjustment in other components in the same activity system. This was the focus for research, such as Psycharis and Potari (2017), where a new teaching method, integrating real-world modelling tasks into school classrooms, was introduced. The tertiary level of contradictions occurs when the object of a culturally more advanced activity system is introduced into another activity system, causing resistance within the other activity system. Anastasakis et al.'s (2020) research about the differences between school and university mathematics could be viewed as being about contradictions at this level. The quaternary level of contradictions is when it is not just the object, but also other elements of the juxtaposed activity systems that are disturbed. Engeström (2014) described this level of contradiction as "conflicts and resistances appearing in the course of the 'implementation' of the outcomes of the central activity in the system of the object activity" (p. 72). Solomon et al.'s (2014) research on the views of students and lecturers about university mathematics can be considered as illustrating contradictions across more components of different activity systems, not just the objects.

In examining the interviews with the MSs, we focused on the contradictions that could appear from the juxtapositioning of the two activity systems of teacher education and mathematics school teaching and so were interested in tertiary and quaternary levels. We were interested in determining where and how expansive learning could occur when research skills and understandings, from the teacher education activity system, were introduced as an object into the school mathematics teaching activity system. We wanted to determine if the interview data could be analysed with 3GAT to provide insights that could be used in reflections on our own practices.

Methodology

The MSs were interviewed a few weeks after they had submitted their theses, but before they had received their grades (grading was done by others, not supervisors). As supervisors of two of the MSs, the choice of interviewees was one of convenience. In their master's projects, the MSs had collaboratively designed and implemented a teaching task for Grade 2 students where the students were expected to develop individual number stories, or *regnefortelling* in Norwegian. A regnefortelling usually includes a written problem, a drawing and a solution, sometimes provided through a symbolic algorithm. The MSs collected the regnefortelling and interviewed students to better understand their written and oral mathematical argumentation. Each MS had analysed different aspects of the collected data to produce individual theses. At the time of the interviews, all three MSs had accepted jobs as Grade 1 teachers for the coming academic year.

The interviews were semi-structured, undertaken by the first and third authors, in a mix of Norwegian and English. All responses were translated into English. The focus of the interviews was on how the MSs saw the usefulness of their newly acquired research understandings to their future work as teachers. The analysis was done by first finding the utterances in each individual interview around one topic, that was often connected to a particular thread of questioning. Sometimes this was one utterance, at other times it was two or more consecutive utterances spread across several minutes. For each of these topic discussions, we completed Engeström's (2001) matrix formed from the four questions and five principles. We then identified where contradictions occurred and their level.

We focussed on the contradictions that the MSs described when reflecting on the juxtaposed activity systems because the MSs were in between activity systems. At the time of the interview, they had not started their roles as teachers in the school mathematics teaching activity system but had left the teacher education activity system. Thus, the MSs did not have possibilities to transform either activity system. If expansive learning were to come from reflections on the activity systems, it was for us, as teacher educators, to use knowledge of the contradictions to reconfigure, at least aspects of, the teacher education activity system, while accepting that changing activity system takes time (Engeström, 2001). Although the interviews were individual, sometimes the same contradictions appeared. As discussed in the results section, it was not always straightforward to identify whether the contradictions were at the tertiary and quaternary levels because of the complexity that surrounded the contradictions.

Results and Discussions

In this section, we first describe the discussion topics that produce contradictions at the tertiary level, then at the quaternary level, before discussing the contradictions that were not clearly one or another. In each section, the identification of the contradictions is not straight forward, requiring consideration of what Engeström's (2014) contradictions can contribute to understanding learning.

Tertiary level contradictions

Tertiary level contradictions occur, according to Engeström (2014), when an object and motive from a more culturally advanced activity system is introduced into the central activity of a related activity system. In our data, we took this to mean that tertiary level contradictions would appear when the object of the teacher education system, research skills and understanding, was introduced into the related activity system, that of school mathematics teaching.

One example of a tertiary level contradiction was when two of the MSs reflected on the use of different representations or modes in children's argumentation in their regnefortelling in their individual interviews. From their research, they were able to see how the students were helped in explaining their thinking by using different representations. For example, MS3 described how they decided to not just look at the students' writing and drawings but to interview them, as another way to understand their thinking. This was connected to having the freedom to design their research projects, "I think that is the most interesting part of the project, and also that we could do whatever we wanted to do" (Utterance 12). The valuing of different representations, thus, originated in the teacher education activity system. MS1 highlighted how having students talk about their regnefortelling could be useful in her teaching of Grade 1 students, who may not yet know how to write. Having students talk about their regnefortelling was at this point imagined in relationship to the activity system of school mathematics teaching. MS2 had similar reflections about how drawings, as another mode of representation, could support her as a teacher to understand children's mathematical thinking but also act as a mediating artefact that could help the students to think mathematically, "I as a teacher can see how they have thought, but also that they themselves may be able to see clearly how they think, that they can use drawing for themselves as a thinking tool" (Utterance 11).

The valuing of the use of different representations as tools for students' thinking arose from the MSs' research but gave the MSs insights into different practices that they could use in their future classroom teaching, both for their own benefit but also for their students'. This could be considered an example of a reworking of what Engeström (2014) described as the established structures to do with the usual text production in schools:

> This object is molded by pupils in a curious manner: the outcome of their activity is above all the same text reproduced and modified orally or in written form (summarized, classified, organized, recombined, and applied in a strictly predetermined manner to solve well-structured, "closed" problems). (p. 80)

By valuing students' thinking and supporting them to use a range of modes to engage in mathematical argumentation, the MSs would be providing their imagined, future students with culturally more advanced forms of mathematical argumentation, in which the students had more control of the kind of thinking they were doing. However, it is not clear if the MSs considered this to be a contradiction that arose as result of the object being imposed on the school mathematics activity systems. For the MSs, the contradiction may be at the secondary level in that having students make choices about how to represent their thinking, or even to think, would result in changes within the school mathematics teaching activity system as it redefined who did what in mathematics classrooms. As a result, the possibilities for using research skills to develop their teaching may be de-valued.

For teacher educators, the contradiction between the activity systems from adding research skills and understandings was more obvious in that it made us reflect on aspects of the teacher education activity system, beyond the research skills. MS2 told that in their teacher education, no one had made them aware of the value of drawings to support students to think mathematically and to show their thinking. The contradiction between the two activity systems is complex in that it was not clear if the MSs saw the valuing of other ways for students to show their mathematical thinking as being in contradiction with the existing methods or just something extra to be added on top. Yet, the implied contradiction with what was provided in teacher education can only have an impact on the teacher education activity system if teacher educators take note of what the MSs state they were missing.

Quaternary level of contradictions

Quaternary contradictions occur when there are tensions between two or more neighbouring activity systems to do with a range of constituent components. An example of this could be when the MSs discussed how they could work collaboratively when they became Grade 1 teachers. They were asked about this because all three MSs described how valuable they had found working together on their research projects, "I thought it was very positive, because it was very nice to have several master students together as well" (MS1, Utterance 62). MS3 indicated that the MSs had already thought about how they could do this:

> We are talking about having these Google docs sites of all the (master's) students that are working together now, to just share ideas. And I think it will also be possible to – like take some parts of this project and try it out, absolutely. And we are in so different parts of Bergen as well, so it will be nice to see. (Utterance 40)

In the interviews, there were no reference to multivoicedness or historicity to do with either activity system, except to the other MSs' voices about their experiences of their collaboration. The traditions about teachers working together in schools, which perhaps could have had some connection to what they were suggesting, was not referred to. Without knowledge of how collaborations are expected to occur in the school mathematics teaching activity system, the MSs did not articulate any potential contradiction in trying to collaborate across schools. On the other hand, as teacher educators, we were aware that a contradiction could arise if this form of collaboration that had occurred during research were implemented when the MSs worked as teachers. It did provide us with information that we could take into consideration in designing our future teacher education.

Contradictions that have aspects of both tertiary and quaternary levels

Some discussion topics, raised by the MSs, seemed to be between the tertiary level and the quaternary level of contradictions. One such discussion topic, which appeared in all three interviews, was when the MSs reflected on how asking students about their mathematical thinking provided them with other kinds of information than when teachers usually asked children questions in mathematics classrooms. For example, MS1 described that by showing curiosity about the students' thinking, the students talked to the MSs in a different way, "(we) said that we just want to know what you think, and in a way started talking a little bit about the number story they had, then they started talking a little more freely" (Utterance 11). MS3 discussed how this led her to understand the importance of asking the students about their thinking:

> Just to talk with the students, like … Yeah, just ask the student "oh, what were you thinking here?" That I also think is an important starter to do, and then maybe it will be easier to talk about regnefortelling together afterwards. It will start with saying it's okay to explain how you're thinking, and it's okay to not have the right answer, but it's better to know how to explain it than to have the right answer and not explaining it. (Utterance 79)

This indicated that interviewing skills from her data collection changed her ideas about what was important when talking with students. MS3 seemed to consider that the mediating artefact of doing research interviews could support her to achieve the goal of improving her teaching mathematics in school by moving beyond just being interested in the correct answer. The multivoicedness about this discussion topic can be seen when MS3 used "you" to refer to the students. There were also traces of historicity in that there is a sense that traditionally mathematics teaching has focused on the correct answer and not on the students' thinking.

Although this discussion topic is about the object of research interviews being integrated into teaching, it is difficult to know if the contradiction with traditional classroom discussion practices is likely to stay within the object component and thus be at the tertiary level or affect other components of the school mathematics activity system and be at the quaternary level. The object, research interviews, from teacher education activity system, did disrupt the object of classroom discussions in the school mathematics activity system:

> I have seen that it is very interesting to talk a little more with students about how they think, than to just stand at the front and question them one by one like that, that you get more out if you ask a few questions where you can dig into a little with each individual student. (MS2, Utterance 47)

However, the complexity of implementing these alternative types of classroom discussion may mean that other components of the activity system would not be affected:

> It takes a lot of time, and you have to be so focused on one student, so then you cannot have twenty students sitting there, you have to have control over them as well. So maybe you have to

> collaborate with more teachers, divide into stations, do it a little differently so that you can get a little… Yes, a little help from others. Maybe also sign up for some such research projects, and … Mhm, so you can get help there. (MS2, Utterance 54)

MS1 also suggested ways of getting the same benefits from interviewing students, while managing the rest of the class, “maybe they could have had a conversation with each other and in a way argued with each other, then. But then we must have worked with a lot of argumentation” (Utterance 33). This indicates that even when imagining alternative ways of gaining useful information about the students’ thinking, there were issues in that the students would need to be taught argumentation before they could engage in talking to each other about their regnefortelling.

These quotes indicate that the contradiction raised by valuing the information provided by the interviews was in conflict with the MSs’ understanding of the realities of classrooms, which would not allow for individual interviews and where argumentation needed to be taught before students could use it. At this point in their careers, the historicity to do with mathematics classroom teaching had provided the MSs with a view that their main job was to ensure all students in the class were occupied appropriately, making it difficult to do individual interviews. However, identifying the contradiction between wanting to hear about students’ thinking and keeping all students occupied made the MSs imagine potential solutions. The MSs seemed to say that the contradiction could affect several components of the school mathematics teaching activity system, but their suggestions for implementing alternative approaches seemed uncertain. This could be because the MSs were not yet working as teachers so imagining system level changes was difficult and, as Engeström (2001) stated, transforming activity systems is a collective endeavour, taken over time. Nonetheless, the multiple voices about the school mathematics teaching activity system for these MSs now included the researcher voice, which allowed them to query a focus on the students having the right answer.

The MSs’ suggestions of alternative ways of hearing about students’ thinking suggested that the contradiction was at the quaternary level because more components than just the goal of the activity system were discussed. However, it is not clear if this could lead to school mathematics activity system changing. For the teacher education activity system to change, we as teacher educators need to also reflect upon what the MSs described as difficulties in the implementation of new practices around listening to students’ mathematical thinking.

Conclusion

Although activity theory has been used in different mathematics education projects (Anastasakis et al., 2020; Psycharis & Potari, 2017; Solomon et al., 2014), our analysis had a different purpose. We wanted to determine if it could provide useful insights from MSs’ interviews that could help us to reflect on our work as teacher educators. 3GAT did provide insights on how the MSs considered research understandings and mathematical argumentation using regnefortelling from the teacher education activity system, could be integrated into the other activity system, school mathematics teaching. In Engeström’s (2001) description of a project with Finnish health care system, there was a need for participants to be able to articulate the contradictions across activity systems in order for possible alternative practices to be designed. MSs did not always seem to identify a contradiction between the activity systems. As teacher educators, we could identify the contradictions but the connection to how to change our practices and connect them to the school mathematics activity system was not clear. Some of these issues may be with the data rather than with 3GAT. As the MSs were not yet in the school mathematics teaching activity system, they may not have been able to imagine difficulties often associated with implementing new practices in schools (see for example, Psycharis & Potari, 2017). The value of 3GAT was that the aspirations, challenges and obstacles, that the MSs identify, are reconfigured from being problems of individuals into what they should be perceived as, i.e., tensions and contradictions in and between activity systems. This provided other insights, which had the potential to contribute to more substantial changes in the activity systems.

Acknowledgment

The data for this project came from the Learning about Argumentation for Critical Mathematics Education in multilingual classrooms (LATACME) funded by the Research Council of Norway.

Coordinating conceptual frameworks for an in-depth understanding of knowledge when teaching mathematics

Malin Gardesten

Linnaeus University, Sweden; malin.gardesten@lnu.se

This paper is methodological and theoretical, focusing on how teachers' knowledge in action and interaction when teaching mathematics can be explored. The two conceptual frameworks adopted, The Knowledge Quartet and the Pedagogical Relational Teachership, are coordinated, as they grasp disparate aspects of knowledge in action and interaction when teaching mathematics. An empirical example is given to illustrate how these two conceptual frameworks can be adopted in coordination with each other. The results show that the coordination of these two conceptual frameworks used as a methodological framework can contribute to a deeper understanding of the characteristics of teachers' pedagogical content knowledge and relational abilities when teaching mathematics.

Keywords: Mathematics teaching, networking frameworks, relational abilities, teachers' knowledge.

Introduction

This paper is methodological and theoretical, focusing on how teachers' knowledge in action and interaction when teaching mathematics can be explored. This exploration is based on a classroom study conducted in a Swedish Grade 5 class. It is part of a research project intended to contribute to a more profound understanding of inclusive mathematics education regarding the connections between teachers' knowledge and relational abilities when teaching mathematics. Thus, this paper focuses on the use of a methodological framework based on two conceptual frameworks rather than interpreting the implications for mathematics education in the classroom.

Previous studies have shown that relational leadership promotes inclusive mathematics education (Schmidt, 2015). Furthermore, Roos (2019) concluded that inclusive mathematics education requires the teacher to have mathematical, didactic, and pedagogical skills as well as relational competencies in seeing each student as a person and understanding their needs. Roos' conclusion concurs with that of Ernest (2019). The latter stated that teaching mathematics involves the responsibility to treat students with care and respect and teach mathematics in a manner that benefits students effectively. Additionally, Valero (2005) pointed to the need to view the student as a whole human being, not just as a cognitive subject of mathematical thinking, to fully understand the student's intentions when acting in social mathematics teaching and learning situations.

Several analytical models deal with mathematics teaching, for example, Mathematical Knowledge for Teaching (Ball et al., 2008), The Teaching Triad (Jaworski, 1992; Potari & Jaworski, 2002), and The Knowledge Quartet (KQ) (Rowland, 2013). Ball et al. (2008) aimed to elaborate theoretically on the concepts of subject matter knowledge and pedagogical content knowledge (Rowland, 2013). Potari and Jaworski (2002) acknowledged sensitivity to students as one of the three keystones, making their framework useful as an analytic tool. However, they gave no further descriptions of how teachers act in interactions.

Based on the above, this paper is concerned with coordinating conceptual frameworks that can surface the complexity of teachers' knowledge when teaching mathematics in inclusive classrooms, considering knowledge in action and interaction with students. This complexity is addressed in this paper by illustrating two conceptual frameworks complementing each other using networking strategies (Bikner-Ahsbahs & Prediger, 2010) as guiding heuristics. The two conceptual frameworks are the KQ (Rowland, 2013), which frames how mathematical subject knowledge plays out in teaching, and the Pedagogical Relational Teachership (PeRT) (Ljungblad, 2019), which frames teachers' relational abilities, are coordinated. Thus, this paper aims to illustrate how these two different conceptual frameworks may contribute to exploring teachers' knowledge in action and interaction with students when teaching mathematics in inclusive classrooms.

The two conceptual frameworks

First, the two conceptual frameworks are introduced. Then the common core elements between the conceptual frameworks are presented.

The Knowledge Quartet

The KQ is a conceptual framework of four categories: *foundation*, *transformation*, *connection*, and *contingency*. Each of the four categories consists of several methodological codes to be used when analyzing empirical material (Table 1), from which the four dimensions of the KQ are extracted.

Foundation is related to the teacher's theoretical background in and knowledge of mathematics, making it possible for the teacher to use mathematical terminology deliberately, be aware of its purpose and identify errors (Rowland, 2013). Epistemologically, foundation can be seen as propositional knowledge, involving knowledge about mathematics and the purpose of mathematics teaching (Hundeland et al., 2017). *Transformation* refers to how a teacher's foundational knowledge is transformed into action when teaching, such as demonstrating mathematical content through examples, instructional materials, and mathematical representations (Rowland et al., 2005). Epistemologically, transformation can be seen as knowledge in action, as this knowledge is situated in and visible in teaching moments (Hundeland et al., 2017). *Connection* refers to the connections made by the teacher concerning the coherence of the teaching across a shorter or longer period, for example, connections between procedures, concepts, and sequenced examples (Rowland et al., 2005). Epistemologically, connection can be seen as knowledge in action, as this knowledge is situated in and visible in teaching moments (Hundeland et al., 2017). *Contingency* refers to the teacher responding to ideas from students for which it is impossible to plan and represents deviations from the intended actions in a planned lesson, but which make the teaching meaningful for students (Rowland et al., 2005). Epistemologically, contingency can be seen as knowledge in interaction, as this knowledge is situated in and visible in teaching moments when interacting with students (Hundeland et al., 2017).

The Pedagogical Relational Teachership

The PeRT is a theoretical relational perspective involving a taxonomy categorized under two themes, *tact* and *an inclusive stance* (Ljungblad, 2019), which is then further organized into smaller units of codes to be used when analyzing empirical material (see Table 2) (Ljungblad, 2021).

Tact is situated and improvised and can be observed in the teacher's different ways of relating to the students and their situated needs. Tact can be expressed verbally and non-verbally. The verbal expressions of tact are connected to how teachers use the tone of voice, degree of loudness, and rate of speech. Tact is expressed non-verbally through the teacher's eye contact, movements, gestures, and facial expressions. Epistemologically, tact can be seen as knowledge in action as well as in interaction, as tact is situated in the teaching and visible in the teaching as the teacher relates to the students (Ljungblad, 2016). *An inclusive stance* is connected to the teachers' sensible choices and can be observed in how the teacher takes responsibility for teaching and developing sustainable relationships within the classroom. Epistemologically, an inclusive stance can be seen as knowledge in action as well as in interaction and is both situated in and visible in teaching (Ljungblad, 2016).

Common core elements

Strategies of networking theoretical approaches are research practices that may provide a more comprehensive view of the complexity of teaching and learning mathematics. Various strategies to use more than one theoretical approach have been systematized described as a continuum, from understanding others and making their theories understandable to synthesizing and integrating locally. Somewhere in the middle of the spectrum of the degree of integration is to *coordinate* theoretical approaches. Coordinating multiple theoretical approaches can contribute to a conceptual framework for understanding empirical data (Bikner-Ahsbahs & Prediger, 2010).

In this paper, coordinating two conceptual frameworks implies three consecutive analyses on the same data source, complementing each other in a methodological framework. The two conceptual frameworks are chosen to elaborate on the interactions between a teacher and a student and the teacher's action reflecting the student's responses. The teacher's foundational mathematical knowledge plays out in the teaching, referring to the dimensions of transformation, connection and contingency. Unlike, the teacher's responses to the individual student's actions refer to tact and an inclusive stance dimensions, as well as contingency. Epistemologically, the dimension of contingency intersects with the dimensions of tact and inclusive stance. They are both seen as knowledge in interaction, addressing how the teacher's mathematical knowledge and relational ability unfold in the teaching in unpredictable ways. The common core elements are based on knowledge in interaction between the teacher and the student since they are connected to a context. When teaching mathematics, the teacher's actions are influenced by the context. However, when interacting with the student, the teacher responds to the student's ideas and emotions, which means the teacher influences the context.

Coordinating the two conceptual frameworks

The two conceptual frameworks were used to analyze video-recorded observations of mathematics lessons carried out in an intervention that was ongoing during a school year. The video-recorded classroom observations from this study were transcribed and coded in NVivo. In the analysis, first, the codes from the KQ (Table 1) were used to mark up the data material.

Table 1: Methodological codes from the KQ (Rowland, 2013)

Foundation	awareness of purpose (AP); identifying errors (IE); overt subject knowledge (OSK); the theoretical underpinning of pedagogy (TUP); use of terminology (UT); use of textbook (ATB); and reliance on procedures (COP)
Transformation	teacher demonstration (DT); use of instructional materials (UIM); choice of representation (CUR); and choice of examples (CUE)
Connection	making connections between procedures (MCP); making connections between concepts (MCC); anticipation of complexity (AC); decisions about sequencing (DS); and recognition of conceptual appropriateness (RCA)
Contingency	responding to students' ideas (RSI); deviation from agenda (DA); teacher insight (TI); and (un)availability of resources (RAT)

Then, as a second layer on the same data material, the codes from the PeRT (Table 2) were used. The sequence was first coded by me and then again by three senior researchers and two doctoral students to increase interrater reliability. Discussions were carried out among the experts involved until a consensus was reached regarding the codes used.

Table 2: Methodological codes from the PeRT (Ljungblad, 2021)

Tact	improvising shifts of tact (A11); seeking contact by showing interest in students' different ways of working and reasoning (A21); seeking contact with students by showing interest in the person (A22); meeting the students with respect (A31); and meeting the students in different ways in the same teaching situation (A32)
An Inclusive stance	taking responsibility for the teaching (B11); taking responsibility for the relationships (B12); listening to students when creating space for them to speak in their own way (B21); creating space for students to listen to each other (B22); showing students different possible ways to explore the content (B31); and encouraging students by showing trust in the students' ability and willingness to explore the content mutually (B32)

The third step implied an inductive analysis of students' participation in mathematics education on instances categorized into three groups: i) coded to both KQ and PeRT, ii) coded to only KQ, and iii) coded to only PeRT, exploring differences and similarities of students possibilities to participate in mathematics education. In this paper however, only the first and second deductive steps are focused on and thus not the third inductive step.

An empirical example using the KQ and the PeRT as lenses

In this section, one empirical example is first introduced and coded to illustrate how the coordination of the conceptual frameworks was carried out. The empirical example is from a Swedish Grade 5 classroom with two teachers, a mathematics teacher and a special education teacher in mathematics.

This empirical example was chosen for this paper because the codes from the two conceptual frameworks sometimes overlapped. The codes are written in brackets to the right. Codes from the KQ are in *italics*, and codes from the PeRT are underlined.

First, the mathematics teacher, Felicia, introduces a task about a jogging tour to the whole class. The special education teacher in mathematics (Selma) is present during the lesson. The task describes a jogging tour that took the form of a circle. There is a picture of the circle on the task paper, where the circle's circumference (3,140 m) and radius (500 m) are written. The jogging tour has a shortcut straight across the circle, along its diameter. Subtask b is: Fatima is jogging half the distance and then taking the shortcut home. How long is Fatima's jogging round? Tanja, a student, raises her hand when the transcript below starts. The teachers consider Tanja a student in special educational needs in mathematics (SEM), as she often struggles to participate in mathematics. Selma, who is nearby, stops beside Tanja's right side, bends down, leans her forearms on the desk, and quietly asks Tanja about her thoughts on subtask b while looking at her task paper. Tanja asks about how to figure out the distance.

62	Selma:	How are we about to figure out the half then?	(A11, A21, B32, *RAT*)
63		(Quiet, 7 sec.)	(B21)
64	Selma:	How can we do it?	(B32)

Next, after a passage where Tanja is being silent, Selma asks:

67	Selma:	How long is the whole [circle]?	(*RSI*)

After a wrongly read number, Tanja quickly answers correctly.

71	Selma:	Yes. Suppose we pretend that this is three thousand. How long would the half be then?	(A11, B32, *MCP*)
72	Tanja:	Two and a half. No.	(B21)
74	Selma:	Not two and a half. Instead? What if you and I would split these three?	(A11, B32, *RAT*)
75	Tanja:	Mm.	(B21)
76	Selma:	How much do each of us get?	(A11, *RAT*)
77	Tanja:	Three and a half.	(B21)
78	Selma:	Do we get three and a half if we split three?!	(A11, *IE*, *RAT*)
79	Tanja:	No. (Giggles.)	(B21)
80	Selma:	No. (Laughs.)	(A11)
81	Tanja:	One and a half.	(B21)
82	Selma:	One and a half. And, what does it mean in meters in this task?	(A11, *MCP*)
83		(Quiet, 2 sec.)	(B21)
84	Selma:	Instead of three thousand?	(A11, *MCP*)
85		(Quiet, 2 sec.)	(B21)
86	Selma:	If we split, instead of meters, if there were [Swedish] crowns instead. Suppose we split three	

		thousand [Swedish crowns] you and me.	(A11, *UIM*, *RAT*)
87	Tanja:	Mm.	(B21)
88	Selma:	How many [Swedish crowns] do we get each?	(B32, *UIM*, *RAT*)
89		(Quiet, 4 sec.)	(B21, *RSI*)
90	Tanja:	One and a half.	(B21)

Above is an example where most lines are only coded with codes from the PeRT. In these lines, the special education teacher actively listens to the student or make room for her to speak (code B21, lines 63, 72, 75, 77, 79, 81, 83, 85, 87, 90). In another line, the special education teacher acknowledges that they work together using "we" in her talk, signalling that they will complete the task together (code B32, line 64). She changes her voice tone to a joyful tone (code A11, line 80) and seeks contact, interested in the student's reasoning (code A21, line 91). These lines coded only to the PeRT could be seen as the teacher responding to the student's needs as a person.

One line is coded only to the KQ. Here, the teacher responds to the student's silence by asking an easy question to which the information for the answer is written on the task paper (code *RSI*, line 67). The line could be seen as the teacher wants the student to give an answer related to the mathematical content, as she chooses a question to which the student already knows the answer.

There are also lines with codes from both the KQ and the PeRT. Lines coded to both the KQ and the PeRT display the special education teacher shifts tact while she contingently uses her fingers as manipulatives (codes A11 and *RAT*, lines 62, 74, 76, 78, 86). In some of these lines, the teacher also shows interest in the student's way of reasoning (code A21, line 62) and acknowledges that they together, using "we" in her talk, will be able to complete the task (code B32 line 62, 74). Yet another line shows the teacher suggesting they together, "we", can pretend the number is 3000 instead of 3140 while making a connection between the procedures of dividing 3140 by 2 and dividing 3000 by 2 (codes B32 and *MCP*, line 71). Further, one line displays the teacher pointing to her three fingers when identifying a wrong answer and changing her voice to a joking, surprising tone when asking a question (codes *RAT*, *IE* and A11, line 78). More, there are lines where the teacher connects one and a half to 1500 while changing the direction of her gaze to look at the student and changing her speech rate to slow and gentle (codes *MCP* and A11, lines 82, 84). Another line implies that the teacher again gazes at the student talking about money as imagined manipulatives (three thousand Swedish crowns) while pointing at her three fingers (codes A11, *RAT* and *UIM*, line 86). Again, the teacher uses "we", asking the student about how they can split the money (B32, *RAT* and *UIM*, line 88). The teacher is silent long enough, so the student finally answers (B21, *RSI*, line 89). The lines coded to both the KQ and the PeRT could be seen as the teacher responding to the student's needs as a person as well as adapting her foundational mathematical knowledge to this particular social setting.

Conclusions

This paper aimed to illustrate how the two conceptual frameworks used as a methodological framework can contribute to exploring a teacher's knowledge in action and interaction with a student when teaching mathematics in an inclusive classroom. The empirical example illustrates how the two frameworks make aspects beyond teachers' knowledge respective relational abilities surfaced. That is, from the dimensions of the KQ (Rowland, 2013), the special education teacher in mathematics shows foundational mathematical knowledge connected to procedures (lines 71, 82, 84), choosing (unavailable) materials and representations (lines 62, 74, 76,78, 86, 88), and responding to a student's silence (lines 67, 88, 89). From the dimensions of the PeRT (Ljungblad, 2021), the special education teacher uses verbal and non-verbal expressions to seek contact with the student and shows interest in her ways of reasoning. That is, the special education teacher creates space for the student to speak with her voice (lines 63, 72, 75, 77, 79, 81, 83, 85, 87, 89, 90), acknowledging her answers, although her answers are sometimes incorrect (lines 71, 82). The teacher tactfully makes jokes (line 78), supports the student, and shows trust that they two will solve the task (lines 62, 64, 71, 74, 78, 86, 88). Thus, based on the interaction with the student, the special education teacher adapts her actions to the specific student within the particular situation in time and space, using relational abilities. When using relational abilities, the special education teacher's foundational mathematical knowledge is transformed through adaption to the specific student in the interaction (lines 62, 71, 74, 76, 78, 82, 84, 86, 88, 89). Thus, when coordinating the KQ and the PeRT, the features of a teachers' relational abilities concerning a specific student's diverse interests and prerequisites contribute to our understanding of the complex situations of mathematics teaching and how they evolve.

Earlier studies on mathematics teaching have either focused on teachers' knowledge (for example, Ball et al., 2008; Jaworski, 1992; Potari & Jaworski, 2002; Rowland, 2013) or teachers' relational abilities (Roos, 2019; Schmidt, 2015; Valero, 205) and the approaches of the KQ and the PeRT function as frameworks of their own. They both can be used to analyze mathematics teaching but grasp disparate aspects of teachers' actions or interactions with students. However, coordinating the KQ and the PeRT may contribute to an understanding of mathematics teaching in inclusive classrooms from an extended perspective. The above-illustrated two-step deductive analysis makes it possible to carry out a forthcoming third inductive analysis of the instances where the codes from the KQ and the PeRT overlap and don't overlap. This analysis will make visible if and then how teachers relational and/or mathematical knowledge influence student participation in mathematics.

Acknowledgments

This paper and the research behind it were made possible by the support of Linnaeus University and the Swedish National Research School Special Education for Teacher Educators (SET), funded by the Swedish Research Council (grant no. 2017-06039). Teachers' decision-making as a context for networking theories of mathematics teaching

Patricio Herbst[1] and Daniel Chazan[2]

[1]University of Michigan, U.S.A., pgherbst@umich.edu;
[2]University of Maryland, U.S.A; dchazan@umd.edu

This paper illustrates how teacher decision making, as an arena of teaching practice, can be a locus for networking structural and individualist theories of teaching. We use the decision of what problem to give to students as a context for illustrating how those diverse perspectives can be coordinated conceptually in the context of a middle-range theory of teaching practice and the decision of how to respond to students to illustrate how such coordination can combine perspectives in the context of empirical studies of mathematics teaching.

Keywords: Teaching practice, theories of teaching, teacher knowledge, decision making

Introduction: Middle-range theorizing

Variability in theoretical accounts of the work of teaching has existed in education research for decades. This is also the case in mathematics education, where accounts of teachers' actions, beliefs, knowledge, noticing, or of teaching contracts, patterns, or norms, have run somewhat in parallel for decades. In this paper, we discuss teachers' decision-making as a context for networking different theoretical perspectives on the work of mathematics teaching and propose how research using scenario-based assessments could facilitate such networking. Our perspective on the networking of theories builds on Merton's (1967) notion of *middle-range theory* as an alternative between grand theories and local empirical hypotheses: A middle-range theory starts by scoping a terrain of human practice (e.g., mathematics teaching) and builds itself through adapting language to coherently accommodate potentially competing empirical assertions and developing conjectures that could be studied empirically to increase what is known. Middle-range theorizing is thus conceptual and empirical, and it includes activities that Prediger et al. (2008) called *comparing and contrasting* (e.g., by identifying the different observables and predictions each theory would attend to when looking at a complex phenomenon). It also includes what Prediger et al. (2008) call *coordinating and combining* (e.g., by identifying research designs, designing instruments, and specifying statistical models that can help discern the contribution of each theory to the understanding of the phenomenon).

Setting the stage: Different takes on the work of teaching

Scholars who study educational systems have often seen teaching as a production function shaped by institutional structures and policies such as evaluations, incentives, and requirements as well as the characteristics of classrooms (Doyle, 1986; Firestone & Pennell, 1993). In mathematics education, this structural conditioning of the work of teaching, has been apparent in research that describes teaching as the implementation of a curriculum through the enactment of role-relationships among teacher, students, and content established by a hypothetical didactical contract (Brousseau, 1997). Building on the latter, in our own work (e.g., Herbst, 2002, 2006) we have described observations of teaching in terms of effecting symbolic exchanges between student work and knowledge at stake required by the didactical contract—we refer to this as the theory of instructional exchanges. From this structural perspective, the work of teaching includes adapting to these structural demands.

A completely different approach is seen in work by scholars who seek to capture the experience of individual teachers, often drawing on psychological concepts. In these accounts, the sense that teachers bring to the work of teaching their individual characteristics (e.g., identity) or assets (e.g., knowledge) have often been used to explain unique episodes of teaching actions as expressions of self. Schoenfeld's (2010) ROG (Resources-Orientations-Goals) theory, for example, attempts to account for individual teacher actions as a moment-by-moment cognitive calculation of what to do, fed by the individual's Resources, Orientations, and Goals, with resources including teacher knowledge and orientations including teacher beliefs. Likewise, research on teacher noticing (e.g., Sherin et al., 2011) has produced models of the cognitive processes that lead teachers to act on the basis of what they notice. Other approaches, such as those that explain teaching as a projection of a teacher's individual beliefs may vary in the extent to which they hypothesize consciousness but also seek explanations of action inside the individual (Mason, 2002). The number of different perspectives taken to account for teaching as an individual activity evinces how dominant this perspective has been in mathematics education research.

Progress in research on teaching has benefitted from both structural and individual perspectives, yet each has its drawbacks. The first approach risks deprofessionalizing the work of mathematics teaching while the second approach risks burdening individual teachers with an ever-increasing set of resources and orientations to be acquired and used. These observations suggest the need for coordinating and combining what we learn from these perspectives. The development of a middle-range theory of the practice of mathematics teaching can support such coordination. A variety of practice theories have emerged in social research (Nicolini, 2012); among these perspectives, Bourdieu's (1990) logic of practice supports theoretical development that allows researchers to coordinate structural and individual perspectives. Such development can incorporate Stigler and Hiebert's (1998) perspective of teaching as a cultural practice and the notion that improving instruction requires improving teaching rather than teachers (Hiebert & Morris, 2012). We use research on teacher decision-making to sketch how such networking could proceed.

Coordinating theories for conceptualizing teacher decision-making

Decision-making is an important locus for the coordination of theories of mathematics teaching partly because of the marked contrast that can be gleaned between objective (structural) and subjective (individual) perspectives. An objective perspective that sees teaching as a response to structural conditions and constraints might see a teacher's decisions as discrete events: within a lesson, choosing which work to assign to students and how much scaffolding to provide would likely be one of such decisions, and see it as capable of being optimized on the basis of structural characteristics such as learning objectives and class level. A subjective perspective might, in contrast, account for the work of teaching as the continual enactment of individual agency in response to information from the specific context of action, where the actions of one person depend on their noticing of the context and the activation of personal commitments to address perceived needs of the context.

The conceptual work involved in coordinating these perspectives can be seen in the example Lampert (1985) offered to motivate her conceptualization of teaching as managing dilemmas. Lampert had noted the boisterous nature of boys in her class and decided to seat them closer to the front of the class so that she could manage their behavior. After doing that, she realized that her decision left girls farther from the blackboard having fewer opportunities to hear and see the mathematical content of instruction. She found herself second-guessing whether a decision could solve a problem in teaching. Instead, she came to embrace the notion that while decisions need to be made, no choice can be made once and forever. Two important generalizations can be abducted from this example. First, the field of education provides structured structures such as the need to attend to associations between gender differences and achievement and between achievement and opportunity to learn that require a teacher to be a steward of the learning environment. Second, the lived experience of an experienced teacher provides structuring structures such as the disposition to see boisterousness as not beneficial to a productive learning environment and physical proximity to a teacher as conducive for individual students to engage in productive behaviors. These two types of elements played a role in Lampert's analysis, requiring her to accept some structural basis for her decision making and act first to move boys to seats where she could monitor them. This decision changed some structural characteristics of the class so that she might feel less called to attend to discipline. In analyzing this new position, her personal, gendered experience, enabled her to notice a new gender imbalance issued from her decision (e.g., boys receiving more attention) that might need a different decision (viz., to spend more of her time in the back of the room).

Like Lampert, we want to embrace, but complicate, the theme of decision-making when it is applied to teaching mathematics. Yet given how prominent the expectation is among the mathematics education research community that teachers will exercise agency and enact personal commitments as they work in their context, we state our thesis in an alternative way: The study of teachers' decision-making needs to coordinate the usual attention to teachers' personal characteristics and assets with the recognition that there are structures in the field of mathematics teaching that require teachers to make decisions and that activate expectations for what those decisions ought to be. Even when teachers' personal commitments may compel them to deviate from such expectations as well as vary in the decisions they make as they handle specific contextual information, these decisions are best understood in terms of their fit with structures of the environment in which those decisions are made. In the two following sections we take two examples of decisions in mathematics teaching to illustrate two aspects of the coordinating approach we propose, which involves (1) the conceptual articulation that leads to (2) the empirical work that fleshes out of a middle-range theory. The cases are (1) What problem to give to students, and (2) What to say in response to students' contributions.

The decision of what problem to give to students

We examine the decision of what problem to give to students to demonstrate how a middle-range theory of practice can develop conceptual resources to coordinate structural and individual perspectives. The literature on the cognitive demands of tasks (e.g., Stein et al., 1996) has noted that cognitive demands usually lower in the transit from how the tasks are stated in curriculum materials, through how they are presented to students, to when students enact them. From a structural perspective, one could explain this in reference to how such tasks fit in the didactical contract. There are structures in the field of mathematics teaching that situate the practitioner and her students in a place from which they are more or less likely to do things. The course of studies with its institutionalized learning goals and expectations of students' attainment are such structures. Thus, the notion that a mathematics teacher must assign to students work related to the learning goals of the course of studies and the officially acknowledged capabilities of students is a structural characteristic of the field of mathematics teaching. It suggests that tasks that do not fit with courses of studies and learning objectives would likely receive little attention; both teachers and students would adapt to the point of neglecting tasks that fit little with the institutional expectations on them. Similar structural analysis also led Doyle (1988) to explain why novel tasks tend to be transformed into familiar ones.

An individual-centered perspective (e.g., Schoenfeld, 2010), would prompt researchers to see the maintenance of tasks' cognitive demand as a call to understand teachers' use of their personal resources (e.g., relational skills with students, personal goals), shaped by individual commitments or orientations to a variety of other issues emerging from personal readings of the context and mediated by the teacher's own noticing capacities. The subjectivist perspective would affirm teachers' individual agency and identify beliefs that some topics in the curriculum are more important than others, the need for this or that knowledge, and commitment to particular meanings of what learning those topics means as sources for explaining what happens with a task in the classroom.

We argue that the job of mathematics teacher in an educational institution positions the teacher to exercise their individual agency in ways that, while not determined by, can be described as habitual responses to structures such as the didactical contract. Furthermore, as Bourdieu would have it, these habitual responses also function as structuring structures, that is they further constitute ways of shaping future action even if the experience of individual agency continues. The notion of teaching as a cultural activity (Stigler & Hiebert, 1998) accounts for the variability in what can fit as appropriate kinds of things to ask students to do--the cultural forms that students' academic work can take: whether students may be expected to interact with the real world, be occupied in the same task for a long time, or speak to the whole class are examples of structuring structures that will shape the likelihood for a teacher to ask one or another question and for the students to interpret the request the teacher makes.

But there are also such structuring structures within a didactical contract. In our work studying algebra 1 and geometry classrooms in American high schools, we had conceptualized *instructional situations* as local didactical contracts which are specific to courses of studies and organize what tasks teachers assign to students and how they manage the framing of novel problems. Examples of instructional situations include solving equations and doing proofs—these situations include normative task statements (e.g., the use of the word "prove" vs. the word "solve") as well as expectations on the teacher's action (e.g., to provide a diagram that labels all the points to be used in the proof vs. providing all the information needed and no more in a word problem) and expectations on the students' work (e.g., to justify each statement before moving on to the next statement in a proof vs. doing one algebraic step at the time and writing it below the prior statement of equality). These situations initially appear as tasks canonically adapted to curricular structures (and may even be exemplified explicitly for students in study material), and one might use them to recognize the structural difference between novel and familiar tasks (Doyle, 1988). But instructional situations can also be recognized as capable of structuring how teachers see their field of possibilities when deciding how to engage students in more novel work. While teachers may design or adapt a variety of tasks for their students, the instructional situations available to them in a course of studies will structure how they exercise their agency, particularly how they engage in repair strategies with students to support students' identification of what is possible for them to do when they have chosen a task for students to work on. The instructional situations in a course of studies exemplify elements of the habitus of a mathematics teacher not necessarily by dictating what the teacher ought to do when assigning students' work, but by providing a set of expectations that the teacher needs to consider as they negotiate what will get students to engage with a mathematical task. Thus, in the case of engaging students with novel problems such as the question "what can you say about the angle bisectors of a parallelogram?" and the goal of using this question to practice proving, a teacher may feel compelled to suggest that students draw a figure and later label the vertices of the parallelogram and of the quadrilateral formed by the intersection of its angle bisectors. While this compulsion may be experienced as a personal decision to respond to noticed students' difficulties getting started thinking about the problem or getting started with a proof, the norms of the instructional situation of doing proofs (which stipulate that problems are posed in a diagrammatic register) will have likely structured the teacher's attention to expect students' difficulties writing the statements for the proof and to anticipate what they might be expected to do to preempt those difficulties.

The foregoing considerations suggest that research on teacher decision-making can be a productive site for empirical research to support the networking of theories of mathematics teaching. Research can and should investigate this terrain in a variety of ways, including (1) finding patterns in how textbooks and tests present work for students and how that influences what problems teachers choose to assign to their classes and (2) describing from the teachers' perspective how they plan and devolve responsibility for students' work on novel tasks. If this conceptual development seems worthwhile as one that can help us understand the specific ways in which teachers might feel compelled to adapt novel tasks for their students, empirical work can help uncover the structural resources available to teachers in different courses of study: What are the instructional situations available for teachers of a course of studies to frame students' work on novel problems and how do they help account for the ways in which practitioners notice the difficulties students have engaging in those problems and the particular moves they feel compelled to make? Particularly in the context of deciding to use tasks that are cognitively demanding (Stein et al., 1996), identification of the instructional situations that can help a teacher frame those tasks can help refine the instruments for empirical research that builds middle-range theory by combining structural and individual perspectives.

Studying how teachers respond to students' contributions

To show how the development of a middle-range theory of practice benefits from conceptual developments, such as the proposition of instructional situation to describe a type of resource for the teacher's framing of novel task, we sketch out empirical work that could help discern how variability of decisions responds to individual and structural factors. Scenario-based assessments (Herbst & Chazan, 2015) allow the study at scale of questions of teaching practice while also enabling rich representations of the contexts of teachers' work by using cartoon characters to render nonverbal aspects of practice and hence summon their feel for the game in real practice. Scenario-based items can be used to immerse teachers in classroom episodes framed or not framed by an instructional situation. They can be used, in the context of experimental design and regression analysis with covariates to study the complementarity of theoretical concepts suggested by structural and individual perspectives on decision-making. We illustrate it in the case of responding to students' contributions.

The interest in teacher responding to students' contributions (e.g., Jacobs & Empson, 2016) has emerged in mathematics education against what is often described as the pervasiveness of teacher evaluation of student responses, connected to the I-R-F (Initiation-Reply-Feedback) pattern. The research on teacher noticing has contributed to describing an individual-centered perspective on decision making that seeks to understand cognitive mechanisms for a decision: Attending to students' thinking enables the teacher to interpret what the student said, which in turn leads to deciding how to act. While individual centered perspectives might emphasize teachers' pedagogical knowledge and commitments to students' thinking as important to account for how teachers' respond to students, structural perspectives might put the emphasis on class level (e.g., advanced vs remedial) and the status of the student's response (correct, incorrect) as predictors of responses.

Our approach to the practical rationality of mathematics teaching models the context in which teachers are called to make such decisions. Accordingly, *instructional situations*, originally defined as structures behind similar recurrent tasks observed in courses of studies, do more than distinguish familiar from novel tasks: As frames that teachers can use to structure students' mathematical work, they can be used to understand the variability of teachers' responding to students' contributions. To understand a teacher's decision on how to respond to students' contributions we consider that noticing, interpreting, and responding are resources not only available to the individual teacher but also primed by the framing that prior instructional situations can provide to those interactions. The following sketches an experiment that we think could be used to investigate the sources of variability in teacher responding, including individual resources and structural characteristics.

Consider teachers who vary in terms of personal resources (knowledge, beliefs, discursive competence, and experience teaching beginning Algebra), matched in cohorts of 4 individuals who are equivalent on those personal characteristics to make 4 equivalent groups that receive A-control, R-control, A-treatment, and R-treatment items. Each group receives items that depict scenarios described explicitly as happening in an introductory algebra class (A-items presenting cases in an avowedly advanced algebra class and R-items in an avowedly remedial algebra class). In all cases students have already learned how to represent linear functions using tables, graphs, and formulas and participants are told that the goal of the lesson is to develop the idea of inverse of a linear function. In all conditions participants see the teacher present the same mis-en-scene:

Someone comes to the front desk of Parks and Recreations to pay a team's fees for the upcoming softball season. Two other teams came in earlier and paid but you are not sure how fees were calculated. You know there is a league fee per team and a separate fee per player. You see a few handwritten receipts still on the counter. One says 12 players and $554. Another says 17 players and $639. The supervisor has stepped away and cannot be reached. The customer insists on paying now and he was told over the phone how much to pay. The customer gives you a check for $605 and leaves.

After that mis-en-scene, the two control groups see the teacher ask the class "You now need to record the team fee and determine the number of players on the team," while the two treatment groups see the teacher ask “How could you express the relationship between team players and team fees to solve the problem of how many players a team has?”. This last question purportedly frames the problem as one of posing and solving an equation, while the control statement of the problem does not do that.

All groups would then be offered opportunities to respond to students’ ideas ranging from numerical guesses, accounts of incomplete procedures, disorganized calculations, tables, and equations, including equal number of correct and incorrect, partial and complete responses. Teachers are asked to compose how they would respond to each student. A structural conjecture would suggest that teachers would evaluate students’ responses varying in their response depending on the correctness of the answer and the level of the class. An individualist perspective would suggest that individual characteristics of teachers (e.g., beliefs, knowledge of students thinking) would predict their responses to students. A practice-based perspective would suggest that the group which saw the teacher frame the problem as one about equations, would tend to respond to students in ways that privilege equation-based solutions, though recognizing variations depending on correctness and also showing individual variability. The analysis of the various regression models that can be proposed to investigate variables that significantly account for teachers’ responses is then the instrument for coordination between theoretical perspectives in a middle range theory of teachers’ decision making.

Conclusion

The experiment sketched above illustrates one way to combine theories of mathematics teaching: In the context of researching decision making in mathematics teaching, regression analysis of teacher responses to scenario-based assessments can summon the concrete experiences of practitioners in contexts framed by different practical and structural considerations, which can be operationalized using experimental design. While sketchy especially on how to examine teacher’s decisions, the design makes visible the possibility that resources from various perspectives could be integrated to allocating sources of variability to all the factors involved.

A multifocal lens on qualitative data analysis: an affordance of networking theoretical approaches

Heather Lynn Johnson, Evan McClintock and Nancy L. Leech

University of Colorado Denver, USA; heather.johnson@ucdenver.edu
evan.mcclintock@ucdenver.edu nancy.leech@ucdenver.edu

We address the problem of interplay between methods of qualitative data analysis and the networking of theories. When we call a multifocal lens on data analysis an "affordance," we mean a benefit or resource that people may perceive possible when networking theoretical approaches. To situate our argument, we draw parallels between challenges in the fields of mixed methods and mathematics education. Examining the analysis methods in an empirical study of students' conceptions of what graphs represent, we argue that a multifocal lens can help to explain complexities when investigating students' reasoning. Our work contributes to efforts to advance the scope and depth of data analysis techniques employed when researchers network theories.

Keywords: Theories, data analysis, qualitative research, graphs.

Mathematics education researchers have appealed to a plethora of theoretical approaches, and this diversity brings richness to the field (Bikner-Ahsbahs, 2009). By networking, or connecting, different theories, researchers can embrace this diversity (Bikner et al., 2019; Prediger et al., 2008). The networking of theories is more than an intellectual endeavor; it has pragmatic roots, to contend with problems (Bikner et al., 2019). Those problems can encompass the enactment of research in mathematics education. The problem we address is methodological: the interplay between methods of qualitative data analysis and the networking of theories. Our aim is to contribute to efforts to advance the scope and depth of data analysis techniques employed in the field.

We argue that a multifocal lens on qualitative data analysis is an affordance of the networking of theories. By affordance, we mean a benefit or resource that people may perceive to be possible with a particular approach. One reason we use the term "affordance" is because of the reflexivity it implies. Our use is consistent with that of Chan and Clarke (2019), who offered the term "mutual affordance" to describe a back-and-forth relationship between theory and method, one that it is flexible and responsive rather than prescriptive. While Clarke and Chan (2019) address a broader scope of methods, we focus on data analysis. We do this in part because of the crucial role that competent analysis plays in qualitative research (Miles & Huberman, 1994).

The work of theorizing can bring forth many images for researchers. Simon (2009) put forward two images, tools and lenses, as metaphors for ways in which researchers can employ theories. A tool can function for a particular purpose; some tools serve multiple purposes, while others are more specialized. A lens can influence how people perceive a situation; different lenses can result in different explanations of a situation.

We have chosen the term "multifocal lens" to communicate how an analytic lens can make room for multiple perspectives of a single situation. One way to think of each perspective is in regard to a "focal construct" (Chan & Clarke, 2021), on which researchers may focus when analyzing a source of data. For example, researchers may focus on students' thinking and their affect. With a multifocal lens on data analysis, researchers can investigate and coordinate different focal constructs. Multifocal approaches can strengthen qualitative data analysis, by allowing researchers to triangulate within and across different analysis methods (Leech & Onwuegbuzie, 2007).

We contend that researchers' responses to challenges facing the field of mixed methods (Onwuegbuzie & Leech, 2005) can offer insights into the interplay between the networking of theories and methods of qualitative data analysis. We highlight two such challenges, and make connections to the field of mathematics education. The first addresses a relationship between the research methodology (quantitative, qualitative, or mixed) and data analysis methods. This challenge is analogous to Chan and Clarke's (2019) argument that a relationship between theory and method be one of affordance, rather than prescription. The second addresses whether and how researchers may mix quantitative and qualitative methodologies. This challenge is analogous to the networking of theories, as researchers grapple with whether and how theories may be connected (e.g., Bikner-Ahsbahs, 2009; Prediger et al., 2008).

To organize this paper, first we draw parallels between obstacles to mixed methods research and the networking of theories. Second, we explain why we examine interplay between the networking of theories and methods of data analysis. Third, we look at analysis methods reported on Johnson et al. (2020), in which the researchers networked different theories. Our purpose is to show how a multifocal lens on qualitative data analysis can explain complexities in students' reasoning.

Parallels between networking theories and mixed methods

One aim for researchers who network, or connect, theories is to solve problems that demand multiple lenses (Bikner-Ahsbahs et al., 2019). There is a continuum of ways in which researchers may network theories (Bikner-Ahsbahs & Prediger, 2010). On one end of the continuum, researchers can develop understanding of the assumptions underlying different theories. Moving along the continuum, researchers may compare or contrast, combine, synthesize, or locally integrate different theories.

An obstacle to the networking of theories is theoretical competition in response to a quest for coherence in mathematics education. If researchers view different theoretical perspectives to be in competition with each other, the field may appear disjointed (e.g., Prediger et al., 2008). Rather than theoretical competition, researchers who advocate for the networking of theories take a pluralistic approach (Bikner-Ahsbahs, 2009; Bikner-Ahsbahs et al., 2019; Prediger et al., 2008). Meaning, a goal is to interconnect theories, rather than to advocate for the adoption of singular, unifying theories (Bikner-Ahsbahs et al., 2019). This approach can benefit empirical research, by allowing researchers "to gain an increasing explanatory, descriptive, or prescriptive power" (Prediger et al., 2008, p. 169).

An aim for researchers in the field of mixed methods is to solve problems via qualitative and quantitative methods (Onwuegbuzie & Leech, 2005). As with networking theories, there is a continuum of ways in which researchers may mix methods (Leech & Onwuegbuzie, 2009). After employing both qualitative and quantitative methods, researchers may mix these methods within and/or across different phases of the research.

An obstacle to mixed methods research is a perception of dichotomies between qualitative and qualitative methodologies (Onwuegbuzie & Leech, 2005). When researchers identify with only a qualitative or quantitative paradigm, it can create polarization. Onwuegbuzie and Leech (2005) argue for methodological pluralism. Rather than binding methods to a qualitative or quantitative paradigm, they offer a reconceptualization, such that the same type of method may cut across paradigms. For example, researchers may employ exploratory methods from qualitative and quantitative paradigms. Such an approach can serve to dismantle boundaries between qualitative and quantitative research traditions (Onwuegbuzie & Leech, 2005).

The term “pragmatic researcher” describes researchers who embrace methodological pluralism:

> Becoming a pragmatic researcher offers a myriad of advantages for individuals. First and foremost, it enables researchers to be flexible in their investigative techniques, as they attempt to address a range of research questions that arise. (Onwuegbuzie & Leech, 2005, p. 383)

The field of mixed methods is a pragmatic response to the obstacle of a perceived dichotomy between qualitative and quantitative methods. In a similar way, the networking of theories is pragmatic response to the obstacle of theoretical competition in a quest for coherence in mathematics education. One way to conceive of the networking of theories is as “pragmatic theorizing.” A pragmatic approach to theorizing can allow researchers to leverage different theoretical perspectives to contend with researchable problems. Such an approach demands attention to methods, which we discuss next.

Interplay between the networking of theories and methods of data analysis

The networking of theories happens in conjunction with other aspects of research; it is entangled with researchers’ methodological decisions (Bikner-Ahsbahs et al., 2019). Radford (2008) has posited a conceptualization of theories as triplets that include systems of guiding principles (P), collections of methods and methodologies (M), and sets of overarching research questions (Q). From this perspective, theorizing extends beyond assumptions and principles to practical aspects of research (methods and questions). We view the elements of Radford’s triplets, to afford, rather than prescribe each other. While certain methodologies and research questions may be more typical for researchers operating with a certain system of guiding principles, those connections are not lock step. In our view, Radford’s triplet can extend beyond individual theories. In the networking of theories, researchers weigh principles central to different theories (P), examine how methods and methodologies may intertwine with different assumptions (M), and reflect on how theoretical assumptions can impact responses to research questions (Q).

The networking of theories is something more than triangulation via different data analysis methods (Bikner-Ahsbahs & Prediger, 2014). It is a way of employing a multifocal lens on a research setting. Researchers who network theories can employ different theoretical lenses on a single source of data. In turn, different theoretical lenses transform what gets counted as data. Hence, there is an interplay between theory and method. Drijvers et al. (2013) illuminate this interplay in their comparison of methods between two different theoretical lenses that they employed to investigate a student’s work on a computer algebra task.

In qualitative studies, the use of more than one analytic tool strengthens data analysis, because researchers examine a source of data from different viewpoints (Leech & Onwuegbuzie, 2007). We contend that a multifocal lens on qualitative data analysis is one affordance of the networking of theories. This multifocal lens is something more than a collection of different analytic tools, because the foci of data analysis are intertwined with theoretical perspectives. When researchers employ a multifocal lens on analysis, they can relate contributions from multiple analytic methods to illuminate new dimensions of a phenomenon.

A multifocal lens to explain complexities in students' reasoning

In a survey of recent research on students' mathematical thinking, Goos and Kaya (2020) note the increase in theoretical perspectives as the field has grown. They point to the networking of theories as a promising approach to address coherence amidst diversity in theoretical perspectives. To illustrate how a multifocal lens on data analysis can explain complexities in students' reasoning, we look at an empirical study from Johnson et al. (2020). First, we describe the setting of the study and discuss the theories networked. Second, we describe their data analysis methods, and insights gleaned from their approach. Third, we draw connections between theory and method.

Networking theories to investigate students' conceptions of what graphs represent

Johnson et al. (2020) conducted a qualitative study investigating high school students' conceptions of what graphs represent. There were 13 students in the study; each participated in a series of three individual task-based interviews. Students interacted with digital task sequences, and Johnson served as the interviewer. The digital tasks consisted of an animation of a situation, followed by a series of screens in which students could vary one attribute, then another, then both together. Students then could sketch a graph to relate the attributes. For example, one task involved a situation where a toy car moves along a curved track. Near the track was a small shrub. Students were to focus on two attributes: the toy car's distance traveled along the track and the toy car's distance from the shrub. Students could vary each distance, then both together, then sketch a graph relating those distances. Students' work on these tasks served as a primary source of data.

In their study design, Johnson et al. (2020) networked two theories: Thompson's theory of quantitative reasoning (Thompson 1994, 2011; Thompson & Carlson, 2017) and Marton's variation theory (Kullberg et al., 2017; Marton 2015). To argue for the viability of networking the theories, Johnson et al. (2020) identified a key assumption underlying both: researchers and participants bring different perspectives to the research setting, and hence can have different, yet viable goals.

Thompson's theory focuses on students' conceptualizations of attributes as being possible to measure (Thompson, 1994, 2011). Thompson calls this kind of conception a quantity. Per Thompson's theory, a quantity is something more than a unit attached to a number (e.g., 5 "feet"); it is how a student conceives of the attribute itself. For example, a student may encounter a graph that relates two different distances. Employing Thompson's theory as a lens, researchers may investigate what distance means for students, how students might think about measuring distance attributes, or how students might conceive of relationships between different distance attributes.

Marton's theory focuses on students' discernment, or separation, of some feature from an instance of which it is a feature (Kullberg et al., 2017; Marton, 2015). Marton (2015) proposes conditions under which teachers or researchers may engineer opportunities for learners' discernment. First, juxtapose two features, such that each differs with respect to a certain aspect. Second, let one aspect vary, while the other remains invariant. Employing Marton's theory as a lens, researchers may investigate how students discern aspects of graphs, such as a variable represented on an axis.

Employing a multifocal lens to analyze students' conceptions of graphs: Johnson et al. (2020)

Johnson et al. (2020) employed multiple phases of data analysis, following Wolcott's (1994) process of description, analysis, and interpretation. In the first phase, they described what students sketched (or tried to sketch), how students explained their sketches, and students' physical motions related to their sketches. In the second phase, they coded for students' conceptions of what graphs represented. Codes distinguished conceptions of attributes as being possible to measure (e.g., a distance traveled by the toy car) from the physical objects themselves (e.g., the motion of the toy car). In the third pass, they interpreted students' shifts in their goals for graphing, appealing to the different theoretical lenses.

By analyzing for both students' conceptualization (Thompson's theory) and discernment (Marton's theory), Johnson et al. (2020) embraced pluralism in their analysis methods as well as their theorizing. With Thompson's theory (1994, 2011), they identified three goals for students' graphing, which they linked to different conceptions of what graphs represent. With Marton's theory (2015), they distinguished between what researchers intended for students to discern (intended object of learning), what was made possible for students to discern in the task setting (enacted object of learning), and what students discerned as a result (lived object of learning). Looking across both interpretations, a fourth goal for graphing emerged, what graphs should represent. This fourth goal helped explain why some students had persistent conceptions of graphs as representing aspects of physical motion in a situation (e.g., a graph will turn like the toy car).

Drawing connections between theory and method

In Wolcott's (1994) interpretation phase of analysis, researchers strive to make meaning from the data. One way to make meaning is to turn to theory. In Table 1 we show the theoretical lenses, guiding questions, and student goals for graphing (bold) from Johnson et al. (2020). The text in italics addresses how interpretations from different theoretical lenses informed each other in the data analysis. For instance, employing Marton's theoretical lens has illuminated why some goals for graphing are more stable than others.

In the empirical study from Johnson et al. (2020), there is a relationship of "mutual affordance" between theory and method, as put forward by Chan and Clarke (2019). Neither Thompson's theory (1994, 2011) nor Marton's theory (2015) prescribed analytic techniques to follow Wolcott's (1994) process of description, analysis, and interpretation. Yet, the analytic approach allowed for interpretation from multiple theoretical lenses. While Johnson et al. (2020) employed a multifocal lens in the interpretation phase of Wolcott's process (see Table 1), it is not the only possibility. For instance, Johnson et al. (2020) could have conducted parallel passes of description, analysis, and interpretation for each theoretical lens, then made connections across those passes.

Table 1: A multifocal theoretical lens on Wolcott's (1994) interpretation phase of data analysis

Theoretical Lenses	Quantitative Reasoning Theory: Conceptualization (Thompson 1994; 2011)	Variation Theory: Discernment (Kullberg et al., 2017; Marton, 2015)
Guiding Questions	What are students' conceptions of attributes? How do students conceive of what graphs represent?	What is made possible for students to discern? What do students discern?
Three Student Goals for graphing	**(1) Graphs represent observable features of a situation.** **(2) Graphs represent change in a single attribute.** **(3) Graphs represent relationships between attributes.**	*Researchers intended goal 3 for students. All three goals were enacted objects of learning. Only goals 1 and 3 became lived objects of learning.*
A fourth goal	**(4) There are things that graphs "should" do.** *Students' notions of what a graph "should" represent can impact their graphing.*	

Discussion

Our aim was to address interplay between methods of qualitative data analysis and the networking of theories. We illustrated this interplay within Wolcott's interpretation phase of data analysis, putting forward a multifocal lens on data analysis to be an affordance of theory networking. Looking at the empirical study from Johnson et al. (2020), we illustrated how a multifocal lens on qualitative data analysis can explain complexities in students' reasoning.

We drew parallels between obstacles to mixing methods from qualitative and quantitative paradigms and networking theories in mathematics education. Researchers in both fields (Bikner-Ahsbahs, 2009; Bikner-Ahsbahs et al., 2019; Onwuegbuzie & Leech, 2005; Prediger et al., 2008) advocated for pluralism as a response to obstacles which framed challenges in terms of dichotomies (mixed methods) or competitions (mathematics education). With our discussion of Johnson et al. (2020), we intended to illuminate how pluralism can extend to both theory and method.

A look at researchers' methods, in conjunction with theories and paradigms, can be a way to respond to challenges related to a quest for coherence in mathematics education. To attempt to account for some of the theoretical diversity among researchers investigating students' mathematical reasoning, Goos and Kaya (2020) looked at methods employed across studies. Interestingly, they found the methods implemented to be less diverse than the theoretical perspectives employed. Furthermore, looking at methods helped them to draw connections between these studies, and earlier studies, conducted during an era in which there was less diversity in theoretical perspectives employed by mathematics education researchers. This approach dovetailed with Onwuegbuzie and Leech (2005), who recommended a focus on methods, rather than paradigms, to help to overcome perceived dichotomies between quantitative and qualitative methodologies. Although we limited the scope of this paper to qualitative data analysis, we believe it could apply to quantitative and mixed methods as well. Future steps could include principles and/or typologies for methodological approaches in studies in which researchers network theories.

We put forward a multifocal lens on qualitative data analysis as an affordance of networking theoretical approaches. With such a lens, researchers could analyze data sources from different theoretical perspectives, addressing multiple "focal constructs" (Chan & Clarke, 2021) in a single study. With this approach, we aim to advance the scope and depth of data analysis techniques when researchers employ multiple theoretical perspectives in a study.

Developing an analytical model for mathematical reasoning

Shaista Kanwal

University of Agder, Norway; Shaista.kanwal@uia.no

In this paper, I present an analytical model for mathematical reasoning that considers the effect of the learning environment in the formation of mathematical reasoning. The model is developed by incorporating elements from the conceptual framework of mathematical reasoning (Lithner, 2008) into cultural historical activity theory's (Engeström, 2014; Leont'ev, 1974) concept of activity. The principles of both theoretical stances and the networking approach are explained. The resulting model of reasoning processes is presented along with a brief discussion of its affordances and limitations. An example of data analysis is presented for the purpose of illustration.

Keywords: Mathematical reasoning framework, technological environment, cultural historical activity theory.

Introduction

Theory takes an intermediate position between research, problems, and practices (Silver & Herbst, 2007). It facilitates transforming commonsensical problems into research problems, understanding real life practices through research, and enables identifying problems from certain state of affairs. Mathematics education has no grand theory of its own that could guide on all sorts of matters of mathematics teaching and learning and could distinguish mathematical learning from learning in general (Silver & Herbst, 2007). Multiple theoretical perspectives, with mutually exclusive principles, guide research practices in mathematics education. The diversity of theories is considered as a resource as well as a challenge for the development of the field (Artigue et al., 2006; Bikner-Ahsbahs & Prediger, 2014; Ernest, 1998). Networking of theories is a research practice that promotes dialogue between different theories and seeks to find solutions to problems on the intersection of different theories. Lester (2005) suggests that mathematics education researchers should act as *bricoleurs* by adapting ideas from various theoretical sources to deepen understanding of teaching and learning of mathematics as well as to gain practical wisdom about the problems practitioners care about. Silver and Herbst (2007) call for developing mid-range theories that could inform a discrete variety of practices and study the subfields in mathematics education such as individual mathematical thinking, teaching and learning in classrooms, or mathematics teacher education. Lesh and Sriraman (2005) argue for approaching mathematics education research as a design science and call for developing conceptual systems that address the complex learning problems from multiple theoretical perspectives.

In this paper, I provide an example of networking of theories from my PhD research project in which I combine the conceptual framework of mathematical reasoning (Lithner, 2008) with cultural historical activity theory (CHAT) (Engeström, 2014; Leont'ev, 1974) to develop an analytical model of mathematical reasoning. In what follows, I argue for the need of the new model concerning the research aims. After that, I describe the two theoretical resources used and elaborate on the networking of them. I then present an illustrative empirical example for the developed model. At the end, I attend to limitations and affordances of the developed model.

Mathematical reasoning with regard to the learning environment

Mathematical reasoning is regarded as a vital constituent of mathematical learning. Mathematics curricula at different levels advocate for developing mathematical reasoning competence (Alpers et al., 2013; Niss & Højgaard, 2011). Some theoretical positions regard mathematical reasoning as an individual competence (Niss & Højgaard, 2011) while others regard the effect of the learning environment in forming the individual reasoning competencies (Lithner, 2008). However, previous studies consider the role of individual components of the learning environment, such as textbook, teacher, individual tools, and examination (tasks), in forming mathematical reasoning (cf. Granberg & Olsson, 2015; Lithner, 2000; Lithner, 2004; Olsson, 2019). A holistic perspective on learning environment accounting for both tools and social elements in the analysis of mathematical reasoning has rarely been taken up. In this paper, I seek to form an analytical model by benefitting from existing theoretical stances, which could guide the analysis of the role of the learning environment in the formation of mathematical reasoning.

Conceptual framework for mathematical reasoning

In the conceptual framework of mathematical reasoning (Lithner, 2008), reasoning is manifested in a task solving activity, which comprises the following four steps: i) getting a task or a problematic situation, ii) selecting a strategy, iii) implementing the strategy, and iv) reaching to solution. The step of selecting the strategy entails predictive argumentation, which concerns learners' reasons about why the strategy will work. The step of implementing the strategy entails verificative argumentation, which concerns reasoning for why the strategy did work.

The framework characterizes individual learner's mathematical reasoning as imitative or creative based on the anchoring of mathematical arguments. In creative mathematical reasoning, the learner creates a novel reasoning sequence in which the arguments are rooted in properties of mathematical objects. Imitative reasoning is founded in application methods, which are, for instance, given in textbooks or told by the teacher. The predictive and verificative argumentation is based on the authority of sources of information instead of the mathematical properties involved.

The research framework considers the learner's reasoning sequence guided or limited by individual competencies formed in the learning environment. Lithner's framework has also been used to study the effects of individual components of the learning environment such as textbook, teachers, and examinations (cf. Granberg & Olsson, 2015; Lithner, 2000; Lithner, 2004; Olsson, 2019).

Regarding methodology, the main data source are observations of students' solving of mathematical tasks along with written solutions, think-aloud protocols, pre- and post- interviews, and the textbook materials (Lithner, 2008). Multiple sources of data aid in triangulation and ultimately support trustworthiness of the interpretations. The research questions that the framework seeks to answer focus on distinguishing between creative and imitative mathematical reasoning of individual students, required in tasks administered in textbooks and examination tasks (Lithner, 2003; Palm et al., 2011), and facilitated by digital tools (Granberg & Olsson, 2015).

Cultural historical activity theory

In cultural historical activity theory (CHAT), object-oriented activities are arenas for human learning (Engeström, 2014; Leont'ev, 1974). Learning takes place when individuals participate in human activities. An activity is conceptualized as subject-object interaction at three subject-levels: collective subject, individual subject, and non-conscious subject (Engeström, 2014). Each level entails different forms of learning. The collective subject refers to a group of individuals as a whole and learning at this level concerns mastering the whole activity systems bringing changes into the activity systems.

The individual subject carries out actions through which the activity is realized. The individual actions are directed towards goals linked to the object of an activity. To perform goal-directed actions, the individual devises a plan, a tacit representation of the method to reach the goals, termed as a model. The model is regarded as the tool for carrying out the actions. Based on the way the model is selected, the learning is categorized as: a) productive, or b) reproductive. The productive learning happens when the subject finds a new model through careful experimentation. Reproductive learning refers to the subject selecting the model from previously known methods through blind search or through trial-and-error approach (Engeström, 2014).

The non-conscious human functioning refers to performing automatized operations during the activity. The learning at this level refers to formation of automatic operations and relates to tools in use. The tools at this level are the production tools such as writing instruments (Cole, 1996). The object is perceived as a fixed end and the subject attempts to reach to the object by making simple adaptations with regard to the conditions of the tools.

The action-goal and operation-condition layers are interlinked. That is, the actions upon enough practice may become operations and the operations upon alteration of the conditions of execution may rise back to the level of actions. In this sense, the learning at individual and non-conscious levels are intertwined and have implications for each other. That is, the model chosen at the action-goal layer influences the operations and the operations have implications for the action-goal level.

Regarding methodology, Nardi (1996) infers from CHAT the following four methodological aspects. First, the research frame should include time as human activities evolve over long periods of time. Second, the attention should be paid to large patterns and narrow episodic frames should only be used in view of large patterns. Third, multiple data sources should be considered to conceive the activity system from all possible angles. Fourth, the researcher should be committed to understand the subject’s object. The analysis of shorter episodes enables micro-analyses of processes within an activity and is to be linked to macro aspects of the activity at hand.

The common type of research questions concern exploring relationships between elements of an activity system that affect the realization of the activity’s object into the outcome. The individual subject’s functioning can be analysed in view of the conditions of the activity system.

Combining the two theories: A model of reasoning processes through a cultural historical perspective

The analysis of individual cognition lies at the core of the conceptual framework of mathematical reasoning (Lithner, 2008). In activity theory, the individual learner’s acts only make sense in view of other elements of the activity system. In the reasoning framework, the search and implementation of the strategy are the two main steps of the reasoning sequence. These two steps parallel to searching and implementing of the model in CHAT (see Table 1 for other parallel terms).

The reasoning framework regards mathematical reasoning as a product of the learning that already has taken place in a learning environment. Through activity theory, mathematical reasoning can be associated to the ongoing learning in the activity as the model selection links to productive or reproductive learning. Mathematical reasoning can be viewed as woven in the action-operation dynamics of mathematical learning activities.

Table 1: Parallel terminologies in reasoning research framework and activity theory

Mathematical reasoning framework	Activity theory
Mathematical task	Problem
Strategy	Model
Choosing a strategy	Selecting a model in action-goal layer
Implementing the strategy	Implementing the model in operation-condition layer
Creative mathematical reasoning	Productive learning
Imitative reasoning	Reproductive learning

Thus, I argue that the conceptual framework of reasoning and activity theory can be combined to deepen the understanding of the effect of the learning environment on reasoning processes. The mathematical reasoning process model is achieved by putting reasoning steps from the conceptual framework of reasoning into CHAT's concept of activity. The process of achieving the model is depicted in Figure 1.

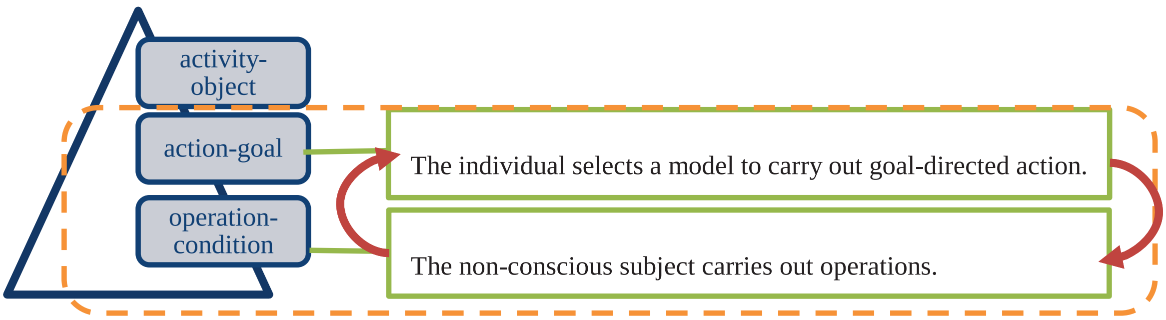

Figure 1: Conceptualizing reasoning processes through CHAT

In Figure 1, the triangle represents the hierarchical layers of the activity (Leont'ev, 1974) while the dotted border shows that the reasoning is entailed in the bottom two layers. That is, the steps of selecting and implementing strategies, the main constituent steps of reasoning when solving a task, are weaved in the action-operation dynamics of the activity (Figure 1). The step of selecting a strategy takes place in the action-goal layer in the form of model selection. The implementation of the strategy takes place in the operation-condition layer (as shown in Figure 1). The fact that the actions and operations in CHAT affect each other implies that the steps of selecting a strategy and implementing the strategy also affect each other (shown with arrows in Figure 1).

The conceptual framework of reasoning provides an outer structure to mathematical reasoning through the two main steps of reasoning. CHAT provides an additional layer to how- and why-aspects of mathematical reasoning and adds an internal dynamic to the reasoning process. That is, CHAT not only allows looking into how reasoning takes place but facilitates understanding why certain actions (e.g., choice of strategies) take place in relation to the condition of the environment (e.g., tools, division of labour). In this way, it allows not only distinguishing between creative and imitative aspects of reasoning to its parallel forms of learning in CHAT, productive and reproductive learning, but also enables analysing the underlying contributing factors from the learning environment. In particular, the action-operation dynamics allow analysing effects of one step onto the other (as shown in Figure 1). Moreover, the role of tools can be analysed clearly and systematically. For instance, the model (Figure 1) enables analysing whether and how the tool operations effect the goals and the selections of models.

In terms of networking strategies (Bikner-Ahsbahs & Prediger, 2014), the practice is regarded as *combining* because the elements from the two theories in concern are fitted together to gain understanding of the empirical phenomenon of mathematical reasoning. In combining theories, the theories do not need to be compatible with regards to their principles as is the case with the theories in consideration — the conceptual framework and CHAT. The resulting conceptual framework is not a theoretical framework but a bricolage for understanding of the phenomenon of reasoning.

An illustrative example of the use of the model

Below, I present an episode from undergraduate engineering students' activity in a digital environment. The data belongs to a larger study, which focuses on student's activities in paper and pencil and digital environment (cf. Kanwal, 2019). This example concerns two students' work on the following task: Solve a definite integral $\int_{-1}^{1} e^{-j\omega t}\, dt$, where j is the complex number with $j^2 = -1$. The definite integral can be solved as follows.

$$\int_{-1}^{1} e^{-j\omega t}\, dt = \frac{-1}{j\omega}\int_{-1}^{1} e^{-j\omega t}\,(-j\omega)dt = \frac{-1}{j\omega} e^{-j\omega t}\Big|_{-1}^{1} = \frac{-1}{j\omega}\left(e^{-j\omega} - e^{j\omega}\right)$$
$$= \frac{j^2}{j\omega}\left(e^{-j\omega} - e^{j\omega}\right) = \frac{j(e^{-j\omega} - e^{j\omega})}{\omega} \quad (1)$$

By using Euler's formula, $e^{j\omega} = cos\omega + j\ sin\omega$ for any real ω, in (1), one gets:

$$\frac{j(e^{-j\omega} - e^{j\omega})}{\omega} = \frac{j[(cos\omega - j\ sin\omega) - (cos\omega + j\ sin\omega)]}{\omega} = \frac{j(-2jsin\omega)}{\omega} = \frac{2sin\omega}{\omega} \quad (2)$$

In the participants' activity, Per and Jan searched on the Internet to make the Maxima code, "j: sqrt (-1); A: e^(-j*w*t); integrate (A, t, -1, 1)". The maxima code served as the model being constructed through the use of Internet with the focus on syntax in Maxima. Involving this model, the task was translated into a Maxima code without the need of taking any integration into consideration.

Later in the implementation phase, Per ran this command, which generated the output, $\frac{\%\mathrm{i}}{\mathrm{e}^{\%\mathrm{iw}}\log(\mathrm{e})\mathrm{w}}$ - $\frac{\%\mathrm{ie}^{\%\mathrm{iw}}}{\log(\mathrm{e})\mathrm{w}}$. The solution is apparently different than the solution given in the textbook ($\frac{j(e^{-j\omega}-e^{j\omega})}{\omega}$ or $\frac{2sin\omega}{\omega}$). The difference is due to the appearance of the two additional terms, %i and $log(e)$, in the Maxima output. In Maxima, $log(e)$ refers to natural logarithm of e. The reason why Maxima did not evaluate $log(e)$ into 1 and produced this term in the output is that Per did not specify 'e' as Euler's number in his input command. The Euler number e is specified by %e in Maxima whereas Per just used 'e'. Also, the term %i represents the imaginary unit, sqrt (-1) in Maxima. Per denoted the imaginary unit with the symbol 'j' in his input command and Maxima replaced it with %i in the output. Replacing $log(e) = 1$ and $\%i = j$ in the output, one gets the textbook solution form.

$$\frac{\%i}{e^{\%iw}log(e)w} - \frac{\%ie^{\%iw}}{\log(e)w} = \frac{j}{e^{jw}w} - \frac{je^{jw}}{w} = \frac{j(e^{-jw}-e^{jw})}{w}$$

Per opened the textbook on the page where the task and its solution were given. Per then remarked on the solution as follows.

131	Per:	That's probably correct, right? It is just that it is written in a way that is crazy hard to…
132	Jan:	Yeah. Probably… Look at the command line for it. What did you write there? [Jan looks at Per's screen whilst preparing to write on his own laptop]
133	Per:	First you have to write… define j.
134	Jan:	Is it so important to write semicolon at the end and that you hold down shift enter?
135	Per:	Yeah. Then you avoid those things… Then it becomes %i and %i is just a symbol that it is…
136	Jan:	It is something.
137	Per:	Yeah, that it is complex…
138	Jan:	Yeah.

Per's suggestive question (131) "that's probably correct, right?" indicates that Per was speculating that the solution was correct. The second part of Per's statement, "it is just that it is written in a way that is crazy hard to…", elucidates that he was aware that the form of the solution was different, and that the participant found the different form difficult to comprehend. Jan also did not seem to be sure, as he replied, "yeah, probably" and started examining the Maxima code by saying "look at the command line for it. What did you write there?". Per responded by reading the command line and pointed out (135) that "%i is just a symbol that it is…", and Jan adds instantly, "it is something". Per completed his sentence by saying that "yes, it is complex" which shows that Per was aware that "%i" represented the imaginary unit in the output. There were no comments regarding the term $log(e)$ and it was probably the main term that was inconceivable. Later, the students ended the discussion by saying that they would ask the lecturer about the correctness of the solution.

This example elucidates only one aspect of the developed reasoning process model, i.e., the manner of model selection affects the model implementation (indicated with the downward arrow in Figure 1). The example shows that the students selected the model in the form of the Maxima code that led them bypass the mathematical operations. The nature of required operations shifted from mathematics to syntax in Maxima. The final solution was correct; however, they were not able to comprehend it due to unfamiliarity with language and symbolism used in Maxima. Based on the implementation phase, the students revisited the initial model to see if it was correct. As the model was a conversion of the integral into Maxima code, the only thing to check was the syntax in Maxima. There were no mistakes in the model (code) and, therefore, the model was not changed. In this particular task, the availability of Maxima shifted the focus away from the integration in itself and the students became more engaged with syntax related issues. The availability of Maxima thus affected the reasoning process in an undesired fashion in this particular example, as the students did not engage with the involved mathematics. Using the developed model (Figure 1) in this example enabled to analyse the reasoning process in the form of individual actions and tool operations rooted in the conditions of the environment. The material conditions of Maxima affected the individual actions and the execution of operations, and hence the reasoning processes, as seen above.

Limitations of the model

The proposed model can only be used in the analysis of reasoning within activities and cannot be used for the analysis of short episodes without understanding the overall activity system. The model also does not guide the analysis of peer interactions while it may enable to consider social actors as division of labour, rules, and the community. Moreover, the reasoning will be interpreted from actions and operations, which may or may not be accompanied by utterances. This requires additional data in terms of stimulated recall interviews in order to make trustworthy interpretations from the data although it will only give access to the activity in an indirect way.

Understanding mathematical work and mathematical thinking through individuals' actions analyses: a networking approach

Alain Kuzniak[1] and Assia Nechache[2]

The theory of Mathematical Working Space (ThMWS) provides theoretical and methodological tools to describe and characterize mathematical work. A particular methodology has been developed to analyse actions produced by subjects when they perform mathematical tasks. In this paper, this methodology is introduced by an example of a geometrical task. Then, we show how two theories on knowledge construction based on actions were combined with ThMWS. Finally, we present the contributions drawn from these networking cases which provide insight into mathematical work as well as the thinking of subjects by articulating their knowledge and actions.

Keywords: Mathematical Working Space, mathematical work and mathematical thinking, action and knowledge, methodology.

Introduction

Within the theory of Mathematical Working Space (ThMWS), the understanding of mathematical work is mainly supported by the analysis of the actions, which students and teachers perform in the school context. In this paper, we wonder how to better understand the cognitive dimension of mathematical work and we explore this issue through common analysis of actions with some cognitive approaches.

We first justify why actions can be used as a common key-point for discussion between ThMWS and cognitive theories. After giving some of the key-constructs of the ThMWS used in the paper, we provide an example to introduce the methodology we have implemented to account for the mathematical work of individuals performing mathematical tasks. We then consider how research using both ThMWS and Abstraction in Context (AiC), or APOS theory, has opened up other avenues to describe and characterize the articulations between actions of individuals and their knowledge. It is thus possible to better understand subjects' mathematical work and mathematical thinking.

Articulating mathematical work and mathematical thinking through subjects' actions analysis

The approach of teaching and learning issues using the notion of mathematical work is relatively new in the field of research on mathematics education. Indeed, the great majority of research on teaching and learning refers to the idea of mathematical thinking as CERME conferences indicate through the topics of the working groups on mathematical contents. These topics have long been expressed in the form of specific modes of thinking such as algebraic thinking, geometric thinking, and probabilistic thinking. The focus on "mathematical thinking" urges to attend “thinking” with the real risk of dissolving the mathematical specificity in all the fields, which are concerned with thinking. Indeed, the study of thinking supposes a multiplicity of approaches, which are often far apart from mathematical concerns.

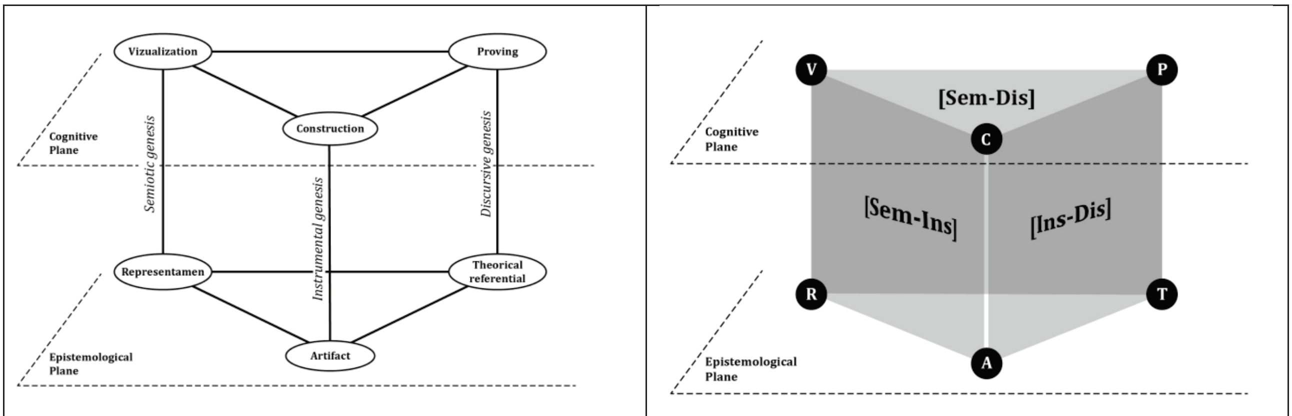
Recently, cognitive sciences have also approached thinking through cognition with the objective of being "the science of thinking". The cognitivist current is itself a composite combination of disciplines such as neuroscience, artificial intelligence, the phenomenology of perception, etc. This current is probably at the origin of the collapse of the primacy of mental representations for the benefit of action in the field of mathematics education. In this view, action is prior to mental representation as the neurobiologist Berthoz (2008) endorses it, and thinking and consciousness relate directly to action and perception. This viewpoint is not new in the field and was already pointed out in his *genetic epistemology* by Piaget who considered that mathematical thinking is not “pre-formed but a creation constantly pursued by actual and new actions which open a new set of possibilities hitherto inconceivable” (Piaget, 1957, p. 34). The support of cognitive sciences gives this approach a new visibility.

This change of perspective on mathematical thinking is valued from the point of view of ThMWS and more generally of studies that favour an entry through mathematical work. In this case, the focus on work naturally places action as a key theoretical and methodological tool in the study of mathematics teaching and learning in school contexts. However, considering mathematical thinking and mathematical work as complementary seems to be necessary to account for the complexity of school mathematics. In particular, some cognitive theories, such as AiC and APOS, focus on the construction of abstract mathematical knowledge and can both complement and benefit from approaches to mathematical work that focus more on the outcomes and processes of work.

Describing and characterizing mathematical work: the ThMWS approach

The theory of MWS: motivations and issues

In the theory of MWS (Kuzniak et al., 2016), mathematical work is considered as intellectual work that involves significant cognitive activity of which the orientation and purpose are defined and supported by mathematics. In this framework, mathematics is envisaged as a specific human work and therefore, mathematical work is seen in both its cognitive and epistemological dimensions.



The Mathematical Working Space (MWS) | The vertical planes of the MWS

Figure 1: The MWS diagrams

To grasp the specific activity of students solving problems in mathematics, the two epistemological and cognitive facets of mathematics are present and articulated in two planes: one of an epistemological nature in close relation to the mathematical content; the other of a cognitive nature, related to the visible action of the individual solving problems (Figure 1, left). Three components in interaction are introduced for the purpose of describing the work in its epistemological dimension: a set of concrete and tangible signs (R), a set of artefacts (A), and a theoretical system of reference (T). The second level is centred in the subject; three cognitive components are introduced as follows: visualisation (V) related to deciphering and interpreting signs; construction (C) depending on the used artefacts and the associated techniques; proving (P) conveyed through discourses producing validations, and based on the theoretical system of reference.

Analysing mathematical work through ThMWS aims at tracking down the process of bridging the epistemological plane and the cognitive plane in accordance with three different geneses: An instrumental genesis (Ins) related to the use of artefacts, a discursive genesis (Dis) related to theoretical part of work, and finally a semiotic genesis (Sem) that expresses the importance of signs for mathematical work. The elaboration of mathematical work is perceived as the harmonious networking and intertwining of these geneses within the vertical planes of the diagram (Figure 1, right).

To achieve the description and characterization of mathematical work, studies performed within ThMWS theory are based on the analysis of the subject's various actions. Thus, the methodology of studying subjects' actions is central in the approach and is developed in the next section.

A cognitive analysis of subject's actions: The example of Alphonse's Parcel

Our starting point is that cognitive activities of a subject at work are not directly observable but they can be deduced from the visible actions of the subjects when they are performing mathematical tasks. The methodology we use must both consider mathematical content and give access to subjects' cognitive processes. We have chosen to introduce our methodology by an example, which is used along the text to show the combination of the different theories involved in the networking study: Alphonse's parcel (Kuzniak & Nechache, 2021). The task statement is given in the form of a text to be read.

> Alphonse has just returned from a trip in Périgord where he saw a parcel of land in the shape of a quadrilateral that had interested his family. He would like to estimate its area. To do this, during his trip, he successively measured the four sides of the plot and found, approximately, 300 m, 900 m, 610 m, 440 m. He's having a hard time finding the area. Can you help him by showing him the method to be followed?

Data given in the task does not enable to find a unique solution to the problem because quadrilaterals with the same side lengths can have different forms and areas. However, the majority of students used the following very common Theorem in Act (TiA): figures with the same perimeter or the same side lengths have the same area. The main objective of the whole didactic situation explicitly destabilized the students and helped them to banish this false Theorem in Act.

To give a general overview of our methodology, we provide an analysis of Francis's solution of the problem. It is based on a corpus of data collected during the resolution of the mathematical task.

This corpus consists of his written and oral productions. We start dividing his activity into episodes. Each of the episodes is related to a sub-task self-prescribed by the student to achieve the global task: it includes a sequence of mathematical actions that lead to the realization of the sub-task. All the actions are analysed in detail by using ThMWS. The MWS diagrams are also used to visualize the circulation of work during the resolution of the task (Kuzniak & Nechache, 2021).

Table 1. Francis' work division in three episodes each with two actions.

Episode 1: Construction of the figure	Episode 2: Justification of the nature of the figure
	I took the large base 900 m then from the two ends of the 900m with the compass, I made 440 on one side and 610 on each side and then with the ruler I tried to find the 300 with the two arcs of circle. I drew a perpendicular to the large base and this line perpendicular to the large base was also perpendicular to the small base of 300m and as two lines are perpendicular to the same line, they are parallel so it makes a trapezoid.
Action 1: Choice of scale Action 2. Construction of the figure	Action 3. Francis' explanation of his construction Action 4. Francis' description of the fact that it is a trapezium.
Episode 3: Determining the area of the figure. Action 5: Measurement of the height h of the trapezoid Action 6: Calculation of the area from the formula *(B+b). h/2*	

Then a bottom-up analysis gives a summary overview of the different episodes, and helps to deduce the logical organization of Francis' mathematical actions. The analysis seeks to identify how the work-generating processes interact within the components of MWS. From the data, we surmise that mathematical work produced by Francis is triggered by the referential and initiated in the [Sem-Ins] plane to construct a convex quadrilateral with the shape of a trapezoid using technological tools. These tools are used by the student as semiotic tools to collect data and make measurements. Construction of the quadrilateral is then justified with the use of theoretical tools characterizing the trapezoid. The formula for calculating the area of a trapezoid (technological tool) is applied to produce the result (in this case, the area of the land). To conclude the analysis, observations made during the two previous steps are used to characterize the mathematical work. In Francis' case, we may consider that his work circulates through the different geneses and planes of the MWS diagram. He uses drawing and measure tools to support his reasoning and argues about a particular figure, so his work is compliant with a geometrical paradigm based on measurement and drawing

(Geometry I, see Kuzniak & Nechache, 2021). Finally, his mathematical work is not mathematically correct, as the result is false and based on a construction of an inappropriate figure and TiA theorem.

The description above provides the most accurate account possible of the student's choices and actions. However, it is sometimes difficult to be sure, of what really triggered and motivated these actions. Some of Francis' actions are material and easy to interpret, such as constructing the trapezium, but others are more challenging. Why did he choose to use a scale for the construction and then measure in the drawing? When did he focus on the trapezoid? Why didn't he finally see his mistake? To progress with the interpretation of subjects' actions, we explore other methods of action analysis based on theories, which are rather focused on mathematical thinking.

Combining ThMWS with cognitive theories

Several studies have combined ThMWS and cognitive theories. In this paper, we only refer on the studies with AiC and APOS. For each research, we first present its general purpose and introduce the method, which the authors used. Then, we apply this method to Alphonse's task and show the new contribution that can be drawn from the approaches to advance the analysis of Francis' actions and progress in its understanding.

A joint study between the AiC and MWS theories

In their study of the development of functional thinking of students working in four different MWS, Psycharis et al. (2021) combined Abstraction in Context (AiC theory, Dreyfus et al., 2015) and ThMWS. Using a task on the optimal shape of a gutter, they analysed students' progress in their understanding of covariation by having them work successively on four gutter models in different environments (sheet of paper, DGS, etc.). Each of these models is associated with a different MWS. The connections between these MWS are described and explained thanks to the MWS geneses involved. This first analysis through the MWS theory is completed with the AiC theory to account for the processes of constructing abstract mathematical knowledge. In this theory, abstraction is defined as an activity of vertical reorganization of previous mathematical constructs into a new abstract construct. According to the authors, the process of abstraction passes through three stages of knowledge construction shaped by three epistemic actions: recognizing (R), building-with (B) and constructing (C). These actions are nested. They allow tracing the process of knowledge construction and are used as a methodological tool for analysis.

Using AiC for Alphonse's solution of the task, we first focus on *recognizing*. If we look again at episode 1 (figure construction), we surmise that the student *recognized* a construction problem as a previous meta-construct (R0) for which he knew mathematical knowledge involved in the figure construction. While constructing, using the given side lengths but ignoring the word "successive", he recognized (R1) a partially correct construct, a trapezoid, and with it its area formula, another previous construct (R2). Thus, he realized its shape by an approximation and calculated its area via measuring, the latter being a building-with (B) action built on the recognized constructs. The mathematical object "trapezoid" determines the follow-up of Francis' work and as it is only partially correct, he cannot construct the expected knowledge about the various areas of quadrilaterals having the same side lengths –construction of a new construct (C). In the example of the work carried out by Francis, the mathematical object named “trapezoid” is considered under different aspects during the completion of the task and referring to the three components of the epistemological plane: its drawing aspect (representamen), the material artefact aspect (ruler, compass, square) or symbolic artefact (area calculation formula) associated with the trapezoid, and its property and definition. All these elements constitute what we call the Epistemological Entity associated to the trapezoid overlapping with what is called Context in AiC.

The subject’s visualization of the "trapezoid" object as being a quadrilateral with two parallel lines, his construction of a figure and the area with techniques associated with the artefacts to develop the trapezoid, and his justification of these constructions by citing the properties that characterize the trapezoid are all part of what we name the Cognitive Unit associated with the mathematical object “trapezoid”. Identifying the existence and role of the Cognitive Unit and Epistemological Entity associated with the mathematical object “trapezoid” enables to characterize the mathematical work and understand mathematical thinking in terms of epistemic actions developed by AiC.

A joint study between the APOS (Action, Process, Object, Schemas) and MWS theories

In her research, Camacho (2021) uses the APOS (Arnon et al., 2014) and ThMWS together to study the linear algebraic concepts of eigenvalues and eigenvectors in relation to their geometrical representation in the plane. This study helps to further consider *action* by underlining the diversity of meanings of this term. Indeed, in the APOS theory, which assumes the heritage of Piaget, the term Action is one of the basic terms of the theory. The acronym APOS stands for Action, Process, Object and Schema. The action to which it refers is a mental structure that must be distinguished from "material action", which Dubinsky interpreted as actions that are performed by a subject but are external to the subject (Arnon et al., 2014, p. 7). From a set of actions on objects, the subject can derive a property arriving at a more general Action that allows passing from Action to Process through the mental mechanism of *interiorization.* The mechanism of *encapsulation* then transforms the Process into an Object as a cognitive entity. A Schema is then build by acting on the mathematical object. In her research methodology, Camacho applies an approach, specific to APOS theory, which consists of discovering the cognitive functioning of subjects according to their failure or success about an Object in some mathematics tasks. It is then a matter of recognizing, which of the components of the quadruplet (APOS) is operative or not. In Alphonse task, the starting point of the analysis is an initial reflection on the mathematical Object, with its Schemas, which is at stake in the situation. For us, it is the Area of a quadrilateral (Object) and this area is associated to a decomposition by triangulation (Schema) or more generally to the triangulation of any polygon, (Kuzniak & Nechache, 2021). Francis however, activates another scheme acting on another mathematical object: he constructs a trapezoid by approximation and calculates its area with a formula via measuring. The actions as conducted do not lead to processes of building the area of a quadrilateral with the given side lengths because he elaborates the schema of an already existing mathematical object (trapezoid area), which is insufficient for the task.

In APOS, authors seek to elaborate the genetic decomposition of the Object of concern to be more precise in their analysis. Camacho elaborates the genetic decomposition of the Object "collinearity" within a digital environment and in terms of the different MWS geneses. When we analyse Francis' work with the MWS, we may notice that he relies on his old and well-established knowledge of the trapezium of which he knows both the different elements (signs, artefacts, properties) in relation to what we referred to as the Epistemological Entity associated with the trapezium. He also knows the cognitive processes related to the use of the corresponding cognitive unit. He knows well the Object "trapezoid", unfortunately, it is not the right Object, which should be used to perform this task about the area of a generic quadrilateral. The case of Francis shows that students do not really regulate their work once they have embarked on a solution that seems to be in line with their knowledge. An illusion of knowing-how that fosters certainty in action emerges. In the example, it was however possible to see that the order of the sides used in the construction was not the one indicated by the statement (semiotic control). It was also possible to see that different quadrilaterals fulfilled the same condition since Francis searched, by approximation, among these figures the one with parallel sides (semiotic and instrumental control). An internal control of the instruments (instrumental control) should have been based on another construction without approximation. Finally, it is interesting to see that his proof reasoning is biased to reach the desired result (discursive control).

Conclusion and perspectives

All of the studies we reviewed emphasise that ThMWS and its organization around the three geneses was an important structuring element in the analysis of actions and helped to describe and better understand the relationship between cognitive and epistemological aspects. Conversely, the triadic and prismatic geometric structure of the MWS generates theoretical notions that are not always easy to interpret as a tool for studying issues of mathematics teaching and learning. However, these joint studies on students' mathematical actions focussing on cognitive aspects enrich and flesh out a number of emerging notions in ThMWS. In particular, they have provided us with a better understanding of the importance and value of the following ideas:

1. The Epistemological Entities and Cognitive Units account for the importance of knowledge and cognitive functioning of individuals who perform a task using particular mathematical objects. To achieve description and characterization of mathematical work, which captures adequately interactions between cognitive and epistemological aspects, it is important to make visible the mathematical knowledge involved in the solution by identifying precisely the components of the Epistemological Entity and the Cognitive Unit associated with a mathematical object

2. These Cognitive units and Epistemological Entities depend on forms of work implemented, which can be described by different paradigms associated with the teaching contents. Based on AiC epistemic actions and on APOS contributions, it is thus possible to describe how the observed work conforms to particular modes of mathematical reasoning.

3. Finally, we have also made progress in understanding the regulation and control of outcomes through the importance of knowledge and cognitive repository as tools for regulating actions. However, we also met the attracting force of an “illusion of knowing” on acting.

The question of actions regulation and control is a research direction that we plan to develop further. Controls and regulation questions are not new in the field of mathematics education, it has existed since at least the first research on problem solving, seeking to make students more autonomous. Particularly Arzarello and Sabena (2011), who also emphasise the variety of actions implemented by students and the teacher, have recently addressed this. They have analysed the way in which gestures, considered as a semiotic resource, intervene in the learning and teaching process of mathematics. This extension of research to gestures and the body raises the question of how to analyse and identify their real impact on students' actions and beyond on their mathematical work and thinking. We are now engaged in a new project (E-ESMEA) dealing with enacting in astronomy education. We are mainly interested in the mathematical part of the project: relations between proportionality and velocity. The project focuses on the concept of embodied action, which assigns a key role to perceptual and bodily processes in the formation of abstract concepts and knowledge. The sensory-motor engagement of the body carries these processes in situations out that constitute the functional system, on which actions are based. From this study, we expect that it will help us to identify the limits and the right levels of analysis of mathematical action that are really necessary to advance in the mastery of mathematical work and in the learning of mathematical knowledge. This is, in our opinion, a fundamental question to develop a didactic approach in phase with the school reality.

Keywords: Methodological tool, describing mathematical work, characterizing mathematical work, forming mathematical work

The theory of Mathematical Working Space (Kuzniak & Nechache, 2021), provides theoretical and methodological tools to study three main issues on mathematical work: its description, its characterization, and its formation and/or transformation. Description and characterization of mathematical work help to understand and then to transform it, especially when it is not correct. We intend here to show how focusing on these three issues can help to design didactical situations based on the theory of Mathematical Working Space (MWS).

Describing mathematical work

Describing mathematical work aims at capturing the work undertaken in an educational context. The description is based on the constructs of MWS theory and has an explanatory purpose.

Describing the development of mathematical work within a mathematical domain

In their research on the teaching of geometry, Kuzniak and Nechache (2015) used the theory of MWS to describe the different components and processes of the work as they emerged during a teaching sequence (consisting of 5 sessions) on the notion of the circle in Grade 4 - 6 lessons. In their study, they introduce the use of a "comics" as a set of MWS diagrams to give a global and quick vision of the development of mathematical work throughout a teaching sequence.

Describing the circulation of work between different mathematical domains

Derouet's (2017) research on the teaching of continued probability distributions in high school classes to describe the interactions and circulations between mathematical domains and subdomains. She used of coding (red for what is the students' responsibility, green for the teacher) combined with the MWS diagram. This enabled to highlight the various transitions between different MWS associated with three domains: Probability, Statistics, and Integral Calculus during the completion of task by students (high school).

Describing the subject's personal work

To provide an account of the mathematical work actually produced by student teachers, Kuzniak and Nechache (2021) designed an analysis method based on a division of the students' activity into episodes. Each of these episodes comprises a sequence of mathematical actions, which lead to achieve a subtask. In this view, each episode corresponds to a sub-task self-prescribed by a student and includes the sequence of mathematical actions used to solve the task. All these actions are then analysed in great detail using the theory of MWS.

Characterizing mathematical work

The objective of characterizing mathematical work is to identify certain invariants from the description of work.

Cognitive unit associated with a mathematical entity

To Kuzniak and Nechache (2015), the mathematical work is structured according to a cognitive unit associated with a mathematical entity. In this way, they differentiate the cognitive and epistemological aspects of a mathematical object. The mathematical entity associated with a mathematical object is defined as being a triplet of elements of the epistemological plane, composed of representamen or signs, artefacts, and the mathematical properties and definition associated with the object. This Cognitive Unit is generated from the interaction of the three MWS geneses: instrumental, semiotic, and discursive (Kuzniak & Nechache, 2021), which trigger the cognitive processes.

Forms of mathematical work

Kuzniak and Nechache (2021) sought to characterise forms of mathematical work developed by students preparing for a master's degree. The authors gave three criteria for assessing the process, outcome, and circulation of mathematical work in the MWS: compliance, correctness, and completeness.

Forming mathematical work

Research on the formation or transformation of mathematical work aims to build a new structure for the epistemological plane of work or to provide a new structure for the cognitive plane. The method used by Reyes (2020), to develop and form mathematical work around the notion of 'function' to make it more accessible to students, is based on task design using the theory of MWS. Reyes uses MWS theory to account for the flow of mathematical work produced by students (using the MWS diagram) and to analyse how the work was completed.

Struggling with the problem of complexity or how to (not) arrive at a general theory of what happens in mathematics classrooms

Felix Lensing[1] and Roland Pilous[2]

[1]Freie Universität Berlin, Berlin, Germany; lensing@zedat.fu-berlin.de

[2]Fachhochschule Nordwestschweiz, Basel, Switzerland; roland.pilous@fhnw.ch

For about half a century now, it has been known and widely discussed that the field of study of mathematics education research is extremely complex. In mathematics classrooms, mathematics emerges from a complex interplay between bodily, cognitive, and social processes; and the crucial question for mathematics education research is: How can we develop methodical and theoretical means to 'tackle' these complexities? Given this challenge, which we will call the complexity problem, this paper aims at two things: First, to indicate at what point we think two well-known theories, namely Ernst von Glasersfeld's Radical Constructivism and Anna Sfard's Theory of Commognition fail at the complexity problem; and second, to attempt to point out an alternative route to a general theory that might be able to account for the complex dynamics between the bodily, cognitive, and social dimension of mathematics classrooms.

Keywords: complexity, transdisciplinarity, the social turn, commognition, radical constructivism

Introduction: The complexity problem

For about half a century now, it has been known and discussed that the field of study of mathematics education research is "characterized by an *extreme complexity*" (Steiner, 1985, p. 11). In order to provide some evidence for this thesis, it is, we think, helpful to take a look at the 'prototypical' object of study – the mathematics classroom – and ask: What does actually go on in there?

First of all, in every mathematics classroom there is communication that takes place. Teachers and students talk about mathematical topics, about mathematical problems and their solutions, and of course also about extra-mathematical issues (e.g. about an upcoming class trip). Regardless of how much the *particular forms* of communication may vary from one classroom to another, one will always observe *some* sort of communication processes between teachers and students. So, the first aspect that must be considered when answering the question above is communication – or, more general: *the social dimension* of mathematics classrooms. Now when social processes unfold, at the same time, numerous cognitive activities take place. Both teachers and students are presumably thinking, imagining, expecting, or fearing something when participating in classroom communication. Thus, besides the social dimension, there is also *the cognitive dimension* of mathematics classrooms that must be taken into account. Finally, a third area also comes into play: *the bodily dimension* of mathematics classrooms. Whether teacher or student, everyone participates with his or her body in the classroom – be it sitting, standing, walking or lying – and, for instance, reacts completely different to social events on the neuronal level than on the cognitive level.

So, one is always confronted with the *simultaneity* of at least three different kinds of processes – namely, the simultaneity of bodily, cognitive, and social processes – that are involved in one way or another when mathematics is constituted in the classroom. Now the crucial point about these three kinds of processes is that their simultaneity rules out the possibility of one of them being considered ‘the’ cause of the other two. It is rather that each of the three dimensions obeys its own logic. Each dimension (and that justifies the use of this metaphor) is able to vary independently from the other two dimensions. And yet it is precisely this complex web of bodily, cognitive, and social processes that one inevitably encounters in the study of mathematics classrooms.

This brief description of what happens in mathematics classrooms leads to a more general problem, which lies at the core of research in mathematics education: How can we, as mathematics education researchers, handle the extreme complexity of our field of study? How can we design theoretical and methodical tools which can account for the complex relationships between the bodily, cognitive, and social dimension of mathematical activity in its many facets and forms? It shall be this fundamental challenge to research in mathematics education which we will call *the complexity problem*. Once the complexity problem has been identified, it becomes apparent in what a difficult situation research in mathematics education finds itself in. For to arrive at a theory capable of accounting for the complexities of mathematical activities in educational contexts, the analytical tools of psychology, sociology, or biology are not sufficient. If we ask, for instance, for the conditions of success of a teaching-learning process in a mathematics classroom, we ask about a process that lies perpendicular to the boundaries between these three disciplines: Mathematical teaching-learning processes are processes that require cognitive activities on the part of both students and teachers, and these activities, in turn, depend on neural activities and other bodily processes. If one now continues and asks how teachers can teach and students can learn what they are taught, one encounters the mediating function of communication. Teachers affect the cognitive activities of their students and students affect the cognitive activities of their teachers by participating in communication. To ask about the conditions of success for such complex processes, thus, means to choose a unit of analysis that goes beyond the respective ‘fields of responsibility’ of the three disciplines. Because here it is about the question of the possible *relationships* between the social, cognitive, and bodily dimension of classroom events.

But how do we deal with this situation in our field? Is the complexity problem already solved? Are there theories that are not only able to describe either the bodily, the cognitive, or the social dimension, but all of them together with their interrelationships? And on what grounds can such a general theory be built? These are precisely the questions we would like to explore in this paper.

From the cognitive to the social dimension and back again

We begin with a brief look at the history of mathematics education research and discuss how two theories – Glasersfeld’s *Radical Constructivism* (1) and Sfard’s *Theory of Commognition* (2) – struggle with the complexity problem. By choosing these two much-discussed theories, we aim to show that the complexity problem is indeed of key importance for research in mathematics education. Thereby, we will focus on one aspect of the complexity problem, namely, how to theorize the relationship between the cognitive and the social dimension of teaching and learning in mathematics classrooms.

(1) *Radical Constructivism* is based on the assumption that only the mind of an individual can be considered as the ‘bearer’ of knowing and knowledge. To Glasersfeld, all processes of knowing –

and thus also: all knowledge structures – must be located in the mind of an individual. But how does one get from this focus on cognitive activities of the individual to the social dimension? Against all critics who accuse Piaget of not paying attention to the social dimension, Glasersfeld argues:

> But the child's experiential world also comes to contain other people, and the almost constant interaction with them is an even richer source of perturbation and consequent accommodations. Piaget has stressed many times that the most frequent cause of accommodation is the interaction, especially linguistic interaction, with others. Yet he is often criticized for not having taken into account the social component. (Glasersfeld, 2003, p. 66)

If a child calls a rectangle 'square', then it is corrected in communication; and this communicative correction then leads in many cases to a *perturbation* (i.e. to a disappointment of its expectation that the word 'square' fits these environmental circumstances) and then perhaps to an *accommodation* (i.e. to an alteration of its knowledge base through an adjustment of this expectation). Thus, without a doubt, it is possible to account for the social dimension from the standpoint of Radical Constructivism. But the social is considered only insofar as it appears on the 'screen' of an individual mind. Social events can be investigated for their causal contributions on the individual's cognitive development. They have the character of an *external* 'source of perturbation', which may then lead (or not lead) to an *internal* reorganization of what an individual knows and believes. Hence, Radical Constructivism is and remains a purely psychological perspective on the social. The 'unit of analysis' is the individual knower and his or her processes of knowing.

It was *this* unit of analysis that a number of researchers objected to in the second half of the 1980s. The representatives of this new 'movement', which Stephan Lerman called 'the social turn in mathematics education research' a decade later, no longer had in mind the study of the social from the perspective of an individual mind.

> The *social turn* is intended to signal something different; namely, the emergence into the mathematics education research community of theories that see meaning, thinking, and reasoning as products of social activity. This goes beyond the idea that social interactions provide a spark that generates or stimulates an individual's internal meaning-making activity. (Lerman, 2000, p. 23)

From this standpoint, the social should thus be understood from within itself. To account for the fact that the social obeys its own logic, the unit of analysis was shifted from the cognitive to the social dimension. Although familiar concepts such as knowing, learning, or meaning continued to be used, these concepts were no longer tied to the mind of the individual, but were located in the social. The question was no longer, 'How do social events influence the constructions of an individual mind?'. But rather, 'How is the individual mind participating in the social?'. Researchers of the social turn began to study cognitive activities from the perspective of the social, and the crucial question then became whether the individuality of the individual could still be accounted for in this way:

> A major challenge for theories from the social turn is to account for individual cognition and difference, and to incorporate the substantial body of research on mathematical cognition, as products of social activity. (Lerman, 2000, p. 23)

The challenge for Lerman, then, is to make the insights of psychologically inspired theories accessible again from the sociological perspective without having to return to a primacy of the individual mind. The question that has emerged from the social turn is therefore: If one apparently cannot get from a theory of mind to a substantial theory of the social, does it perhaps work the other way around?

(2) It is, we believe, Anna Sfard who has most decisively pursued this question with her *Theory of Commognition*. Sfard's theoretical program can be read as a systematic exploration of the question of how far one can get with a theory of mind when starting from a theory of the social. In the introduction to her book, Sfard writes:

> In this book […] thinking is defined as the *individualized version of interpersonal communication* – as a communicative interaction in which one person plays the roles of all interlocutors. The term *commognition*, a combination of *communication* and *cognition*, stresses that interpersonal communication and individual thinking are two facets of the same phenomenon. (Sfard, 2010, p. xvii)

The key word for a proper understanding of this theoretical program is: 'defined'. Sfard does not claim that there is no need to distinguish empirically between thinking and communication, between the cognitive and the social dimension. Rather, her thesis is that one can *define* the *concept* of thinking by means of the *concept* of communication. Sfard does not make a statement about the empirical world, but about the theoretical description of it. She claims that one can get to a substantial theory of mind from a theory of the social. For this, Sfard argues, one can start with a concept of communication and then characterize thinking as self-communication–more precisely: as an 'individualized version of communication in which one person plays the role of all interlocutors.' But it is precisely the extraordinarily clear way in which Sfard presents her theoretical program that also reveals a potential weakness: Thinking is *by definition* declared to be a special case of communication. If one can now come up with an example of a cognitive function that is different *in type* from communication in Sfard's sense, then the theoretical program is, at best, incomplete. Sfard herself states: "In my case, no such instance comes to mind" (Sfard, 2010, p. 82). In contrast, we believe that the *cognitive function of perception* can be deployed to generate such a counterexample. Sfard admits that she is "prepared to compromise and leave the more primitive form of perceiving, that which leads to immediate instinctive reactions, out of the realm of thinking" (Sfard, 2010, p. 82). This move, however, which may seem 'generous' at first glance, undermines, we believe, the whole theory of mind. For it is precisely the primitive form of perceiving in which all higher cognitive functions – especially all those functions that presuppose the use of signs, such as all sorts of mathematical thinking (Duval, 2006) – are ultimately founded.[1] Although a comprehensive development of the counterexample is beyond the scope of this paper (see Lensing, 2021, pp. 43–52), we will at least hint at how the argument runs: Sfard defines a communicational action recursively as an action A which is followed by an action B so that A is interpreted by B as being an action *about* an object (cf. Sfard, 2010, pp. 86–89). A communication is thus seen by Sfard as an operation that

[1] It was probably Edmund Husserl (1992) who showed most impressively in *Experience and Judgement* that every theory of logical and mathematical thinking finds its ultimate support in a theory of experience (cf. §1-14, especially: §10).

always processes a distinction. Action A must be ‘seen’ by action B in a dual way, namely as a communication about a certain object. In a second step, it is then argued that elementary perceptual processes are not processing distinctions. For example, one sees a figure in front of a ground and not the distinction between figure and ground. It is then concluded that the cognitive function of perception cannot be characterized as a specific mode of communication in Sfard’s sense.

The social turn had emerged in mathematics education research around the problem that one could not get from a theory of mind to a substantial theory of the social. However, as we have argued in this section, more recent attempts to travel the same route in opposite direction do not seem to be completely successful either. But if there is no clear evidence so far that the path is viable in either direction, what should we do then? Should we consider ourselves defeated by the complexity problem and accept that, while we may well be able to study certain *aspects* of what happens in mathematics classrooms, we will probably never make the *whole picture* accessible to theoretical description?

We believe that there is in fact another way out. It comes into sight if one asks: What do the two aforementioned attempts at bridging the gap between the cognitive and the social dimension have in common? Both, Glasersfeld as well as Sfard, begin their theoretical endeavors by aligning themselves with a particular discipline: psychology in Glaserfeld’s case, sociology in Sfard’s case.[2] While Glasersfeld takes a psychological perspective and thus does not get through to the social dimension, Sfard starts from a sociological perspective and does not get a grip of the cognitive dimension. And it is this beginning, the alignment of one’s theoretical program to one particular discipline, be it psychology or sociology, that we believe to be undermining the possibility of arriving at a general theory. To put it bluntly: *Developing a general theory that can actually ‘grasp’ the complexities of mathematics classrooms must be considered as a transdisciplinary endeavor from the very beginning*. However, such a theory can only be developed from a theoretical standpoint that is not associated with any of the classical disciplines. But how can this be possible? What ways of theorizing might lead to such a transdisciplinary theory?

The formal method: Following the example of modern mathematics

In order to address those questions, we believe it is helpful to take modern mathematics as an example and adopt a theorizing strategy that has revolutionized the field of mathematics over the last two centuries. We will call this theorizing strategy the *formal method*. Now what is the formal method and how can it be employed for theorizing in mathematics education research?

In his or her undergraduate studies, every mathematics student learns concepts from abstract algebra, order theory, topology, measure theory, and so on these days. These theories provide concepts (e.g. the algebraic concepts of group, ring, and field) that allow for relating the seemingly most remote

---

[2] That we make this assignment arises from the unit of analysis that the two theorists choose as their starting point: While Glasersfeld chooses the individual knower and his or her processes of knowing as his unit of analysis (= psychological perspective), Sfard starts from the concept of communication and defines it in such a way that communication can only emerge through a certain kind of recursive linking of the actions of at least two different individuals (= sociological perspective).

areas of mathematics (e.g. permutations, geometric transformations, and numbers). Although these *new concepts* have become part of the standard repertoire of a mathematician, surprisingly, it is rarely stated explicitly from which *new way of theorizing* those concepts have actually emerged.

It was most likely Edmund Husserl who, in 1900, in the first volume of his *Logical Investigations*, first provided a satisfactory answer to the question of what was new about these revolutionary developments in mathematics from a methodological standpoint. Husserl argued that the key idea was to *formalize* existing mathematical theories *in their entirety*. Thus, instead of investigating mathematical domains consisting of entities with a determinate content (e.g. numbers and their operations or geometrical transformations and their compositions), mathematicians proceeded to investigate their purely formal counterparts. That is to say, they no longer investigated *particular* mathematical domains, but rather *general* 'domain-*forms*' (Husserl, 2012, §70): In this sense, abstract algebra is no longer concerned with *particular* operations on *particular* kinds of numbers. Rather, it is concerned with the question of what can be said about mathematical domains of a particular *form*, namely about all those domain-forms in which certain operations on objects are defined by their operational laws. When the addition symbol '+' is used in group theory, it does not stand for the operation of addition, which composes two numbers giving their sum, but for *any* operation that satisfies the group axioms. What these operations and objects on which they are performed then actually look like remains completely indeterminate in terms of content. Not the content of the objects and operations is determined, but only certain conditions for their form are demanded. A theory in abstract algebra, such as group theory, is actually a *theory-form*. It is freed from all numerical or geometrical content. By means of formalization, these contents are "converted into indeterminates, modes of the empty 'anything-whatever'" (Husserl, 1969, §29). And it is this particular way of theorizing, this 'conversion' of a theory (or of a whole class of theories) with a determinate content into its (their) corresponding theory-form which we want to call the *formal method*.

With this in mind, it is no longer difficult to understand the networking power of 'theories' such as abstract algebra or topology. Since these 'theories' are theory-forms, they do not really consist of concepts, theorems, and proofs, but of concept-*forms*, theorem-*forms*, and proof-*forms* (cf. Husserl, 1969, §29). And since a theory-form is precisely something that many theories can have in common, it seems quite natural that one can study connections between remote mathematical domains this way. But what, one may now ask, does any of this have to do with research in mathematics education?

Towards a transdisciplinary approach to research in mathematics education

The crucial point is that a proper understanding of the formal method suggests an entirely new approach to theorizing in mathematics education research. Rather than concluding from the striking similarities between cognitive and social processes (e.g., both kinds of processes utilize signs, process meanings, and refer to all sorts of objects through these very meanings) that they are essentially "two facets of the same phenomenon" (Sfard, 2010, p. xvii), our proposal is that they are in fact two quite different phenomena that share a common form. And we hence believe that it may be better to start from an appropriate *theory-form* to explain similarities *and* differences between these processes. In order to avoid a potential misunderstanding right away: Our proposal here is not to apply mathematical theories in the human sciences, but rather to adopt a particular way of theorizing, namely the formal method, and apply it for theorizing in these fields. Fortunately, such a project does not need to be started from scratch. By formalizing and enriching the theory of autopoietic systems, which was first developed by Maturana and Varela as a *biological* theory (Maturana, 2002), Niklas Luhmann was able to arrive at a general theory of autopoietic systems (or more correctly: at a general theory-*form* of autopoietic system-*forms*). And just as the formalized complement of the concept of addition in group theory is no longer about numbers, the formalized complement of the concept of autopoiesis in this general theory is no longer about organic processes. Rather, the formalized version of the concept (= its concept-form) merely captures a certain self-referential form of (re-)production: “We want to call systems *autopoietic*, which produce and reproduce the elements of which they are composed by the elements of which they are composed” (Luhmann, 1985, p. 403, translated by F.L.). The criticism of an illegitimate transfer of biological concepts to social and cognitive phenomena is hence unfounded, because such a transfer simply does not take place. Instead what Luhmann does is formalizing the biological concept of autopoiesis. He first converts all biological terms into empty forms (‘system’, ‘element’, and so on) and then asks for the concrete modes of reproduction that characterize social and cognitive systems. In this way, Luhmann is able to conduct a systematic study of similarities *and* differences between organic, cognitive, and social systems and arrives at a *theory of mind* (Luhmann, 1985) as well as a *theory of the social* (Luhmann, 1995). And it is this work that Lensing (2021) takes as a point of departure to develop the outlines of a general theory which can account for the bodily, cognitive, and social dimension of mathematical activity and model such phenomena as mathematical teaching-learning processes within a single theoretical framework.

Since a detailed exposition of this theoretical program hardly seems possible on the few lines we have left, we would like to conclude this paper with a brief indication of how the formal method may operate for mathematics education research. For this purpose, we have chosen a concept that is used quite frequently in our field, but almost never explicitly discussed with respect to its conceptual content: the concept of *structure*. In Lerman (2020), for example, authors speak of ‘knowledge structures’, ‘mental structures’, ‘cognitive structures’, but also of ‘social structures’, the ‘structure of classroom discussions’, ‘structures of power and control’, and many more. What is striking about this list is the ‘parallel terminology’ that cuts across various disciplines: Psychology deals with cognitive or mental structures, sociology examines all sorts of social structures, and mathematics education research is concerned with both areas and how the formation of structures in one area might have a bearing on the formation of structures in another (i.e., how certain structures of communication in mathematics classrooms affect the formation of students’ cognitive structures). These considerations indicate that it might be of great value to our field to gain possession of a concept of structure that is not bound to any of the disciplines relevant to mathematics education research, a concept that, due to its formality, can be employed in both the cognitive as well as the social sphere.

But how do we actually get to such a formal level of analysis? The answer is: by starting off at the empirical level and then employing the formal method to work our way up. We may start, for instance, with the well-known example of the ‘IRF-Pattern’ (Initiation – Response – Feedback) and the observation that this social structure constraints the possibilities of the occurrence and linking of communications in the classroom. The pattern thus structures communication events as they occur in the classroom in two respects: communications should be of certain types (initiation, response, feedback) and they should be linked in a certain way (first, initiation, then, response, and so on). If we now continue and include other kinds of social structures, such as norms, roles, social positions, etc., we can see that the way in which these structures exceed constraints on social events varies greatly from case to case, but that all instances of social structure at least agree in that there is some sort of constraints: A structure of a social system, quite generally, constraints the possibilities of the occurrence and linking of social events in that system. With this step we still reside in the realm of social theory and the next step of formalization would then be to abandon the qualification of events as social events and thus elevate our 'definition' of structure to the transdisciplinary level of a general theory of autopoietic systems: A structure of an autopoietic system constraints the possibilities of the occurrence and linking of elements in that system.

Clearly, this brief example is only a very rough sketch of how the formal method may be employed for the purposes of theorizing in mathematics education research. Yet we hope that it will at least motivate the thesis that this method allows for theorizing that yields to a theory that is beyond all disciplinary boundaries. And it is the transition to this transdisciplinary level of theory that we believe provides a possible starting point for solving the complexity problem.

The interplay between person and environment, cognition and emotion: Using the concept of perezhivanie in mathematics education

Vygotsky's concept of perezhivanie considers the interplay between cognition and emotion of an individual's development within an environment. Empirical research using perezhivanie has mainly focused on early years education and has hardly ever been used in mathematics education. This theoretical paper starts with the problematic issue of the role of the environment in cognition and proposes the use of perezhivanie as a unifying concept to study an individual's development in mathematics education. We provide an exposition of the concept of perezhivanie, seeking to understand its relation to key memorable events and threshold concepts, which are currently being used to analyse classroom activities and events. We conclude by pointing out the importance of perezhivanie as an analytical approach to four areas of study in mathematics education.

Keywords: Perezhivanie, university mathematics education, emotion, cognition.

The Russian word perezhivanie (plural pereshivaniya; from *zhivat* – to live, and *pere* – carrying something over something) has been used in educational research to describe a series of personally-significant, emotionally-charged experiences and how an individual has overcome them to become the person they are today. The concept has rarely been used in mathematics or science education research literature (e.g., Black et al., 2019; Fragkiadaki & Ravanis, 2021), and it has predominantly been used in research on early years education (e.g., Ng & Renshaw, 2019). Perezhivanie nevertheless is a powerful concept that considers the unity of person-environment and cognition-emotion as central to explain an individual's development, something that in general has not been prominent in mathematics education research. For instance, some theoretical perspectives have looked through a mental cognitive lens (e.g., the development of student's algebraic thinking is characterised by the use of alphanumeric symbolism). Some others have studied emotions from the individual's perspective without regard to how socio-cultural factors shape those emotions and hence the cognitive processes of the person. These perspectives neglect or downgrade the inherent relation between cognition and emotion. In response, we agree with Radford (2014) that a study of the development of students' mathematical thinking should be thought of as an unfolding dialectic process of culturally and historically constituted forms of knowing which involves, for example, embodied forms of thinking and emotional and ethical engagement, amongst others.

Hence, we take the position that perezhivanie is a meaningful research tool for a developmental account of an individual but how to conceptualise and investigate it is still “an open research problem for sure” (Radford, 2014, p.275). Therefore, this paper aims to advance the understanding and use of perezhivanie in mathematics education research. We explore the concept of perezhivanie within the research literature of mathematics education and beyond. We start with an introduction to the problem of the environment as it was conceived by Vygotsky (1934/1994) and an exposition of the concept of perezhivanie as understood by him and later expanded by other scholars. We then seek to understand its relation with other concepts used in mathematics education literature, which relate to emotion (i.e., key memorable events) or cognition (i.e., threshold concepts) and that seem to be used to study similar problems to those that can be studied with perezhivanie. We ask: How does perezhivanie provide a deep and detailed understanding of individual development, not captured by key memorable events or threshold concepts? We conclude with a discussion on the added value of perezhivanie in four areas of study in mathematics education.

The problem of the environment

In *The Problem of the Enviroment,* Vygotsky used the word perezhivanie in relation to the study of the role that a child’s social environment has in the formation of their personality, as opposed to the part played by their genetic inheritance. Central to Vygotsky’s thought was the idea that rather than a setting, the environment should be considered as dialectically related to a person’s development:

> “environment should not be regarded as a condition of development which purely objectively determines the development of a child by virtue of the fact that it contains certain qualities or features, but one should always approach environment from the point of view of the relationship which exists between the child and its environment at a given stage of his development.” (Vygotsky, 1934/1994, p. 338)

Vygotsky exemplified the two-way relation between person and environment from his own research. The example was that of three children experiencing the same environmental condition (mother with alcoholism) in different ways. The youngest child developed neurotic symptoms, the second demonstrated contrasting emotional attitudes towards his mother, whereas the third and eldest acted as a senior member of his family to protect his youngest siblings.

Through the interactions with the different aspects of a given environment, an individual’s perezhivanie determines what influence this environment has on their development. In that sense, in order to analyse the impact of a learning environment on developmental processes, one should consider both cognitive and emotional aspects. In the research field of mathematics education there are studies that consider these aspects, but separately. For instance, Key Memorable Events (Marmur & Koichu, 2018) focus on emotion to study events in the classroom with which students identify or strongly remember. By using this concept one can point out various prominent events that take place in the mathematics classroom and that could potentially be important for students’ learning; but research on these events has no direct link to students’ development as (mathematics) learners. Further, Threshold Concepts have been used in mathematics education to study cognitive events. The learning of concepts such as the limit, continuity, etc. in calculus, are fundamental for students' mathematical development. The existing literature nevertheless leaves aside the emotional aspects or the contextual factors that the learning of these concepts entails. Hence, there is a need in the field for the use of a concept that takes into account both cognitive and emotional aspects in the interaction of an individual with their learning environment and that highlights the influences on their development.

What is perezhivanie?

Perezhivaniya are the events, episodes, activities, happenings or experiences in which people are active participants. The perezhivaniya in someone's life help them answer the question "Who am I?", by showing who they were and how they came to be the person they are now – the experiences they had and how these formed them.

In relation to learning, Kim (2021) argued that perezhivanie experiences can facilitate the learning process when the learner recognises meaning in the environment, evaluating or appraising the experience as important. In other words, the experience provides "what is available to the person to do something with" (van Lier, 2004, p. 90), thereby becoming developmentally significant. Hence, perezhivaniya become for the person that which proves to be personally significant for them (Rubenstein, 1957). They are the chapters of one's autobiography, the events that were life-changing and emotionally-charged.

As a research tool, perezhivaniya are the units of consciousness or of the personality as a whole. They encompass intellect, affect, memory, attention, will, etc. They are experiences as a whole, and each has their own plot, its own inception and movement towards its close (Dewey, 1939). Perezhivaniya are *both* subjective and objective, they are both personal and environmental (e.g., the loss of a job for a young person is not the same as for someone whose job is their entire career). A perezhivanie is the prism through which the subject refracts the influence of the environment. Vygotsky (1934/1994, p. 342) remarked that "in perezhivanie we are always dealing with an indivisible unity of personal characteristics and situational characteristics".

These experiences are life-changing in the sense that they are problematic, and one has to overcome, survive or over-live (überleben) them. Perezhivaniya do not have to be only painful, there can be good perezhivaniya (e.g., a risk that paid off and opened a new life phase) (Kotik-Friedgut, 2007).

Success in overcoming a perezhivanie entails changing the social situation, either by transforming the object of activity, transforming the subject or both. Blunden (2016) asserts that development comes from a process of catharsis. In ancient Greece, catharsis was the experience of an audience who, when watching a play at the theatre, externalised their emotions by empathising with the performers who were acting the emotional experience out for them. This had a "purging" effect. Blunden (2016) points out that Freud (1914) was also familiar with perezhivanie, and that he used psychoanalysis to make a patient remember and repeat an emotional experience and working through it, overcoming and "surviving", 'transcending" it, or "sublating" it (in the manner of Hegel). The psychoanalytic process seems to suggest that the aid of another person, who is capable of objectifying and reflecting back the feelings of the person going through a perezhivanie, of guiding them and making use of the resources of the culture to assist them in finding and accommodating their new situation, is usually needed (e.g., teacher, therapist).

The concept of perezhivanie also allows us to understand experiences that are not so dramatic, and what has been said above applies to those relatively minor joys and embarrassments that “stick in our minds” and become part of our development, that evoke an emotional response and are connected with our motivation, without becoming life-changing traumas.

How is the concept of perezhivanie related to other concepts of emotion or cognition that are used in mathematics education literature?

In spite of its potential, perezhivanie is rarely used in mathematics education research. In this section, we seek to understand the concept of perezhivanie by critically analysing the concepts of Key Memorable Events and Threshold Concepts that seek to explain similar phenomena with perezhivanie in mathematics education.

Key memorable events

The concept of Key Memorable Events (KMEs) refers to classroom events that are accompanied by either positive or negative strong emotions and are imprinted as meaningful in students’ memory, because of their contribution to students’ learning (Marmur & Koichu, 2018). In that sense, KMEs can be used as a theoretical lens for analysing affective moments and gaining an insight into the learning process. With their use, one can recollect memories and thoughts of emotionally loaded events that seem to be particularly interesting for the individual. In this way one can consider the role that affect plays in students’ experiences during the learning of mathematics and in this regard we can recognise a similarity with the concept of perezhivanie. However, for us, the difference is in the consequences that this experience has for the development of the individual. With KMEs we have a tool for listing and categorising the kind of events that stay in the individual’s memory and can have an effect on their learning. Perezhivanie provides us with a very detailed process, where different perspectives and aspects are considered with the scope to give us a deeper understanding of the situation and of the impact on the individual’s learning trajectory and development.

The use of KMEs as an analytical tool in mathematics education research requires particular methodologies, such as the stimulated recall methodology. Students are assisted in recollecting their experiences from a particular lesson and provide information regarding their thought-processes. This raises criticism regarding the degree of importance of each event in students’ learning, since the students are reminded of specific classroom events and then comment on them, instead of recalling themselves what was distinctly important for them. We assert that an experience becomes significant for an individual (and not necessarily for others) and changes outcomes for that individual by requiring a challenging situation that has been overcome and resulted in a cathartic outcome.

Furthermore, although with the KMEs one can identify and classify emotionally charged events that take place in the learning of mathematics, there is not an explicit way to understand whether the students act or not upon these events. For instance, in a recent work by Marmur and Koichu (2018) where the concept was used in order to pinpoint the incidents that were memorable for students during undergraduate mathematics tutorials, most of the students referred to events that played a role in their motivations regarding the learning of mathematics (e.g., “It was beautiful. It’s an eye opener.”), rather than their engagement. Based on these recollected events it is not clear if students took action in changing their ways of learning or if these events had an impact on their identities as mathematics learners, something that is crucial in perezhivanie. Overall, KMEs can be a useful instrument for classifying strong affective moments and explain various phenomena that take place during the learning of mathematics in the classroom (or in the lecture hall). They can improve the lesson design by analysing students' emotional reactions to particular teaching practices, but they do not give us a clear picture of the impact that these emotionally-charged situations have on students' further learning and engagement with the subject.

Threshold concepts

Threshold concepts are topics that are considered crucial when a person tries to master a certain subject. Meyer and Land (2006) described threshold concepts as portals which open a new and previously inaccessible way of thinking about a subject. According to them, threshold concepts have five characteristics that can be used in identifying them: (1) they are transformative i.e., they result in a shift of a person's perception of a subject; (2) they are irreversible, meaning that the change in perception is irreversible; (3) they are integrative due to their ability to allow connections of previously unrelated concepts to be made; (4) they are bounded because they might lie at the conceptual border between disciplinary areas; and (5) they are troublesome because they are inherently difficult to grasp.

In the mathematics education literature, Breen and O'Shea (2016) proposed that limits, functions, cosets and quotient groups are mathematical topics that hold the above characteristics and can thus be considered threshold concepts in analysis and group theory. They argued that traditional teaching approaches and curricula in undergraduate mathematics often result in memorising content and procedures which leads to shallow or rote learning. In order to address these issues, Breen and O'Shea proposed to change the curriculum (often built around the structure of mathematics and a linear fashion of teaching content) to one structured around threshold concepts (leading to a recursive design that enables learners to revisit threshold concepts throughout the duration of the course).

Threshold concepts offer ways of identifying topics that act as portals and thus represent important stages of a learner's mathematical development. As a construct, threshold concepts relate to the cognitive aspects of learning mathematics, i.e., what has to be learned in order to master a certain topic. However, their transformative and troublesome nature suggests that a learner's experience in understanding a threshold concept could result in an emotionally charged situation, an aspect that is not acknowledged or taken into account by threshold concepts. In that sense, perezhivanie offers a more holistic account that can capture the interplay between both the cognitive and emotional phenomena involved while a learner tries to master a threshold concept.

In summary, choosing a threshold concept as context may be useful for researching an individual's mathematical development and for introducing perezhivanie as a research tool. In contrast to key memorable events, perezhivanie identifies significant experiences of an individual in a certain environment; importantly, perezhivanie considers the working over of such experiences that characterise the development of an individual as well as who they came to be regarding those experiences.

Final reflections on perezhivanie in mathematics education

The concept of perezhivanie was left unfinished by Vygotsky. Many scholars have since contributed to its development and the concept has recently received increased attention by researchers interested in the topics of emotion, motivation and subjectivity. In empirical research in education, perezhivanie has been used as an analytical approach to the unity of emotion and cognition (e.g., Fleer & Hammer, 2013) and/or the unity of individual and environment (e.g., Chen, 2015). Researchers using perezhivanie have mainly focused on understanding the refracting prism of an individual who interacts with an environment and interprets it in a subjective way (e.g., Adams & March, 2015). Perezhivanie has rarely been used to study the experiences that are significant for the individual and, due to its *cathartic* nature, play a significant role in their development and life-long learning. We contend that this was Vygotsky's main aim at developing the concept of perezhivanie.

We take the position that perezhivanie is a useful tool and concept in mathematics education research, by providing an analytical approach to a phenomenon under study that considers the unity of cognition and emotion and/or individual and environment, while allowing researchers to see how these units become the key pieces in an individual's development. These are powerful features that can offer new, in-depth understandings in mathematics education research and practice. Based on our readings of the literature, we present four areas of mathematics education research as examples of where perezhivanie could be a useful research tool. The majority of empirical research using perezhivanie has focused on early years; we will focus on areas of the study of older students.

The first area is the study of educational transitions (e.g., mathematics transition to university) and the identification of students at risk of dropping out. For many students, the transition to university is a highly emotional event where past experiences merge with the social relations and material aspects of the new environment. Studying the prism through which individuals refract transitional events, researchers can understand the situations that help or hinder students in different ways to make an un/successful transition and document a pool of perezhivaniya experiences from longitudinal data, or from cross-cultural comparisons. The cathartic nature of these experiences is evident since the transition to university is a defining event in students' lives; some see it as a 'rite of passage', or an opportunity to become someone new, hence determining their development as individuals.

The second area we suggest is the study of mathematical resilience. Researchers have related resilience to individuals' cognitive and affective abilities to overcome obstacles and challenging situations in the learning process, turning them into situations that support them (Hutauruk & Priatna, 2017). A view of resilience as relational between the individual and their environment can be potently studied through perezhivanie. Research on the perezhivaniya of resilient learners (i.e., the reflected lived experience of overcoming a challenging situation) might illuminate practices that encourage dispositions that allow individuals to negotiate their contexts in advantageous ways (cf. Hernandez-Martinez & Williams, 2013).

A third area of study is the research of life-changing decisions with respect to mathematics education, particularly the choices of women or other underrepresented groups in mathematically-demanding careers. Perezhivanie can be used to understand those choices where objective circumstances are refracted through the prism of gendered or racialised subjectivities. Using perezhivanie as the lenses through which we understand these choices allows for a holistic perspective of the life trajectories of these individuals.

A final area is the study of how individuals become professional mathematicians. A study of this type, which uses perezhivanie as a research tool, would look for events that steered an individual to become interested in mathematics, the contexts and circumstances that made possible for that individual to sustain, or even nurture, their mathematical identity. Surprisingly, research into narratives of being or becoming a mathematician, or different ways to be a mathematician, is still limited; stereotypical views of mathematicians as “geniuses” or “eccentric” are still widespread among students and society at large, which in turn discourage many from pursuing a career in mathematics.

This paper described the concept of perezhivanie as first conceived by Vygotsky and subsequently extended by many other scholars. We compared this concept with others in the mathematics education literature that share commonalities with perezhivanie, and described how the concept could be used in mathematics education research. We believe that this concept is useful in understanding the interplay between cognition and emotion, and personal and environmental factors in a way that other theoretical frameworks do not.

Students’ concept images of differentiability from the perspective of the mathematical thinking competency

Mathilde Kjær Pedersen

Danish School of Education, Aarhus University, Denmark; mkp@edu.au.dk

Keywords: Mathematical thinking competency, concept definition and concept image, semiotic registers, differentiability

This poster presents an empirical case of two students working with a task sequence on the concept of differentiability, designed with the purpose of investigating students’ mathematical thinking competency (MTC), as defined in the Danish competency framework (KOM). The MTC is one of eight distinct, yet mutually related, mathematical competencies that all together constitute the KOM framework (Niss & Højgaard, 2019). The MTC involves the ability to distinguish “between different types and roles of mathematical statements (including definitions, if-then claims, universal claims, existence claims, statements concerning singular cases, and conjectures), and navigating with regard to the role of logical connectives and quantifiers in such statements” (ibid., p. 15). Hence, students’ work with definitions is part of their MTC.

In relation to the topic of analysis, the theoretical distinction between concept definition and concept image has proved useful (e.g., Tall & Vinner, 1981). The concept image is “the total cognitive structure that is associated with the concept, which includes all the mental pictures and associated properties and processes” (p. 152). Thus, concept images and the distinction to concept definition are part of the MTC. Due to the MTC’s focus on processes of doing mathematics and to access the students’ concept images, it is suitable, in this case, to study what the students are saying, writing and doing as part of their work with the concept of differentiability. For this, Duval’s (2006) perspective of semiotic registers offers a promising lens. Transformations of representations, namely treatments within one register (e.g., symbol manipulation) and, in particular, conversions between registers (e.g., from a symbolic expression to its corresponding graph) are key to mathematical activity and the mathematical way of thinking. Duval (2006) argues that considering comprehension as being conceptual and mental and semiotic representations as being external is a deceptive division. “In fact, mental representations that are useful or pertinent in mathematics are always interiorized semiotic representations” (ibid., p. 126). Hence, the semiotic representations are part of students’ concept images. Thus, with this poster, I address the question: *How does the ‘concept definition’-‘concept image’ distinction in the case of differentiability assist in characterizing students’ MTC, and how may an attention to conversions between different registers add to such characterization?*

The empirical case reported stemmed from a study carried out in a class of 29 students in Danish upper secondary school (age 16-17) during two 90-minute lessons on the topic of differentiability. The students were working in groups of two or three sharing one computer. Their actions on the computer were recorded using screencasts, also capturing webcam and audio, resulting in 14 recordings. The present case was selected due to the students’ thorough work with the concept definition of differentiability, while still not connecting the concept definition to their work with the graphs of non-differentiable functions. The two students were working on the final set of tasks, where they are to explain with their own words, when a function is differentiable and when it is not; then to construct an example of a function that is not differentiable, and then a function that is continuous but not differentiable. The case illustrated how the students shifted, both written and orally, between the semiotic registers of natural language, symbolic representations, and graphic representations. However, using natural language, the students elaborated on the symbolic representation of differentiability as a limit in terms of graphic representations. Afterwards, when attempting to construct a discontinuous function, the students typed in a piecewise defined function f_1 using a template in TI-nspire, such that f_1 consisted of a linear function for x<0 and a quadratic function for x>0. Thus, f_1 was not defined for x=0. When the students drew the graph of f_1 in TI-nspire, they saw that the graph "jumped" just around x=0, why they concluded that f_1 was discontinuous, hence non-differentiable, without taking into account that the domain of the function did not include 0. Notably, even though the students made shifts between representations of different semiotic registers, and related to the definition of differentiability, their concept image of differentiability was based on their notion that a graphic representation of a function should not "jump."

The three theoretical perspectives serve different roles. KOM's MTC frames the interest and purpose of the study: to investigate students' MTC. For such investigation, the distinction between concept definition and concept image provides a terminology for the students' associations with their work related to the formal concept definition (of differentiability). Furthermore, it focuses on the cognitive processes by which mathematical concepts are conceived (Tall & Vinner, 1981). The perspective of semiotic registers helps to elaborate students' concept images by explaining cognitive processes related to transformations of representations (Duval, 2006). This is to say that they are both of cognitive nature, as is the KOM framework, but focusing on different objects as part of the cognitive processes. Hence, with the application of the two lenses, there is a potential for a 'coordinated' analysis. Such 'coordination', focusing on the students' concept images, elaborated through the lens of semiotic registers, can help characterize students' work related to the formal concept definition. From the perspective of MTC, the two perspectives can elaborate on the processes of relating to the roles and types of mathematical statements, even though the students may not work with consistent concept images coherent with the formal concept definition. Thus, this case implies that Duval's (2006) perspective of semiotic registers offers an analytic tool to focus on the students' activities with different representations and thereby elaborate on students' concept images related to the cognitive processes of MTC.

Analyzing semiotics in an imaging teaching scheme through a case study in physics virtual classes: towards a conceptual framework

In this poster, we explore the contributions that a cultural-historical approach and a semiotic point of view can provide to the analysis of teacher's conceptualization processes in the frame of the notion of *scheme* (Vergnaud, 1998). This notion has been introduced as the invariant organization of the activity for addressing a class of professional situations corresponding to the same aim. Pointing out that conceptualization is crucial in the development of mathematical and professional competences; Vergnaud (1998) adds that "the fact that this process of conceptualization is not directly observable, and has to be reconstructed from observed behaviors, makes it a challenge for research" (p. 231). The study was carried out by observing physics classes at distance through Microsoft Teams, during the COVID-19 pandemic. Thinking about the characteristics of the empirical data collected, the conceptual framework is structured considering the networking strategies for connecting theoretical approaches (Prediger et al., 2008); thus, we *combine* the theoretical elements mentioned below.

Theoretical elements: scheme, artifacts, semiotics

Vergnaud (1998) defines *scheme* as: "Invariant organization of behavior for a certain class of situations" (p. 229). The organization consists of four components: (1) Goals, subgoals and expectations of the activity; (2) Rules of action; (3) Operational invariants: mainly *concept-in-action*, and *theorems-in-action* (proposition considered true); and (4) Possibilities of inference. In addition, a concept considers a set of linguistic and symbolic representations (Vergnaud, 2009).

Wartofsky (1979) conceives of *artifacts* as cognitive means for representing the mode of activity in which they are used or produced. He highlights that modes of representation in mathematics and science have their genesis in the modes of representation that emerge simultaneously with social and linguistic practice. Thus, the production of artifacts (e.g., tools, signs, language, gestures, social organizations and interactions) links closely to their sociocultural context and historical development.

Wartofsky (1979) places representations as a central element of cognitive practice. He states that concepts "are the ways in which the scientist has learned to understand complex phenomena, to realize their mutual relations and to represent them in communicable form." (Wartofsky, 1981, p. 21). Their importance lies in the fact that once a concept is articulated, its meanings and relationships can be studied by themselves; so, one can study not only what the concepts refer to, but also the concepts themselves and their influence on the modes of activity. In a particular way, Wartofsky (1979) says that, in mathematics and in the other sciences, we organize symbols of our experience or our thinking with the aim of understanding this experience or explaining it to others. Therefore, the teaching-learning processes constitute semiotic conceptualization processes where teachers and students mobilize artifacts, seeking to give meaning to the mathematical objects that are presented to them.

Method

We observed (from France) physics classes at distance through Microsoft Teams, during the COVID-19 pandemic, of a Mexican teacher with 7 years of teaching experience. The classes took place in a high school in Mexico City, and we observed nine sessions (of 2 hours each). Each session was recorded. The observation took place during the teaching of different contents related to the subject of optics. Here we report findings from two sessions on the topic of "image formation" in the unit of "optical systems and geometric optics" where there is a close relationship between mathematical and physical concepts.

To analyze the data, we define the *Imaging Teaching Scheme* (ITS) as a stable invariant organization of the teaching activity corresponding to the process of the generation of images through mirrors and lenses; that is to say, how to teach that an object, with a defined visual structure, produces a visual representation (image) that manifests its visual appearance. The objectives of ITS correspond to what are the artifacts the teacher uses to teach the process of the generation of images. The rules of actions and the operational invariants correspond to the use of two geometric laws associated with the formation of images: law of reflection and law of refraction (Snell's law). We carried out the data analysis with the objective of identifying the operational invariants in the ITS based on the use of artifacts by the teacher and relating them to semiotic representations (mobilized by the same teacher).

Results and implications

In each session, we analyzed the teacher-student interactions and we distinguish a situation related to ITS: (1) *imaging* in a convergent spherical mirror, and (2) *imaging* in converging thin lenses. We analyzed the semiotics involved in ITS and its operational invariants through the coordinated mobilization of three main artifacts: a Microsoft Word document, ray diagrams (representation of the possible paths light can take to get from one place to another), and gestures. The semiotic analysis allowed us to deepen the analysis of a teacher's conceptualization processes to the extent that the teacher's activity, besides being organized in schemes, was perceived by the researchers in this study as an activity of signification carried out by means of cultural elements: artifacts.

Ethical issues play an important role in moulding the philosophy of mathematics education. The present study spells out ethical features of mathematical learning in terms of inclusion. We present the OPEN-MATH project that aims at accomplishing inclusive mathematics learning environments and a teaching learning model based in such a framework.

Keywords: Ethics, inclusion, differentiation, theory of objectification, networking.

Introduction

In this contribution, we present a networking of theories that goes beyond the realm of mathematics education. We are interested in the possible connections between mathematics education and special education. The enlarging of the networking space beyond mathematics education has been prompted by the need to realize inclusive learning of mathematics. The study has been carried out within the OPEN MATH project funded by the University of Bolzano[1], which aimed at the design of a teaching model that fosters inclusive learning of mathematics. The project acknowledges the growing interest in foundational issues regarding ethics, equity and the political in Mathematics Education (Ernest, 2018; Radford, 2021). Inclusion is located at the point of intersection of cognition and learning in mathematics, equity, ethics and the political, and we believe that research in the issue of inclusion in mathematics is a breeding ground both for the foundational features of mathematics education and inclusive education. Furthermore, an inclusive outlook on mathematics education, besides addressing ethical issues, fosters further reflections and investigations about the principles behind the learning of mathematics. The OPEN-MATH project addresses the need for research in the field of inclusion, outlined by Roos (2018) that intertwines theoretical framing of this feature of Mathematics Education and its translation into effective school practices. We focus on the dialogue between the theory of objectification (Radford, 2021) and differentiation (Tomlinson, 2014) to frame inclusion in mathematics and thereby design a model implemented to embody inclusion in the reality of the mathematics practices. The aim of our study is creating a conceptual framework for inclusive mathematical teaching–learning activities. The outcome is a consistent definition of inclusion and a teaching model that accomplishes inclusion in mathematics.

Didactical Differentiation

We refer to a broad definition of inclusion, not focused solely on students with disabilities: inclusion is understood as a process that aims to identify and overcome any barriers that hinder students from accessing education and achieving optimal outcomes, both in learning and socialization (Ainscow, 2016), therefore, it applies to each student, and not only to a specific category.

To promote participation and learning for all, teaching must simultaneously be sensitive to differences and recognize the similarities of all in being part of a shared community. Teachers and educators are required to face a great challenge. They cannot disregard the use of specific measures for some, which risks an unfair flattening of differences, but neither enhance such differences thereby stigmatizing some students.

Based on these premises, the methodological plan of inclusive teaching requires a design that alternates settings aimed at creating a space in which each student can follow his or her own individual and unique path of learning and others that offer an opportunity for collaborative action, in which each can contribute in his or her own way to a common project. The methodology of teaching differentiation, introduced by Tomlinson (2014), attempts to strike this balance. In the OPEN-MATH, the development of classroom environments encourages both plural and decentralized learning processes, and personal paths in which the student is led to choose according to their needs. This allows for differentiation for all pupils. Furthermore, the centrality of freedom of choice on the part of pupils introduces the possibility of "self-determined differentiation": in a learning landscape that offers multiple opportunities, teachers no longer need to design the most appropriate delivery for each student but support subjective and competent choice on the part of girls and boys.

We can say that the vision of the student according to the perspective of differentiation is that which sees them capable of self-determination and of positioning themselves with respect to the community, they belong to, without, however, losing the link with it. In the OPEN-MATH project, this perspective leads the teacher to pay specific attention to the preparation of each student, and their interests and motivations to learn. The design of activities is adapted to the individual because the assignment is broad or because the single task becomes plural, divided into multiple activities that the student can choose autonomously. An example of this approach can be found in *stations* (Demo, 2016), where different learning activities related to a main topic characterized by specific learning objectives are structured and made available in the classroom. Students can move from station to station and choose which ones to complete and which ones not to complete. The activities that characterize each station allow differentiated forms of thinking and action. A final passport serves as a way for the student to make note of the stations completed, the difficulties encountered, and what enabled them to learn in the most effective or enjoyable way, but it also allows the teacher to keep track of and understand individual differences in math learning.

The Theory of Objectification

In this section, we outline to basic features of the theory of objectification that allow us to realize inclusive mathematics inclusion as differentiation for all, described in the previous section. We will discuss learning as a double-sided construct whose elements are *processes of objectification* and *processes of subjectification*.

The theory of objectification, embedded in sociocultural perspectives, stems from a profound intertwining between culture and the individuals, accomplished in activity. Activity is the ontological category of the theory of objectification as it realizes the consubstantiality between individuals and their culture. In the stance of the TO, mathematical thinking and learning are not processes confined in the mind, but they are intertwined with individuals' activity. Signs and artefacts play an important role in the TO, beyond the role of something that stands for something else or as mediators of activity. They are considered an integral part of human thinking and human activity (Radford, 2021).

Learning as objectification

The issue of learning is rooted in the dialectics between the individual and their culture. Learning is a movement pushed by the intrinsic differential between the individual and cultural knowledge. In fact, in attending to knowledge the student has to cope with something that in the beginning is different from him, an alterity that challenges, resists and opposes him. Learning is the process that erases such a difference in order to make sense of cultural knowledge and transform it into something familiar that allows new forms of action, thinking, imagination and feeling. In order to reduce the distance between the individual and cultural knowledge, students engage in processes of objectification, i.e., the sensuous activity interrelated with signs and artifacts that allows them to meaningfully encounter mathematical knowledge (Radford, 2021).

We remark that according to the TO, signs and artefacts are constitutive of the activity (Radford, 2021) that leads students to notice mathematical knowledge. They are bearers of an embodied intelligence and culturally endowed with specific patterns of activity that individuals use in their meaning-making processes.

In view of accomplishing inclusive mathematical learning, objectification has a fundamental feature in realizing inclusion as differentiation. Objectification is a multimodal process deriving from the variety of sensorial channels (sight, touch, movement, imagination etc.) and the diversity of semiotic means of objectification (objects, tools, gestures, linguistic devices, icons, symbolic language etc.) interwoven with mathematical activity. The multimodality of mathematical thinking and learning allows each student to learn according to their specific and unique potentials, difficulties, cognitive style and sensorial channels that suit him best.

The dialectics between the individual and his cultural-historical environment is not fully accomplished by objectification. The TO pays special attention to the production of subjectivities in the learning processes. The basic idea is that humans are unfinished projects of life, subjects in continuous transformation in the creation of a singular and unique cultural and historical subject. Learning is a double-faced construct. We analysed objectification as one of the two facets. Its entangled counterpart is *subjectification.*

Learning as subjectification

"Processes of subjectification are based on the idea that humans are always unfinished projects of life, subjects perpetually in the making". (Radford, 2021, p. 35). Subjectification is related to the production and transformation of subjectivities and to the continuous co-production of singular and unique individuals against the backdrop of their cultural-historical domain. It allows students to critically position themselves in cultural-historical mathematical practice, realizing new ways of thought and action (Radford, 2021).

The notion of subjectification is coherently linked to the basic tenet of the theory of objectification that establishes the intertwining between individuals, their sociocultural environment and activity. The individual and their culture live in a dialectical relationship in which individuals produce reality as much as reality produces them. On the one hand, the student acts, thinks and feels according to the social and cultural reality he encounters in the classroom. On the other hand, in realizing their unique and specific project of life, the student critically and creatively establishes a reflexive and agentic relationship with the world that allows him to change it.

Subjectification accomplishes the ethical, social, and psychological nature of inclusion fostering self-determination, self-realization, attention, and respect of other human beings contributing to the creation of an educational and social environment where teachers and students co-produce themselves in the dialectical relationship with their cultural-historical context.

Networking strategies: a conceptual framework for inclusive mathematics learning

Mathematical learning develops along two complementary plots: social interaction and self-determination. Social interaction is the fabric of the learning of mathematics envisaged as a joint activity that involves teacher and students towards the production of mathematical knowledge. Self-determination nurtures individual's unique distinctive traits, needs, potentials, desires as they creatively engage in mathematical learning. True inclusion cannot be accomplished if we neglect one of the two plots. If we disregard self-determination, the student might not have the possibility to enter the mathematical practices, thus being excluded, or learning mathematics clashes against his needs, desires and individual features. If we disregard social interaction, a meaningful learning of mathematics cannot occur, and we miss the political and ethical issues of mathematics education that call for the production of ethical subjects open to others and their culture. A feature that our conceptual framework should encompass is the multimodal mode of activity students deploy in the learning of mathematics.

In the previous section, we have described the tenets of the TO and differentiated learning featured as open learning. We now sketch how we used the networking strategies devised by mathematics education to construct a conceptual framework for inclusive learning in mathematics.

Lotman's semiosphere

We will carry out networking within Lotman's (1990) semiosphere. A semiosphere is characterized by the following elements: a system of practices, a meta-language, themes, plots that can be developed within this sociocultural space, and the coexistence of multicultural identities, which in our project refer to mathematics and special education.

The semiosphere is extremely effective to study the connection of theories since it is a space that fosters interaction and dialogue between different theories. Networking can be conceived as a dialogue between theories that takes place in the semiosphere using a metalanguage that allows the different theoretical perspectives to communicate and interact. In a networking perspective, the semiosphere blends two important plots: integration that refers to the intertwining between theories and identity that refers to the internal consistency and distinctive traits of a theory. The dialogue between theories overcomes barriers respecting their identity and consistency.

The semiosphere plays a prominent role in our study, in the light of establishing a dialogue between two theoretical perspectives belonging to different disciplines within the educational domain. In fact, we enlarged the semiosphere to include mathematics education and special education in the meta-theoretical dialogue. Within the enlarged semiosphere, we established a specific meta-language, we acknowledged the common system of practices, we allowed the co-existence of the culture of math education and inclusive education in our research, and we developed the plots of integration and identity.

Connecting strategies

Prediger and Bikner-Ahsbahs (2014) outline a "landscape" of possible connecting strategies, which balance the plots of identity and integration. For the scope of our work, we reckoned *coordinating* as an effective networking strategy. Coordinating leads to a conceptual framework built by "fitting together elements from different theories for making sense of an empirical phenomenon" (Bikner-Ahsbahs & Prediger, 2014, p. 120). Combining is an appropriate strategy when networking theories whose systems of principle are complementary to one another.

For the objectives of OPEN-MATH, the outcome of the networking strategy should encompass the following features connected to inclusion as differentiation: i) Outline the notion of inclusion in mathematics ii) Provide learning activities that meet personal needs, potentials, and talents of each student, allowing them to be included in the sociocultural activity. iii) Nurture both the individual's distinctive traits and social interaction. iv) Outline a teaching–learning model to be implemented in everyday mathematics classroom, which in our study involves grade seven students.

Within the enlarged semiosphere of educational sciences, the Theory of Objectification and the Open Learning Approach are not completely compatible. The former rests on sociocultural underpinnings centred on joint labour and being with others, whereas the latter on socio-constructivist underpinnings that stress the role of autonomy and self-determination. Social interaction and the individual's agency are present in both theories but with a different hierarchical position in their system of principles. They are not conflicting theories, and they can be coordinated to get a multi-faceted insight into inclusive mathematical practices and fit together elements from the two theories in view of a conceptual framework for inclusion in mathematics.

A conceptual framework for inclusion in mathematics education

To frame the project, we introduced a tentative framework of inclusion that links the attention to the individual with their specificities and mathematics learning as a process of objectification. We list here the *defining principles* of our conceptual framework.

Inclusion is conceived from the student perspective (subjectification), as "the dialectical and critical positioning of all students in the cultural-historical practice of mathematics, who act, feel and think according to their individual distinctive traits to pursue their project of life*."* (Demo et al., 2021 p. 8)

Mathematical activity, in its multimodal acceptation, is the meeting point of the social and individual dimension of mathematical learning. Multimodality and sensuous cognition link the individual self-determination and the social interaction. In particular, the semiotic means of objectification, which define the modes of activity of both the single student and the class, can be considered the bridge between the subject and the culture.

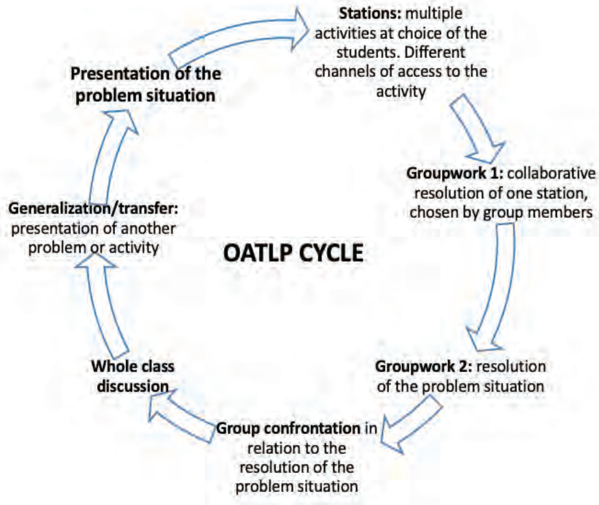

Figure 1: The Open Activity Theory Lesson Plan cycle

Starting from these two principles, we designed a new model of activity that blends self-determination with social interaction. Such a blending is realized by alternating group work with stations. Both group work and stations are informed by the multimodality of objectification and the co-production of subjectivities as they position, according to the notion of subjectification mentioned above, in the sociocultural environment of the classroom. Figure 1 shows the structure of the model that we termed Open Activity Theory Lesson Plan (OATLP) to underline the coordination of activity and open learning that characterize the theory of objectification and differentiation. OATLP is the outcome of the experimentation with a grade 7 class carried out in school year 2020/2021 during the research project.

An example of OATLP

To show how the main phases of the OATLP cycle are built and interact in accordance with the networking of Theory of objectification and Didactical Differentiation we give here an example. The topic of the implemented cycles was chosen in agreement with the mathematics teacher, consistently with the planning of the classroom: in March, we proposed a cycle where the main learning goal could be identified in the resolution of problems related to the estimation of areas. The first individual phase, station work, consisted in several activities that could be chosen by the single student in order to work on the fixed learning goal. In Figure 2, we show as an example two stations: the first, on the left, is more related to a verbal learning approach, while the second, on the right, is more related to a visual learning approach. In the second one, the student is asked to colour the squares in the figure of a tree first considering only the squares that are fully contained within the tree and to count them, and then she is asked to colour the squares that are also partially contained. Then the student is required to estimate the area of the figure as required by the task.

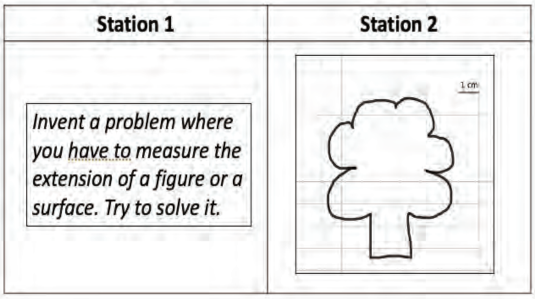

Figure 2: Two stations out of six from the OATLP cycle of March.

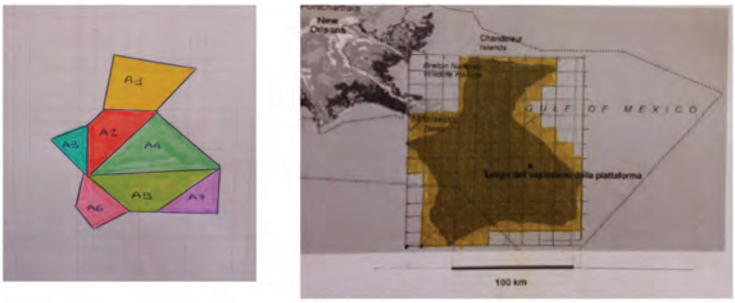

Figure 3: The resolution to the problem situation given by two different groups.

Figure 2 shows two different activities the students were exposed to in two learning stations devoted to the learning of geometry. We can see in this brief example how stations, a didactical methodology that characterizes Open Learning, helps us to exploit the multimodality of mathematics in order to allow each student to choose her path in the learning process, positioning herself with respect to a shared aim. This is also strongly consistent with the principles of Didactical Differentiation: Tomlinson (2014) highlights how differentiation is possible only when the aim of the activity is clear and the essential learning goals are defined. In this example, the aim of the activity is the estimation of areas and the learning goal is defined is a multimodal approach to solving problem.

The individual phase of the OATLP cycle helps the students to access the group work activities according to their individual characteristics and potentialities, and to have a moment to reflect on eventual personal difficulties with the topic, sharing them with a peer or with the teacher before the group work starts. Continuing in the description of the OATLP cycle, after the stations, students were asked to solve a problem, again about area estimation that was more contextualized, and requested the application of a proportion. In Figure 3, we show two solutions of a problem concerning an oil slick in the sea, and the student had to find a method to calculate its area and to justify it.

In addition, within the group work attention was given with respect to the possibility for every student to position herself in the learning goal: in this case, the positioning of the student is made with the other group members in an effort for mutual understanding and joint labour. The phase of group confrontation closes the problem-solving phase allowing each group, and student to justify her work, and to ask for justification to the other: This allows the students to be reciprocal critical friends, and to deepen the understanding of their respective work.

Summarizing, the whole cycle is designed so that there is a balance among the social and the individual dimension of learning, and in order to give every student the possibility to be included, in the sense made explicit above, that is related to the process of becoming a subject that critically position herself with respect to mathematical culture, according to her own characteristics.

Conclusions

Ernest (2018) has singled out ontology and metaphysics, aesthetics, epistemology, learning theory, social and political philosophy, and ethics as the prominent elements of a philosophy of mathematics education. The author deems ethics the *first* philosophy of mathematics education advocating the awareness that we are all the same but different and we are in our present condition (fortunate or unfortunate) only by luck and contingency. He recalls that our subjectivity is formed in and through our subjected-ness to the other, prior to the development of cognition, language, modelling etc. Being-with-others (Radford, 2021) is the true and meaningful motor of learning mathematics, in that the student is engaged in the dialectical interplay between the sociocultural environment of the classroom and their reflexive agency. Resorting to coordinating as a networking strategy, we networked the theory of objectification with differentiation for all, conceived as open learning, to provide a conceptual framework that defines inclusion in mathematics as the intertwining of objectification and subjectification processes. We envisage inclusive mathematics as the production of reflective and ethical subjects who position themselves critically and creatively in mathematical practices, a condition that should be available to all students and respectful of their differences. Inclusion is accomplished via the OATLP teaching model that reflects the coordinating strategy by fostering both social interaction and individual activity in a teaching learning project that involves all students.

Concrete–abstract–new-concrete: Freudenthal and Davydov in advancing embodied design framework

Anna Shvarts, Michiel Doorman and Rosa Alberto

Utrecht University, the Netherlands; a.y.shvarts@uu.nl m.doorman@uu.nl r.a.alberto@uu.nl

Freudenthal and Davydov—two giants of mathematics education research—had a similar sophisticated vision on the position of mathematical models and symbols in abstract–concrete dialectics. In our vertical analysis of those approaches, we integrate them in a spiral *vision of mathematics learning. Starting from concrete enactment, students abstract previously latent aspects of their reality. Further, students fixate abstract ideas in mathematical artifacts, which in turn enable new concrete experiences. We show how local integration of two theoretical approaches can support an empirical analysis of embodied design for proportions and act as backing a design heuristic for embodied technologically supported activities.*

Introduction

The relation between abstraction and concrete experience inevitably lies in the core of mathematics education studies. Should concrete experience become a starting point for teaching abstraction? Can abstract ideas be derived from empirical observation or enactment with concrete objects, or shall abstract ideas be exposed to students directly, through 'symbolically structured environments' (Coles & Sinclair, 2019)? Traditional views on abstract and concrete—established within inductive empirical science—are questioned in contemporary investigations of mathematics learning, particularly by those who take an embodied stand.

The variety of visions on the problem of abstraction in mathematics learning creates a need to base theoretical work on a solid ground. In this paper, we coordinate the approaches of two giants in the field of mathematics education research, Davydov and Freudenthal, with respect to the role of mathematical artifacts and students' concrete experiences in teaching abstract ideas. Revealed similarities in the views of such major yet independent figures makes, in our opinion, the emerging theoretical proposal particularly strong and related design heuristics well backed up. The compatibility of views is based on Davydov's approach belonging to the Marxist tradition of cultural-historical activity theory, which can be aligned with Freudenthal's approach to mathematics as a human activity of mathematizing. Neither Davydov, nor Freudenthal used the term *artifacts*, however symbols, models, and visuals lied in the core of their ideas. We refer to these and any other instances of material culture developed within mathematical activity as *mathematical artifacts*. We interpret *cultural artifacts* as a broader category of entities developed within cultural practices.

The paper consists of two main parts. Firstly, we integrate Davydov's and Freudenthal's thinking into a joint view on concrete and abstract. For this local integration of theories (Bikner-Ahsbahs & Prediger, 2014) we conduct a *vertical analysis* (Shvarts & Bakker, 2021) as we go beyond comparing current states of the theories and dive into the history and philosophical roots of their development. Secondly, we apply the results of this theoretical analysis to guide an analysis of students' interaction with (cultural) artifacts within embodied design (Abrahamson & Sánchez-

García, 2016) and further suggest some design heuristics for technologically supported embodied activities. Two research questions guide our study: (1) What are Freudenthal's and Davydov's positions towards the role of mathematical artifacts in facilitating concrete experiences and abstract ideas? (2) How to introduce mathematical artifacts in embodied designs informed by the integrated Freudenthal-Davydov approach to mathematical abstraction?

Freudenthal and Davydov: concrete, abstraction, and mathematical artifacts

Freudenthal dedicated quite some publications to Davydov's approach (Freudenthal, 1974, 1977, 1979). Moreover, the Davydov's curriculum has been implemented in some Dutch schools, and compared to Wiskobas—a curriculum inspired by Freudenthal (Nelissen, 1987). In our view, Freudenthals' interest in Davydov is rooted in a deep agreement on the research and teaching methods. Within both research programs, intensive investigatory implementations were conducted in schools and referred to as *formative experiments* in Russia and *developmental research* in the Netherlands, presenting historical variants of what we know now as design research (Bakker, 2018). As we explain below, the similarities in the teaching methods convey insights on abstraction, the role of cultural artifacts, and the progressive development of concrete experiences.

(1) An abstraction is not based on recollection of empirical impressions

The fundamental innovation of the Davydov approach lies in an intensive critique of empirical thinking and pedagogy that treats abstraction as deriving from empirical examples (Davydov, 1990). As van Oers (2019) explains, Ernest Cassirer was apparently the first to criticize this type of abstraction because of the impossibility to limit the set of empirical observations from which to derive abstract qualities. Per Davydov (1990), new classes of objects are created within human practical activity, and theoretical thinking later describes those classes not through empirical observation but through transformative actions that reveal otherwise hidden properties. In the course of learning, students are to "develop special object-related actions by which they can disclose in the instructional material and reproduce in models the essential connection in an entity, then study its properties" (p. 174). Analyzing Davydov's approach, Freudenthal highly appreciated this perspective on abstraction and stressed that “abstraction and generality are—in many cases—not reached by abstracting and generalizing from a large number of concrete and special cases” (Freudenthal, 1974, p. 412). Later, Freudenthal tried out Davydov's approach of deriving arithmetic operations from practical actions with magnitudes—such as length and volume—with his grandson and found this approach to be effective (Freudenthal, 1977, 2002b, p. 102).

(2) Children need to reinvent mathematical models and symbols

Another point of the clear coordination between the approaches of Davydov and Freudenthal lies in addressing the role of mathematical models and symbols. Per Freudenthal, the mathematical activity consists of progressive schematization and algorithmization of solving problems that are meaningful for students. Those schematizations and algorithmizations are later preserved in the form of mathematical models and formalized rules (Freudenthal, 2002a). The rules preserve the history of problem-solving for those who came up with them in their own problem-solving. So, the only way for the learners to meaningfully extend their understanding of reality through mathematics, lies in reinventing mathematical rules and symbols. Otherwise, “having been imposed, they [rules and symbols], never had a real chance to develop into common sense of a higher order" (p. 8).

Davydov similarly assigned a primary role in scientific thinking to models, symbols, and signs. "Symbols and signs, as well as mixed forms of them, serve as the material means of idealizing and constructing scientific objectness" (Davydov, 1990, p. 121). Constructing these material means (artifacts) is exactly a process of abstraction, which fixates (reifies) the essential (for a practical activity) aspects of the object under investigation: "The construction of this new object [idealized model] functions as a certain mode of activity—as abstraction" (p. 117). In learning, children pass through a quasi-investigation, in which they uncover an essential (theoretical, mathematical) aspect of an object and reproduce it "in particular object-related, graphic, or symbolic models" (p. 174).

(3) Progressive development of concrete experiences

The origins of Freudenthal's ideas lie in the observation that mathematics education tends to inverse the development of mathematical ideas by presenting students the final products. He referred to his approach as phenomenological, and—although he insisted on the divergence with Husserl, Hegel, and Heidegger (Freudenthal, 2002b, p. 28)—he was apparently essentially influenced by phenomenological thinking. This influence can be traced in his ideas of developing *common sense*: in "the course of life, common sense generates common habits, in particular, where arithmetic is concerned, algorithms and patterns of actions and thoughts, initially supported by paradigms, which in the long run are superseded by abstractions" (Freudenthal, 2002a, p. 7). So, mathematical abstraction, such as arithmetic, derives from the common sense experience of acting and thinking. Further, those mathematical abstractions support later common sense experiences: "These products of common sense acquire in turn the behavioural status of common sense, while their common sense ancestry may have even been forgotten" (p. 7). Per Freudenthal, good mathematical education develops students' ability to *see* reality mathematically; mathematical symbolism is a lens for this *newly developed common sense*.

We find Freudenthal's idea of developing common sense to be close to the dialectical materialist method of *ascending from abstract to concrete* that Davydov exploited. This method does not mean presenting abstraction from the beginning. As Ilyenkov explains, "the ascent from the abstract to the concrete without its opposite, without the ascent from the concrete to the abstract would become a purely scholastic linking up of ready-made meager abstractions borrowed uncritically" (Ilyenkov, 2008, p. 137-138). So, abstraction starts from concrete experience, as well as progresses towards concrete experience: "the ascent from the concrete to the abstract and the ascent from the abstract to the concrete, are two mutually assuming forms of theoretical assimilation of the world, of abstract thinking" (p. 137). However, those two directions are not forward and backward. Abstraction reveals the latent aspects of initially experienced concrete reality, and those aspects further become salient in the theoretically grounded concrete perception of the objects. So, *ascending from the abstract to concrete* does not mean a detachment from the initial concrete experiences but a transformation of perception towards *seeing concrete objects in a new way—through* the lens of abstraction, facilitated by the artifacts as if superimposed on the perceptual field.

Concluding the theoretical analysis

Answering our first research question, we interpret Freudenthal's and Davydov's positions towards concrete experiences and abstract notions preserved by mathematical artifacts as converging in the following vision of the learning process. Students derive an abstract understanding from the concrete experiences within a specially organized practical problem-solving activity. This practical transformative activity elicits latent aspects of the world, which students fixate in cultural artifacts, such as mathematical models and symbols (movement from concrete to abstract). Having constituted an abstraction supported by the artifacts, students can put these artifacts into action and distinguish new initially latent aspects (movement from abstract to new concrete). In this iteration, students develop their *common sense* (in Freudenthal's words) or *ascend from abstract to concrete* (in Davydov's words) in establishing a theoretical vision of an object. Thus, we see students' development as *a spiral*: from concrete approaching the world in practical activities to abstracting latent aspects and fixating them in mathematical artifacts, and further towards establishing *new-concrete* perception mediated by those artifacts. From this approach, cultural artifacts emerge as reifications of the actions, which have elicited abstract features. Students need to actively constitute those artifacts to preserve the history of initial concrete enactment.

Concrete–abstract–new-concrete in implementing embodied design

Embodied action-based design is one of the quickly developing paradigms related to radical-embodied-enactivist-phenomenological reconsiderations within cognitive science (Abrahamson & Sánchez-García, 2016). The learning sequence in this design genre consists of a few major steps (Alberto et al., 2021; Abrahamson et al., 2020). At first, students are invited to solve a motor problem, i.e. discover a new coordination between their hands based on continuous feedback, and uncover the rule of positive feedback to their actions. Later, artifacts are introduced into the problem space, and students are guided towards the quantification of their experiences. Within this paradigm, the researchers have intensively questioned the position of embodied activities and cultural artifacts within abstract–concrete dialectics. In particular, they consider a sensorimotor scheme as "the epistemological core of mathematical learning and knowing" (Rosen et al., 2016, p. 1509), which can be further developed in both directions: towards abstract notions through semiotic signification by cultural artifacts, and towards concrete situations through providing context. Our empirical analysis of embodied activities through the lens of a joint view of Freudenthal and Davydov hints towards another role of the artifacts in abstract–concrete dialectics and further advances the design framework.

Stage 1. Action-based abstraction: Seeing new structures in concrete embodied experience

When solving a motor problem, students discover new abstract qualities,—at first at the embodied level and later in conversations with tutors—such as a proportional relation between the length of two bars, or a coordination of a unit circle circumference and an x-coordinate of a sine graph. Solving a motor problem is coherent with Freudenthal's and Davydov's ideas about abstraction as emerging from a goal-oriented practical actions. Technological environments restrict students' degrees of freedom, thus facilitating quasi-investigation, as Davydov would insist. Although restricted, the students appear to come up with a multiplicity of personal strategies and perceptual orientations, thus meeting Freudenthal's idea of reinventing rather than exposing culture. So, initial embodied enactment with concrete, tangible objects enables the discovery of abstract mathematical relations.

Stage 2. New-concrete: Looking through the lens of emerging cultural artifacts

While the phase of solving a motor problem has been extensively studied, researchers paid relatively less attention to the stage when artifacts are introduced. Therefore, we bring forth a small classroom episode from an experimental tryout of an embodied action-based design for proportions in an ordinary third grade (8-9 years old) classroom in the Netherlands (see a description of the data collection in Alberto, van Helden, Bakker, submitted). Four student pairs were video recorded and the following episode is selected to provide the best insights on the use of mathematical artifacts in establishing new understanding. Two girls (Iris and Frida) collaborated in the tablet-based activity: they manipulated two bars on a screen, which turned green when their lengths were in a particular fixed ratio. The girls were required to keep the bars green while moving and later "to guess a code" that determines the bars' green color, thus describing the proportional relation between the green bars' lengths. In the analysis, we contrast the use of two cultural artifacts: **a dice**, which was spontaneously appropriated by the students, and **a grid**, which was imposed by the educators.

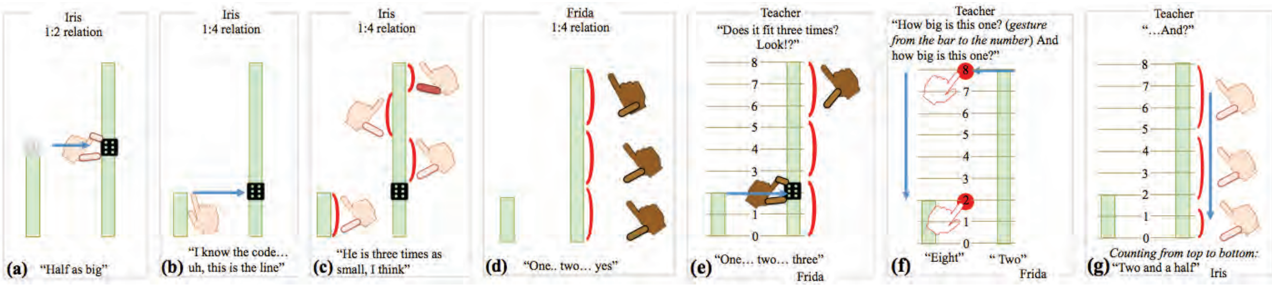

Fig. 1. (a, b, c, d): Seeing proportional relation through a dice. (e, f, g,): Missing proportional relation when applying a grid

By the moment of the episode, the girls have already solved the task with the bars being in ratio 1:2. In order to see that the length of one bar is doubled in the length of another bar, the girls spontaneously used a dice that was occasionally lying on a table: They positioned the dice in the middle of the big bar, marking that small bar fits in it two times (Fig. 1a). In the next task, the bars turned green at a ratio 1:4, but the girls did not know this yet. Adjusting one hand upwards somewhat slower than the other one, Iris found several green positions. She exhibited a general abstract strategy of maintaining two lengths in the same proportional relation, which needs to be concretized in quantifying the exact relation. Iris again took a dice and marked the length of the shorted bar on the longer bar (Fig. 1b), thus marking a unit of measurement that would help assess how many times the small bars would fit into the big one—a concretization of the abstract relation of "fitting into the other one." Then both girls tried to measure with their fingers how many times the length of the short bar would fit into the long bar (Fig. 1 c, d). The relation between two bars is seen through the lens of a cultural artifact, a dice, which here means *marking down a measurement unit*. The dice served as a reification of previous sensory-motor coordination; it allowed for distinguishing a *new-concrete*, new previously invisible aspects of the bars, namely a measurement unit that helps assess how many times one bar fits in another bar. A common sense action, in Freudenthal's terms, developed for Iris towards seeing the big bar as containing some number of small bars. Iris ascended from abstract coordination of two lengths to concrete quantification of their relation mediated by a dice (in a very physical sense). Unfortunately, a dice was barely an appropriate artifact for marking the small bar length: its own size distorted the measurement. As a result, the girls efficiently exploit an abstract idea of proportional relation as "fitting some number times in" but miscalculated the relation as 1:3 (combining two possible mistakes, see Fig 1 c, d).

The activity progressed towards the next stage of introducing cultural artifacts (Abrahamson et al., 2020), in which the girls were asked to confirm their code using an imposed grid (Fig. 1 e, f, g). With the help of a teacher, two bars were positioned at lines 8 and 2 and the bars were green. The teacher asked: "What does it mean?" expecting that 2:8 relation was obvious enough to dissolve students' 1:3 hypothesis. "Three times smaller" was the answer. The teacher invited the students to check: "Does it fit in three times? Look?" Frida did not use the grid, but took the dice (!), and marked the length of a small bar on the large bar by a horizontal gesture (Fig. 1e). Despite ignoring the imposed grid, by this horizontal gesture, Frida *re-invented* the functionality of grid's horizontal lines, as both artifacts serve the same function of marking equal units of measurement. The dice was big, and an approximate measurement led to the answer 1:3 again. Supporting the use of the imposed mathematical artifact, the teacher guided the students' perception towards the grid (Abrahamson & Sánchez-García, 2016): She gestured the horizontal alignment of the large bar and number 8 and then pointed at number 2, Frida read the numbers (Fig. 1f). However, their relation did not guide further enactment. Following the sequence of the teacher's gestures from top to bottom, Iris made a new measuring attempt counting from the top without clear measurement unit (Fig. 1g). She came up with an answer 2,5. The initial abstraction of "fitting in" was lost, and the students could not concretize (quantify) abstract proportional relation using the grid.

The dice was a natural continuation of the students' thinking and bodily enactment (see Shvarts et al., 2021 for conceptualization of this situation as a body-artifact functional system), and it allowed the girls' common sense development. By exploiting the dice, the girls could mark a measurement unit and concretize an abstract embodied idea of proportional relations in the given situation. Contrary, an imposed grid was not reinvented and stayed alien to the emerging abstraction. The teacher could see the bars' proportional relation naturally through the grid, while the girls could use the grid in this way. Their phenomenological realm did not the grid, contrary, a dice that became a mediator for a *new concrete*, i.e. for distinguishing new mathematical aspects of reality.

Towards a new design heuristic

As the theoretical and empirical analyses reveal, a cultural artifact might become a reification of practical actions, which helped to distinguish an abstract relation—a proportional relation between the bars, tangible as "small bar fitting into the big one." Importantly, an imposed mathematical artifact (a grid, see Abrahamson et al., 2020) did not fulfill this function, even with the teacher's guidance. Another artifact (a dice) spontaneously was appropriated by the students to reify an action of distinguishing a unit of measurement and served as an instrument in concretizing the ratio. Yet, this other artifact was barely appropriate for fulfilling this function. A design solution to this dilemma might be in creating an environment where students could spontaneously find suitable materials for creating the target artifacts. Such material might include thin sticks to mark the horizontal position of a small bar, paper stripes for creating a measuring unit and overlaying it on the big bar, or even a ruler, which was spontaneously and efficiently appropriated by some other pairs in the study. This way, a classroom can be enriched by appropriate means for progressive mathematizing/modeling of the situation, which could support establishing the perception and use of new mathematical aspects of concrete situations, thus distinguishing *new concrete*.

Concluding remarks

Freudenthal and Davydov are unique figures by the scale of their influence on the mathematics education and educational psychology communities. However, the program of each of them does not flourish nowadays in the countries where they were working despite intensive and successful experiment-based elaborations. Our analysis brings forth the complexity of their understanding of mathematical abstraction and concrete experience. Those approaches aim to develop in students a new ability to see an object concretely within its mathematical interrelations, i.e., developing *a new common sense*. From a concrete action-based experience, students come to distinguish abstract relations that are later reified in cultural artifacts. Further, the artifacts come to illuminate their *new-concrete* experiences. We hope that contemporary technologies can support students and teachers in fulfilling the aim of learning to see the world mathematically. This type of mathematics learning is in particular valuable for the 21st century with routine calculations being outsourced to the machines and increasing importance of skills such as mathematical modeling and recognizing mathematical patterns in everyday situations (Gravemeijer et al., 2017).

Looking back at the interaction of theoretical ideas and design heuristics, we notice that we used two prominent theoretical approaches as a way of backing a design idea that has been already emerging in our design work and empirical data. We uncovered the essential coherence of two approaches in seeing cultural artifacts as instruments that transform students' concrete experiences. The fact that those approaches are widely recognized as highly valuable strengthens the design heuristic of re-inventing mathematical artifacts and its potential for curriculum design.

Mathematical picture of the world and understanding

Nail Tuktamyshov[1]

[1]Kazan State University of Architecture and Engineering, Transport building institute, Kazan, Russia Federation; nail1954@gmail.com

The aim of the article is to analyze the phenomenon of understanding in mathematics. Two concepts are introduced: mathematical picture of the world (MPW) and individual mathematical picture of the world (IMPW). A distinctive feature of the work is that understanding in mathematics is treated as a process of forming IMPW. The basic element of IMPW and its structure are distinguished. It is accepted that a coherent and complete representation of a basic element of IMPW means understanding of a mathematical concept. The paper offers a scheme enabling the formation of mathematical concepts among students.

Keywords: Understanding, image, meaning, personal meaning

Introduction

Problems related to understanding in mathematics have long been the subject of discussion (e.g., Pirie & Kieren, 1989; Sierpinska, 1990; Skemp, 1976; Tall & Vinner, 1981). Skemp (1976) divides understanding into two categories: relational understanding and instrumental understanding. The difficulty is that remembering a large number of common problems or tasks is already a problem. Tall and Vinner (1981) introduce the *concept image*, which is a total cognitive structure bearing a definition of a mathematical concept. Sierpinska (1990) offers a methodology of "acts of understanding". Pirie and Kieren (1989) conceive of understanding as a dynamic, transcendent, recursive, non-linear process. Even though decades have passed since these studies were published, but the problem of understanding in mathematics continues to be of interest to researchers.

It is clear that a subject cannot identify, classify, name any object unless they have a corresponding *mathematical picture of the world* (MPW), an image of the world (according to Leontiev's (1975, p. 73) terminology). Since mathematical concepts cannot exist in isolation from each other, learning mathematics is the construction of *an individual mathematical picture of the world* (IMPW) in the learner's mind. Mathematical development occurs as the formation of a holistic structure (network) through its relationship with other concepts, namely, through the formation of MPW. The aim of this paper is to investigate understanding as the formation of an MPW of the learner.

Theoretical background

Further, we will proceed from the definition: "A world picture is a general idea of the world, its structure, types of objects and their interrelations. All world pictures are distinguished according to two main features: 1) degree of generality and 2) means of modeling reality" (Lebedev, 2004, p. 48). Stepin (2003) has made a classification of *scientific pictures of the world*.

The objective mathematical picture of the world is a "horizon of systematization of knowledge" (Stepin, 2003, p. 213, own translation) in mathematics. This MPW represents a base of objective mathematical data for the students; it participates in the formation of mathematical concepts and relations. The problem in teaching math deals with how to form an MPW in the consciousness of a learner. The formation of an IMPW means that the learner is able to identify the basic concepts of a studied area of mathematics and to build a network linking the basic selected mathematical concepts.

The ideas of Vygotsky's cultural-historical approach (2005) and Leontiev's theory of activity (1975) became a psychological foundation for constructing the basic element of the IMPW. Vygotsky proposed to consider the social environment as the main source of personality development that determines the formation of higher mental functions of an individual. The main feature of higher mental functions is that they are mediated by certain *psychological tools*, namely, the sign systems that have arisen as a result of the long socio-historical development of mankind. Sign systems include, for example, language, writing, speech, and counting systems. Mental function, such as attention, memory, thinking, and imagination pass the stage of external activity in which the cultural means—*psychological tools*—have an object form and are related to a certain sequence of actions. This sequence is then interiorised (i.e. it is transferred from the external to the internal plane). From Leontiev's point of view (1975), the condition for adequate perception of an individual object is the adequate perception of the object world as a whole and the object's relation to this world. Leontiev stressed: "The predetermination of this indicated, meaningful subject world to a concrete act of perception, the necessity of "inclusion" of this act in an already ready picture of the world" (1983, p. 36, own translation). According to Leontiev's theory of activity, the existence of the IMPW and the MPW is interdependent and necessary, since the formation of the IMPW can be imagined as "drawing out" a subjective image of the world (world picture) from the objective MPW. The IMPW is the imprint of the learner's interaction with the MPW.

The thinking process is carried out with the help of sign system and the accompanying idea of semiotic mediation (Presmeg et al., 2016). As a result of multi-level abstraction, each mathematical object is represented by a special sign, which forms, together with the rule of operations on them, a mathematical language. A prerequisite for students to build their MPW is the knowledge content of the names of the objects being studied and their meanings, as well as having motivation. Any sign denotes a concept and connects a concept and a name into a single whole, therefore finding out the structure of a sign reveal the structure of a concept as well. According to Leontiev, any sign consists of three components: an *image*, which is "an encoded representation of the object of activity; *meaning* as a transformed, coiled in the structure of language ideal form of existence of the objective world, its properties, connections, relations revealed by social practice" (1975, p. 68, own translation); *personal meaning* or "meaning for me, which connects the available experience of the subject of activity, and the *meaning* of the object. Let us use the structural representation of the sign given in Panov (2015, p. 42) and specify that the sign is interesting for us first of all because it denotes some mathematical concept. The sign and its structure can be represented in the form of a pyramid. A subject’s awareness of the pyramid structure and relations between its components means understanding of the concept. The basic element of the subject's MPW is this pyramid, which can be called a pyramid of understanding (Figure 1). The base of the pyramid represents the essence of a mathematical concept (triangle of understanding). Consider the components of the pyramid of understanding.

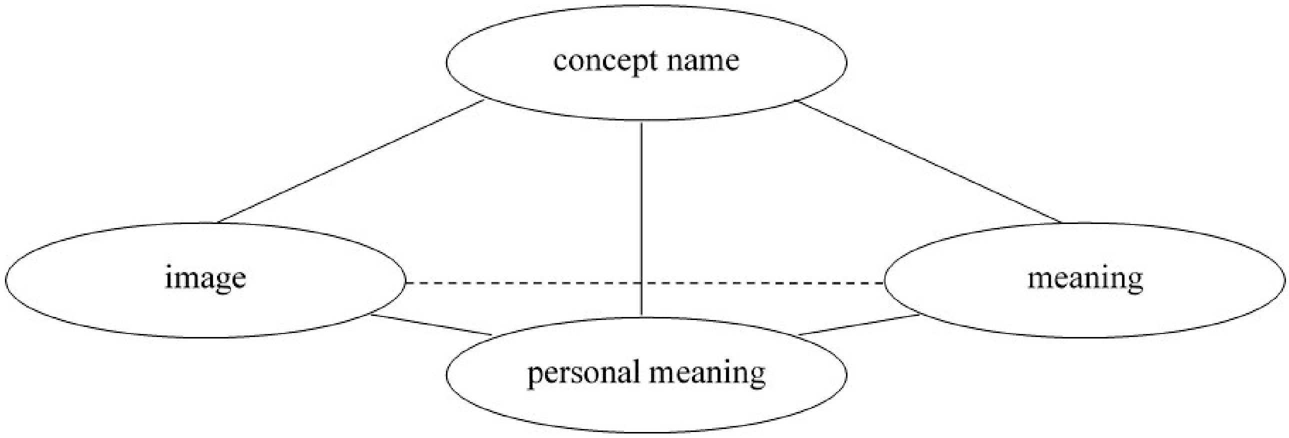

Figure 1: The Pyramid of Understanding

The *image* of a mathematical concept is created not so much by direct perception, but with the help of five processes: imagination, memory, a certain idea in the process of abstraction, generalization, and idealization of objects and phenomena. In contrast to perceptions, which have a sense-object character, the mental image of a concept reflects its content, which expands and enriches as the mathematical experience of the cognizing subject is refined. Mathematical imagery, on the one hand, has the function of supporting mathematical thought and, on the other hand, it is an inseparable part of the conceptual structure. If mathematical images are formed, the learner operates not so much with the given algorithms of working with mathematical objects, as with the mathematical objects themselves. The presence of images allows the mathematical concept to be presented holistically. Herewith only controlled images (Aspinwall et al., 1997) serve the formation of adequate mathematical representations.

Meanings are the result of cognitive activity of people, a system of laws. Meaning is transferable without loss of sense. A set of meanings is a systematically organized knowledge base that exists objectively. The concept of meaning expresses the connectivity of individual consciousness to social consciousness. The concept of meaning captures the fact that human consciousness develops within a cultural whole, that is, within an MPW, in which the experience of mathematical activity, communication and world view is historically crystallized, which the individual must *appropriate*, thereby creating an IMPW.

Personal meaning or "meaning for me" connects objects and properties of reality with the experience and present needs of the subject, and is always emotional and sensitive in nature, giving the picture of the world a special individual nuance. Personal meaning determines the extent to which a given object or process or attitude corresponds to the needs the subject's needs. The concept of personal meaning indicates that understanding cannot be reduced to impersonal knowledge. Rather, it expresses the rootedness of individual consciousness in human being. Understanding presupposes a close connection between the learner's interests and the problem to be solved.

Osipov and colleagues state that "an image without meaning reflects incompleteness of perception as a categorization process, while *meaning* without *personal meaning* reflects the learner's non-involvement in the activity" (2017, p. 75, own translation). Naming connects the three components into a unified structure, so that the sign and its components become elements of the subject's mathematical language system. In this way, the concept is incorporated into the IMPW.

If image, meaning and personal meaning do not form a coherent whole in the learning process, the image is called a *percept*, that is, an image of perception; in this case the meaning is only used for this particular situation and called a *functional meaning* (Panov, 2015, p. 38). The functional meaning of an object allows the learner to use it to carry out specific operations to solve concrete tasks.

Most often in the course of learning elements of a concept (triangle of understanding) are formed at the beginning. Here is the scheme of thought movement from percept to the functional meaning and from here to the choice of *goal* (i.e. to satisfaction of a concrete, temporary need). Because in this case the pyramid of understanding is not closed, this approach does not allow looking at a mathematical concept holistically, so there is a need to give the name of the concept (Osipov et al., 2017). The model constructed allows us to outline a six-item scheme of reasoning (presented next), which is useful for facilitating an understanding of mathematical concept.

1. Based on the similarity or difference with an object known to the subject, the learner's perception is formed independently or with the help of the teacher. The teacher's presentation of the image presupposes the preservation of the essential geometrical properties of the object and should take into account students' practice of using it. A mathematical concept should be presented in different ways, because different students usually have different visualizations.

2. The initial percept is superimposed on the student's past experience of using the given or similar image, which forms the functional meaning of the given concept and leads to the primary pair *percept – functional meaning*. On the basis of the percept formed in item 1 and the existing experience, the student develops an idea of what can be done or what this percept allows to be done. Thus, the formation of a functional meaning takes place. The process of forming this relationship is dynamic (i.e. an initial perception emerges). For this perception the student looks for a suitable image for a perception with an appropriate application, which may not be accurate. Then the initial image is changed or refined depending on the function of the image. At this stage, the role of the teacher is important in helping in establishing the *percept – functional meaning* connection.

3. The functional meaning obtained in item 2 is then compared with the goal (i.e. the suitability of the functional meaning for solving the problem is assessed). If the obtained functional meaning does not enable the problem to be solved, the student revises the initial perception independently or with the help of the teacher. This process (percept ↔ functional meaning) is repeated as many times as necessary until the functional meaning suitable for the solution of this particular problem is determined and the process is usually interrupted by the teacher.

4. The functional meaning obtained in item 3 is compared with the name characterizing this functional meaning taken from the MPW. If the meaning of a concept accepted by mathematicians is close to the functional meaning, a *name of the sign – meaning* relationship emerges. It is linked to the original percept, which from this point can be called an image. If it turns out that the functional meaning and the exact accepted meaning are not close, there is a return to the formation of the percept. This convergence of meanings is carried out through communication with the teacher in the form of a

dialogue. It is desirable to carry out a dialogue in a flexible, probabilistic form. In general, this item implies a repeated transition to item 2, which creates a certain cyclical process (item 4 $\rightarrow$ item 2 $\rightarrow$ item 3 $\rightarrow$ item 4), which is interrupted when the student achieves an adequate image concept. The teacher intuitively knows when interrupt the process.

5. Image formation is a dynamic process because it is, usually, the result of repeatedly going through the sequence from item 1 to item 4, and it influences the student's initial need for solving the problem. In addition, it enriches and generalizes the student's idea of the problem, generating personal meaning from the temporal need. Thus, through the pair *name – functional meaning* there is a connection with the name of the concept, which means that the functional meaning has turned into meaning and the temporal need has turned into personal meaning.

6. Ultimately, understanding means that a learner knows the sign structure of the given concept, which is made up by binding image, personal meaning and meaning through the name of a concept. Independently or with the help of the teacher, the learner interconnects all components of the sign.

In contrast to Panov (2015), the scheme presented here is more flexible, as the discussion of a concept can start not only with the image, but also with other items, and also takes into account the fact that formation of a concept usually takes place with the help of the teacher. Let us consider an example of a dialogue, which shows how the above scheme functions in real practice. The conversation is with the 1st year bachelor students of the Institute of Transport Structures of Kazan State University of Architecture and Engineering. At the lecture before the conversation the definition of a function and, in particular, linear function was given. Below P stands for the professor, S1 to S5 for the students.

1	P:	What can you say about the function $y = 2x + 3$?
2	S1:	It is a straight line on the plane.
3	P:	How is such a function called?
4	S:	I don't know exactly, but e.g. The function $y = x + 3$ is the same.
5	P:	Is the function $y = 3x$ a straight line in the plane?
6	S:	Yes. (Makes a drawing).
7	P:	Is a straight line a function $y = -2x$ or a species $y = ax + b$ in general?
8	S1:	(Thinking). Yes. Such functions always define a straight line in the plane.
9	P:	How are the variables x y related to each other and in the case of a straight line?
10	S1:	When the argument changes by the same amount, the value of the function also changes by the same amount. Increases x, increases also y, for example, for a function $y = 2x + 3$.
11	P:	And how exactly does the value of the function change when the value of the argument changes?
12	S1:	It simply increases.
13	P:	Take the function $y = 2x + 3$ and calculate the value of the function at $x = 1$, and then calculate the value of the function at $x = 2$.
14	S:	For $x = 1$ we have $y = 5$, and for $x = 2$ we have $y = 7$.
15	P:	Now calculate the difference of the function values and find the value of the function at $x = 3$.
16	S1:	This difference is 2 and the value at $x = 3$ will be $y = 9$.
17	P:	Find now the difference of the values at $x = 3$ and $x = 2$.
18	S1:	The difference is equal to 2. The same difference as was before.
19	P:	Yes. When the argument changes by the certain amount, the value of the function also changes by the certain amount. This is true for any function of the form $y = ax + b$. You can see it on your own. (Students do it in general

		form and confirm the conclusion). This function is called a linear function. In which problems can you observe a dependence of the form $y = ax + b$?
20	S2:	In speed problems. When moving at a constant speed. When moving at a constant speed, the distance as a function of time changes according to the formula $s = vt$. Here s is distance, v - speed, t - time.
21	P:	What do you imagine when you see a linear function of the form $y = ax + b$?
22	S3:	I imagine a straight line on a plane.
23	S4:	And I see uniform motion.
24	P:	Uniform rectilinear motion?
25	S4:	Yes. It turns out that a linear function in the plane is always represented by a straight line. And are there other applications of functions of the form $y = ax + b$?
26	P:	There are many such applications in physics, mechanics. For example, Hooke's law $F = k\Delta l$ is known in the theory of elasticity, where F is force, which stretches (compresses) a rod, Δl is absolute elongation (compression) of the rod, k is known coefficient of elasticity. We see that the force is a linear function of Δl.
27	S5:	Ah ... ah, we had Hooke's law. It turns out to be a linear function.
28	P:	So, a function of the form $y = ax + b$ is called linear, here a called the angular coefficient, b is the free member. So, what is a function of the form $y = ax + b$ called?

The analysis of the dialogue shows that in lines 4, 6, and 8 a percept of the concept of linear function is formed (this corresponds to the first item of the scheme of actualization of understanding), and from line 10 the formation of a connection between the percept and the functional meaning begins. This continues in lines 12, 14, 16, and 18 (items 2 and 3 of the scheme apply here). The student at this stage can use the concept of linear function only concretely, without presenting the general properties of a linear function. In lines 20, 22, 23, and 25 the functional meaning is associated with the name, which leads to an awareness of the image of the linear function (corresponding to item 4 of the aforementioned scheme). Line 25 shows the manifestation of personal meaning, as it becomes important for the students to apply the concept of linear function in other areas, which means the implementation of item 5 of the scheme. Line 27 already shows that the name of the function has been associated with the meaning and personal meaning. Line 29 shows the students' understanding of the concept of linear function within our model. Lines 25, 27, and 29 correspond to item 6 of the scheme.

Results

This article offers a model how students learn mathematics by forming an IMPW. The IMPW is a network consisting of basic elements of mathematical picture of the world (network nodes). The basic element of the IMPW is seen as a structure having the following components: image, meaning, and personal meaning. By connecting these three components through naming, a holistic structure, the pyramid of understanding, can be formed. In this paper it is accepted that a holistic and coherent representation of the pyramid of understanding means the student's understanding of the concept.

Discussion and conclusions

Understanding does not happen in isolation, it means *getting into* a network of known relationships and connections (i.e. fitting into a certain picture of the world, so understanding can only be realized within a certain picture of the world). The subject's picture of the world is a sign-mediated picture of the world.

Tall and Vinner (1981) introduced *concept image* and *concept definition* to carefully analyze students' understanding of limits and continuity, as well as other concepts. The concept image can be attributed to the image component of a sign in our model, while the concept definition is consonant with a functional meaning.

Serpienska's model (1990) proposes a methodology of acts of understanding through the categories of identification, discrimination, generalization, synthesis. Skemp (1976) defines understanding in terms of *knowledge* rather the functional meaning of the concept. Pierie and Kieren's model (1989) takes into account both image representation of mathematical objects and abstract, operational representation. The proposed model of understanding in mathematics does not contradict the main known models of understanding, but complements them, considering the social and psychological dimensions of understanding in unity.

This paper proposes a new model for understanding mathematical concepts that link the components of understanding (meaning, image, and personal meaning) into a coherent whole through naming. Particularly, the model allowed us to recognize the importance, value and power of the following ideas:

1. Understanding cannot be viewed only in a social or psychological framework (as most of the mentioned authors in the article suggest), nor can it be reduced to one of these.

2. The introduction of personal meaning into the structure of understanding is a new view. Personal meaning is not only a condition of understanding, but is a necessary component in the structure of understanding. Understanding cannot be reduced to impersonal knowledge.

3. The introduction of the concept of mathematical picture of the world is a new idea. The MPW is intrinsically necessary as a fundamental condition of cognitive activity of students. The IMPW is an imprint of the MPW in the learner's mind.

It seems that further research could go in the following direction: wide testing of this approach for different sections of mathematics.

Metaphor, Enaction and Adidactical Situations in Mathematics Education

Amaranta Valdés-Zorrilla[1], Daniela Diaz-Rojas[2] and Jorge Soto-Andrade[1],

[1]University of Chile, Math Dept. & CIAE; Santiago, Chile; amvaldes@uchile.cl sotoandrade@uchile.cl [2]University of Oxford, UK; daniela.diazrojas@education.ox.ac.uk

We aim at exploring the relationships and intertwinings of the theories of metaphor, a-didactic situations and enactivism in mathematics education. We present and discuss some illustrative examples of the didactical implications of these theoretical approaches, involving geometry and probability, drawn from our teaching to a rather broad spectrum of learners, including humanistic first year university students, besides mathematically inclined students.

Keywords: Metaphor, Enaction, Enactivism, Adidactic Situation, Mathematics Education.

Introduction.

Our aim in this paper is to focus on three cognitive theories which are especially relevant to mathematics education, and which we have been exploring for more than a decade, to wit: the theory of metaphor (English 1997; Lakoff & Núñez, 2000; Sfard, 2008, 2009; Soto-Andrade, 2014, 2018), the theory of enaction (Varela, Rosch & Thompson, 1991; Riegler & Vörös, 2017) and the theory of (a)-didactic situations (Brousseau, 1998; Brousseau & Warfield, 2014). We are interested in the relationships and intertwining of these theories as well as in their epistemological stances. Operationally these relations may be complex. For instance, in what follows, we use metaphorising as a meta-theory to describe theories, which we see just as "unfoldings" of *poietic* metaphors (Soto-Andrade, 2014, 2018). This applies also to metaphor itself, in a circular way (cf. Ricoeur, 1975). Also, Brousseau's theory of a-didactic situations, an unfolding of the emergence metaphor for mathematical concepts, may be seen as a forerunner of enactivist approaches to mathematics education. Indeed Brousseau coined himself the term "experimental epistemology of mathematics" to refer to his theoretical approach, in the 60's, at the same time that Maturana and Varela (1992) set up their laboratory with the same name at the University of Chile.

We recall first the main tenets of metaphor theory, enaction (and enactivism) and a-didactic situation theory. We discuss then some concrete examples of their implementation with a rather broad spectrum of learners in Chile, involving math inclined as well as humanistic first year university students.

Metaphorising in cognitive science and mathematics education.

Notice that we focus on *metaphorising*, the *action* of "looking" at something and "seeing" something else, carried out by a cognitive subject, instead of *metaphor*, the *object*, independent of an observer. It is acknowledged nowadays that metaphor serves as the often-unknowing foundation for human thought (Gibbs 2008, Sfard, 2009) since our ordinary conceptual system, in terms of which we both think and act, is fundamentally metaphorical in nature (Johnson and Lakoff, 2003). In our view, though, the classical theory of metaphor is just "the tip of the iceberg", regarding human cognition. Metaphors are not just rhetorical devices but powerful cognitive tools that help us in building or grasping new concepts, as well as in solving problems in an efficient and friendly way (Chiu 2000;

Diaz-Rojas and Soto-Andrade 2015; English 1997; Lakoff and Núñez 2000; Sfard 2008, 2009; Soto-Andrade, 2014; and many others).

Lakoff and Núñez (2000) highlight the intensive (and often unconscious) use we make of *conceptual metaphors* that appear—metaphorically—as inference-preserving mappings from a more concrete or down to earth 'source domain' into a more abstract or opaque 'target domain', enabling us to fathom the latter in terms of the former. In our view, *representations* go the other way around. Indeed, we *re-present* something given beforehand, typically to explain it, and we usually *metaphorise* to try to fathom something unknown or not yet constructed. Our approach to the learning of mathematics emphasises the *poietic* (from the Greek *poiesis* = creation) role of metaphorising, which brings concepts into existence. For instance, we create the concept of probability when, while watching the random walk of a "fair frog" jumping equally likely right or left on a row of stones in a pond, we "hallucinate" (Seth, 2021) seeing it *splitting* into two equal halves that go right and left! This "metaphoric sleight of hand" turns a random process into a deterministic one, and we just need to keep track of the frog's splitting into pieces to answer "impossible questions" like "Where will the frog be after *n* jumps?". The probability of finding the frog at a given stone after *n* jumps is *constructed* as the *portion of the frog* landing there after *n* splittings. (Soto-Andrade, 2018).

In this connection, it is pertinent to recall that in the German school of didactics of mathematics, originally mostly concerned with primary mathematics education and going back to Pestalozzi (vom Hofe 1995), representation and metaphor were ubiquitous: as *Darstellung*—representation, aiming at explaining something to others—and *Vorstellung*—a personal way to figure out or fathom something, operationally equivalent to metaphor (Reyes-Santander and Soto-Andrade 2012). So metaphorising has a long history in German didactics of mathematics, well before its irruption from cognitive psychology and linguistics into mathematics education (Lakoff and Núñez 2000).

The ubiquity of metaphorising in mathematics education should not be underestimated: Besides bringing into existence mathematical concepts or objects and helping learners to fathom them, unconscious metaphorising often dramatically shapes the way teachers teach, for instance. A foremost example is afforded by the "second nature" metaphor 'teaching is transmitting knowledge'. Unperceived here is the 'acquisition metaphor' (Sfard 2009, Soto-Andrade 2014), that sees learning as acquiring an accumulated commodity. This is criticised in Plutarch's metaphor: 'A mind is a fire to be kindled, not a vessel to be filled' (Sfard 2009). Paraphrasing Bachelard (1938), who advocated epistemological vigilance, we suggest nowadays to practise metaphorical vigilance, i.e., the art of noticing our unconscious or implicit metaphors, that shape our way of interacting with the world (even to construct it) and particularly our approach to teaching and learning.

Last but not least, metaphorising plays also a key epistemological role. We have claimed elsewhere (Diaz-Rojas and Soto-Andrade 2015) that, metaphorically, a theory is just the 'unfolding' of a metaphor (a process, that may be laborious and technical, though). A paradigmatic example is the 'tree of life' metaphor in Darwin's theory of evolution. We will use below metaphorising as a meta-theory to describe other theories relevant to us in terms of their generating metaphors, something more helpful to fathoming how they arose than just describing them a posteriori.

Enaction and enactivism

An unfolding metaphor for enaction is Machado's poem (Machado 1988, p. 142): "Caminante, son tus huellas el camino, y nada más; caminante, no hay camino, se hace camino al andar" [Wanderer, your footsteps are the path, nothing else; there is no path, you lay down a path in walking]. Indeed, Varela himself metaphorized enaction in this verse (Varela, 1987, p. 63), when he introduced the enactive approach in cognitive science (Varela, Thompson, & Rosch, 1991) writing: "The world is not something that is given to us but something we engage in by moving, touching, breathing, and eating. This is what I call cognition as enaction since enaction connotes this bringing forth by concrete handling". He also metaphorised it with the well-known *Drawing Hands* lithograph by Escher where each hand draws the other into existence (Varela, 1984).

Key aspects of enaction are: perceptually guided action, embodiment and structural coupling through recurrent sensorimotor patterns (Varela et al. 1991; Reid and Mgombelo 2015). In an aphorism: 'All doing is knowing, and all knowing is doing' (Maturana and Varela 1992, p. 26). Notice *en passant* how the 'laying a path in walking' metaphor is transversal to the traditional one for learning as following a pre- given well-marked path.

Enaction in mathematics education may be traced back to Bruner (1953), who was following the traces of Dewey's (1910) "learning by doing", when he described the *enactive, iconic and symbolic* modes of representation. Bruner's enaction, which means essentially acting out or doing, is however far less radical than Varela's, in that it does not challenge the notion of a reality 'out there', that we represent to our selves more or less successfully. Dewey, however, emphasised the role of sensorimotor coordination in perception, acknowledging that movement is primary and sensation is secondary (Gallagher and Lindgren 2015).

In what follows, to to avoid confusion between Bruner's and Varela's enaction, we use the now prevalent terms *enactivism* and *enactivist* to refer to Varela's anti-representationalist 'enactive program', which sees cognition as embodied action, more precisely, cognition as enaction. We will speak then of an *enactivist approach* to problem solving or to mathematics education. On the other hand, unless otherwise explicitly stated, 'enact', 'enacting' and 'enactive' are to be understood in the sense of everyday language and also in the sense of Dewey (1997) and Bruner (1966), i.e., as synonyms of 'acting out' or 'acted out', in an embodied way. So 'enacting a metaphor' just means 'to act it out', with your body, as in Gallagher and Lindgren (2015), where they refer to 'enactive metaphors' (metaphors in action, that we act out bodily) as opposed to what they call 'sitting metaphors'. We use 'enactive metaphorising' below in this sense.

Learning is neither determined by a didactical environment nor a result of teaching; it arises from the interaction of the learner's structure and environment, which plays at most the role of a 'trigger'. Traditionally, however, problem solving involves problems given beforehand, lying 'out there', waiting to be solved, independently of us as.. In the enactivist perspective, because of our structural coupling with the world (Varela et al. 1991), we bring forth emergent problematic situations instead. This is what Varela calls problem posing, opposing the usual *gas fitter metaphor*, where solvers look into their toolboxes of predefined strategies and choose the appropriate one for solving the problem at hand, instead of mathematical strategies emerging continually in the interaction of solver and problematic situation. In an enactivist didactics of mathematics, the teacher is an enactivist practitioner acting in situation and learning is an emergent, situated and embodied process (Proulx &Simmt 2013). For a survey of enactivism in mathematics education, see Goodchild (2014).

According to Varela, we are always 'enacting' a world, most of the time unconsciously. So we cannot choose to enact or not to enact (in his sense); enaction is just the way we cognise as living beings. We may nevertheless entertain the 'representationalist illusion' (a privilege of humankind!) that we are perceiving and representing an objective reality 'out there'. Also, we can choose to enact (in the everyday sense of the term, of bodily acting out) a given metaphor or situation or not, for instance. Paradoxically, we are definitely able to teach in a way that ignores enaction (in Varela's sense) and does not allow for enacting (as bodily acting out): a non-enactivist stance that paves the way for cognitive bullying to the learners. Our enactivist approach to education, distilled in the 'lying down a path in walking' metaphor for cognition and learning, leads us on the contrary to foster metaphor enacting among the learners.

Adidactic situations and didactic contract

The theory of didactic situations (Brousseau, 1998; Brousseau & Warfield, 2014) may be seen as an unfolding of the "emergence metaphor" for mathematical content. Indeed, mathematical concepts or procedures we intend to teach, instead of being parachuted from Olympus as in traditional and abusive teaching, should *emerge* in a suitable challenging situation the learner is enmeshed in, as the only means to "save her/his life". This type of situation is called a *didactic situation*, because of the avowed didactical intent of the teacher who set it up. It becomes an *a-didactic* situation when the teacher steps back, to let the learners interact (enactively) on their own with the situation, unable to fathom beforehand the teacher's didactical design or the mathematical content she is aiming at.

Brousseau (1998), aiming at accounting for the actions and reactions of the partners involved in a didactic situation, also introduced the metaphor of a "didactic contract" as an interpretative embodiment of their mutual expectations, beliefs and commitments (Brousseau, Sarrazy & Novotna, 2014). This sort of contract is necessarily tacit and unspoken; its effects are nevertheless often perverse and dramatic. Indeed, the prevailing didactic contract in our classrooms usually thwarts idiosyncratic metaphorising and enacting among the learners.

Illustrative examples

We discuss some examples, in geometry and probability, drawn from our teaching at the University of Chile, which illustrate important aspects of the implementation of our different theoretical perspectives and their intertwining. Our learners include prospective secondary school math teachers, undergraduate math students, humanistic first year students and in service primary school teachers. They usually work in (random) small groups of 3 to 4, and they were observed by teacher and assistants, in the spirit of ethnomethodology (Ingram & Elliot, 2020).

Example 1. Angles in polygons and stars.

One radically enactivist way in which we approached this topic (which includes the classical "sum of inner angles and exterior angles" problems) was to just show the students or participants in a workshop, the weird irregular seven-pointed star of Figure 1 and keep silent, waiting for their reactions to arise. If a student asks: "But, which is the question?", our answer is: "That is the question!"

Participants and students were at first puzzled and intrigued. Some even said “Splash!” Especially, in service teachers and mathematics educators tried to make sense of the star by *decomposing* it somehow, into triangles. The reaction of *deforming* the given weird star to a friendlier regular, one did not appear spontaneously. After some prompting: Do you like this star? What would you like to do with it? they recalled the magician’s star, or the ubiquitous regular star in our flag. Most students did not dare to change anything, because of the prevailing didactical contract: the star was not an object to be explored. Primary school teachers noticed the way the star was drawn, like the usual regular five pointed star, approaching the problem in an enactive way in the sense of Bruner (1966), see Fig. 2. They recalled that for the regular five pointed star, they could calculate easily the values of the inner acute angles, but not so with irregular stars. However, by deforming enactively their drawing of the star they realised that stretching one arm of the star decreases the corresponding inner acute angle and increases the others. So the conjecture emerged that maybe the sum of all inner acute angles was *preserved* under deformation, a clever insight indeed! Notice that this way of thinking: looking for invarians under deformation of a system, is unfortunately not much fostered in our math classrooms.

Figure 1: A weird seven- pointed star.

Our approach was radically enactivist in that no specific problem or task was given to our subjects to solve, but only a situational seed or germ for them to explore and make sense of. They were enactive in Bruner’s sense when they drew the stars themselves and deformed it. This enaction allowed them to bodily feel the compensation between increasing and decreasing inner angles, when varying their free hand drawing.

Nevertheless, a more enactive approach to the angle sum problem is possible, inspired by the “laying down a path in walking”. We have indeed described elsewhere (Soto-Andrade, 2018) how the value of the sum of the *exterior* angles of a polygon may be “seen”, with no calculation, just by “lying down a polygon in walking”. When you go around the polygon, inflecting your rectilinear trajectory at each vertex as needed, you are summing up all exterior angles! In our case, students were able to “lay down a star in walking”! And so they gleaned immediately the value of the sum of its inner acute angles. They realised that the most clever walking, among various possibilities, is to follow the path that we lay down when drawing the star, starting as indicated by the arrow in Figure 2. To add up the inner angles at the points of the star, we should be able to “span” or “sweep” them somehow, while walking across the star. If metaphorising is already unleashed among the students, many avatars of the walker may emerge. Among them, a metaphorical hummingbird flying back and forth along our star.

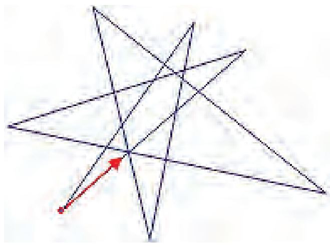

Figure 2: The irregular seven pointed star revisited.

The bird begins its flight as indicated by the red arrow in Fig. 2, but when arriving to the next vertex, it sweeps (i.e. spans) the corresponding inner angle with its *tail* and then flies *backwards* along the next edge. Then it sweeps the inner angle at the next vertex with its beak and flies forwards, and so on. So it will sweep the inner angles: tail-beak-tail-beak-tail-beak-tail, to end up at the initial vertex again, but looking in the opposite direction. Moreover, during its flight, it always turned its beak clockwise at each vertex. So *our flying hummingbird teaches us that the sum of all inner acute angles is just half a turn*. A playful enactment arises, where one student enacts the hummingbird's flight, wearing a fake beak and tail, and another keeps track of the rotation of the beak or tail. In one of our workshops, a couple of primary school teachers discovered this idea on their own, walking across the star holding a duster.

We see that in this case an enactivist approach to a "concrete" geometric problem triggers all the same significant idiosyncratic metaphorising among the learners, which is also enactive (in Bruner's sense).

Example 2. Various avatars of the frog's random walk.

We claim that random walks constitute a royal road to probability, because they are ubiquitous, they constitute models for sundry probabilistic problems, which can be easily enacted and simulated, and when approached metaphorically, they allow learners to construct along the way the "abstract" notion of probability (Diaz-Rojas & Soto-Andrade, 2015; Soto-Andrade, 2013; Soto-Andrade, Diaz-Rojas, Reyes-Santander, 2018).

A typical example is the case of a frog random jumping asymmetrically between just two stones A and B in a pond (with a non-zero probability of remaining stationary), which may be seen as a metaphor (or a model) of an unmerciful market struggle between two yoghurt producers A and B, which month after month seduce each other's consumers according to a fixed pattern. The random walk is a metaphor for the market struggle, or the other way around, according to whether the involved learner is more acquainted with jumping frogs or with market struggles.

In our courses, we told the students the tale of Filomena, a frog which jumps randomly but symmetrically (like heads or tails, to its two next neighbours each time), on a row of 6 stones (tagged 0 to 5), starting at stone 3. Stones 0 and 5, however, are in fact two lurking alligators, called Anibal and Artemio, camouflaged as stones. Filomena will be instantly swallowed if it ever lands on the head of either alligator. Naturally, the students wonder about Filomena's fate...

We also told these students about the classical "ruin problem" : two players *A* and *B*, having a certain amount of euros each, flip repeatedly a fair coin to decide who wins. After each flip, the winner receives one euro from the loser. No credit is available, so the game ends when any player runs out of money (is "ruined"). In our case, *A* would have an initial "fortune" of three euros, and *B* would have only two (metaphorically, A's ruin means that Filomena was eaten by Anibal). Sundry questions arise, like: *How likely is that in the long run A, or B, becomes ruined? How likely is that the game goes on forever?* Students tackling the ruin problem might move metaphorically to the frog's walk, and then in turn, to a splitting process or to a water draining process. Notice here that metaphorising involves a cascade of metaphors, so the skill to move between them becomes significant for the learners.

We were interested in investigating students' reaction when being proposed both the frog's random walk and the ruin problem (with the same data) in a (prepandemic) test. We found that our students, who have being exposed to traditional teaching leaving no room for metaphorising, had trouble in recognising both problems as the "same", but in different guises. Some even solved one right, and the other wrong! A few, less than 5%, realising that they were given the same problem twice, did not dare to say so; another effect of the prevailing didactic contract, we deem.

Discussion

From our viewpoint, the theories associated with enaction, metaphorising and a-didactic situations, besides helping us understand complex phenomena in mathematics education, provide us with an epistemological perspective, which positions us in a particular relationship with what we observe. That is, we see the enactive as inherent in the learning-teaching processes of mathematics, beyond the merely embodied. Likewise, metaphorising would be a ubiquitous emergent, whether or not we are aware of its presence or its role in mathematics education. They would both be, therefore, inevitable phenomena.

The perspective resulting from embracing these theories forces us to rethink the pedagogical chore, the didactics, the methodologies, the methods. In this way, it becomes necessary to open up spaces (construct situations, contexts) where the emergence of (idiosyncratic) metaphorising is welcomed as a legitimate possibility of mathematical thinking, exploring what it allows, and being aware of its limitations. This exploration, accompanied by an enactivist approach, means valuing "learning by doing" in the context of problem-posing instead of problem-solving. In other words, we will need to propose situations where students have the freedom to interact and re-construct, giving raise to the emergence of their own problems. In this context, the approach from a-didactic situations provides not only a theoretical frame of reference in the didactics of mathematics education, but also proposes to the teacher a way of doing, where she will need to step back and allow students to interact with each other and with embodied mathematical knowledge, where enaction and metaphorising are even more visible than in traditional didactics.

The tree of perception as being phenomenologically grounded, intuition as a mathematical space generator and Vygotsky's perezhivanie as emotional transcendental lived experience

Andonis Zagorianakos

National and Kapodistrian University of Athens, Greece; matheart7@math.uoa.gr

Keywords: Perception, perezhivanie, lived experience, phenomenology, intuition.

This study is based on revisiting a previously analysed (Zagorianakos & Shvarts, 2015) learning episode. Mary, a prospective teacher of mathematics, engaged in a mathematical task that was initiated in an embodied manner, which utterly permeated her noetic treatment of the task. The study opens new space for discussing *perception* in mathematics education, as being phenomenologically grounded, while linking it with the late Vygotskyan *perezhivanie* (Vygotsky, 1994), as being a critical learning phenomenon, concerning the challenge of a rich environment. What Vygotsky (2012, p. 110) calls "the ascent to concept formation" is investigated here through a phenomenological methodological lens (Zagorianakos, 2019, p. 3081), with a movement from the *natural* to the *phenomenological attitude*.

This study introduces allusions concerning crossroads between phenomenology and Vygotskyan cultural historical activity theory, crossroads that emanate from perezhivanie, a so far untranslated Vygotskian term. For Vygotsky (1994, p. 343) perezhivanie is an "emotional experience", a (psychological) "unit", "a unity of environmental and personal features". He sees perezhivanie as a *refraction* of the environment through the personal psychological state (p. 341) and the current research takes it as pointing towards the analysis of "how I, myself, am experiencing this (i.e., the interplay of) all the personal characteristics and all the environmental characteristics" (p. 342), aiming at reviving discussions on perezhivanie in the existing literature (e.g., Roth & Jornet, 2016).

Mary's bird's-eye-view intuition, her tree of perception and perezhivanie

The task was set for the students by asking them to embody the line that is equidistant from a wall and a fixed point that is set at a distance of 10 paces from the wall (Zagoriankos & Shvarts, 2015). As Mary was attempting to embody the fixed point in her group of three students, she was thinking that the sought, equidistant line must be a parallel line to the wall, halfway between the wall and the fixed point. Hence, Mary was utterly confused during her initial perezhivanie (lived experience) of the task. When she came home, she used grid paper, a ruler and coloured pencils in order to represent the classroom setting, as she drew the wall and the fixed point. And then the *bird's-eye-view* intuition of her diagram surfaced. Her intuition transformed both her diagram and her classroom experience, allowing her to acquire a new sense for both of them, starting with the wall, which was perceived as infinitely long. With her *bird's-eye-view* intuition Mary entered into a *constitutional mode*, drawing from the communicating vessels of *pre-reflective and reflective perception* (see Figure 1: soil-trunk/pre-reflective and branches-crops/reflective parts of the tree). Her task *perception* was filled with crops/mathematical results, serving as an exemplification of how intuitions operate as *mathematical space generators*.

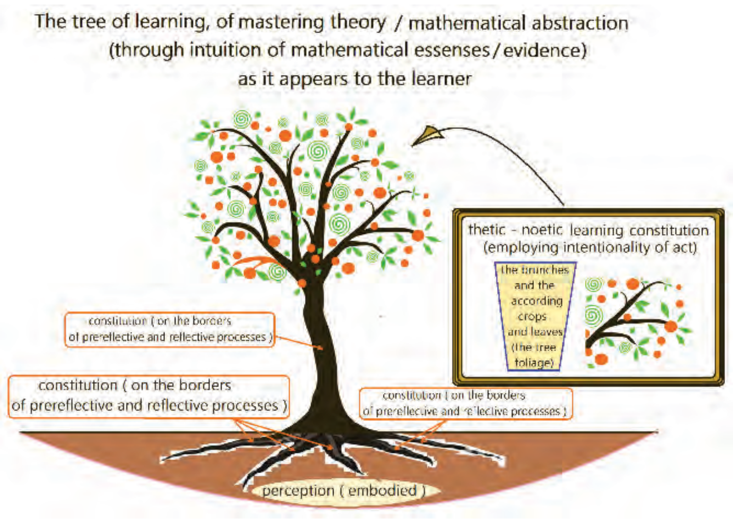

Figure 1: The tree of perception

The tree of perception (Figure 1) exemplifies the personal characteristics that “are represented in an emotional experience [perezhivanie]” (Vygotsky, 1994, p. 342). The environment set by the teacher was allowing ample breadth of scope that each student could push towards. Mary’s bird’s-eye-view intuition transformed her class experience, as the cultural artefacts (ruler, pencils, grid paper, Cartesian plane) opened up abstract geometrical/algebraic affordances. Hence, the growing of her *tree of task perception* also represents the features of the student’s environment, in the sense that for Vygotsky (1994) perezhivanie is a unit, namely a vital and irreducible part of the whole, a significant unit in which personal and environmental components are represented. The suggested crossroad between phenomenology and activity theory is concerned with the inextricable interplay between the complementary and irreducible poles of personal perceptions and of the environment’s affordances, for the constitutions emanating from the former, as they are refracting the latter, rendering perezhivanie as an emotional transcendental lived experience. To better understand “how a child becomes aware of, interprets, [and] emotionally relates to a certain [learning] event” (p. 341).

In this paper, we review all of the contributions to TWG18, focusing on the range of research interests, theoretical perspectives and frameworks, and methodological approaches. From this review, the presentations, and discussions, the following future directions have emerged in relation to teacher education (TE): 1) Establishing and exploring research informed design principles; 2) summarising relevant theoretical directions; 3) exploring teacher change from an ethical perspective; and 4) scaling up innovative approaches within TE. In relation to professional development (PD), the following future directions have emerged: 1) Exploring the different roles of participants in PD; 2) exploring what makes change difficult and how professional growth best can be supported; and 3) understanding how we can best build on previous research, and each other, in order to develop the field of mathematics PD research.

Keywords: Educational research, mathematics teacher education, professional development.

Introduction.

Over recent decades, the study of mathematics teacher education (TE) and professional development (PD) has been a central focus of research. During previous ERME conferences, various research activities regarding these topics have been presented and discussed. Hošpesová et al. (2018) thematised the history of Thematic Working Group 18 (TWG18) and linked those topics addressed since CERME1 to questions related to theory and practice, collaborative environments, and reflection. In the CERME12 call for papers, TWG18 addressed a focus on research into prospective mathematics teachers' professional preparation as well as in-service teachers' professional development. The call invited discussions in relation to models and programs of PD as well as related practices (e.g., contents, methods, tools, and impacts). Within TWG18, 27 papers and 14 poster proposals were presented and discussed. Due to this large number of submissions, the TWG was divided into two sub-groups, specifically:

- TWG18a: **Mathematics Teacher Education** (TE) and Professional Development
- TWG18b: Mathematics Teacher Education and **Professional Development** (PD)

By offering a communicative, collegial, and critical forum for the discussion of these and other related issues, TWG18 attracts research from a diverse range of perspectives and theoretical approaches and contributes to the development of our knowledge and understanding as researchers, educators, and practitioners. TWG sessions 18a and 18b comprised both plenary and sub-group working phases. During the plenary phases, two or three papers and/or poster proposals were presented for a maximum of five minutes each, in which the authors highlighted their research interests, the main perspectives and frameworks (explicit, conceptual, theoretical, or practical), as well as the main methodological considerations in their research. These short presentations were followed by one or two discussants reacting to the research presented. Plenaries were followed by parallel sub-group discussions, which were each chaired by one of the discussants. Participants were able to choose and join a sub-group, where discussions lasted for approximately 20 minutes. All sub-group participants then came back together where central topics and issues were shared from each of the discussions. These central topics and issues, which came out of group discussions, often highlighted issues beyond the papers' scope and were recorded in the TWG's Padlet. Examples of issues beyond the papers' scope are ethical considerations in relation to teacher change and exploring how we can learn more about different participants' roles in PD. The content recorded in the Padlet was used when arranging specific topic discussions within TWG 18. The outcome, in form of emerging issues for the future, is described in the final section of this paper.

Building on Eisenhart (1991) and Lester (2005), this review of submissions to TWG18 is organised around three key aspects concerning the research process. The first aspect concerns the phenomenon of interest in the specific study, and how that research interest is justified, positioned, and explained. The second aspect is the choice of framework (theoretical, conceptual, or practical). According to Eisenhart (1991), theoretical perspectives include pre-defined concepts and assumptions that guide the research design. A *theoretical* framework uses a formal theory to establish explanations about a phenomenon. A *conceptual* framework can be viewed as a skeleton that justifies the study in relation to the aim (i.e., a set of assumptions about reality that underlies the research). A *practical* framework is guided by finding approaches that work in practice. Lester (2005) points out that the aim of research is not solely to select and use a conceptual framework, rather, researchers need to adjust and justify the conceptual framework in relation to their specific study. The final aspect concerning the research process is the set of methodological considerations concerning how to reduce the empirical material into meaningful data and how to present the results.

Based on this, this review paper will include sections aiming at answering the following questions:

- What were the **research interests** in the papers and poster proposals within TWG18?
- What were the main **perspectives and frameworks** in the papers and poster proposals?
- What were the main **methodological considerations** in the papers and poster proposals?

In addition to these three aspects, as explained above, we also summarise the emergent issues from the presentations and discussions within the groups, which we present towards the end of the paper.

Research interests.

A diverse range of research interests were presented within TWG18. Within TWG18a, research presented involved all phases of mathematics TE (primary, middle, and secondary phases). Most commonly, research was focused on prospective mathematics teachers (PMTs) and their responses to: tasks and resources; hypothetical or real student(s); hypothetical or real interactions between teacher(s) and student(s); other prospective teachers; teacher educators; learning environments and tools. In TWG18b, many papers and poster proposals explored the design of research-based PD interventions as well as researching the different aspects of these interventions. The main aim of the PDs studied and presented in TWG18b can be summarised as collaboration between teachers or teachers and teacher educators or researchers in order to develop teaching practices, mainly towards more explorative approaches to teaching. In the PD research presented, the roles as facilitators, teachers, students (one or several) were explored.

Research interests: Teacher education.

Concerning the way PMTs respond to tasks and resources, *Sødal* researched PMTs' views in relation to the benefits of different aspects of working with resources in university coursework in preparing them for teaching mathematics. She found that working with resources can provide PMTs with practical and useful experiences as well as a way of combining content knowledge and core practices, to close the perceived gap between theory and practice. With regards to researching how PMTs respond to students' mathematics, *Henriques and Oliveira* researched the development of PMTs' knowledge in relation to students' mathematics reasoning. In this study, the PMTs' interpretations of students' mathematical reasoning processes were analysed and findings suggested that, over time, PMTs knowledge level improved. With a focus on the interactions between teachers and students, *Schnell and Fellenz* researched the role of 'Perspective Taking' in relation to PMTs' noticing students' mathematical thinking. In their study, they analysed the content of PMTs' written responses to a video clip of a mathematical interview. They found the most common perspective taken was one of task solver as opposed to teacher or student. Only two papers presented placed their focus upon the mathematics teacher educators (MTEs). *Longwe-Mandala and Fauskanger* explored ways in which MTEs in Malawi invite PMTs to participate during teacher education programmes, to better understand how these PMTs are enculturated into the practice of inviting learners to participate actively in lessons about number concepts and operations. *Ebbelind and Helliwell* explored the experiences of a group of primary PMTs during their teacher education programme in relation to the language-in-use of one MTE in Sweden.

Research interests also included ways to develop meaningful designs of mathematics teacher education programmes. Across the papers and poster proposals, researchers utilised well-established, as well as innovative pedagogical approaches within mathematics TE which, in some cases, became their focus of research. Examples of innovations include *Frejd et al's* use of a team-teaching approach called Socratic lectures to develop PMTs' communication skills and *Samková's* use of concept cartoons in primary teacher education to help assess prospective primary school teachers' knowledge on topics related to the primary school curriculum.

Research interests: Professional development.

As an example of research that explored the design of research-based PD interventions, *Grimeland et al.* investigated what kind of co-learning and learning gaps could be identified in a PD session on the topic of programming, a topic newly included in the Norwegian curriculum across grade levels.

Their findings indicate that both teachers and teacher educators learn about programming and lesson planning for programming during the PD. In addition, teacher educators learn about teachers' programming knowledge. One of the learning gaps identified is teacher educators' knowledge about use of programming in school.

Aiming at understanding how teachers reason about the role of high-quality mathematical tasks, a second example study analyses three groups of mathematics teachers engaged in collegial discussions as part of a national large-scale PD programme in Sweden. In this study, *Kaufmann* explores how the teachers reflect upon and explain the role of high-quality mathematical tasks when choosing tasks for use in their lessons. *Kaufmann*'s results indicate that the teachers appreciate high-quality tasks for providing student-to-student talk and for supporting students' collaborative efforts to solve problems. However, although these teachers appreciate high-quality tasks, they referred to such tasks as inappropriate for their students, blaming their students' capabilities, their lack of motivation to engage in such tasks, and their lack of experience with such tasks.

Problem solving was a focus of attention in several contributions. As an example, *Keller and Kohen* explore the learning processes occurring in online discussion forums as part of a 2-year PD programme where the teachers first acted as learners through collaborative solution of complex mathematical problems in small groups. Secondly, they led collaborative problem solving in forums as mentors. Based on exploring what is reflected in the teachers' pedagogical activities, *Keller and Kohen* conclude that problem solving forums have a high potential for developing teachers' own self-regulation skills, increasing their effectiveness in collaborative problem solving and empowering their support to students in solving complex mathematical problems.

In relation to exploring the roles of those participating in PD, one example is the study by *Skott and Ding* who focussed on the facilitator's role in lesson study by comparing how facilitators talk with teachers and what they focus their talk on. They use a framework consisting of mentoring strategies and content categories; both developed empirically in a Chinese and European context respectively. Their analysis showed big differences in the facilitators' ways of engaging in talk with teachers, including the dynamic and relational patterns in the Danish case as compared to the lengthy talk in the Chinese context. Based on their analysis, *Skott and Ding* argue that these differences are not only related to the fact that lesson study is new in Denmark, but also to social and cultural differences.

Perspectives and frameworks.

The studies shared within TWG18 were based on a wide variety of frameworks, depending on the research questions being answered and on the researchers' perspectives. In TWG18a different theoretical perspectives were used for the different facets of the teaching profession that the PMTs were prepared for. In TWG18b, different theoretical perspectives were used to guide the design of the PD programmes and also as underlying sets of concepts and ideas guiding the research design and the analysis.

Perspectives and frameworks: Teacher education.

Among the frameworks informing the facets of the teaching profession that the PMTs were prepared for, all three main objectives could be found in the papers and posters: knowledge, beliefs, and practices, both individually and combined. From the perspective of Shulman's (1986) subject-matter knowledge (SMK) and pedagogical content knowledge (PCK), the majority of the papers and posters focused on PCK. In several cases (e.g., *Reitz-Koncebovski et al.*), SMK was connected to PCK via the model of school-related content knowledge (Dreher et al., 2018). The contributions studying PCK focused on one or more components of mathematical knowledge for teaching according to Ball et al. (2008) (e.g., *Schreiber*), on professional vision and noticing according to van Es and Sherin (2021) (e.g., *Karatsioli et al.*), or on diagnostic judgement according to Loibl et al. (2020) (e.g., *Schreiter et al.*). From the perspective of PMTs' beliefs and motivations, there were papers focusing on beliefs about resources for teaching mathematics (*Sødal*) or on motivation and communication skills (*Frejd et al.*). From the perspective of PMTs' practices, *Chikiwa and Graven* proceeded from the six-lens framework for guiding teachers' reflections on video-recorded lessons (Karsenty & Arcavi, 2017). One of the papers (*Karagoz Akar et al.*) focused on knowledge, beliefs, and practices all at once, and studied consistencies among them.

In TWG18a a wide range of different approaches to TE were introduced, including some recent or innovative approaches: for instance, transferring the concept of lesson study from PD to TE (*Ponte and Quaresma*), or transferring clinical simulations from the context of professional preparation of pilots, medical doctors, or nurses to the context of professional preparation of mathematics teachers (*Schreiber*).

Perspectives and frameworks: Professional development.

Among the frameworks informing the structure of the presented PD programmes, collaborative work between teachers is a common factor. The implementation of lesson study in new contexts was the focus of some studies including *Haringová and Medová* who studied the implementation of the lesson study approach in Slovakia. A further example of collaborative work in PD programmes can be found in the study by *Nurick et al.* where teachers participated in the VIDEO-LM project and discussed videotaped mathematics lessons using the "six-lens framework" (Karsenty & Arcavi, 2017).

There was a wide variety of approaches among the frameworks used to analyse research data and explain the phenomena behind them. The meta-didactical transposition framework (Chevallard, 1999) was used by *Pocalana et al.* as an interpretative lens to describe the interactions between teachers participating in PD and researchers acting as facilitators in the PD. In particular, they focused on the evolution of the praxeologies of both communities. In addition, *Pocalana et al.* used the boundary objects (BO) framework (Akkerman & Bakker, 2011) to explain the development of a shared praxeology between teachers and researchers, the internalisation processes of new elements for both communities, and the learning mechanisms activated by the design choices made by researchers for the PD program. Another study using the BO framework is the one by *Casi and Sabena* who interpreted museum collections to be BO connecting communities of students, teachers, and museum staff. As BOs, components of non-scientific museums acted as prompts for epistemological discussions about mathematics.

Collaboration among teachers has also been the focus of research analysis. *Keller and Kohen* studied the interactions of teachers in an online environment, where teachers participated in online forums. They analysed the participation of one teacher in the forum using the framework of collaborative mathematics problem solving and its taxonomy of interactions (Clark et al., 2014), together with the components included in the Self-Regulated Learning framework (Boekaerts et al., 2000).

Methodological considerations.

Methodology can be understood as methods used for creating, gathering, or collecting empirical material and the specific reasons researchers have for using such techniques. As highlighted by Eisenhart (1991), this step also concerns how to reduce the empirical material into meaningful data worth highlighting in the result section. This section focuses therefore on the research design and sample size, methods for generating empirical material, structuring information, and generating data material for the results section in TWG18a and TWG18b.

Methodological considerations: Teacher education.

Research presented in TWG18a covered various research designs: qualitative, quantitative, and mixed methods research. Quantitative research included intervention studies involving a pre– and post– intervention test. For instance, the study by *Volkmer*. Other quantitative studies used written formats as data, such as *Dröse*, who used written diagnostic judgements from a group of PMTs (n = 26). These written judgements were coded with relation to knowledge elements for current or prior learning content using two dimensions of procedures and concepts. Quantitative studies consisted of up to 300 participants.

Half of all papers and posters related to TE were qualitative, covering single-case studies to those consisting of more than 50 participants. For example, *Samková* used indicative questions concerning a concept cartoon. The participants worked on tasks individually, and the data collected was processed using open coding and constant comparison to display subject-matter knowledge. *Ebbelind and Helliwell*, on the other hand, used a methodological tool to structure their empirical material from different contexts. Four contributions involved mixed methods. *Schreiter's* use of eye-tracking as a data collection method was a novel methodology within the TWG18a group.

Because of the various sample sizes and methods, the nature of the data is diverse. Methods for generating empirical material in TE research related to either: written reflections, answers to indicative questions, task solutions, lesson plans, questionnaires, recorded or transcribed interviews, video-recorded lessons, task analyses and movement tracking (mouse and eye). It is sometimes mentioned that theory sets standards for methodology, however, those researchers that use Loibl et al's (2020) diagnostic judgement use the full range of methods displayed within the TWG18a group.

Methodological considerations: Professional development.

Studies on teachers' PD in TWG18b included a systematic review of the literature on PD programmes and their relationship with student achievement (*Peri & Gomez Zaccarelli*) and a survey project on professional journals for mathematics teachers (*Asami-Johansson & Otaki*). The sample sizes in the presented studies ranged from two to 47 and up to several hundred participants: *Österling* conducted a visual and fine-grained analysis of two teachers' lessons in order to develop a framework for representing changes in mathematics teaching over time; *Keller and Kohen* explored the learning processes of 47 teachers when engaging in collaborative problem solving in online discussion forums. *Knaudt et al.* aim at developing adaptive training modules for in-service teachers at 125 primary schools with the aim to foster teachers' diagnostic competences whilst considering the heterogeneity in the participants' individual learning prerequisites.

The majority of the presented studies in TWG18b used qualitative methods for investigating the participating teachers' professional growth: Data sources were videos from lessons (e.g., *Österling*), videos from PD sessions (*Nurick et al.*; *Haringová & Medová*) or interviews (e.g., *Neururer & Shúilleabháin*). In their comparative case study, for instance, *Koellner et al.* conducted semi-structured interviews using think aloud protocols for an in-depth investigation into teachers' practices five years after taking part in a PD programme. Many of the studies analysed written reflections or responses from teachers (e.g., *Keller & Kohen; Knaudt et al.*). *Kaufmann*, for example, analysed data on the reflections from teachers engaged in collegial discussion about the role of high-quality mathematical tasks. *Skott and Ding* investigated teachers' planning of lessons as data sources and explored potential changes. Only two studies (*Pocalana et al.; Knaudt et al.*) also made use of questionnaires: *Pocalana et al.*, for instance, administered a questionnaire to investigate teachers' praxeologies including teachers' beliefs about their students and about the teaching and learning of mathematics to complement qualitative data collected through interviews, written protocols, video recordings and reports about teachers' classroom experimentations. Looking across all studies addressing the professional growth of in-service teachers, various analytical frameworks were applied to analyse and structure the collected data: the commognitive framework (*Österling*); boundary objects theory (*Casi et al.; Pocalana et al.*); directed content analysis (*Keller & Kohen*); co-learning dimensions (*Grimeland et al.*), abductive process analysis (*Kaufmann*) or comparative case study analysis (*Koellner et al.*). Corresponding to the research focus of the respective studies, coding of participants' responses was, for instance, also based on levels of teacher noticing (*Fauskanger & Bjuland*) or stages of teachers' concern (*Neururer & Shúilleabháin*).

Emerging issues.

As highlighted in the introduction of this paper, group discussions often highlighted issues beyond the papers' scope. Therefore TWG18a and TWG18b arranged specific topic discussions during the conference. These issues were highlighted as emerging issues for the future and can serve as inspiration for forthcoming CERME conferences.

Issues from the discussions during TWG18a related to future TE research can be summarised as follows. Firstly, exploring whether it would be possible to establish a set of research based design principles for TE courses that would be applicable across different contexts, and what such principles might look like is a next step for TE research. To accomplish this, there is a need to share concrete task and course designs for TE programmes. Secondly, there is a need to summarise relevant theoretical directions in TE, to get a better sense of the different frameworks used within our community. A better understanding of different perspectives will not only strengthen our own research, but also contribute to more nuanced discussions in the future. Thirdly, teacher change was considered from an ethical perspective, with questions asked such as whether it is right to try to change teachers in certain ways, and who should make those decisions. Such ethical perspectives is in need for future explorations. Lastly, the question of how our research community might scale up innovative approaches should be explored.

Issues from the discussions during TWG18b related to future PD research can be summarised as follows. Firstly, future research should aim at exploring how we can learn more about different participants' roles in PD (i.e., students, teachers, teacher educators and researchers) whilst, at the same time, facilitate collaboration between all participants. Secondly, there is a need for exploring what makes change difficult and how professional growth best can be supported. Lastly, better understanding how we can build on previous research and each other in order to develop the field of mathematics PD research is an implication for future research.

Journals for disseminating professional scholarship of mathematics teachers

This presentation describes a framework and an analytical method we employ in our project, the aim of which is investigating the characteristics of professional journals for mathematics teachers in different countries. Professional journals for schoolteachers in mathematics function as an important venue to disseminate different kinds of professional knowledge necessary for carrying out teaching. The contents of journals can deal with individual teacher's work for designing lessons in certain area, proposals for different methods for assessment, philosophical articles about mathematics education, columns by mathematicians, presentation of results from research, etc. The selecting and editing from such possible contents depends on the needs of the readers—the roles and responsibilities of schoolteachers that are devolved from a given society to which they belong. What similarities and differences are there between different journals around the world? As a first step for answering this question, we report here a preliminary analysis on a Swedish journal *Nämnaren* (The Denominator).

Levels of didactic co-determinacy and paradidactic stakes

A sequence of didactic situations in classroom depends upon a family of *conditions* of different kinds and origins. The hierarchy of such conditions is modeled by the anthropological theory of the didactic as a *scale of levels of didactic co-determinacy* (e.g., Chevallard, 2019). We apply the scale to situate foci—or *paradidactic stakes* (Otaki et al., 2020)—of journals, for identifying the properties of the journals. We have categorised the contents of the articles and related them to the different levels of the co-determinacy as the following: *Society*, related to general issues, e.g., Swedish national traits, culture and world trend. *School*, related to school educational issues, e.g., national curriculum, Swedish school and its policies. *Pedagogy*, related to generic teaching principles e.g., methods for promoting students' interaction. *Discipline*, related to mathematics itself as an academic subject or school subject. *Domain*, related to relatively general areas in mathematics such as algebra, geometry, function, etc. *Sector*, related to the general topics of mathematical objects such as equations, similarity, operations. *Theme*, related to contents of teachers' activity such as how to teach the concept of triangles, etc. *Subject*, related to one simple type of task (in a lesson) and a corresponding solving method. From this point of view, our research question in this survey project is formulated as the following: *what levels of paradidactic stakes do professional journals for mathematics teachers include or exclude?*

Pilot analysis on *Nämnaren*

Nämnaren has been established in 1974 and publishes four issues a year. The journal is currently directed by the National Center for Mathematics Education, the task of which is to support the development of mathematics education from preschool to secondary school levels. Authors of articles are mixture between teachers in service in different levels, teacher educators, researchers in mathematics education and mathematicians. In this pilot study, four numbers from the year 2020 are analysed. The total number of published articles in these four numbers is 58, and the main issues of the submitted articles are following: teachers' activities, students' phycology and special pedagogy, history of mathematics, research and survey reports, and use of manipulatives and ICT. Of the 58 articles, 49 of them aim at primary and (mostly lower) secondary levels. The rest aims at pre-school education, adult education, and education in general. *Nämnaren* has three standard topics in every issue: book reviews on newly published educational books, problem bank and language column. The last two topics often deal with the issues related to lower levels such as theme and subject. Contents of several articles are related to more than one level of the co-determinacy. For example, an article, which describes using double number lines for better understanding for algebra, deals with conceptual description of algebra and equations (sector), but its actual focus was giving suggestions for teaching design (theme) and task examples (subject). Even though two articles present activities on number theory, the focus of one article is on the level of theme, while the other is related strongly to the pedagogy level. In the same way, one article treats a topic of Pascal's triangle for an analysis of a sports context (theme), while the other describes conceptual differences of algorithms using Pascal's triangle in different institutions in several countries (sector). As a summary, two articles are related to the society level, five to the school level, 15 to the pedagogy level, four to the discipline level, three to the domain level, seven to the sector level, 24 to the theme level, and 15 to the subject level.

The tendency that the paradidactic stake of the journal tend to gather in the lower levels *and* the level of pedagogy is not surprising, since the readers of the journal could have a disposition so called *the paradidactic bipolarization* (Otaki et al., 2020). This phenomenon indicates that schoolteachers' interest and their professional knowledge lie exclusively either pinpoint mathematical matters or general-purpose teaching methods. A notable fact is that a professional journal, one of the missions of which is disseminating teachers' professional scholarship, traces the pattern of the bipolarisation of schoolteachers' scholarship. In our view, this illustrates an aspect of the functioning of the *teaching profession*, whereby schoolteachers are reproduced together with the didactic worldview supported by certain *norms* (remember the expression "normal school"). Such institutional structure may hinder forthcoming reforms of mathematics education. Understanding the epistemological economy (and ecology) of the teaching profession—which is often recognised as a *semi-profession*—is crucial, not only for research but also for practice. The information on current states of the teaching profession should be useful for developmental actions for teacher education in the future.

Teaching planning as a process and as a tool to develop didactic analysis

This work addresses the question: What are the criteria used in planning a class on the perimeter, by preservice teachers? The objective refers to identifying the criteria that preservice mathematics teachers (PMT) use to assess the didactic suitability (DS) in managing a study process, in the class plans for teaching the perimeter. The inquiry process to construct plausible plans is guided by the Onto-semiotic Approach (OSA) of Mathematical Knowledge and Instruction (Godino et al., 2007).

Theoretical framework

The Ontosemiotic Approach (OSA) of Mathematical Knowledge and Instruction (Godino et al., 2007) is assumed; several features related to didactic analysis (DA) are studied, such as the notion of didactic suitability (DS) and normative system (NS) in the context of pre-service mathematics teachers' teaching practices.

Methodological framework

The research was conducted with six preservice mathematics teachers based on a qualitative research approach which allows obtaining complex details related to human thought and emotions. Data was obtained through interviews including previous personal ideas about planning before the interventions and then about actions, evaluation and improvements done to their previously presented lesson plans regarding the topic of perimeter for sixth grade students.

The general fieldwork was organized in three phases: in phase 1, the object of this report, previous and personal ideas about planning and evaluation that students use when designing a class plan are studied; in phase 2, an intervention-training is implanted, to analyze the didactic suitability in the study process; and in phase 3, the actions and evaluation and improvement criteria used in the redesign of the plans to teach the perimeter object projected in phase 1 are studied. In the first phase information was obtained by recording video audios, transcripts and reviewing student responses (I-1), and data on the reflection on the planning of "my class in mathematics (I-2)".

Analysis

The First Phase of the research, focused on the elaboration and a priori analysis of the lesson plans designed by the PMT, has four moments: moment 1) contextualization and investigation of previous ideas about teaching planning; moment 2) application of I-1, and discussion of designed plans;

moment 3) application of the I-2 instrument and discussion; moment 4) analysis in teams on a lesson plan based on I-1 and I-2.

On the a priori criteria emerging

Based on the coding, initially open and then axial (Strauss & Corbin, 2012) of the actions and reasons (A-R) present in the plans, we could to identify eight groups of actions-reasons with different levels of presence- shown in Table 1-. Some of the configured A-R groups presented in the PMT plans are described and explained:

Table 1: Action groups and reasons (A-R) emerging in planning. Source: Authors

Action groups and reasons (A-R) emerging in planning	Emerging A-R in lesson plans and level of prevalence
A-R1. According to training area	Curricular (32%), didactic (7%), disciplinary (44%) and formative-pedagogical (17%)
A-R2. According to the nature of the meanings	Institutional (68%) and personal (32%)
A-R3. According to the teaching model or trajectory	Active-constructivist (11%), problem-based (10%), collaborative (10%), lecture-mechanistic (17%), traditional-expositive (52%)
A-R4. Depending on the time of the class	Start (32%), development (32%) and closure (36%)
A-R5. According to the role of the students	Passive receiver (30%), collaborative (15%), individualist (11%) and active receiver (44%)
A-R6. According to the teaching intentions	Use of technological tools (54%) and motivation with games (46%)
A-R7. On the approach to the mathematical object to be taught	Routine exercises (29%), associated properties (2%), related concepts (20%), definition-concept of perimeter (7%), procedures (14%), representations (13%) and problem situations (14%)
A-R8. On processes associated with the development of mathematical thinking	Problem solving and problem posing (14%), reasoning (14%), communication (8%), formulation and application of procedures (47%)

These results confirm that the criteria and norms used by the PMT, emerging from the plans, are descriptive and evaluative. They are organized based on indicators associated with the different components that make up the didactic suitability criteria. The other A-R groups identified in the plans are related to interactional aspects in the A-R linked to the teaching model. In this sense, according to Table 2, A-R groups identified and organized according to lesson plans, are related to interactional ID criteria. The same occurs with A-Rs referring to the teaching model (A-R3). Concerning epistemic and cognitive ID criteria, they are found in the approach to the mathematical object to be taught (A-R7), as well as in the processes associated with the development of mathematical thinking (A-R8).

Informal mathematics experiences in museums: what potential for teacher professional development?

Raffaele Casi[1] and Cristina Sabena[1]

Keywords: In-service teacher professional development, informal mathematics education, co-design.

Informal mathematics education

In informal mathematics education research, learning spaces other than school are explored, and experiences with mathematics that are different from the traditional ones offered by the educational institution are lived. According to Nemirovsky and colleagues (Nemirovsky et al., 2017), informal mathematics education contexts differ from school-based mathematics activities mainly due to three structural features: the voluntariness of learners' participation, the fluidity of disciplinary boundaries, and the absence of traditional forms of assessment. In recent years, we have been involved in projects aiming at preventing school dropout in disadvantaged neighborhoods of some Italian cities, namely the Proud of You project (Carotenuto et al., 2020) in Napoli and the Next-land project in Torino. In both projects informal mathematics learning was chosen for its potential to convey alternative visions of mathematics and to engage all learners in ways that are creative and different from usual school practice, with the underlying hypothesis that engaging students and changing their vision of mathematics may contribute to prevent school dropout. In accordance with the perspective of Culturally Responsive Mathematical Education (Gay, 2010), we decided to situate the informal mathematical learning activities in the history and culture of the students' own territory, allowing them to create, recreate, and shape their meanings. In our experience, two elements emerged as crucial for reaching the desired aims: the collaboration with teachers in co-designing the activities, and the relationship between informal and formal mathematics learning. They need further investigation, and in this contribution we will focus on the idea of exploiting the informal settings provided by museums (and specifically non-scientific museums) in a teacher development perspective. Our starting point is our experience of co-designing informal mathematics learning activities with museum experts. This was accomplished within the Next-land project, which we will briefly introduce.

The co-design experience in the Next-land project

In the Next-land project (https://www.next-level.it/progetti/next-land/), grade 7 students from disadvantaged areas of Torino (Italy) are involved in out-of-school workshops, during the first two weeks of school in their curricular hours. Workshops vary a lot as regarding locations and content. Our research group[1] is responsible for the mathematics workshops, which are located in four museums (Egyptian Museum, Museum of the Risorgimento, Palazzo Madama, Park of Living Art). In collaboration with the staff of each museum, we co-designed four workshops aimed at learning mathematics through the discovery of historical and artistic heritage of the City of Torino, involving students in experiences of observation, exploration and manipulation.

[1] The research group is composed by the authors and by two teacher-researchers: Valentina Leo and Chiara Pizzarelli.

In Autumn 2020, about 200 students, accompanied by their teachers, took part in the workshops, led by the staff of the museums. From our own field observation and the feedback given by the teachers, the students and the museum staff, we gained evidence of some positive results with respect to the project aims. However, we found also that the lack of the teachers' engagement in co-designing the activities limited the workshop experience to just an interesting activity that had no further implication on the students' mathematics experience, and therefore on the possibility of changing their view of mathematics on the long run. But how may teachers be involved in co-designing informal mathematics education activities in collaboration with mathematics educators and museum experts? The need for teacher professional development emerged in a striking way.

What potential for teacher professional development?

Based on our co-design experience with museum experts, we are convinced that informal learning in non-scientific museums may be exploited to engage teachers in rethinking their teaching practice and their relationship with mathematics. The informal character of teaching by workshops in museums and the encounter with different knowledge coming from other domains (like history and art) will favor the teachers' creativity in designing tasks to be carried out, with the perspective to develop in students an *emergent learning* rather than achieving predefined goals. Since informal education is still under-researched in relation to student learning, and to our knowledge has not yet been studied for teacher education, we plan to work by letting teachers first experience the workshops of the Next-land project, and then co-design more workshops with museum experts and mathematics educators. It is our hypothesis that the museum collections can be the boundary objects (Akkerman & Bakker, 2011) connecting the three communities, prompting a discussion about an epistemological analysis of mathematics and bringing to the fore different visions of mathematics itself.

The teacher development process will be the focus of a PhD study aiming to answer the following research questions: What difficulties may teachers experience in designing informal mathematics workshops, and how may they overcome these difficulties? What actions can be implemented to support teachers? What changes can be generated in teachers' practices and beliefs? What impact on the usual classroom activity? To answer these questions, we will collect data through questionnaires, focus groups and audio/video recordings of meetings, which will be analyzed under a qualitative lens.

How the six-lens framework supports pre-service teachers' reflections

Samukeliso Chikiwa and Mellony Graven

Rhodes University, Faculty of Education, South Africa; s.chikiwa@ru.ac.za; m.graven@ru.ac.za

Keywords: Pre-service teachers/teacher education, six-lens framework, reflective practice.

Introduction.

The ability to reflect on one's practice is an essential skill for all mathematics teachers because of its significance in promoting effective teaching and learning. Pre-service teacher education (PTE) in South Africa is foregrounding this skill as one way to redress the long-standing record of poor performance in mathematics. This poor mathematics performance is often attributed to poor teaching which result from teachers' inadequate knowledge for teaching mathematics. Reflective practice (RP) is potentially useful for developing this knowledge. A mathematics methods lecturer at a South African university engaged her third-year pre-service teachers (PSTs) in three sessions of video-based lesson analysis to develop their RP for mathematics teaching. She employed the six-lens framework (SLF) developed by Karsenty et al. (2015) to guide mathematics teachers as they reflected on selected video-recorded mathematics lessons. Our research explored how the SLF supported the primary PSTs during the process of reflective practice development. We sought to answer the question: How do the various lenses of the six-lens framework influence how pre-service teachers reflect on video lessons?

Reflective practice and the six-lens framework

Although RP is a difficult concept to define or understand, it has many educational benefits. Scholars such as Dewey as early as 1933 suggested "it is impossible to become and remain an effective teacher without commitment to reflective practice" (p.9). The multiple perspectives on RP however have led to a lack of common definition and furthermore it is increasingly acknowledged that it is a skill that is difficult to develop (Russell, 2005). However, the skill is critically important as teachers reflecting on their teaching regularly tend to improve their own professional practices and adapt to the day-to-day ever-changing teaching demands (Dewey, 1933). In support of developing this critical skill Karsenty at al. (2015) developed the SLF to assist teachers to consider and reflect on six important aspects of lessons, namely: mathematical and meta-mathematical ideas (MMI); explicit and implicit goals; tasks and activities (T&A); dilemmas and decision making (DDM); interactions with the students, and teacher beliefs.

Methodology

The empirical field for the research was three lecture sessions on video-based lesson analysis (using the SLF) provided by a lecturer to her 52 third year PSTs at a South African university in 2017. The lecturer explained each lens to the PSTs before requesting them to use these lenses as they analysed the given video-recorded lessons. We employed a qualitative case study with 19 PSTs who volunteered to take part in the research. All written reflections of these participants were analysed across the three 2-hour lecture sessions. Our poster focuses on the written reflections during the third session where PSTs used all six lenses. We analyzed the reflections of the 14 PSTs who indicated each lens in structuring their reflections (5 PSTs did not indicate lenses). We analysed the reflections per lens to understand and ascertain how the different lenses influenced the nature and levels of PST reflections. We used content analysis and our four levels of reflection model (adapted from Lee, 2005 and Muir & Beswick, 2007) to analyse and summarise the data. The levels of reflection from first to fourth were Description; Explanation; Suggestion and Reflectivity. We also classified reflections as general (G) or mathematical (M).

Findings and discussions

The 14 PSTs wrote 628 reflections using the six lenses. Table 1 below shows how the reflections were spread over the six lenses and over general versus mathematical reflections.

Table 1 The results of the analysis of 14 PSTs reflections by lens

Lens	Level 1		Level 2		Level 3		Level 4		Total	G		M	
MMI	116	85%	19	14%	1	1%	0	0%	136	49	36%	87	64%
Goals	64	82%	15	19%	0	0%	0	0%	79	17	22%	62	78%
T&A	128	84%	22	14%	3	2%	0	0%	153	50	33%	103	67%
Interactions	89	82%	18	17%	1	1%	0	0%	108	98	91%	10	9%
DDM	62	83%	10	13%	3	4%	0	0%	75	47	63%	28	37%
Beliefs	63	82%	11		3		0	0%	77	48	62%	28	38%

From the table we noted that some lenses like T&A and MMI attracted more reflections than others and some (e.g. goals, MMI and T&A) tended to lean students towards greater mathematical rather than general focus. Of interest across all lenses PSTs tended to focus on description and explanation rather than suggestion and reflectivity. In the presentation we will talk to some further insights and implications for teacher education.

Lesson study in prospective mathematics teachers' education

João Pedro da Ponte[1] and Marisa Quaresma[2]

[1]Instituto de Educação, Universidade de Lisboa, Portugal; jpponte@ie.ulisboa.pt;

maquaresma@ie.ulisboa.pt

This communication presents a lesson study conducted with prospective mathematics teachers and seeks to know what the participants consider having learned and what is their perception of the lesson study. The participants are 14 prospective mathematics teachers with a master's degree in teaching. Data collection was made by participant observation with a research journal and individual interviews with six prospective teachers. The results show that the participants needed some time to understand this formative process but recognize that they made significant learning in several aspects concerning mathematics teaching.

Keywords: Lesson study, initial teacher education, prospective mathematics teachers, knowledge of mathematics teaching.

Introduction

Lesson study is a process of professional development of teachers originated from Japan (as *jugyokenkyuu*) in the late 19th century, popularized since the late 20th century from the USA (Stigler & Hiebert, 1999), and currently used worldwide (Huang et al., 2019). The work done in a lesson study focuses on students' learning. This work is informed by the curriculum guidelines and research related to a given theme, assuming a collaborative nature and center on school practice.

A lesson study is developed from the identification of a learning problem identified by the participants, who study curriculum documents, research and professional papers, textbooks, and other relevant material that can help to understand how to deal with this problem and, based on this study, plan a lesson in detail. This lesson, called research lesson, is taught by one of the participants and observed by the others, and is then the subject of a post-lesson reflection. Finally, the participants present their experience, in particular to other teachers. It is a process close to an investigation on professional practice, involving the definition of a research problem, the realization of preparatory work that includes a literature review, the realization of an experiment (the research lesson), the analysis of data related to that experience, and the dissemination of results.

Lesson study is a formative process developed for in-service teachers. Given the agenda of initial teacher education (ITE) in preparing future teachers regarding all aspects of teaching practice, the question arises if lesson study can be used in this field and how that may be done (Larssen et al., 2018; Ponte, 2017). Given the specificities and constraints related to ITE, there are several questions that need to be considered, such as: (i) How to define the research question? (ii) In which class can the research lesson be taught? (iii) Who teaches this lesson, the class teacher, a prospective teacher, or the university teacher? (iv) Who observes the research lesson? In cases where the prospective teachers constitute a large group, it is not easy to establish an organization to carry out the lesson study, and microteaching experiments have been carried out with the prospective teachers teaching each other in small groups (Fernández, 2005). In this communication, we present the main aspects of a lesson study conducted with prospective mathematics teachers during the 2020-2021 school year. Our aim is to know what the participants consider having learned and what is their perception of the lesson study.

Theoretical framework

Many different organizational arrangements have been used to introduce lesson study in prospective teacher education (Ponte, 2017). Two main situations may arise: the lesson study is made with a relatively large group of prospective teachers, in the frame of a university course, or the lesson study is carried out during student teaching with very small groups of prospective teachers. For example, in an experience carried out in the USA, Burroughs and Luebeck (2010) describe a lesson study made in the frame of a middle school mathematics methods course with 24 prospective teachers. The lesson study was carried out by a team of seven experienced mathematics teachers from local schools, with the prospective teachers in the role of observers of this activity, collecting and analyzing data from specific moments of the lesson study sessions. The research lessons were observed by just a few prospective teachers that reported to the whole class.

An example of an experience carried out during student teaching is described by Nakamura (2019), with the case of a prospective teacher in Japan involved in lesson study that focused on problem solving. The work was done in three weeks, with teaching in three mathematics classes, following the steps of preparation, teaching and reflection. The participants were the cooperating teacher and other prospective teachers (5 or 6) but there was no participation of a university teacher. The preparation of the lessons was made by the prospective teacher in interaction with the cooperating teacher but with no interaction with other prospective teachers. The most distinctive aspects of this activity were the intensity of the work carried out and the key role of the cooperating teacher.

One of the main aspects of the preparation of prospective mathematics teachers concerns the development of their knowledge about mathematics and mathematics teaching. Current discussions about such knowledge are framed in a decisive way by the seminal work of Shulman (1987) who called attention for a kind of knowledge that he considered neglected in initial teacher education—pedagogical content knowledge. Following the European tradition of defining didactics as the study of teaching and learning in different curriculum subjects, (Ponte, 2012) highlights the central role of the teacher's knowledge of the teaching process, that includes key concepts necessary to develop a practice aligned with curriculum frameworks, particularly the notions of task and classroom communication. Besides the content of knowledge to develop in future teachers, another important issue concerns the processes of development of such knowledge. In this respect, a key contribution was provided by Ball and Cohen (1999) who consider the work in practice-based situations a fundamental strategy for teacher education.

Lesson study allows to establish a relation among these theoretical perspectives. On one hand, it has a strong connection with practice, developing around the preparation, undertaking, and reflection of a lesson. On the other hand, lesson study requires the mobilization of knowledge of the content, regarding concepts, procedures, solving strategies and representations and of didactics knowledge, in key issues such as lesson planning, selection of tasks, and analysis of students thinking processes and of classroom communication. What prospective teachers learn in a lesson study depends very much of the emphasis of the work (Ponte, 2017). They may learn about mathematics teaching including the planning of a lesson, the features of tasks that best support students' learning, the strategies and difficulties of students, the dynamics of a mathematics class (Burroughs & Luebeck, 2010; Ponte 2017) and develop professional competences such as reflection and collaboration (Gunnarsdóttir & Pálsdóttir, 2011; Lewis, 2019).

Research methodology

This study took place in a semester course (in February to May 2021). The participants were 14 prospective teachers who attended the first year of master's degree in teaching (a 2-year course after a 3-year bachelor's degree). Two of these prospective teachers, come from the bachelor's degree in mathematics and 12 come from degrees in other areas. The course had two co-teaching instructors (the authors of this paper). We chose to organize the 14 participants in 4 groups, doing 4 lesson studies in parallel, with some superimpositions in the preparatory phase. Although the teacher education program does not require the prospective teachers to teach lessons during this semester (but only in the 3rd semester), the research lessons were taught by two prospective teachers in their classes since they were already teaching. The analysis of the school curriculum planning and the university calendar circumscribed the possible topics to address. Clarisse, who was teaching grade 7, choose the theme "Internal and external angles of a triangle" and Joana, who was teaching grade 8, choose the theme "Isometries". Thus, two lessons were held in grade 7 with the topics (i) Justification of the properties of the internal and external angles of a triangle and (ii) Problem solving involving internal and external angles of a triangle. Two other lessons were held in grade 8 with the topics (i) Rotation, and (ii) Central Symmetry. This option for the organization of the class into 4 groups was based on the idea that work, to be productive, must be organized into groups with a small number of elements.

The work on the four lesson studies had 12 sessions (S) and developed in four strands, addressing different aspects of teacher knowledge. The first strand (S1-S2) focused on mathematics, including solving mathematical tasks and reflecting on solving strategies and representations. The second strand (S3-S4) addressed students' strategies and difficulties on the topics. The third strand (S5-S8) concerned the detailed planning of four lessons, considering the curriculum documents. Finally, the fourth strand (S9-S12) included the observation and reflection on the lessons. A very important emphasis of all activity was work from tasks (Swan, 2017-2018). Prospective teachers were required to look for tasks that could be used in the research lessons. The tasks were solved and their features were discussed in detail according to the learning objectives defined, as well as the possible difficulties of the students in solving them. Another important emphasis was the organization of the mathematics class based on a work on tasks that can contribute to students' learning, in a perspective identical to what Japanese researchers call "structured problem solving" (Fujii, 2018).

Data collection was made by participant observation with a research journal of sessions (S*x*) and individual final interviews (FI) with 6 prospective teachers. For these interviews (all transcribed), we selected prospective teachers with different profiles, with some or no professional experience and with high or low participation in the classes. As data analysis strategies, we use content analysis (Bardin, 1979). Data analysis began by identifying significant moments in the sessions and interviews, that is, moments in which future teachers' discourse may be a signal of teachers' learning, taking into account the prospective teachers' perspectives about the work done in the different sessions, namely about the (1) lesson study's organization in the course; (2) the work on tasks; (3) the preparation of the lesson plan; and (4) the preparation of the observation of the research lesson. Regarding their perspectives about mathematics knowledge, we analyzed, (5) their awareness of own difficulties in mathematics, and, regarding their knowledge of mathematics teaching, we considered (6) lesson planning; (7) selecting tasks; (8) anticipating the reasoning and difficulties of students; and (9) conducting classroom communication. The interpretation of data was originally made by one of the authors and cross-checked by the other author. In some cases, the original interpretation was revised.

Results

Understanding and getting involved in the lesson study process

In the first session of the course, the work to be carried out throughout the semester was presented, with a complete script indicating all phases of the lesson study. It was in the second session that the work in the lesson study really began. A document was presented explaining in detail the work that was to be carried out and an article with a detailed description of a lesson study was discussed. However, for the prospective teachers, it was not sufficiently clear what was to be done. In the final summing up, carried out in the last session of the course, several prospective teachers indicated that they were confused regarding the work of the lesson study, namely the exploration of tasks related to the chosen topics:

Joana: Well, I think that at first the [course] was a little confusing. [...] First, we were looking at textbooks for a long-time and... I think that it was too much time for that. When we started being more oriented [by the teachers] and we realized what it was to do, I think it went very well. I think it was quite interesting. (S12)

Carolina: I confess that only from the third session I begun reading about it and I realized what we were doing [laughs]. Really, we were studying textbooks and [I thought] "and now we're going to have to study the textbooks?" Then I understood what we were actually doing... And I really enjoyed it. (S12)

Clearly, the prospective teachers were not used to do the type of work that was proposed – working in detail with mathematics tasks. For the first time, they were asked to select and analyze tasks in depth, anticipate possible strategies and difficulties of students, and plan a lesson. They began by not understanding why doing that. At the very beginning, they showed some difficulty in foreseeing and understanding the whole process. However, this problem was overcome in later sessions, with the continuation of the work, as they saw the structure of the lessons to be taught getting shape.

The planning of four research lessons at distance was very demanding and the prospective teachers suggested the need for more time for the planning, to prepare the observation, and to elaborate and reflect on the observation script:

Joana: So, I think if we had a little more time there to think a little more about these issues and write a better script... Not that our scripts were horrendous, but I think I could have a little more time there on the observation part. Especially in this issue, I think it was very fast. It was just one lesson, basically. (FI)

In a similar direction, Carolina indicated that observation is a very demanding process:

Carolina: The issue of focus... Of the focus spoken by [the teacher] in the last session… That was important to me because I dispersed a bit and tried to focus and even then after the lesson I ended up dispersing myself because I had not pointed [some aspects] and even as I had the script and still did not record everything I wanted... I ended up not being able to point well the times... And other things... (FI)

Learning about mathematics and mathematics teaching

Despite the initial difficulties of understanding the formative model, the prospective teachers considered important the opportunity they had to put into practice the knowledge recommended in the course. They valued that they had the opportunity to plan a lesson in great detail, even if the course does not yet provide for prospective teachers to teach:

Olga: I ended up liking this course very much, because it was a course where I could feel a little bit of what my future will be like as a teacher [...] and then do that with a grade 7 class. I managed to have participative students, enthusiastic about the tasks.

> I do not know if it was good for me or not, but I will continue with the positive feeling that students will like the tasks ... And I always try to enthusiasm them. (FI)

For Olga, the lesson study was a complete experience with the preparation of a lesson that was then taught by another prospective teacher. Olga was excited with the outcome that the lesson that she planned with her group and, more specifically, the tasks, had on the students, and expressed a wish to maintain a similar practice in the future.

The whole group was involved in a deep analysis and reflection on the nature of tasks, their relevance to the learning of the selected topics, as well as the possible difficulties that could arise for students, culminating in the observation of students' work in these tasks. The prospective teachers had already studied in other courses the classification and characteristics of the different types of tasks, so they already knew some of the language associated to this theme. They acknowledged, however, that the deep work of solving and analyzing tasks, considering the objectives defined for the research lessons, provided them with new knowledge: "the work on tasks added something to what we already knew..." (Beatriz, FI). It also led them to deepen the previous knowledge "about the type of tasks we had already seen in the 1st semester" (Carolina, FI). They highlighted that this work became more productive because it was practical: "the most productive work on tasks is as practical as possible" (Carolina, FI).

Clarisse, the prospective teacher who taught the grade 7 research lessons, pointed out that, despite already having some teaching experience, she did not use to solve the tasks before proposing them to her students, "most of the tasks I did not solve and took immediately to lessons" (Clarisse, FI). The solution of the tasks and the analysis of their suitability for the objectives of the lesson and the students made her learn and value the solution of the tasks and the anticipation of the students' strategies and difficulties "Ah! I've learned a lot about teaching. The planning part, the part of bringing responses already foreseen, possible answers from students" (Clarisse, FI).

Joana, the prospective teacher who taught the grade 8 research lessons, also mentioned that she learned several issues about tasks. She became to value exploratory tasks, recognizing that they provide the opportunity for students to do practical work and build their own knowledge:

> Joana: To take a task that is to practice, it is to do something, it is not to stay there just listening to the formula, hear the concept, but start from something and go working that task to learn the concepts, I found it very interesting... (FI)

Although Joana already knew some of the characteristics of exploratory tasks from the work previously carried out in other courses, it was the planning of a lesson based on such tasks that had more novelty for her:

> Joana: In fact, I had never thought of beginning a lesson, although we had heard enough in [a previous course] about investigation and exploration tasks, I had never thought of doing a lesson around the task itself. […] I found it interesting also that certain lessons could unfold just from the task... Really, beginning from a task and preparing the lesson based on it and observing the difficulties of the students and what is expected from them and what can be done from this is very interesting. (FI)

In the lessons led by Joana, on isometries, the moment of whole class discussion did not go as planned. She had difficulty in orchestrating the discussion because the students were not very involved and did not know this way of working. However, Joana valued the moment of whole class discussion: "and also, yes, the moments of discussion, although in my lesson it did not go very well..." (FI).

The prospective teachers had already worked on many of the ideas on mathematics teaching considered in the lesson study. However, when they had to put these ideas into practice, supervised by the teachers of the course, these ideas acquired greater meaning, much closer of what it will be in their profession. This is what Vítor says: “I had heard of exploratory lesson in [previous courses], but it is one thing to speak in a theoretical way and it is another thing to do it” (FI).

For Clarisse, who taught the grade 7 lessons, the experience with a new approach to teaching was positive: “I think it went very well (…) and the students also liked it very much”. The lesson ran according to her expectations and the students were very involved. This led her to value exploratory teaching based on the learning that students may develop, “but I think it’s really essential, I even think that learning is much faster achieved in this type of teaching than in a type of teaching that I have being doing perhaps wrongly” (FI).

The detailed planning work of the lessons also caused initial confusion to the prospective teachers. For example, Clarisse pointed out that “we had some initial difficulty in planning” (FI) while Vítor found some difficulty in determining the desirable level of detail “I don’t know if we didn’t exaggerate in detail” (FI). Despite the difficulties with the preparation of the lesson plan, Carolina stressed that the realization of the plan, in the context of the lesson study, allowed them to understand the relevance of each of the elements of this plan and how it was thought:

Carolina: I had heard of planning and one person ends up copying the plan from some other place... Or from the internet. But the fact that we […] realize that column, that topic of planning, is important and then, in practice we realize that it is effectively important. […] This here in the planning […] it even seemed like it wasn’t important and then we ended up... The students ended up having a different reaction in that part and even should have been more thought of, wasn’t it? [...] (FI)

In addition, Carolina recognized that the fact that they had also observed the lesson in practice makes each of the reflections and elements of the lesson plan more important to understand the work and learning of students. She recognized the importance of elaborating such a detailed lesson plan.

For Beatriz, all this detail in the preparation of the lesson plan made her more aware of the fact that there are different ways to solve a task and also of the importance of the teacher to be attentive to different solutions and value them in the classroom:

Beatriz: Not so much in the way of looking at students, more in the way of looking at the diversity of student solutions. That’s right, because sometimes we only think in one way and when we see, there are several students who have several ways to solve and that is also correct, and I think it is important to give due value. (FI)

All prospective teachers assumed that they made significant learning on mathematics teaching issues, in some cases with new ideas, in other cases bringing a different perspective on things that they already knew. This contrasts with their views regarding mathematics, in which they did not identify any significant learning. However, we note that there were several discussions on mathematical issues in which the prospective teachers seemed somehow confused. This happened, for example, with the issue of how to prove that the sum of the measures of the internal angles of a triangle is 360º, as they were willing to accept that a physical demonstration involving cutting vertices from a triangular sheet of paper could be seen as a mathematical proof. It seems that the fact that they had made many courses in mathematics previously, in their undergraduate study, led them to assume that they had a strong mathematical preparation despite the discussions in the course sessions seemed to suggest that they had several ideas to revise and clarify.

Conclusion

Several prospective teachers indicated an initial confusion regarding the work to be carried out in the lesson study, namely the exploration of tasks related to the chosen topics. More than a difficulty in understand the lesson study process, the teachers had difficulty in understanding why to do a so detailed analysis of tasks related to the chosen topics. Perhaps this needs to be better explained in the future.

In previous courses, the prospective teachers had already studied the classification and characterization of different types of tasks. However, they tended to look at the tasks superficially. They selected tasks to propose to students without solving them and without analyzing the possible strategies and difficulties involved in their solution. The deep work of task analysis and anticipation of students' strategies, as well as the detailed planning of an exploratory lesson, as well as its observation, provided significant learning on the teaching of mathematics. As indicated in Ni Shuilleabhain and Bjuland (2019), the future teachers highlight the value of going to the school in order to plan a lesson that is then put into practice, emphasizing that this experience favors the understanding of the characteristics of the tasks. In the end of the course, the future teachers also emphasized the importance of the practical work of selection, analysis and discussion of tasks, underlying the value of working from practice for the development of teachers' knowledge (Ball & Cohen, 1999; Smith, 2001).

The format proposed for the planning of research lessons also caused some initial confusion. However, after observing the lesson, the prospective teachers tended to value the realization of a detailed planning, recognizing the importance of anticipating the possible strategies and difficulties of students, as pointed by Burroughs and Luebeck (2010). Overall, the prospective teachers highlighted significant learning about the teaching of mathematics but not on mathematics. This may be regarded as natural, given that so far, they had many courses in mathematics, but they still do not have much experience in mathematics teaching.

The pandemic brought some challenges to the lesson study, namely the difficulty in accessing classrooms. The definition of an organizational model with a group of 14 participants proved to be challenging. As in the study by Burroughs and Luebeck (2010), the proposed format contemplated the division of the group into 4 subgroups. However, contrary to this experience, two future teachers taught the research lesson. In previous experiences, the research lesson was led by a cooperating teacher who contributes with his practical experience to the definition of research questions. The option that we assumed in this course, provided an important opportunity for these two future teachers, who are already teaching with other qualification, to reflect on their own practice. Despite the restrictions imposed, it should be noted that, contrary to what happened in the study by Burroughs and Luebeck (2010), this division into 4 subgroups allowed all future teachers to attend the research lesson they planned, completing the entire cycle of the lesson study, with the observation of the research lesson, so valued by them. Although the overall view taken by the prospective teachers regarding the work done is very positive, it is important to adjust the distribution of lesson study sessions to the number of research lessons to plan, considering, in particular, also the need for a deep preparation of the observation of the research lessons.

Measuring mathematical knowledge for teaching: the case of algebra in pre-service teacher education in the Netherlands

Dédé de Haan[1], Siebrich de Vries[2], Paul Drijvers[1] and Gerrit Roorda[3]

Keywords: Mathematical Knowledge for Teaching, measurement instrument, algebra, lower secondary education, pre-service teacher training

Introduction

Algebra is central in mathematics education in secondary school: in problem solving, in representing relationships and functions, in describing patterns and structures, as a language. Algebra education aims at integrating procedural skills and conceptual understanding (Drijvers et al., 2011). This requires good mathematics teachers, who have sufficient content knowledge (CK) as well as pedagogical content knowledge (PCK). Learning to teach, however, takes time and is complex (Korthagen, 2010). At the same time, in the Netherlands, teachers are given full responsibility for their own classes from the start of their career. This means that the mathematical knowledge for teaching of pre-service teachers needs to be at a high level. To improve their pedagogical content knowledge (PCK), and, if necessary, the corresponding content knowledge (CK), we need to identify the omissions in their knowledge. PCK, however, is a complex concept that is hard to measure. Ball et al. (2008) have elaborated the knowledge needed to teach mathematics into the Mathematical Knowledge for Teaching (MKT) framework. The goal of the study presented here is to find out whether there exist instruments to measure MKT for algebra teaching in lower secondary education, appropriate for the Dutch context. This is done by conducting a meta-study on existing instruments. The poster will report on the meta-study, its methods, its results and its conclusion.

Theoretical Framework

Next to CK, teachers also need PCK (Shulman, 1986). Within mathematics education, especially at the University of Michigan, research has been conducted into the nature of CK and PCK of mathematics teachers, by collecting data from mathematics lessons in practice, and by analyzing and categorizing these data. This resulted in 2008 in a subdivision of MKT. Parts of the subdivision focus on general CK and PCK, and parts of the subdivision focus on the teaching practice itself: Specialized Content Knowledge (SCK), Knowledge of Content and Students (KCS) and Knowledge of Content and Teachers (KCT). SCK is the mathematical knowledge needed to teach, such as: being able to answer a “why” question. Central to KCS is the knowledge of students' thinking, and of their misconceptions about mathematical subjects. Central to KCT is the design of the instruction, for instance the order of the examples that are used.

Research question

The research question we want to answer is: to what extent are instruments, developed to measure mathematical knowledge for teaching algebra in grade 7-9, appropriate for measuring pre-service teachers’ SCK, KCS and KCT in the Netherlands?

Method

We have conducted a literature review. Keywords used were SCK, KCS and KCT, algebra, (variants of) pre-service education. The databases searched were ERIC, Web of Science, Scopus and PsychInfo. Because the first search yielded a review article (Kim, 2018) in which all measurement instruments of MKT up to 2012 are listed, we restricted the search to the timeframe from 2012 to present. The articles found were analyzed on the measurement of SCK, KCS and KCT for algebra within pre-service teacher education. For example, the target group, tasks of teaching and categories of knowledge were considered to decide to what extent the instrument would be appropriate for the Dutch context. Criteria used in this evaluation, such as the role of conceptual understanding and the extent to which SCK, KCS and KCT are measured separately, will be presented in the poster. The search resulted in fifteen articles.

Results

Findings show thirteen instruments, ranging from the instrument for measuring Knowledge for Algebra Teaching (McCrory et al., 2012) which has been extensively tested and validated, to a questionnaire. Some instruments focus on one particular topic (for example variable). Most instruments consist of items that mainly measure SCK, next to Common Content Knowledge. In general there is no breakdown into the three different domains SCK, KCS and KCT. The instruments and their applicability to the Dutch context will be presented in the poster.

Conclusion

The articles we found in our review show that instruments developed for measuring MKT seem to pay little attention to separately measuring KCS and KCT, which raises the question why this is the case, and whether this is necessary. To measure SCK, KCS and KCT for teaching algebra of pre-service teachers in lower secondary education in the Netherlands, we need to combine items from different instruments and we need to extend this with items to measure KCS and KCT.

Prospective teachers' diagnostic judgments on students' understanding of conditional probabilities

Jennifer Dröse[1], Birgit Griese[1] and Lena Wessel[1]

[1]Paderborn University, Germany, jennifer.droese@math.upb.de; birgit.griese@math.upb.de; lena.wessel@math.upb.de

In recent years, different studies have emphasized the necessity to improve prospective teachers' professional knowledge and teaching competences, especially prospective teachers' diagnostic competence, which accounts for perception, interpretation, and decision-making concerning students' individual thinking processes and learning obstacles. In order to do so, this paper follows a content-related approach that focuses specifically on diagnostic judgments on conceptual under-standing and procedural skills of students' understanding of conditional probabilities and their underlying prior knowledge elements. Prospective teachers are known to face challenges in adequately focusing on these aspects in their diagnostic judgments. Therefore, written diagnostic judgments of 26 prospective teachers on two transcript vignettes are investigated. The results indicate that prospective teachers show a high focus on prior knowledge and on procedures in their diagnostic judgments.

Keywords: Diagnostic judgments, conditional probabilities, prospective teachers, vignettes.

Introduction

As part of prospective teachers' professional preparation student-centered teaching plays an important role. The latter requires teachers to diagnose skillfully, i.e. to master the mental processes of perceiving, interpreting, and decision-making (Empson & Jacobs, 2008). In order to prepare prospective teachers for adequate diagnostic judgements, it is necessary to gain deeper insights into their diagnostic thinking processes, that can be inferred from their diagnostic judgements. Already existing studies line out that prospective teachers are known to struggle with addressing conceptual understanding and procedural skills in their diagnostic judgments (Bartell et al., 2013). This underlines the importance of focusing on the mathematical content, such as relevant knowledge elements of the current learning content as well as the underlying procedural skills and conceptual understanding in prospective teachers' diagnostic judgements (Prediger, 2020). Therefore, our research interest is to investigate which elements of the mathematical content teachers perceive and interpret (as processes of diagnostic thinking) in students' understanding of conditional probabilities in a one-to-one teacher-student discussion. This topic was chosen as it is a pivotal, but often challenging concept and holds relevance in vocational contexts (Binder et al., 2020).

Theoretical Background

Prospective teachers' content-related diagnostic judgments

Teachers' diagnostic competence has been found to be important for student-centered teaching (Empson & Jacobs, 2008). Synthesizing different approaches on diagnostic thinking and diagnostic competence, Loibl et al. (2020) provide a framework for locating different research approaches (see Figure 1). In addition, the framework displays the impact of the diagnostic thinking processes on diagnostic behaviors.

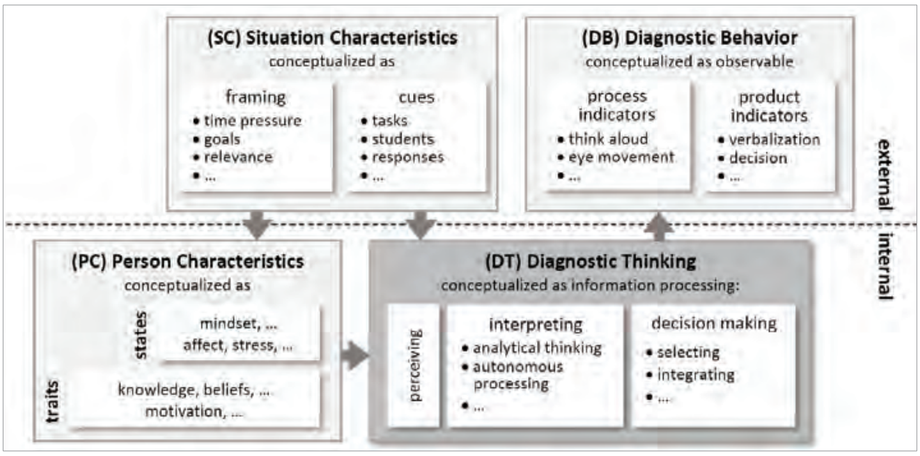

Figure 1: DiaCom framework of diagnostic thinking (Loibl et al., 2020, p. 3)

Therefore, those processes can be derived from diagnostic judgements, influenced by situation and person characteristics. Stahnke et al. (2016), with their systematic review of different studies and research approaches, show that although most of the studies investigating diagnostic competence use a particular mathematical content, only few studies explicitly integrate the content into the analysis of the diagnostic judgments. The study presented in this paper also focuses on content-related aspects in analyzing the diagnostic judgments, following Dröse and Prediger (submitted).

When taking this content-related approach, the principal distinction (as in Kilpatrick et al., 2001) is between conceptual understanding (as meaning of mathematical concepts, operations, and terms) and procedural skills (as procedures for algorithms and solution strategies). This allows for conceptualizing students' understanding as a network of the main mathematical knowledge elements, conceptual and procedural (Hiebert & Carpenter, 1992). The ensuing network contains knowledge elements of the current learning content as well as prior knowledge elements, i.e. conceptual understanding and procedural skills from previous years as a foundation (Prediger, 2020; Dröse & Prediger, submitted).

Prospective teachers in particular have been shown to focus (in the sense of perceiving and interpreting) more on general aspects of learning in their diagnostic judgments than on mathematics- and content-specific aspects (Jansen & Spitzer, 2009). Moreover, when focusing on content-related aspects, prospective teachers are more likely to perceive procedural obstacles – albeit not their cause (Cooper, 2009). What is more, they often misinterpret conceptual obstacles as procedural (Son, 2013). While obstacles are mostly interpreted by prospective teachers as lack of a procedural skill, when it comes to students' resources, prospective teachers often interpret students' statements as indicating conceptual understanding – even if the aspects they refer to are procedural skills (Bartell et al., 2013).

Against this background, it makes sense to first take a closer look at the conceptual understanding and procedural skills concerning conditional probabilities and the related students' obstacles.

Knowledge elements and students' understanding of conditional probabilities

For the *current mathematical content* of conditional probabilities, procedural skills as well as conceptual understanding are relevant learning goals. Conceptual understanding of conditional probabilities implies concepts concerning stochastic (in)dependence for describing the likelihood of an event under certain conditions or independent of conditions (Hoffrage et al., 2015). Students face various obstacles in the area of conditional probabilities, e.g. distinguishing joint and conditional probabilities (Shaughnessy, 1992). For determining conditional probabilities and solving Bayesian problems, different visualizations and solution strategies can be used, e.g. tree diagrams, frequency grids, unit squares, or 2x2 tables, viewed as procedural skills (see overview in Binder et al., 2020).

These knowledge elements for conditional probabilities build on *prior mathematical content* knowledge, especially the part-whole relationship as well as the part-of-part determination as an important mental model for the multiplication of fractions. Both belong to the conceptual understanding of fractions (Post & Prediger, 2020; Prediger & Schink, 2009) and are known to present serious obstacles, e.g. in identifying the appropriate whole (Prediger & Schink, 2009). In this context, procedural skills (e.g. routine calculations with fractions, decimal numbers, and percentages) may also constitute a learning difficulty (e.g. Prediger & Schink, 2009).

In this paper, we will focus on the procedural skills and conceptual understanding of the current learning content, conditional probabilities, and its underlying prior knowledge elements, in connection to possible students' obstacles and individual mental models, found in the diagnostic judgments of prospective teachers. For designing adequate learning opportunities for prospective teachers, it is important to investigate the knowledge elements addressed in their diagnostic judgments.

Considering this design interest as well as the research areas and gaps, our research question reads: *Which concepts or procedures of the current / prior learning content do prospective teachers include in their diagnostic judgments on students' understanding of conditional probabilities*?

Methods

Data collection

The data was collected in a university mathematics education course for German prospective secondary school teachers. The sample consists of n = 26 prospective teachers, 81% studying for secondary and upper secondary school, and 19% for vocational schools. All students have reached the last year of their bachelor program, 69% after three and 31% after four years. They attended the first and second author's university course, which covered content knowledge as well as pedagogical content knowledge on conditional probabilities, e.g. students' errors, and related knowledge elements.

The prospective teachers' written diagnostic judgments were gained by analyzing a vignette as part of the weekly assignments (see Figure 2 for our vignette). Vignettes can be seen as an established instrument for investigating prospective teachers' competences (cf. overview in Buchbinder & Kuntze, 2018) and have been used to investigate content-related diagnostic judgements on procedural and conceptual knowledge elements in the mathematical content of arithmetic (Dröse & Prediger, submitted).

Our vignette consists of a task, two written student solutions and transcripts of subsequent dialogues between student and teacher. For the transcript, a real dialogue (based on transcripts in Post & Prediger, 2020; Post, in preparation) was chosen as basis, which was adapted taking theoretical considerations on conditional probabilities into account (current learning content from Hoffrage et al., 2015; Shaughnessy, 1992; Binder et al., 2020; prior learning content perspectives from Post & Prediger, 2020; Prediger & Schink, 2009).

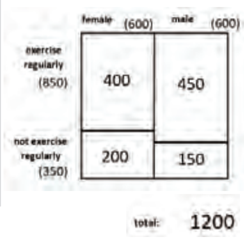
Transcript vignette

For the following task you should put yourself in the teachers' position and react appropriately within the situation. Background information for the following scene: The class in a German upper secondary school has covered conditional probabilities and their calculation. In the following you will read two transcripts displaying excerpts from conversations between two students (Ole and Nazan) and their teacher, regarding the task displayed on the right.

Task: Exercising Teenagers

In a survey, 1200 teenagers were asked if they exercise regularly. 600 out of the 1200 teenagers are female. $\frac{1}{3}$ of the female teenagers do not exercise regularly. $\frac{3}{8}$ of the teenagers are male and exercise on a regular basis. What is the probability that a random male person exercises regularly?

(JIM study 2018)



Part 1: Ole solves the task. He writes down the following solution.

$\frac{3}{8}$ = 0.375= 0.375%, the probability is 0.375%.

The following interaction with the teacher evolves:

1 T: Ole, how did you solve the task?

2 Ole: Actually, there is not much to calculate. The text says that '$\frac{3}{8}$ of all teenager are male and do sports' [reads from the text]. And then I just have to convert this into percentages and that is 0.375%.

3 T: Aha. This share is very small. Hm. Perhaps it might help you, if we had a look at the unit square below the task again? *[Points at the unit square that is printed below the task.]*

4 Ole: So, look at this numbers here, 600 male *[points at the labelling "male (600)"]* and 850 exercising. The 600 are male and the 450 are the ones who exercise, in addition. So, these are the 450 *[points to the area with the number 450]*.

5 T: And what's the size the share that is sought in the task?

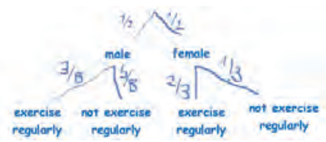
6 Ole: Ehm, the share is 450 of the whole, 1,200? Ehm *[reads the question again]* no, in the question there is just this group here *[points at the area with the labelling "male (600)"]* so this, these are the males, but these here *[points at the two areas on the left]*, those are not considered in the denominator, and the counter would be 450 *[points to the area with 450]*. Or in other words: This is the whole group, these are the males and this is the share of them exercising regularly.

7 T: Good, so you have the fraction $\frac{450}{600}$. But what about the probability or… ehm the share that you calculated before, so the $\frac{3}{8}$?

8 Ole: Perhaps it can be cancelled, and then it is equal.

Part 2: Nazan also solves the task. She writes down the following solution.

$$\frac{3}{8} \cdot \frac{1}{2} = \frac{3}{8} \cdot \frac{4}{8} = \frac{12}{64} = 0{,}1875 = 18.75\ \%$$



The following interaction with the teacher evolves:

1 T: Nazan, how did you solve the task?

2 Nazan: So at first I calculated that the probability for boys is 50%, that is $\frac{1}{2}$. Than I can write this into the tree diagram *[points at her tree diagram*] and then I have to calculate $\frac{1}{2}$ times $\frac{3}{8}$. So you convert them to the same denominator, and $\frac{1}{2}$ is equal to $\frac{2}{4}$ *[points to her written calculation]* and multiplied this is $\frac{12}{64}$. And this is 18.75 percent. So the probability is 18.75%.

3 T: Let's have a look at the unit square below the task to be sure. Which parts do we have to look at? *[Points at the unit square below the task.]*

4 Nazan: So for the numbers we have 600 here *[points at the label "male (600)"]* and 850 exercising *[points at the label "exercising (850)"]*. Yes, and then this is $\frac{600}{1200}$ times $\frac{850}{1200}$, because ehm those are the important issues, male and exercising.

5 T: And how did you transfer that into your tree diagram?

6 Nazan: So, the $\frac{600}{1200}$, that is $\frac{1}{2}$ in my tree diagramm, the probability for boys. $\frac{600}{1200} = \frac{1}{2}$, cancelled out. Are $\frac{3}{8}$ the same as $\frac{850}{1200}$, if you cancel? Somehow this has to beo, because in the text says teenager, who are male and exercise regularly, and that is the same as in the question. Just the "and" here, that has changed in the question *[points at the "and" in the text and then at the question]*.

Task: Analyze the two transcripts:

(1) Describe which prior knowledge and resources (conceptual knowledge, procedural knowledge, representations, etc.) Ole and Nazan draw on.

(2) Describe which obstacles Ole and Nazan display. Explain the possible causes of these obstacles.

Give transcript lines for (1) and (2) that underpin where you locate the aspect within the transcript or the notes.

Figure 2: Transcript vignette with task for prospective teachers

The transcript vignette therefore provides sample insights into students' understanding of conditional probabilities and the underlying prior knowledge elements, and thus sufficient possibilities for diagnostic judgements on conceptual understanding and procedural skills as well as knowledge elements of the current learning content and prior knowledge elements. Cues for the different knowledge elements are presented in equal numbers.

Data analysis

The 26 written diagnostic judgments were coded with respect to the knowledge elements for the current or prior learning content in the two dimensions of procedures and concepts. The coding scheme was deducted from the theoretical analysis of the knowledge elements and inductively enriched by the knowledge elements named by the prospective teachers. Two raters following the coding scheme yielded an interrater reliability of Cohen's $\kappa = 0.86$, which is almost perfect. Table 1 displays the codes used and excerpts of exemplary diagnostic judgements.

Table 1: Excerpt of a written diagnostic judgement and knowledge elements assigned to them

	Conceptual understanding	**Procedural skills**
Current learning content	Knowledge element: understanding conditional and joint probabilities Excerpt: "Does not know the difference between $P(A\cap B)$ and $P(B\|A)$."	Knowledge element: calculating and solution strategies for conditional probabilities Excerpt: "Difficulties in calculating conditional probabilities."
Prior learning content	Knowledge element: understanding of fractions (part-of-part), unit square Excerpt: "Ole has an understanding of part-of-parts"	Knowledge element: calculating with fractions, decimal numbers and percentages Excerpt: "Ole can transform fractions into decimal numbers."

Empirical findings on prospective teachers' diagnostic judgments

In total, 327 codes were set for the statements of the 26 prospective teachers. Figure 3 displays the coded knowledge elements in prospective teachers' diagnostic judgments. Table 1 provides first excerpts of written diagnostic judgements. In the following the relationships between the coded knowledge elements are described and enriched by excerpts of the written diagnostic judgements.

Comparing the knowledge elements, the results indicate that the prospective teachers tend to focus more on the *prior learning content* in their diagnostic judgments than on knowledge elements of the *current learning content* (Figure 3, first line). In Addition, their statements address a higher amount of *procedural knowledge elements* than of *conceptual knowledge elements* (Figure 3, second line). For the procedural elements there seems to be a higher number of obstacles addressed, while for conceptual knowledge elements a higher amount of statements is related to *resources*.

For the *current learning content* (Figure 3, third line), *procedural* and *conceptual* elements seem to be addressed equally. While the conceptual elements are equally described as *resources* and *obstacles* (e.g. conceptual resource: "has a concept of probabilities", conceptual obstacle: "doesn't know the difference between joint and conditional probabilities"), only few statements concerning procedural skills address them as resources (e.g. procedural resource: “knows how to calculate joint probabilities”, procedural obstacle: “has difficulties in calculating conditional probabilities”).

Most of the statements for the *prior learning content* as well as most of the statements overall concern *procedural* skills, e.g. operating with fractions, decimal numbers, and percentages (Figure 3, third line). These elements are equally addressed as *resources* and as *obstacles* (e.g. procedural resource: “can shorten fractions”, procedural obstacles: “cannot convert fractions into decimal numbers”). The addressed elements of *conceptual* understanding are expressed more often as *resources* than as *obstacles* (e.g. conceptual resource: “can interpret parts in the unit square”, conceptual obstacle: “cannot derive part-of-part relations from the unit square”).

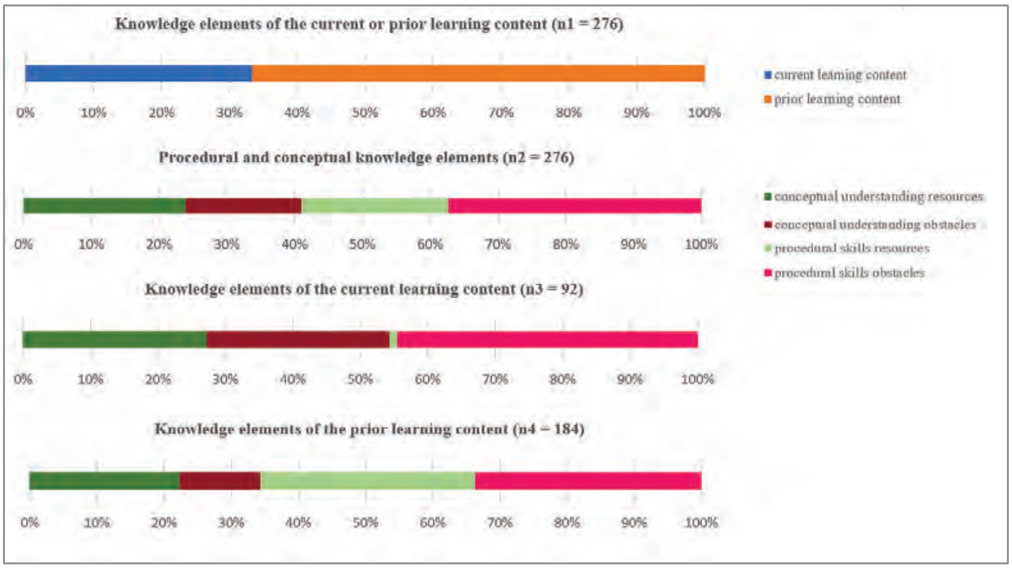


Figure 3: Knowledge elements in diagnostic judgments

Discussion and outlook

Referring to the research question (*Which concepts or procedures of the current / prior learning content do prospective teachers include in their diagnostic judgments on students' understanding of conditional probabilities?*), our content-related approach revealed the following findings:

In general, the prospective teachers in our study focus more extensively on *procedural skills* than on *conceptual understanding*. These findings are in line with previous research (Cooper, 2009; Son, 2013; Bartell et al., 2013). For the current learning content, however, statements on conceptual understanding are dominant. Further qualitative investigations (e.g. interviews) are needed to interpret this result, which is divergent to previous research. By distinguishing resources and obstacles, we saw that procedural skills are far more often addressed as obstacles than as resources overall, although they are categorized equally as obstacles and resources for the prior learning content. As Cooper (2009) indicates, prospective teachers are more likely to perceive procedural obstacles in students' utterances but not their origins which might be conceptual. Future studies could ask prospective teachers to classify their judgements as referring to conceptual or to procedural knowledge elements, as Son (2013) revealed that prospective teachers misinterpret conceptual obstacles as procedural. However, the current study can provide no insights here. Yet, it might present a problem if prospective teachers (in terms of the DiaCom framework) mostly perceive and identify procedural obstacles in students’ utterances, as that might influence their decision-making as active teachers, hindering them to address conceptual learning adequately (see Loibl et al., 2020, for details). On the basis of these findings, starting points for redesigned learning opportunities can be identified, e.g. using authentic tasks for diagnosis and discussing with prospective teachers’ options for student activities that explicitly promote conceptual understanding.

In addition, by distinguishing *prior and current learning content*, we found that prospective teachers are indeed able to describe different content elements building upon each other. This is relevant, as an interconnected network of mathematical knowledge is paramount for the sustainable learning of mathematics. In particular, low-performing students have been shown to lack sufficient prior content knowledge for keeping up with the current learning content (Prediger, 2020). Therefore, our analysis reveals possible potentials of prospective teachers’ diagnostic judgements that have not yet been investigated in depth and can provide first starting-points for offering further learning opportunities and developing teaching-learning arrangements, e.g combining and connecting university courses concerning CK and PCK more deeply.

Due to the aforementioned aspects it would be beneficial to compare the prospective teachers’ diagnostic judgements and the identified knowledge elements to the diagnostic judgments of experienced in-service teachers or teacher educators. By doing so, it might be possible to identify further aspects that could in turn be integrated as learning content in prospective teachers’ courses at university.

Our research is limited due to the following aspects: (a) Our sample comprises only 26 prospective teachers all from the same university. Future research is planned to extend the sample size and the sample itself to in-service teachers. (b) Our research addresses a specific content. As diagnostic judgments might vary between contents, other content should also be investigated. (c) The use of a transcript vignette meant that it could have been read several times. It is possible that the diagnostic judgments would focus on less aspects in a different format, e.g. video vignettes (Buchbinder & Kuntze, 2018). (d) The vignette displays a teacher-student one-to-one interaction and not a whole group classroom discussion. Where the vignette can be extended to in the future. Future research should also clarify and investigate these limitations. In addition, it should be explored how transcript vignettes can be used to foster prospective teachers’ diagnostic judgments.

Acknowledgment

We thank Sarah Dohle and Lukas Bartsch for their support in the data analysis as part of their bachelor and master theses, and our colleagues and experts for their collaboration.

What you teach is what you get? Exploring the experiences of prospective mathematics teachers during a teacher education programme

Andreas Ebbelind[1] and Tracy Helliwell[2]

[1]Linnaeus University, Faculty of Technology, Växjö, Sweden; andreas.ebbelind@lnu.se

[2]University of Bristol, School of Education, Bristol, UK; tracy.helliwell@bristol.ac.uk

The role of the teacher education programme in preparing mathematics teachers to teach mathematics is an under-researched area within mathematics education. In this paper, we analyse four components of empirical material, each captured from a teacher education programme based in Sweden. Using a methodological approach informed by enactivism and Systemic Functional Linguistics, we build on previous analysis of the language-in-use of one mathematics teacher educator to situate a further layer of analysis, this time, from the perspective of a prospective mathematics teacher. Our findings suggest the prospective teacher in this study, who had positive experiences of mathematics at school, learns to align linguistically with the mathematics teacher educator's contrasting views of mathematics teaching and learning, and in doing so, creates herself a safe space.

Keywords: Mathematics teacher education programmes, mathematics teacher educator language, prospective mathematics teachers, enactivism, systemic functional linguistics.

Background and context of the study

This paper sets out to illustrate a problem related to mathematics teacher education, as part of a more extensive study, to understand how prospective mathematics teachers negotiate meaning from the language of mathematics teacher educators during teacher education situations (Ebbelind, 2020). We set out to address the relationship between interactions during teacher education situations and the kinds of meanings realised by the prospective mathematics teachers. Previously our focus has been on developing a methodology for studying the language-in-use of the mathematics teacher educator (see, Ebbelind & Helliwell, 2021), whereas in this paper, we foreground the prospective mathematics teacher. Specifically, we turn our attention to how one prospective teacher, Lisa, discursively assembles language-in-use when taking part in her teacher education programme. Our research question is: *How does one prospective primary teacher navigate her initial mathematics teacher education programme?* We are interested in what can be learned, as mathematics teacher educators, from exploring the experiences of prospective teachers during their mathematics teacher education programmes in relation to the language-in-use of mathematics teacher educators.

The empirical material used for this paper consists of four components, each captured during a teacher education situation in Sweden. The first component is a transcript from a mathematics teacher education lecture, the second is a transcript from a seminar where a group of prospective teachers worked on a task set during the lecture, the third is a transcript from an interview with one of those prospective teachers, Lisa, and the fourth is a set of extended field notes (Delamont, 2008) that were taken based on Lisa's reflections on the lecture. Lisa is in her early 20s and began teacher education directly after finishing school. She described herself as an extremely competitive athlete playing soccer (football) at a high national level. Much of her terminology can be interpreted as related to sports and management. During Lisa's teacher education programme, she studied 30 ECTS credits (one full semester) in mathematics education. Lisa perceived herself as a "good" mathematician when re-engaging in her past school mathematical experiences at upper secondary school (aged 17-19 years). After her education she will work as a teacher in an upper primary school (aged 10-12 years). The context in Swedish mathematics teacher education is the reform mathematics movement that "promotes a vision of school mathematics that focuses on students' creative engagement in exploratory and problem-solving activities as they develop their understandings of significant mathematical concepts and procedures" (Skott et al., 2018, p. 164). In Sweden, prospective teachers at primary level (aged 7-12 years) educate to become generalists, as opposed to subject specialists. As a consequence, primary teachers in Sweden will teach a range of different subjects as well as mathematics and their level of education in each of the school subjects is often modest. In Sweden (Ebbelind, 2020), and other western countries (Stoehr, 2015), the professional background of a primary teacher is linked less to the teaching of specific subjects than to the profession as a whole. The subject of mathematics itself becomes subordinated for these prospective teachers, and social development becomes the primary aim of schooling. As a result, prospective teachers create a "safe space" for themselves and their future students (Gellert, 2000).

The role of teacher education programmes for prospective mathematics teachers

The role of teacher education programmes in the educational system is increasingly discussed and problematised. There is an underlying assumption in the research field of mathematics education that teachers matter in relation to students' learning. To become a mathematics teacher at primary level concerns a shift from viewing oneself as a learner of mathematics in school to a perspective of oneself as a mathematics teacher who teaches others to learn mathematics. Being enrolled in a teacher education programme has been shown to change the relationship one has to mathematics teaching and learning (Hošpesová et al., 2018).

Some researchers regard becoming a primary school teacher through teacher education as problematic because of the relationship prospective teachers have regarding their own past school-related experience, even concluding that teacher education has little impact on prospective teachers' beliefs, with a limited chance of affecting their future teaching (Ebbelind, 2020). Prospective teachers past experiences will shape the way they become teachers. Those prospective teachers who struggled with mathematics at school continue to struggle during their teacher education programmes, whilst the prospective teachers who enjoyed mathematics in school also continue to do so (Player-Koro, 2011). The political agenda, as well as some research into teachers' knowledge and beliefs, have both established a deficit model of prospective mathematics teachers (Askew, 2008). Much attention has been given to what prospective teachers do *not* know (based on formulations of what they *need* to know) and how to improve their knowledge by incorporating more mathematical content within teacher education programmes. However, as Hemmi and Ryve (2015) explain, this deficit story needs to be used gently by the research community, otherwise the therapeutic (pastoral) aspect of teacher education becomes too dominant (Hannula, 2002). The deficit story, and the pastoral aspect of teacher education, are considered a part of Swedish teacher education (Hemmi & Ryve, 2015; Player-Koro, 2011). Gaining insights into the experiences of prospective primary school teachers in relation to their development during teacher education programmes is a gap that this study seeks to address.

Methodology: A recursive inquiry

In our research, we draw on enactivism as our theoretical and methodological basis. From an enactivist perspective cognition is viewed as “the enactment of a world and a mind on the basis of a history of the variety of actions that a being in the world performs” (Varela et al., 1991, p. 9). One corollary of this view is that, as individuals, the way we see and act in the world is determined by our own unique history of experiences and interactions. On this basis, we look to explore how prospective mathematics teachers, whose past experiences of mathematics teaching and learning are many and diverse, experience, and thus navigate, their teacher education programmes, specifically in relation to the practices and language-in-use of mathematics teacher educators.

Reid (1996) sets out two features of enactivist research, derived from key principles of enactivism (Varela et al., 1991), that are “the importance of working from and with multiple perspectives, and the creation of models and theories which are good-enough for, not definitively of” (p. 207). From an enactivist perspective, any model or theory used to describe and explain a phenomenon cannot be definitively of some external truth. This does not mean that models and theories are of no use, rather, models and theories are accepted as being good-enough descriptions and explanations for the phenomenon under study rather than mirrors of reality. Thus, utilising multiple perspectives is one way of expanding what is possible to grasp during the research process. In combining our different methodological approaches, we also aim to disrupt the potential interdependency of theory and research findings that are often associated with the use of single perspectives, particularly in relation to sociologically related research within mathematics education (Gellert, 2008). As researchers we bring with us our “theories, beliefs, and biases” (Reid, 1996, p. 206), determined by our own history of experiences and interactions which shape the way we view and analyse the data that we collect. Thus, in addition to utilising multiple perspectives, an important methodological principle for us is to share some of our history as teachers and researchers so that our analysis can be framed within this context.

Since an enactivist perspective endorses a view of learning (and thus researching) as “a recursive process linked to actions in the world giving feedback leading to adapted actions” (Brown, 2015, p. 192), we have adopted a recursive approach to our research design. For an inquiry to be recursive, it involves an iterative process of data collection and analysis, where for example, the initial analysis of data feeds into subsequent analyses in an ongoing process. In this recursive inquiry, we utilise our multiple perspectives through looking at the same empirical data but through different lenses, making multiple revisitations of the data. In this paper, we use our previous analysis of the language-in-use of one mathematics teacher educator (Ebbelind & Helliwell, 2021) to situate a further layer of analysis, this time, from the perspective of a prospective mathematics teacher. We include our own reflections on the process of analysis alongside any observations and findings that emerge as a result of the analysis, which we share with one another in an ongoing dialogue, which then feeds into the next stage of analysis. Specifically, we see enactivism as an overarching methodological framework within which systematic functional linguistics (SFL) provides a complementary analytical tool.

Previously we have developed a detailed description of our research methodology for analysing the language-in-use of a mathematics teacher educator. This research methodology was developed by extending the enactivist informed “methodology for studying talk” described by Coles (2015, p. 235) through utilising SFL as a systematic tool for identifying patterns in the transcript of the mathematics teacher education lecture. In the next section we begin by sharing some of our own history and context (as explained above) before summarising findings from our previous analysis (see Ebbelind & Helliwell, 2021) where our focus was on the interpersonal aspects of the mathematics teacher educator's language-in-use such as voice, tense, polarity, and modality (or certainty) during an early mathematics teacher education lecture for a group of prospective primary teachers in Sweden (the transcript of this lecture providing the first component of empirical material used in this study). Having established our reading of the mathematics teacher education lecture from analysing the language of the teacher educator, we then move on to explore the perspective of one prospective teacher, Lisa, in relation to the same lecture and the mathematics teacher education programme more generally.

Analysis

The authors of this paper were both mathematics teachers before becoming university-based mathematics teacher educators and researchers. Andreas teaches prospective pre-school (aged 1-6 years) and prospective primary (aged 7-12 years) school mathematics teachers in Sweden. His research background links in different ways to social practice theory and symbolic interaction. Tracy teaches prospective mathematics teachers on a one-year postgraduate course for secondary (aged 11-18 years) mathematics teachers in the UK. Her research background links to the perspective used in this study, enactivism, which she has used in researching mathematics teacher and mathematics teacher educator learning and development.

During the lecture, the mathematics teacher educator, who from this point we refer to as Ian, talks about what it means to know something, for example, "one has an understanding of things when one does not have to remember what one must remember to be able to know". He positions the prospective teachers as a unit, and ascribes the prospective teachers as all having had negative experiences of mathematics [note: in the transcripts that follow, ... represents a pause, [...] represents some missing text]:

Ian: I think most students here today… who have gone through the whole school system and high school do not feel that way... was mathematics not really something you had to remember ... do this here and it will be alright [...] Students often do not have the skills needed to be able to present their thinking in for example writing ... It is not simply [...] how many doors do you have at home? What you come up with, we will then try to bring into this lecture. You should start thinking ...

One possibility here is that Ian, perhaps unintentionally, is suggesting that the prospective teachers have had negative past experiences of mathematics as a way of promoting the reform agenda. When Ian focuses on current and future practices, we interpret this as relating to the deficit story of prospective teachers:

Ian: Too many students have not understood anything ... We know that from the national board of education reports. If you understand, you do not have to keep such a lot in mind because you know why it is as it is, and you can pick it up and use it, and we want our students to be able to do that in the future.

The level of certainty in Ian's utterances is low when he speaks in relation to the prospective teachers. For instance, when he talks about the prospective teachers as solving the problem. The level of certainty is also low when Ian addresses the prospective teachers, encouraging the prospective teachers to make sense for themselves of the lecture's content. There are also low levels of certainty relating to mathematics as something for students to master.

In the background, there seems to be a theme of general failure in relation to the past teaching of mathematics. This theme of failure is potentially being used to promote another type of teaching by Ian, "We must… you must in the future be able to write yourself mathematically ... we have to give students these tools to pass the national tests." We interpret that Ian is (perhaps unintentionally) positioning all prospective teachers within a deficit story. Even though he promotes another agenda, the reform agenda, the perplexity, or exclusivity of mathematics is still a part of how the lecture is conveyed. There seems to be a narrative style that can be identified within the transcript of the lecture in that there is a story that unfolds, a story that involves the prospective teachers themselves. Throughout this lecture, Ian promotes the idea that there is another story to tell about teaching and learning mathematics than the expected experience of the prospective teachers.

Following the lecture was a seminar where Ian set tasks for the prospective teachers to complete in their study groups (each study group consisting of a subgroup of the prospective primary teachers). The lecture and seminar were both based around the prospective teachers' past participation in mathematics education, whether that participation was experienced as positive or negative. However, Ian made no reference to any positive experiences during the lecture, and neither did any of the prospective teachers. During the lecture, the majority of the prospective teachers commented on their lack of positive experiences as mathematics students. For prospective teacher Lisa, it became clear that her positive experiences of learning mathematics at school were uncommon within the group. When the different study groups were given a task related to the lecture concerning how their own experiences may have differed from those portrayed during the lecture, Lisa and her peers, Kira, and Dina, expressed how the reform-oriented ideas troubled them. This is reflected in the extended field notes from this session.

> On the way to the group work, Kira [one of Lisa's study-group members] says that this is different from what she expected, something different from what she had done in school. The prospective teachers in this study group had good experiences of mathematics, they are interested in mathematics and seem to understand the mathematics to a higher extent than many of the others.

During the seminar, members of Lisa's study group indicate that some of their own experiences do not align with those emphasised in the seminar questions introduced by Ian, the teacher educator. Kira contrasts her past in relation to the present teaching during the teacher education programme, "[my past mathematics teachers] did not demonstrate mathematics in that way, with all these words on the board, that is said to be so good." Lisa adds, "but doing mathematics was something that I was good at... I liked the textbook." In relation to the reform-oriented teaching promoted by Ian, Dina concluded that "it was probably only later on in the national test you had to [do problem-solving questions] but otherwise, we were not allowed discussions in our class." The three prospective teachers reacted to Ian's utterances which emphasised the failure of schools, the prospective teachers' "old" mathematics teachers, and the school system more generally, all of which contributed, according to Ian, to the prospective teachers' "dislike" of the subject of mathematics. However, no one within this study group "disliked" mathematics, instead, they enjoyed it. They recall enjoying being challenged either by the mathematics textbook or the competitive elements or competitive teaching strategies.

Before calling the study groups back to the lecture hall, Ian has brief discussions with each study group. Lisa's study group is the last group that Ian attends. He seems hurried and begins by discussing their negative feelings against the subject without asking them about their experiences:

Ian:	It seems that you got into the same thing as all the groups, I think, and that is probably it. Typical, that what you bring with you into this course. Is it possible to change this then? It will be a nice task ahead. Yes, you are to become excellent maths teachers.

However, Lisa, Kira and Dina do not challenge Ian during this discussion, instead, they seem to play along and have a tentative conversation with him, aligning with his views. This deviation is brought up in an interview with Lisa one week after the seminar:

Andreas:	I attended your seminar when you had a group discussion ... and from what I perceived, you had a pretty good discussion, but then I thought, when [Ian] came, suddenly, he started talking ...
Lisa:	About many things that we did not discuss.
Andreas:	I was wondering ...
Lisa:	It felt a bit strange because it felt like what we had done was very wrong ... at the same time, it felt like we answered the questions ... and he replied ... it did not feel as if things were connected [...] Yes, it was bizarre [laughing]. But at the same time, you understand what he says, but it is not like you have considered ... often when you think back, you remember what was good ... one does not think in this way when you are young ... then, everything was good, and you quickly calculated things in the mathematics textbook, and it was damn good ... great fun and then when he puts it ... so maybe it was not so good ... it was probably a little awakening for us all...

Discussion

We set out, in this paper, to research the ways in which a prospective primary teacher navigates her initial mathematics teacher education programme and what we can learn, as mathematics teacher educators, by exploring the experiences of prospective teachers in relation to the language-in-use of mathematics teacher educators. In this section we present some tentative findings that prospective mathematics teacher Lisa, who had positive experiences of mathematics at school, learns to align linguistically with Ian's (the mathematics teacher educator) contrasting views of mathematics teaching and learning, and in doing so, creates herself a safe space.

The prospective teachers Lisa, Dina, and Kira all expressed their appreciation of mathematics as related to the way it was taught. They each remember the positive feelings that they had when participating in mathematics as students in school. However, Ian's argumentation is somewhat different. He promotes another way of teaching mathematics, together with rejecting the teaching that, for example, Lisa recalls as being positive. There seem to be conflicting stories about effective teaching and learning of mathematics. When the prospective teachers participate in these teacher education situations, they can experience a form of tension, realising that their view of effective mathematics teaching is not accepted as valid within the teacher education programme. Lisa, Kira, and Dina, who enjoyed mathematics at school, re-negotiated the content taught by Ian. One interpretation here is that the prospective teachers do this as a way of creating a "safe space" (Gellert, 2000) allowing them to continue enjoying mathematics in their own ways (Player-Koro, 2011).

The deficit model of prospective teachers (Askew, 2008) seems to guide the story of the lecture, but at the same time, Ian seems to be convincing the prospective teachers that more (and different) subject knowledge is needed as part of mathematics teacher education. The complex phenomenon arising is that while expressing mathematics as being difficult, Ian is simultaneously enacting the pastoral side of teacher education (Hannula, 2002). In other words, one potential challenge for the mathematics teacher educator is to create an environment where prospective teachers, who may be looked upon as problematic, are convinced that a problem indeed exists (within mathematics teaching and learning), without themselves becoming dejected. The majority of the prospective teachers embrace the ideas presented at the mathematics education course as a revelation, and Lisa, Dina and Kira also embrace the intentions *linguistically*. This means that when they participate in the teacher education setting, they align their language with the language of the teacher educator. However, beyond the formal setting, these prospective teachers express a different view of mathematics teaching and learning, to that being encouraged within the teacher education programme. The prospective teachers engage in different social practices, or in enactivist terms, they bring forth different "worlds of significance" (Reid & Mgombelo, 2015, p.181), triggered by the different environments (the formal and the informal) in which they participate.

From an enactivist perspective, the way we respond to situations is determined by our history of experiences. The situation itself does not (and cannot) determine how an individual might respond, rather, different environments trigger different responses. From this position, a vital aspect of mathematics education programmes is acknowledging and working with the experiences (however varied these experiences may be) of the group of prospective teachers. By foregrounding the experiences of the prospective teachers, we need not abandon the quest to improve mathematics teaching and learning, but the emphasis shifts to supporting the prospective teachers in realising, for themselves, what might be possible in the mathematics classroom, that they have not yet themselves encountered. We are left with a set of new questions, both as mathematics teacher educators and researchers: How do prospective teachers in teacher education situations prioritise the content taught during mathematics teacher education programmes? Do prospective teachers prioritise the content taught during the teacher education programme, or do they prioritise something other than what seems to be expected from the mathematics teacher educator's point of view? What is essential or relevant from the perspective of prospective teachers' when attending the teacher education programme in general and in mathematics education in particular? How can we foreground the diverse experiences of the prospective teachers whilst supporting them to explore potentially new ways of teaching and learning mathematics? These questions we take with us into the future.

Opportunities to learn professional noticing while co-planning, rehearsing, co-enacting and reflecting on mathematics instruction

Janne Fauskanger and Raymond Bjuland

University of Stavanger, Faculty of Arts and Education, Department of Education and Sports Science, Norway; janne.fauskanger@uis.no; raymond.bjuland@uis.no

The study explores teachers' opportunities to learn professional noticing while co-planning, rehearsing, co-enacting and reflecting on mathematics instruction in learning cycles of enactment and investigation. Fourteen primary school in-service teachers collaborated with teacher educators in the cycles and the study focuses on exploring what and how these teachers noticed. A framework of noticing was applied in the analyses with the aim of shedding light on the ways in which the participation in learning cycles enables teachers to collectively learn professional noticing. Findings reveal that teachers were provided with opportunities to learn high-level noticing. For instance, they attended to particular students' mathematical thinking and made connections between teaching strategies and students' mathematical thinking.

Keywords: Professional development, learning cycles, professional noticing.

Introduction

Equipping teachers with practices that support students from diverse backgrounds is a critical role of professional development (*PD*). Such teaching practices "aim to deepen students' understanding of mathematical ideas" and support the learning of all students "across ethnic, racial, class and gender categories" (McDonald et al., 2013, p. 385). Teachers' professional *noticing* – a process through which teachers make sense of what occurs during instruction and make plans to respond to students' mathematical thinking (*SMT*) – has become widely accepted as a key teaching practice. What and how teachers notice, matters for student learning (van Es & Sherin, 2021). Novice teachers are often able to talk about SMT (i.e., students' strategies, representations and reasonings), but they find the enactment of practices based on what they noticed challenging (e.g., Thompson et al., 2013). Also experienced teachers are unprepared to notice SMT (Empson & Jakobs, 2008). Learning to enact practices that support all students takes time and because "teachers can be responsive only to what has been noticed" (Jacobs & Spangler, 2017, p. 192) learning such practices is important for PD (e.g., Kavanagh et al., 2019). Such learning is explored in this study.

Noticing is an awareness that enables action and skilled teachers are quicker to identify situations that require intervention (van Es, 2011). Because it can lead to changed teaching practices, noticing is "a key component of teaching expertise and of mathematics teaching expertise in particular" (Sherin et al., 2011, p. 79). Teacher noticing is conceptualised in a variety of ways (van Es & Sherin, 2021). The term is here considered to include a) attending to SMT throughout *learning cycles* of enactment and investigation (Figure 1), b) reasoning about SMT, and c) making informed teaching decisions according to an analysis of observations of SMT.

Developing the ability to notice can be learned through collaboration and scaffolded support (e.g., Star et al., 2011). In the *Mastering Ambitious Mathematics teaching* project (*MAM*), in-service *teachers* collaborated in learning cycles so they could develop their ability to notice SMT and enact on what they noticed. The analysis meets the call from previous research (Stockero, 2021) when drawing on sociocultural perspectives while aiming at shedding light on the ways in which learning cycles might enable teachers to collectively learn to notice SMT. Within MAM, an exploration *what* teachers prepare to notice in co-planning discussions suggests that the teachers focused both on particular SMT and on pedagogy (Fauskanger & Bjuland, 2021b). In addition, Fauskanger and Bjuland (2021a) suggest that developing the ability to notice – both *what* to notice and *how* to notice (van Es, 2011) – can be learned through scaffolded support and collaboration in co-enactments in MAM. While these previous studies within MAM offer the field a glimpse into co-planning and co-enactment in the context of PD, they point out that in order to make clearer conclusions, we need to develop our understanding of how all the different elements in whole learning cycles provide teachers with opportunities to learn professional noticing. Bearing this in mind, the present study examines one representative learning cycle. It draws to a large degree on the analysis of teachers' learning from participation in video-based programs (for a review, see Santagata et al., 2021). However, our work augments the literature by situating practicing teachers in the authentic work of teaching (asked for by Stockero, 2021). By also exploring co-planning, this study meets limitations from previous research, namely the lack of focus on preparation to notice (Choy et al., 2017). Exploring *what* as well as *how* teachers notice in whole learning cycles is one way to meet this call. The following research question is addressed: How can teachers' engagement in learning cycles provide them with opportunities for learning *what* and *how* to notice?

Methods

Sociocultural views on teacher learning inform the presented study which draws on a description of learning, thinking and knowing as "relations among people engaged in activity in, with, and arising from the socially and culturally structured world" (Lave, 1991, p. 67). We see learning cycles as contexts for having reasoned dialogues (i.e, dialogues where everyone engages critically but constructively with each other's ideas and where everyone's ideas are treated as worthy of consideration) providing "affordances for changing participation and practice" and thus opportunities for the participants to learn (Greeno & Gresalfi, 2008, p. 172). *Opportunities to learn* is understood as emerging in activities, and from this perspective, teacher learning includes developing the ability to engage in particular practices. Learning cycles (Figure 1) were designed to engage teachers in learning professional noticing.

Figure 1: Cycle of enactment and investigation for PD (Wæge & Fauskanger, 2021)

In designing the cycles, we gave the teachers repeated opportunities to co-plan, rehearse, co-enact and reflect upon a set of intentionally selected instructional activities (e.g., choral counting, quick images, number strings) with teacher educators as supervisors. The activities supported the teachers in noticing SMT and in making judgments on how to respond in principled, instructive ways (Kavanagh et al., 2019). Throughout the cycles, the teachers were encouraged to 1) ask questions, explain and justify their mathematical and instructional ideas, 2) find multiple strategies and 3) try to understand what other participants said and did. Thus, a setting was developed where teachers could be engaged in the joint enterprise of learning to notice in which questions and disagreements were viewed as a productive part of the enterprise. Fourteen Norwegian primary-school teachers (divided into two groups) met for nine full learning cycles over the course of two years, producing 18 videotaped cycles. In this paper, the analysed data material has been taken from video recordings of one representative cycle (shaded in Table 1) where the instructional activity worked on was a quick image (Figure 2, more about quick images at https://tedd.org/quick-images-2/).

Table 1: Video material analysed – an overview (group 2, session 4)

MAM cycle/ group	Collective analysis (all groups)	Co-plan-ning (gr2)	Re-hearsal (gr2)	Co-enact-ment (gr2)	Collective analysis (gr2)	Discussion (all groups)	Discussion (supervisors/researchers)
4/2	24:51	59:21	21:29	26:46	19:56	29:42	58:18

A framework developed by van Es (2011) was used to analyse the depth and analytic stance of noticing, focusing on the teachers' discussions. This framework includes four levels. The first two levels (*baseline* and *mixed*) are considered as low-level noticing since the noticing is related to the class as a whole and teacher pedagogy (*what* teachers notice), and the teachers provide descriptive and evaluative comments from particular events throughout the learning cycle (*how* teachers notice). van Es (2011) denotes the two next levels (*focused* and *extended*) as high-level noticing since the teachers are then attending to particular SMT, or they are concerned with the connections between teaching strategies and particular SMT (*what* they notice). The extended level of noticing (*how* teachers notice) is described by van Es (2011, p. 139) as highlighting "noteworthy events", providing "interpretive comments", referring "to specific events and interactions as evidence", elaborating on "events and interactions", making "connections between events and principles of teaching and learning", "using interpretations", and proposing "alternative pedagogical solutions." The co-planning and the collective reflection session were divided into small sequences of utterances which were coded baseline, mixed, focused and extended respectively. Each Teacher Time Out (TTO) in the rehearsal as well as in the co-enactment were coded including these four levels of noticing.

Our analytical stance has primarily been to focus on high-level noticing, identifying whether the teachers are attending SMT and highlighting noteworthy events. When presenting findings from the exploration of how the teachers' engagement in this particular learning cycle provides them with opportunities for learning *what* and *how* to notice (whether they interpret, explain and give reasons in their discussions), we will follow the learning cycle (Figure 1) step by step, starting with the co-planning session.

Findings and discussion

The focus of attention in the co-planning discussion is summarised in Table 2.

Table 2: The co-planning session

Time	Focus of the co-planning discussion
00:00-22:00	The teachers present student strategies based on student responses from trying out the quick image in their own classrooms. The supervisor writes the strategies on the smartboard. The strategies are then illustrated on a quick image before the participants discuss how to write the students' strategies by using symbols. Based on this discussion, the supervisor initiates a discussion of the commutative property (i.e., 8 × 3 = 3 × 8).
22:00-51:40	The supervisor initiates a discussion about what goal for students learning they should aim at. The associative property of multiplication, as well as the idea of generalisation (extending the quick image) is discussed. About 45 minutes into the discussion, the supervisor suggests a goal from their previous discussion: "Yes, what mathematical idea should we focus on? Is it the associative property or is it more to develop a general expression for the total amount of chocolates in the boxes? [the dots in the quick image *represent* pieces of chocolate]." They agree to aim at the associative property.
51:00-59:21	Discussion of practical teaching strategies and how to structure and teach the activity for the students.

Whereas practicalities were the focus of attention in the last part of the co-planning discussion, different levels of noticing were visible in the first two parts. When predicting student strategies and representing them in the quick image as well as by using symbols, the teachers attend both to the relationship between particular SMT (*what*, *focused*) and between teaching strategies and SMT (*how*, *extended*). As an example, the suggestion "I see four times three, twice" from one of the teachers is followed by a discussion of how this strategy might be represented in the quick image as well as by using mathematical symbols. The teachers make connections between SMT and teaching strategies (*how*, *extended*). In the mid part of the co-planning session, a discussion of the connection between student strategies and teaching is visible when the aim for the lesson is in focus. It ends by a decision that they will challenge the students to develop their strategies into three factors (e.g., 8 × 3 = 4 × 2 × 3) in order to aim for the goal for the lesson: the associative property of multiplication (e.g., (4 × 2) × 3 = 4 × (2 × 3)). Throughout the co-planning session the participants return to the commutative property of multiplication and some of the participants seem to mix commutativity and associativity.

However – and similar to findings from Fauskanger and Bjuland (2021b) – the participants' preparation to notice (Choy et al., 2017) seems to provide the teachers with affordances for changing practices of *how* and *what* to notice on extended levels (van Es, 2011) and thus opportunities for the participants to learn (Greeno & Gresalfi, 2008) professional noticing.

In the rehearsal as well as in co-enactment in MAM, the participants can pause the instruction by initiating a TTO (Figure 1) so they can think out loud together in the moment, discuss how the teacher might respond to students' contributions and determine the direction of the further instruction. In the rehearsals across all learning cycles in MAM, 175 TTOs were asked for (Wæge & Fauskanger, 2021), 18 in the particular rehearsal analysed here. In four of the TTOs from this particular rehearsal, the participants focused on representing anticipated students' strategies in a quick image, discussing how to write the mathematical ideas in a symbolic language (2 × 12 and 4 × 6). We will show one example from the participants' discussion in one of these TTOs to illustrate their opportunity to reason and to gain insights into SMT. This is an important component of high-level noticing (van Es, 2011). One of the teachers came up with the following strategy: "I saw another pattern: eight in each row," and went to the board and showed three groups of eight dots (Figure 2b). Based on this initiative, the teacher, who was chosen as the instructor in the enactment, wrote 3 × 8 on the board and said: "In which way is it possible to see the eight here [points to the first row]." Another teacher went to the board and showed two groups of four dots in the quick image. Based on this initiative, the instructor wrote 3 × (2 × 4) (Figure 2c). This example shows how predicted student strategies are discussed and represented in the quick image by the participants, gaining insights into SMT (*focused*). The instructor expressed the following utterance: "We have three factors in each and then they [the students] can talk together about what they see." This utterance indicates that the participants are attending to the relationship between SMT and between teaching strategies and SMT (*extended*). Teacher noticing is conceptualised in a variety of ways (van Es & Sherin, 2021). This example in one of these TTOs illustrates signs of the two interrelated and cyclical processes of attending and making sense of particular events (SMT and teacher strategies), often involved in teacher noticing (Sherin et al., 2011). At the end of this rehearsal, the goal set for the enactment, focusing on the associative property of multiplication was briefly mentioned.

In the co-enactments across all learning cycles in MAM, 189 TTOs were asked for (Fauskanger, 2019) and out of these 125 were identified as opportunities to learn professional noticing on various levels (Fauskanger & Bjuland, 2021b). The co-enactment in the learning cycle analysed here included three TTOs and two out of these were instances of high-level noticing (van Es, 2011). In the following, we delve into one of these TTOs to illustrate the teachers' opportunity to reason about SMT and to make informed teaching decisions based on these observations made in the moment of instruction. Just before the TTO, a student presents her strategy as seeing four six times in the quick image. The teacher circles four dots six times in the image (Figure 2d). When invited to the board, this student writes 4 × 6 = 24.

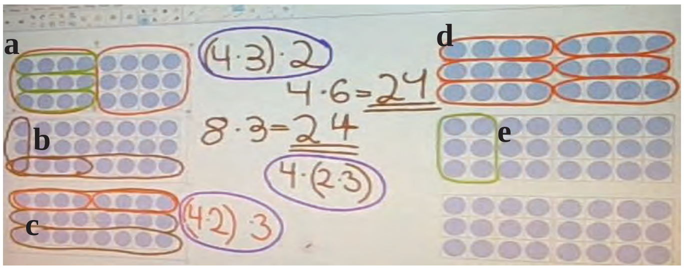

Figure 2: All student strategies from the co-enactment (The multiplication sign used is "·". This is the most common sign to use in Norway. In this paper we decided to use "×" for easier reading.)

The teacher asks the students how to split the 6 in 4 × 6 into "another multiplication task." A student answers: "two times three" and the instructor writes 4 × (2 × 3) on the board and says that she realised that 4 × (2 × 3) could not be represented as the six fours in the image (Figure 2d). From what follows, the teacher obviously is thinking of 2 × 3 as six dots and is confused. She draws six in Figure 2e. The supervisor asks for TTO saying: "I think I see the six in the upper image (Figure 2d)" and asks the students if they "see six" in Figure 2d. They point to the six fours. This TTO invites the participants to attend to the relationship between particular SMT (i.e., that six in this quick image could be represented as six groups of four dots (Figure 2c)), SMT (i.e., six in this quick image represented as six dots (Figure 2e)) and teaching strategies such as representing SMT (*what*) and to work on alternative pedagogical solutions (*how*) as alternative ways of representing students' strategies. Whereas this TTO provides the teachers with opportunities for learning *extended* noticing, in the second TTO the teachers attended to particular students' mathematical thinking (*focused*). In the third TTO, time issues were discussed. Similar to findings from Fauskanger and Bjuland (2021a), our findings indicate that by being provided with affordances for changing practices, the participants have opportunities to learn (Greeno & Gresalfi, 2008) extended levels of noticing (van Es, 2011) in-the-moment of teaching in the co-enactment analysed.

In the collective reflection discussion following the co-enactment, all participants looked at the smartboard from the co-enactment and focused on the different student strategies represented in the quick image (Figure 2). The focus of attention is summarised in Table 3.

Table 2: The co-planning session

Time	Focus of the collective reflection after co-enactment
00:00-05:30	The participants focus particularly on two ideas introduced by two individual students from enactment. One of the students expressed that he/she "saw a box with four across and three upwards, then there were two boxes and I took [multiplied] eight times three", writing 8 × 3 = 24 on the board (see Figure 2a). Another idea was to see four six times in the quick image, writing 4 × 6 = 24 on the board (Figure 2d).
05:30-13:20	They put efforts into practical issues related to the instructional activity of the quick image. One of the participants thinks that only spending 20 minutes on this activity is too demanding and suggests that 45

	minutes would be a more realistic time frame. They are also discussing the use of talk moves and mathematical language related to mathematical terms and concepts.
13:20-19:57	The participants focus particularly on the commutative and associative property of multiplication. The teacher (instructor) posed quite a few questions related to these properties. This is exemplified by the following questions, presented in Fauskanger and Bjuland (2019, p. 126): "Why is it called commutative [property for multiplication] when there are two [factors] and associative [property for multiplication] when there are three [factors]? What's the difference? Why couldn't we just use [the word] commutative, why is another word used there? It's just the same, isn't it? It's all about the order of the factors, or are they [commutative and associative properties of multiplication] two different things?"

As seen in Table 3, the second part of the discussion after the enactment attends to the whole class environment with general descriptions and teacher pedagogy related to time frames, the use of mathematical language and the use of talk moves. This indicates low levels of noticing. Whereas a discussion related to the commutative and the associative property of multiplication was the focus of attention in the last part of this session (no levels of noticing), higher levels of noticing were visible in the first part. From one of the student strategies, seeing eight times three (*what*, *focused*), the participants agreed that it seemed to be difficult for the students to split the eight ($8 \times 3 = 24$), illustrating the mathematical representation in the quick image, $(4 \times 2) \times 3$ (*how*, *focused*). The supervisor elaborated on this particular event (SMT) and challenged the participants to consider how to use this idea with the aim for three factors which are related to their mathematical learning goal for the lesson (*how*, *extended*). In a similar way, they discussed the other student's idea ($4 \times 6 = 24$ on the board), how to "split the six", reiterating this situation from the enactment. The supervisor summarises this discussion by concluding that "the number six could be represented in the quick image in different ways, depending on whether six is seen as the number of groups or as dots within a group" (Fauskanger & Bjuland, 2019, p. 139).

Conclusion and implications

Meeting the call from Stockero (2021) – to explore noticing in-the-moment during the act of teaching – and from Chong et al. (2017) – to explore teachers' noticing while planning instruction – this study explores how teachers' engagement in learning cycles (Figure 1) provides them with opportunities for learning professional noticing. Our analysis indicates that all parts of the learning cycles are contexts where teachers can learn to notice students' ideas and respond to them. When working together in learning cycles, the participants practise how to build on SMT (Empson & Jacobs, 2008), as has been endorsed in many reform documents. In conclusion, developing the ability to notice – both *what* to notice and *how* to notice (van Es, 2011) – can be supported through collaboration (e.g., Star et al., 2011) as in the learning cycles in MAM.

While this study provides the field with a glimpse into one learning cycle in the context of PD, more research is needed. Compared to studies of teacher noticing in video clubs (Santagata et al., 2021), the learning cycles (McDonald et al., 2013) appear to provide teachers with opportunities to learn higher levels of noticing. However, in order to be able to make clearer conclusions we need to provide systematic explorations of more learning cycles, inside as well as outside of the MAM project.

Developing pre-service teachers' communications skills using Socratic lectures: The audience's perspective

Peter Frejd[1], Jonas Bergman Ärlebäck[1] and Micaela Bergfors[1]

[1]Linköping University, Sweden; peter.frejd@liu.se; jonas.bergman.arleback@liu.se; micaela.bergfors@liu.se

This study investigates the potential of engaging secondary pre-service teachers in a team-teaching approach called Socratic lectures to develop their communicational skills. An intervention was designed centered around a workshop sandwiched between a pre- and a post-presentation on natural logarithmic and derivatives to an audience of undergraduate students. A quantitative and qualitative analysis of 155 pre- and 92 documented post-experiences of the undergraduate students' shows that the pre-service teachers' presentations and communicating skills developed positively over the course of the intervention. The accompanying statistical analysis of Likert evaluation items shows a significant increase of multiple communicational aspects of the pre-service teachers, and the line-by-line analysis of written evaluations support this claim regarding the pre-service teachers' interactivity. Issues about generalizability and future research is also discussed.

Keywords: Interaction, pre-service teachers, socratic lectures, team teaching, questions.

Introduction

Asking the right questions to support, motivate and engage students in learning is a central part of the teaching profession (Paoletti et al. 2018). Mathematics teaching in Sweden has a long history of *traditional teaching*, a method based on directing students' learning by presenting mathematical content at the blackboard followed by individual work in the textbook. Research reports (Jablonka & Johanssson, 2010) show that the traditional teaching influence students to lose interest in mathematics. In this research project, we investigate the potential of so-called *Socratic lectures* to develop pre-service secondary teachers' strategies to ask different types of questions with different purposes to motivate and engage students to learn mathematics. We report on preliminary results from an intervention, organized around a workshop introducing the Socratic lecture strategy, where 48 pre-service secondary teachers (PSSTs) prepared and presented a focused mathematical content to undergraduate students before (*Pre*) and after (*Post*) a workshop. In this paper, we focus on a set of empirical data gathered on the audience's experiences of their level of engagement in the intervention (the undergraduate students') during the PSSTs' the pre- and post-presentations.

Socratic lectures is a teaching strategy we have developed from research literature on *Self-Determination Theory* (SDT, see e.g. Ryan & Decis, 2000), *rhetoric* and *team-teaching/co-teaching* (see e.g. De Backer et al., 2021; Kamens, 2007). The teaching strategy, which is based on the Socratic method (Thompson, 1998), is constructed in the form of a play, where two lecturers use the Socratic method by asking questions to each other (and to the audience) in the form of a dialogue and thereby engaging the audience to make them interested. The teaching strategy is to some extent applied in computer courses at the Department of Computer and Information Science at Linköping University and has been praised by students as an engaging and productive way of teaching. Students' course evaluations have emphasized communicational aspects, such as developing a friendly and pedagogic atmosphere for discussions, as fruitful for their learning. Motivated by these positive evaluations and that team teaching has shown many valuable effects in research literature, such as *increased dialog about learning and teaching* (De Backer et al., 2021), we aim to explore if applying Socratic lectures by PSSTs also develop their communication skills in the teaching of mathematics. Communication is here broadly understood as "a process by which information is exchanged between individuals through a common system of symbols, signs, or behavior" (Merriam-Webster, n.d.), which include written, verbal and non-verbal interactions. The research question posed to address the aim is:

How, if at all, did the PSSTs' communication skills in the mathematics of teaching, viewed from undergraduate students' expressed experiences, develop after participating in the workshop on Socratic lectures?

Socratic lectures

Self-Determination Theory (SDT, see e.g. Ryan & Decis, 2000) emphasizes *competence*, *autonomy*, and *relatedness* as central psychological features for increasing motivation. Thus, participation in social contexts (relatedness) affects individuals' motivation to learn if the contexts entail opportunities to influence (autonomy) and to draw own conclusions (competence). Adopting a feeling of being interested in something and being involved in one's own learning are keys to success in school, which also applies to the subject of mathematics (Murayama et al., 2013). In trade and sales, it is important to ask the right questions to make customers feel that they 'really' need a certain product. Salespeople often use rhetorical tricks and techniques based on asking questions, which lead the customer to think in a certain direction, so that they desire to buy the product. One such technique used in courtrooms and in political discussions is the Socratic method (Thompson, 1998), which is based on asking leading questions to steer other people's thinking in a certain direction. The central parts of the method are the questions themselves and questioning, because they can facilitate students' knowledge production (Lew et al., 2017). There are several categorizations of the types of questions used in teaching, such as *fact*, *next step*, *proof framework*, *warrant*, *evaluation*, and *convention* (Paoletti et al. 2018). Frequently the different types of questions are connected to factual-, procedural-, conceptual-, or meta cognitive knowledge (Smith & Julie, 2014), which also illustrates the importance of using different types of questions to enhance the development of all types of knowledge.

Socratic lectures as a teaching strategy is related the paradigm of *team teaching* sometimes, also sometimes called *co-teaching*, which refers to "two or more professionals jointly deliver substantive instruction to a diverse, or blended, group of students in a single physical space" (Cook & Friend, 1995, p. 1). In teaching practices, however, the level of collaboration between teachers and how they jointly deliver instructions may vary. Based on a research literature review, Baeten and Simons (2014) identified five models for team teaching: *the observation model*, *the coaching model*, *the assistant teaching model*, *the equal status model* and *the teaming model*. The models capture the roles of the actors in terms of taking passive or active responsibility for the teaching. The models range from passive to active participation in the classroom. One of the teachers can act as a passive observer, to coaching students to assisting the other teacher or even taking more active responsibilities by sharing the working load and splitting the number of students and/or the content to teach as in the equal status model. The teaming model is the ideal model where the teachers collaborate in all phases of planning, delivery, and evaluation, with the characteristics of two teachers “in front of the entire class group and there is a lot of interaction and dialogue between them” (Baeten & Simons, 2014, p. 94). Socratic lectures has these features and should be categorized in accordance to this model. A recent literature review (De Backer et al., 2021) concluded that team teaching has the advantages of increased support, increased dialog about learning and teaching, professional growth, and personal growth, but also potentially the disadvantages of lack of compatibility of peers, comparison between peers, difficulty of providing constructive feedback and increased workload. In this paper, we only investigate on the potential of increased dialog about learning and teaching, which exactly emphasize the frequent opportunities of team teaching for PSSTs to discuss and evaluate teaching approaches between each other. While there is a wide corpus of literature about team teaching in educational research generally, to date this strand of research in mathematics education it is more limited. The existing literature concerns how experienced teachers can teach together with teacher students (Yopp-Edwards et al., 2014), and the use of "team teaching" for developing special education courses on mathematics teaching and learning (Guðjónsdóttir & Kristinsdóttir, 2011), but to our knowledge no research focusing on how PSSTs develop their ability to teach in dialogue. This study will contribute with new knowledge in this area of research as well as address the call by Kamens (2007, p. 156) “to include realistic classroom-based experiences in co-teaching” in teacher education.

The intervention and data collection

The 48 participating PSSTs were enrolled in a first course on mathematics education in a secondary teacher training programme. About two thirds (30 out of 48) of the PSSTs had completed a 2,5-week introductory course in educational science and started taking a mathematics course in algebra prior to participating in the study, the other third had taken a course in geometry as well as started the algebra course, in addition to courses at the university for a year on other subjects, such as English or Biology. The intervention was designed in three parts a *pre-presentation*, a *workshop* and a *post-presentation*. After the pre-presentation the PSSTs had one week of teaching practical practice a at regular school before attending the workshop, thereafter, a few days until the post-presentation.

For the pre-presentation the PSSTs were grouped in 24 pairs and instructed to prepare and present a 15-minute presentation on a given mathematical content for a set of undergraduate students enrolled in a preparatory course on secondary mathematics for achieving qualification for entering the university. The PSSTs were asked to present either the basic rules for differentiating (i) polynomials and power functions; (ii) exponential functions of type $y=a^{kx}$; or (iii) natural exponential function and how work with the logarithm rules. The aim for the pre-presentation was to deepen and consolidate the undergraduate students’ knowledge in these areas, since the undergraduate students previously had received two lectures within their course on these topics. The PSSTs were not instructed how to organize and arrange their presentation more than to observe basic principle such as engage and motivate the students, write clear and concise, use proper mathematical notations, speak so the audience can hear, don’t talk to fast, etc. In other words, the instructions provided the PSSTs with freedom to independently select presentation strategy. The undergraduate students were organized in ten classrooms and experienced two or three pairs of Socratic lectures by the PSSTs.

The 4-hour workshop on Socratic lectures was mandatory for all PSSTs and was taught and organized by four teachers from the Department of Computer and Information Science. The first and third authors were observing and videotaping the activities during the workshop. The workshop included both theory on the teaching strategy and practical training. In short, the workshop was organized in the following blocks: *an introduction (30 min)* describing the background of Socratic lectures and the basic principles of using a dialog conversation mode in pair teaching; *a first practical training session (45 min)* where students were instructed to re-work their pre-presentation using the Socratic teaching strategy, including a presentation of one of the PSSTs pairs whom also received feedback from the four teachers; *more theory (15 min)* a presentation on how to engage the audience using questions; *a second practical training session (45 min)* were organized as the first practical session, but with the exception that the PSSTs were instructed re-work their presentation again to also engage the audience.; *a model example (20 min)* on recursion presented by two of the programming teachers to show how the method is used in one of their courses; and finally *a concluding discussions (35min)* where the teachers summarized the day and opened up the floor for more discussions and comments. The four teachers teaching the workshop applied the strategy of Socratic lectures during their theoretical presentations and assisted and coached the students during the practical training blocks.

In preparing their 15-minute post-presentation the pairs of PSSTs were instructed to use their notes from the workshop and to implement the Socratic lectures strategy to the same undergraduate students as in the pre-presentation. The PSSTs tasks in their post-presentation were to demonstrate and discuss solutions of assessment tasks on differentiation and logarithms, such as: *Find the local maximum and minimum values to* $f(x)= x^2- 2x^4+ (5/8)$ and *Find the maximum area of a perpendicular triangle inscribed with its base on the x axis and its upper corner on the parabola* $y = 36 - 3x^2$.

The data collected document: the video recordings of all PSSTs pre- and post-presentations; the PSSTs' written reflection of their experiences and expressed views after each presentation; and the undergraduate students' evaluations of the pairs of PSSTs' presentations. This paper focuses on the undergraduate students' evaluation forms, which were distributed and filled out individually directly after each presentation. The pre- and post-presentation evaluation forms were identical and included seven statements to be ranked on a 5-point Likert scale, and three open questions. The Likert items concerned: *if the content was relevant*; *if the presentation was instructive*; *if the presentation was at the right level*; *if the presentation was inspiring*; *if the PSSTs engaged in good dialogs with the students*; *if the PSSTs asked enough questions*; and *if they like mathematics*. The three open questions were *What aspects have you experienced as positive in the presentation? What can be further developed in the presentations?* and *Additional comments*. There was also a question about the undergraduate students' last grades in mathematics from secondary education. The question *if they like mathematics* and last grades do not focus on communication and are not analyzed in this paper.

Analysis and results

The undergraduate students' responses, 155 on the pre- and 92 on the post-evaluation forms were, copied into a spreadsheet (SPSS). Answers on all Likert items were analyzed and compared using descriptive statistics and paired sample tests (dependent t-tests). The answers to the two first open questions in the evaluation forms filled out by the undergraduate students were short in length (from just a few words to a few sentences). These answers were explored through a qualitative iterative process of open coding using a line-by-line analysis (cf. Chenail, 2012), with a focus on what communicational aspects in the presentations were emphasized and what aspects were expressed to be potentially improved. The open codes were grouped into six themes, which are discussed below.

First however, we report on the statistical analysis of the undergraduate students' responses on the evaluation forms regarding their expressed experiences about the presentations in terms of the presentations being *relevant*; at the right *level*; *instructive*; *inspiring*; engaging the in *dialogs;* and regarding the use of *adequately many questions* (see Table. 1 below).

Table 1: Undergraduates' expressed experiences of PSSTs' presentations

		Relevant	Level	Instructive	Inspiring	Dialogs	Question.
Pre	***Mean***	4,47	3,77	3,60	3,52	3,18	3,51
	N	155	155	154	155	155	153
	Std. Dev.	0,70	0,95	1,09	1,03	1,10	1,12
Post	***Mean***	4,60	4,22	3,88	3,89	4,08	4,01
	N	92	92	92	92	92	91
	Std. Dev.	0,54	0,75	1,00	0,89	1,06	0,94

With respect to the undergraduates' experience of the PSSTs' engagements in *dialogs*, Table 1 indicates that the workshop made a significant positive impact on the PSSTs' interactions with the undergraduate students (M_{pre} = 3,18, SD_{pre} = 1,10; M_{post} = 4,08, SD_{post} = 1,06; t(91)= -5,75, p = .000). There was also a significant increase found with respect to the undergraduates' experiences of the PSSTs use of *questions* (M_{pre} = 3,51, SD_{pre} = 1,12; M_{post} = 4,01, SD_{post} = 0,94; t(91)= -3,46, p = .001), as well as the workshop having a significant positive impact on the PSSTs communication skill in terms of adopting an accurate *level* of presentation (t(91)= -3,68, p = .000); being *relevant* (t(91)= -2,23, p = .028); being *instructive* (t(90)= -2,49, p = .015); and being *inspiring* (t(91)= -2,05, p = .043).

The line-by-line analysis of the undergraduate students' answers on the pre- and post-evaluation forms to the open questions *What aspects have you experienced positive in the presentation?* and *What can be further developed in the presentations?* generated six themes: *(i) personal attributes* such as if the PSSTs were experienced as friendly, confident, nervous, etc.; *(ii) interactivity* focuses on aspects of discussions, checking, opening th floor for questions, developing a positive atmosphere, etc.; *(iii) planning* captures the experienced prepared communication in terms of suitable level of instructions, how to end, choice of tasks, etc.; *(iv) delivering* focuses on the instrumental aspects of communicating such as black board skills, being loud and clear, pedagogic, etc.; *(v) mathematics* relate to aspects of how the content of mathematics was presented such as step-by-step explanation, mathematical rules, use of mathematical language, arguments for why, etc.; and *(vi) collaboration* concerns the communication dynamics between the presenting PSSTs. To compare the undergraduates' answers between the pre- and post- evaluation forms we report, in table 2 below, on the relative frequency of codes in the themes, as well as the frequency of those undergraduates that explicitly answered the question about what aspects of the presentation that could further be developed with lines such as "everything was good" or "hard to find aspects to improve".

Table 2: Undergraduates' answers to the two open questions in the evaluation form

Themes:	***Attri.***	***Interac.***	***Plan.***	***Deliver.***	***Math***	***Collab.***	***Good***	**N**
Pre +	11%	13%	25%	38%	10%	3%		313
Post +	7%	25%	25%	39%	4%	0%		177
Pre -	10%	15%	14%	38%	16%	2%	6%	150
Post -	5%	8%	16%	36%	14%	2%	20%	64

The thematic categorization of the undergraduate students' answers as displayed in table 2 show that the proportion of codes in the themes of *planning* and *delivering* the presentations was stable between the two occasions both regarding what was positive (+) and what can be further developed (-). The same can be concluded with respect to the question of what could further be developed when presenting the *mathematical content*. Commonly among the third of the undergraduates that provided an answer within this theme in the pre-evaluation suggested the PSSTs to be more explicit: "Please ask more questions and explain **WHY** you do as you do and why I should learn this" or "Explain why it is like that, not just say it is". In the post-evaluation forms these types of suggestions were sparse. The first quote above indicates a suggestion to the PSSTs to try to interact more with the audience by asking question. This was a frequently found argument in the pre-evaluation answers, but a type of argument that decreased in number in the post-evaluation. The undergraduates' suggestions on the post workshop presentations instead commented on the use of too many questions: "The organization of the presentation was messy and they asked too many questions just like being students". Regarding the relative frequency of codes in the *interactivity* theme there is an increase of positive experiences after the workshop and a decrease in suggestions for improvement. Although the workshop focused on the collaboration between the presenters, the undergraduates only provide a few comments within this theme (*collaboration*) and the relative frequency was low and quite stable between the pre- and post-presentations. The results from the Likert items showed that the undergraduates were more satisfied with the post-presentation, which also is supported by the increase of relative frequency within the category addressing that presentation was *good* (an increase from 6% to 20%) and that hardly any further suggestions for improvement were provided in the post-evaluation.

Conclusion and discussion

The statistical analysis of the answers on the Likert questions showed a significant increase between the pre- and post-presentation of many communicational aspects of the PSSTs. We therefore conclude that the PSSTs' presentations and their communicating skills developed during the intervention as experienced by the undergraduate students. This conclusion is also supported by the line-by-line analysis regarding the increase of the relative frequency of *interactivity* and the quality of the presentations as experienced as *good*. The results may be summarized by the following quote of an undergraduate students on the post-evaluation arguing: "*They asked a lot of questions to all of us in the group, good pace, an incredible improvement since last time*".

The results presented in this paper are in accordance with other research studies (e.g. Baeten & Simons, 2014; De Backer et al., 2021) showing that team teaching provides a platform where interaction and dialogue between the presenters and their audience is a central component of the activity. From the line-by-line analysis of the pre-presentation experiences, the undergraduates voiced that the PSSTs showed the procedures to apply when solving tasks, but they were missing explanations of "why" the mathematical procedures were applied. A possible reason for this is the PSSTs' lack of experience of doing presentation. Indeed, for two thirds of the PSSTs this might have been their first chance to act as a teacher and presenting mathematical content. In addition, since all PSSTs just had begun to study mathematics at the university level, they might not have felt confident enough regarding the mathematical topics to get into conceptual issues. The type and number of questions asked by the PSSTs could better be explored using video analysis of the actual situations, which we will follow up with in an upcoming study. The results show, however, that undergraduate students experienced that the interactivity increased after the workshop possibly indicating that the number of questions increased.

What effect the workshop had on the results, require further analysis. On the one hand, all PSSTs attended the workshop and practically tested the new teaching strategy of Socratic lectures focusing on their communicational skills. But, on the other hand, the students also had a week of teaching practice in regular school where they also had opportunities to work on their communicational skills when presenting to a group of students. In addition, the decrease between the undergraduate students participating in the pre- and post-presentations could be another reason for the increase in positive experiences. The students that did not enjoy the first presentation may not have attended the second presentation, which may impact on the results. In addition, the mathematical content presented in the two presentations (logarithmic rules and differentiation), might have invited the PSSTs to focus on standardized solution strategies and procedures for calculating and simplifying, and hence impacted on the type of communication they engaged in. Likely other mathematical content would have generated another result. We are careful not to generalize our results beyond the intervention, the mathematical content presented, the participating PSSTs and undergraduates. Therefore, our first results, that the intervention had a positive effect on the development of the participating PSSTs' communication skills, needs further justifications of new research studies on Socratic lectures.

Pre-service teachers learn to analyse students’ problem-solving strategies with cartoon vignettes

Marita Friesen[1] and Alyssa Knox[1]

[1]University of Education Freiburg, Germany; marita.friesen@ph-freiburg.de, alyssa.knox@stud.ph-freiburg.de

The flexible use of different problem-solving strategies is key for processing mathematical problems successfully. The question of how future teachers can be supported to learn about such strategies and their use in the mathematics classroom is consequently of high relevance. In a one-semester university course, we provided a unit on problem solving focusing on the use of primary-school students’ problem-solving strategies. To support the pre-service teachers’ learning, we designed two types of cartoon vignettes: short cartoons, each illustrating a different problem-solving strategy (e.g., work backwards) and more complex cartoons providing the opportunity to analyse how students make use of different strategies and/or struggle while solving a non-routine problem. Our evaluation showed that the participants perceived the cartoons as valuable learning opportunities. Learning to analyse students’ problem-solving strategies could be supported but remained a challenging task.

Keywords: Vignettes, cartoons, problem-solving strategies, teachers’ competence of analysing.

Introduction

Mathematical problem solving is considered a core mathematical activity and it has been incorporated as a key component in mathematics curricula and national standards worldwide (Liljedahl et al., 2016). Related studies have provided evidence that the flexible use of so-called heuristics or problem-solving strategies can enhance problem solving (e.g., Carlson & Bloom, 2005). Various mathematical problem-solving strategies, such as *make a table*, *draw a picture* or *look for a pattern*, can already be introduced for primary school children (Charles et al., 1992) and corresponding instruction achieved a positive impact on students’ use of strategies and problem-solving abilities (Verschaffel et al., 1999). However, there are also studies showing that many students do not spontaneously use problem-solving strategies or struggle when applying them to non-routine problems (e.g., Schoenfeld, 1992). It can therefore be assumed that mathematics teachers do not only need professional knowledge about students’ problem-solving strategies but must also be able to analyse their students’ strategy use in order to provide them with support. With this study, we build on prior research into mathematics teachers’ analysing of classroom situations, described as the competence to link classroom observations with relevant professional knowledge in order to make sense of what has been observed (e.g., Friesen & Kuntze, 2020). In the present study, we were particularly interested in the question of how future primary-school teachers can be supported in their professional learning to analyse students’ problem-solving strategies. The study was conducted in the framework of the ERASMUS+ project coReflect@maths, aiming at designing and evaluating vignette-based learning material in mathematics teacher education courses with a particular focus on cartoon vignettes (cf. Ivars et al., 2020). Correspondingly, we explored in this study the potential of different types of cartoon-based vignettes for (1) developing pre-service teachers’ professional knowledge about various problem-solving strategies and (2) their competence to analyse primary-school students’ use of such strategies in classroom situations. The following sections outline the theoretical background of the study, in particular with respect to mathematical problem-solving strategies and teachers' corresponding competence to analyse classroom situations. We then introduce our vignette-based approach and describe the unit about problem solving in which the pre-service teachers of this study participated.

Mathematical problems and the use of problem-solving strategies

We follow Schoenfeld's (1983) definition of a mathematical problem as an *unfamiliar situation for which an individual does not know how to carry out its solution* since no routine or familiar procedures are (yet) available to him or her. Such problems are often described as non-routine problems in contrast to routine problems, where students can apply familiar or routine solution methods to solve them (Elia et al., 2009). Solving non-routine mathematical problems, in contrast, requires the use of so-called heuristics or problem-solving strategies (Liljedahl et al., 2016). Various problem-solving strategies can already be introduced to primary-school children, such as guess–check–revise, draw a picture, act out the problem, use objects, solve a simpler problem, make a table, look for a pattern, make an organized list, write an equation or work backwards (cf. Charles et al., 1992). A study with primary-school children by Elia et al. (2009) showed that the flexible use of strategies (adapting the strategy to the given task or changing in case the chosen strategy was not successful) led to higher performance in problem solving. Knowing various problem-solving strategies and being able to change or modify a chosen strategy is therefore an important prerequisite for the successful solving of problems. However, the same study also showed that many of the primary-school children struggled with applying different strategies or could not reach a correct answer since they did not have a sufficient understanding of the problem (Elia et al., 2009). These findings highlight in particular the important role of the teacher in supporting the students in understanding the given problem as well as in choosing, applying and reflecting on the use of different problem-solving strategies.

Analysing classroom situations regarding the use of problem-solving strategies

In order to support students in using different problem-solving strategies in a flexible manner, a mathematics teacher must know about different strategies, how students can apply them to problem-solving tasks and where they might struggle. Taken together with the definition of problem solving which is characterised by the fact that the problem-solver cannot simply apply a routine or familiar solution method (e.g., Schoenfeld, 1983), a mathematics teacher's knowledge about *content and students* (KCS, cf. Ball et al., 2008) can be assumed to form an important prerequisite in this context. However, to provide learners with appropriate support, teachers must also be able to *apply their knowledge* in the course of instruction, meaning that they have to link relevant observations in the classroom with their knowledge to make sense of what they have observed in order to make follow-up decisions. Based on the concept of teacher noticing (Sherin et al., 2011), we described such ability as teachers' competence of *analysing classroom situations* (e.g., Friesen & Kuntze, 2020). Numerous studies have shown that teachers' analysing of classroom situations informs their decision-making and is highly relevant for instructional quality and student learning (Sherin et al., 2011). A teacher who is competent in analysing classroom situations regarding the use of problem-solving strategies is consequently able to identify the problem-solving strategies used by his or her students and to evaluate the strategies' potential for solving a particular task. Such competence is an essential prerequisite for supporting students in choosing and applying problem-solving strategies, for helping students where they struggle and for engaging them in reflection on the use of different strategies. In the following section, we describe the potential of using vignettes for developing and evaluating pre-service teachers' professional growth in this context alongside with the cartoon-based approach we take in the framework of the ERASMUS+ project coReflect@maths (Ivars et al., 2020).

Vignette-based learning and the potential of cartoons for teacher education

Using representations of classroom practice, so-called *vignettes*, in the form of short video clips, teacher-student dialogues or cartoons, has proven to be an effective approach in teacher education and corresponding research (e.g., Buchbinder & Kuntze, 2018). Vignettes provide the opportunity to engage in classroom practice without the pressure to act and can help future teachers to analyse classroom situations and to discuss and reflect on alternative approaches. In this way, vignettes can become both, representations of practice *and* theory: As learning opportunities, vignettes are often used to illustrate particular aspects of quality teaching or where norms are challenged and can therefore support future teachers in applying their theoretical knowledge to teaching practice in a safe context. Vignettes have, therefore, also proved to be an effective method to assess development in teacher education courses (Jeffries & Maeder, 2005). Correspondingly, questions regarding possible designs of vignette-based learning and testing environments have become essential and the potential of cartoon vignettes has gained increased attention. Cartoon vignettes combine numerous advantages ascribed to vignettes in the formats video and text: They allow the systematic, theory-based design and variation of classroom situations where individual characteristics that are important to comprehend a classroom situation can be added easily (Friesen, 2017). Compared to the formats of video and text, cartoon-based vignettes can be equally suitable to assess and foster teachers' competence in analysing classroom situations (Friesen, 2017). The design and evaluation of cartoon-based learning material is a main objective of the ERASMUS+ project coReflect@maths and the present study has been conducted in the framework of this project. The following section describes the organisation and contents of the university course in which the study was conducted as well as the design and use of the cartoon-based learning material.

The university course: organisation and cartoon-based learning material

The present study was conducted in a one-semester university course (April-July 2021) for pre-service teachers studying to teach mathematics at primary schools. The course took place at a University of Education in the south of Germany where primary school comprises the first four years of schooling for students aged between six and ten years. Due to the pandemic situation, the course had to be delivered completely online with meetings organised as video calls and study material provided via the university's online learning platform. The course covered different topics related to the teaching and learning of mathematics at the primary-school level. Problem solving was one unit within the course covering four weeks and three group meetings (3 x 90 minutes). The problem-solving unit contained key topics with special regard to the primary-school context (e.g., what are mathematical non-routine problems, problem solving according to Polya, problem-solving strategies, how can learners be supported). Figure 1 (on the left) shows the organisation and contents of the unit. In order to support the pre-service teachers' learning about students' problem-solving strategies, we designed two types of cartoon-based vignettes: (1) short cartoons with the aim to develop the participants' professional knowledge about different problem-solving strategies and (2) more complex cartoons with the aim to develop their competence to analyse primary-school students' use of such strategies in classroom situations. Figure 1 (on the right) shows one of the short cartoons illustrating the problem-solving strategy "work backwards". Based on Haering (2016) who describes various problem-solving strategies used by primary-school students, 16 of such short cartoons were designed, each depicting a problem-solving task and how one or several students solve that task using a particular strategy. The other cartoons of that type show strategies such as: guess–check–revise, draw a picture, act out the problem, use objects, solve a simpler problem, make a table, look for a pattern, make an organized list, write an equation, etc. (cf. Charles et al., 1992).

Week I	Week II
online meeting I: introduction of unit; release of online learning material and study plan	online meeting II: questions, group work
Week III	Week IV
self-study time	online meeting III: presentation of tasks, questions, **course evaluation**
between meetings: self-study time with online material supported by study groups and online forum	

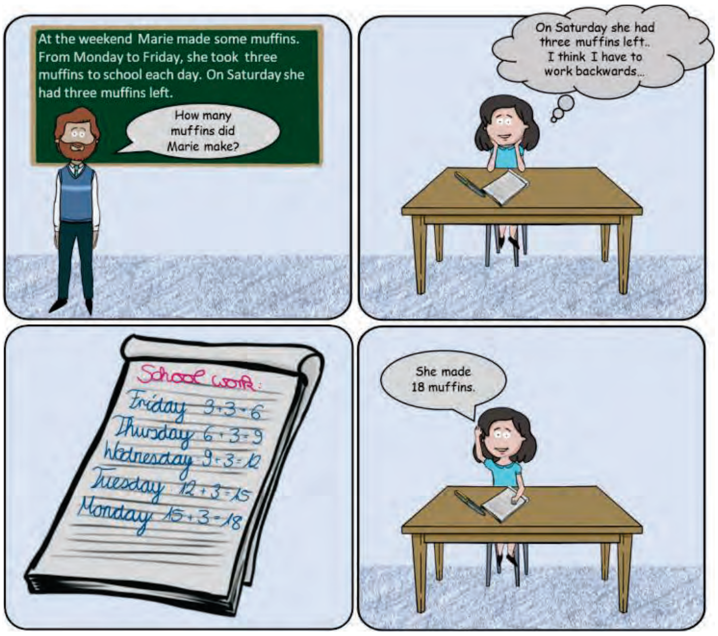

Figure 1: Organisation and contents of the unit on problem solving (left); Short cartoon vignette illustrating the problem-solving strategy "work backwards" (right); (cartoon designed by Alyssa Knox based on Haering (2016); characters drawn by Michael Weninger)

During the unit, the pre-service teachers worked on different tasks provided with the vignettes. They explained, e.g., the strategies used in the cartoons and verified their use with the cartoon characters' solutions or comments. They were also asked what alternative strategies students could have made use of for solving the given task and to compare and reflect on the potential of different strategies.

Figure 2 shows one of the more complex cartoon vignettes. These vignettes were designed based on lesson transcripts by Rasch (2016), representing typical classroom scenarios around primary-school childrens' solving of non-routine word problems. Four vignettes of that type were used in the unit about problem solving, each showing one or several students who use various strategies while solving a non-routine task, who struggle in choosing and/or applying a strategy and who are supported by their teacher. The participants of the course were asked to identify the strategies used by the cartoon students and to evaluate their potential for solving the task. They were also asked to make assumptions about reasons for the students' difficulties in solving the task and to verify their answers with the students' use of strategies as shown in written solutions, use of material or comments. Finally, the participants were given the task to evaluate the teacher's support and to think about alternative approaches. For sharing these approaches, they received a cartoon with empty speech bubbles that could be adapted. In this article, we focus on the students' use of problem-solving strategies.

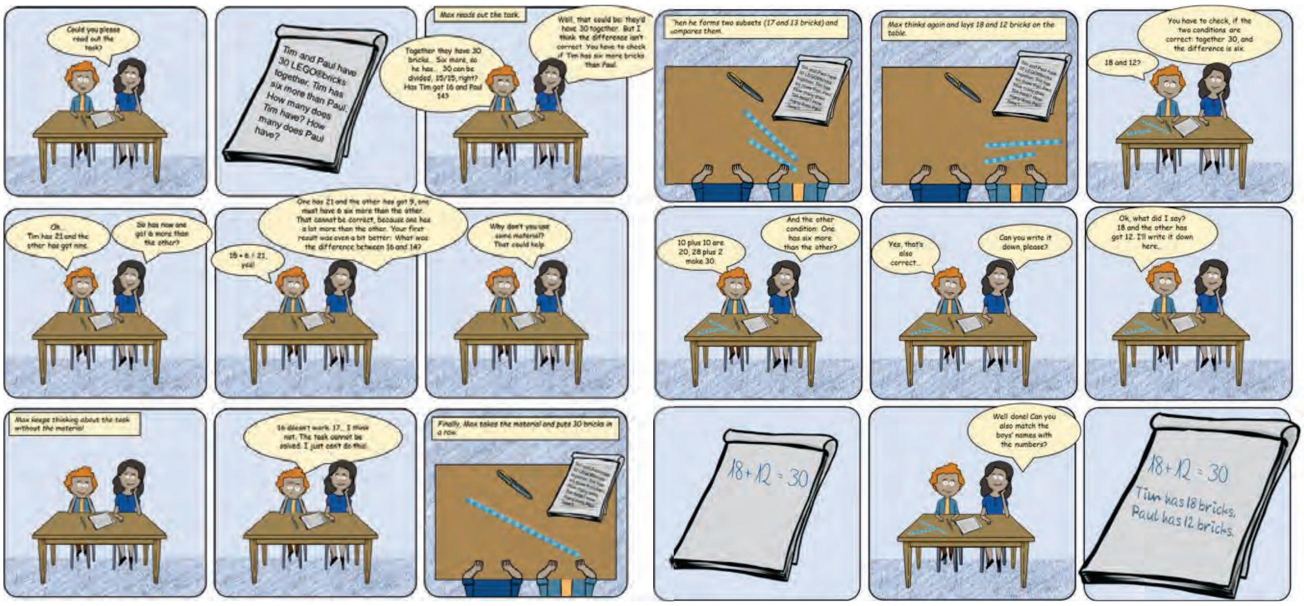

Figure 2: Complex cartoon vignette illustrating different strategies and need for learning support (designed by Alyssa Knox based on Rasch, 2016; cartoon characters drawn by Michael Weninger)

Research interest and research questions

This study aimed at exploring the potential of cartoon-based vignettes for pre-service teachers' professional learning regarding students' use of problem-solving strategies. Accordingly, we addressed the participants' own perceptions regarding their learning with the cartoons and their competence to analyse students' use of problem-solving strategies in classroom situations at the end of the unit. The research questions were the following: (1) How do the participating pre-service teachers perceive the potential of cartoon vignettes in terms of their professional learning? (2) To what extend are the participating pre-service teachers able to identify the strategies used by students when analysing a complex cartoon vignette? (3) Can they suggest alternative strategies?

Sample and methods

The course evaluation took place at the end of the unit on problem-solving after the fourth online meeting (cf. Figure 1). The pre-service teachers received an online questionnaire and were asked to analyse a complex cartoon vignette and to evaluate the cartoon-based learning material in terms of their professional learning. They could use their course material and as much time as they needed. *N*=42 pre-service teachers gave consent to have their data analysed in an anonymised way and participated in the study. The items for the pre-service teachers' evaluation of the cartoon vignettes in terms of their learning (RQ 1) are displayed in Table 3. Since participants' engagement with vignettes is an essential pre-requisite for analysing them (cf. Friesen, 2017), items 1–3 addressed the pre-service teachers' perceived motivation, authenticity and immersion when working with the cartoons. Items 4–5 evaluated to what extent the participants felt supported by the use of cartoons in their learning about problem solving and items 6–7 evaluated the perceived potential of cartoons for teacher education in a more general way. Figure 2 shows the cartoon used for the course evaluation (RQ 2+3) together with the following task: *In the presented situation from a second grade classroom, Max is working out the solution to a problem-solving task while his teacher is supporting him. Please read through the situation and answer the following questions: What problem-solving strategies does Max use to solve the task? What other problem-solving strategies could he have used to find a solution?*

Data analysis and results

Related to the first research question, Figure 3 displays the results of the participants' evaluation of the cartoon vignettes in terms of their learning. Regarding pre-service teachers' engagement with the cartoon vignettes, they rated their perceived authenticity, motivation and immersion on average as positive. The pre-service teachers perceived the cartoons as supportive for their learning regarding students' different strategies and difficulties in solving problems. They evaluated the use of cartoons in teacher education as helpful and as a good connection to practice.

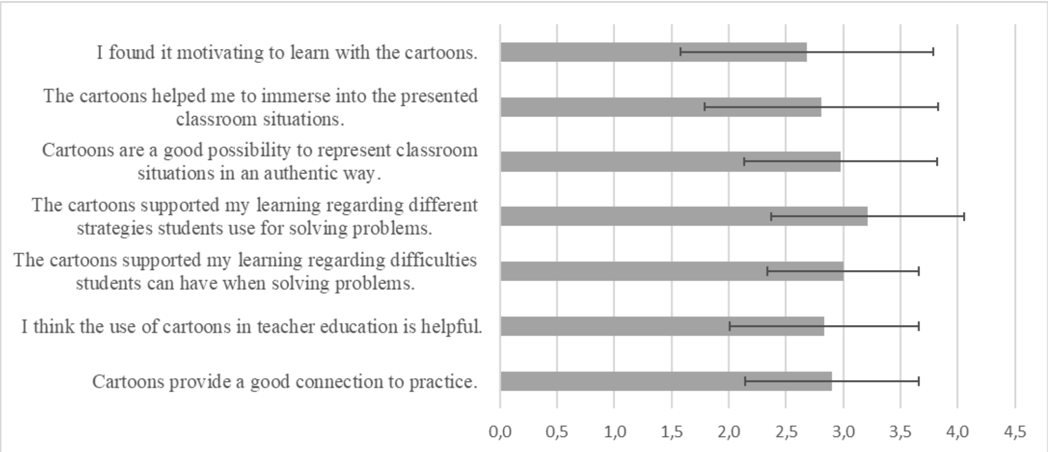

Figure 3: Pre-service teachers' own perceptions of their learning with cartoons (means and standard deviations; *0* = I strongly disagree; *4* = I strongly agree.)

To answer research question 2, an a priori analysis of the cartoon vignette used for the evaluation (see Figure 2) was conducted. In this way, the strategies used by the student in the cartoon vignette (e.g., work backwards, use objects, guess-check-revise) and further potential strategies for solving the given task were identified (e.g., try systematically, make a table). The pre-service teachers' written analyses for the complex cartoon vignette were coded accordingly. The findings show that all of the participants were able to correctly identify at least one strategy used by the student in the complex cartoon; 32 pre-service teachers (76.2%) were able to correctly identify two or three strategies and eight pre-service teachers (19.0%) were able to correctly identify four or five strategies. There were, however, also participants who identified strategies that were not appropriate (e.g., “write an equation” although the student did not use the equation to solve the problem, but only when writing down the answer). In this context, 21 pre-service teachers (50.0%) described one or two such unsuitable strategies and five participants (11.9%) matched three or four strategies in an incorrect way. Although not explicitly asked for, providing explanations for the choice of the strategy was found to be significantly correlated ($r(40) = .41$, $p = .008$) with the number of correctly identified strategies. All of the participants were able to suggest between one and four suitable alternative strategies for solving the task in the vignette. However, 27 participants (64.3%) suggested also one or two unsuitable alternatives; 11 participants (26.2%) suggested three or four.

Table 1: Sample answers showing the relation between correctly identified strategies and explanation for the choice of strategy by referring to relevant events in the vignette

(…)“Try systematically” as he goes through examples in order (first 16, then 17, then 18) and comes to a result this way (PST #2)	(…)“Look for a pattern” as he always has to check for two numbers (difference 6 and result 30) (PST #2)	(…) When he works with the objects later, he also tries systematically, because he notices for 17 and 13 that the difference is still too small and moves one brick from the bar with 13 bricks to the bar with 17 bricks. (PST #22)

Summary and discussion

Vignettes provide safe environments for future teachers’ analysing of classroom situations and can support them in connecting classroom observations to theory – an essential prerequisite for making sense of what has been observed when teaching and for making suitable follow-up decisions (Buchbinder & Kuntze, 2018). This study shows that cartoons hold great potential in this context: they can be purposefully designed to represent key aspects of practice and theory on the learning of mathematics while considering different levels of complexity (cf. Friesen, 2017). Although the study has limitations (e.g., no control group or pre-post design), it encourages further research into the use of cartoons in teacher education: The participants perceived the cartoon vignettes as a valuable learning opportunity, not only in the context of problem solving but also for teacher education in general. The findings show that pre-service teachers’ analysing results were more often correct when they explained them by referring to relevant events in the given classroom situation. When working with vignettes, validating observations with specific classroom events should be part of that work and pre-service teachers need to be supported in a systematic way. Whereas numerous studies have shown the importance of teachers' analysing for instructional quality and student learning (Sherin et al., 2011), this study contributes by showing how pre-service teachers can learn to analyse in a university course on problem solving and how different types of cartoon vignettes can support their learning.

Keywords: Mathematics trails, pre-service teacher education, digital learning.

The maths trail seminar

A maths trail is a walk through the neighbourhood where one can find objects to solve mathematical problems, such as calculating the volume of a pond (cf. Shoaf et al., 2004). The MathCityMap project enriches the idea of maths trails with new technologies like smartphones and the internet to create an analogue and digital learning experience. After establishing the MathCityMap project to revive the idea of mathematics trails (cf. Ludwig & Jesberg, 2012), there was a need to educate and train teachers using it in classrooms. Because it is known how hard task design is for in-service teachers (Jones & Pepin, 2016). Furthermore, recent studies have shown positive effects of maths trails on pupils' learning outcomes and motivation (cf. Zender et al., 2021). All this leads to the decision to implement maths trails in pre-service teacher education. So that maths trail seminars were offered for pre-service primary school teachers in the summer semester of 2021 at the University of Koblenz-Landau, at which 45 students took part. The idea was to offer a varied learning experience, analogue and digital, building competencies for the upcoming teachers in outdoor mathematics. Therefore, theory and practice have been equal parts of the seminars: Learning about the theory of outdoor education on the one hand and creating an outdoor learning environment on the other hand. The mathematical topics of the seminar are related to algebraic and geometric content for primary school. The seminar closed with an oral exam: the students produced a video of a task they had created and analysed it from a didactic perspective (cf. Geisen & Zender, 2022).

The conceptualisation of the seminar is based on the interconnected model of professional growth of Clarke and Hollingsworth (2002) for professional development in teacher training, since the seminar for pre-service teachers can be considered similar to training for in-service teachers (see Geisen & Zender, 2022). In this regard, Clarke and Hollingsworth (2002) identified the following four domains as relevant: Personal Domain ("Knowledge, Beliefs and Attitude"), External Domain ("External Source of Information or Stimulus"), Domain of Practice ("Professional Experimentation") and Domain of Cobcequences ("Salient Outcomes") (ibid., p. p. 951). Changes concerning these domains can occur through reflection and enactment processes (ibid., p. 950). The practical implementation of theoretical content imparted in teacher training impacts the learners' learning processes. That can be reflected by the teachers and ultimately lead to a changed practise (ibid.). At university and in particular, in terms of the maths trail seminars, theoretical content is conveyed to pre-service teachers like that in teacher training. Nevertheless, in most cases, they cannot implement this input in school practice. However, they can analyse and reflect on the level of lesson preparation, which can also lead to changes concerning the Domain of consequences and the Personal Domain.

Exploratory evaluation study

The aim of the study is accompanying research to check the effectiveness of the maths trail seminars based on the model for professional growth (cf. Clarke & Hollingsworth, 2002) and the conceptualisation and implementation of the seminar. Therefore the following research questions were fundamental: Is it possible to consider the four domains of the model of professional growth of students through the conceptualisation and implementation of the maths trail seminars? Can this also be confirmed based on the results of the evaluation?

Two digital surveys were used to answer the research questions, the first concerning the seminar itself and the second for the oral exam. The first survey was the general survey of the university to evaluate the lectures and seminars. It was inserted at the end of the semester and contained 64 items, most of them evaluating demographical data or being six-point Likert scales. The second survey contained seven items (4-point Likert scale) and the possibility of leaving a comment for checking the oral exams about its suitability for querying acquired competencies, enabling a multi-stage learning process and a long-term learning effect.

Results and Conclusions

The seminar addressed all four domains of importance for learning identified by Clarke and Hollingsworth (2002): Personal, External, Practice, and Consequences. In the survey, most students agreed that the seminar "established a connection between theory and practice", "makes me interested in the topic", and "makes me want to work on the content". In addition, students reported being highly motivated and voluntarily invested much time into the seminar. Finally, in written feedback, students highlighted the experience and new perspective on mathematics and stated that they felt confident implementing outdoor mathematics in school. Hopefully, the students remember their impressions when being in-service teachers at schools.

Co-learning in an IBL-inspired PD session on programming

Benedikte Grimeland, Øystein Skartsæterhagen and Svein Arne Sikko

Norwegian University of Science and Technology, Norway; benedikte.grimeland@ntnu.no, oystein.skartsaterhagen@ntnu.no, svein.a.sikko@ntnu.no

In this study we investigated what kind of co-learning and learning gaps could be identified in a professional development session on the topic of programming. We found that both teachers and teacher educators learned about programming and lesson planning for programming. Teacher educators also learned about what kinds of knowledge teachers possessed about programming. Learning gaps identified were teacher educators' knowledge about didactical aspects of programming as well as the use of programming in school. We found that teachers express a need to learn more programming.

Keywords: Mathematical literacy, teacher professional development, inquiry-based learning, co-learning, programming.

Background and theory

Programming

In the new national curriculum in Norway launched in 2020, programming is introduced as an integrated part of mathematics and science. This comes in addition to digital skills as one of the basic skills that are to embrace all subjects. At year 5 the mathematics curriculum specifies that “The pupil is expected to be able to create and programme algorithms with the use of variables, conditions and loops” (Utdanningsdirektoratet, 2020a, bullet 10). The science curriculum for years 5–7 specifies that “The pupil is expected to explore, create and programme technological systems that consist of parts that work together” (Utdanningsdirektoratet, 2020b, bullet 7). Programming is a new theme in the national curriculum in science and mathematics for primary school, which implies that there is an authentic need for professional development. Programming is a new theme for teachers, both because they have not been teaching it but also because they themselves have never studied this theme. At the same time programming is new for teacher educators. Even if they may have studied programming at university, they have to a very limited degree been teaching it as teacher educators. Inquiry-based learning (IBL) is a way to investigate and explore new ideas in the classroom and may be a helpful approach in introducing a new curriculum. This leads us to our research question in this paper: What kind of co-learning and which learning gaps can be identified in an IBL-inspired professional development session on programming?

Inquiry-based learning (IBL)

IBL is seen as a way to organize education so as to make students able to function in a society which is changing and where the ability to think, reason and ask new questions are more important and higher valued than the ability to re-answer questions already asked. Bruder and Prescott (2013) point out that IBL is beneficial for motivation and understanding of mathematics and science, as well as beliefs about relevance for society. Our understanding of IBL builds on the model developed in the EU Primas project (e.g., Artigue & Blomhøj, 2013; Maaß et al., 2017). In IBL students inquire, pose questions and engage in exploration in collaborative settings. Teachers foster students' reasoning, connect to student experiences and scaffold learning. The classroom culture is dialogic, and questions are open, experienced as real and relevant with multiple solution strategies. It is thus a goal to foster inquiring minds and build understanding of the nature of science and mathematics. Referring to Jaworski (2006) we consider three forms of inquiry practice in an inquiry community of teachers and educators: inquiry in mathematics (pupils engage in inquiry to learn mathematics), inquiry in teaching mathematics (teachers engage in inquiry to develop the teaching of mathematics), inquiry in research on developing teaching of mathematics (teachers and educators engage in inquiry into the research).

Four co-learning dimensions

Jaworski (2003) launched a four-dimensional framework for investigating the development of mathematics teaching and learning. Development is seen as processes of inquiry, involving critical reflection, in a community of inquiry. In the community experiences are shared, this supports individual inquiry and the development of norms. Hence, there are elements of both individual and community relationships that allow the inquiry and reflection to take place, which is seen as the learning and development. Participants can be insiders in the community or outsiders supporting the research and development. This gives rise to four interrelated reflexive pairs: Knowledge and learning, Inquiry and reflection, Insider and outsider, Individual and community. Investigations along these four dimensions are suitable and will provide insights into the inquiries and co-learning taking place in a learning community consisting of teachers, educators and students. Jaworski (2003) suggests guiding questions for each reflexive pair. To answer our research question, it will be helpful to answer questions related to each of the four dimensions:

Knowledge and learning: Who is learning and what knowledge is being developed?

Inquiry and reflection: Who is inquiring and into what? What kind of reflections are taking place?

Insider and outsider: Who are the insiders and who are the outsiders, and in what situations?

Individual and community: How is the community comprised, and how is the dialectical relationship between individuals and community played out?

By searching within each of the four dimensions, a more complete picture may appear of what kind of co-learning is taking place and of which learning gaps can remain.

Methods

The professional development session studied in this paper was carried out as part of a larger, longitudinal research project with focus on mathematical and scientific literacy and IBL. Participants were three mathematics and two science teacher educators from the university, and five teachers from a local school (teaching grade 4, 5 and 6, and one teacher leader). All teachers were generalist teachers. The TEs all had PhDs in mathematics or science, some with teacher education in addition. The lesson study was carried out according to the following plan: a) Teachers suggested a theme and a lesson plan, b) Teacher educators (TEs), including both mathematics teacher educators (MTEs) and science teacher educators (STEs), discussed the suggested theme and plan, c) Teachers and TEs met in a joint planning meeting, d) Two lesson iterations with reflection and redesign in between. Teaching carried out by one teacher, with other teachers and TEs observing. Final reflection after the second iteration.

The theme suggested by the teachers for this session was programming with micro:bit (https://microbit.org/). Micro:bit is a small computer originally launched by BBC in 2015 with the purpose to be used in schools for pupils to learn programming. To program the micro:bit, pupils use a block-based visual programming language on a computer or tablet, and then transfer the program to the micro:bit using Bluetooth or a USB cable. In the lesson plan suggested by the teachers, pairs of pupils were given the task to make a flashing heart on the micro:bit's LEDs, and then try to make the heart flash with the same rate as their own heart rate. The teachers based this plan on an example found on the Norwegian website Lær Kidsa Koding, which provides resources related to teaching programming to children (Lær Kidsa Koding, n.d.). In the TEs' meeting, the main discussion related to whether the proposed plan opened up for sufficient inquiry or whether it was too focused on following recipes. An alternative task involving using the micro:bit to steer a car was launched. In the joint planning meeting, it was agreed that the lesson plan suggested initially by the teachers would be kept, but some changes were made in the material that the pupils would use.

The following data material was collected: Proposed lesson plan and final lesson plan, field notes from the TEs' meeting, audio recordings of the joint planning meeting and the two reflection and redesign meetings.

The audio recordings from the joint planning meeting and the first reflection and redesign meeting were transcribed. The three authors coded the transcript from the joint planning meeting separately, using the four dimensions from Jaworski's framework as categories (Jaworski, 2003). The three different versions of the coded data were then discussed to come to a joint understanding of each category. To help in guiding the discussion, the lesson plan and field notes were consulted. Subsequently the transcript of the first reflection and redesign meeting was coded separately using the new understanding of the categories. The audio recording of the second reflection and redesign meeting was also analysed using the common understanding of the categories. After this the findings were compiled. The project has been submitted to, and approved by, NSD – Norwegian centre for research data. In this paper, teachers are referred to as T name, where all names are pseudonyms.

Findings

The findings are structured according to the four dimensions suggested by Jaworski (2003).

Knowledge and learning

Our data shows multiple answers to questions related to knowledge and learning. The participants can be divided into three groups according to their prior knowledge of programming, see Table 1.

Table 1. Participants' prior knowledge of programming

Extensive knowledge	Some knowledge	No knowledge

MTE Øystein, STE Arne	MTE Benedikte, MTE Svein	STE Ragnhild, T Fay, T Camilla, T Marie, T Erik, T Jenny

Teachers Fay and Erik had some experience with micro:bit in fourth and sixth grade, respectively. Apart from that, no participants had any prior knowledge of programming in school. Four of the TEs had knowledge of programming from university courses and have used it at some level. Having sufficient programming knowledge at university level is however not sufficient to design tasks that function well at primary school level. The tasks discussed by the TEs in their prior meeting turned out to progress too fast to a too advanced level.

MTE Svein: It can be that, when we talked about it, that it took off and became too advanced.
T Jenny: Is it too advanced?
STE Arne: It is hard for me to say, really, since I have the knowledge.

STE Arne was not able to judge whether the task at hand would be too advanced for the pupils. He had extensive knowledge of programming, so could do the task himself, but did not have experience with programming in primary school, and so needed teachers' inside knowledge of their pupils' abilities and prior knowledge as feedback to judge the appropriability of the task.

Teachers' lack of knowledge about programming is clearly an obstacle for developing good teaching plans that would enhance pupil knowledge.

T Fay: We don't have sufficient knowledge in programming to design good enough tasks.

TEs had knowledge of programming, but not in a school setting. Teachers had knowledge of their pupils, but not of programming. Through the cooperation, both groups had opportunity to enhance their knowledge into new ground. Teachers were given opportunities to develop their knowledge of programming in school:

T Camilla: I ask a lot of questions because I need input on how to continue teaching programming.

We thus see that teachers are learning about teaching programming by cooperating with TEs who have programming knowledge. TEs learn about teachers' knowledge of pupils, and how to integrate knowledge about programming with knowledge of pupils to develop lesson plans. So both teachers and TEs learn how to plan a programming lesson in mathematics or science.

Inquiry and reflection

Several types of inquiry and reflection are evident in the data. During the planning meetings and reflections, ideas were discussed and assessed according to whether they were easy or difficult for the students (mainly with input from teachers) and easy or difficult to program (mainly with input from TEs). Together these constitute inquiry into teaching. Teachers and TEs inquired into pupil knowledge and learning after observing lessons, with reflection on the teaching and how the pupils reacted to the teaching, including how they were able to cooperate and work together in pairs.

As the lessons are to be IBL-inspired, a common quest regards whether the suggested activities offer opportunities for the pupils to inquire and explore. In our case this quest led to a discussion about whether doing programming would provide opportunities for inquiry or whether the programming had to be embedded in something else.

STE Arne: In this particular task at hand, there is little inquiry involved (…) Because, in terms of programming it is not so much exploring.

T Jenny: I believe, we were satisfied when we came up with this about heart rate, since that may be inquiring.

STE Arne wanted to make the programming itself more explorable, while the teachers had put programming into the context of heart rate to make it into something the pupils could explore. Discussions continued regarding how to make it more IBL-like, and inquire in programming:

T Jenny: Do you think that, it is possible to do inquiry with the programming; and that it will be too difficult to combine it with exploring their own heart-rate in addition?

The question relates to what types of inquiry is possible if you haven't done any programming? Teachers expressed thoughts that when something is new to you, then maybe it does exactly give you opportunities to explore. Since the pupils have not worked with programming or micro:bit before, starting playing is exactly to engage in exploration and inquiry. This was expressed at various points during the planning.

T Fay: We were thinking that it will be some kind of inquiry since they haven't worked with it before.

T Fay: Like this, now, like when I am trying it out, it is inquiry for me; will it not be the same for the pupils?

A teacher asks whether there will be multiple solutions and strategies, relating to an important part of IBL:

T Erik: Will there be many different methods for how they can solve it? Will they come up with more examples of how they have done it?

In order to solve the task, the pupils had to find an appropriate pause (in number of milliseconds) between each heart beat shown on the micro:bit, in order to make it match their own heart-rate. Two possible strategies were mentioned:

T Fay: Some will do as I do now, just trying to make it equal, just moving the numbers around. Or some will try to compute the number of heart beats in a minute.

During the planning meeting, only these two solution strategies were suggested. In the reflection meetings, it became clear that this did not correspond well to what actually happened during teaching. Most of the students did, to a certain extent, follow one of these two strategies, but many of them did so in ways that were not expected. Of those following the strategy of trying out different numbers, many pupils changed the numbers in so small increments that there was no noticeable effect of the change. Those following the strategy of finding the number of heart beats in a minute did not continue in the expected way by computing the correct pause to use in their programs, but rather used the number of heart beats as the length of the pause.

At the reflection after the first lesson, it became apparent that the way the task was designed made it difficult to observe what impact changing the input in the program had. For example, if pupils changed input from 60 to 70, they were not able to observe any change since those numbers are in milliseconds. In addition, the program block used to display a heart on the LEDs had a built-in pause of 600 ms, meaning that even if pupils put their own correct numbers into the program, the output would be wrong by 0.6 seconds.

MTE Øystein: So that is the biggest problem. That if someone has understood it, and apparently does everything right, they get the wrong result.

As we have seen, the main type of inquiry was inquiry into the teaching, with critical reflection on the lesson and the task.

Insider and outsider

The data reveal several pairs of insider-outsider configurations. An obvious instance is that teachers are insiders in school while TEs are outsiders. Among the teachers, class-teachers are insiders regarding knowledge of the particular group of students, while other teachers and TEs are outsiders. Moving to the classroom, both teachers and TEs are outsiders inquiring into how pupils work during the lesson.

The insider-outsider perspective also relates to programming. Those who know programming are insiders, while those who don't are outsiders. Without pre-knowledge of programming, you don't know what the possibilities and options are, e.g., what is easy to accomplish and what is more difficult. Those who don't know programming are bound by following given recipes. Those who know programming can supply information/knowledge on how to use the recipe, and change it, for their own means. Even so, pupils have to be guided, like STE Arne is guiding the group during the planning:

STE Arne: They either need a recipe, or you have to tell them, like I do now.
T Fay: Yes, if we have a recipe, then it is quite OK.

Part of being an insider in programming is knowing about the terms and concepts and what possibilities these may constitute. Before you reach that level, having a recipe constitutes a safety net.

Individual and community

A prominent example of how the community of teachers, TEs (and pupils) relate to the wider society is the fact that programming as a theme in mathematics and science in the school curriculum was imposed from the government without much support from teachers, and to a degree resistance, from teacher organisations and teacher educators. The competence aims formulated in the national curriculum provided the basis for the session, and were referred to several times during the discussions, to assure that the task designed for the lesson was appropriate for fulfilling the learning goal formulated in the curriculum.

STE Arne: But then it is not that competence aim, then it is another competence aim.
T Marie: Because it says "design and make a program based on user needs".

An interesting aspect is connected to what resources that are available, e.g., the micro:bit technology that was used in this session. Why and how had the micro:bit technology been chosen? Was the decision made by the teachers or the school or at some higher level? It turns out that the micro:bit technology has been launched at national level:

T Fay:	All schools in our commune have been given class-sets of these.
STE Ragnhild:	All schools in the whole country have been given such class-sets.

Thus the society at large influenced the lesson both concerning the theme (the curriculum) and the resources (micro:bit). The influence of the national curriculum is obvious and natural. The choice of technology is more surprising, and shows that apparently random choices have big influence on lesson design.

Discussion and conclusion

This lesson study provided ample possibilities for co-learning for teachers and TEs as programming as a theme in school was new to all participants. Misfeldt et al. (2019) point out that even if teachers have a positive attitude towards working with programming, they do not feel prepared to take on the task. Miller (2019) states that the school as a system needs to provide support and opportunities for teachers to gain skills in how to implement computational thinking and coding. Since programming in school was new to all participants in our project, all were learning at some level: a) Teachers learned about teaching in/with programming, b) TEs learned about what teachers know about programming, c) Teachers and TEs learned how to plan a lesson in/about programming, d) Teachers and TEs learned about programming in school.

Learning to teach programming concerns the interplay between teachers' knowledge about teaching and pupils, and TEs' knowledge about programming. How to find or develop a common language? Through the cooperation, teachers provided knowledge about what may work in school so that the two types of knowledge, teacher educators' knowledge of programming and teachers' knowledge of the school setting, resulted in co-learning about programming in primary school.

How easy is it to understand that programming is open to inquiry? Programming involves making algorithms, recipes, which make programming appear "closed". On the other hand, making changes to the code is easy, just do it and see what happens, thus programming is very open to inquiry. Maybe there is an analogy with Lego? You can follow the recipe on the box or play with the pieces freely. We found that teachers with little experience in programming tended to view programming as a closed activity that simply consists of following pre-made recipes. The teachers did, however, also express the view that there is inquiry involved in learning to program.

In the professional development session studied here, both teachers and TEs neglected to work completely through the planned task before the lesson. Everyone simply agreed that the task could be solved, and there was only a very brief discussion about possible solution strategies. It seems clear to us that all teachers and TEs should have attempted to solve the task completely during the planning meeting. This would have made the teachers better prepared for teaching the lesson. But perhaps more importantly, it would mean that the teachers and TEs would sit together actually doing programming (as opposed to just talking about programming), which we believe would have given good opportunities for additional co-learning.

Our findings indicate that teacher educators need to acquire more knowledge about didactical aspects of programming and the use of programming in mathematics and science for primary school. Teachers expressed a need to learn more about programming, learn coding, and thereby gain knowledge that will help them choose or design tasks that are relevant, both in the sense of being relevant for pupils in their learning of programming, and relevant in the sense that they are attainable for the age group.

Math trails supporting the collaboration between mathematics teachers in professional development

Silvia Haringová and Janka Medová

Constantine the Philosopher University in Nitra, Faculty of Natural Sciences, Department of Mathematics, Nitra, Slovakia; silvia.haringova@ukf.sk, jmedova@ukf.sk

Keywords: Math trail, lesson study, professional development, teachers' knowledge, beliefs.

Professional development and collaboration

Nowadays, collaboration among teachers in activities closely linked to mathematics lessons is considered to be the most appropriate form of professional development of in-service (mathematics) teachers (Prediger, 2020). Current Slovak legislation makes it possible to situate in-service teacher training directly in schools. A well-designed in-service professional development programme influences the knowledge and beliefs of mathematics teachers.

Lesson study, when experienced teachers of mathematics and didactitians work together to design an optimal lesson on a pre-agreed topic, seems to be a suitable method of professional development. It has a cyclic nature consisting of four stages: study, plan, teach and reflect (Lewis et al., 2019) intervening changes in teachers' knowledge, beliefs, routines of professional learning and pedagogies which influence the instruction and therefore students' learning. Beliefs play an important role in assessing curricula, teaching, learning and assessing students' knowledge and are grounded in teachers' knowledge and experience (Carrillo-Yañez et al., 2018). Teacher knowledge and beliefs influence various areas of mathematics lesson planning, implementation, and reflection (Ball et al., 2008; Carrillo-Yañez et al., 2018) including the use of student-oriented teaching methods such as a math trail.

Mathematical trails in teachers' professional development

A math trail is a path during which students can discover and solve mathematical problems related to real objects. MathCityMap trails (MCM trails) are part of outdoor education supported by mobile technologies (Barlovits & Ludwig, 2020). They use a 'bring your own device' approach in school as well as in out-of-school contexts. The purpose of the MCM trails is not only to popularize mathematics for the general public, but also to offer students the opportunity for collaborative problem solving related to their lives. In addition to the mathematical version of geocaching, students engaged in MCM trails solve mathematical problems related to real objects (Čeretková & Bulková, 2020), create the original solutions of the problems and communicate their ideas, reasoning and strategies during collaboration in teams what makes math trails a suitable tool to develop the competences for 21st century.

Methodology

Implementation of the lesson study varies across the countries and needs to be tailored to the national context. Based on the interviews with experienced mathematics teachers, the students in Slovakia lack the opportunities to develop the competences for 21st century. We suggest that it may be caused by teachers' insufficient repertoire and experience with instructional tools and routines. The following research question is addressed: What mathematics teachers' specialised knowledge is addressed during reflection on enacted MCM trails in form of lesson study? The lesson studies will be conducted with mathematics teachers in Slovakia. Didactitians will be participant-observers. First, the teachers solve the MCM trail prepared by didactitians to allow them to experience the MCM trail from the students' view. During the design of the MCM trail for grade 8 students, the teachers gain a different perspective on problem-based learning. Communication with students during the trails and subsequent whole-class discussion after its implementation is different than in transmissive teaching prevalent in Slovakia. All the four steps of lesson study will be audio- or videotaped to enable thorough analysis of obtained data. The mathematics teachers' specialised knowledge will be categorised according to Carrillo-Yañez et al. (2018). The preliminary results from the lesson study conducted in autumn 2021 will be presented.

The growing knowledge of prospective teachers about mathematical justification in a teacher education course

Ana Henriques[1] and Hélia Oliveira[1]

[1]Instituto de Educação, Universidade de Lisboa, Portugal

achenriques@ie.ulisboa.pt; hmoliveira@ie.ulisboa.pt

The importance of developing students' mathematical reasoning (MR) is emphasized, both in curriculum documents and research, as an essential skill for their learning. Nevertheless, as the teaching practice for promoting MR is often challenging for prospective mathematics teachers (PTs), it is essential to highlight MR as a goal for preservice teacher education. This study aims to analyse the growing knowledge of a group of 13 middle school and secondary mathematics PTs about the justification process, a critical component of MR, throughout a teacher education course. The results show that before working on this theme in the course, PTs revealed difficulties in the interpretation of MR processes and lower levels of knowledge about justification. However, their knowledge level has improved, which may confirm that the type of work carried out in the course was valuable to a deeper and adequate MR knowledge necessary for their future practices.

Keywords: Mathematical reasoning, justification, pre-service teacher education, prospective teachers´ knowledge.

Introduction

The development of students' mathematical reasoning (MR) is currently emphasized in national and international curriculum documents for teaching mathematics (ME, 2018; NCTM, 2000), as it is recognized as an essential skill for students to succeed in understanding mathematics by making sense of concepts and actively constructing mathematical ideas (Lannin et al., 2011; Stylianides et al., 2013). From this perspective, it is important that teachers place greater emphasis on MR in their practices, by providing students the opportunity to engage in and develop MR processes, since their learning depends on the experiences that teachers offer to them in mathematics lessons (Boston & Smith, 2011; Breen & O'Shea 2019).

This recommendation is significant in Portugal, since the curricular documents emphasize the development of students' MR ability, including justifying as an essential MR process to also help them reach a broad nature generalization (ME, 2018). However, school practices are still not consolidated and focused on the promotion of this MR process, since it is challenging for prospective teachers (PTs). Even though they struggle to produce and identify justifications, commonly judge empirical arguments by seeing examples as justifications for a generalization, as they may not have that experience as students and are unfamiliar with the MR meaning and processes (Melhuish et al., 2018; Stylianides et al., 2013). Therefore, it is essential highlighting MR as a goal for pre-service teacher education, to develop the required prospective teachers' knowledge about MR (Stylianides & Stylianides, 2006) to be proficient in promoting this students' skill in their future practices (Buchbinder & McCrone, 2020; Loong et al., 2017; Ponte & Chapman, 2015).

Mathematical tasks involving the analysis of students' reasoning processes may provide opportunities to develop the PTs' knowledge in the context of initial teacher education focused on MR, but how they interpret and understand it and notice students' justification process is still an under researched issue (Melhuish et al., 2018; Park & Magiera, 2020). The current study aims to analyse the growing knowledge of middle school and secondary mathematics PTs about the process of justification, throughout a teacher education course focused on MR. In particular, we address the following question: What improvement do the PTs evidence in their knowledge about the justification process, when they analyse examples of students' work in solving MR tasks, before and after a teacher education course?

Thus, this study may contribute to support the development of PTs' reasoning and the necessary enhancement of the design principles of the teacher education course to better assist prospective teachers in developing the needed knowledge of MR to carry out practices focused on it.

Theoretical framework

Mathematical reasoning

Mathematical reasoning, a process of making justified inferences based on previously known information (Jeannotte & Kieran, 2017; Mata-Pereira & Ponte, 2018), covers diverse kinds of reasoning: inductive and abductive to infer and draw new information, particularly plausible conjectures, and a general conclusion, based on examples and empirical experience; and deductive reasoning using formal rules to validate the inferences made from that information.

In addition, the MR conceptualization and the engagement in this activity involves diverse reasoning processes (Jeannotte & Kieran, 2017): generalizing and justifying processes, which are recognized as central for mathematical reasoning and may be achieved by inductive, abductive, and deductive reasoning; and also exemplifying, which is conceived as a relevant support for generalization and justification (Mata-Pereira & Ponte, 2018). Generalization starts from a conclusion or conjecture about a property or procedure, often based on patterns identification after an exploration of specific examples using inductive reasoning, to assert that it is common or valid to a set of objects. Afterwards, the conclusion or conjecture needs to be validated by testing examples or find counterexamples, checking if it works for diverse objects, or also justifying it through deductive reasoning (Jeannotte & Kieran, 2017; Lannin et al., 2011). Justification involves generating arguments, and explaining why they are true, to provide compelling reasons for established conjectures, but students often evidence difficulties in writing their justifications (Bersch, 2019). The understanding of the definitions and counterexamples' roles in this process allows students to make their reasoning clear and to increase their conceptual understanding, recognizing that a justification validity is a critical component of MR that is expected to be supported by mathematical procedures, properties, and definitions.

Finally, exemplifying appears associated with other reasoning processes, and involvies finding examples to support the identification of similarities and differences, and performing a validation to support the justification (Jeannotte & Kieran, 2017).

Prospective teachers' knowledge of mathematical reasoning

As mentioned in literature, it is essential that PTs learn how to create learning environments for promoting their students' reasoning, attending to the mathematical education demands (Davidson et al., 2019). PTs' knowledge of MR involves different dimensions, particularly the concept of reasoning and the kinds and processes it encompasses. Moreover, that knowledge involves recognizing the importance of developing students' MR as it is essential for their learning, and to be able to identify the reasoning processes they are able to use, namely justification, to support them through mathematical reasoning tasks (Bersch, 2019; Cihan & Akkoç, 2019; Park & Magiera, 2020;). However, several studies (e.g., Lannin et al., 2011; Stylianides & Stylianides, 2009) show that PTs usually express incorrect ideas on MR processes, especially about justification, even after having attending courses targeting this process.

Regarding these difficulties, there is a need to study how PTs may develop that knowledge during their teacher education programs. For PTs access to MR, it is essential that in teacher education they read and discuss documents focus on framework concerning MR (meaning, kinds and processes) and are asked to solve mathematical learning tasks from a school student's perspective (Jeannote & Kieran, 2017; Mata-Pereira & Ponte, 2017). Complementarily, the PTs' engagement on tasks, focused on noticing evidenced distinct ways of student's reasoning, require them to justify and sharing interpretations of MR. This PTs' analysis of students' work, in a first stage of teacher education course, may provide information that helps them to increase the required justification knowledge throughout the training course (Park & Magiera, 2020). To analyse this improvement of PTs' knowledge on MR, their interpretation of justification process should be assessed at initial and final phases of the course, using distinct levels which may characterize the diverse understanding of specific aspects associated to MR processes. For this purpose, we adopt a framework to describe the PTs' knowledge about MR processes, focusing on generalizing and justifying (Rodrigues et al., 2021).

This framework identifies six important levels (subcategories) to classify the knowledge of the reasoning processes and to characterize distinctions among main activities (Table 1), which provide "a tool to assess the learning of the prospective teachers in this domain" (p.10).

Table 1: Subcategories for classifying the knowledge of the reasoning process (Rodrigues et al., 2021, p. 6)

Category	Subcategories
Knowledge of the reasoning process	5. Knowledge of the process fits the definition presented, and includes its relationship with the other reasoning processes 4. Knowledge of the process fits the definition presented, and is explicitly outlined by enunciating the properties of the process 3. Knowledge of the process fits the definition presented, and is explicitly outlined through illustrative example(s) 2. Recognising a reasoning process though considering only 'correct' processes 1. Knowledge of the process takes on the meaning of the term in everyday language 0. The process is confused with other processes

According to these authors, the lower levels (0, 1 and 2) are recognized as insufficient knowledge of the reasoning processes, as do not reveal understanding of their distinct characteristics by attributing meanings to associated terms. The other upper levels (3, 4 and 5) already correspond to better MR knowledge of processes, illustrated mainly by the identification of examples and specific properties that characterize the process as defined in literature, and being able to presuppose relationships of inclusion.

Context and methods

This study has a qualitative nature (Erickson, 1986), and assumes a descriptive and interpretative analysis of PTs' growing knowledge about justification. It developed during a preservice teacher education course in the context of the REASON project (http://reason.ie.ulisboa.pt/en/english/) that aims to develop PTs' knowledge to promote students' MR. The participants are 13 (3 male and 10 female) Portuguese PTs who attended the 1st year of a master's program in the teaching of mathematics for middle and secondary school levels. The majority of them had a degree in mathematics, with about 3 years of advanced mathematics study, or a degree in an area with a strong mathematical component, complement with mathematics subjects in the master's program. All PTs volunteered to participate in the study and are identified by a random capital letter for guaranteeing their anonymity.

The eight sessions (two hours each) of this course on MR were conducted by the first author and observed by second, as researcher, and were part of one semester mathematics education methods course. The sessions were conceived to deepen PTs' knowledge about MR, where they autonomously (individually and in pairs) solved mathematical tasks involving Algebra and Geometry topics that required them to make generalizations and justifications. And after that they analysed episodes revealing some students' reasoning processes in solving the same tasks. In addition, their work on the tasks was collectively discussed with the intention of giving them opportunities to better understand the MR processes. The sessions also considered the reading and whole class discussion of documents focused on a framework concerning MR (Jeannotte & Kieran, 2017) and theoretical principles for task design to promote RM.

Data collection for this study concerns two phases of the PTs' work which includes their written answers to an initial task proposed on the course before working on MR and one task at the end of the course, in order to analyse their knowledge development. Both proposed tasks include some students' resolutions of them, and a question that asks PTs' analysis of the reasoning processes illustrated in students' answers, as following, intending to gather a wide diversity of data regarding their knowledge of justification process:

> ***Initial task question*:** For each of the students' written work on the task, identify how they attempted to justify the stated property. Which students' answers evidence "convincing justifications"? Justify your answer.
>
> ***Final task question*:** Analyse each of the students' written work on the task and characterize the justifications they present. Specify the ones you consider most "convincing" and explain why.

In data analysis, to answer the question of this study, we used the framework reported above (Rodrigues et al., 2021) to analyse PT's knowledge about the reasoning process of justification in both tasks. Based on that, we present in table 2 a quantitative description levels of knowledge exhibited by the PTs in the process of justifying based on their answers of the tasks, and comparing them to illustrate their knowledge development. The PTs' answers were independently coded by the authors, focus on the identification of the categories proposed. Divergent interpretations or doubts concerning a codification were then discussed by both authors to reach a full agreement. After that, we also present some examples of the PTs' answers to the tasks that show the discrepancies of the process meaning attributed by them and their interpretation of students' answers, associated to each subcategory. This examples may provide evidence of PTs' MR knowledge and difficulties they reveal in their work.

Results: PTs' knowledge about justification

Table 2 shows the PTs' different levels of knowledge about justification, based on their answers in each task. Generally, the results show that PTs have improved their knowledge in the reported answers and the interpretation of the students' answers.

Table 2: Levels of PTs' knowledge about justification

	PTs	**Levels of reasoning process**	
		Initial task (*)	**Final task**
justifying	**A**	1	5
	D	0	4
	F	0	3
	K	0	4
	L	0	3
	M	0	4
	N	-	2
	O	3	4
	P	3	4
	R	0	3
	S	4	4
	T	-	4
	U	-	3

* Three PTs did not answer this question in the initial task

In the *initial task*, most PTs (6 + 1) evidenced lower levels (0 and 1) of knowledge about reasoning process of justifying, which is indicative of the common PTs' difficulties in interpretation of MR processes. They mainly confuse the justifying process with others, namely with the generalizing. For example, to contend for the convincing justifications in students' task answers, in their answers they argue that:

> The most convincing justification is the one that reaches generalization … He concluded that all even numbers added to odd numbers give odd … without exemplifying or generalizing. (D)

> The student used the generalization and verified its divisibility by 2. (F)

> They perceive the property and generalize. (M)

One PT also associated this process with the use of a mathematical procedure, a term used in everyday language as illustration of the process, although the procedure in the student's answer is clearly not justified: "The resolution is accessible and assertive. They seek to justify from the use of algebraic addition" (A).

Only few PTs (2 + 1) showed higher levels (3 and 4), that comply with the definition process, although two of them just identified the justification through transcribed examples of the students' answers associated to this process, mentioning for instance that: "Use of equations and acquired knowledge of the sum of even and odd numbers" (P) and "Uses algebraic language and concept of parity" (O).

We also observe that one PT already evidenced deeper knowledge about justification, outlining its properties, recognizing an algebraic expression and mathematical properties as relevant characteristics of this process: "Generalizes algebraically … and uses the property that says the sum of two even numbers is an even number" (S).

At the *final task*, compared to the initial one, the PTs' levels of knowledge of justification have increased (2 to 5). The only PT at level 2 assumes that, for considering the justification as a reasoning process, it needs to be properly complete and correct, namely using mathematical logic: "he is not able to come to a logical justification" (N).

We also find, in this task, that the most common levels are 3 and 4, as evidenced by 11 PTs (4 + 7). The four PTs showing level 3 were able to identify the justification process through transcribed examples of the students' answers, for example:

> it was based on previous knowledge and reached a new conjecture and validated; justified through examples and search for patterns. (F)

> part of a general case to justify this property. (R)

The answers of the PTs' most evidenced level (4) express knowledge of justification and outline their properties, recognizing an algebraic expression and mathematical properties as relevant characteristics of this process. For example:

> The justifications presented use inductions, for generic examples and formal demonstrations; reveal the understanding of the concepts involved and necessary for the demonstration, even though ... general algebraic expressions are used. (T)
>
> He relies on geometric construction…, on knowledge that he already possesses… and gives a deductive generic example. (M)
>
> Resolution D is an example of a justification through deductive reasoning characterizing justifications; justifies through examples, …where its representation allowed reaching the property and justifying. (P)

Finally, we remark that one PT has reached the highest level of knowledge (5), as in her answer she identifies the justification and highlights the relationship between this process and generalization, by assuming that the last is inherent to the first: "The student … ended up finding two regularities that justify his reasoning quite well … discovers the regularity, making a generalization" (A).

Conclusions

This study investigated the improvement of middle school and secondary mathematics PTs' knowledge about the MR process of justification, in the context of a pre-service teacher education course, particularly focused on how they recognize this process in students' solution approaches in MR tasks which are analysed by them at an initial and final moment of the course. The PTs' work on those two moments of the course and its comparative analysis provided an opportunity to evidence their growing levels of knowledge regarding justification process, based on the framework by Rodrigues et al. (2021) and recognised by the authors as essential to establish the progression of MR knowledge. Although almost all PTs had a solid mathematical background, with about 3 years of advanced mathematics study, at the beginning of the course, most of them still revealed difficulties with this MR process that is central to the mathematical activity. They seem not to be familiar with MR knowledge, as they reveal lower levels of knowledge about justification. This is indicative of common and serious PTs' difficulties in the interpretation of MR processes before working on this theme in teacher education, as pointed out also by other studies (Buchbinder & McCrone, 2020; Lannin et al., 2011; Stylianides & Stylianides, 2009).

As expected, after being involved in the teacher education course, it seems that in the final task, the PTs were using knowledge they have learn during the course, as all of them show a progress in their level of justification knowledge, although revealing a wide diversity among them.

Finally, we remark, concerning the research question, that the results of the study evidence that the PTs have improved their knowledge, which confirm the importance of providing PTs opportunity to develop their MR knowledge in initial teacher education. The results of this research could also indicate that the privileged type of work carried out in the course, particularly the discussion of theoretical texts about MR meaning (definition, types, and processes) and the exploration and analysis of tasks proposed to students focused on their types and processes of MR, was valuable to bringing them closer to a deeper MR knowledge necessary for their future practices.

The limitations of this study are related to the fact it only focuses on the PTs' justification process and does not analyse other relevant MR processes worked on the course, but the research will be extended to adress more dimensions of PTs' MR knowledge.

A concept to handle teachers' heterogeneity within PD trainings

[1]Raja Herold-Blasius, [1]Katharina Knaudt and [1]Christoph Selter

[1]TU Dortmund University, Germany; katharina.knaudt@tu-dortmund.de

Keywords: Heterogeneity, primary school, professional development training, teacher.

Introduction and theoretical background

On the basis of the adjustments in the school system and the accompanying requirements of the teachers, in-service training aiming at continuous professional development (PD) is indispensable. In this context, Prediger et al. (2019) differentiate between three different levels: classroom level, teacher PD level and facilitator PD level. On the 'classroom level', many studies have been carried out looking at the heterogeneity of students and teachers dealing with this heterogeneity. However, within the 'teacher PD level', hardly any research was found dealing with the heterogeneity of teachers within PD trainings. In order to design effective PD trainings, Barzel and Selter (2015) identified six design principles: 1) competence orientation, 2) participant orientation, 3) teaching-learning diversity, 4) case reference, 5) stimulating cooperation and 6) promoting reflection. Participant orientation means taking into account the "individual, heterogeneous prerequisites and needs of the participants" and "fostering and demanding their active and autonomous participation" (p. 271, translated by RH).

Based on these six design principles, Korten et al. (2019) developed an evaluated, blended-learning training concept. This is divided into an individual distance learning program and a joint attendance program. The aim of the study was to support teachers in inclusive classrooms and to investigate their diagnostic competence. They found that although they considered participant orientation, there was a great deal of heterogeneity among teachers in terms of their diagnostic competence when attending the training. This implies that their blended-learning concept needs further development in order to successfully address in-service teachers' heterogeneity within all learning phases of a PD training.

Research interest and design of the study

Embedded in the broader project 'School makes strong' (Schule macht stark), we investigate the following questions: (1) How could a PD training be designed (e.g. using design principle 'participant orientation') to address teachers' heterogeneity in a holistic way? (2) By which elements it could be enriched meaningfully for heterogenous in-service teachers? The project 'School makes strong' aims at supporting schools in socially challenging situations. To do so, trainings for in-service teachers at a total of 125 primary schools are being developed. Content wise, we focus on mathematical basic skills, e.g. basic arithmetic operations, number sense and the interlinking of theory and practice.

Our study is conducted using topic-specific didactical design research (Hußmann et. al., 2016). Three cycles – each consisting of a design and a research process – will be passed through. At the moment, we carry out the first cycle, in which we develop a concept for the structure of the in-service trainings and material to design the PD trainings. Within the research process of the first cycle, we will collect various data: (1) questionnaires to evaluate if and how the teachers work with the mini-modules; (2) vignette-based interviews to learn more about the teachers' heterogeneity and their learning progress by the mini-modules and (3) observations of the teachers' lessons to identify how new learning is implemented within mathematics teaching.

Structure of a PD training focusing on teachers' heterogeneity

Building on the theoretical background, the in-service training courses are planned in a holistic way (see Figure 1). Classically, there will be built two training sessions according to the six design principles, focusing on participant orientation. Each training session is structured in the same way: welcome, (reflection phase), theoretical input, planning of practical phase. A differentiated, individual study phase is integrated between the trainings consisting of mini-modules and a practical phase.

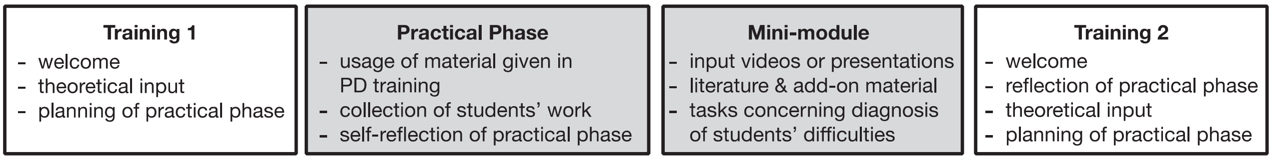

Figure 1: Concept to handle teachers' heterogeneity in PD trainings

Within the *practical phase*, teachers are encouraged to implement their new knowledge in their regular lessons by implementing the new material in their lessons. The teachers are then asked to collect the students' work and reflect their teaching after the lesson. The students' work and the teachers' self-reflection build the basis of the group discussion in the reflection phase of the next training.

Between the trainings, all teachers are offered *mini-modules*. These aim at building and activating knowledge about mathematical or didactical issues, e.g. understanding of mathematical operations.

Future steps

In the future, the concept will be piloted, evaluated and revised within the next design research cycles. A focus will be on the design, planning and reflection of the practical phase and the mini-modules.

In this study, we report on data from videotapes of two prospective secondary mathematics teachers' practicum teachings. The aim of the study was to investigate the relationship between prospective teachers' mathematical knowledge for teaching and their perspectives on mathematics, mathematics learning and mathematics teaching. We analyzed data using both the Teacher Perspectives and Knowledge Quartet frameworks. Results showed that prospective teachers having a progressive incorporation perspective or perception-based perspective depicted all the codes in Knowledge Quartet; indicating that they held mathematical knowledge for teaching. Yet, results pointed that they had different reasons behind their actions indicating their mathematical knowledge for teaching. We discuss implications of these results on teacher education.

Keywords: Teacher perspectives, mathematical knowledge for teaching, prospective secondary mathematics teachers.

Background and Rationale

Teachers' having mathematical knowledge for teaching is important (e.g., Rowland et al., 2005). In this regard, considerable amount of research conducted with both in-service and prospective teachers pointed that although focusing on what teachers have or lack has importantly informed the field (e.g., Wilson & Cooney, 2002), consistencies among knowledge, beliefs, and practices (prospective) teachers might hold need to be given further attention (Chapman, 2016).

Teacher perspectives as a robust construct is one of the ways to investigate such consistency. Researchers stated that perspectives "…can be thought about as … paradigms with respect to the development of mathematical knowledge...the term paradigm emphasizes the existence of internally coherent systems..." (Simon et al., 2000, p. 599). That is, a teacher's perspective (i.e., meaning making systems) underlies the teaching practices that indicate not only what teachers think about, know, believe and do but also everything that contributes to their teaching (planning, assessing, interacting with students) (Simon et al., 2000). Therefore, teacher perspectives go beyond understanding particular knowledge and beliefs in the context of practice of teachers in transition (Simon et al., 2000) which have affordances and limitations on their teaching (Jin & Tzur, 2011). Particularly, doing research with in-service teachers, researchers reported on teacher perspectives in a continuum between traditional perspective, perception-based perspective (PBP) and conception-based perspective (CBP) on mathematics, mathematics learning and mathematics teaching (Simon et al., 2000; Heinz et al., 2000; Tzur et al., 2001). Later, Jin and Tzur (2011) have placed the progressive incorporation perspective (PIP) between the (PBP) and the (CBP). Tzur et al. (2001) stated that teachers holding (CBP) act accordingly with the views of radical and social-constructivist epistemology such that knowledge is actively built by the learner; so knowledge is re-invented. And, individual and social mathematical learning are reflexively related. Therefore, CBP has two important aspects: First, teachers are aware of his/her current mathematical understandings being qualitatively different from their students' understandings (Jin & Tzur, 2011); and second, teachers focus on what students currently know rather than what they don't know (e.g., Heinz et.al., 2000). On the contrary, (PBP) like the traditional approach, views mathematics as part of the external world independent of the knower, compatible with Platonist view of knowledge (Jin & Tzur, 2011). Thus teachers expect their students to see mathematical situations in the same way as they do. That is, mathematics learning means coming to see a first-hand experience of mathematical reality shared by all through discovery. Mathematics teaching occurs through teachers creating situations that reveal the mathematical ideas. Teachers having this view, in contrast to having a CBP, focus on what students *do not* understand (Heinz, et.al., 2000). Jin and Tzur (2011) postulating an intermediate perspective (PIP) stated that PIP "underlies an integrated stance on knowing and learning---reflecting both 'existence outside the learner' (hence, teacher involvement) and 'dependent on what a learner knows' (hence, student active problem solving)". Mathematics learning is therefore an active mental process. Teachers' main goal is to create learning opportunities for all students to activate their existing knowledge related to the intended mathematics, the old incorporating the new rather than being transformed as in CBP. Thus, we concur that perspectives not only include the foundational knowledge one needs to hold but also how such knowledge is embedded into teaching.

Table 1: Placing PIP within teacher perspectives (Jin & Tzur, 2011, p. 20)

Perspectives	View of knowing	View of learning	View of teaching
Traditional Perspective (TP)	Independent of the knower, out there	Learning is passive reception	Transmission, lecturing instructor
Perception-Based Perspective (PB)	Independent of the knower, out there	Learning is discovery via active perception	Teachers as explainer (points out)
PIP (PIP)	Dialecticallyindependent and dependent on the knower	Learning is active (mentally); focus on the known required as start, new is incorporated in to known	Teacher as guide and engineer of learning conducive conditions
Conception-based Perspective (CBP)	Dynamic; depends on theknower's assimilatory schemes	Active construction of the new as transformation in the known (via reflection)	Engaging students in problem solving; Orienting reflection; facilitator

This takes us to mathematics knowledge for teaching in action (MKT) depicted in the Knowledge Quartet framework (Rowland et al., 2005). Knowledge Quartet (KQ) framework is based on four main categories (See Table 2). The foundation dimension relates to teachers' beliefs on the nature of mathematics and mathematics learning and teaching. It is also about teachers' knowing 'why' behind the mathematics they teach. Transformation regards teachers' presentation of ideas to learners in the form of illustrations, examples, explanations and demonstrations. Connection includes sequencing the material for instruction and awareness of the relative cognitive demands of different topics and tasks. Finally, contingency is the ability to make cogent, reasoned and well-informed responses to unanticipated and unplanned events during the lessons (Thwaites et al., 2010).

Table 2: The Knowledge Quartet: dimensions and contributory codes (Thwaites et al., 2010, p.86)

Dimension	Contibutory Codes
Foundation (1)	(1.a) theoretical underpinning of pedagogy (1.b) awareness of purpose (1.c) identifying pupil errors (1.d) overt display of subject knowledge (1.e) use of mathematical terminology (1.f) adherence to textbook (1.g) concentration on procedures
Transformation (2)	(2.a) teacher demonstration (2.b) use of instructional materials (2.c) choice of representations (2.d) choice of examples
Connection (3)	(3.a) making connections between procedures (3.b) making connections between concepts, (3.c) anticipation of complexity (3.d) decisions about sequencing (3.e) recognition of conceptual appropriateness
Contingency (4)	(4.a) responding to students' ideas (4.b) deviation from lesson agenda (4.c) teacher insight (4.d) responding to the (un)availability of tools and resources

So, we hypothesized that the three dimensions, the nature of mathematics, mathematics learning and mathematics teaching expressed in the perspectives corresponds with the (KQ) framework (Rowland et al., 2005). This is because as well the theoretical knowledge and beliefs related to mathematics and mathematics education are handled in KQ, the theoretical knowledge possessed by teachers is transformed into teaching through connections and the existence of contingency moments revealing students' thoughts, mistakes and difficulties. This implies a link between teacher perspectives and MKT; yet, there is few studies focusing on their relationship (Karagoz Akar, 2016; Bukova Guzel et al., 2019). Also, we hypothesize that (prospective) teachers holding different perspectives might depict different codes in KQ (Karagoz Akar, 2016). By the same token, even if (prospective) teachers depict the same codes referring to their MKT they might do so with having different reasons (Weston, 2013). Therefore, we conjectured that once prospective teachers had different perspectives, their MKT would reveal itself at different levels during their teaching. Scrutinizing the coherency between teacher perspectives and MKT is important: it might help uncover the reasoning behind (prospective) teachers' MKT. Diagnosing the reasons might provide teacher educators with particular steps to follow towards establishing more sophisticated perspectives and a full grasp of MKT on part of not only (prospective) teachers but also in-service teachers during professional development studies. With the results reported in this study we also aim to contribute to the field in the following ways:

First, how the practices of prospective mathematics teachers with PBP and PIP before, during, and after teaching will be depicted. Secondly, how such practices comprehensively revealing the relation between these perspectives' characteristics and the codes of KQ through empirical data, including before-during-after teachings and interviews, will be shown. It is in this respect that, in this study, we investigated the following research questions: What are the indicators that prospective teachers have a particular teacher perspective? How is their mathematical knowledge for teaching revealed in the act of teaching? How are prospective teachers' perspectives reflected in their mathematical knowledge for teaching?

Methods

Participants and Data Collection

In the larger study, participants were six prospective secondary mathematics teachers who were senior students at one of the universities, in which the medium of language is English, in Turkey. We chose to work with these participants since they volunteered to participate in the continuing set of interviews and the practice teaching sessions till the end of the study. Data from six prospective teachers depicted that four of them hold PBP perspective and two of them hold PIP perspective. For the report in this paper, we specifically depict data from two prospective teachers, Alin and Meryem for illustrative purposes as the data from them were providing context to examine the relationship between the two perspectives (e.g., (PBP) and (PIP)) and (MKT). For the larger study, six prospective teachers' two practicum teachings and interviews were videotaped and transcribed. Also, we conducted pre-interviews on their lesson plans, observed the teachings and conducted post-interviews upon completion of the teachings within the same week. For instance, in the pre-interviews, we asked the rationale behind prospective teachers' choice of learning goal(s), the tasks and how they consider the tasks they have chosen would allow students to learn meaningfully. In this paper, the reports will be on Alin's and Meryem's practice teachings. Alin taught an 80-minute lesson to the 10th grade students at a private high school. Alin had created a task for her students to make sense of the graph of the function $f(x) = ax^2 + bx + c$ in terms of the meaning of real coefficients a, b, and c. Meryem taught a 40-minute lesson to the 11th grade students at a public high school. Meryem had modified a task for her students to make sense of piecewise functions.

Data Analysis

We analysed the data using coded analysis (Clement, 2000). First, based on previous research results (e.g., Jin & Tzur, 2011; Simon et al., 2000) we created a chart regarding teacher perspective characteristics. Following, each researcher read the lesson plans, transcripts from the pre-interviews, the practice teachings and the post-interviews line by line, looking for participants' explanations regarding their perspective. Using the characteristics of teacher perspectives, we looked for their existing meanings. Once we spotted a line of explanation regarding their meanings in any of the data sources in terms of mathematics, mathematics learning, and mathematics teaching, we also checked other sources to possibly provide further evidence of such meaning. Then, we came together to have a consensus on the data set and our analyses going back to the whole data set to challenge our conjectures. Following, we created the table showing the frequencies of the teacher perspectives. The reason was that in different data sources, the same characteristic has been represented more than once.

For instance, the code PIP.1a1 was depicted five times within the lesson plan. Secondly, engaging in the same process using the codes from KQ we examined both this same data set and read further each of the data sources line by line to determine their MKT. Then, again we came together to have a consensus on the whole data set to challenge our conjectures. For example, the code KQ.1a was depicted five times in all the data sources for Alin. Finally, we wrote the narratives.

Results

Data showed that, Alin had a PIP and Meryem had a PBP. Also, compared to Meryem's practice teaching, the number of KQ codes from each data source from Alin's practice teaching indicated that Alin had shown more actions regarding the MKT in every aspect of the teaching. Now, based on some data from Alin and Meryem (the pre-interview data), we explicate how different perspectives and MKT are depicted and how some of the same KQ codes might reveal different reasoning patterns pertaining to different teacher perspectives. As mentioned earlier, Alin had created a task (PIP 1a) for her students to make sense of the graph of the quadratics functions, $f(x) = ax^2 + bx + c$ in terms of the meanings of coefficients a, b, and c. During the pre-interview, when asked how the lesson plan would possibly promote the learning goal Alin had in mind for her students, Alin stated the following:

Researcher: Why do you think this [lesson] plan will promote your students' learning?

Alin: I'm starting with the amount of change in $y = x^2$; therefore, students need to recognize the arms of the graph gets open and there is a decrease, I mean, there is a change in slope... Starting always with $y = x^2$, how this change is formed and how this change affects the graph, so thinking this point… I mean, my activity provides quantitative operations by playing with something existing in their mind that they know.

Researcher: You said playing with something they know, what do they know? Like could you explain one more time what is quantitative operations?

Alin: They know what $y = x^2$ is, what its roots are, how the change occurs in $y = x^2$, I mean, how the slope is changing and how it looks in the graph. However, they don't have any idea about what happens to the graph when "a" changes, because they don't observe $ax^2 + bx + c$ for changing "a" values. Therefore, the quantitative operations formed in their mind when they changed "a", I mean the thing they know in their mind, is like how the slope in $y = x^2$ is, how the amount of increase is, and drawing the graph…. we need to observe the change of "a" one by one, and keep "b" and "c" constant so that we can only be aware of the change in "a"…Let me say the amount of change in y in terms of x, rather than amount of increase, because "a" can be negative too. It is necessary for students to observe how the amount of change in y is changing. When "a" changed and x changed as one unit, they can compare the amount of change corresponding to y, so that they can have an idea about the shape of the graph, I mean the arms (referring to the parts of the parabola)… Actually, what I am learning is to compare the amount of change in y with respect to change in x as one unit for different "a" values.

In terms of MKT, data showed that Alin had an awareness of purpose for her teaching (KQ 1b). She also effectively analysed which mental operations students need to engage in to make sense of the effect of the coefficient "a" on the graph, in her own words: "compare the amount of change in y with respect to change in x as one unit for different "a" values". Her analyses revealed that she has a strong subject knowledge and theoretical background about coefficient "a" for quadratic functions (KQ 1a and 1d). Also, she anticipated the complexity of the concept: She planned her lesson in such a way that by keeping "b" and "c" constant, students' examining the change of "a" would be more efficient (KQ 3c). In addition, her consideration of graphical demonstrations such as starting with the graph of $y = x^2$ while students were examining the coefficient "a" together with the tables showing x and y values showed that Alin had knowledge about different representations (KQ 2c) and she could integrate these representations into her lesson with relations to each other (KQ 2d). Regarding the perspectives, data showed that Alin's statement about comparing the amount of change in the dependent variable with respect to the one unit change in the independent variable suggested that for Alin students might create an idea about the graph of the quadratic functions and its structure through their mental operations (covariation). This suggested that Alin considered mathematics as constructed on the learner's mind. Alin's planning her lesson hypothetically depending on her students' mental operations and actions (PIP 1a1) also suggested that she considered mathematics dependent on the knower. In fact, further data in her written lesson plan pointed to more evidence for this claim: She articulated how students might possibly reason on the questions in the task sequence for different values of a such as a=1, 2, 4 and 10. Alin wrote: "By giving "a" different values and obtaining related y values, this time students compare the respective rate of changes in y values for different values of "a". For the same change in x values, the rate of change in y gets bigger as absolute value of "a" increases. Meanwhile, in students' minds legs of the parabola gets steeper and hence the width of the opening of the parabola gets narrower." Data suggested that she was hypothetically envisioning how students would reason given different values of "a". In other words, she would expect students to go through the mental activity, the simultaneous comparison of the change in the variables x and y, so that they would know the reason behind the effects of the changes in the values of "a" on the graph (PIP 1a1). In addition, her choice of example y= x^2 to start the lesson indicated that she has chosen this example as a conceptual anchor to activate what they already know for the intended learning to take place (PIP1b). Alin stated "It is because $y = x^2$, I mean it will be easier for them to understand, to start with, they can start from what they can compare, like for that reason I did not include bx+c first, so that they don't get confused. This way, because $y = x^2$ stays on the symmetry axis, like this is what they already know, they do not have to deal with finding the roots, they can focus on the changes on "a" more easily". On the contrary, regarding the same interview question, Meryem stated:

Researcher: Why do you think this [lesson] plan will promote your students' learning?

Meryem: I will be asking "could you explain for each of the graph?" I mean, after they have written for the first graph, the second graph, the third graph, I think they will realize the sets of domain and range will differ, like for different intervals we will be writing them. I think they will realize this. I mean I will ask again after they work on the examples, "if anything gets your attention", "if you see anything similar in those examples?" If they can see, they can say for different intervals of domain corresponds to different intervals of range, then I will ask them how they can name it. Like I will ask for their guess, like they can say this or that. If they like they cannot say anything then I will ask them to write down domain and range sets for each example…If like noting comes from them, then I will tell them if we can call these functions as piecewise, "do you think this makes sense?" Then I will ask if they can support my explanation by different examples. I think they can say that. I mean I do not expect them to write it but they can see it in the graphs like they can explain that the graphs start and end at some points and then start again at the same point. I think they can give examples. Then I will summarize the lesson.

In fact, Meryem had planned to provide three problem situations to the students based on which she expected them to draw the graphs. Regarding MKT, Meryem had a sense of awareness of purpose such that she had modified the task based on her learning goal for the students (KQ1b). Similarly, once asked how she determined the leaning goal, Meryem stated that she had read about a research article on students' understanding of piecewise functions. The article was about how students made sense of domain and range of different functions. Such analyses also revealed that she had a strong subject knowledge and theoretical background about piecewise functions (KQ1a and 1d). She further stated "If I have enough time, like I will ask them to draw graphs of linear, quadratic and constant piecewise functions". Her choice of examples (KQ 2d) in her lesson plan together with her further planning of including different piecewise functions also indicated that she had sequenced examples supporting students' deductions (KQ 3d). In terms of the perspectives, though, Meryem expected her students to see a similarity among the graphs they would construct based on the problem scenarios. That is, after their examination of the graphs visually students would realize that the domain and range of those functions would differ. This suggested that Meryem had expected her students to see the mathematics obvious to her in those representations (PBP 1b). Her use of problem scenarios having similar characteristic suggested that she wanted to create a learning trajectory for students so that those problems would make the mathematical relationships as apparent to them as possible (PBP 1a). In contrast to Alin's planning of her lesson on her students' background knowledge, Meryem's focus was on mathematics of other students. That is, albeit important, Meryem's rationale for how she has chosen the learning goal for her students was based on some other students' understanding of the domain and range of different functions. This also suggested that she might have believed that mathematics as part of objective reality existed in those representations ready for students' perception through engaging in tasks that would allow them to 'see' and connect the intended ideas (PBP 1c).

Conclusion

This study investigated prospective teachers' mathematical knowledge for teaching and their perspectives. In particular, data from two prospective teachers having a PIP and a PBP revealed that prospective teachers having both PBP and PIP depicted all the codes in Knowledge Quartet; indicating that they held mathematical knowledge for teaching (MKT). Data from the pre-interviews both from Alin and Meryem had shown that they did not adhere to the textbooks, rather they focused on students' prior knowledge while they were deciding and arranging the lesson activities, they had a sense of choice of examples and sequence of ideas within the lesson. Similarly, they had strong subject matter knowledge and theoretical background about the topics they have taught. Yet, their reasons behind such knowledge were different: Alin's focus on students' mind activities and their abstracting the relationships between the covarying quantities (the dependent and independent variables) suggested that she thought of mathematics as dependent on the knower. Similarly, this suggested that Alin viewed mathematics learning occurring through students' own activities. On the other hand, Meryem had different reasoning behind such mathematical knowledge that she viewed mathematics as depicted in the graphs and examples she expected students to perceive. These results are consistent with Weston (2013) results, who found that although different prospective teachers demonstrated the same codes in KQ, the nature of such demonstration differed from one prospective teacher to the other in terms of how much of such knowledge they had. Results suggest that teachers with different teacher perspectives might depict a strong MKT albeit different reasons behind such knowledge. This therefore suggests the need to pay attention to teachers' mathematical knowledge together with their rationale behind it. Yet we acknowledge that the data came from only two prospective teachers. Therefore, we suggest further examination of MKT of prospective and in-service teachers having different perspectives. Also, since the results suggest that prospective teachers having PIP might have a strong rationale behind their MKT we suggest to promote at least the development of a PIP on the part of prospective and in-service teachers during professional development studies.

This paper proposes an analytical tool for the evaluation of prospective mathematics teachers' (PTs) diagnostic competencies through noticing critical incidents in hypothetical classroom situations (mathtasks). Data were collected from nineteen PTs attending an undergraduate course for one semester. Data analysis highlighted variations within the four characteristics of teachers' diagnostic competencies that are described by four internal levels inspired by how teachers notice. This analysis resulted to the analytical rubric we present and exemplify in this paper. We see the potential of the proposed rubric in research and mathematics teacher professional development.

Keywords: Noticing, mathtask, prospective teachers (PTs), professional development.

Introduction

Research has highlighted the significant role of critical incidents, which, according to the Goodell (2006), are classroom incidents that have the potential to trigger teacher reflections on students' mathematical learning. Such reflections have been connected to the development of diagnostic competencies, namely their competencies to interpret students' mathematical actions by identifying the rationale behind these actions (Prediger, 2010). Very often, teachers encounter unanticipated situations in their lessons to which they are expected to respond on the spot. Especially prospective teachers, with limited teaching experience, often face difficulties to give immediate interpretations and multifaceted responses when they needed. For that reason, teachers' education on ways of analyzing students' thinking and different teaching practices is pertinent (Grossman, 2011). Such education can be supported by the analysis of critical incidents (Psycharis & Potari, 2017). Also, studies report improvement in teachers' engagement with mathematical and pedagogical terminology when they interpret students' reasoning (Grisham et al., 2002).

Recently, researchers have been using videos, pictures or texts from classroom incidents in order to support teachers' observation of students' reactions (Prediger & Zindel, 2017; Sherin & Van Es, 2003; Van Es, 2011). The ability of teachers to observe students' mathematical thinking is attributed by Van Es (2011) to their ability of *noticing*. She argues that teachers need to learn how to observe and interpret classroom interactions that affect learning. Teacher noticing is analyzed in three dimensions: the monitoring of noteworthy events; their justification; and, their interpretation in order to make an appropriate teaching plan. The key element for teachers' noticing ability is whether the substantiation of their arguments is based on the principles of teaching and learning. Van Es proposed a two-component analytical framework for teacher noticing: *What teachers notice* and *How teachers notice*. The How teachers notice component can be categorized into four levels: *Level 1*, when the analysis of a fact they notice includes general impressions, providing descriptive and evaluative comments, with little or no evidence to support it; *Level 2*, when in addition to Level

1 the analysis includes some interpretive comments referring to noteworthy events or interactions as evidence; *Level 3*, when in addition to Level 2 the analysis includes interpretive comments and the elaboration of specific noteworthy events and interactions; and, *Level 4*, when in addition to Level 3 the analysis include connections between the events and principles of teaching and learning and proposals for alternative pedagogical solutions (Van Es, 2011).

Noticing has also been connected to the diagnostic competences of PTs through their interpretation of aspects they have noticed in familiar or non-familiar instructional episodes (Prediger & Zindel, 2017). Characterisation of mathematics teachers' diagnostic competencies is related to the work of Biza et al. (2018). In their work, Biza and colleagues design hypothetical classroom situations (mathtasks[1], see Figure 1) that are inspired by mathematical and pedagogical issues likely to occur in the mathematics teaching practice, and they invite mathematics PTs and in-service teachers to reflect on these situations. The classroom situations, although hypothetical, are designed with potential critical incidents in mind (in the sense of Goodell, 2006) that PTs are invited to notice, interpret, and propose intended actions. Mathtasks were used in the study we present here towards the familiarisation of PTs with critical incidents that may arise in their classroom as we explain in the next section. In earlier work of Biza et al. (2018), the analysis of teacher responses to mathtasks proposed a typology of four characteristics of teachers' diagnostic competencies in recognising the issues in the incident described in the classroom situation and in responding to students' needs: *consistency*, how *consistent* a response is in the way it conveys the link between the respondent's stated pedagogical priorities and their intended actions; *specificity*, how *contextualized and specific* a response is to the incident under consideration; *reification of pedagogical discourse (RPD)*, how *reified*[2] the pedagogical discourse of the response is in order to describe and interpret the pedagogical and mathematical issues of the incident and to propose appropriate actions; and, *reification of mathematical discourse (RMD)*, how *reified* the *mathematical discourse* of the response is in order to describe and interpret the underpinning mathematical content of the incident and to propose appropriate actions (Biza et al., 2018). The four characteristics are attentive to teachers' both mathematical and pedagogical discourses. However, the operationalization of the typology in analysis requires more transparency on the level of sophistication within each one of the four characteristics (e.g., what does justify a high level of RPD?). Such lack of transparency is addressed by this study that examines the research question: "what levels of variation can be identified within each one of the four characteristics of PTs' diagnostic competencies as evident in their responses to hypothetical classroom situations (mathtasks)". To address this issue, we propose an analytical tool that draws on Van Es's (2011) levels of *how teachers notice* in order to describe variations within each one of the four characteristics as we exemplify through the analysis of empirical data in the next section.

---

[1]Mathtasks are designed in the context of the MathTASK research and development program on mathematics teachers' pedagogical and mathematical discourses (https://www.uea.ac.uk/groups-and-centres/a-z/mathtask).

[2] Reified means that the mathematical discourse (the mathematical content and practices PTs have become familiar during their studies) and the pedagogical discourse (the theories and findings from mathematics education research PTs have become familiar during their studies) have been integrated productively into PTs' responses.

Methodology

The research took place in the context of a 14-week mathematics education undergraduate course at a Greek university with nineteen PTs. The 19 PTs who participated in the research were also those who participated in the semester course.The condition for attending the course was the completion by PTs of mathematical courses and at least four courses related to psychology, philosophy and mathematics education. During the course, PTs engaged with school based activities – such as lesson observations, lesson planning, delivering sessions, noticing of critical events from the classroom and the interpretation of these events – and university based activities – such as introduction to theories and findings from research into the teaching and learning of mathematics, engagement with mathtasks and discussion on PTs' school school based activities. One of the aims of the course was the development of PTs' pedagogical discourse also through their engagement with research in mathematics education literature.

Reasoning

In a class of maths, students are asked to solve the following problem:
"Can you make the two columns of numbers below add up to the same total by swapping just two numbers between the columns? Explain why or why not."

1	7
3	2
8	4
5	9

The following conversation between students A and B takes place:

Student A: If I add up the number in the columns, I get totals of, umm…17 and 22. So we need to make these the same.

Student B: How about we just try swapping some numbers and see what happens!

Student A: Okay, let's try the top two numbers first…If we swap 1 and 7, we get new totals of 23 and 16. That's worse than before!

Student B: Let's try some others…what about swapping 5 and 7?

Student A: No, that gives 19 and 20.

Student B: We're getting closer, though!

Student A: What about if we swap two numbers that are close together, like 2 and 3?

Student B: Ummm…that gives 16 and 23, that can't be right.

Student A: We could be here doing this forever!

Student C joins the conversation.

Student C: Maybe it can't be done and we have to show why not.

Student A: How would we do that then? We can't try every single possible swap…that would take too long!

You have just heard this exchange between students A, B and C.

Questions: **Lesson for: (specify the class)**

a. Solve this mathematical problem. What is the main goal of this problem?

b. For what reasons do you believe that this episode is important? (from mathematical and pedagogical view)

c. How you would interpret this dialogue? (refer to the literature)

d. How would you respond to Students A, B and C and to the whole class?

In this paper we draw on PTs responses to the mathtask of Figure 1 (translated from Greek), the last of the three mathtasks used in the course as instances of potential critical incidents, that was given to PTs towards the end of the semester. PTs' responses were collected electonically one week after the assignment. The hypothetical scenario of the mathtask is based on an open mathematical problem, different from what is considered as usual in the Greek mathematics school curriculum. We expected PTs to analyze the goals of the activity, to identify the flexibility of using it in different classes (and specify the class), to notice the issues in students' dialogue, to interpret these issues and to respond to them accordingly. Thus, we aimed to trigger PTs' noticing in the given incident and through this to analyze and evaluate their diagnostic competencies. All the PTs who attended the course consented to the use of their work for research purposes. The research was implemented within the framework of the qualitative research methodology.

The data were coded with the analytical tool of a rubric (Andrande, 2000) with two-dimentions (see Table 1): the typology of the four characteristics (criteria) proposed by Biza et al. (2018) in rows; and within each of the characteristics, in columns, the four levels inspired by Van Es's (2011) levels of *how teachers notice* and concern quality differences within each characteristic.

Initially, the first author analysed PTs' responses in relation to the four characteristics by looking for quality differences within each characteristic. Then, the quality differences between these levels were described with an adaptation of Van Es's (2011) levels. The rubric in Table 1 is the outcome of this phase of the analysis. Finally, PTs' responses were analysed again with the use of the rubric. The other two authors validated the analysis in each one of the three phases described above. In this paper we present the rubric together with examples from the final analysis that concerns the RPD characteristic with some reference to the other characteristics.

Results

In Table 1 we present the rubric with the four characteristics in each row and the levels in each column. Then, we exemplify the RPD levels from the responses of PTs to the mathtask of Figure 1.

Table 1: The rubric of four characteristics

	Level 1: Irrelevant	Level 2: Superficial	Level 3: Evolving	Level 4: Multidimensional
Consistency	There is no consistency in the interpretation of the incident and the proposed actions.	There is consistency in the interpretation of the incident and the proposed actions. There are general references to the incident with superficial interpretation of what is happening in it.	There is consistency in the interpretation of the incident and the proposed actions. There are specific references to the incident with interpretations and identification of connections of what is happening in it.	There is consistency in the interpretation of the incident and the proposed actions. There are targeted suggestions based on evidence from what is happening in the incident, specific and/or alternative approaches, links to principles of teaching and learning related to them.
Specificity	There is no accuracy in the descriptions of the incident.	There is accuracy in the descriptions of the incident. There is a general reference to what is happening in the incident.	There is accuracy in the description of the incident. There are specific references to the incident with interpretations and identification of connections of what is happening in it.	There is accuracy in the description of the incident. There are detailed interpretations based on evidence of what is happening in the incident, which are connected to teaching and learning principles related to them.

RPD	Wrong, irrelevant or no use of pedagogical terminology.	Limited use of pedagogical terminology. There is general reference to pedagogical issues from the incident.	Good use of pedagogical terminology. There is interpretation of interactions happening in the incident with evidence, using pedagogical terms related to principles of teaching and learning.	Very good use of pedagogical terminology. There are interpretations and identification of connections in what is happening in the incident with reference to relevant literature of principles of teaching and learning and alternative pedagogical suggestions.
RMD	Wrong or no use of mathematical terminology.	Limited use of mathematical terminology. There is general reference to pedagogical issues from the incident.	Good use of mathematical terminology. There is interpretation of interactions happening in the incident with evidence, using mathematical terms and description of suggestions based on the mathematical content.	Very good use of mathematical terminology. There are interpretations and identification of connections in what is happening in the incident with reference to the relevant literature of the basic principles of teaching and learning and alternative suggestions focused on the mathematical content.

Exemplification of RPD levels

The Levels in Table 1 are inspired by Van Es's (2011) levels and the headings in the table were named in order to attribute the quality differences from one level to another. To exemplify the levels of the RPD characteristic we present characteristic examples from four different PTs' interpretations at various levels in terms of the RPD. The levels within each one of the characteristics are interconnected in the responses of each one of the PTs. Due to space limitation, we only exemplify the rubric from PTs' responses to questions b and c of the mathtask in Figure 1.

Specifically, at the *Irrelevant level* (L1), Mania responds to question b:

> From the teaching point of view, we can see how the students manage a problem without solution and how the need of the concept of the proof emerges, as student C quote**.**

Mania seems to recognize two teaching objectives: managing a problem without solution and the emergence of a need for proving. Then, in question c, she writes:

> The concept of proof is not a standalone concept, it comes together with the sense of "legitimizing a proposition" and "theory" [her quotation marks]. … It requires a substantial transition of the student to an epistemological state: the transition from a practical state (ruled by a kind of practical logic) to a theoretical state (ruled by the physical particularity of a theory).

Her response above includes text retrieved from the internet. This is not necessarily a problem when the right reference is used, which she has not done. Also, it seems that she is using terminology without connection to elements arising from the dialogue in Figure 1. Yet it is not clear, when she refers to "theory" and "epistemological state" if she means proof and, while she refers to "a practical state", if she means the tests that students make when they try to give a solution.

Mania’s responses are coded as L1 for the other three characteristics as well, which means that she does not interpret the elements from the dialogue, neither she proposes how she could manage this open-ended task in a classroom. Especially for L1 in RMD, she presents a few tests from MATLAB as solution and insisted on experimentation, which alone is not enough to help students to think of an algebraic explanation.

At the *Superficial level* (L2), we present part of Anna’s response to question b in which she highlights the pedagogical interest of the episode because:

> The dialogue, the exchange of views and the collaboration between students are encouraged in this episode. Moreover, the intervention of the teacher cultivates the mathematical thinking and ability of abstraction. It is an open-ended problem that allows students to take initiatives.

Then, in question c, she writes:

> [she describes a mathematical solution] This problem was given to the class with the aim [to make] students to distinguish the meaning of even and odd [numbers].

She notes that through an open-ended activity, dialogue and different ways of resolving are favored. Nevertheless, the comments in her interpretation are general without connection to points of the episode. Moreover, she doesn’t cite any reference from relevant literature. Overall, Anna focuses on the mathematical content both to her response the problem and to her interpretation of students’ answers, without making any reference or connection to the principles of teaching and learning. We notice that comments such as “exchange of views and cooperation are encouraged” or “teacher cultivates mathematical thinking and abstract abilities” and “open-ended problems allow students take initiatives” are general in terms of the pedagogical content and brief that they can be applied to other cases as well. In addition, she does not support her points with evidence from the incident under consideration and with references to student interactions. The difference between Mania and Anna is the relevance of Anna’s pedagogical comments to the critical incidents she identified in the dialogue. Moreover, in relation to the characteristics of Consistency and Specificity, Anna’s response is at L2. However, in relation to the RMD characteristic, her response is at L3: Anna’s interpretations are based on the mathematical content of the problem and she proposes specific interventions as a response to the difficulties of the students she identified in the dialogue.

At the *Evolving level* (L3), Vaso’s response in question b included the following:

> The teacher lets the students discuss the exercise with each other without intervening. This practice encourages the exploration and the exchange of views. The problem is a good example of a task that sharpens students’ mathematical thinking and curiosity. The students are expected to engage actively and try to think of a shorter way to solve it.

Here she points out that the teacher promotes the dialogue without guiding the students. Furthermore, she commends students’ involvement as important in the demanding activity of the incident. However, she neither makes any comment on students' approaches nor she makes connections to the dialogue. Continuing with her interpretation, she comments in question c:

> …students face difficulties in relating the proof with their attempts to find a solution. The literature confirms that a large percentage of students find it difficult to acknowledge the importance and usefulness of proof. This often happens because students do not understand why the proof validates the original claim or they do not yet fully understand the meaning of proof. In this example, proof occurs as a result of a conjecture-and-test process to solve a problem which turns into an algorithmic exercise. The students seem to find it difficult to move from conjecture to proof.

Finally, we notice that Vaso refers to basic principles of teaching and learning such as tasks of high or low demand, key points of the proof (tests, conjecture, and proof), students' difficulties in understanding the meaning of a task, student habits with algorithmic solutions. This indicates that Vaso has studied the relevant literature suggested by the course although she does not refer directly to it. This approach is more detailed and focused in comparison to Anna's. Vaso's interpretation is more justified as she uses evidence from the situation to describe students' interactions through pedagogical terms. In relation to the other characteristics, Vaso's response is at L4.

At the *Multidimensional level* (L4), Anastasia's response involves pedagogical terms connected with the incident and references to relevant literature. In question b, Anastasia noticed some significant points of the dialogue like the cooperation between the students through the discussion, the investigation through tests to lead to the conjecture and the proof. Moreover, she focuses on the type of activity and the flexibility of strategies it allows to the students. She also refers to time effectiveness, number of tests and the conjecture-proof relationship. Later in question c she writes:

> According to F. Furinghetti, open problems include activities with a short formulation that does not imply the solution method, but instead stimulate the production of conjectures and encourage discovery. As M. Mariotti points out, the teacher plays a key role in helping students dealing with such problems. […] Student A observes that the solution to the problem seems time consuming. This student concern could clearly be a sign of despair or lack of willingness on his part to be further involved in the solution process. On the other hand, it may be a way by which the student expresses the need to change the way they work, or try to come up with a shorter solution.[…] It is possible, however, that student A's observation that the problem is time-consuming may have caused student C to "think cunningly" and assume that something else might have happened. [...] In any case, he seems [student C] to have realized part - if not all - of the functions of the mathematical proof (according to Bell, Hanna and de Villiers), that is, to verify the truth of a proposition, to explain it, to contribute to the discovery and exploration of new situations, concepts and properties and to "communicate" the new knowledge. The evolution of the event is expected to be critical too.

Here Anastasia describes in detail what happens in the incident by commenting on students' reactions. Her answers reveal familiarity with the curriculum and the relevant literature on teaching and learning. She refers to the open problems that motivate the production of conjectures and she comments on the role of the teacher in managing such problems in the classroom, with references to relevant literature. The pedagogical terminology she uses is constantly in connection with points of the incident. The importance she gives to the interaction is crucial in order to provoke further dialogue about the mathematical proof. Overall, she approached the incident comprehensively by interpreting the students' reactions and their interactions and offered alternative pedagogical solutions. All the above with the fact that she connects the pedagogical terms with the literature, classify her response as L4. Finally, Anastasia’s response is at L4 for all the other characteristics.

Conclusion

In this paper, we address the lack of transparency on the level of sophistication of PTs diagnostic competencies and we proposed an analytical rubric that describes how teachers notice within each one of the four characteristics of PTs’ diagnostic competencies (Biza et al., 2018). At the broader research, in which this rubric was used, we explore the levels of the characteristics of PTs in three consecutive mathtasks, the third one (Figure 1) is discussed in this paper, in order to study the development of PTs diagnostic competencies across the course. The analysis evidence that the typology of the four characteristics and the proposed quality differences within them provide a detailed picture of PTs’ diagnostic competencies and their development as PTs moved from the first mathtask to the third one across the course. We note that such development is attributed to the course design that prioritized appropriate connections to the teaching and learning of mathematics literature and supported PTs’ reflective activities. Therefore, we would say that the results agree with studies that report the benefit of teachers’ interpretation of their students’ mathematical thinking (e.g., Psycharis & Potari 2017; Van Es & Sherin 2010). Also these results reinforce research findings that emphasize the critical role of the kind of intervention (in our case based on the use of critical incidents in hypothetical classroom situations) on the improvement of PTs’ diagnostic competence (Prediger & Zindel, 2017). The proposed rubric has affordances to map out PTs’ development across the course and to identify areas for further enhancement. Following Grisham er al. (2002) observations about teachers’ engagement with terminology, the co-existence of mathematical and pedagogical aspects in the MathTASK activities and the proposed rubric makes them valuable tools for PTs’ education and teacher professional development as well.

In this paper, we chose to present the levels of RPD in a classroom situation related to a mathematical problem that was not familiar to PTs due to the critical role of the teacher in such situations and the variety of responses we elicited in our data. The choice of the classroom situation and its impact on PTs’ response is of interest for future research. Moreover, we observed interrelations between the four characteristics. For instance, PTs who improved their RMD level across the course, they demonstrated similar improvement in the Consistency levels of their responses. In the future, it would be interesting to see in more detail the factors that influence the level change of one characteristic in comparison to the level change of another.

These tasks are very good but inappropriate for my students

Odd Tore Kaufmann

Østfold University College, Faculty of Education, Halden, Norway; odd.t.kaufmann@hiof.no

This paper investigates how teachers reflect on and explain the role of high-quality mathematical tasks when selecting tasks for use in lessons. By analysing data from three groups of mathematics teachers engaged in collegial discussions, this study aims to elucidate how teachers rationalize the role of high-quality mathematical tasks. The results indicate that teachers appreciate high-quality tasks in providing discussions among students and supporting the collaborative efforts to solve problems. Conversely, despite this appreciation, teachers refer to such tasks as inappropriate for their students. For this reason, they pointed to the capabilities, lack of motivation to engage, and the lack experience of their students.

Keywords: Professional development, collegial discussion, high-quality tasks.

Introduction

The reform movement in mathematics education, which emphasizes the learning of additional mathematical competencies apart from procedural fluency, typically encourages the development and reorganization of syllabi, curriculum materials, and classroom practices. A central policy initiative that facilitates change frequently involves professional development (PD), which aims to support teachers in establishing productive classroom practices. A typically important component of such PD programs is the collegial discussions of teachers (Cobb & Jackson, 2011; Cobb et al., 2018). Within PD programs, collegial discussions may be viewed as a means for facilitating teacher development, which, in turn, is conceptualized as a means for improving and changing classroom practices (Desimone, 2009). According to Munter (2014), collaborations between teachers are less effective unless they share vision of high-quality instruction that gives meaning and purpose. High-quality instruction can be defined in three related dimensions of classroom instruction (Munter, 2014). The first is the role of the teacher, where the teacher supports students in learning mathematics by facilitating understanding. The second is developing a classroom community. Teachers are responsible for orchestrating discussions, such that students can share multiple problem-solving strategies, analyse relationships among strategies, and explore contradictions in ideas to provide more insight into mathematical thinking. The third dimension is the role of mathematical tasks. High-quality tasks should support students in developing problem-solving strategies (Hiebert et al., 1997) and should hold the potential to "engage students in solving challenging, ambiguously defined problems without the suggestion of a particular procedure or path to a solution" (Munter, 2014, p. 607). A central aspect of a concept labeled "ambitions instruction" (Kazemi et al., 2009) is using cognitively demanding tasks to challenge students. Engaging students in cognitively demanding and challenging tasks is characteristic of a reform-oriented approach to mathematics instruction. The study focuses on the third dimension, that is, the role of mathematical tasks and, specifically, how teachers rationalize the role of mathematical tasks in collegial discussions as they engage with a PD program in mathematics education. Investigating the explanation of teachers regarding the role of mathematical tasks when selecting tasks to use in lessons is important for understanding their reflection on the role of mathematical tasks. In this context, the following research question guides this paper: "How do three groups of teachers, who are participating in a PD program in Sweden, rationalize the role of mathematical tasks in collective planning with colleagues?" I seek to answer this question by analysing three groups of mathematics teachers engaged in collegial discussions as part of a national large-scale PD program in Sweden. In the context of the current study, I understand collegial discussion in a pragmatic manner. In other words, when teachers work in teams with the support of the large-scale program, the boost in mathematics is designed to support such groups of teachers to engage in collegial discussions regarding resources as well as planning lessons and collective reflections on classroom instruction.

Relevant research

The notion of high-quality or challenging tasks is relatively common (Ingram et al., 2020). Through tasks in the mathematics classroom, compared with other methods, opportunities to learn are made available to students (Munter, 2014). Therefore, considering the mathematical ideas behind a task, the potential to engage students in solving such challenging problems, and possible solutions, strategies, and misconceptions that students may provide when attempting to solve a task is important prior to teaching (Munter, 2014). Based on the importance of high-quality tasks in mathematics teaching and learning, scholars have investigated the justification and characterization of teachers regarding the tasks they opt to use in terms of the potential of the task for students' work. For example, Heyd-Metzuyanim et al. (2019) interviewed two teachers as they participated in a PD program. The authors found that the main justification of teachers for selecting tasks was their location in a certain place in the curriculum, instead of mathematical goals. Another justification for selecting a task was that the task would lead to a discussion. However, the two teachers did not explicate the nature of this discussion during the interview. Through analyses of teacher interviews, Sun (2019) examined the beliefs of four teachers about mathematical tasks. The author found that their beliefs are frequently related to the concept that certain forms of mathematical activity are not viable for certain groups of students due to their different innate abilities. Thus, students with low achievement tend to be excluded from engaging in high-quality tasks.

Researchers also distinguish between high- and low-quality tasks. Cobb et al. (2018) investigated the aspect required to support the development of ambitious instructional practice among teachers. One of Cobb et al.'s. (2018) perspectives in this large-scale PD program was the nature of the task. One distinction is whether a task is of low or high cognitive demand. For tasks with low cognitive demand, students apply known procedures. Thus, little ambiguity exists in solving such tasks. High-cognitive tasks are frequently open-ended and can be solved using various strategies. In other words, students tend to struggle with such tasks for a certain period without intervention from the teacher. One of the findings by Cobb et al. (2018) was that maintaining the cognitive demand of a task is challenging for teachers. As a result, they frequently reduce the challenge of the task over the course of the lesson. Their views on high-quality tasks are that these tasks do not align with their structure of the lesson. Moreover, these tasks are considered inappropriate for the students. Munter (2014) developed a framework for characterizing the perceptions of teachers toward high- and low-quality tasks on the basis of more than 900 interviews. In this manner, he modeled the trajectories of the perceptions of high-quality instruction along the findings in the literature. At the lowest level, teachers fail to view tasks as being of high or low quality. At the next level, the responses of teachers suggest that tasks can vary in quality. However, those performed by the students should first enable procedural practice before problem-solving and application. At the third level, teachers refer to more sophisticated descriptions of high-quality tasks, such as tasks that require multiple solutions or support the conceptual understanding of students. At the highest level, teachers refer to the rationale that high-quality tasks support students in learning and doing mathematics, such as making and testing conjectures, opening up for examining, and comparing several strategies. To better understand how teachers discuss and reflect on the role of mathematical tasks, I have opted to focus on the collective planning of teachers with colleagues during a PD project.

Method

The Swedish National Agency for Education launched a curriculum-based PD project. Called "Boost for Mathematics[1]" (Skolverket, 2018), this project intends to improve the teaching of mathematics. Its major components are 24 modules, where eight are disseminated per grade level (1–3, 4–6, and 7–9). Each module focuses on certain mathematical contents, the manner in which students learn these contents, and how teachers can support learning. A central part of these modules is high-quality tasks.[1] Each module presents several high-quality tasks and encourages teachers to discuss these tasks, such as selecting which ones to use in lessons and adjusting the task to be suitable for their class. The curriculum, which is distributed digitally on a website, includes articles, instructions, high-quality tasks, and videos. Each module is designed to support groups of teachers in engaging in eight iterations, comprising individual preparation, conducting collective planning with colleagues, teaching individual classrooms, and facilitating collective reflections in classroom instruction. This study focuses on the collective planning of teachers with colleagues at three selected schools. The selection process was based on two factors. Selecting one group of teachers from each of these three grade levels was convenient, because the data material was intended teachers from each grade level (i.e., 1–3, 4–6, and 7–9). The other process of selecting groups was including groups that opted to study the module in terms of problem-solving, which included high-quality tasks. Data were collected by videotaping two meetings with each group for a total of six sessions. The first meeting was based on collective planning with colleagues during the first semester, whereas the second was based on collective planning with colleagues during the second semester.

Analysis

To understand what teachers engage in when focusing on high-quality tasks in collegial discussions, as previously described, I have chosen to deeply examine the collective planning of the three groups of teachers for their classroom instruction. As part of data reduction, I identified and transcribed all discussion episodes that involved the teachers in the discussion of tasks. For analysis, I defined an episode of pedagogical reasoning as a coding unit:

> Units of teacher-to-teacher talk allow teachers to exhibit their understanding of an issue in their practice. Specifically, episodes of pedagogical reasoning are moments within teachers' interactions in which they describe issues in, or raise questions about, teaching practices that are accompanied by some elaboration of reasons, explanations, or justifications. (Horn, 2007, p. 46)

Episodes of pedagogical reasoning, in which the teachers explicitly discussed the tasks presented in the PD, were analysed. The abductive process was used to develop the analytical framework for the research (Bryman, 2016). Inspired by the framework of Munter (2014), I made modifications to their

---

1 The modules and the high-quality tasks: https://larportalen.skolverket.se/#/moduler/1-matematik/alla/alla

categories to create a total of three categories. Developing the analytical framework has been a continuous process, which required moving back and forth between the data and the analytical framework. Gradually, I made clear distinctions between different categories with a focus on entire episodes of the discussions among teachers regarding high-quality tasks. Munter (2014) categorized the different views of teachers about high-quality tasks. At the first level, they are aware that tasks can vary in quality; however, students require procedural practice before working with high-quality tasks. In the data material, several utterances occurred about the difficulties, limitations, and inabilities of students in working with high-quality tasks. These utterances were categorized as appropriateness for the students. At the next level, the teachers described the nature of tasks as being oriented toward reform. However, they fail to describe a function or describe it in terms of increasing interest levels and student engagement (Munter, 2014). Moreover, teachers were concerned about leisure gained from tasks and their potential to lead to discussions. Such views were categorized as the function of tasks. At the highest level, Munter (2014) described the view of teachers about high-quality tasks to support student learning and performing mathematics and to provide content for the entire class discussion. In the data material, the teachers were concerned about the structure of the lesson and the presentation and discussion of tasks across the phases of the lesson. These concerns were, therefore, categorized as the structure of the lesson. The results section provides further elaboration on these categories. Table 1 demonstrates the overview of schools and number of episodes identified for each category.

Table 1: Analysis of video materials — an overview

School (pseudonyms) and modules	Teachers (pseudonyms)	Video-Recorded Meetings.	Function of tasks	Structure of lessons	Appropriateness for students
Rafford 1–3. Problem-solving and number sense	Amy, Maria, Helen, Grace, Julie, and Hannah	First session: 50 min. Second session: 49 min.	3	5	12
Hadlow 4–6. Problem-solving and number sense	Mary, Mona, Celia, Fred, Josie, and Nicole	First session: 83 min. Second session: 55 min.	3	5	6
Padstow 7–9. Problem-solving and teaching mathematics using IT.	Emely, Michael, Lily, Tyler, and Stella	First session: 63 min. Second session: 57 min.	5	3	9

Results

This section presents an elaborate characterization of the rationalization of the three groups of teachers with regard to high-quality tasks during their participation in the PD program for mathematics education. The results from the three teacher groups were combined and discussed in the following sections in terms of appropriateness for students, the function of tasks, and structure of lessons.

Appropriateness for students

This category was the most dominant when the teachers discussed high-quality tasks. Although the teachers agreed that high-quality tasks are beneficial, because they support the conceptual understanding of students and enable multiple solutions, they were relatively concerned regarding whether the tasks were appropriate for students. Nearly all arguments involved these tasks as being extremely difficult for students. I categorized these arguments of the appropriateness of high-quality tasks, which resulted in five aspects, namely, 1) students are only concerned with one correct answer and are satisfied when they arrive at a solution; 2) students do not challenge themselves but want an immediate answer; 3) students lack the patience to work on a task over time; 4) students are *locked* and unable to *think outside the box*, an aspect frequently required by such tasks; lastly, 5) students are preoccupied with the mathematics textbook and believe that all work apart from those that involve the textbook is not mathematics. For these reasons, the teachers explained that the students are unwilling to work with high-quality tasks. The following excerpt illustrate teachers refer to students being extremely *locked* and unable to *think outside the box*:

Mary: What about these tasks? How do you think the students are able to place a number of given fractions on a number line? What would it look like in your groups? Are they able to put them on a number line?

Mona: I think this is very difficult, at least for my students. Many of these tasks, it feels like it's too high a level. So, it's good for us to think, maybe, but it's not, not for my students anyway, so it feels too difficult.

Celia: No, it's too difficult.

Mary: Is it too difficult?

Fred: Yes. And my students are too locked, they'll get stuck, they're not able to think outside the box.

Mary raises an issue about her students' ability to mark fractions on a number line. This scenario is viewed as extremely difficult for Mona's students with agreement from Fred and Celia. The difficulty is partially related to the students' abilities and partially to the high level of task difficulty. As Fred mentioned, these students are too locked and unable to think outside the box, which Fred believes is a demand of such high-level tasks.

Function of tasks

The teachers presented three main arguments regarding the function of tasks. Two of these, which are the most common, are that the tasks should be fun for students and that the tasks should lead to and open discussions. In these categories, the teachers did not emphasize how these tasks can support the learning of mathematics. In one case out of all arguments, however, they discussed how tasks can support student learning, which is illustrated by the following excerpt:

Stella: We want to capture students' knowledge, whether they know this or that. Then we should choose the tasks based on that, I think, what we should work on or think that we benefit from getting to know about them. What gives us the most. How I as a teacher have intended to continue working, so that I choose a task that suits how I think I can continue working with it later.

In this case, Stella is looking for assignments that reveal the knowledge of students in mathematics and how the assignment can be used as a starting point for a further understanding of mathematics. This excerpt is an exception to the arguments that the teachers made regarding the function of tasks. The most common argument was that the tasks should be fun and motivating for the students, as shown in the next excerpt:

Josie:	This one might not be so exciting for them, so they should … this with decimals, they should just …. I think they would think this was cool.

This case is an example of the fairly common argument that teachers use tasks that they consider fun for students. Thus, no argument was raised about the type of mathematics that students should work with or how the tasks can lead to learning.

Structure of lessons

A three-phase classroom activity structure, namely, the phases of introduction, students working on mathematical tasks, and finalizing the lesson, was recurrent in the collegial discussions. The teachers frequently referred to this structure as introduction, pair or alone, and all. According to Jackson et al. (2013), a common lesson structure in a reform-oriented mathematics curriculum is the three-phase lesson (which these teachers refer to), where a complex task is introduced, students work on solving it, and the teacher orchestrates a conclusive discussion with the entire class. This structure is typical of lessons in PD. These descriptions of the classroom structure espouse the reform-oriented view on the structure of lessons, although such characterizations may fail to describe the introduction of the task and the content of the interaction among students. According to the content of the interaction, the teachers are more concerned about holding a discussion or the tasks leading to a discussion instead of the quality and content of the discussion based on high-quality tasks. Furthermore, in the discussions, they frequently emphasized lowering the cognitive demand for high-quality tasks during their introduction:

Helen:	Actually (...) what should I do, should we do a problem first together or should we just (..).
Amy:	Don't you think yours (students) can do one?
Helen:	Yeah, some of them.
Hannah:	Mmm (...) mine are rather weak.
Helen:	But eh (Amy (C): mm), yes but we'll do one, we'll formulate a problem based on an image.
Maria:	Yes, you do a similar problem then (Hannah: mm).
Julie:	With your group.
Maria:	So they (Helen: mm) have a similar (...) structure to follow (Hannah: mm).

Helen expresses concern about whether the students should tackle tasks/solve problems immediately or if the lesson should start with an introduction. The teachers plan to introduce a problem based on arguments about the capacity of the students and the necessity for a teacher to provide structure for them. Other studies (e.g., Boston & Smith, 2009) have demonstrated that teachers experience difficulty in maintaining the cognitive demand of tasks during teaching. As seen in this example, the teachers are concerned about the difficulty of high-quality tasks. Therefore, they decide to lower the cognitive demand of the task to ensure that each student has the opportunity to work with it.

Discussion and conclusion

This article contributes to research on the collegial discussions of teachers engaged in a PD program on teachers' development as a process of change toward a reform-oriented educational practice (Cobb et al., 2018; Jackson et al., 2013). Specifically, this study adds to the literature by highlighting the views of teachers about high-quality tasks. Analysis indicates that the teachers are relatively ambivalent about using high-quality tasks in their lessons. On the one hand, they share certain elements of high-quality instruction that are aligned with the reform-oriented teacher practice. In other words, they emphasize and appreciate high-quality tasks as they correspond to their structure of the lesson according to the three-phase lesson structure called introduction, working together in pairs or alone, or both and summaries the lesson in whole-group discussions (Jackson et al., 2013). Within this lesson structure, the teachers are aware of the value and importance of high-quality tasks in promoting discussions among students and supporting their collaborative efforts to solve problems without relying on the teacher for explanations or to offer solution strategies. They emphasize high-quality tasks, because such tasks will support students' discussions better than low-quality tasks. Such discourse communities are unlikely to develop unless students gain opportunities to engage in rich mathematical work, which is typically initiated by a high-quality task (Munter, 2014). This notion forms part of a reform-oriented classroom practice (Cobb et al., 2018). An important aspect of reform-oriented teacher practice is the use of cognitively demanding tasks (Kazemi et al., 2009). On the other hand, although these teachers appreciate high-quality tasks, they stated, nearly in unison, that they referred to such tasks as inappropriate for students. For this reason, they blamed the capabilities, lack of motivation to engage, and lack of experience of their students with such tasks. The teachers' discussion about the role of high-quality tasks may be helpful in understanding their potential for learning in collaborative meetings to improve and change classroom practices (Desimone, 2009). The current findings reveal an ambivalent vision regarding high-quality tasks in relation to the reform-oriented teacher practice (Jackson et al., 2013). Such ambivalent views may influence the potential offered by implementing the reform-oriented classroom practice, given that teachers hold an unproductive framing of the capabilities of their students (Jackson et al., 2017; Sun, 2019).

Teachers’ development of self-regulation and problem solving skills in online forums as learners and mentors

Nelly Keller[1] and Zehavit Kohen[2]

[1]Technion – Israel Institute of Technology, Israel; nellyk@campus.technion.ac.il; zehavit@technion.ac.il

The current study explores the learning processes occurring in online discussion forums, from a perspective of self-regulation learning which facilitates in planning, monitoring and reflecting on learning. Participants were 47 teachers, who took part in a 2-year mathematics teachers professional development program. The study was conducted in two stages. In the first stage the teachers acted as learners through collaborative solution of complex mathematical problems in small groups, while in the second stage they led collaborative problem solving in forums as mentors. The study showed that problem solving forums have a high potential for developing teachers' own self-regulation skills and increasing their effectiveness in collaborative problem solving. This experience is reflected in their pedagogical activities, aimed at developing self-regulation skills of their students. It also empowers teachers to support students in solving complex mathematical problems.

Keywords: Problem solving, online forums in social networks, self-regulated learning, professional development of teachers.

Introduction

Currently, the mathematical community has largely reached a consensus on the importance of mathematics problem-solving (PS) as a central goal for mathematics teachers. Mathematics problem-solving involves active role of students, which are involved in a discussion with each other for solving the mathematical problem. Technology allows the application of such collaborative mathematical problem-solving through the use of Problem-Solving Forums (PSF). Studies of the effectiveness of PSF for teaching mathematics has shown that PSF has great teaching potential due to a number of key features such as a shared discussion space, opportunity for asynchrony communication, or preservation of the content of the discussion for a long time. The virtual property of PSF significantly expands the boundaries of classroom both in the space and in time (Kramarski, 2012). Studies show that over time, students participating in PSF develop norms of collaboration, the most important of which is the habit of sharing the ideas in the process of solving problems, rather than publishing the final result or the complete solution (Koichu & Keller, 2019). However, research has shown that realizing the potential of discussion forums is challenging (Koichu & Keller, 2019). One of the main reasons for these difficulties, according to the literature, is the lack of skills in non-traditional forms of education for both teachers and students (Kilpatrick, 2016; Lester & Cai, 2016; Schoenfeld, 2013).

Participation in PSF requires students to be motivated, able to plan, track ideas and results, and reflect on the work done. All of these skills are key components of Self-Regulatory Learning (SRL) (Pintrich, 2000; Zimmerman, 2000). Thus, the effectiveness of the learning process, which includes PSF as an integral part, requires the teacher to use teaching methods that focus on the development of SRL skills and use them in collaborative problem solving (Hogan, et al., 2015). A number of studies have shown that one of the priority ways for teachers to acquire the skills needed to successfully implement new methods is to first test those methods on themselves as learners (e.g. Kramarski & Kohen, 2017).

Specifically, it was found that projects aimed at developing SRL skills in teachers also develop their pedagogical skills focused on developing SRL skills among their students. This approach to education has been called self-regulated teaching (SRT) (Kramarski & Kohen, 2017; Kramarski & Mikhalsky, 2009). The purpose of this study is to study the processes of forming SRL and SRT skills among teachers who participate in PSF, first in the role of learners, and t-hen in the role of mentors.

Theoretical framework

Collaborative mathematics problem solving

In recent years, collaborative problem solving in small groups as form of learning based on problem solving has been widely studied. Proponents of this method argue that it is based on mathematical discourse that fosters mathematical thinking (Hogar & Harney, 2014; Shindler & Bakker, 2020). The effectiveness of group work largely depends on the type of interactions between its participants (Carlson, & Bloom, 2005). Clark and colleagues have suggested a taxonomy of interactions in the process of collaborative problem solving in two dimensions. The first of these are questions directed to another member or the whole group, such as questions to clarify or define the group's status in moving towards an intended goal. The second-dimension concerns group synergy, which the authors define as long-term collaboration in which participants continue and develop each other's ideas. According to the researchers, the group progresses in learning when group synergy is the most significant interaction in its activities (Clark, et al., 2014). Modern technologies allow using online forums in social networks as one of the possible platforms for collaborative solving of math problems in small groups. This is possible due to the characteristics of online forums as having a common space for discussion, asynchrony, preservation of discussion content and virtuality.

Self-Regulated Learning (SRL)

In this study, SRL is defined according to Pitrich and Zimmerman, as a cyclic recursive process combining motivational, cognitive and meta-cognitive components (Pitrich, 2000; Zimmerman, 2000). In this definition, cognition refers to direct mathematical actions aimed at solving a problem; meta-cognition refers to the ability to understand and control cognitive processes, and motivation refers to the student's attitude to his/her abilities to solve a problem. According to Schoenfeld (2013), the meta-cognitive aspect – including the ability to plan, monitor and reflect on the work done – is especially important for the successful solution of mathematical problems. To successfully tackle complex challenges in collaborative learning, in addition to each student's SRL, meta-cognitive collaboration is required, where team members or groups act as a unit, defining common goals and choosing common strategies (e.g. Hogar & Harney, 2014). Research shows that SRL skills are not acquired spontaneously. Their development requires an environment, targeted learning, and guidance referred to as Self-Regulated Teaching (SRT) (Kramarski & Michalsky, 2009).

Many studies point out the need of developing advanced training programs for mathematics teachers, that will help them develop the SRL skills of their students (Hoover et al., 2016; Kramarski & Michalsky, 2009). In recent years, a theory of the teacher's dual role in the acquisition of SRL skills has been developed. The theory has proven the effectivity of developing SRL skills in teachers, to increase their ability to develop these skills in students (e.g., Kramarski & Kohen, 2017). Research on teacher professional development (PD) in online environment, which has become widespread in the past few years, has shown that the online environment has a positive effect on the development of teacher skills in SRL (e.g., Broadbent et al., 2021).

Research questions (RQs) are: a) How do teachers' SRL and collaborative PS skills evolve during their continued participation in PSF as learners? and b) How are the teachers' SRT and PS skills reflected in leading a PSF as mentors?

Methodology

The study took place in two stages. At the first stage, within the framework of the course "Fundamentals of Geometry: Plane Transformations", each teacher participated in six PSF meetings as a learner in a group of four. Each meeting was devoted to joint discussion and solution of a complex geometric problem. At the second stage, within the framework of the course "Methods of teaching mathematics", each of the participants acted as a mentor (teacher) in two forums, where students, under their guidance, also solved complex geometric problems. Throughout the study, teachers received targeted SRL support by the facilitator of the PD program, through collaborative discussions on forum processes, and guidelines during the forums themselves.

Participants and research background

The study was conducted as part of a 2-year Mathematics Teacher PD Program at the Faculty of Education in Science and Technology at the Technion, Israel. The program aims at expanding the mathematical and pedagogical knowledge and skills of teachers, for the goal of reaching a teaching license that will enable them to teach all levels of mathematics. The study involved 47 teachers with 5 to 15 years of experience, teaching in high schools in the north of the country. This paper focuses on the activity of one of the teachers, named John. John (35 years old) is a math teacher at a school in the north of Israel with 12 years of experience. John was selected as a case study for two reasons. On the one hand, his activity in the forums in which he acted as a learner, which was evaluated by the number of statements he posed, was similar to the average number of statements posed by the entire group of teachers. On the other hand, John's example shows clear patterns of change relating to his PS and SRL skills, as was reflected in the forum in which he acted in the role of a mentor.

Data and data analysis

In the course of the study, 96 protocols of the forums' work were obtained and analyzed. Of these, 72 protocols of the work of the forums, in which teachers acted as learners (12 groups with a permanent composition) and 24 forums, in which some of the teachers acted as mentors. This paper focuses on the analysis of the PSF protocols of three forums of John's group, where John and the other participants act as learners in three forums (with the facilitator of the PD program as a mentor) and one forum in which John acts as a mentor, while the other forum participants are in the role of learners. For responding the first RQ, we present PSF protocols analysis that reflects the development of all participating teachers' SRL and PS. For responding the second RQ, we focus the analysis of the PSF protocols on the activity of John.

We have applied directed content analysis (Hsieh & Shannon, 2005) to code forums in light of SRL and collaborative PS theories. For the research unit, the message (post) sent by the participant was selected. Most of them were text messages, but sometimes participants posted a photo of a drawing or part of a solution. This method of analysis allowed us to analyze the data qualitatively as well as quantify it as described below. First, we distributed the forum to posts, where each post was assigned two codes – one for collaborative PS and one for SRL. For collaborative PS, data analysis was based on the taxonomy proposed by Clark et al. (2014). This study examines the success of the PSF in terms of the level of group synergy achieved in the forum. There was evidence of group synergy in cases where a group of related posts from several participants discussed ideas for solving a problem. We calculated the ratio between the number of posts included in the synergy chains and the total number of messages on this forum. On the SRL aspect, forum posts were codified in accordance with the definitions of SRL models by Pintrich (2000) and Zimmerman (2000). We determined the level of SRL in each of the forums, both as a whole and per individual components. The SRL attributes were defined as follows: a post was classified as motivational if it indicated the participant's attitude to his knowledge, capabilities, and teamwork in the forum. A post was classified as cognitive if it contains specific mathematical actions aimed at solving a problem, such as: in my opinion point B will move to B'. With regard to metacognitive attributes, it was determined that a post refers to planning if it concerns the general analysis of the problem, the choice of the solution strategy, the definition of the general and intermediate goals, such as: Shall we start rotation around the center of a circle? Monitoring attribution was assigned to a post if it evaluates progress towards a solution in terms of correctness and effectiveness in achieving a goal, such as: Moment, checking. So, after the rotation K moved to M, then… Finally, a post was classified as reflection if it includes a retrospective look at the process of solving a solution problem, such as: The problem is interesting in that its first part solves a standard with a section of means. After assigning a classification for each message, we calculated the ratio between the number of messages for each component and the total number of messages in a given forum. These values are presented in the findings as percentages.

Findings

We will present three forums out of six in which John participated as learner: at the beginning (PSF1), in the middle (PSF3) and at the end (PSF6) of the part of the study in which the teachers were in the role of learners. All problems proposed for discussion in the forums were carefully selected in accordance with the criteria specified in the theoretical base and were equal in complexity. As an example, we will give a problem that was proposed to the participants for discussion in the first forum: "Given a square ABCD. Point K is on segment BC, and point M is on segment DC. Line AM bisects the angle KAD. Prove that the length of the segment AK is equal to the sum of the lengths of the segments BK and DM". The following table summarizes the performance of the group of teachers that John was a member of throughout the study.

Responding to the first RQ request, Table 1 and Table 2 present the SRL attributes and group synergy scores (respectively) that were assigned to all posts made by the entire group of teachers in these forums. Data is presented in percentage of the total number of posts in the presented forum.

The data indicate that with long-term participation in the PSF, the weight of group synergy in the discussion increases significantly, in parallel with increase in the number of messages related to the collaborative PS. In the final forum, almost all posts are related to SRL: 48% of them are meta-cognitive, while in the initial forums only 28% of posts were meta-cognitive.

Table 1: Indicators of SRL attributes at the initial, middle and final stages of teacher participation in forums as learners (P = planning; M = monitoring; R = reflection; Other = non-SRL messages)

SRL components		PSF 1	PSF 3	PSF 6
Metacognition	P	5	13	17
	M	14	16	17
	R	9	3	14
gCognition		23	22	24
Motivation		19	22	24
Other		30	24	4

Table 2: Indicators of group synergy at the initial, middle and final stages of teacher participation in forums as learners

PS interaction	PSF 1	PSF 3	PSF 6
Group synergy	9	32	61
Others	91	68	39

Moving forward to John's case, we might delve into these changes, as well as responding to the second RQ that aims to explore the SRT and collaborative PS skills of John's who were reflected in the forum in which he took part in the role of a mentor. Figure 1 demonstrates the dynamics of changes in the SRL components and the participation in the group synergy of John as an individual teacher. This figure contains characteristics that describe the forums in which John was in the role of learner, as well as the one forum he was in the role of mentor. The data in the figure is presented as the percentage of John's posts that we attributed to a certain type when analyzing the data, out of the total number of John's posts in the presented forum. For example, 66% of John's posts in the first forum had been classified as "Cognition". An additional column shows John's participation in the group collaboration (the percentage of his posts that make up the group synergy of all his posts).

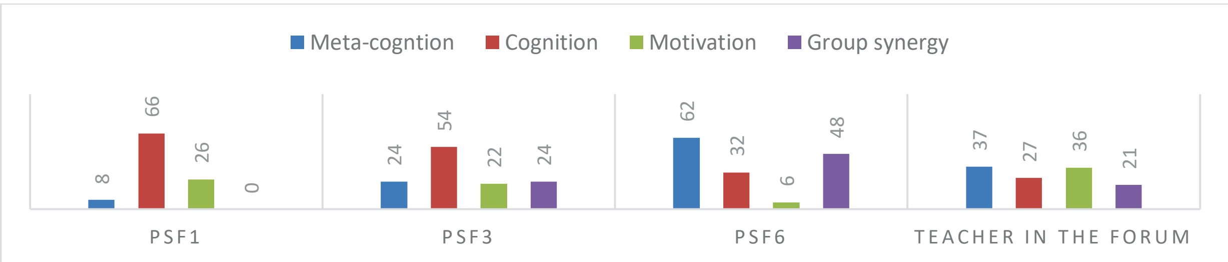

Figure 1: Jonn's activities in PSF as a learner and as a teacher

Figure 1 shows that, as in the group as a whole, an increase relating to the meta-cognitive component was seen in John’s posts, in the forums where he participates as a learner. While low indication for metacognitive activity was revealed in the first forum, in the third forum over 60% of his posts were characterized as metacognitive. Another increase had been seen in the participation of John in group synergy. Particularly, in the third forum, group synergy was accounted for over 60% of group interactions and half of John's interactions. Below we describe the events that took place in each of the forums, focusing on John's activity.

Forum 1 is John's first attempt at PSF as a student. On this forum after a while (about 20 minutes) he published a complete solution to the problem. Soon, he removed the solution, saying it was wrong. John did not participate in the discussion. His motivational messages were about appeals to think, indications that the task is simple and multiple references to his successful solution. Forum 3 was John's third attempt to collaborate on the forum as a student. This time, John also did not participate in the discussion for a relatively significant period of time (about 15 minutes). He solved the problem again on his own. However, he did not publish the complete solution, but took part in the discussion, sharing his ideas. His reasoning was meta-cognitive in nature. For example, he shared with the group: "To prove that a polygon is a square, I started looking for segments that could be equal, and angles that should be 90. This gave me the idea to prove the equality of triangles in advance ...". In the last forum where John participated in the student role (Forum 6), he unexpectedly took the lead in the discussion. He reasoned and involved others in the discussion. The share of group synergy in this forum was 61%. And the average length of the synergetic chain (a number of interconnected and continuing each other messages related to the solution of the problem) was equal to 10.5 messages. This demonstrates the collective nature of the search for a solution. John was very much involved in the discussion. Often, a new round of discussion began with his proposal to think about other tasks of this kind or a proposal to return and analyze the data.

John's work as a teacher deserves special attention. Figure 1 shows that at this stage he has achieved a balanced proportion of SRL characteristics that are equally expressed. John participated in the discussion to stimulate group synergy in the students' work. He motivated them to jointly search for ways to solve the problem with phrases such as "Listen to each other. It will give you good thoughts." Most of John's advice was meta-cognitive. For example, "Let's talk about the essence of the problem and outline an action plan." The cognitive notes hinted at a way to solve the problem, not a direct solution. Many of John's posts as a teacher had prototypes in his student forums. These were either the lines of the group mentor or colleagues.

Discussion

The results of the study support the conclusions made in previous studies about the beneficial effect of self- experience as learners on the pedagogical activity of teachers, especially when it comes to the use of non-standard teaching methods (Hoover et al., 2016). Using the example of John and other teachers, we traced how their ability to listen and help the development of other people's ideas developed in the process of participation in the PSF, which is especially important in pedagogy aimed at developing independent thinking in students. We recorded a significant increase in the role of the meta-cognitive approach in solving problems by teachers, which was subsequently reflected in the role of John as a mentor of his colleagues. The participating teachers did not require the provision of a complete error-free solution by each learner separately, but facilitated a discussion aimed at understanding the essence of the mathematical ideas inherent in the problems. At the same time, in the development of the idea of the double role of the teacher in light of the theory of SRL-SRT (e.g., Kramarski, 2012), it was found that the process of forming SRT in PSF environment occurs not only sequentially, but also in parallel with the development of SRL. It can be assumed that the explanation of the discovered phenomenon lies in the fact that the development of SRL skills in the process of participation in the work of forums contributes to the desire for a meta-cognitive assessment not only of the cognitive processes pertaining to the solution of the problem, but also a “top-down” view of the entire communicative and cognitive process, occurring in the forum. This conclusion is confirmed by numerous episodes of teachers' reflection on the processes taking place at the forum, both from the point of view of the ways of solving the problem, and from the point of view of the analysis of the interactions that took place. The discovered phenomenon makes it possible to use PSF, in which teachers solve mathematical problems, in a new context, as a model for exploring the mechanisms of development of communicative and mathematical aspects of teaching.

The present study has demonstrated the dynamics in the development of group synergy as participants gain experience of participating in PSF. A friendly, safe atmosphere has emerged in the forums, including mutual interest, willingness to listen and accept someone else's opinion, and not to be afraid to make mistakes in expressing one's opinion, which, according to Schindler & Bakker (2020), is necessary for the successful work of the group. We found that with an increase in the proportion of episodes of group synergy among interactions in the forum, groups progressed not only in terms of efficiency in solving problems, as Clarke and colleagues' research (2014) shows, but also in terms of self-regulation of their participants, in particular, their meta-cognitive approach to problem solving. It might be that the orientation of the participants towards self-regulation allowed them to notice and evaluate the episodes of successful joint work and purposefully strive to expand them, thus contributing to the emergence and strengthening of group synergy in the forums as a factor contributing to success.

In conclusion, this study contributes to the theory of the mutual influence of the collaborative solution of mathematical problems, in particular in the PSF environment, and the development of self-regulation skills. The fact that the participants of the forums are teachers allowed us to move to the next level of understanding of this issue and to trace the reflection of these processes on the pedagogical activities of teachers, in particular as mentors of PSF.

Acknowledgment

We would like to thank Prof. Boris Koichu from Weizmann Institute of Science, Israel, for his important role in this study.

Mathematics professional development (PD) has been prevalent, and scholars have been investigating interventions that target teacher knowledge, while also maintaining a focus on instructional practice and student learning. Findings have been mixed and we hypothesize that teacher learning takes time and that teachers learn more than studies report. Case study analysis allow for an in-depth investigation into what teachers take up and enact in their classroom context. The study that is the focus of this paper uses comparative case study analysis to examine three different and distinct professional development programs that are geographically situated across the US, focused on different mathematical content, and utilize different PD structures. This paper highlights three cases of enduring and evolving teacher practices resulting from their three respective PDs.

Keywords: Professional development, teacher knowledge, case studies, mathematics.

Introduction

There continues to be a widespread effort within the international research community to carefully consider how to support teachers' on-going professional development (c.f. Bautista & Ortega-Ruiz, 2015). Mathematics professional development (PD) has been prevalent, and scholars have been investigating interventions that target teacher knowledge, while also maintaining a focus on instructional practice and student learning (Jacobs et al., 2020). Funding opportunities typically target large quantitative proposals that study impact using pre post measures usually across one academic year and two at most. Findings have been mixed. Some studies have found incremental gains related to content and instructional practices (Koellner & Jacobs, 2015) and others have found no change at all (Santagata & Yeh, 2014) We hypothesize that teacher learning takes time and that teachers learn more than these studies have reported. This study investigates the impact of three different National Science Foundation (NSF) funded PD projects and what teachers use in their mathematics classrooms today. More specifically the research question that this study addressed is: What do teachers take up and use from participation in mathematics PD four to five years after engagement in the workshops?

Theoretical Frameworks

Situative theorists define learning as changes in participation in socially organized activity (Greeno et al., 1996). They consider the acquisition and use of knowledge as aspects of an individual's participation in social practices. With respect to professional learning, situative theorists focus on the importance of creating opportunities for teachers to work together on improving their practice and locating these learning opportunities in the everyday practice of teaching. All three PDs were designed around this premise. For instance, all three PD studied in this paper used a collaborative approach and focused on relevant content that was currently being used in teachers' classrooms. In addition, artifacts of practice such as student work or video tapes of teachers' classrooms anchored conversations and connected the classroom to the PD. Lastly, resources were used that were aligned with curriculum and standards. A situative perspective suggests that groups of teachers who take part in different PD workshops using different materials, with different facilitators, and are situated within different educational contexts (e.g., different geographical locations within the United States) might have very different learning opportunities and experiences impacted by the role of context.

Overview of TaDD Project

The Taking a Deep Dive (TaDD) project is collecting qualitative data from three large U.S. National Science Foundation PD projects to use case studies and cross case analysis to further inform what teachers take up and use from participating in different PDs in different contexts and examine why some teachers appear to take up and use more than others. The TaDD study is unique and does not follow the typical impact methodology in that it utilizes a qualitative theoretically based case design. Additionally, as opposed to quantitative studies that typically examine impact one year after the intervention, this study examines impact of different PD models in classrooms four to five years after the intervention. This approach allows for a deep dive into the variations among models of PD and across teachers. As noted, the field has conducted numerous scale-up studies focused on the impact of PD on teacher and student learning with positive but not necessarily dramatic results – the TaDD project seeks to uncover what specifically teachers take up from professional learning opportunities and the factors associated with impact. TaDD utilizes a multi-case method (Stake, 2013) which centers on a common focus of what content, pedagogy and materials teachers take up from PD experiences.

Case study analysis allow for an in-depth investigation into what teachers take up and enact in their classroom context five years after participating in PD. The case study allows us to understand the different ways teachers interpret and take up aspects of content and pedagogy from a PD. It allows us to unpack teachers' thinking and their practice through interviews and videotapes respectively. Additionally, case study analysis allows us to consider the context in which teachers work, their philosophy of teaching and learning, and the ways they work with diverse learners in their classroom. The construct of variance between teachers and types of PD has the potential to shed light on the factors that are associated with uptake, and the similarities, differences and subtle nuances of teacher uptake and use. These factors have implications for PD design, PD selection and associated policy and would be an important contribution to the field of research on PD.

Using a specified sampling procedure, TaDD selected teachers from each of three PD projects to serve as case study teachers (n=19). This paper highlights three cases of enduring and evolving teacher practices resulting from their three respective PDs. In the next section, we briefly describe the three different PD projects.

Learning and Teaching Geometry (LTG)
